THE cultivation of the Peach and Nectarine in unfavourable situations is not only attended with considerable difficulty, but the results are far more frequently unsatisfactory than otherwise; in fact, the uncertainty of the crop, the loss of time and injudicious employment of means in cultivating the Peach and Nectarine against walls is very unprofitable as well as disappointing. I am aware that good fruit has been grown for many years, and still is in favourable localities against walls, yet in some localities the crop of late years has been very tantalising, the trees have become very unhealthy, and in many cases have died. It is questionable if a remedy is to be found for this, hence I conclude that where these

fruits do not ripen satisfactory crops against walls the only safe way is to grow them under glass. Everybody knows this, but there is an assumed advantage in striving to grow Peaches and Nectarines against walls—viz., in having them much later than would be the case where they are grown under glass. Such, however, is not the fact, though we readily grant that if the cultivator wishes to hasten the ripening of the fruit it is readily effected by husbanding the sun's heat in early closing the ventilators; but by making efficient provision for ventilation (which does not always receive the attention it demands, or not until afterwards), and under proper management the fruit can be had from trees under glass quite as late, if not later, and of better quality as well as appearance as the fruit on open walls.

Where a good return is the first consideration houses of the simplest description consistent with stability and efficiency, well glazed and properly ventilated, may invariably be depended upon for giving full crops of Peaches and Nectarines of the finest quality. They are not more expensive than walls, but where those exist they can be covered with glass at a cheaper rate than erecting new ones, as the wall is certainly equivalent to one side of the cost of a span, with the disadvantage that it will only give half the fruit. I by no means wish to discourage covering walls with glass, yet I cannot forbear drawing attention to the fact that narrow houses erected to shelter trees against a wall are not the best means of doing so, as with a wider house trees almost as large can be accommodated on a crescent-shaped trellis in front, and that without any detriment to the trees against the wall. Narrow lean-to's may have their advantages, as I was reminded the other day by an enthusiast, as, besides protecting the Peach trees on the wall, a narrow house accommodated a row of Tea Roses along the front, blooming early and late, and was a capital place for Violets, where they bloomed the whole winter long. Our friend found the front of these narrow houses suitable for late Strawberries, famous for a row of Peas, to come in long before those in the open, and for wintering salads. Still I consider that walls can be of more use in gardens than as supports for glass houses. Surely Pears are valuable after summer fruits are over, and what position is more suitable for them in unfavourable localities than a south wall?

Why cannot we have the roofs of houses made to cover Peach walls so that the whole of it could be removed in a very short time, and as quickly replaced? I know there are some that answer this description, but I think it would be an advantage if they could be made to run up or down as quickly as the old-fashioned sliding lights. The advantages sought would consist in the trees being exposed to rains, cleansing the foliage and thoroughly moistening the roots, which would considerably lessen the necessity for syringing and watering.

Wide borders are not necessary, in fact are injurious, as the trees do better when the roots are restricted than when having the run of unlimited space. Requiring very copious supplies of water when in growth, good drainage is essential, 9 inches to a foot thickness of brickbats answering perfectly if there be drains below it to carry off superfluous water, the drainage being secured by a layer of turf grass side downwards, and 2 feet depth of soil is ample. Strong calcareous loam with a liberal admixture of old lime rubble put together firmly will produce clean, healthy, short-jointed growths thickly set with triple buds.

The conditions requisite to keep the trees in a healthy bearing state are few, as to insure thoroughly ripened wood biennial lifting or root-pruning should be adopted. Fan-training on a trellis 12 inches, and not more than 15 inches from the glass, answers best, as at this distance the fruit and wood get the fullest benefit of heat and light. Disbudding should be practised early, and should be somewhat severe, as it is important that the wood for future bearing should be trained in rather thinly, so that it has full exposure to light and air. Overcrowding, especially in late houses, is fatal to the ripening of the wood, hence no more wood should be allowed than can have proper exposure. The trees should be pruned as soon as the last fruits on each tree are gathered, cutting out the bearing wood of the current year, leaving those only that are required for next year's crop or extension; and after this the house should be kept dry and warm in the daytime by moderating the ventilation, but keeping it cool at night by admitting air more or less, continuing this until the foliage is ripe, when the ventilators may be thrown open for the winter, and if the trees could be exposed for a time by removing the lights it would be an advantage.

As spring approaches the flowering should be retarded as much as possible to keep them safe from spring frosts, and when ready artificial impregnation should be resorted to, to insure a good set; but where there are bees it will not be necessary, and the house should be freely ventilated. To insure fine fruit mulch the border with short manure, and water copiously when the fruit is swelling, and insects must be kept down by forcible syringings. Overcropping

is a great evil, a fruit to every square foot of trellis covered by the trees being ample.

As to the selection of varieties, much will depend upon the means. In large gardens where there are several houses, and there succeed them, such varieties as *Grosse Mignonne, Belle Baucé, *Royal George, Noblesse, Bellegarde, Barrington, *Stirling Castle, Violette Hâtive, Late Admirable, and *Walburton Admirable. To these may be added Sea Eagle, Lord Palmerston, Princess of Wales, Desse Tardive, Golden Eagle, and Osprey, all of which are large, good-looking, and for late varieties not bad in flavour. In gardens that rely on a supply of fruit from the middle of July from walls or an unheated house, such varieties as *Alexander, *Hale's Early, Early Alfred, *Dr. Hogg, Dagmar, Rivers' Early York, Early Grosse Mignonne, Dymond, A Bec, Condor, and Goshawk may be added to those named, which all but the two last-named will precede. If only a few are wanted those marked with an asterisk will give a supply in ordinary seasons from the middle of July to a similar time in October, or for three months.

Perhaps there is nothing so undesirable in small establishments as large trees. They give a glut, and there is no succession. Trees of moderate size are most serviceable and more easily managed than large trees in the matter of root-pruning and lifting; in fact, a tree of each of those named could be grown in a small house as single or double oblique cordons, and which is so characteristically exemplified in the Royal Horticultural Society's garden at Chiswick.—G. ABBEY.

STOKING—FUEL—GAS AND OIL STOVES.

I AM pleased to see Mr. Inglis's letter on the economy of stoking, as some of the points referred to are more important than many think or will admit. An instance in point has just occurred with a boiler recently supplied. Complaint was made that the fire (made up at 9 P.M.) had burnt out and the pipes were quite cold long before six in the morning. The boiler was properly set, and there was said to be a perfect draught, as the chimney "roared again." Here was the fault plainly visible, but the man could not see it. "A furnace was no use if you could not make it roar up the chimney," so he had been taught in the old days of flue-heating, and consistently practised. The boiler was condemned as a failure, it must be returned, &c. After much persuasion the damper was nearly closed and very little air was admitted under the fire. With a few trials the fire kept in over twelve hours, but the pipes were scarcely warm. The other extreme had been reached—there was too slow a combustion, and a common coal was used which gave very little heat; but the fault was chiefly in not having raised the heat early enough in the evening. Again, the man was begged to make a good fire and the pipes thoroughly hot by 6 P.M., opening the roof ventilators an inch for a few minutes if the temperature became too high, after that to increase the air supply under the fire, and bank up (which always reduces the heat), when it was found that the fire kept in and the pipes comfortably hot till seven the next morning. Less fuel was burnt, less labour required, and a more regular heat obtained than with the "roaring fire." A special test in an almost empty house some time ago showed that when closed one afternoon the thermometer stood at 62°, three hours later it had fallen to 45°. A fire was lighted and raised it to 50° in two hours, then fire made up for the night, and the next morning there was registered a maximum of 52° and a minimum of 40°. The next day the fire was lighted, when the house was closed at 60°; in three hours it was 55°; it was then made up and left for the night, the range registered in the morning being from 58° to 50°. Precisely the same quantity and class of fuel was used in each case, the outside minimum being 1° lower on the second occasion.

As to Fuel.—A gentleman had a large boiler fixed for twelve houses, and determined nothing should be spared in the way of good fuel. Best coal and coke were mixed, but the conduct of that boiler or its fire was decidedly erratic for a long time; but on examination it was explained, through the coke being thrown in just as it came, sometimes large lumps that would not burn through, and then small pieces with an excess of coal burning quickly. Small broken coke and breeze was advised, with a harder coal equally mixed, when an improvement was manifest at once, and ultimately common breeze alone, costing 3s. a ton (or chaldron, I forget which) besides its cartage, was found most satisfactory at half the cost or less.

Flues.—A boiler was replaced elsewhere by one of greater nominal power, having the same size of fire-hox but one-third more piping on, and the same class of fuel (anthracite and coke) was burnt, but sufficient heat was not attainable. On inquiry I found that less fuel was being burnt to do more work; but the man said it would not burn more, which was true. The previous boiler had an upper flue in it, and thence over the top direct to the chimney, in which you could "hear it roar." The new boiler had inner flues and then underneath, making three times the distance to the chimney, which was too short for good draught, consequently the fire burnt too slowly. Five feet was added to the chimney shaft, the coke broken small, and now the extra pipes are heated well with the same fuel as formerly.

Gas or Oil.—The importance of raising heat early in the evening is more marked, and most necessary where gas or oil is used as fuel, as, owing to the less surface acted upon by flames, a less degree of heat is of course obtainable. Many persons who have bought a gas apparatus

because it was so clean and easily attended to, have been terribly disappointed to find one morning that frost has nipped some of their tender plants near the glass, though the gas was burning full and the pipes hot at 9 A.M.; the fact being that they had not lighted the gas till 8 P.M., and before the water could become hot the frost had done its mischief; but afterwards, say at 6 A.M., the pipes got comfortably warm, and increased as morning advanced. Had the gas been lighted three or four hours earlier and the water raised to boiling point, or nearly so, a less consumption of gas would have kept it hot during the remainder of the night. On the management of oil or gas stoves very much might be written to account for the many failures and few successes therewith.—B. W. WARHURST.

AUTUMN PROPAGATION OF ROSES.

MANY methods of striking Rose cuttings are mentioned in the *Journal of Horticulture* from time to time, and of course failures in doing so are also recorded. I find the following plan to answer well.

Take well-ripened cuttings 8 to 10 inches long, and place them in boxes (leaving two or three eyes above the soil) any time from the end of October to the end of November, and place them until March where they will be protected from east winds and hard frosts. Then put the boxes into a frame with a little bottom heat. Most of the cuttings that are callused will grow, and can be transferred into 6-inch pots in another month, pruned as soon as established, afterwards hardened off and planted out in May, or even in June, taking care that the roots are as little disturbed as possible. Mulch the ground with decayed manure after planting out, and supply water if necessary.

The boxes should be about a foot deep, and the bottom should have a few holes bored through for drainage and covered with about half an inch of sand, the cuttings to be inserted very firmly. When the cuttings are ready for potting knock the bottom of the box out or take it in pieces, as the roots would be too much broken if any attempt was made to dig them up. I make the cuttings without a heel and plant them rather thickly, as many will not callus, and some that do will die. I know some of your readers will say, "What a lot of trouble!" but if Roses are worth growing on their own roots surely they are worth a little trouble, especially as you get good strong plants that bloom the first season. The above only refers to Hybrid Perpetuals, as I find that Teas will root almost at any time with the assistance of a frame.

I do not wish anyone to think that Roses on their own roots bloom as freely as when budded on the Manetti, Briar cuttings, or seedling Briars, as they do not, and the free-blooming varieties only should be used. The best, I find, is Marie Baumann. John Hopper and some few varieties bloom fairly well, whilst others make large plants, plenty of wood, but no blooms worth mentioning.—W. BOYES, *Milford, Derby*.

DEEP SOIL BEST FOR POTATOES.

LAST spring we began to trench a large quarter in the kitchen garden here, but the weather and other work prevented us finishing it, and only part of it was turned up to the depth of 2 feet, the remainder being dug over in the ordinary way. In trenching a large quantity of all kinds of rough garden refuse was turned into the bottom, and finally a quantity of manure was forked into the surface. This was used to both the trenched and dug portion, deep drills being opened 3 feet apart and Potatoes planted all over the piece. By-and-by a row of Broccoli plants was placed between the drills of Potatoes, and all the stems of the latter appeared to be of the same bulk and strength, but on lifting the roots the other day the crops were widely different on the trenched and untrenched ground. The variety was the Scotch Champion, and on the ground which was only dug over the crop might be termed light, but on the trenched part it was very good indeed, and according to measure we had as many from two rows on the trenched soil as in three on the shallow-tilled part. The size, too, was more uniform on the trenched piece, and the results altogether are decidedly in favour of trenching or deep digging.—J. MUIR.

SEASONABLE FLORAL DECORATIONS.

WE have had an exceptionally busy fortnight of floral decoration, beginning early every morning with the arrangement of cut flowers and foliage for sitting-rooms, and ending each evening with a brisk three hours of dinner-table decoration, the greater part of the last day being given to the decoration of a church for a harvest festival. This has recently occurred, and has left behind it a keen sense of knowledge gained, of views enlarged, altered, or strengthened; and what is even more important, has afforded much insight into the difficulties which beset the efforts of beginners in a branch of gardening that not unfrequently puts the skill, taste, and originality of old practitioners to the severest test. It is hoped, therefore, that a few hints may again be usefully jotted down for the assistance of many of your readers whose efforts in this work are beset with doubts and difficulties; and first let us give some attention to the

Choice of Materials.—Tameless and monotonous repetition are to be avoided. Let us therefore strive to impart a season-

able air to our designs by the free use of as many hardy flowers and leaves as prove suitable for tasteful combinations, for all such are undoubtedly admissible, and the true artist never objects to foliage or flowers because it is familiar or common, and has no sympathy with that ultra-refinement which rejects all but rare exotics or costly forced flowers for house or table decoration. Rather does he cherish a fondness for beauty of form and colour under whatever guise it presents itself, not in obedience to arbitrary rules or canons of taste, but involuntarily, and from a habit and sense of pleasure that grows in keenness and intensity as he learns with Kingsley to "Drink in all the forms of beauty which lie in leaves and pebbles, and mossy nooks of damp tree roots, and all the lowly intricacies of Nature." Autumn is especially rich in the lovely tints of decaying foliage that brighten the woods and hedgerows with a wealth of colour on which the eye lingers all the more fondly for its brief duration. The garden, too, has its own special autumnal brightness, affording us ample materials for our work.

A Virginian Creeper on a southern gable was first this autumn to change from sober green to gorgeous crimson, and very useful were its bold handsome pinnate leaves, especially for large flower stands. *Ampelopsis Veitchii* soon followed it, and has now on the last Saturday in October been in full beauty for several weeks. Many of its leaves have fallen, but some lovely patches of them, each covering many square yards, remain, and are all aglow with scarlet, crimson, carmine, purple, yellow, and green, all blent and shaded in most gorgeous brilliancy. How beautiful it is! and how exceedingly useful are the full-sized leaves, or rather leaves of all sizes, as well as the long slender growth of the current year. The huge specimen of it here continues spreading on all sides so fast that there really appears to be no limit to its growth. I have made no actual measurement, but from my knowledge of the height of the building against which it grows I may safely say that it already covers an area of some 4000 square feet, and from its habit of taking hold of everything it touches it may become twice as large in course of time, for there is ample space for it to do so.

Polygonum Sieboldi has also been very useful. Its handsome foliage changed to a rich orange, occasionally blotched with crimson, and while at its best the long slender shoots made charming wreaths and sprays. *Æsculus laciniatum* also afforded an abundant supply of bright yellow leaves, doubly useful from the elegant fan-shaped form, lighter in colour, and with narrower lobes than the common Horse Chestnut, which, however, possesses a beauty of its own that, however familiar, calls for special mention. The foliage of one particular tree of it here, with branches pendent almost to the ground, changed to a deep rich yellow, and formed a golden bower of wonderful beauty, especially on a bright and sunny day.

Acer polymorphum atropurpureum still retains its lovely foliage now of a bright crimson-scarlet hue. The cut sprays of it are most useful to mix both with blossom and foliage. It is so beautiful that several have been planted here. One of the best specimens is growing near an *Æsculus laciniatum*, and the effect of the masses of crimson and yellow foliage has been very striking. Hardy Azaleas have changed to many shades of crimson, some to a deep purple, and others of various shades of yellow, so that one hardly knows whether they are not more beautiful now than when they afford us the full glory of their gay flowers. The scarlet Dogwood, the soft green slender sprays of *Spiræa Thunbergiana*, the bright yellow leaves and scarlet berries of the Japanese Rose, the deep crimson leaves and glossy berries of *Viburnum Opulus*, crimson and yellow leaves of the Dutch Medlar, bright crimson leaves of common Blackberry, the silvery-awned seed clusters of *Clematis Vitalba*, with green Fern fronds and silvery plumes of dried Grasses, have all been used in pleasing combinations, and are all mentioned to show what is really useful at this season of the year. All are hardy, and so easily established as permanent trees and plants that there should be no difficulty in obtaining a supply from every garden. A lady of undoubted taste having recently to arrange some cut flowers and foliage at a house where she was staying, complained to me that although the garden contained numerous glass houses filled with choice plants as well as beds and borders of flowers in the open air, yet it was sadly deficient in suitable materials for what she had to do.

Of flowers single Dahlias and tuberous-rooted Begonias have borne with impunity one sharp frost. Both are delightful modern innovations in our flower borders, and both are remarkable for what may be termed an affinity of usefulness. Easily raised from seed in spring, they grow so quickly that they come early into bloom in summer, and continue in full beauty late in

autumn. Single Dahlias are so lovely that I have used them for almost every purpose for which cut flowers are required. They make an excellent change for the dinner table, and tell well in vases and bowls of all sizes. For a tripod stand some 3 feet high, supporting a large bowl, they have had the preference for many weeks. I have arranged them in it in a variety of ways; at the present moment as follows:—The bowl is filled with moist sand; about eight large fronds of *Lastrea Filix-mas* are thrust into the sand and bent down over the edge of the bowl; three long sprays of *Clematis vitalba* are also bent over upon the Fern fronds, curving over them diagonally; three or four clusters of the berries of Japanese Rose, with a few of its yellow leaves mingled with rather large leaves of *Ampelopsis Veitchii* form a margin above them; single Dahlias arranged lightly fill the bowl, rising to a height of about a foot in the centre, and from among them the seed plumes of *Bromus sterilis* (Barren Brome Grass) spring upwards and outwards, some bending over the sides and bending outwards from the centre full 2 feet above the highest Dahlias. Flowers of early Chrysanthemums are ready, but none will be used till the Dahlias are over.

For the dinner table flowers may frequently be dispensed with entirely at this season of the year, and foliage used instead. Large central bowls of the shape of c, fig. 73. told well with fronds of Male Fern bent down and resting on the tablecloth, a long shoot of *Cissus discolor* with well-coloured leaves curved right round well out from the bowl and resting upon the Fern fronds,

Fig. 73.

Useful forms of vases for dinner-table decoration. A is of iridescent and crackled glass, 6 inches high and 2 $\frac{3}{4}$ inches in diameter at top. B is a slender vase, 7 inches high and 1 $\frac{1}{2}$ inch in diameter at top. C is a plain transparent glass bowl of various sizes, used singly, and in circles and clusters; they are also useful for suspending from chandeliers by slender wires fastened under the rim.

then came clusters of scarlet leaves of *Ampelopsis Veitchii*, three or four sprays of *Polygonum Sieboldii*, some small leaves of *Caladium Wightii*, shoots of *Coleus Pompadour* and Royal Purple, dried spikes of *Briza maxima* among the foliage and slightly raised above it, with tall silvery spikes of common Hair Grass and *Poa pratensis* above all. A few crimson leaves with Maidenhair Fern and trailing shoots of *Selaginella cœsia* suffice for such vases as B, fig. 73, of which circles may be arranged round the large central bowls, with a wreath of crimson leaves upon the tablecloth winding gracefully about among the vases and dishes.

Of the materials used for church decoration for the harvest festival the principal were plenty of nice fresh green moss, leaves of *Ampelopsis Veitchii*, *Aesculus laciniatum*, Japanese Rose, *Polygonum*, and crimson-blotched leaves of Grape Vines, little sheaves of Wheat, Barley, and Oats about a foot in height, large flowers of scarlet Cactus Dahlia Fire King, berries of wild Guelder Rose, hips of Dog Rose, and berries of *Cotoneaster Simmonsii*, fronds of common Bracken, with fruit of Fearn's Pippin Apple, Beurré Clairgeau Pear, Tomatoes, and Capsicums. With these simple materials a bright and tasteful effect was obtained, and all vulgar display avoided.—EDWARD LUCKHURST.

THE BEST WHITE BEDDING PELARGONIUM.—Inquiries have been made in your Journal by "S. C." as to the best white-flowering bedding Pelargonium. I quite agree with him with regard to White Vesuvius; it is not so good as Madame Vaucher, indeed I think this is the best white we have. If "S. C." has any, or can procure any, old plants of Madame Vaucher, cut the roots well in so as to get them into large thumbs or 60-size pots, shift them in the spring into 5 or 6-inch pots instead of turning the plants out of their pots at the bedding-out season, and plunge the pots deep enough to hide them. The plants will make less foliage

and more flower, though they will require planting closer together to give the desired effect. I have used the same plants three years in succession, and they gave every satisfaction.—J. PITHERS.

PEAR TREE IN FULL BLOSSOM IN NOVEMBER.

I HAVE forwarded a few sprays of blossom of the Jargonelle Pear. The tree, which is 20 feet high, is one mass of blossom, and to us the effect is extraordinary. The tree flowered in the spring and produced fruit. In July it suddenly lost all its foliage, and now it is, as you see from the specimens sent, flowering again from every bud. We should like to hear through the Journal what you think about this enrious freak.—JOHN MALLETT, *Gardener to H. Collier, Esq, Hoe Street, Walthamstow.*

[We have not had a box of prettier flowers this year, every spur—and there are thirty-three of them on the branchlets—terminating in a cluster of flowers as fine as we ever saw Pear blossom in the spring, but appearing more beautiful now in its isolation. The result is due to the check the tree received in July. Had it continued growing the force of the sap supplied by the roots would have found expression in the leaves, but since these were lost it forced the blossom; the tree, in fact, went temporarily to rest, had its little winter in July, now followed by its spring in November. The blossom has expanded now instead of next March, and a similar display must not be expected at the ordinary period of blooming next year.

It is not unusual for Pears to occasionally produce some blossom in the autumn, or even in summer. The Windsor Pear is especially apt to do this in dry soils and hot districts. A partial cessation of growth occurs by the heat and drought, and the tree rests; most genial weather follows, and it starts into growth again, blossoms, and even bears fruit. This is notably the case in France, hence the Pear has become known as *Poire Figue, Figue Musquée* and *Deux fois l'an*. The same peculiarity has, however, been observed in this country upwards of three centuries ago, for Sir Hugh Plat, in giving the authority of "Master Hill," who lived about 1563, "Why trees transplanted doe alter," says, "Trees that bear early, or often in the year, as Pear trees upon Windsor Hill, which bear three times in a year; these though they be removed to as rich, or richer soil, yet they do seldom bear so early, or so often, except the soil be of the same hot nature, and have the like advantages of situation, and other circumstances with those of Windsor. And, therefore, commonly the second fruit of that Pear tree being removed, doth seldom ripen in other places."]

CRATÆGUS AZAROLUS.

UNQUESTIONABLY this is one of the most beautiful Thorns we have, and it richly deserves the attention of those whose time and minds will be occupied during the next two or three months in planting and replanting various kinds of evergreens and deciduous trees and shrubs. At this time of the year it certainly has a very attractive and charming appearance, and cannot fail to elicit admiration from many who are not habitually close observers of the beauties of Nature, but whose innate love of bold and striking objects compels them, unconsciously as it were, to notice anything above mediocrity. For planting out on lawns or in parks as single specimens it is admirably adapted, and where it does not already exist a few trees would add much to the scenery, and greatly improve the surroundings of any country or suburban residence. Its blossoms are probably less showy than any of the scarlet or common white Thorns, but the haws which the trees are still bearing are exceedingly pretty, being of a beautiful bright orange-scarlet in colour, almost as large as Cherries, and borne in clusters of from three to ten, render it very conspicuous from a considerable distance. Although the character of the tree is seen to the best advantage when growing singly, we do not doubt but that clumps or rows along the outskirts of woods and plantations would be equally effective. If it were desired to heighten the effect a few clumps of Pampas Grass planted in front would form a very pleasing and striking contrast.—J. HORSEFIELD, *Heytesbury.*

PANSIES AND VIOLAS.

It is easier to answer the query of "H. Notts," respecting the distinction of the Pelargonium and the Geranium than it is to distinguish the so-called Viola from the Pansy. Mr. H. Cannell, jun., seems to have solved the question without difficulty, and the varieties he mentions are no doubt true off-springs from *Viola cornuta*—hence the distinction from the Pansy. But going further, and referring to Cannell's Guide, at Violas, for instance, I find—"Holyrood, deep indigo blue, dark blotch;" then turning to Show Pansies (selfs) I find, "Bluegown, deep blue self, dark blotch;" then *Viola Countess of Kintore* and *Pansy Magpie*. I cannot see here the distinction of the two sections Violas and Pansies.

Some three or four years ago when on a visit to Sale I called upon Mr. Brownhill. He then had two beds of seedlings, one of Violas and the other of Show and Fancy Pansies. There were about 1200 plants flowering in each bed, the first bed producing moderate Show and Fancy Pansies and Violas, so-called, the latter producing Violas and Show and Fancy Pansies. It was just at this time when the question was asked, "What is the difference between the Viola and the Pansy?"

There is no doubt a wide difference between the Show and Fancy Pansy and the true *Viola cornuta*; but when we come to such varieties as Holyrood, Waverley, Pilrig Park, Admiration, and others, I fail to

see any trace of *V. cornuta* in them, and they appear nothing more or less than inferior varieties of the Pansy, as Mr. Plant well observes.

It rather puzzles me that any true form of the *Viola cornuta* should drive out of the field such good old plants as Purple King Verbena and yellow *Calceolarias*, but I am fully aware that it does not take much to please some people.

The *Violas* Mr. Cannell speaks about so highly no doubt are good in their way, but if they were planted side by side with such charming varieties of Pansies as *Bluestone*, *David Cavin*, and others I could name, I have no doubt the tables would be turned.

While on the subject I may refer to a sweet-scented Pansy, *Miss Darling*. It has the perfume of *Mignonette*. It is a noble yellow *Fancy*, free-blooming, and ought to be in every collection.—JAMES PERCIVAL, *Smithy Bridge*.

I WILL only intrude a line or two on this subject (*vide* page 374), as I do not consider myself an authority; but the point is important, especially from an exhibition point of view. I was pleased to see Mr. H. Cannell, jun.'s contribution on this subject; and no doubt, as he says, it is easier to distinguish with the eye than to find words to exactly make that distinction plain. What do you say to a rough-and-ready distinction of considering all those with radiating distinctly marked lines from the eye as *Violas*, and the others Pansies—*Show*, *Fancy*, or *scifs*? Mrs. Gray, Countess of Kintore, *Favourite*, &c., would come under the former, though very beautiful.—W. J. MURPHY, *Clonmel*.

STORED-UP SAP IN VINES.

It is impossible to reconcile Mr. Taylor's theory of stored-up sap in Vines (p. 372) with facts or common observation, and I believe there are few experienced gardeners who believe that Vines subsist on "the stored-up food" of the previous autumn till the shoots are 7 inches long and the leaves 5 inches broad, as Mr. Taylor states. What is meant by root-action is the absorption of food from the soil, and this begins as soon as the Vines are started. If this is not so, will Mr. Taylor explain the well-ascertained fact that a Vine cut off at the root does barely more than burst its bud-scales before it dies? And will he also state why Vines "bleed" before they break, and stop bleeding as soon as severed at the neck? Does such a flood of sap come from the roots, and are the roots in action or not when they do so draw it up? Is this sap what Mr. Taylor calls "food," which he speaks of coming from the roots to put colour in the leaves? If it is not food, why does the loss of it enfeeble a Vine and cause it to push weakly shoots and pale small foliage? Sometimes people wrongly apply the term "root-action" to root-growth or extension, which does begin later than that of the branches; but Mr. Taylor makes it clear that by root-action he means drinking up food, and he tells us he acts consistently with that meaning by not applying water to the roots till root-action begins. I shall be much obliged by an answer to these questions as they are put by—A NON-BELIEVER.

LILIUMS.

LILIES! What a number of beautiful forms pass in review at the mention of this name! We can fancy we are enjoying afresh their associations, beginning early in the season with the charming little scarlet-flowered *L. tenuifolium*, and ending with the indispensable *L. speciosum* and its varieties still lingering with us. The most charming of all bulbous plants they are, and it is desirable to make the most of them. What can be more serviceable and lovely than the Trumpet Lilies? Take *L. longiflorum* and its several varieties for instance. Very easily I have had great enjoyment from this species, having the first flower expanded on the 16th of May, and have still pure white flowers by the dozen, and this is the 5th of October. The first flowers were from the excellent variety named *L. Harrisii*, and the same variety is now in its second flowering state. Some bulbs are even producing a third set of stems for this season. Of course a good number of bulbs have been worked to maintain such a lengthened display, and all the well-known forms of *L. longiflorum* have been utilised, commencing with *L. Harrisii*. The next to flower was the type, and in order *L. Takesima*, *L. eximium*, *L. albo-marginatum*, and *L. Harrisii* the second time. It is difficult to over-estimate the value of Lilies for garden decoration, as the numerous kinds flower at different periods throughout the season from April to October, and can thus be enjoyed. Of course a judicious selection is necessary.

Cultural Requirements.—These are by no means so numerous as we have been led to believe. Some of the commoner species have been cultivated for centuries and are still favourites, little or no trouble being taken to insure their happiness. Speaking broadly Lilies are happiest when left alone, especially if the position they occupy is not too impoverished. When planting this should be considered, and a good supply of thoroughly decayed manure be well incorporated with the soil near them. Lilies are gross feeders, and enjoy a liberal supply of good manure. There is no doubt they also enjoy a well-drained sandy soil, and plenty of moisture when in full activity. A good

method when planting the bulbs, especially if they have been out of the ground long, is to place a layer of gritty sand about them, which not only insures drainage for the bulbs, but appears to have some other advantages more difficult to explain than appreciate. The question of positions as regards sunlight is one respecting which Lily growers disagree. In my opinion the position as regards the health of the plant's matters little, in relation to sunlight, if the roots are right; the flowers are most likely of less duration when fully exposed to sunshine than otherwise. I have seen equally as good examples of several species of *Lilium* grown in very open positions as in partially or even entirely shady ones. The secret is undoubtedly when they are grown in exposed positions to keep the roots cool, which is easily managed by carpeting the surface with *Sedums*, *Saxifrages*, or similar dwarf plants, for as simple a matter as it may seem, it is most advantageous to the Lilies. Of course when huge masses are formed, so that the foliage is thick enough to thoroughly shade the surface, nothing of the kind is necessary, and the system of covering the ground is decidedly desirable from an artistic point of consideration. Bare ground is truly an eyesore to the lover of Nature. Here is an example of a style of gardening which should be greatly encouraged, and which has for the last three weeks been very charming. The ground is covered with *Corydalis lutea* and the old *Plumbago Larpentæ*; rising above and from amongst this groundwork are *Fuchsia virginialis*, *Amaryllis Belladonna*, and *Lilium speciosum rubrum*, the two latter in grand masses.

Lilies are more than ever grown in pots for decorative purposes, especially *L. auratum*. The varieties of *L. speciosum*, *L. longiflorum*, and even the old *L. candidum* are sharing largely in popular favour for this purpose. No time should now be lost in getting them potted and placed in a cold frame until they have drawn roots well. The bulbs of *L. longiflorum* are generally placed three in a pot, when a good show of bloom is secured. Of course, unless home-grown bulbs of *L. auratum* are secured these cannot be potted until they arrive from Japan, which is usually well into November, or even December. A great mistake is often made in potting bulbs of this Lily. They are put into the flowering pots at once, and very often watered freely, the result being the bulbs frequently decay through the abundance of wet soil about them. They should be placed in small pots, which will just take the bulbs and allow of a layer of sand about them, and be kept in them till they draw roots well, when they may be transferred to the flowering pots, using a rich compost for that shift.

Much is said and written about preserving the bulbs of *L. auratum* after flowering, which could be dispensed with. One thing is certain—the bulbs in nine cases out of ten grown in pots are almost useless for blooming the following year; the game is hardly worth the powder and shot when the low price at which they may be purchased is taken into consideration. Good bulbs are usually sold at 6d. and 9d. each. The plan I adopt is to make fresh purchases yearly, and plant out the old bulbs after once flowering into well-prepared rich ground, and pinch off all flowers which show themselves the following year, and in due course the bulbs get strength and reach again a good healthy flowering stage. The species and varieties described below are only a small portion of the kinds obtainable from specialists, but they constitute a good series, the flowering period extending over several months, and those the most enjoyable of the year in the outside garden.

L. auratum, Lindl.—This grand species is too well known to require any description in these pages, being now grown by all lovers of flowers, the price being within the means even of all enthusiasts. There are, however, some varieties of it which are but little known, such as *rubro-vittatum* and *cruentum*, the former with broad crimson bands taking the place of the yellow bands in the typical form of flower, the latter resembling it, but with maroon bands and purplish crimson spots. These are both magnificent varieties. Flowers from August to October. Japan.

L. Batemannia, Wallace.—A very charming slender-growing species, 3 to 4 feet high, with narrow leaves. Flowers erect, in umbels of from three to eight; perianth nearly cup-shaped, of a rich, deep apricot colour, and about 4 inches across. It resembles very closely some of the *L. Thunbergianum* varieties, to which species it undoubtedly belongs botanically. Native of Japan, flowering in this country from the end of July to September.

L. Browni, Miell.—A very highly appreciated species, growing from 2 to 3 feet high, with numerous deep green lanceolate leaves, and large, mostly solitary, flowers; perianth tubular, bell shaped, 6 inches or more long, with a spreading limb with revolute segments, pure ivory white inside, and deep purplish brown outside, the colours contrasting very finely. Native of Japan, and is closely related to *L. japonicum*, if indeed anything more than a

variety of that species, but from a gardening point of consideration it may be regarded as distinct, flowering in July and August.

L. bulbiferum, Parkinson.—An old-fashioned and well-known Lily, so frequently seen with *L. croceum* in cottage gardens, producing stems from 2 to 3 feet high, or even more in some soils, carrying umbels of deep red flowers about 3 inches across. Native of southern and central Europe, flowering in June and July. Among the earliest of Lilies.

L. candidum, Linn.—The Madonna or old white garden Lily, so well known to everybody, and more than ever appreciated with its tall stems of bright green leaves and racemes of pure white flowers. When planted this Lily should not be frequently disturbed, or it will flower very indifferently. There is a variety called *speciosum*, which is more robust, floriferous, and with rather larger flowers. Another form named *striatum* produces flowers striped with purple, while another produces double flowers. None is more serviceable than the typical form. Southern Europe, &c. July to September.

L. canadense, Linn.—This is a very variable Lily, including a large number of varietal forms, geographical as well as local. The type grows about 2 feet high, with slender stems and whorls of narrow leaves. Flowers nodding, usually umbellate, bright orange or yellow, freely spotted. North America; flowering in August, sometimes in July. A good variety of it is named *parvum*, growing taller with many-flowered racemes of yellow-spotted flowers.

L. carniolicum, Bernh.—This is a handsome Lily, growing from 2 to 3 feet high, with numerous lanceolate leaves clothing the rather slender stems. Flowers few, in a raceme of a bright orange-red colour, finely spotted inside, from 2 to 3 inches across, with the segments revolute. Native of southern and eastern Europe, flowering in June and July.

L. chalcedonicum, Linn.—The Scarlet Martagon, as it is frequently called. Stems erect, from 2 to 4 feet high, thickly clad with narrow, lanceolate, light green leaves. Flowers in racemes, usually few; the perianth of a bright vermilion colour, frequently finely spotted upon the inner surface, with the segments sharply revolute. Native of southern Europe, flowering in July and August. This Lily makes but poor growth the first season after planting even if the bulbs are strong. Last autumn I planted several bulbs, and they flowered very indifferently and were very dwarf. A few days ago I lifted some of them, and they were making excellent root and bulb growth. It is a most lovely kind, not at all fastidious, growing almost anywhere, and is a universal favourite.

L. Columbianum, Hanson.—This is perhaps only a slender-growing dwarf variety of *L. Humboldti*, but for cultural purposes it may be considered distinct. Stems from 2 to 4 feet high, with a few leaves in whorls. Flowers in umbels or racemes, few or numerous; perianth of a rich orange-red colour, freely spotted with deep purple spots, the segments sharply reflexed. Native of Oregon and British Columbia; flowering in July. It is a very graceful and pretty kind, growing freely in light sandy soil.

L. croceum, Chaix (the common Orange Lily).—A well-known old garden favourite, growing from 2 to 5 feet high, with numerous narrow leaves, and large deltoid racemes of bright orange-coloured flowers 3 to 4 inches across the open perianths. Native of southern Europe, flowering in July close upon the heels of *L. bulbiferum*, to which it is closely related. One of the most useful Lilies for planting in the border and woodland.

—T.

(To be continued.)

MESSRS. GEORGE BUNYARD & CO.'S NURSERY, MAIDSTONE.

THE town of Maidstone, picturesquely and pleasantly situated on the Medway, is in the centre of a large fruit and Hop-growing district, and Messrs. Bunyard's nursery has long been known in connection with it; but it is not until of late years that it has so rapidly developed its fruit-tree-growing character; and as it was to see this portion of the nursery that I went I shall leave on one side the other departments, merely saying that there is a fine stock of Conifers and shrubs out of doors and an excellent collection of Camellias in the Camellia house. There are about eighty acres of ground, and the largest piece of about forty acres is that through which I went the other day, and concerning which I should like to record my impressions. Mr. Bunyard is a successful Rose exhibitor, and anyone seeing the very beautiful stock which he has mainly on the seedling Briar (although there is a large quantity on the Manetti) would not be surprised at his success. The stock is not so large as that of many of our great Rose-growers, but I have nowhere seen finer plants; and as some were being lifted in the execution of orders, I can testify to the splendid roots, which showed how well the soil suited them, and is not of that especially heavy character which

oftentimes makes it difficult to grow the plants which have revelled in it; while the breezy character of the situation on high ground insures a certain amount of hardiness which is so favourable to their transportation into climates which are not, perhaps, peculiarly favourable to Roses. The Tea Roses on the Briar were especially good, and many lovely blooms of this favourite class were expanding their beauties in the warm October sun. How lovely they have been this season!

While other counties may grow and do grow Pears, Plums, and Apples, Kent is essentially the county for Cherries, and anything more beautiful than the stock of these it is impossible to conceive. In the various quarters there were upwards of 13,000 standard Cherry trees, and of these Amber Heart, Bedford Prolific, Kentish Bigarreau, Napoleon, Frogmore, Large French, Early Rivers, Early Elton, Governor Wood, East Kent, Turkey Heart, Kentish Red, Tartarian Black are the kinds most in demand, and of which the largest stock is kept.

The Apples were in almost untold numbers; but while perhaps 120 sorts are grown, there are some for which there is an almost universal demand, and these are grown in very large quantities. To those who desire to plant for profit the following are recommended:—Of dessert Apples Blenheim Pippin, good for dessert as well; Cox's Pomona, Duchess of Oldenburg, Gipsy King, Margil, Mr. Gladstone, of these there were 1000 trees; Old Winter Nonpareil, Scarlet Nonpareil, Claygate Pearmain, Worcester Pearmain, of this beautifully coloured Apple 2500 splendid trees were grown; Cox's Orange Pippin, of this the king of all dessert Apples there were upwards of 3000 trees; Summer Golden Pippin, Ribston Pippin. By-the-by, what a superstition there is about this. How frequently we are told that it is dying out, and that the Ribston will be soon a thing of the past. Why, here were thousands of fine plants without any trace of canker or decay. Delicious as a good Ribston is it must yield, I think, to the Cox's, which is not so hard, yet crisp and delicious—even, I think, in flavour superior to the Ribston. Red Quarrenden, King of the Pippins, Reinette de Canada, and Washington, a grand Apple. Then of kitchen Apples the most marketable varieties are Annie Elizabeth, Belle Dubois or Gloria Mundi, Cellini Pippin, of this were some marvellously coloured fruits on small trees; Keswick Codlin, a variety greatly in request; Ecklinville, another grand Apple; Gascoyne's Scarlet, a Kentish variety; Grenadier, a most desirable fruit (one of the few Apples certificated at the Congress); New Hawthornden, Lady Henniker, Loddington or Stone, a grand kitchen Apple of Kentish origin; Lord Suffield, of this well-known Apple there is no need to say anything; Lord Derby, another grand fruit; Northern Greening, very late; Queen Caroline, Small's Admirable, Warner's King, very fine; Wellington, and Winter Queening. The standards of these trees had stems from 5½ to 6½ feet.

Among the multitudinous varieties of Pears there are some which always command attention as market Pears, such as Bon Chrétien, Beurré Bosc, Beurré de Capiaumont, Beurré Clairgeau, Bishop's Thumb, Calebasse Bosc, Doyenné d'Été, Rivers' Fertility, and Hessel; while for those who desire in their gardens to have the most delicious Pears grown the following are recommended:—Beurré d'Assomption, Beurré Superfin, Doyenné du Comice, the finest flavoured of all October Pears; Comte de Lamy, small but most delicious; Glou Morceau, Jargonelle, Marie Louise, Louise Bonne of Jersey, Pitmaston Duchess, Souvenir du Congrès, and Josephine de Malines. The trees are of all kinds—standards, half standards, dwarfs on Pear and Quince stocks, some double-grafted, others of Rivers' variety of Quince.

Plums and Damsons are very largely grown—budded plants of a year old with clean growths of from 6 to 10 feet, while the two-year-old plants were so vigorous that the junction had completely grown over, and all fear of loss was obviated. Thus of the Bush Plum, a Kentish variety, there are 5000 trees, of Cox's Emperor 5000, of the Pershore Egg Plum 2500, of Rivers' Early Prolific 5000, Orleans 5000. The others most in request for market purposes are Pond's Seedling, Prince Engelbert, Royal Dauphine, The Czar, The Sultan; while for garden purposes Coe's Golden Drop, Green Gage, Jefferson, Oullins Golden Gage, Transparent Gage, and Washington are always in request; but of the Plum tribe the most remarkable growth is that of the Farleigh or Cluster Damson, of which there are from 40,000 to 50,000 trees. This is a Kentish variety and most astonishingly prolific, hardly ever failing to produce fruit, and that in the greatest profusion. It is stated that one Kentish grower sent last year 3000 bushels to market, which realised 14s. a bushel. So great is the demand for it that every year Messrs. Bunyard dispose of from 10,000 to 15,000 trees.

If Cherries are the first great speciality of Kent, Nuts are the next in importance. The Kent Filbert is famous, but it is now being rapidly superseded by the Cob Nut, as being much more profitable and a more constant bearer, and of this Messrs. Bunyard have about 20,000 trees, and the demand for them is rapidly increasing.

Of Gooseberries, Currants, Raspberries, Mulberries it is needless to say that there is an immense stock of the best varieties, and any fruit-grower either for market or for their own use will find in these nurseries everything to satisfy their wants, no matter how great their demand may be. I may perhaps best exemplify what Messrs. Bunyard can do by stating what they *did* for Lord Sudeley. His lordship determined on going in largely for fruit-growing as a profitable investment. At his seat at Toddington, Gloucestershire, he has begun by planting 500 acres, and he was so satisfied with some smaller transactions that he had with Mr. George Bunyard that he placed the matter in his hands. The particulars of the trees supplied were published on page 170, the issue of March 1st of the present year. This was indeed a gigantic operation, and it is much to Mr. Bunyard's credit that it was conducted entirely to

Lord Sudeley's satisfaction. Nor is this to be wondered at. Mr. Bunyard is young and active, he superintends everything himself—is not satisfied with entrusting it to others however capable, and can thus guarantee whatever he sends out from his establishment.

There are many other things of which I might speak, but I must not trespass on your space, and can only add that I was received with the utmost courtesy, a fact which those who know Mr. Bunyard will not be surprised at. After I left him I went to see my old and valued friend Mr. Jno. Hollingworth, who was loud in his praises of the fruit-bearing properties of some pyramid fruit trees he had obtained from Mr. Bunyard, showing that in his own neighbourhood, as well as at a distance, the character of his culture stands high.—D., Deal.

HEREFORD APPLE AND PEAR EXHIBITION.

I AM anxious to correct an error that appears in my report of above Exhibition last week in reference to the Onibury Pippin. This excellent dessert Apple cannot be too widely made known and recommended; indeed, I believe it to be worthy a place in every collection however small, where it might form a well-matched triplet with one of the very best and hardiest culinary Apples, Wormsley Pippin, and that well-known late dessert Pear, the Monarch; all *chef d'œuvres* of that indefatigable pomologist, Andrew Knight. It was a subject of general regret that a choice collection of cider Apples (some fifty varieties), expressly sent from Normandy to the Exhibition at Hereford, arrived too late. From a cursory glance I have had there is hardly any resemblance to be now traced between them and our present Norman cider varieties, presumed to have been introduced from Normandy into our Herefordshire orchards by Lord Seudamore of Holme Lacey about the early part of the seventeenth century. I will only mention that the nomenclature of the several varieties, as now grown in the different countries, are as widely different as their structural and other characteristics; but this is not the occasion to more than allude to this interesting subject.—THE HEREFORDSHIRE INCUMBENT.

THE ROYAL BOTANIC SOCIETY'S SHOW FIXTURES for 1884 are as follows:—Exhibitions of Spring Flowers, March 26th and April 23rd; Summer Exhibitions, May 21st and June 18th; Evening Fête, July 2nd; Promenades will be held on the other Wednesdays in May, June, and July; Botanical Lectures will be held on each Friday in May and June.

— IN connection with the Fisheries Exhibition Mr. J. D. DICK the resident official of the Royal Horticultural Society, was placed in charge of the turnstiles, and thus the enormous sum of money that was taken passed through his hands. His staff, to the number of thirty, entertained Mr. Dick and his assistant, Mr. G. Browning, at dinner last Thursday evening, and presented them with a ring each, bearing the following inscription—"Presented to J. D. Dick, Esq., as a mark of esteem by his staff, I. F. E., 1883." "Presented to Mr. Geo. Browning as a mark of esteem by his staff, I. F. E., 1883." The dinner was kindly given by Messrs. Bertram & Roberts. We are very pleased to record this mark of recognition of the urbanity of Mr. Dick, and further trust that his services will be handsomely recognised by the Fisheries Committee.

— WE learn that an EXHIBITION OF CHRYSANTHEMUMS will be held by T. H. Bryant, Esq., in his grounds at Glencairn, Surbiton, on Thursday, Friday, and Saturday, November 15th, 16th, and 17th, the admission to which will be 1s., and the proceeds are to be devoted to the Surbiton Cottage Hospital. The Show will be open from 1 until 10 P.M. each day, the tents being lighted by the electric light in the evening. The St. Mark's band will also attend. Those who saw the handsome plants at Kingston last year will remember what a fine display they afforded, and numerous visitors will doubtless be desirous of seeing this year's productions.

— LETTERS have reached us directing attention to the undesirable CLASHING OF CHRYSANTHEMUM SHOWS. This is no doubt in a great measure unavoidable, and the objection that has been taken to the Committee of the Kingston Society fixing their Show on the same date as that of Mr. Bryant's Show above alluded to is certainly not merited. The date of the Kingston Show was announced last December, but the notification of the Surbiton Hill Exhibition only reached us a fortnight

ago, and its fixture was certainly not made public antecedent to that of Kingston. It is unfortunate that two shows in the same district should be held on the same date, as the public are deprived of visiting both on the opening day. The Kingston Show, which is expected to be a very fine one, will naturally have the preference. They will, however, have the opportunity of visiting the Surbiton Hill Exhibition on the second and third days. Surely such a clashing as this might have been avoided, and more especially as it is calculated to prejudice the fund for a hospital.

— THE beautiful variegated form of *SIBTHORPIA EUROPEA* is rarely seen in the neighbourhood of London in such condition as represented in the Heath house at Kew. This plant is rather difficult to grow, and it is only after many experiments and some failures that success has been attained. It was, we learn, grown in a cool frame in a rather shady situation with the pot standing in a pan of water, and under no condition is water given over the foliage. It is now almost as much at home as the common form.

— "J. A. W., Alderminster," writes:—"Where *LILIUM AURATUM*, *L. SPECIOSUM ALBUM*, &c., are very late out of doors, as they are very often the first year, and look as though they would not open, let them be cut down with a long stalk and placed in water in a deep vase, where they will gradually unfold their beauty and fill the house with their rich perfume. The same may be done with the unopened buds of the *Magnolia*, only in this case if you do not care to cut off any wood you must use a bowl and not a vase."

— MR. J. ROBERTS, The Gardens, Tam-y-Bwlch, Merionethshire, sends a box of blooms of the *MARIE LOUISE VIOLET*, which he considers is not surpassed by any other variety, and observes—"We grow thousands here, and are not without blooms one month out of the twelve." The flowers are very fine, but not equal in size or colour to examples of *V. odorata pendula* of New York that were sent to us in January last by Mr. Beachey of Kingskerswell, who grows "twenty-six varieties of Violets, but has none which equals New York for general utility." Does Mr. Roberts grow this variety?

— WE are informed that the *CHRYSANTHEMUMS AT SLOUGH* are in remarkably fine condition this year. Mr. Charles Turner's collection comprises many thousand plants in all the leading varieties. They are now approaching perfection, and an inspection is invited. The principal houses will be illuminated on Wednesday the 14th inst., from 6 till 9 o'clock P.M., and the effect will undoubtedly be very beautiful; but for a critical examination of the varieties an inspection during the day is preferable. The Royal Nurseries are worthy of a visit at any time, but never more so than during the Chrysanthemum season.

— IT appears from the programme announced at the closing of the Fisheries Exhibition last week that there is little prospect of a large INTERNATIONAL HORTICULTURAL EXHIBITION being held in London for several years. It is true that the Food Exhibition for 1884, the Machinery and Invention Exhibition for the year 1885, and the Colonial Exhibition in the following year will afford some scope to horticulturists in the various departments, but no display of a special nature is promised; and it is to be regretted that the statement officially announced a short time since should have been made when no definite course had been decided upon. Each of the Exhibitions proposed will be interesting and instructive, but it is doubtful if they will attract the public in the same proportion as the one just terminated has done. Over two millions and a half is an enormous number, far exceeding the expectations of the most sanguine of the projectors.

— "AMONG the many *Androsaces* now in cultivation," writes "D. D.," "none, I think, is more suited for rockwork decoration than *ANDROSACE LANUGINOSA*. When once well established it is almost an continuous flowerer. The flowers, which are produced in loose umbels, are of a light mauve colour. The leaves, which are densely clothed with silky hairs, present a lively appearance at all times of the year. It does not, however, relish a damp situation, and I find after various experiments that planting just behind a ledge or sloping stone, and allowing the long straggling shoots to scramble over its surface, is the most successful treatment."

— THE PUBLIC CHRYSANTHEMUM SHOWS in London continue to attract large numbers of visitors. Both the Temple collections have now a greater number of blooms open, and Mr. McIntyre has his usual interesting display in Victoria Park. During the next week they will be

all at their best, and visitors to the principal competitive exhibitions should by no means miss the opportunity of seeing how Chrysanthemums can be grown in the midst of London smoke and fogs.

— PROPOSED NATIONAL CHRYSANTHEMUM SOCIETY.—We are informed that at a full meeting of the Borough of Hackney Chrysanthemum Society, held on Tuesday night, it was resolved and carried almost unanimously that at the end of the current year this Society be constituted a National Chrysanthemum Society.

— THE "JOURNAL OF FORESTRY" for November contains, amongst other papers, interesting articles on "Forest Rambles in Finland," "Through Sherwood Forest," "Industries of Shetland," and "An Excursion to Ettrick Forest," together with a variety of news and notes.

— THE DURHAM, NORTHUMBERLAND, AND NEWCASTLE, INCORPORATED HORTICULTURAL AND BOTANICAL SOCIETY held their fifty-ninth annual meeting in the Alexandra Hotel, Mayton Street West, on October 31st. Councillor Thos. Gray presided. The Secretary, Mr. Gillespie, read the report, which showed the income was in excess of the expenditure by £143 16s. 8d. Paying a balance of debt of £86 7s. 1d. leaves now to the credit of the Society £57 9s. 7d. It must be a matter of congratulation to all connected with this Society that it is out of debt, and that it will be able to still further aid the development of horticulture in the north. The Society will hold its spring show on April 23rd and 24th, 1884, and the summer show on the 23rd, 24th, and 25th of July. The President this year is H. G. Mayton, Esq., West Denton, and the Vice-president the Mayor of Newcastle.

— GARDENING APPOINTMENTS.—Mr. J. Clark, recently gardener to Lord A. E. Hill Trevor, Brynkinalt, Chirk, has been appointed gardener to J. F. Le Trove Bateman, Esq., Moor Park, Farnham, Surrey. Mr. Frederiek Burgess, lately foreman at Idsworth, Horndean, Hants, has been appointed gardener to W. Pink, Esq., Shrover Hall, Horndean, Hants. Mr. G. Grant has resigned his situation as gardener to J. B. Cooper, Esq., Horley Hall, Surrey, to take charge of the garden and grounds of the New County Asylum, Cane Hill, Surrey, and is succeeded at Horley Hall by Mr. Squibb, his late foreman. Mr. J. Mabin, late gardener to Sir J. Astley, Orleans Club, Twickenham, has been appointed gardener to Col. Carden, Stargrove, Newbury, Berks. Mr. James Lloyd, foreman at Ashton Court Gardens, Bristol, has been appointed gardener to Vincent Stucky, Esq., Hill House, Langport.

— SELDOM is KNIPHOFIA QUARTINIANA seen in such perfection as it is at present near the new rockery at Kew. This is the most distinct of all the Kniphofias, and even when out of flower the fine glaucous leaves are quite ornamental; they are from 1 to 2 feet long, and gradually tapering from the base to the point. The flower spike is from 2 to 3 feet high; and the individual flowers, which are about 1 inch long, are of a dull red before opening, changing when fully expanded to deep orange; the anthers are bright yellow, and protrude above the flower. In habit this much resembles one lately received from Natal, and which is said to be the finest of the genus. We believe a painting was made by Miss North during her recent visit to South Africa, and is included amongst the pictures now being added to the collection in the north gallery at Kew.

— THE Secretary of the INTERNATIONAL FORESTRY EXHIBITION has received the following letter from Her Majesty's Secretary of State for Foreign Affairs, which is highly gratifying to the promoters of what bids fair to be an undertaking of national importance, alike in its educational as in its commercial aspects:—"Foreign Office, October 27th, 1883. The attention of Her Majesty's Government has been directed to a project for an International Exhibition of Forestry to be held at Edinburgh in the summer of 1884, the organisers of which are desirous of securing the co-operation therein of such foreign countries as the matter may concern. There is reason to believe that the proposed Exhibition, for which the necessary funds have been guaranteed, will be influentially and ably supported. The object is one which, in the opinion of Her Majesty's Government, deserves every encouragement, scientific forestry having hitherto been much neglected in this country; and I have therefore to request that you will bring the Exhibition in question to the notice of the Government to which you are accredited, as being one in which their participation might be attended with advantage to both countries. I enclose for communication to the proper quarters copies of programmes and other documents connected with the proposed Exhibition, which have been supplied by the Committee.—I

am, with great truth, your most obedient humble servant, Signed (for Earl Granville), EDMOND FITZMAURICE."

— WRITING to the *London Daily News* in reference to KENTISH APPLES AND THE APPLETONS, Mr. Lewis Appleton says:—"In connection with the National Apple Congress, it has been justly stated that the county of Kent is the chief English contributor. Reaching back as far as the eleventh century, Kent has been famous for its Apple gardens and orchards. In 1066, the year that William of Normandy invaded, conquered, and was crowned King of England, several of his Royal followers settled in Kent, amongst whom was a lady of his court named Mahilia. This lady fixed her residence in the vicinity of a forest of Apple orchards, and in consequence she received the surname of Mahilia d'Appleton, or Mahilia of the Apple Orchards. From this Norman lady sprang the family of the Appletons, who for eight centuries have maintained their ground as an ancient family in Kent and the adjacent counties. In 1641 a member of this family, John Appleton, was one of the 'Puritan Fathers' who sailed in the 'Mayflower' for the American continent, and from him sprang the family of Appletons in the United States. Charles Sumner and the poet Longfellow intermarried into that family. The crest of the family became, at a very early date, a bough with leaves and Apples, and it still remains the crest of the family, of which I subscribe myself a humble descendant."

— A WRITER in the *American Gardener's Monthly* thus describes the GARDENS AT VICTORIA, VANCOUVER'S ISLAND:—"Though the mountain tops some fifty miles away are perpetually white with snow, except when the morning and evening sun lights them up in purple and gold, the air in the town is warm, though without sultriness, owing to the long day's sun (sixteen hours now) warming the sheltered spots where the high mountain ridges keep off the arctic winds. The people are fond of flowers, and almost every cottage was embowered in Vines, and seemed ready to break down with their load of blossoms. In my early life in England I have memories of whole buildings completely covered from roof to the ground with sweet Roses and gratefully scented Honeysuckles, but I have often found that early memories become magnified. The distance of time lends an enchantment to the early view. I had come to suspect that the Roses may not have been quite so strong, nor the Honeysuckles quite so sweet, as these early memories recorded them. But here they were even excelling these impressions and giving a new echo to the voices of youth. The tale was true. The wild English Honeysuckle, running up by the cottage door, rambling under the eaves to almost gable end, dropping in festoons between the windows, and only by the aid of art permitting a glimpse of the within, and giving out thousands—yes, thousands of bunches of their deliciously scented purple and white and yellow flowers. And the Roses, and the Pyracantha, and the evergreen Ivy, and scores of other plants—here may they be seen climbing in wonderful luxuriance, or making bushes, in some cases nearly as large as the abitations they adorned.

— "It is wonderful how the Roses do here. Even the standard or tree Rose is grown to an enormous extent, and make the same beautiful ornaments in yards that they make in the Old World. And the indigenous Rose—*Rosa cinnamomea* or Cinnamon Rose—grows in a state which I may almost call grandeur. I have it growing in my Germantown garden, but about 3 feet is all the height it cares to grow for me. Here you may see bushes—nay, masses—scores of feet in diameter, 10 feet or more high, and bearing thousands of their remarkably sweet rosy flowers, giving a fragrance to the air for long distances away. In many instances the Sweet Briar and Eglantine of the Old World had become naturalised, and had got into the fraternal embraces of their native brother; but these also were growing with equal luxuriance, showing that it is the climate which does it all."

GRAPES AT CHISWICK.

ALL who had not the opportunity of seeing the great show of Apples recently held at Chiswick certainly lost a rare treat. I availed myself of the opportunity to visit the show, and did so for a threefold purpose. First, to see the large collections of Apples; second, to see Chiswick; third, to see the Grape conservatory. The last, but not least, was a sight worth seeing. This may be termed the school for Grape-growing, for here no doubt Mr. Barron has made it the base of operations in compiling his treatise on the cultivation of the Grape Vine.

This is a very able and masterly work, which I can strongly recommend to all interested in Grape-growing. The Grapes in this huge vinery gave evidence of the correct treatment they had received, and fully detailed by Mr. Barron in his treatise. We were particularly struck

with the condition of Gros Guillaume, which seemed to be as free and regular as the Black Hamburg. On our leaving the large conservatory we passed a long narrow vinery with span roof; this was full of ripe Grapes, fine developed berries, and as black as sloe. They appeared to us to be Gros Colman. Of black Grapes this variety appears to be the leading article in Covent Garden Market.—A. O. W.

EXHIBITING CHRYSANTHEMUMS.

Now that the critical time has arrived for watching exhibition flowers a few hints may be useful to some of your subscribers, among whom may be many amateurs. Earwigs must be closely sought for, as one of these in a flower often spoils it in a night. The florets must also be kept in their place as they are produced. Sometimes they come twisted or curled, hence

Fig. 74.—Board for Chrysanthemums, under side.

need attention with the tweezers, and occasionally one or two may require removing, yet the less taken from an incurved flower the better.

Collars will be required for rather loose flowers of the Queen tribe, and these should be placed on in time to keep the bloom solid. Circular pieces of cardboard are the best for this purpose with a small piece taken out of the centre, and a straight cut from the centre to the outer extremity of card, which will enable it to be placed very easily round the stem of the flower.

A few hints may be useful to young beginners at the forthcoming shows with regard to boards for exhibiting. In staging forty-eight blooms it is the most convenient to have two boards made for twenty-four flowers, which should be 24 by 18 inches; three-quarter-inch deal answers admirably painted a rather light green. The legs should be made to screw in and out of battens at the back and front, and should be of the right length for raising the board 6 inches at the back and 3 inches in front. The engraving (fig. 74) represents the underneath side of a board. Tubes can be made by any tinman, and must, of course, be a little shorter than the legs of the board.

Cups (fig. 75) in three sizes are required; the largest for the back row may be 3 inches long, for the middle a little more than 2½ inches, and for the front row a trifle shorter. These cups may be of wood and turned in a lathe, or may be purchased in tin from such florists as Mr. Cannell.

The blooms also require to be fixed firmly in their places by wedging the stems with small pieces of soft wood or cork, or, as is often used, a piece of the stem taken off the bloom stalk, as that is always at hand. This must be done from the bottom of the cup, as shown in fig. 76.

When flowers are inclined to come with short centre florets, placing the blooms in a dark cupboard or in the exhibiting box will often draw them up in the centre, and in some cases improve the colour in light varieties.

Larger boards are necessary for Japanese flowers, as these are far more spreading; higher cups also are necessary. Every grower should have a pair of tweezers, but beginners must be careful in using them, as the blooms are easily spoiled. The quills and short petals are all that should be removed, and many flowers need no dressing at all. Be sure also to shade from bright sun, as this reflexes the incurved flowers sooner than anything. Also too much heat without air will have the same effect.—GROWER AND EXHIBITOR.

[The above notes, by a very experienced cultivator, will be useful to those who have not seen Chrysanthemum blooms prepared for the stands. Boards and boxes (fig. 77) for containing them, tier above tier, are made of a superior order, and can be had ready for use. Such are represented in the figure we are enabled to submit by favour of Messrs. Cannell and Sons of Swanley. Our artist has represented one of the cups with such fidelity as to show a part of the stem, as it has been broken accidentally; this part, as will be apparent, is for inserting in the tube.]

PELARGONIUMS AND GERANIUMS.—The botanical differences between these are clear and distinct, and there is none of the confusion that exists amongst so-called Violas and Pansies. The Pelargonium has a five-

parted irregular corolla, and the upper segment of the calyx on the outer covering ending in a nectariferous tube running down the peduncle, while the Geranium being a regular flower—that is, the petals being all alike, and having no nectariferous tubes. The Pelargoniums I think are all from the Cape of Good Hope, and are not hardy; while the Geranium is perfectly hardy, and at least a dozen species natives of Britain, annuals and perennials, while exotic species are amongst our finest hardy herbaceous plants.—JAMES PERCIVAL.

WORK AMONG APPLE TREES.

As the time for planting Apples is at hand I send a few notes, the result of my experience with Apples on a light but rich soil, in which vegetables of the Cabbage tribe, Lettuces, and French Beans make wonderful growth, but in which Carrots always fail, and it is not suitable for most other root crops. A peculiarity with Apple trees is, that all varieties canker in the wood to some degree; trees on the Paradise stock being so much more subject to canker than those on the Crab, that in the case of Blenheim Pippin, which cankers very badly on the Crab, has died out entirely budded on the Paradise stock. Wellington (Dumelow's Seedling) again, which only cankers very slightly on the Crab stock, does so to a great extent on the Paradise stock. Another result of my experience is to plant maiden trees only. In order to obtain a number of bearing trees of a few good and reliable varieties, we a few years ago purchased a number of 2s. 6d. trees, but the only kind of these that has at all done well has been Stirling Castle; others will be burned this autumn, and their places taken by maidens prepared in the garden. Maidens planted two and three years have borne larger crops and handsomer fruit than prepared trees planted seven years ago.

Our work amongst Apples this autumn includes the lifting of a large number of maidens planted two years ago, and of older trees that were lifted two years ago. We have also a large number of home-budded plants to transfer from the rows in which they were budded, and to place in fruiting rows. If we had a command of turf, each of these home-prepared maidens would have its roots placed between two layers of turf, in which the trees would form a good foundation. A few of the more particular sorts will be so treated, but not all. Some that were two years ago planted in a mixture of decayed vegetable refuse have done so well that the others will be planted in the same manner. The older trees are lifted with a ball of soil and at once replanted. Some decayed refuse will be placed round and over the roots of these; and not to be forgotten is a mulching of horse-droppings given to each tree. Each tree is also supported by a stake. Fresh-planted trees are not pruned, but such buds as are not wanted are rubbed off in spring, and the foundation of a plant formed with those left.

As to work among older trees, so long as the trees grow well and bear

Fig. 75.—Tube and Cups for Chrysanthemums.

freely I do not know that it is wise to disturb the trees. Our plan has been to leave yearly a large amount of young well-ripened wood, and to cut out any cankered or bare branches. Four years ago a number of old trees, free-bearing sorts, were lifted and replanted in another part of the garden. Though the roots with them were destitute of fibres, all except one have grown, and this year the others have borne heavy crops of fruit. It is, doubtful, however, if it would not be a better plan to replant with healthy young trees which produce much better fruit than can be obtained from old trees.

As to the varieties to grow, there is no doubt that those which do well in one locality do not succeed in others. As instances I may say that such generally good sorts as Blenheim Pippin, Cellini, and Hawthornden do not succeed here. The first cankers in the wood, the second is small in the fruit which cracks badly, and the last simply stands still without making any progress from year to year. My plan is to increase the number of trees of really good varieties, so that those which will be grown

after a few years, though limited as to number, will be sure to bear even in bad seasons, and thus secure a supply of fruit when it is most wanted.—B.

SINGLE ROSES.

I MUST begin by saying I am not by any means a great admirer of single Dahlias, about which just now there seems to be a craze, but as I

Fig. 76.—Fixing flower in cup.

love every flower by all means let them be exhibited. However, I fully agree with "A. C." (page 354), as to the propriety of classes at the National and other great shows for single Roses. Before, however, we do have such classes, it would be wise to lay down some guide as to the properties of the single Rose. I have seen single Dahlias with from eight to ten petals. Surely this must be a mistake. Is not eight the legitimate number? It seems to me that in single flowers with large petals the number of petals should be strictly limited. In your issue of October 18th are engravings of two single Dahlias—Lucy Ireland, with eight petals, and Fairy Pet with, well, it is difficult to say, but I should fancy at least twelve to sixteen. Moreover, in this variety, if I may so put it, the row of petals seems to be double. If this multiplication of petals continues it will be very difficult to say what constitutes a single Dahlia. I cannot help thinking eight the legitimate number, but I should be glad if the voice of authority spoke on this matter. As a boy I well remember the old single Dahlia, which, as I imagined, by selection was converted into the show Dahlia of the present day; perhaps, however, I am wrong in this.

As regards a single Rose, however, I imagine the proper number of petals is five, but if there is a looseness of regulation as regards the Dahlia, why not for the Rose? I apprehend that one great point in judging the single bloom in flowers professing to be round must be its rotundity, with as little of the stellate character as possible. Of course if more than five petals are allowed for the Rose, and more than six or eight for the Dahlia, it is easy to obtain the circular outline by number of petals, which would obviate the otherwise stellate appearance. This, it seems to me, should not be permitted; hence arises the necessity in making these single flowers—show flowers—of adopting some hard-and-fast line as to the number of petals. A Pansy with six or eight petals would immediately be out of the running. Why not a single Dahlia exceeding a certain number of petals?

It must be allowed that the single Roses would be very beautiful. The round cupped form, the beauty, arrangement, and number of the stamens, and the obtaining of some colours, as in the orange-and-yellow, at present unattained in exhibition varieties, would all add to the fascinations of a Rose exhibition, and I hope "A. C.'s" appeal to our good friend "D., Deal," may not be lost. But before the ball is opened let the subject be well ventilated, and thanking "A. C." for his kind notice of the Rose election, I send these thoughts for consideration on the subject.—JOSEPH HINTON.

MADAME FALCOT ROSE.—Let me recommend this beautiful and very hardy Tea Rose. It has rich, clean, dark foliage, is a certain and

abundant bloomer, exquisite in bud-colour, a rich apricot, and very lasting. Few surpass this old friend. Madame Falcot never sticks or damages, neither, I think, does Marie Van Houtte. Many of the close Roses, as Madame Bravy, President Willermoz, do.—A. M. B.

AUTUMN-BEARING RASPBERRIES.

THESE are not so extensively cultivated as they deserve to be, seeing that they come into bearing just at the time the supply of kindred fruits is being exhausted, and continue to yield good supplies until stopped by the frost, a fact which considerably enhances their value. This year the crop is, as it has been for several years past, very good, the canes being until late in October studded with fruit. Belle de Fontenay is the variety we principally grow, and is the best autumn-bearing Raspberry that I am acquainted with. It is a robust grower and prolific bearer of large dark red fruit, having a pleasant flavour.

Raspberries, like everything else worthy of being cultivated, pay well for liberal treatment. Therefore a piece of ground in a warm situation should at once be deeply trenched and liberally manured. In this plant the canes in rows 4 feet apart and 6 or 7 inches asunder in the row. And the stronger the canes are when planted the better will be the results the following year; for although the canes now planted will have to be cut down to within an inch or two of the ground in February or March next, the young canes subsequently proceeding from these stools, and which will produce fruit during the autumn, will, in proportion to the strength of the latter, be more or less strong. When planted the canes should be tied either to a couple of wires strained to light oak posts driven firmly into the ground 18 or 20 feet from each other, or strings fastened to sticks, the former being the better and neater way of training; and then have a mulching 3 or 4 inches thick of half-decayed dung placed on between the rows.

It will be seen by the foregoing remarks that the autumn-bearing Raspberries, unlike the summer-bearing varieties, bear fruit on the current year's shoots, those of the preceding year's growth being, as already stated, cut away in early spring; therefore, all superfluous growths in the way of suckers should be kept cut away during the summer months, so as to concentrate the flow of sap to the development and consolidation of fruiting canes, otherwise the result, although all other cultural details may have been properly attended to, will not be satisfactory. In conclusion I may add that the size and quantity of the fruit will be greatly increased by giving the canes half a dozen good soakings of liquid manure during the interval from the middle of August to the middle or end of September; indeed, in the absence of

Fig. 77.—Chrysanthemum stand and box.

rain at that time such waterings will be absolutely necessary to assist the fruit attaining a presentable size.—H. W. WARD.

THE PHYLLOXERA.

A KENTISH correspondent having forwarded to us some Vine roots which we examined and found infested with the phylloxera, has in reply to our notification of the fact sent us the following letter with additional specimens of Vine roots.

"I send you another piece of root from the same Vine, and you will find it even more thickly covered with insects than the former; also a piece of lateral shoot and leaf to show you the vigour of the Vine, which is a Black Hamburg. The introduction of the pest here is a mystery,

unless it was introduced with the Vines five years ago; no Vines having been planted since then with the exception of one this year, which is quite clean so far. If it was introduced with the Vines, how come they to be so vigorous now? This Hamburg Vine, one of seven, the others being Muscats, has always given good crops of well-finished Grapes; this year it and the Muscats are more vigorous than ever. Is it possible to introduce phylloxera with imported Lilacs?

"The infested Vines have already been consigned to the fire. The border (which is an inside one and completely isolated from the others) is being wheeled out. The glass, woodwork, and wires will be washed with petroleum, the brickwork washed with hot lime; the drainage will be drenched with a solution of soap and petroleum, and dusted with hot lime afterwards, and then we shall plant again. But where are Vines free from phylloxera to be had?—R. GRAY."

[The portion of cane sent is very good, and the leaf large and of a deep green colour indicative of perfect health. Both portions are clean. The insects on the root are very small, and have apparently not been numerous until recently, and as yet not made any impression on the very healthy Vines. Next year the Vines must inevitably have changed for the worse, and they have been wisely destroyed. We fear this Vine scourge is more prevalent than is generally supposed, and its spread has not been limited by keeping its presence a secret, as if it were a disgrace to a gardener to have it on the Vines in his charge. It is no more a disgrace to him than it is to have the Potato disease in his crop in the garden, and not half so much as having thrips and red spider on the occupants of a vinery, as these are preventible. We are quite unable to answer the question relative to the probability of the phylloxera being introduced with Lilacs, but we do not think it very likely that it would live on the roots of those shrubs. Can any of our correspondents give information on this point? As to the inquiry of "where are Vines free from phylloxera to be had?" we assume it was not expected to elicit an answer, but rather intended to convey the writer's opinion of the general and wide-spread existence of the pest in this country.]

UVULARIAS.

RARELY do we see any record of the species of *Uvularia* cultivated in gardens, and we may imagine under the circumstances that it is a genus of plants either little cared for or not sufficiently well known to cause their cultivation to be more extended. By some they may be looked upon as plants more curious than beautiful; but singular and beautiful they are beyond doubt, and they only need to be well grown and disposed in suitable nooks in the garden to gain the high appreciation they so well deserve. Plants are often wanted for a shady position, or to cover spots where most plants refuse to flourish or even grow. The *Uvularias* are well adapted for such work, and they would look well if associated with hardy Ferns so employed, and at the same time afford a display of bloom such as few other plants would do under similar conditions. In the case of a venerable old tree growing on a lawn nothing could be more advantageously employed to enliven its immediate surrounding than the members of this genus, along with several species of *Gaultheria*, Ferns, and other shade-loving plants. When so employed a top-dressing of decayed leaves would prove highly beneficial both to the *Uvularias* and the rest of the plants.

So far I have simply stated how the *Uvularias* may be employed in occupying spots where the usual kinds of herbaceous plants would prove a failure. They are worthy of being represented amongst the choicest collections of hardy plants. They are of inestimable value for planting in dells, either with rock plants, or in moist positions with hardy Ferns and bog plants, with which they harmonise admirably. A noble form of Solomon's Seal on a moist rock, and a *Uvularia* on another, would indeed produce a most pleasing feature.

All the species enjoy a light and moist soil, consisting mainly of decomposed leaves, peat, and sand. Under such treatment they thrive surprisingly. In general aspect they approach nearer to the Solomon's Seals than to any plant I am acquainted with; but the flowers, which are invariably pendent, vary from 1 to 2 inches in length, according to the species producing them. The underground stems are very similar to those of the Lily of the Valley and as densely produced. The species under cultivation in this country are few, and are the North American representatives of the genus. *U. grandiflora* is probably the most noble of all. It grows a foot high, and its distant perfoliate leaves are 3 or more inches in length by about 1 inch in diameter. Each stem, which is indeed a perfect plant, bears about three flowers, which are produced singly from the axils of the leaves on long, gracefully drooping peduncles, which are furnished with a leaf identical in outline with those of the main stem but smaller. The flowers of this species are probably the most decided yellow of all. *U. perfoliata* is known from this by its almost truly ovate leaves, which are $1\frac{1}{2}$ inch or more

across, and rather smaller flowers. *U. puberula* is somewhat dwarfer, with sessile, not stem-clasping leaves, and pale yellow flowers. *U. sessilifolia* is the least of all, attaining a height of 6 inches, with leaves 2 inches long by half an inch in diameter; its solitary buff-coloured flower with inconspicuous green streaks pendent and terminating the main stem. All the species have the flower segments free to the base and slightly spreading.

Their flowering season is from the end of April or early in May to June. Dividing and replanting is best attended to in autumn, as they are not absolutely at rest during the winter months any more than are the Snowdrop and Crocus.—T. ENTWISTLE, *Wood Lawn, Didsbury.*

LEAF SOIL.

BY parcel post I send you a sample of leaf soil made by us from last year's leaves, ready for use in September last, or nine months after being gathered. We proceed very much on Nature's plan, and if you think the sample a near approach to the leaf soil of the Belgians, perhaps the following note may be of interest to those of your readers who have not a large extent of woods to gather leaf soil as manufactured by Nature.

In an out-of-the-way corner of a wood near the garden we have a space cleared of all underwood, and levelled so that surface water does not collect on it. Here we place all the clean leaves as they are collected, leaving them barrowload deep only, so that they do not heat to any extent. During the early months of the year a good quantity of these is used for hotbeds, forcing Rhubarb, &c. About March the remainder of the leaves is spread out about a foot deep, and then thrown into narrow ridges by running a fork along the bottom and packing the leaves up on each side. In a few weeks the birds generally pretty near level the ridges down, when the fork is run along the middle of the old ridges, piling them up as before. This is repeated as often as is necessary till midsummer. The object to be aimed at is to get them into a half-decayed state without allowing them to ferment or become saturated with wet.

After midsummer we take the first opportunity of dry weather to shake the whole of it over and remove the shortest to a dry shed, and by September it is fit for use after being passed through a half-inch sieve. The remainder is again thrown into ridges, and is placed under cover before the ground is wanted for leaves of the current year. We make no selection of leaves, but I may say that Oak predominates. I have practised this mode of making leaf soil with more or less success, according to the season and amount of care taken with it, for several years, and I think it was from reading something in your pages which first led me to do so. On a clay bottom it is rather difficult to make a good sample in a wet season, on account of the moisture absorbed. On a gravelly bottom it is much easier. The difficulty of moisture can be overcome where the use of an open shed can be spared.—R. INGLIS.

[This sample sent is similar in character to the Belgian leaf soil, but is not equal to it in quality.]

GARDENERS' BENEFIT SOCIETIES.

I AM very glad to see the article on page 349 of our Journal on the United Horticultural Benefit Society, and I have no doubt hundreds will derive benefit from it, as very little has been heard about this Society previously. I should think all gardeners who are not members of a benefit society will flock to its colours at once, and then, as unity gives strength, its funds will probably be in an even more satisfactory condition than they are at present.

I think we ought to patronise a *bonâ fide* gardeners' society in preference to a mixed one, for two reasons. First, because we are helping our brethren in the profession, and we are told by the highest authority to show charity at home first.

Secondly, looking at it as a business matter it is far the best, because gardeners are not so liable to require aid in this way as mechanics and others, as their occupation is far more healthy, and also their social life and morals are considerably better, so that it is not fair for them to pay their hard-earned wages into a mixed club on the same scale as the other members. I am told this is recognised by some of the life insurance companies, and that they insure a gardener's life at a much lower premium than mechanics and others. Another instance of this is the small cost per member for sick pay last year in the Gardeners' United Provident—only $4\frac{3}{4}\%$ for the year; whereas I could mention a mixed club—a branch of a very extensive brotherhood—that paid away more last quarter for sickness, &c., than their receipts amounted to for the same period.

There is one thing connected with our other Society, the Royal Benevolent, which I cannot understand. Perhaps the Secretary will kindly enlighten me through your pages, as I have no doubt others would like to know a little about it.

A friend of mine paid ten guineas to this Society, thinking thereby to provide for a rainy day. By-and-by he became seventy years of age and unable to pursue his calling any longer. On applying to be placed on the pension list he says he was told he had paid the ten guineas as a donation, and consequently was not eligible for a pension. I mention this for the benefit of others who may be thinking of joining in this

way, under the impression that a single payment of ten guineas is equivalent to a yearly subscription. Such was my opinion, but since the above case occurred I feel rather doubtful on the subject, especially since I have carefully read the rules again, and can find nothing there, as far as my judgment goes, which would enable my friend to claim his pension. I also notice all the so-called life subscriptions are entered as donations.—W. H. DIVERS, *Burghley Gardens, Stamford.*

YOUR correspondent, "A Sussex Gardener," seems to have placed his hand on the one blot in the otherwise excellent system of management of the Society to which he refers—viz., its failure to let the great body of gardeners know of its existence. Peculiar circumstances have brought it to the front. Let it step into the position rightly assigned to it as the real gardeners' society, and not hide its light under a bushel, but give a wide publicity to its worthy aims; for as we have been well told, advertising is to business what steam is to machinery, the grand propelling power. In this connection will you kindly allow me through the medium of your columns to venture to offer a suggestion to the Executive? It is this—that your excellent article on the Gardeners' Society, which appeared a fortnight ago, be reprinted, and a copy sent to every gardener in the United Kingdom, with a circular from the Committee drawing attention to it. The materials for carrying this into effect are contained in the useful and indispensable "Horticultural Directory." Unless I am greatly mistaken the result of this would be a considerable accession to the muster roll of this deserving Society. Events seem to be conspiring for the benefit of the "United," and with the advent of a new year it seems a fitting time to turn over a new leaf and take a new departure.—J. B.

SHRUBBY CALCEOLARIAS.

HAVING seen a reference to the "uncertain yellow Calceolaria," and as I think nothing is better as a yellow bedding plant when it does well, I submit my experience to your readers. I took charge of a foreman's place some time since, and was told by the man in charge of the flower garden that Calceolarias would not grow there, so I took extra trouble to make them. I struck the cuttings in an ordinary box on a spent hotbed. The box was shallow, and when the soil was in 6 inches space was left for the cuttings. The soil consisted of one-half sifted red sand or gravel and half soil from a Cucumber frame, covered with half an inch of the sand. The cuttings were inserted thickly early in October, and had a good watering; they were syringed lightly and shaded on bright days while necessary, and had plenty of air through the winter. As soon as growth commenced in February I pinched out the points, and the first week in March the young Calceolarias were planted in the garden, the soil being well dressed with the manure of an old Mushroom bed, and protection afforded. The plants were watered sufficiently, and all flowering shoots pinched out. Although in consequence of the spring bedding it was June when they were bedded out, they came up with balls as large as a man's head, and so never experienced any check. They were soon masses of yellow, and remained so the whole summer in spite of a shallow sandy soil, and they were never watered except once when they were planted. I was in that situation over three years, and they did equally well each year. I entered on my present charge in June, and found nearly all the Calceolarias dead. I was told they "wunt du here." On inquiry I found they had stood in the cutting-pit till bedding time. Whether I shall succeed in making them "du" remains to be proved. I shall try, the soil being heavy. I shall dig gritty matter in the beds, and will in due time record the result. I may mention that I protect the plants with mats till the first or second week in May.—A. L. G.

GARDENS ABOUT BRISTOL.

(Continued from page 361.)

SNEYD PARK.

THE gardens attached to the picturesque residence of J. Derham, Esq., are more remarkable for their completeness than for their extent. No expense appears to have been spared either in the construction of the mansion, the terraces, pleasure grounds, or the fruit and plant houses. The same remarks, perhaps, apply to innumerable other places, but it cannot be said of very many such that everything has been subsequently maintained in such good order as at Sneyd Park, this being alike creditable to the owner as well as the gardener, Mr. W. Rye. A small conservatory adjoins the residence, and this at the time of my visit was gay with the usual autumn occupants of such buildings. The flower beds would look better if grouped farther away from the front of the house, and if fewer in number and much larger might be much more effectively planted. As it is, the best is done with them. There are great numbers of Coniferæ and shrubs in the pleasure grounds, but not having been many years planted they are not of noteworthy size.

The kitchen garden and plant and fruit houses are situated at the bottom of the pleasure grounds. The principal range of houses is about 200 feet in length, and presents a particular noble appearance from whatever quarter viewed. Appearance, however, was too much studied by the architect, and the range might well have been less expensive and better adapted for the various purposes to which it is applied. The central house has a high-domed roof, and if, instead of an ugly fountain, the centre had been planted with a few stately Palms, the effect must

have been grand and striking. There are a considerable number of well-grown flowering and other plants in this house, and many still better in the plant houses to the right and left of it, one being devoted to tropical plants, the other to plants requiring a greenhouse temperature. In the former are several grand well-coloured specimen Crotons, such as *C. undulatus*, *C. Weismannii*, *C. irregularis*, *C. majesticus*, and *C. variegatus*, and there are besides very fine specimens of *Cycas revoluta* and *Dæmonorops palembanicus*, *Dracenas* in variety, the curiously flowered *Ceropegia Sandersoniana*, *Marantas*, &c. In other compartments *Gardenias*, *Dipladenias*, *Allamandas*, *Begonias*, *Ferns* in great variety, *Pancratiums*, *Eucharises*, *Orchids* in variety, *Poinsettias*, and many other heat-loving plants are all to be seen in excellent condition and in goodly quantities. In one of the cool plant houses Fisher Holmes, fine variety of *Lapageria*, is extensively grown, and several *Ericas*, *Genetyllis*, *Azaleas*, and other hardwooded plants are well represented. *Bouvardias* are particularly well grown, and most serviceable they must prove. During the summer and early autumn months they are planted in cool pits, and were recently potted up for their long flowering period. *Cinerarias*, *Solanums*, and *Primulas* are also well grown. Crowding is avoided in all the plant houses, and cleanliness rules everywhere.

In addition to being a good plant-grower Mr. Rye is also noted for the excellence of the fruit grown under his management. The Grape Vines generally are in a very satisfactory condition, the Black Hamburgs being especially well finished. The crop was fairly heavy, and a rod of Black Alicante—the result of inarching on the Hamburg—was also carrying a heavy crop of well-finished bunches. This variety under cool treatment, however, is generally inferior in quality, and well repays for a little extra fire heat. In another house the Vines of Muscat of Alexandria, Gros Colman, Syrian, and Madresfield Court were all well cropped with fair-sized bunches, and the foliage in every case was clean and good. The Peach house standing in the upper part of the kitchen garden is fully 100 feet in length and 30 feet wide, with a high circular span roof, both this and the above-mentioned range of houses being built with iron and glazed without putty. The centre bed is filled with two rows of standard Peach and Nectarine trees, all of which are in excellent condition, and annually perfect heavy crops of fine fruit. Unfortunately the fruits as a rule are of poor colour and somewhat sour. The fronts and ends are all covered with trained trees, and these again fruit heavily, while each of the circular iron girders are utilised for Rose-growing. The varieties preferred are Adam, Safrano, Devoniensis, Celine Forestier, and Gloire de Dijon, and all are budded on the Briar. They are grown on the single-rod system—that is to say, the leading growth was gradually taken up, and all side shoots have since been annually spurred in at the winter pruning. In this manner large quantities of superior blooms are cut during the spring, summer, and autumn months. A wing has recently been added to this fine house, and here were growing remarkably fine crops of Tomatoes, the favourite varieties being Hathaway's Excelsior and Vick's Criterion. I ought, perhaps, to add that the varieties of Peaches preferred are Rivers' Early York, Early Grosse Mignonne, Grosse Mignonne, Royal George, Noblesse, and Barrington; and Nectarines Lord Napier, Pitmaston Orange, Pine Apple, and Elruge.

The Pear trees trained to the walls are exceptionally healthy and fruitful, and the same may be said of the large number of closely planted pyramidal Pear and Apple trees that fringe the whole of the walks in the kitchen garden. Neither the position nor the soil can be considered particularly favourable to the production of such crops of fine clear-skinned fruits, and the success is due to the frequent liftings and root-prunings the trees receive. About one-third of the pyramids are completely lifted and turned half round every season, each tree in this manner having its turn every third or fourth year. By season in this case I mean any favourable time from November to March. By no other means could exuberant growth be checked and the trees prevented from becoming unduly crowded; and as the trees are thus prevented forming large rambling roots, but on the contrary have abundance of close growing fibres, no great check is given, and it is very rarely the trees fail to bloom abundantly and strongly. From these pyramidal trees many dishes of fruit have been exhibited at the Bristol and Bath Shows, and these have been awarded first prizes both in large and small classes. The Pears most preferred as being good bearers and superior in quality are Beurré d'Amanlis, Souvenir du Congrès, Beurre de l'Assomption, a less sure bearer than the preceding variety, Marie Louise d'Uccle, Beurré Superfin, Duchesse d'Angoulême, Beurré Hardy, this bearing every other year, Beurré Diel, always good, Easter Beurré, Marie Louise, Louise Bonne of Jersey, Marie Louise, Nouvelle, Bergamotte Esperen, Conseiller de la Cour, Tyson, and Jersey Gratioli. In addition to the pyramids, Apples are also trained over a long archway, and for this purpose Cox's Pomona would appear particularly well adapted. Other profitable sorts, especially as pyramids, are Cox's Orange Pippin, Mother Apple, Ribston Pippin, Golden Pippin, Braddick's Nonpareil, Court of Wick, Golden Reinette, Irish Peach, Pearson's Plate, Sam Young, Sturmer Pippin, and Reinette de Canada. In concluding these brief notes it is a pleasure to add that Mr. Derham takes great interest in every department of his garden, and that in Mr. Rye he has a painstaking gardener in every way equal to the place.—W. IGGULDEN.

SINGLE FLOWERS.

AMONG the first communications you honoured me by publishing was one advocating the cultivation of single flowers, and directing attention to the fact that not a few natives are possessed of a beauty and an elegance

well entitling them to a higher place in the esteem of flower lovers. My communication was subjected to much criticism. But, in language now classical and much hackneyed, "many things have happened since then," and one of the most marked changes in public taste then just beginning to appear has become fully developed. I mean the now fashionable taste for single flowers. Having once been in the fashion, and thereby drawn the attention of all classes, it is not likely that single flowers will again become unduly despised, or double ones unduly exalted, though at present single ones are the craze. The word "craze" is written advisedly, for with many it is not love of flowers, but love of fashion. The great tall-growing, huge-flowering Sunflowers have a decidedly strong claim on those who have a garden; and they are handsome, bold, and beautiful when properly employed. But as breast bouquets —!

The great beauty of most single flowers is their elegance or their neatness. There seems a deep-rooted idea that it is in their size. Just get a flower larger than usual and the producer is delighted beyond measure. His idea is that nothing can be too lank, and as for coarseness, nothing is too coarse for an unrefined taste. Happily, very happily, a strong opinion exists that we have been having our things too large, and a decided flow of public opinion is setting in in favour of good things no matter what their size may be. Indeed it may be doubted if there is not an inclination towards favouring things because of their smallness.

But it depends on what it is. If it is a *Dendrobium* or an *Odontoglossum*, then the larger the better; if a *Dahlia*, the smaller. Now the taste that prefers an *Odontoglossum* simply because it is a little larger than some other equally beautiful in every other respect may be questioned. Taste with such persons is a mathematical matter. However, we have no fault to find with those who prefer their beauty on a large scale, only we confess to a liking for having many things not larger than now but smaller. If Sunflowers are to be used for buttonholes and breast bouquets (which they will not a couple of years hence) instead of the great glaring disks so often employed, would not neat little Daisy-like flowers like *Marguerites* or some of the smaller *Dahlia*s be more proper?

Speaking of *Dahlia*s, it may be doubted if there are many more shades producible that are worth striving for—unless the blue can be evolved. What seems the most desirable points to secure are dwarfness, floriferousness, and, above all, flowers that will not so readily drop their ray florets. There remains something to be done in this direction.

It is a wonder that no single *Chrysanthemums* are forthcoming. They would be certain to take at the present juncture. An Ox-eye Daisy or a Corn Marigold at Christmas, if presented in its thousands, ought to be enough to make a little fortune to its producer. *Marguerites* silver and gold, ought to be in much demand.—S. H.

NEW CHRYSANTHEMUMS AT CAMBERWELL.

DURING several years Mr. Davis, 66, Warner Road, Camberwell, has made a speciality of *Chrysanthemums*, and has made a point of procuring all the principal new varieties annually raised on the continent to compare with the older and better known favourites. His collection has steadily increased, notwithstanding that the proved useless varieties are discarded to make room for the more meritorious, and it now comprises over 900 varieties, including many old curiosities and all the finest of the additions obtained within recent years. Considerable attention has also been paid to raising seedlings, and one large bed of Pompons contains several of great promise, while a series of "single varieties" bear such popular names as *Oscar Wilde*, *Æsthetic*, *Iolanthe*, and others of a similar character. The one last named is very promising, and without doubt the whole group will be welcome in a decorative point of view. This rapid extension of the collection has rendered the old business premises insufficient for the purpose, and ground has been procured that will allow much more scope for the cultivation of the plants in large quantities. Several houses there of moderate dimensions are already filled, but others will soon be required to contain the stock.

It need scarcely be said that the plants throughout are in admirable condition, and a large number of the blooms are fit for any exhibition stand, and, moreover, would require no "dressing" to prepare them for that place of honour. Mr. Davis rightly considers that numbers of varieties when thoroughly well grown do not need any manipulation, as the mere act of placing them in their cups brings the blooms into suitable form. This is especially notable in the case of the *Mrs. G. Rundle* family, which this season have proved remarkably good there, and with such handsome varieties as *Queen of England*, *Empress of India*, and *Alfred Salter*, with the golden types of the two former are simply magnificent. In several cases it is indeed doubtful if better examples will be staged this season. Some fine blooms of *Nil Desperandum* are also notable, particularly on plants that were cut down to within 6 inches of the soil in May last, the two shoots taken up from each plant bearing blooms of great size and substance, far superior to those on other plants not so stopped. This is a hint that is worth attention, as several other varieties appear to be advantageously treated in the same way. All the finest of the incurved varieties are grown, but novelties in this section are not numerous. One of the best is

Reine des Blanches, which, though scarcely up to exhibition standard, will be most valuable for decorative purposes, as it is extremely free, the blooms very large, pure white, with broad substantial florets. This will undoubtedly become a great favourite.

Madame Texier.—This was received as a sport from Fair Maid of Guernsey, which it resembles in habit and foliage; but the blooms are incurved, white tipped with purple, and likely to be an acquisition, though it has not yet been sufficiently proved.

Japanese varieties are similarly largely grown to the preceding, such old favourites as *Elaine* being in strong force. There have been indeed about 300 blooms of this open, and a large proportion of them are all that could be desired; substantial, full, and pure. *Thunberg* is also unusually fine, its grand golden blooms being very numerous. *James Salter* is similarly handsome, and in one case three plants in a large pot have had over sixty flowers, quite a display in themselves. *Comte de Germiny*, *L'Incomparable*, *M. Ardene*, and *M. Audiguier* are all in first-rate condition, especially the last, some blooms of which bid fair to rival Mr. Molyneux's grand exhibits last year. Of the novelties the following demand special note.

Rosca Superba.—Rosy purple, with reflexed florets; large, and of good colour.

Mary Major.—White, tinted rose, with strangely twisted florets; fine handsome flower.

Source d'Or.—One of last year's novelties. Of a rich bronze-amber hue, with fluted florets; of moderate size, but very free.

Mons. Pantheon.—This is also one of last year's varieties, and is regarded as an improvement upon *Bouquet Fait*. It is equally free, but with much larger, deeper, purplish lilac blooms.

Mons. Juan Cruz d'Equileor.—A handsome variety, with flat florets; rich maroon, gold on the under surface, which has a fine effect when a few florets are turned over.

Angèle.—A very distinct form of a lilac-purple tint, with flat twisted florets somewhat after the manner of *James Salter*, but forming a dense fall from which the narrow points of the florets protrude in a curious manner.

Souvenir d'Amsterdam.—Remarkable for the distinct shade of colouring, quite a violet-crimson; the florets are flat.

Simon Delaux.—Like all of the *Delaux* family this is very good, and reaches a great size, blooms having measured a foot in diameter. The colour is deep crimson with a yellowish shading.

L'Or du Rhin.—A sturdy variety, of free compact habit, and likely to be very useful for decorative purposes. The florets are rich yellow, fluted; the blooms are from 3 to 4 inches in diameter, and are produced in great numbers.

Pompons form an important feature both in old and new varieties, Mr. Davis having paid especial attention to them. Of the old form the pretty fringed *Marabout*, the neat bronzy yellow *Lizzie Holmes*, the lilac *Atila*, the yellow *La Vogue*, *Model of Perfection*, and *Madame Marthe*, are excellent, while several additions to the greys are noteworthy.

Purple Pompons.—A French variety with a good-sized full crimson-purple bloom, much like *Comte de Morny*, but the latter has flatter florets, apparently the only distinction, and that may not be a constant one.

M. Micou.—Bloom neat in form, bronzy red, with a little yellow.

Prinee of Orange.—Fine orange-yellow; an improvement on *Aurore Boreale*.

Golden Circle.—A beautiful free and early yellow Pompon, which is much like a sport Mr. Davis obtained some years ago from *St. Thais*, but which was then lost.

La Pureté.—A free-flowering white variety; blooms neat in form.

The *Anemone* type is well represented, many large blooms being observable of *Empress* and *Lady Marguerite*; but the most remarkable of all is a new Spanish variety.

Fabias di Maderanax.—This is lilac and white, tinted in its early stages with gold; but the great peculiarity is in the form, the centre florets being very narrow and twisted into a ball, while the lower ray florets are strongly reflexed, giving a curious and distinct appearance to the bloom.

The early-flowering varieties are now past their best, but good blossoms are still to be seen on that useful white, *Mrs. Cullingford*; the other good white varieties being *Madame Desgranges* and *La Vièrge*, the latter being preferred to *Sœur Melanie*, though as generally seen the last is much the better.

Some discussion took place last season in reference to *King of the Crimson*s. Mr. Davis has two varieties similar, but quite distinct, one under the above name and the other called *Crimson King*. The latter is of more straggling habit than the other, the blooms being weaker and of a crimson-maroon tint, the other being a reddish maroon much less bright. The larger variety is thought by Mr. Davis to be the older variety, but nothing certain is known respecting its history. The other he received from Liverpool through Mr. Molyneux. Both have evidently been known for a considerable time, but the present *King of Crimson*s is much finer than the other, and is a really handsome bloom for exhibition or general culture.—L. CASTLE.

PENLLERGARE, SWANSEA.

THIS fine old country seat is the residence of J. T. D. Llewelyn, Esq. It is situated five miles inland and northwards from the thriving town of Swansea, and there is no place in the neighbourhood more noted for the excellency of the garden and the beauties of its associations. Mr. Llewelyn is a real gardener himself, a gardener's friend, and a true promoter of horticulture. He is, too, one of the most popular gentlemen in Wales, as the substantial hand and help he constantly extends to every good work which has the slightest tendency to elevate or amuse the community has long gained for him the warmest esteem of the whole of the principality, and the interest he takes in horticulture is of no local order. To many outside Wales he is also well known, and there is

nothing connected with gardening too great or too small to command his attention. In considering these facts, and many more too numerous to mention, it would be expected that the attractions at Penllergare were of a highly interesting character, and they really are so, with every indication of increasing.

In leaving Swansea the surroundings are a constant repetition of mineral and manufacturing works, with innumerable small houses and no ornamental vegetation intervening; and although we cannot help admiring industries of the kind, it is quite a relief to leave them behind and gain the country beyond. The sides of the highway leading to Penllergare were beautifully studded with clusters of red and white Heather, and in passing through the lodge gates along the winding avenue, with its woodland slopes, lakes, and ravines, it can be seen at a glance that the present squire is not the only owner of Penllergare who has taken a delight in beautifying their home. The woods are so numerous and dense that a stranger can hardly tell the elevation of the ground, but in passing up the drive the ground slopes away to the right to a stream which forms several large lakes with waterfall outlets, and their margins are richly adorned with vegetation, whilst the ground near bears a happy aspect of half woodland, half pleasure ground, the large Coniferous and other choice trees being seen in great luxuriance, and the size, beauty, and numbers of the Rhododendrons are proverbial in the whole country side. No one interested in such subjects will be long in Wales without being asked if they have seen the Rhododendrons at Penllergare while in bloom; and the question is not a frivolous one, as the vast banks and bushes of these when in bloom must be attractive in the highest degree, and in my opinion the best place to secure a full view of them would be in a boat in the centre of some of the lakes, as from the edges of some of these the Rhododendron banks rise sharply up to the height of 90 feet or so and extend for more than 200 yards. The plants are mostly hybrids, and all healthy well-developed bushes. These banks are intercepted with walks, and in spring and early summer the scene here must surpass description. Some of the banks are close to the house, and from this substantial structure many fine trees and shrubs can be seen in all directions.

The flower garden occupies a large space on one side of the mansion, and on the other side there is another old-fashioned garden, chiefly filled with Carnations and Picotees. At the time of my visit the modern flower garden was highly attractive, as the well-arranged beds were in the height of their beauty. One large bed with a massive centre of *Lobelia fulgens* Queen Victoria, and edged with *Centaurea ragusina*, was most attractive and charming in its effect, and some large beds completely filled with China and Quilled Asters were certainly the finest masses of these favourite annuals I have seen for a long time. In a ribbon border were some large Sunflowers in the back, and further forward the old *Calceolaria amplexicaulis* was showing well. Altogether the arrangements in this part were admirably carried out. On the carriage entrance side of the house there is a portico which forms a good receptacle for pot plants in bloom, and, at the time I saw it, it was beautifully decorated with well-grown Zonal Pelargoniums, Vallotas, Tuberos Begonias, Lilliums, &c. Further round still than this there is a large conservatory, also attached to the house, and there Camellias are a great feature. They are mostly planted out in beds and growing very luxuriantly. The roof of this house is very attractively draped with Fuchsias, Roses, and Lapagerias.

Near to this conservatory is the old-fashioned flower garden, and before going further we glance into it. It is a snug little corner railed round and well protected with ornamental bushes, and it is here Mr. Llewelyn keeps all his show Auriculas, Pansies, Carnations, and flowers of this class. The collections are very large, containing all the newest and best varieties in cultivation, as well as many home-raised seedlings of great merit, and the whole are in first-rate condition. They are evidently well cared for, and they reflect great credit on Mr. Stafford the gardener Mr. Llewelyn has to attend exclusively to this department.

Crossing the road from here we enter another garden, which was the special resort of the late Mrs. Llewelyn, and is a very comfortable enjoyable spot. It was designed and formed by Mr. William Barron, the well-known South Wales landscape gardener of Sketty, Swansea, and is a masterly piece of work. It was made and planted in 1868, and the choice Coniferæ and Rhododendrons have progressed well since, as many of the Cupressus and other plants are 20 feet high. Rhododendrons fringe the boundaries, and must be glorious when in bloom. The grass here is in excellent order, and the beds contain many old-fashioned plants.

Some little distance from the house we come to the kitchen garden and fruit and other houses. The vegetable garden is about five acres in extent. The crops consist of the kinds generally found in a well-managed garden. Every square yard of ground was fully occupied with vegetables in every way excellent for the table, and the winter crops gave promise of gaining the most useful proportions. The vineries are four in number. Black Hamburgs and Lady Downe's are the favourite varieties, and it would be difficult to imagine anything more perfect than the quality attained by the Black Hamburgs. Heavy crops of high-class fruits were the rule. One long lean-to house of Lady Downe's was most noteworthy on account of the splendid crop each rod was carrying. Peaches are confined to the open walls, and the crops were much above the average of this year; and in speaking of fruit I may say that Gooseberries are found most prolific and serviceable on north walls. I was rather surprised to see the fruit hanging profusely on the bushes on the 31st of August, and the last of them were not gathered for some time after that. Dan's Mistake, Souter Johnny, and Thumper are three of the latest of all.

The plant houses are rather scattered, but they contain some fine specimens, especially of Orchids. The chief of these are to be seen in a small span-roofed house. Here we saw a fine *Aerides odoratum purpurascens* 11 feet high, with thirty side shoots, which at one time not very long ago produced ninety-one spikes, and some of them opened as many as sixty flowers; this plant is a grand sight. *Vanda cœrulescens* is 3 feet high, and *Vanda teres* 4 feet. *Calanthe Veitchii* has bulbs 18 inches long. *Dendrobium pulchellum* has made splendid growth in a basket, as also has *Cypripedium Parishii* in a pan. *Peristeria elata* is represented by a grand specimen; and the *Cœlogynes*, *Phalænopsis*, *Cattleyas*, *Odontoglossums*, and many more of the finest of the Orchids have been grown into fine plants. *Nepenthes Rafflesiana* was bearing thirty-six fine pitchers, and the plants generally were in excellent condition; in fact the whole place is a great credit to Mr. Warmington, the gardener, who has managed the things so well, and although my visit was rather a hurried one, I promised to visit the garden again when the Rhododendrons are in bloom.—M. M.

ROSE SOUVENIR DE LA MALMAISON.

THIS old Bourbon Rose is one of the very best that can be grown for producing flowers in autumn when the majority of other varieties have done flowering. Where a good supply of blooms are wanted at this season of the year, and those planted outside have to be relied upon for producing them, none will be found to surpass, if equal, this beautiful fragrant free-flowering variety. It is worthy of being planted largely in every garden, for it is one of the first to open its flowers early in the season, and what more delightful can be desired than its blush white flowers in a half-expanded state? or even when fully developed they cannot be despised. This Rose should commend itself especially to those residing near towns, for it appears to thrive where smoke abounds better than the majority of varieties. This variety does much better on its own roots than when worked upon any stock, and will thrive wonderfully in soil of a much lighter nature than is required in which to grow many varieties to perfection. When planted not only for the first batch of blooms or those that continue to be produced more or less the whole season, but more especially for autumn, when Rose blooms and free-flowering varieties for that season are scarce, none should be planted but those on their own roots. This is important, for the plants will throw up abundantly towards autumn strong growths from the base which terminate with a large bunch of flowers. These shoots are those that must be encouraged to produce flowers at this season of the year which are not so freely or liberally produced from worked plants.

When planting the autumn should be kept in view, and the plants placed together as far as practical on a border where they can be temporarily protected. To insure good blooms at this season of the year it is necessary that this provision be made, not only to shelter them from early frosts, but the heavy falls of rain that are so frequent at this season of the year, and which do more harm than slight frosts to unfolded Rose buds.

The system of protection that is most desirable is that of placing old lights over them, and if planted with that end in view but little labour is occasioned in so doing. A few stakes should be driven into the border—as many as are necessary—and a few boards nailed to them at the back and front; in fact, make round them a temporary frame upon which the lights can rest to protect them from frost and heavy rains. During fine days the lights can be removed or tilted to give the plants abundance of air. By planting this variety and affording them this simple mode of protection some beautiful blooms will be produced for a long time, and which will more than repay for the labour expended in their production.—SCIENTIA.

TUBEROUS BEGONIAS.

ALLOW me to corroborate what your able correspondent "Experientia Docet" says on page 288 respecting the above useful class of plants, and to give my experience of the same. We obtained a small packet of seed, which was sown on the 23rd April last. From this, which was sown in a pot and placed in a temperature of about 60°, we raised a number of seedlings. As soon as these were large enough they were pricked out in boxes, and from thence into a three-light frame. This was prepared by placing at the bottom some partially decayed manure, about 4 inches in depth, and on this nearly 3 inches of good soil. In this they were planted about 4 inches apart each way, and well attended to in every respect. When well established in their new quarters all the air possible was given them; in fact, on all favourable occasions the lights were removed during the day and replaced at night, being left open 2 inches at the top all night. In this position and with the treatment mentioned they grew very fast, so much so that by the end of September they were almost one mass of growth and flowers. We now determined to have the best potted so that they could be used for decorative purposes as well as to prolong their season of usefulness. We therefore lifted them carefully with a trowel, retaining a good ball of soil to each, and potted them in 4-inch pots. This done they were transferred into a house, had a good soaking of water given them, and were kept rather close for a few days, and slightly sprinkled overhead occasionally with the syringe. As a result, they are now (October 26th) looking grand, and will do so for at least another fortnight.

That they will make good specimens the first year our plants testify,

and I have no doubt they will do equally well outside with the liberal treatment your correspondent has so fully described. Ours average 8 inches high with about three or four stout stems to each; and some of the blooms, which are of various colours from deep scarlet down to almost pure white, measure as much as $4\frac{1}{4}$ inches across.

As they become more known and their cultivation better understood I have no doubt they will become popular bedding plants, and deservedly so too.—J. RICHARDSON, *Calverton Hall, Notts.*

NOTES FROM THE RIDDINGS.

RIDDINGS HOUSE, the residence of T. H. Oakes, Esq., is three-quarters of a mile from Pye Bridge station, and in a district abounding in coal pits and ironworks, therefore it is hardly the place we should go to in order to see high-class gardening in all its branches, but there it is nevertheless; plants, fruit, and vegetables are all grown in great quantity and of high quality.

The ornamental grounds, though not extensive, are neatly laid out and well kept, the principal feature being the fine collection of specimen Hollies, which are regularly pruned and cared for. In one part of the grounds is a semi-octagonal-shaped conservatory built many years ago, the beginning of the present large extent of glass, the roof of which is covered with *Lapageria alba* and *L. rubra*, bearing at the present time some hundreds of their lovely flowers. Adjoining the mansion is a beautiful structure in two divisions containing fine specimen Palms and Ferns, one of the latter (*Cibotium spectabile*) being one of the finest plants in the country. In close proximity is a good plant of *Dicksonia Youngii*. At the opposite end and in the cool division are several very healthy and fine examples of those much-neglected though strikingly handsome plants, *Beaucarneas* and *Dasyliroids*. Leaving a block of houses on our left, consisting of two early vineries and two other houses filled with well-budded *Azaleas* and specimen *Lapagerias* and *Bougainvilleas* that are now resting after doing duty at some of the leading horticultural exhibitions, we proceed to another part of the grounds, and enter a block of houses consisting of a beautiful and well-furnished winter garden, Orchid house, *Ixora* and *Croton* house, two hip-roofed Peach houses, span-roofed Palm house and stove, two propagating pits, &c. To give a detailed account of the contents of all this glass would occupy too much space, but suffice it to say that all the occupants are clean and in the most robust health.

Some distance from the house and grounds, and in another part of the village, is a walled-in garden filled with glass structures devoted to the culture of Grapes, Peaches, Pines, Melons, and Strawberries, and one large span-roofed house is filled with specimen New Holland plants and gigantic *Kalosanthes*. *Ericas* in variety are 3 to 5 feet in diameter, and with foliage to the rim of the pots. *Genetyllis* and *Dracophyllums* are similar. This house alone is well worth a journey to see, so well trained and cultivated are its occupants.

The Peach trees have borne excellent crops of fruit, and are now ripening good fruiting wood carrying clean and healthy foliage. The late vineries contain heavy crops of well-finished fruit of all varieties except *Gros Colman*; this variety rarely finishes well in late houses, but treated as a midseason Grape it generally colours well, as is here exemplified in an earlier house where, it is finished equally as well as a well-finished *Lady Downe's*; indeed I have never seen *Gros Colman* carrying so much bloom before. *Muscats*, *Alicantes*, *Lady Downe's*, *Trebbianos*, and *Madresfield Courts* are all well grown by Mr. Ward, as has been frequently testified in various parts of the country during the past three or four years. A span-roofed Strawberry house in two divisions is at present occupied by French Beans of sturdy habit; these will produce their fruit up to Christmas, when the Strawberries will take their place. There are several other span-roofed houses for forcing Cucumbers all the year round, and Melons in their season, good crops of both being produced every year. Tomatoes are grown in great quantities, as there is a great demand for them at the Riddings. *Trentham Fillbasket* and *American Trophy* are the kinds relied on, but *Fillbasket* appears to be much the best of the two both in flavour and cropping qualities. Pines, which are now rarely grown in private gardens, are extensively and well grown by Mr. Ward, *Queens* and *Smooth Cayennes* appearing to be the favourites.

The kitchen garden is about half a mile from the house, and in another direction, without elaborate walls and walks, but in high cultivation, as is evidenced by everything it contains; whether it be two-year-old *Asparagus* or *Potatoes*, *Cauliflowers* or *Celery*, dwarf *Roses* or dwarf *Apple trees*, the produce is abundant and good. Mr. Ward relies on *Celery Major Clarke*, and speaks very highly of *Potato Suttons' Prize-taker* and *Suttons' King Cauliflower*, but thinks that for general use the *Walcheren Cauliflower* is not easily surpassed.—J. U. S.

GARDEN CHEMISTRY.

BURNING SOILS.

THE advantages of burning heavy clayey soil have long been known, although it has not been so much practised, especially in gardens, as it might have been with every advantage. By properly burning clay and carefully mixing it with the staple, soil may be changed from a half-sterile, ill-to-work, cold, wet condition to one exactly the reverse.

Burnt clay acts mechanically, and it is in order that adhesive soils may be opened that gardeners burn them. But burning clay so alters it chemically that it has often been substituted by farmers for

manure in numerous cases with no small amount of success. Sixty years ago Major-General Alexander Beatson wrote a book entitled "A New System of Cultivation without Lime, or Dung, or Summer Fallow," and, according to the account given, burnt clay and thorough pulverisation enabled him to raise better crops than his neighbours, who employed all of them. A dressing of burnt Oxford clay enabled Mr. Pusey to increase his Wheat crop from $37\frac{3}{4}$ to $45\frac{1}{2}$ bushels per acre, and Mr. C. Randall mentions the great benefits derived from burning clay—benefits which continued unabated for twenty years after the operation.

Dr. Voelcker found that while unburnt clay only gave 0.269 of soluble potash, the same burnt gave 0.941. The decomposition of rocks by cultivation, frost, application of manure and chemical agents, all tend to liberate potash, but slowly; burning does so rapidly. Much of the potash in most soils exists in the form of silicate, which is insoluble in water, and not readily attacked by garden plants, though grasses and cereals have a greater power of attacking them. In the process of burning any lime present is converted into caustic lime, which attacks potassic silicate and decomposes it, calcic silicate being formed and potash being set free. Burning also alters the iron in most soils to a more soluble form. When it is present to an injurious extent this is no small advantage, as much is then easily removed by the water passing through. Any soluble phosphates present are rendered insoluble. This has been considered an unfavourable result of burning, an opinion which must be modified in the face of Mr. Jamieson's experiments, and which should never have obtained credence in the face of the fact that clay soil after burning is more fertile than before. This increased fertility is largely due to a greater amount of available potash, a fact that indicates the desirability of using potash more frequently than is the case. Burning dispels the nitrogen which may be present as well as any organic matter, but the porosity gained, and the greater absorptive power of the friable clay, far more than counterbalance such loss, the more especially as in such soils as are most benefited by burning the organic matter present containing the nitrogen is very rarely of much use other than mechanical. Because of this absorptive power burnt clay is a capital deodoriser, and for mixing with sewage and similar matter is of extreme value.

Wherever fuel can be had the burning of clay is a simple matter. The way we have usually seen adopted in gardens is to trench over the piece to be operated upon, laying as much clay from the subsoil over the good earth as it is intended to burn. Sometimes the surface soil itself is burnt; but it is a pity to burn the only soil fit for forming a proper staple, and, when properly done, the under soil is nearly as good. It is apt to burn into brick-like masses, but this may be avoided with care. The clay should only be baked or charred, not burnt as bricks are.

Having the piece trenched and the fuel in proper condition, a fire should be started in the middle. Some care is needed in building the fire properly. If wood is used it ought to be cut in regular lengths, and split so that it may burn readily. If coal be used dress is best, as lumps are very apt to burn too fiercely and burn the clay into ballast, unless special care can be taken. But wood is to be preferred. The fuel should be built pyramid fashion, broad at base and narrow at the top. The centre should be of twigs readily ignitable, and the outside of stout pieces capable of supporting spadefuls of clay laid against them in the way that earth is heaped against a Potato pit. After the fire is fairly going the clay should be laid spade thick all over the pyramid or ridge. If it is dry at all it will speedily become hot and the fire will break through in all directions. This should be prevented by heaping on more clay until the fire within declines, when the heap should be pulled to pieces, more fuel added, and clay again, until enough has been secured or the stock of fuel exhausted. If fuel enough can be secured it may be well to do the whole garden at once, but even when only a small quantity now and again can be got much improvement may be worked piecemeal. Fruit-tree borders, flower beds, and other particular spots may be done first, and the body of the garden attacked as material can be secured. Prunings, Cabbage stumps, old Pea sticks, and similar rubbish if kept dry are all fit for the purpose on a small scale.

There can be no room for doubting that burning is at once the cheapest and most effectual way of improving tenacious clays when ordinary opening material is not at hand. So much does it improve such, and so much have we been struck with the alteration from almost unworkable clays into which roots could hardly penetrate or rain pass, to excellent friable soil, that we would not hesitate to make Vine borders out of the toughest agricultural clay, with nothing else, if we only had fuel to char part of it, and borders, too, not deficient in a single thing necessary. But there is no garden crop that may not be benefited by it.

In addition to clays, peats are frequently benefited by burning, and the ashes resulting from charred peat are often found excellent applications to almost any kind of soil, but especially heavy ones. The tough turf that forms on poor moorland is also often burned,

after which sometimes a rotation of crops are taken and the moor laid down again in grass. Oftener it is for the purpose of destroying the hard innutritious grasses that clothe such soils. After such burnings fine tender grasses spring up to be by-and-by extirpated by coarse grasses, which are again burnt. But these are more farming than garden operations.

When heaps of weeds are burnt—a very wasteful process, as thereby the nitrogen present is dissipated—much earth is charred, and more might be if added for the purpose.

All charred soil should be perfectly incorporated with the soil in the manner already described.—SINGLE-HANDED.

HAMWOOD, CO. MEATH.

AMONG gardens of interest in this part of Ireland (Co. Meath), one of the most notable is Hamwood, Clonee, occupied by G. Hamilton, Esq. Although not so extensive as many demesnes, the garden is well cared for, especially the flower garden, which is admirably kept, and some very pretty beds were to be seen at the time of my visit last month. When flowers are past their best the flower beds are so arranged as to always afford something to meet the eye, instead of being bare. There are in most of the beds well-kept shrubs, such as Golden Hollies, the foliage of which was the brightest I have seen. Golden Yews and other shrubs are also employed in other beds. Ageratum Lady Jane is much prized, being better than Cannell's Dwarf. Iresine Lindeni is also much used; and of Pelargoniums John Gibbons and Amaranth are in request. Maréchal McMahon and Crystal Palace Gem are grown in thousands, as is a really good pink Zonal called Mrs. Masters, the best pink I have seen in this locality. Carpet bedding receives due attention, but was past its best on my visit. Some noble specimens of Conifers are notable, including Araucaria imbricata, Cedrus Deodara, Picea Pinsapo, P. Nordmanniana, and many others tastefully arranged.

The glass houses are numerous, and every inch of space is occupied. In one house the back wall is covered with Heliotrope, where Mr. Latimer, the gardener, tells me he can always cut quantities of bloom winter and summer. In this house are large plants of the most useful scented Pelargoniums, as a large quantity of cut flowers are needed here in the winter months. A stove contains flowering plants, amongst which are some very healthy Gardenias grown in large pans. One part of the house is filled with Tuberous Begonias, Abutilons, and Pelargoniums, and very fresh they looked. Another house contained Tomatoes in pots, which have produced a large quantity of fruit, and as soon as a plant has been cleared another is in readiness to take its place, so that there is every likelihood of being plenty till Christmas.

At the east end of the kitchen garden are some fine herbaceous beds and borders. One border was very effective, having a back row of Lobelia cardinalis, next to it Anemone japonica alba loaded with flowers, and a row of Tuberous Begonias, which produced a grand effect. Through the centre of the kitchen garden runs a broad walk, over which are trained cordon Apples, meeting in the centre and loaded with fruit. These have a very fine appearance. There are numbers of cordon fruit trees in all styles. Every provision is made for the protection of vegetables by Beech hedges, which are about 10 or 12 feet high, these dividing the garden into squares. Here we find some luxuriant beds of Lily of the Valley, and a fine border of Roses. The squares are filled with superb crops of vegetables, looking remarkably vigorous with the exception of Spinach, which Mr. Latimer tells me he has much trouble with. Large quantities of Violets are grown in cold pits, also Lettuces, Endive, and other salads. In another was a quantity of Primulas and Cinerarias all in good health. Large clumps of Hellebores assist in yielding a supply of flowers during the winter months. Mignonette in pots, and other useful winter-flowering plants, occupy several pits. Chrysanthemums do not receive the same attention here that they do in some parts of England, although numbers of useful plants are grown for flower supply. Out of doors, too, is a large bed of Schizostylis coccinea, from which roots are lifted and potted for winter flowering, proving extremely useful. In the Mushroom house were two beds bearing freely, a second just showing, and a third bed just spawned.

The walks are exceedingly well kept, adding very much to the appearance of the garden. I have seen a kitchen garden well cropped where the walks were green with weeds, which spoiled the whole. It is not the case at Hamwood, as the walks are solid and dry, covered with very fine shingle or gravel of a slate colour, reminding one of the walks in some of the London parks. The garden altogether reflects much credit on Mr. Latimer.—J. PITHERS, *Summerhill*.

KITCHEN GARDEN.

Digging and Trenching.—Vegetable quarters are now becoming vacant, and as soon as they are cleared it is a great advantage to turn

them up that the soil may be fully exposed to the weather. In spring, when the soil is being turned up immediately before putting in the crops, the surface of the soil is generally made quite fine; but at this season it cannot be left too rough, and that which is turned on to the surface, whether in digging or trenching, should be thrown down in spadefuls without any breaking. Deep cultivation is one of the secrets in securing first-class vegetables, and all surface-worked soils should be trenched to the depth of 2 feet or more. In our large kitchen garden we cannot trench it all annually, but we do one or two of the quarters every winter, and the whole of the garden has to be trenched in succession.

Sowing Peas.—The early half of November is the proper time to sow autumn Peas, and in many instances these will supply pods several days earlier than those sown in the spring months. Peas at all seasons delight in a deep rich soil, and previous to sowing the seed the ground should be deeply dug or trenched and well manured. Borders are generally better for sowing in at this time than open quarters. The position should be a sunny and warm one, and as much out of currents of wind as possible. One of the best to sow now is William I. The rows should be 5 or 6 feet apart, the drills 3 inches deep, and after the seed is covered with the soil, a thin layer of ashes should be spread over the surface of each row to prevent snails and other vermin from eating the young growths when they are tender and just coming through the soil.

Broad Beans.—Where these are valued early in spring a sowing may be made now. They are very hardy and bear severe weather well. They will grow in any kind of soil which has been well manured, and they may be treated in sowing in much the same way as we have advised for Peas.

Forcing Asparagus.—Asparagus is not much valued when Peas and other choice summer vegetables are plentiful, but in many instances it would be acceptable from the time the last Peas are gathered until they come again. This is our experience, and we do our best to meet it. The first roots were put into a bed of a Cucumber pit on October 26th, and on the 1st of November some of the young growths were 2 inches above the soil. When the crowns are well developed and thoroughly matured they force very easily at this time, and as time goes on and the roots are longer rested they grow still more freely. The heat never exceeds 70° at the bottom and 65° in the air, with fire heat. In lifting the roots for forcing, the fibres should be preserved as much as possible, and in putting them into force the crowns should be covered with any light rich soil. In cutting, the strongest will of course be sent to the kitchen, and should there be any straw-like growths they should be cut away soon, as they do no good, and their share of nourishment may be thrown into some of the stronger heads. The best of all places to force Asparagus is a Cucumber pit, but where this is not available a good hotbed and frame will answer the purpose very well, and some may be inclined to try it in a Mushroom house, in which case it will come white, and then it will be found flavourless and next to worthless.

Parsley.—It is of the utmost importance that a good supply of this should be kept up during the winter, as in the majority of kitchens it is in demand daily, and any deficiency causes great inconvenience. Where it is deficient of growth and showing signs of being eaten at the root with worms, it should have a good watering with water in which 2 ozs. of guano has been dissolved per gallon. Protect with frames where necessary.

FRUIT-FORCING.

PEACHES AND NECTARINES.—Earliest Forced House.—Where ripe fruit is required at the close of April or beginning of May the trees will have been pruned, dressed, and secured to the trellis, the lights being replaced, and everything prepared for a fresh start. If, however, the lights have not been replaced they should be placed on at once, and the house in either case closed by the middle of the month. The outside border should be covered with 9 inches to a foot thickness of dry fern or litter, and if with a good slope, so that by placing shutters or tarpaulin over it in rainy or snowy weather to throw off the wet, it would be a great advantage. Should the roof lights not have been removed it is likely the inside border will be dry, in which case it will be necessary to give the border a thorough soaking with tepid water, or if the trees are weak employ liquid manure in a tepid state. No fire heat will be needed if the weather be mild during the first fortnight, or only to exclude frost, the day temperature not exceeding 50°, at and above which ventilate freely, and 40° to 45° at night. The trees may be syringed in the morning, and again in the afternoon if they become dry, but they must not be kept constantly dripping with moisture, and should be so damped that the branches, become fairly dry before nightfall. When obtainable, a bed of fermenting materials made up in the house will be a great aid to the swelling of the buds by the maintenance of a moist genial atmosphere. Two-thirds leaves, Oak or Beech, to one of stable litter thrown into a heap and turned over once or twice, and then introduced to the house at the beginning of December, will greatly facilitate the forcing process, as well as lessen the necessity for fire heat.

Succession Houses.—The trees in all but the latest houses have become leafless, and ought to be pruned and dressed as soon as possible, the houses being also thoroughly cleansed. The surface soil of the borders should be removed down to the roots, presuming this has not been done already in lifting or root-pruning and renovating the borders, removing the remains of the mulching and the loose surface soil, and replace with good loam, to which has been added some crushed bones and charred refuse, and give a good watering, although this may not be needed in the case of trees that have been exposed to atmospheric

influence for some time by the removal of the lights, but in the case of the lights not being removed a good watering will be of great service in settling the fresh soil about the roots and keeping the buds plump and sound during the resting period, for should the soil become dry at that season it is likely the buds will fall. The lights having been removed they need not be replaced until severe weather commences. If the lights are fixed ventilate fully day and night whenever frost does not prevail; and unless there are plants that need safety from frost do not employ fire heat to exclude it, as the cooler the trees are kept the more complete the rest, so essential to a vigorous blossom and after-growth.

Late Houses.—The foliage will be ripening, and the trees may be assisted in shedding it by lightly brushing them with a broom, but no forcible removal of the foliage must be attempted. In the case of trees that have not yet ripened the wood gentle fire heat by day with free ventilation will be serviceable, but no fire heat should be employed at night, and air must circulate through the house constantly. A somewhat dry condition of the atmosphere is advisable, but there must not be any deficiency of water at the roots, or the buds will not be plumped. In the case of trees that do not ripen the wood kindly a trench taken out at about one-third the distance from the stem the trees cover in extent of trellis, and as low as the roots, detaching all roots and leaving the trench open for about a fortnight, will assist them wonderfully, and then removing the soil from the trench inwards to the stem down to the roots, lifting if necessary and laying-in in fresh compost, ramming firmly, as also in the trench, and giving a good watering, fresh rootlets will be admitted in readiness for the support of the blossom. Trees in unheated late houses may be treated similarly, but in no case operate on the trees except by taking out a trench until the wood is firm and the foliage is becoming mature.

Cucumbers.—During such mild weather as has lately prevailed very little fire heat has been necessary, and the atmospheric moisture under those conditions has necessarily had to be reduced. This needs some judgment and prompt attention, as to keep the house close, moist, and warm during such weather is apt to cause the plants to become succulent and ill fitted to bear the vicissitudes of our variable climate. With a change to severe and bright weather more moisture will be necessary, but as a rule damping all available surfaces in the morning and afternoon will be sufficient, with a light syringing early in the afternoon of exceptionally fine days. Autumn fruiters, or the plants that were put out early in September, will be showing fruit freely, and as the results at Christmas to March depend entirely on the treatment in this and next month, it is necessary that the plants be not now allowed to crop heavily, removing all superfluity forthwith, and attend carefully to stopping, thinning, and tying the young shoots, disposing them evenly and avoiding overcrowding. Remove any decayed portion of wood or foliage that may appear, and keep the glass clean both inside and out, as every ray of light is now of consequence.

PINES.—Fermenting Beds.—Tree leaves in many places are still employed as a heating medium for Pines, and where plentiful supplies can be obtained they will with ordinary care when made up into beds afford heat for a long time quite sufficient for the requirements of young growing stock, the nature of the heat not being surpassed if equalled by that obtained by any other means. Oak and Beech leaves, from their hard texture, and therefore more lasting, are the best—indeed those that should be used. The chief point in their management is to collect them when dry or in a moderately moist condition, as they do not in that state decompose so quickly, and a prolonged supply of heat of a general and evaporating character is thereby secured. To plunge the pots in about a foot of tan is better than leaves, and has a neat appearance which in private establishments is of considerable importance.

General Remarks.—The weather has not yet necessitated sharp firing, and so long as the recent mild weather continues the temperature indicated in our recent calendars may remain in force; but with the setting-in of severe weather it is better to be content with 5° less in each department than have recourse to hard firing. Coverings as aids to the heating apparatus are of importance, and less the plants feel the effects of sharp firing the better, which coverings in severe weather considerably molify, as well as the fuel bill. Be careful in the application of water to the roots, and only apply it when necessary, but then thoroughly. Keep the glass free of accumulation of dirt, as every ray of light kept from the plants is representative of so much depreciation in their health.

PLANT HOUSES.

Primula obconica.—This is a most useful Primula for cultivation in pots, and is admirably adapted for conservatory decoration at this season of the year. It is very free-flowering in a small state; in fact, the plants we possess flowered more or less all the season, and the strongest are now in grand condition. It should be raised from seed either sown at once or early in the new year, but the sooner the better, for the greater size and strength the plants attain the more attractive and beautiful they are. The flowers, which are pale lilac in colour, are by no means showy when the plants are small and only bearing one or two trusses of flowers, but when strong and a dozen or more are borne above the foliage, with as many others to succeed them, they are invaluable. The seed should be sown in an intermediate temperature, and the young plants grown on afterwards the same as the varieties of *Primula sinensis*. After they are placed in the pots they are intended to flower in, 6 or 7-inch pots being a good size, they can be stood outside until autumn, and then housed in the greenhouse when required to be brought forward into flower.

Carnation Souvenir de la Malmaison.—Those requiring plants in pots

of this and its pink form Lady Middleton to flower next June, July, or August, and the same plants to flower the following year during March and April, should make a start at once. Young plants that have been layered outside and are strong and dwarf should be selected and placed in 4-inch pots in a cold frame, which should be kept close until they are well rooted. Early in the season when these pots are full of roots place them in 7-inch pots, and from these into 10-inch when ready. Those required for flowering during the first month mentioned should do so in the 7-inch pots, but those for the last two months in the last-named size. These plants should be grown under glass to do them well, especially so when wanted to flower in early spring the following year. After flowering, the growths that start from the base should be pegged or layered on the surface of the soil, and plants for spring flowering will be produced that will carry from six to nine spikes of large flowers.

Rhododendrons.—The early-flowering varieties, such as *R. Early Gem*, *R. præcox*, *R. multiflorum*, and others that have been planted out and required for flowering early, should be lifted and potted without delay. These when lifted should be placed under glass, and when required to flower should only be brought forward slowly and gradually, or else their buds will stand still and refuse to open. The flowers from lifted plants do not last so long or are so readily induced to flower as those that are established in pots. We have discontinued the lifting practice with these varieties, and advise all that require them early in flower to do the same. The forcing required can be done under glass in the spring, and the plants will unfold their flowers under almost natural treatment early in autumn. Our earliest batch would come into flower in about three weeks if kept close and we required them. They are still outside and will remain for some time, but in case of frost they will have the protection of mats.

THE BEE-KEEPER.

BEE-FARMING.

"F. H. P." wishes to gain some information concerning bee-farming. Although bee-keeping has been a hobby with us for many years, and we have mainly indulged in the pursuit because of the pleasure and recreation thereby obtained, at the same time we have endeavoured to make it a profitable undertaking from a pecuniary point of view. We are therefore able to some extent to reply to "F. H. P.'s" questions on page 365. However, our experience has not been with a very large number of stocks, the most we ever kept at one time being under fifty. We have kept year by year an accurate account of the outlay and income in respect of our apiary, and can therefore give some idea as to the profit or loss to be expected in bee-keeping. We cannot say how far these results would be affected either way by keeping a large bee-farm such as is contemplated by "F. H. P." We will answer the questions in order:—

1, Bee-keeping is decidedly profitable if well managed and under certain conditions. With proper care and attention heavy losses in bad seasons are not to be expected, but a certain amount of expenditure will be incurred with no income. It must not be expected that all the income is to be derived from the sale of honey alone; bee-farmers derive their income from several sources—the breeding of queens, the sale of swarms, of bee appliances, &c. A bad honey year is often productive of many swarms, and the accounts are balanced by the sale of the same.

2, There are doubtless men who could obtain, and who do obtain, a substantial income from bee-keeping, but it is only by much labour and skill that a large apiary can be managed with success.

3, We can confidently say that in a fairly good neighbourhood, taking an average of seven or ten years, £1 per hive per annum can be counted on as profit. This is, as we have before stated, the case where not more than fifty hives have been taken into account. A neighbourhood may no doubt be overstocked, and in order to obtain a nett income of £400, some 400 stocks should be kept. These would have to be scattered over a large area, not all kept on one plot of ground. Extra labour would be thus necessary to travel from plot to plot, and expenses would crop up of which we know nothing, nor will we venture to give any advice concerning such a large undertaking.

4, We should certainly say that with such a number of stocks Heather alone could not be depended on to give a profitable return. Such a year as 1882 would render the honey harvest from Heather almost nil. Early summer crops, such as Mustard, bush fruit, Clover, &c., should be within reach of the bees; they would fly for these more than a mile, but of course the nearer the pasture is to the hives the more honey there will be stored.

5, The best hives to use would be well-made double-walled bar-frame hives of large capacity for obtaining surplus back and front or on both sides of brood-nest, as well as over the same. The common English bee or the Ligurian pure or crossed with the former stock are what we should cultivate.

6, We would recommend the careful study of several good books

on bee-keeping. For practical purposes Cowan's is one of the best. Root's "A B C of Bee Culture" will give much valuable information on bee-farming, and Professor Cook's treatise is another excellent work on the subject.

7, The knowledge required in order to successfully manage a large bee-farm could only be obtained after much practical experience and intimate acquaintance with the natural history and habits of bees. If starting an undertaking of such proportions as "F. H. P." proposes, we should advise him to secure the services of a properly certificated expert. In order to hold a first-class certificate a man must have passed an examination by a duly appointed committee of the British Bee-Keepers' Association, and before he can do so he must have made himself thoroughly conversant with the science of bee-keeping both theoretically and practically. Question 8 we cannot answer.—P. H. P.

PASTURAGE FOR BEES.

HAVING experimented quite extensively with honey-producing plants this summer, I will contribute my mite toward improving bee pasturage.

I must join with Mr. J. F. Plummer in pronouncing Borage the plant *par excellence*. Bees will leave everything else if they have that. The honey is as light as white Clover honey, but of better taste and flavour. Next year I intend to sow several acres with this plant. If sown three weeks before white Clover comes into bloom it will be at its best when that plant begins to fail. I sowed some as late as July 1st, after which drought set in, in consequence of which it was very slow in coming up. But it is blooming now, and the heavy frosts we have had this month have not injured it in the least, the bees improving every shining hour on it, especially the Italians. The latter will be out working even when quite cool; the blacks would not.

On Mignonette they worked very little, last year not at all. Last year and the year before I sowed some Sweet Clover, but it never came up; but I have seen the roadsides in Virginia covered with it, but no bees working on it, though there was no other plant in bloom except, perhaps, red Clover, which is very extensively cultivated, but no bees did I see on that either.

Then I received also some twenty different kinds of seed from Switzerland, among which were a few kernels of the Giant Balsam (not Giant Lady Slipper, as someone wants to have it, as it is not related to the Lady Slipper family or species). I am sorry to say the seed did not come up, as also many other kinds did not make their appearance. Some proved to be biennials, not flowering the first year. Among those which bloomed Phacelia was visited the most. All the others the bees treated with indifference.

But one other thing I have noticed, that bee pasturage improves where bees are kept, perhaps, on account of a more extensive fertilisation of the plants by bees, causing a more abundant seeding.—A. R. KOHNKE. —(*American Bee Journal*.)

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Journal des Roscs (*E. B. M.*).—This periodical can be obtained from M. Scipion Cochet, Grisy-Suisnes, Brie-Comte-Robert, Seine-et-Marne, France.

Grubs in Manure (*F. B.*).—We do not think the grubs will do any injury; still you will do well to give your Vine border a good dressing of lime, and point it in lightly, as besides destroying the grubs it would benefit the Vines.

Correspondence (*K. D.*).—We are obliged by your letter, and are glad our columns have been of service to you. The writer you name is in a situation. The other subject to which you allude shall have due consideration. You need not hesitate to send your questions; they will be readily attended to.

Boilers and Stoking (*Dugald*).—Your letter will be readily inserted, as it is well written and relates to a subject of importance. We scarcely suppose that your proposal will meet with universal acceptance; it is, however, worthy of discussion.

A Good Insecticide (*J. Clare*).—We shall be glad if you will send us a sample of the article that has proved so efficacious for examination; we will also have it tried as you suggest, and inform you of the results of any experiments that may prove satisfactory.

Pond Mud (*J. M.*).—Much depends on its nature, but in all probability it will not do any harm on the grass land. Replies in this column are only intended for regular subscribers.

Large Chrysanthemums (*P. M.*).—Large blooms do not depend altogether on what you may give the plants now. Unless they have been well grown during the season, and disbudded at the proper time, the finest examples cannot be obtained by any fertiliser applied at the present time. Sulphate of ammonia is the quickest in action, perhaps, of all fertilisers, and a small thimbleful spread on the surface of the soil of each pot and watered in, or a quarter of an ounce or a little less dissolved in a gallon of water, and in this form given to the plants, will be ample. Clay's fertiliser is good as a top-dressing, and soot water is very beneficial. You may use any of these as may be the most convenient.

Zonal Pelargonium **Hon. Mrs. Oakeley** (*John Roberts*).—This richly coloured double variety raised by you three years ago is decidedly above the average of new varieties that are sent to us. The truss is symmetrical without being "lumpy," the pips large without being so crowded with petals as to prevent free expansion, the colour dark yet not dull—a glowing purplish crimson. As you say the plant is of dwarf habit and very free-flowering, even in winter, you will find it useful for decorative purposes.

Dextrine (*J. P.*).—It is known in chemistry as the soluble or gummy matter into which the interior substance of starch globules is convertible by acids or diastase. It is admirable for securing the petals or florets of flowers that are prone to fall quickly, such as Pelargoniums and single Dahlias. We have some of the latter in our office which will retain their florets until they shrivel, while there is no trace of the presence of anything having been used to secure them. Dextrine is sold by chemists and druggists.

Mushroom Beds (*G. W. S.*).—It would be advisable to turn the straw which is close and wet, choosing a dry warm day for the operation, and if the temperature of the air at the time is above that of the bed there will be no escape of heat from the latter. During very heavy rains outdoor Mushroom beds are occasionally injured if not covered with sheets or something to throw off the wet, and especially if the sides of the beds are too flat, as many are; they should be built as steep as possible, and the top well rounded.

Planting Flower Beds (*A. G. B.*).—As you say you are "expected" to plant the beds in the manner you have shown in the plan before us, by all means carry out your employer's wish, and especially as a "showy" flower garden is particularly desired. The method of arrangement will be bright, and we can only suggest that the effect would perhaps be a little more cheerful if a few purple Violas were mixed with the variegated Pelargoniums in the corner beds, and a few plants of Veronica Andersonii variegata with the Heliotrope if this latter is a very dark variety.

Violets not Flowering (*H. E. B.*).—The plants are perhaps too crowded, and sun and air could not circulate amongst them to develop the crowns. This is the cause of many Violets not flowering freely, especially in the autumn, and your plants may produce blooms in the spring. Stout healthy offsets should be planted a foot apart in good soil in April.

Vine Roots Decayed (*J. Ricks*).—The roots are in a very bad state, but there is no phylloxera on them, nor are there any signs of the insects; not half enough roots, however, were sent for satisfactory examination. They appear to have been taken from a wet sour border.

Propagating Aralia Veitchii (*J. S.*).—This plant can be increased by cuttings, but they are by no means easy to strike, and this mode of increase is a slow one. The custom is to strike such as *A. reticulata* and other narrow-leaved kinds that emit roots freely, and use them as stocks on which *A. Veitchii* is grafted. *Reidia glaucescens* is increased by cuttings of half-ripe wood inserted in sand under a bellglass in a propagating house. *Cocos Weddelliana* and all Palms are raised from seed.

Raising Cucumbers (*Subscriber, Ireland*).—On this matter everything depends on your skill and judgment as a cultivator. Under your circumstances we should sow the seed about Christmas, and have a small heated case in a convenient position in the house for raising the plants. January probably will be a better time for you to commence, and then if the first plants fail you will have time enough to raise others. If you could have a little conversation with Mr. Pithers, the gardener at Summerhill, you would find it advantageous, and he would no doubt readily see you by appointment.

Amarylises (*H. S. P.*).—The plants require turfy loam, with a sixth part of wood ashes and decayed manure, also an admixture of gritty matter to keep the compost porous. They must not be overpotted. When making their growth and producing flower spikes they need a sunny position in a warm house, with sufficient water to keep the soil moist. After flowering they cannot have too much sun, a shelf near the glass being a good position for them, watering them regularly till the leaves are fully developed, then about August keeping the air drier and reducing the supply of water to the roots until the foliage dies down, when water may be withheld for several weeks. Some cultivators keep the plants steadily growing through the winter; but the resting system is practised in the London nurseries, where these beautiful plants are grown so well.

Order not Acknowledged (*W. T., Quebec*).—The best thing we can do under the circumstances is to send your postcard to the tradesman to whom you allude, whom we have always known to be highly respectable. There must have been some mistake, or perhaps a letter may have failed to reach its destination. If you do not hear further on the subject the fault will, in part at least, rest with yourself in not giving your name on the postcard; your address, however, may perhaps enable the order to be traced.

Fuchsia with Petaloid Anther (*J. E. W.*).—The malformation of which you send an example is common, and in some cases the whole stamen becomes petal-like, as in double and semi-double flowers. In the flower submitted one lobe of the anther has been converted into a small petal, and has a strange appearance; the whole bloom is, indeed, deformed, as the style with

one stamen is combined with one of the sepals. Such freaks cannot be accounted for; they simply prove the convertibility of the different organs into others, and indicate the probability of the accepted theory that they have a common origin.

Late Dessert Apples (H. J.).—The following are richly flavoured, late keeping, and good bearing varieties, that will probably answer your purpose:—Scarlet Nonpareil, Braddick's Nonpareil, D'Arcy Spice, and Ashmead's Kernel. We do not know the Gipsy King Apple by any other name, though other names may probably be given to it locally. We are not able to say in what form the record of the late Apple Congress will be published.

Back Wall of Vinery (F. J.).—If the roof of your house is to be thickly covered with Vines you must not expect any very profitable return of fruit of any kind from the back wall, and it will be of little or no use your planting either Peaches or Nectarines, as they would give little fruit, but might produce excellent crops of red spider. We have seen a fairly good crop of Black Alicante Grapes on the back wall of a vinery, also of Brown Turkey Figs; but if no sun can reach the foliage of Vines or fruit trees they cannot be productive. You may grow good crops of Tomatoes for a year or two, but these will not bear freely when the shade becomes dense. Camellias are good for covering the back walls of vineries. We have no preference for either of the boilers you name; both are good, and with pipes arranged properly will answer their purpose. You will not err if you decide on the question of cost.

Vines on the Continent (H. S.).—It is impossible to give categorical replies to your series of questions, for the simple reason that as many methods of treatment are adopted in training and pruning in the French vineyards as are practised here in vineries, and more. In the south of France the fruit needs shade, therefore the growths are allowed to extend from the stem in all directions, and cover the ground much in the same manner that the growths of Brambles are seen at home, but more thinly disposed; and in the winter a selection of the best young canes is made for the next crop, the others being cut away. In other districts they are trained in all the modes that are represented in training Raspberries in British gardens—namely, against fences, secured to stakes of various heights, and the canes bent and secured to each other without stakes. In all cases the bearing parts are cut down and young canes secured for the next crop. We have seen three or four canes tied to a stake 4 or 5 feet high, and we have seen stakes driven in slantingly, three or four round each Vine, and a cane secured to each. Disbudding is a question of judgment, and depends on locality, as in the hot districts, as before stated, shade is needed by the fruit; in the colder more direct sun is essential to its ripening. The number of bunches left on the laterals depends on the strength of the growth and the size of the bunches, as in English vineries, and the stopping the growths is practically the same in both countries. There is no rule-of-thumb process adaptable to all circumstances in the culture of Vines, either under glass or in the open air.

Planting Shrubs (A. H. P.).—We have never had greater success in transplanting Hollies than when the work was done in April; but small shrubs of all the kinds you name for inserting in quantity may be planted as soon as your ground is ready for them, provided the weather be mild and the soil is in free working condition. When planting is deferred until spring it is of the utmost importance that the roots of shrubs do not become dry in transit, as they not infrequently do, and failures consequently occur. When the roots are kept moist the shrubs usually succeed admirably. Loudon's "Encyclopædia of Trees and Shrubs" is the best work on that subject you can have. If you require a work on Conifers there is none comparable with Veitch's "Coniferae." Sutherland's "Hardy Herbaceous Plants" also might be useful; but the most complete work of that character is in French—namely, Vilmorin's "Plantes Vivaces de Pleine Terre."

Dog's-tooth Violets (H. A.).—It is getting late for planting the bulbs, as last month would have been the most suitable time, but if the weather continues open and not too wet they may still be planted. The soil should be good loam, not very heavy, and it must be well drained to insure their success—indeed, it is advisable to place a little sand round the bulbs to prevent them decaying. They may be placed in masses, but lines are preferable, and these should be near the front of the border, the bulbs being about 4 inches apart in the rows, and just beneath the surface of the soil. They may be left undisturbed for two or three years, when they can be taken up and divided if necessary, but unless very much crowded they thrive best when undisturbed.

Artesian Wells (W. H.).—Though we are willing to answer your question, "What is an Artesian well?" it is not likely you will make one for supplying water for your Cucumber house. An Artesian well is a perforation, often of many hundreds of feet, into the lower strata of the earth, for tapping the subterranean reservoirs, and securing an unfailing supply of water. The name Artesian is derived from Artois, a province of France, where especial attention has been given to this means of obtaining water; but it appears, from sufficient historical evidence, that wells of this kind were perfectly well known to the ancients. Niebuhr cites a passage from Olympiodorus, who flourished at Alexandria about the middle of the sixth century, in which it is stated that when wells are dug in the Oâsis to the depth of 200, 300, or sometimes 500 yards, rivers of water gush out from their orifices, of which the agriculturists take advantage to irrigate their fields. The oldest Artesian well known to exist in France is in the ancient convent of the Chartreux, at Lillers in Artois. It is said to have been made in 1126. Others exist at Stuttgart of great antiquity, though their dates cannot be fixed with precision. The inhabitants of the great desert of Sahara appear also to have been long acquainted with this mode of obtaining water, and the Chinese are said (but the truth of the statement is questionable) to have practised it for thousands of years. If you reside in a marsh or fen country where there are no rocks an Abyssinian pump might answer your purpose, and of which you can obtain particulars from an ironmonger. Do you store all the rain water that falls on the roofs of your premises?

Dinner-table Decorations (C. E.).—There is no book that will give you the precise information you need. Dinner tables are not so heavily laden with flowers as formerly. Some years ago a very good judge suggested that the following canons of judgment and taste should prevail:—1, The greatest effect produced by the simplest materials ought certainly to be considered

an important point. 2, That it is essential that the tables be not so crowded in the centre that the view is distorted. 3, That large quantities of strongly scented flowers should not be introduced. 4, That harmony of colouring should be considered, and the effect of light on certain colours. For these there are good reasons. The first can hardly admit of cavil. Everywhere and in everything true taste is always simple. What is that which we call "cockneyism" but the flagrant violation of simplicity? What is it we call "ladylike" in dress? is it not simplicity? The second reason ought to be equally as readily acknowledged. It is true people do not talk across the table, and we do not require a clear stage and no favour; but withal, the *coup d'œil* of a dinner party ought to be considered, and to so divide the guests by tall and cumbrous decorations as to make it two dinner parties is clearly a great mistake. We have, by the *diner à la Russe*, got rid of the hot steaming dishes with their strong savoury smells, but we do not want to exchange that for the equally strong odour of highly scented flowers. To have quantities of Lilies, Stephanotis, and such flowers is to load the atmosphere with perfumes which are positively intolerable to some and disagreeable to many. With regard to the fourth, it must be remembered that there are many colours which might harmonise well by day, but which do not look well at night. Blues ought to be avoided, as, although the stands are exhibited by day, they are intended for night when artificial light is used. All deep blue flowers become nearly black at night, and yellows fade into whites. Again, it must be remembered that a good deal of coloured glass is necessarily now used—ruby and green for light wines; and too much colour, then, in the flowers ought to be avoided as tending to glare—the fault, *par excellence*, of bad taste. The Marsh stand is one of the best for the centre of a small dinner table that can be used, because it does not obstruct the view, a point always to be studied in table stands. To arrange such a one in good taste Fern fronds are indispensable. Care must be taken in dressing one of these stands not to crowd them with great variety, or overfill them; a few simple medium-sized flowers, properly and tastefully associated with foliage, being more effective and pleasing than a huge display of large flowers and glaring colours. Small fronds of Lygodiums or frondules of Selaginellas have a beautiful effect trained round the shaft of the stand. Read Mr. Luckhurst's article on this subject in our present issue.

Names of Fruit (J. Mackenzie).—As the small Pear invariably ripens in November it can scarcely be Winter Nelis, but both in size and quality the fruit resembled that variety, which sometimes ripens prematurely; we therefore indicated our uncertainty of the name. No. 2 was so very inferior—in fact, worthless—that we hesitated to name it at all. It may be Beurré d'Amanlis in very bad condition. Beurré Superfin has been bearing fruit for thirty-nine years. (A. J. Browne).—1, Reinette de Canada; 2, Doctor Harvey; 3, Lewis' Incomparable; 4, Claygate Pearmain; 5, Gravenstein; 6, Not known. (R. W.).—Cox's Pomona. (W. W.).—1, Lord Sniffield; 2, Summer Golden Pippin; 3, Sweeny Nonpareil; 4, Not known; 5, Urbaniste. The Lapageria will be referred to. (Capt. Isacke).—The Cluster Golden Pippin and the Bedfordshire Twin Apple frequently grow in the manner of the one you have sent. Does yours often come so? (H. L. K.).—1, Beauty of Kent; 4, Herefordshire Pearmain; 5, Cox's Orange Pippin; 6, Bess Pool. Tickets were displaced from two; the green-striped flat Apple is Yorkshire Greening. (W. A. P.).—1, Cellini; 2, London Pippin; 3, Christie's Pippin; 7, Winter Greening; 10, Minchull Crab; 12, Dumelow's Seedling.

Names of Plants (J. W. Hall).—Gloriosa superba. (W. G.).—As we have stated on many occasions, we do not undertake to name varieties of florists' flowers, but only species of plants. Varieties of Chrysanthemums, Pelargoniums, Fuchsias, &c., that are so readily raised from seed are so numerous, and many of them resemble each other so closely, that it is impossible for anyone to name them with accuracy, except by comparing them with others in a large collection. We do not refuse to give the name of any flower with which we are familiar when a good example is sent; those you have sent are so imperfect that no one could determine their names with accuracy. (W.).—Epidendrum dichromum, var. amabile.

Bees Irritable (E. S. W.).—Bees are always more irritable at times when there is little honey to collect, while we find them most docile during a glut of honey. The past unsettled summer caused bees to be more than usually spiteful. Robber bees are also very touchy customers to deal with. When once they have learnt the practice of habitual robbing (and some few bees in every apiary always seem to become so demoralised) they will often without any molestation dart at the face or hands of a bystander; they seem to consider that every man's hand is against them, and they are ever ready to show fight. Robber bees are readily known by their wavering, fussy habits; they hover before the entrance of this or that hive uncertain as to whether they dare run the gauntlet, whereas the lawful occupants of the hive deliberately settle among the guards or fanners and pass at once through the doorway. The loss of a queen has the effect of making the bees of the bereaved hive wholly demoralised, less careful to collect stores, and to guard that which is already collected, but we do not think such a loss, after the first day or two, tends to render them spiteful. The robbing which you knew nothing about until the hive was entirely depopulated may have been going on all the while the hive was being fed, and all the food given had been taken away by the robbers as fast as it was put on, while the hive really may have been untenanted for a long time by permanent occupiers.

IMPROVED DAIRY CATTLE.

(Continued from page 389.)

AFTER having stated the style and type of Shorthorn cattle which we require for our purpose, we will now refer to the Guernsey stock, not only to the style of cows we shall require

the fancier, as with refined traits of high breeding she combines those of size, vigour, breeding, and milking. Her skin in colour, as seen in the ear, the udder, and, in fact, on any part, is not nominally, but actually, that of gold, and it is not necessary to approach her or open the hair to see her glow. Her breeding is as follows—Bred by Mr. Stephen L. Pelley, St. Andrew's Parish, Guernsey; purchased by D. O. Le Patourel, La Ramee; born in spring of 1875; dam, Elegante; Grad-dam, Tulip; sire, Excelsior 1st. First prize Grand Royal Agricultural Society, Taunton, England, 1879. Before leaving the island she won the second prize of the Royal Agricultural Society, and first prize in the Herd Book Show, where all are selected animals." It appears that this cow was shown in America at the last State fair in the free-to-all class of milch cows, where she met worthy competitors—in fact, Holsteins, Shorthorns, Devons, Jerseys, &c., but she carried off the honours. The cream and milk of the herd, shown at the same time, commanded universal attention by its peculiar colour and quality. In large glass jars the milk showed 30 per cent. cream as the herd average.

There is no doubt that forcing the animal for phenomenal tests by feeding with as much stimulating and rich food as an animal will take is wrong, for it must eventually have an injurious effect on the constitution, and also that a long-continued strain as in an annual record must, more or less, impair the vigour and breeding value of the milch cow. We consider that the general producing capacity of a breed under such circumstances as will not exhaust or stimulate them, and on such foods as a farmer may be generally expected to supply, should be the actual and practical measure of the value of the animals. We are further informed that the largest amount of feed given to this celebrated cow Elegante on Fernwood Farm has been six

FIG. 78.—GUERNSEY COW "ELEGANTE."

in the future, but also to the bulls, as these will be of special importance throughout the changes we propose making in the improved dairy cattle. We do not recommend crossing to yield us a cross-bred stock for the future, as we only intend to take a dip into the Shorthorn blood, and expect thus to obtain all the characteristics required by never using any but Guernsey bulls of the best character and the latest improved strain. To illustrate what we seek we furnish a portrait (fig. 78) taken from the "Agricultural Gazette" of November 13th, 1882, of a Guernsey cow owned by Mr. L. W. Ledyard of Fernwood Farm, Cazenovia, New York, who says—"The cow portrayed is one well known among Guernsey breeders as 'Elegante,' No. 592 (No. 198 in the Island Registry). The engraving conveys a very accurate idea of her in nearly all respects except colour. Her colours are pure white and light lemon-fawn, and the latter is no darker on the head and neck than on the body. She will bear the close inspection of the practical farmer as well as that of

quarts of bran and two of corn meal mixed, and divided into two feeds of four quarts each, one feed in the morning the other at night. No other feed or drink other than water has been allowed. On this it appears she has made of golden-coloured butter, dry and unsalted, 2¼ lbs. per day, or 19¼ lbs. per week. But it must be imagined how much high feeding, with thrice milking daily, would have increased this record with a cow that would eat much more. Persons familiar with the high feeding of dairy cows will be the best judges. We well recollect the fact of a Guernsey cow we possessed many years ago, although only getting good pasture grass she made for several weeks in the month of June 18 lbs. per week of butter of the choicest deep yellow colour. In this case, however, the cow could not hold all the milk, and if she had been milked thrice instead of twice daily the butter record would have been greater without injury to the cow. Another circumstance we recollect, one of the best dairy cows we ever possessed was bred from a Shorthorn cow crossed by a pure-bred

Guernsey bull. Again, whenever we have known the cross reversed we have never seen it result in anything approaching a good dairy cow, and yet we have known it tried in numerous instances between really highly bred stock.

Although we have taken Mr. Ledyard's Guernsey cow *Elegante* as illustrated for our model of what a dairy cow ought to be for producing milk and butter, and at the same time showing a first-rate type and outline, yet we have no information given us as to the flesh-making capacity of the animal. It is therefore the only quality or capacity to which we wish to call the attention of breeders beyond that exhibited in our chosen model. This is, however, of great importance to secure in our attempt to improve the present race of Guernsey cows, for many of them will fatten fairly well when gone dry, but others are more of the style of Jerseys, having neither size or aptitude to fatten to recommend them to the dairy farmer. In order to show the value we ought to place upon the Guernsey cattle we must give the facts relating to their origin and the care which has been taken to preserve and maintain their purity of blood and other valuable characteristics of the breed. Tradition relates that even a century ago their merits were so fully appreciated that it was determined the introduction of any foreign blood must be objectionable. In 1798 we are informed that a law was passed by the Legislature of the island of Guernsey forbidding the importation of any cow, heifer, bull, and calf under a penalty of 200 livres and the forfeiture of the boat and tackle which should bring them, and a further penalty of 50 livres on any sailor on board who should fail to inform of the importation. Since that date we may assume that the cattle of the island of Guernsey have remained as absolutely pure as any breed that is known. The object that has animated the breeders of Guernsey during this long period has been to produce milk in the greatest abundance and cream of marvellous richness, and butter which in grain, flavour, and golden colour which should excel that produced from any other race of cattle.

Mr. W. Ledyard, in a lecture taken from the *Guernsey Star* and quoted in the *Chicago Times* of January 18th, 1882, observes—"The most remarkable characteristics of the Guernsey is the richness of the animal. It is seen in every point; the horn is soft and full of colour, the hoofs are usually like tortoiseshell, the skin is soft and of a golden-yellow tint, and the inside of the ears is still more highly coloured, while the same orange hue seems to glow from the bag, as if there was light under the soft skin. In the mature well-bred animal both eye and hand find evidence that all the secretions are rich and of high quality, and a careful examination prepares the mind for understanding why the butter made from Guernsey cream possesses qualities that are not obtainable from the milk of any other animal." The temper of these cattle we have always found to be affectionate and docile in the extreme, and we know that on the island their care is usually confided to women and children, whose gentle ways are reflected in the docile character of their family favourites. As specimens of the latest illustrations of some of the most valuable Guernsey cattle we refer our readers to Mr. James' Guernsey cow, "Lady Emily Foley," first in her class at Reading; also to a Guernsey bull shown at the Tunbridge Wells meeting, both of which will be found well portrayed in the *Agricultural Gazette* of August 8th, 1881. A Guernsey Herd Book was published under the auspices of the Royal Guernsey Agricultural Society, vol. i. compiled by M. Theophile de Moulpied in 1882—the second volume is now published. This well-intentioned publication meets a real want, and suggests questions which the owners of other herds would do wisely in considering. It is stated that some difficulties have occurred, as it has not been the habit to give names to all their stock, but often only to designate them as "the red cow," "the brindled cow," and so on. Even the Agricultural Society began to give prizes by name only in 1879. Prior to that date they were given to the owners' names.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horse labour will soon be completed on many farms with the exception of land where Turnips and Rape are being fed off by the sheep. It is, however, best to keep the land ploughed and sown simultaneously, for with a freshly ploughed furrow it will be sure to take the seed well when the weather is dry, although slight frosts may occur at night. Still, the usual weather of the month of November is frost or rain, therefore the land to be ploughed from this time should be sown as fast as ploughed, and this is the only way to be safe in our seed time after we have entered on the November month. On all strong flat lands the last few days of October were very favourable for seeding with Wheat, quite in contrast with the same period of last year. Where these strong soils are given to, as they often are, the growth of weeds injurious, such as black bents and yellow cress, the land should be

drilled with Wheat at 10 or 12 inches apart between the rows of plants for when this is done not only can the horse hoes be used freely in March to destroy the weeds, but also to break the surface where the Wheat may be looking yellow and sickly from the effects of adverse weather during the winter months. Without this wide drilling no farmer can be master of his position, and secure the beneficial results of former good tillage or liberal manuring, as the weeds if not destroyed will grow and overwhelm the corn, in the same proportion as it has been cultivated and manured unless the corn is drilled wide apart. Hundreds of acres every year are entirely ruined, because when sown broadcast these weeds before spoken of cannot be destroyed either by hand labour or the machine used for destroying the early weeds like charlock and redweed, because those before named do not appear soon enough to be destroyed by machine, and which can only be done in their infancy by the horse and hand hoes. The odd horse will be daily at work upon the steam-cultivated fallows carting away the couch, in readiness for rafter-ploughing for the winter. Potato-lifting is now going on, the sooner it is done the better, and we must here call the attention of the home farmer to the excellent machine for lifting Potatoes of which a plate was given last week. There is no doubt but that it is quite superior in operation to any other machine previously used for the purpose in every respect. In noticing the working principles of the machine, it not only lifts the Potatoes, but has a peculiar action useful for lifting the couch and weeds out of the land, and leaving them on the surface; and we think that in the spring of the year this machine may be made good use of on the foul fallows, for where the land has laid during winter on the stretch it may be used with benefit in passing along the stretches, by opening the land and casting the couch and weeds on the surface, to be afterwards dealt with by the harrow designed by Messrs. Howard, called the self-lifting drag harrow.

Hand Labour.—As fast as the leaves of Swedish and other Turnips give way, men and women too may be employed in forking out any bunches of couch; and in the same way, as fast as the Mangolds are removed, especially if the land is intended for seeding with Wheat, the lumps of couch may be removed in advance of the ploughs. Unfortunately these matters are often neglected, the farmer feeling satisfied that there is not couch or weeds enough to injure the next crop; but such management may be termed "penny wise and pound foolish."

Live Stock.—The weather in the latter part of October has been very favourable for all animals living now feeding in the open fields upon roots, or on the pastures while feeding on grass, and we notice that a healthy fall of lambs are now being yeanned by the horned Dorset and Somerset ewes. This stock above all others are the most prolific, for it is not uncommon to obtain 150 per cent. of lambs from them, while their general average fall may be called 125 to 130 per cent. It must also be borne in mind that these ewes above all other sorts give the most milk, and are better able to rear a large number of twin lambs than any other breed, especially when they lamb early in October and the first half of November, the ewes having lived upon the best autumn grass up to the time of lambing, and it is also notorious that these ewes will bear higher feeding on luxuriant grass during pregnancy than any other breed of sheep without injury to themselves or the health of the young lambs. Some farmers have fed them with cake before they lambed, but we do not approve of this, for we never begin cake-feeding until the lambs are a fortnight old, unless it is ewes having twins, for these may get the best of food a few days after having yeanned their lambs. The present is the time for the farmer who does not breed all the cattle he requires for winter feeding in the boxes to purchase what he requires, not of poor cattle, but those just beneath the butcher's requirements, and as these will now be clearing out in the grazing districts, they may be bought to pay a full profit.

APPLES AND PEARS FOR SMALL GARDENS.

NOT many years ago small gardens were considered unsuitable for fruit trees, for the sufficient reason that, grown as standards on the Crab stock, the trees occupied too much space; but since dwarfing stocks have become popular and their great merits have been recognised, fruit trees are grown in thousands of gardens that were before practically fruitless, and they might be grown in thousands more. Nothing adds more to the interest of small gardens than fruit trees in appropriate positions, and well managed they are both beautiful and profitable.

In or around most gardens there are walls or fences, and these might be covered with fruit. Then arches of fruit may be formed over walks, thus turning space to account that is usually wasted. These tunnels of fruit trees are very beautiful in spring when covered with blossom, and again in the autumn when studded with fruit, while through the summer the shade they afford is always enjoyable. In Mr. Baring's garden at Coombe Cottage a leader has been taken from each pyramid that is growing in the borders on each side of the central walk and trained to iron rods formed over it. These are about 5 feet apart, and the series forms a fruit bower attractive and profitable. These arched cordons bear abundantly without in the slightest degree limiting the productiveness of the lower parts of the tree—that is to say, the bush or pyramid portion would not bear one more fruit if the tops which bear so well were cut off, while the walk there would not be half so agreeable. This is a distinct gain, and why cannot arcades of fruit be formed over walks as well as bowers of Roses, Clematises, and Honeysuckles?

At Moray Lodge, Kensington, I am informed on good authority that Mr. McElroy has a beautiful arch of Apples, the trellis having been formed of three-quarter-inch iron, five bars of which about a foot apart are fixed longitudinally to stays which arch over at intervals of about 6 feet. Standard trees are planted, the stems being secured to these uprights, and the branches of the trees trained right and left espalier fashion. By this plan the side borders are not shaded at all, while a quantity of fruit will be had when the trees arrive at a bearing state from the space above the walk. In this way fruit may be had in small gardens without reducing the extent of ground for vegetable or flower culture. This is a decided advantage, while the appearance of the garden is greatly improved. Thus fruit trees may be increased in number in small gardens, and the present is the time for amateurs to select the most suitable varieties. This is easy to the expert, but for the inexperienced amateur it is very difficult. These persons require small trees and desire them to bear abundance of fruit yearly, though of course this cannot be insured; but an amateur thinks more of a dozen fruit gathered from trees grown in his own garden than of a bushel bought in the market.

For these small gardens it is no use having trees that have been grafted on strong-growing stocks. Pears should be

grafted on the Quince, and Apples on the English Paradise stock. There are generally positions on walls where a few trees may be planted, and if the aspect is either south, west, or east Pears can be grown. If all three aspects are at command a few Plums may be planted against the east wall.

Of Pears cordon-trained trees will be found the best for amateurs, as several varieties can be had on a comparatively small space of wall; consequently a succession over a lengthened period is secured. Cordons may be procured from any nursery making a speciality in fruit trees. One-year maidens are the best, and care should be taken to have those that are budded close to the ground, so that when planted the union of the stock and scion is about an inch below the surface.

The ground should be properly prepared before the trees are procured. If the soil is in fairly good condition it should be well trenched about 2 feet 6 inches deep. If the subsoil is not very good it should not be brought to the surface, but be well broken up with a fork. At planting time place some good loam around the roots. If the soil is not very suitable for fruit trees it should be prepared as well as means will allow, adding some loam or road scrapings with a little manure. The trees will keep in good condition for many years if they are properly attended, supplying fresh compost to the roots when needed, and giving a surface dressing of manure when the fruit commences swelling freely. Care should be taken that the trees be not over-cropped, a great mistake with amateurs.

The trees should be planted 20 inches apart. The first year train at an angle of 60°, the next year bring them down to 45°, their permanent position. They should not be allowed to bear too freely at first, and especially at the point of the leading shoot, as every encouragement should be given to get the wall furnished.

The following varieties will form a succession:—Beurré d'Amanlis, Beurré Hardy, Beurré Superfin, Marie Louise, Doyenné du Comice, Beurré d'Arenberg, Josephine de Malines, Nouvelle Fulvie, Glou Morceau, Passe Crassane, Bergamotte d'Esperen, and Olivier de Serres.

Apples.—Apple trees on the English Paradise stock may be grown in very small gardens as pyramids or bush trees, and if a system of summer pruning is carried on they do not grow to a large size. In preparing the ground it should be trenched as advised for Pears, and if it can be trenched to the width of 6 or 8 feet so much the better. They may be planted 5 feet apart the first year; as they increase in size every alternate tree should be taken out and planted elsewhere, and if carefully done these will bear a full crop of fruit the next season. Cordons trained diagonally to a trellis are very interesting for an amateur, as the fruit grows to a large size. Horizontally-trained cordons along the margins of walks impart a neat finish to a garden, and often bear excellent crops of fine fruit; they should be trained to a wire stretched 15 inches above the soil.

Planting should always be done if possible during dry weather. Place a little good soil around the roots, which will help to give them a start, firm the soil, and place a covering litter on the surface to protect from frost and drying winds. Amateurs should bear in mind that early planting is the safest and best. I do not think I can do better than repeat the advice which I have previously given—viz., one thing must be borne in mind, that is to procure trees that have been budded or grafted close to the ground, so that when planted the union may be covered with soil. If the trees are lifted once or twice annually after being planted, and the soil well stirred, it will help to make them handsome and fruitful specimens.

The following twelve varieties, culinary and dessert, will be found a good selection for succession:—

Dessert.—Irish Peach, Kerry Pippin, Margil, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Ashmead's Kernel, Duke of Devonshire, Northern Spy, Mannington's Pearmain, Lodgemore Nonpareil, and Sturmer Pippin.
Culinary.—Lord Suffield, Ecklinville Seedling, Gravenstein,

Small's Admirable, Blenheim Pippin, Warner's King, Lodgington, Peasgood's Nonesuch, Rymer, Wormsley Pippin, Dumelow's Seedling, and Northern Greening.

I might have named a greater number of good varieties, but a short list is often of greater service than a long to that great number of persons who only want a "few trees."—A. YOUNG.

LILIUMS.

(Continued from page 397.)

L. davuricum, Gawl.—A very showy Lily, growing from 2 to 3 feet high, with slender stems bearing numerous narrow shining leaves, and terminating with few-flowered umbels of bright red slightly dotted flowers. Native of Central and Eastern Siberia, from the Altai Mountains to Kamtschatka; flowering in this country with *L. croceum*. It is a very variable species, and usually a large number of varietal forms are placed with it, which, however, is a rather difficult matter to decide. It is questionable whether these so-called varieties of *L. davuricum* may not be as closely related to *L. bulbiferum*, and I am not sure that *L. Thunbergianum* may not have been employed in their production. Amongst the best of these forms are *grandiflorum*, *incomparabile*, *Sappho*, *rubens*, and *atrosanguinea*, all of which are grand border kinds; indeed, are some of the best and showiest Lilies for outdoor culture.

L. Hansonii, Leicht.—A very charming Japanese Lily, growing from 3 to 4 feet high, with rather large leaves in whorls. Flowers several in a lax raceme, with the perianths of a rich bright orange colour dotted with purple upon the lower half of the segments, which are revolute. This very handsome species flowers in June and July, and enjoys a damp partially shaded position. One of the brightest of the genus.

L. Humboldtii, Roez. et Leicht.—Another splendid species, growing in good soil from 4 to 6 feet high, with stout stems of whorled leaves. Flowers usually numerous, but varying from six to thirty, arranged in a deltoid panicle; perianth bright orange-red, copiously spotted with claret-coloured dots, with the segments sharply reflexed. Native of California, occurring on the Sierra Nevada, flowering in our gardens in July and August. It is synonymous with *L. Bloomerianum*, and there is a variety named *ocellatum* which is similar to the type, but worth having.

L. Leichtlinii, Hook, fil.—A very elegant Lily from Japan, named in honour of a very enthusiastic cultivator; growing from 2 to 3 feet high, with slender stems clothed with narrow leaves. Flowers usually few in number, with the perianth divisions sharply reflexed, of a bright lemon colour, thick dotted with crimson from the base nearly to the apices. It flowers in July and August, sometimes lasting on into September, enjoying a damp position in peaty soil. I have a nice patch in the bog bed, and have found it do better there than elsewhere. It is very erratic in its method of growth, coming up where you do not expect it, the stems running a good bit beneath the surface.

L. longiflorum, Thunb.—The white Trumpet Lily, one of the most beautiful of all Lilies, and extremely useful, varying considerably in the form and size of the flower as well as the time of flowering. The type is too well known to require description in these pages, with its large pure white trumpet-shaped flowers. I will mention varieties of it which are very desirable in addition to the normal form *eximium*, perhaps the most useful of all, with very fine flowers, coming a month later than the type. *Albomarginatum* has the foliage margined with silvery white. *Harrisii* is very valuable because of its freeness in flowering; after one stem dies down another is sent up. I did not believe it possessed this characteristic, but have abundant proof of it now, having some bulbs which are now sending up the third set of stems for this season, and are evidently producing good flowers. *Wilsonii* is also a good form, with large flowers. By using all these varieties I have had these beautiful Trumpet Lilies in excellent order from the end of May to the present time (Oct. 17th).

L. Martagon, Linn.—The Turk's-cap Lily, a well-known old-fashioned species, one of the earliest known of all Lilies, producing stems from 3 to 6 feet high, with whorls of broadish leaves, and terminated with loose racemes of dark claret-coloured flowers with sharply revolute segments. Native of Southern Europe, extending through modern and eastern Europe, Siberia to Japan. There are some varieties under cultivation, which for garden decoration are much superior to the normal form, two of which I will mention. The white-flowered variety, *album*, is one of the most charming of all Lilies, with racemes of pure white flowers, and it is happily becoming more plentiful. Like all

the *Martagons* it detests being disturbed; you see grand masses of it in some old-fashioned places which have remained undisturbed for very many years. I know of one such batch in particular which was broken up two years since with the idea of improving them, but the result is far from satisfactory. Then there is the very handsome variety named *dalmaticum*, which perhaps is difficult to distinguish from *Cattanea*, which is more vigorous than the type, with very long racemes of flowers, varying in colour from a light purple to a deep blood red, with or without spots. All the *Martagons* are well worth growing, being but little trouble, and flowering from the end of June to August.

L. pardalinum, Kellogg.—A very showy species from the Western States of America, exhibiting a considerable amount of differentiation, so much so that several of its varieties have been placed in specific rank by some authorities. The typical form grows about 3 or 4 feet high, with smooth stems clothed especially in the middle with whorls of shining lightish green leaves. Flowers several, in a loose umbel; perianth about 2½ or 3 inches across, bright red, orange at the base and copiously spotted with deep purplish brown spots, appearing at the end of July and August. Of the varieties under cultivation *californicum* is undoubtedly the best, having rather larger and much brighter-coloured flowers, being rich scarlet shaded orange with very conspicuous spots. Then there are *Bourgæi* and *pallidifolium*, both of which are very desirable. All these grand Lilies should be planted much more extensively than they ever have been yet; and indeed they will be when better known. So graceful in the border or the vase, they simply require to be brought more prominently before the plant-loving community to be vastly appreciated. They grow most freely in ordinary soil, and as regards price are getting within reach of all.

L. Parryi, Watson.—A charming but comparatively rare Lily from California, occurring in San Geronimo Pass and San Bernardino county. It grows from 3 to 6 feet high, with stout stems furnished with narrow lanceolate leaves, terminated with a corymb of flowers of a rich lemon colour sparingly dotted with tiny claret-coloured spots, appearing at the end of July and August. This is a very lovely species, growing very freely in the bog bed, evidently having a preference for peaty soil with leaf mould and sand, although some of my bulbs flowered right well in ordinary soil.

L. spiciosum, Thunb.—This is, perhaps, more frequently called *L. lancifolium*, which is, however, quite a distinct plant. Gardeners especially cling to this erroneous appellation, and by one name or the other it is very generally known and largely cultivated, so that description is unnecessary. There are a large number of varieties under cultivation, but a selection is quite sufficient for general purposes. The following are the best—*album Kretzeri*, white; and *rubrum punctatum*, and *macranthum* shaded and spotted crimson. All are free bloomers and vigorous growers, enjoying a well-drained position with plenty of thoroughly rotten manure. They are among the most useful of all Lilies for pot culture, but rather late for outdoor cultivation unless planted in very sheltered positions, where they are likely to bloom earlier than is usual, and the flowers stand a chance of partial protection from early frosts. Of course the flowers coming in so late are most desirable when but little else is gay outside.—T.

ECONOMY IN STOKING.

I THINK the subject discussed by Mr. Inglis (page 370) is second to none in importance, and one which may be profitably considered, although much has been said and written about it already. Even with the best of boilers anyone can see that a considerable part of the heat is lost, and with the incomplete and badly designed heating apparatus the waste of fuel is often shameful. Boilers of all shapes and forms are made now, but I think the saddle and its near relations the cannon and the Cruciform, are still the best. The worst fault I find with them is that the furnace is generally so long and narrow that it is difficult to keep the neck as clear from ashes and clinkers as it ought to be, and a long boiler seems to me to be most effective. To obviate the difficulty I have just mentioned I have thought of the following plan, and would like to have the opinion of someone more able to judge than I am of its merits.

This is to have a furnace door at each end of the boiler, and to feed from either end alternately, reversing the draught each time by means of dampers. When the fire needed fuel the last put on would be glowing red to burn the smoke from the new coal, and all the cleaning it would require would be to take out the clinker or ashes with the shovel. The door at the back, as I may call it, would come in for a good share of the heat, but the flame might be diverted before directly striking on it. I think the best door would be a heavy plate of iron working up and down like a window sash, and with a chain and weight hung over a pulley to counterbalance it. I would have no ashpit doors, but large outside doors right over the front of the fireplace, with ventilators in the centre opposite the furnace doors, so that by using the ventilator in front of

the hot door the air drawn in would be heated before passing through the fire.

It is surely a mistake to have so little brickwork and so much cool boiler surface in a furnace. To retard the thorough combustion of the coal and to send it up the chimney in volumes of thick black smoke, so much heat is worse than wasted. There are few structures where the smoke after leaving the boiler could not be taken in a flue round a plant stove beneath the stage or some similar place, and the heat be thus all utilised. With the very best boiler if the water is, say, 180°, the air must pass up the chimney at that temperature; and if the fire gets very low with a full draught on, the better the boiler is constructed to extract the heat the sooner the cold draught will cool it.—DUGALD.

SEAKALE AND RHUBARB.

SEAKALE is such a distinct and good vegetable that it is worth some trouble trying to command an unbroken supply throughout the six months or so it is in season. Gardeners who have this to compass as part of their duties are sometimes obliged to make efforts to do so, which are perhaps suitable for their own individual wants but not to be generally recommended. Thus I found it necessary before a sufficient number of plants were raised for our consumption to take a double cutting from the strongest crowns. As a matter of course the second crop thus forced was not nearly so fine as the first cutting from the central crown, but for a few seasons I was glad of it, and mention it now that those in a like position may try a double cutting.

Though it is an impossibility to cut large produce if the summer growth has not been carefully provided for, this is not the time to enter into the preparation of the plants. At the same time it must be understood that much may be done by treatment whilst the plants are being forced to improve the produce, and I will shortly state the system we pursue to produce a continued supply of Seakale.

The first season I entered on my present charge the old system of covering and forcing with leaves was pursued, but the labour of carting the leaves on to the beds in winter, and in spring carting them back to the rubbish quarter, with the continued labour of uncovering the pots and boxes to get at the produce, once and for all set me against ever forcing Seakale in that way again. Accordingly when spring arrived a good breadth of seed was sown, and with plants from this, supplemented with those from the old beds, I made the best of it by contriving places in the hothouses. Afterwards a forcing pit was crected and provision was made for bringing on a supply of early Seakale and Rhubarb in this structure; a Mushroom house was also set going, and a portion of that building has been devoted to Seakale, while a shed erected to prepare the manure for the Mushrooms came in useful for the later batches of Seakale. Thus the two earliest batches are started in the pit. Then from January to April the Mushroom house is depended on, and in April and May we cut from the shed-grown plants. The entire crop, it will be seen, is lifted and forced. In our circumstances this is the cheapest and best mode, and the Seakale is grown year after year by rotation like other crops.

In one of the late winters which frost-bound the earth for so many weeks it was impossible to have a supply lifted. Since then I have had the whole crop lifted when growth was fully finished, and the roots put away for use as required in a cool shed. The crowns are selected at this time, any weakly growths being thrown aside to be planted out. These make the strongest crowns for the following season. The best material I have yet tried for planting the roots to be forced in is one of leaf soil and Mushroom-bed refuse in equal proportions. The latter used alone does very well. It is not well to give much water; in fact, as a rule water is not much required, as there is so little evaporation, owing to the plants being kept isolated from the rest of the house; nevertheless,

the soil is dry a moderate application of lukewarm water is very necessary. A batch is put in to force every three weeks. However, the latest may be a large one, and as they will come on slowly and irregularly the supply from it is kept up for a long time. A higher temperature than 55° should not be given. The crowns should be cut when the growth is about 7 inches in length. When the supply is at any time greater than the demand, all that is ready should be cut and kept till wanted in a cool room. As one batch is cut the roots are removed to a cool shed and covered with sand until wanted to plant out, and another batch is introduced, not using the same soil. For the produce brought on in the shed a few loads of sweetened horse droppings are placed round it, and the whole covered up with bundles of straw. The very latest lot requires merely to be protected from light, and comes on naturally.

Rhubarb is grown in a pit. The same material for rooting in is used as stated for Seakale. Rhubarb intended to be forced should not be gathered from in summer. Both light and air are required in order to give firmness and flavour. A temperature of 55° should not be exceeded, and plenty of water at the root is very necessary for Rhubarb.—B.

MICHAELMAS DAISIES.—These have bloomed well this autumn, the fine open weather we have had being very suitable for the expansion of the flowers. There are two or three kinds very suitable for a rock garden—*Aster alpinum*, *A. ericoides*, and *A. discolor minor*. The last named came under my notice on a recent visit to Kew, and was one of the prettiest and most attractive flowering plants then in bloom on the rockery. It is about 6 inches in height, and deserves a place in every collection. *Aster Amellus* and *A. hyssopifolius* are two good flowering

plants for the herbaceous border in August and September. *A. Amellus* in particular should be planted freely, as it gives very little trouble in staking, and does not encroach too much on other plants. Its height varies from 18 inches to 2 feet. The flowers are large, dark lilac shaded with purple, and with a yellow disc; and of several kinds that I cultivate in my opinion it is the best. *A. Novæ-Angliæ* and some others are now blooming, ranging from 5 to 7 feet in height.—A. HARDING.

DIPLADENIA BREARLEYANA.

THERE are few plants so beautiful, and few that are more useful in the stove than this. Whether trained on a balloon trellis for a drawing-room or warm conservatory decoration, or on a trellis close to the roof for the purpose of cut flowers, its soft pink trumpet-shaped flowers changing to the deepest crimson are invaluable. If in the latter position it is associated with either *Allamanda* or *Stephanotis* the contrast is very striking. When cut the blooms will last some time, and if placed in flat glasses either alone or mixed with those mentioned, with a few sprays of Fern as a thin veil over them, they are exceedingly effective. Being evergreen they must not be allowed to get too dry in the resting season, otherwise they suffer considerably and start into growth in spring very weakly. In February they should be potted in a mixture of three parts peat, one part loam, one part leaf soil, and one of sand. They should be grown freely in a good stove temperature, with an occasional supply of mild liquid manure when in full growth. They must be kept clean by frequent syringing. By this treatment they bloom freely and continuously.—C. W.

THE PHYLLOXERA.

It may throw some light on the case of phylloxera referred to by your correspondent (Mr. Gray, page 401), if I state that several years since I had some correspondence with a gardener in the north of Scotland, who sent me a sample of his Vine roots covered with this destructive pest. He was at a loss to conceive how it could possibly be introduced to his vinery, not having received Vines from anywhere. After urging him to think of everything that occurred in connection with these Vines, he recollected that his employer bought some Roses in France, and that when they were received the ground was so hard frozen that they could not be "heeled in" outdoors; and having a bench full of soil prepared for potting the Vines, the Roses were laid in this soil, and so remained for a time, after which the young Vines were potted in the said soil. No doubt the eggs of the phylloxera had been imported with the Roses, and though the insect lives only on Vines it is quite likely that its eggs might be imported in the soil attached to Lilacs imported from France.—D. THOMSON, *Drumlanrig*.

I BEG to send you a few more particulars about the phylloxera-infested Vines at Chevening. In the first place the Vines were temporary, and therefore there was no need for hesitation to destroy them. They had been planted in what was an old Pine pit, deep and narrow; drainage to the depth of 18 inches had been put in, and the remaining space filled with soil, in which the Vines were doing well. We were in the act of giving more accommodation to the roots of the younger and permanent Vines, which led to the discovery of the pest. I had no doubt what it was, but was glad to have your confirmation of the fact. When digging out the soil I was enabled to make a more minute examination, and found phylloxera on all the main roots, down even to the drainage, a depth of nearly 5 feet; there were none on the rootlets nor small roots. Doubtless this circumstance accounts for the health and vigour of the Vines. Two of the Vines had not many insects on them, which puzzles me. The Black Hamburgh and the three next were very bad.

The question of its introduction to the different places is a very important one indeed, as, if that could be ascertained with any degree of certainty, gardeners would then be able to avoid it or stamp it out. At present I do not believe in the "mysterious theory" of introduction. Little doubt exists in my mind that if no Vines had been bought in there would have been no phylloxera here.

I quite agree with you that keeping its presence secret will do no good; on the contrary, much harm. My employer, as soon as it was made known to him, at once suggested the destruction of the Vines, and is agreeable to let his neighbours know and see the pest if they wish, with a view to its extirpation. Everyone who has the misfortune to have it ought to do the same.—R. GRAY.

BURNING REFUSE.

WHAT with autumn cleanings and winter prunings refuse will now be plentiful in all gardens, and it is to be hoped that the advantage of the crops and the benefit of cultivators that every particle of such material will be collected, saved, and converted into manure. Leaves and anything which will decompose readily may be partially decayed and be used as manure; but prunings and anything in the form of wood cannot be treated in this way, and it is not safe to make manure of weeds until they are burned, as this is the only way of killing the seeds, but it is a simple way of destroying them and should be generally adopted. Prunings from evergreens, fruit trees, hedge-clippings, and everything of this kind should be placed in a large heap and burned. When they are very dry they will soon be consumed, but this destroys them, as little

ashes are left and much good manure lost. It is not merely to get refuse out of the way that we advise burning, but the main object to be kept in view is to secure as many ashes as possible, as for many crops these are most valuable as a manure. In burning a heap of rubbish the flames should never be allowed to ascend, but the whole should smoulder until everything is charred. When we make up our heaps we put all the prunings in the centre, and weeds, edgings of walks, and all short rubbish are thrown over the top, and after this has been submitted to the action of a slow fire there is a large quantity of ashes, which we value above everything for vegetable-growing.—A KITCHEN GARDENER.

SIX MONTHS IN A VINERY.

FEB. 12TH.—We have not had occasion to give air a second time yet, as there has been no continued sunshine since the 8th, but the shoots have strengthened wonderfully, and as our space between the trellis and the glass is limited to about 10 inches we have thought it well to commence tying down the forwardest shoots. About one-third of them have been thus tied to-day and the point of the shoot pinched out at the same time, leaving generally three leaves beyond the bunch besides the one exactly opposite to it. Were there less than 3 feet between the rods we would only allow two leaves beyond the bunch to remain. Of course these leaves are very small at present, and the operation of pinching out the point requires some care, but the sooner it can be done the less will be the loss.

Tying down the shoots is a very delicate work, and can only be done by degrees. A piece of matting a quarter of an inch broad is placed over the shoot beyond the bunch, and a loose loop two or three times as large as the stem is tied. The other end of the matting is brought down to the trellis, and merely pulled and fastened sufficiently tight to bring the head of the shoot down 2 or 3 inches without putting any pressure on the union of the old and young wood. It does not signify at all about the shoot being bow-shaped now, when it becomes tough later on it can be bent to anything, but at present the least little pull too much will snap it off, and there is a risk of disfiguring the Vine for life. I have seen many shoots tied down, apparently safe during a bright day, and the operator congratulated himself about the neat way in which he had done it; but the next morning told a different tale, for during the night while the house was damp and there was less evaporation, the young growth had more than regained its former rigidity, and as the tie would not give way the shoot did.

Feb. 24th.—Since the 12th we have had four bright days—viz. 16th, 18th, 19th and 23rd, and on each of these occasions we have given a little air between 8.30 and 8.45, closing again between 12.30 and 1 P.M. On all other occasions the house was kept close. As the effects of the watering were plainly visible for a fortnight on the surface we have only had occasion to damp down twice since the watering was finished on the 6th. The shoots have been brought further down by placing a shorter tie on them than was given at first, and some of the forwardest are now nearly in a horizontal position; others have only had a first tie, inclining them only slightly as previously mentioned. All have now been stopped with the exception of a few of the very weakest and a few sublaterals—*i.e.*, branchlets springing from the axils of the fruit-bearing shoots (or laterals) have pushed sufficiently to be also stopped to one leaf.

The oldest of the main leaves are enlarged so as to measure 7 to 7½ inches across and about an inch more in length. The green colouring matter is now spread throughout, and the oldest of the leafstalks and veins of the leaves are assuming a brownish red colouring. This colouring is also seen slightly on the stems of the laterals where they are most exposed to the sun, which gives a hardy look, and causes one to think they are getting all they want, and are making good use of the same.

The bunches have been reduced to one on each lateral, the tendrils removed with the finger and thumb, and the ugly-looking or badly balanced shoulders as well.

Written instructions on temperature given on the 15th inst., and still in force, are "55° night and 60° day by fire heat, 80° to 95° with sun."—WM. TAYLOR.

(To be continued.)

CATS *v.* RATS AND MICE.

ON page 374 your correspondent "B. S." asks for information as to the best method of destroying field mice without endangering dogs. I say, writing after rather unpleasant experience, that cats are the only remedy. On taking charge of these gardens I found they were overrun with field mice or voles, and rats, these coming in the first instance from the park and preserves surrounding us. The mice gnawed the bark off the fruit trees under glass and in the open, cut down the Roses in pots, cleared off whole breadths of Carrots, spoilt great quantities of Strawberries for the sake of the seeds, ate all seed peas not

soaked in paraffin, besides doing much damage among Carnations, Pinks, and other flowers. They burrowed in the ground, grew fat, and increased in all directions. Endeavouring to trap them when thus well established was simply waste of time, and although we succeeded in poisoning some, this was both a dangerous—in fact, we killed more birds than mice—and an ineffective remedy. They will not take bait, either in traps or poisoned, similar to the house mice, but must be tempted with the same kind of food they are feeding on, even if this be Rose shoots.

The rats established themselves in the forcing pits, and having a long run through the courses of the hot-heat hot-water pipes, could not be dislodged. They cut down numbers of *Dracænas*, and formed nests with the leaves of these, *Panicum*, Ferns, and other valuable material. Others established themselves in a protected Vine border, and formed a large nest with various materials, and did not forget to destroy the greater portion of our first hatching of ducks. In the houses and pits we trapped and poisoned a few, but the latter, being difficult to get at, nearly poisoned us with the stench arising from their decomposition. Two cats soon changed the whole state of affairs. The mice they gradually cleared out, and the rats soon disappeared, as is their wont when they see danger. Cats, to be serviceable, should be kept entirely in the gardens, as they are of no service in the garden when encouraged in a living-house, especially where there are children, and overfed. A little bread and milk is all ours have, and the rest they must catch for themselves. When our first pair took to poaching in the surrounding game preserves they, after one promised "let off," had to go the way of all poaching cats. This, no doubt, will be the case if "B. S." tries my remedy, but he, like us, will have fully realised their value, and will quickly procure two more strong kittens.—W. IGGULDEN.

ON page 374 a correspondent, "B. S.," complains of the trouble field mice cause him. A few years ago I was troubled in the same way, also with rats, their runs often being at the foot of a south wall; but the rats were generally in the hank of a pond situated in the middle of the kitchen garden, some parts of which were completely honeycombed with their runs. A good cat was on the premises, and used to catch many, but failed to keep them down enough. Placing poison about was not to be thought of, and they are usually wary of traps. One day, however, about two years ago, my attention was attracted at the pond hank to a little animal that I thought at first was a rat, but which proved to be a stoat. On its being pursued it started into one of the many runs the rats had made, and all attempts to catch it were unsuccessful; but I have never seen but one rat in the garden since that time, and only a few mice, as I quite believe the stoat has destroyed them. Afterwards I saw on two occasions the stoat at the runs at the south wall where the mice were so plentiful, and I have been troubled very little with mice since. I have also seen a weasel in the garden, and if either of these little animals cannot be procured, plenty of traps and cats must be provided.—A. HARDING.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

THE admirable article under this heading, which appeared on page 349 of your issue for October 25th, is so seasonable and so kindly appreciative as to deserve the thanks of all gardeners interested in the question. There is no antagonism between the above and the Gardeners' Royal Benevolent Institution. The United Horticultural Benefit Society seeks to assist a class of gardeners that it is very unlikely will ever be in a position to be benefited by the latter, and I trust the publicity you have so generously given to the Society will result in a large accession of members.

I can bear personal testimony to the business-like way in which the affairs of the Society are conducted. As one of the honorary members it has fallen to my lot for two years past to preside at the annual meetings of the Society, and I have been greatly pleased to see the earnest attention given to the affairs of the Society by the numerous body of members that are then brought together. The Committee of Management is openly selected from the members, and there is no previous manipulation of that body by the Secretary or any little clique of members.

Suffer me to take this opportunity of appealing to the trade to support this deserving Society by becoming honorary members. They will be assisting a deserving body of men, as one of the objects of the Society is to create thrifty habits on the part of many gardeners in subordinate positions in the gardening world.—RICHARD DEAN, *Ranclagh Road, Ealing.*

REFERRING to several articles that have appeared recently in your valuable paper respecting the above, allow me to state my experience exactly coincides with Mr. Heales'—viz., the coolness hitherto shown by many gardeners in reference to the Society. No doubt Mr. Divers' assertion, if authentic, respecting gardeners being so favourably recognised by insurance societies will be a welcome surprise to many; till now I have been under the impression such a favour was only allowed to abstainers from intoxicants. If "Sussex Gardener" joins this Society and induces others, and I earnestly hope he will, he will do exactly what most of the members have already done, which has lifted the Society into its present flourishing condition. As to "J.B.'s" concurrence with the addition of the word "hlot," such an expression is uncalled for. After the publication of the article at page 349 surely the allegory, "hiding its light under a bushel," is misapplied; and allow me to respectfully

inform "J. B." the annual meeting of the above Society, the funds invested, &c., have been announced in the *Journal of Horticulture* for years, as well as the *Gardener's Chronicle*.—T. COATES.

[Our correspondent "J. B.," as is obvious, was animated with the best intentions towards the Society, and his letter is at the least as likely to aid it as the one now published. The article on page 349 did not emanate from any member of the Society, and until its appearance, notwithstanding the casual notices alluded to, the real position of the Society was unknown to the great majority of gardeners. We have excellent authority for stating that the Society, and the advantages it offers, would have been made widely known had there been a surplus for that purpose from the management fund. With an accretion of members this fund will increase, and we venture to think that "J. B." deserves the thanks of the directorate rather than otherwise for his letter on this subject.]

TEA ROSES.

GROWING Roses only in a very limited area we are naturally diffident in offering experiences, and yet gardening is such an inestimable, such a health-giving delight, that I cannot refrain from making some observations suggested by the article "The Past Rose Season," from the pen of a very high authority, in the *Journal* of November 1st. I entirely agree with that authority "D., Deal," that the Tea Rose is not anything like so tender as it used to be represented. It is, in my opinion, as hardy as the Hybrid Perpetual. It is more graceful, more delicate in tint, and it is besides invariably perpetual. The Tea Rose may be grown either in the open or under shelter of a wall, and in either situation with me it succeeds. By the wall being at the bottom of a slope I keep the ground open by an application of ashes and fine cinders, laid on in November, and followed by a liberal mulching of manure. In the open, where the soil is lighter and apt to become dry, I seldom use ashes, only the usual mulching. But where Tea, or indeed Hybrid Perpetual, Roses are grown in an exposed situation as dwarfs—and in both cases dwarfs only are in question—I strongly recommend protection by screening with Yew cuttings on the north and east side from February or March up to the middle of May or June. In small gardens this is quite practicable, and the results thoroughly repay the cultivator.

Nothing is more beautiful than the Rose. No flower is more universally admired, and let me add, that no flower really costs as little as the Rose. The first outlay is small, the after expense nominal, the returns certain and satisfying.

I append a list of some Tea Roses whose hardiness I have proved for years—Madame Falcot, Souvenir d'un Ami, Souvenir d'Elise Vardon, Niphotos, Rêve d'Or, Marie Van Houtte, Madame Bravy, Madame Willermoz, Innocente Pirola, Perle des Jardins, Caroline Kuster, Old Devoniensis, Climbing Devoniensis, and Reine Marie Henriette. This last, however, does not appear very perpetual. All the others are thoroughly so.—A. M. B., *Mid-Lincoln*.

[We quite concur in the remarks of our correspondent. All the varieties named, and several others, may be successfully grown in most districts with the aid of a little protection, which they eminently deserve. No flowers are more charming than these, and one of the most useful of all, Niphotos, is admirably represented in the annexed engraving, supplied by Messrs. George Cooling and Son, Bath, and described in their catalogue as the "finest white Rose in cultivation." It should be grown in all gardens, established in pots for greenhouse or conservatory decoration, also for affording cut flowers of the most charming and admired character. This Rose is perhaps grown more largely than any other for supplying blooms for sale, and they appear to be always in demand for personal adornment, bouquets, vases, and wreaths.]

FIGS IN THE OPEN AIR.

THAT Brown Turkey is the best Fig for culture in the open air either against walls or as bushes is a fact too well known to require any special statement to that effect, nor are details of its culture called for either; for whether it is pruned and trained to the greatest nicety, or left to grow with all the freedom of a wilding, it continues bearing excellent fruit annually, alike good in quality and with such uniform abundance in proportion to the number of shoots—whether laterals or leaders—matured during the preceding season of growth, that the size of each tree may fairly be said to be the only limit to the quantity of fruit it bears. Brunswick, too, is eminently worthy of the good character given it by Dr. Hogg in the "Fruit Manual," as "one of the best for outdoor

cultivation against walls." It is true that if taken tree for tree its crop is barely half that of Brown Turkey, but then the large size of its magnificent fruit well atones for the deficiency; and here at any rate we do not gain size at the expense of flavour, for I suppose we have nothing more delicious among our choicest fruits than a Brunswick Fig fully ripe, with its luscious interior temptingly revealed through the bursting skin.

Have we any other Fig worthy to rank with these two for open air culture? I think not; and yet varieties are numerous enough, one of our leading nurserymen enumerating thirty-three, and another twenty-one, which they offer for sale as worthy of cultivation, but not out of doors. White Marseilles is usually said to answer well against open walls, but I cannot say that I have often found it do so. Grizzly Bourjassotte does bear a few perfect fruits every year on a south wall, but it is much too shy a bearer to occupy much wall space, and for all practical purposes I fear we must confine ourselves to Brown Turkey and Brunswick. Now what is the cause of this somewhat singularly restricted culture of Figs in the open air? In an examination of the trees growing here against walls on the last day of October I found Brown Turkey,

Fig. 79.—TEA ROSE NIPHOTOS.

Brunswick, and Grizzly Bourjassotte bare of leaves, with the season's wood growth firm and well ripened; but White Marseilles, Black Ischia and Early Violet had shed hardly any leaves, and White Ischia was not only still in full leaf, but its leaves were as green as they were at mid-summer. Nothing can be more explicit than this. The three sorts which come to early maturity bear ripe fruit every year, and are therefore suitable for our climate; the four sorts, with foliage and wood still immature, are almost barren of ripe fruit, most of the fruit falling prematurely before it is half grown, and they are therefore unsuitable for our climate, requiring a few more degrees of heat than the average temperature of an English summer affords even here in the sunny south.—EDWARD LUCKHURST.

PLEIONES.

THESE are, as Mr. Plant justly observes, very charming little Orchids, and well deserve a place in every warm greenhouse or intermediate

stove. There is no doubt, however, that they are greatly benefited if transferred to a shelf near the glass in the warmest stove from the time their pseudo-bulbs are half swelled until they are fully developed, after which they should be gradually inured to a cooler temperature until their blooms begin to develop, still keeping them close to the glass, as these bright little gems appear to revel in the full sunshine if they receive plenty of water. When the bloom buds appear I find they open more regularly if they are again transferred to a rather warmer house than the one they have been resting in. As cut flowers they are very useful. I would also claim a place for them in the drawing-room as small vase plants. By pricking into the pans or pots a few pieces of variegated *Panicum* and *Adiantum gracillimum* as a substitute for their own absent foliage at this period, they have a very delicate and chaste appearance, and will not suffer the least injury in a dry room for a few days. I find *P. humilis*, although later to bloom, succeeds well by potting precisely as recommended by Mr. Plant, save the cowdung and the addition of a little more sphagnum. I also water it even more freely while growing than the others, and keep it in a more even temperature.—C. W.

THE first meeting of the ROYAL BOTANIC SOCIETY, Regent's Park, since the recess, was held at the Gardens on Saturday last, the Hon. H. M. Best in the chair. The Secretary called the attention of the Fellows to a large plant of *Aralia papyrifera* (Chinese rice paper) now in flower in the conservatory, and to the very flourishing condition of the Mangrove trees presented to the Gardens by the Duke of Buckingham, Vice-President. For many years past they had endeavoured to cultivate them, but without success, the plants invariably dying after a year or two. At the suggestion of the Duke of Buckingham these plants are now watered with sea water, the change proving most beneficial.

— THE TRADE EXHIBITIONS OF CHRYSANTHEMUMS are now very attractive. Messrs. Mahood & Son, and Mr. Stevens, Putney, have large and choice collections, including several novelties. Messrs. H. Cannell and Sons, Swanley, also have an extensive display, and Messrs. Carter & Co have a large number of plants in flower at their Forest Hill nurseries. Messrs. Laing and Co., Forest Hill, and E. G. Henderson, Maida Vale have similar displays.

— THE first meeting of the MANCHESTER HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY was held on the 8th inst., when Mr. Leo H. Grindon read an interesting paper on medicinal and poisonous plants. This Society has been formed under the presidentship of Mr. Bruce Findlay for the mutual improvement of gardeners in the district, and the terms of membership are 2s. 6d. per season. The meetings will be held fortnightly during the months of November, December, January, and February in the Old Town Hall, King Street, Manchester, at 7.30 each evening, at which meetings papers will be read and discussions held. Mr. R. Tait is Treasurer, and Mr. W. Swan of Oakley, Fallowfield, Honorary Secretary.

— WE learn from the *Jersey Gardener* that at the recent Fruit Show held in that island the following were the HEAVIEST PEARS, with their weights:—Belle de Jersey, 30 ozs.; Beurré Diel, 16 ozs.; Beurré Bachelier, 15½ ozs.; Calebasse Grosse, 22 ozs.; Catillac, 22½ ozs.; Doyenné du Comice, 17 ozs.; Duchesse d'Angoulême, 18 ozs.; General Todleben, 17½ ozs.; King Edward, 20 ozs.; and Van Mons Léon le Clerc, 15½ ozs.

— MR. N. CAMPANY, Thedden Grange, Alton, Hants, writes:—"With me *Lilium longiflorum* has flowered very freely twice this year. The plants flowered the first time in April and May. After flowering they were gradually hardened off and placed outside with the Chrysanthemums, and they were not dried, but kept supplied with water the same as the Chrysanthemums, and by the middle of July they commenced producing strong growths, and when they had attained the height of 3 or 4 inches were repotted into two sizes larger pots and placed in cold pits kept rather close, and by the end of September they commenced opening their lovely white flowers, and will continue attractive for some time to come yet. The last batch I have placed in a plant stove. Some of the strongest growths had from three to five large flowers on one

stem, and I find them very useful associated with other plants in jardinettes and vases, and they have been much admired here by visitors."

— THERE is a possibility of large fortunes being made in New Guinea (remarks the *Pioneer Mail*) by the cultivation of the NUTMEG. The Nutmeg tree is found in great abundance in that island, and gives its name to one of the finest pigeons in the world, a bird as large as the hen turkey. Since the collapse of the Nutmeg at Singapore we have been indebted for the most part to our old rivals, the Dutch, for Nutmeg and Mace. But the Nutmeg trees of Singapore were importations; the tree was not so indigenous to the place in New Guinea. The cultivation is, or was, the most profitable of anything we know of, surpassing Cinchona and Coffee in their best days. Singapore owners of Nutmeg plantations—mere compounds planted with the handsome tree—used to realise their £4000 or £5000 a year; but in one dark and memorable year the trees were all stricken with a blight, and numbers of planters enjoying large incomes were reduced to poverty. The tree became white and leafless, a vegetable skeleton; and no attempt to revive the cultivation of the Nutmeg at Singapore has ever proved successful.

— MR. GEORGE MURRAY, of the Natural History department of the British Museum, will deliver a lecture ON THE POTATO DISEASE at the Parkes Museum of Hygiene, 74A, Margaret Street, Regent Street, on Thursday, the 22nd inst., at 8 P.M. Price of admission, 6d.

— THE BOROUGH OF HACKNEY'S THIRTY-SEVENTH ANNUAL EXHIBITION OF CHRYSANTHEMUMS, FRUIT, AND VEGETABLES was held as usual in the Royal Aquarium, Westminster, on the 14th and 15th inst., and proved a great success, exhibits in all the classes being very numerous. The brief time elapsing between the notification of the awards and our going to press permits only a brief note of the winners in the leading classes. Blooms were exceedingly well shown, the competition being most keen in all the classes. With incurved the premier exhibitor was, for twenty-four and eighteen, E. Sanderson, Esq., St. Mary's Road, Harlesden, who won the silver cup, being first in both classes. For twelve seventeen collections were staged, Mr. J. Udale, Shirecliffe Hall, Sheffield, taking the lead with handsome blooms. The best twenty-four Japanese were from Mr. J. Ridout, gardener to T. B. Haywood, Esq., Reigate—a grand collection, Anemone varieties being well shown by Mr. Butcher, Barnet, and Mr. Berry, Roehampton. In the principal class, however, that for forty-eight blooms, twenty-four Japanese and twenty-four incurved, only three collections were staged; the first and second from Messrs. S. Dixon & Co., Hackney, and Mr. C. Herrin, Chalfort Park Gardens, Gerrard's Cross, respectively, being very close in quality, including grand blooms of the best varieties. The smaller classes were all well filled, and presented a fine display. Three collections of twelve new Japanese varieties were entered for Messrs. Dixon's silver cup, Mr. J. J. Hillier, Bow, taking the first place with a good collection. Specimen plants and groups were not very numerous, but fairly good. The principal class for the latter was that in which the Royal Aquarium Company offered a silver cup value £5 as the first prize. Messrs. Mahood & Sons, Putney, obtained this honour with an effective group, closely followed by Mr. G. Stevens.

— FRUIT at the same Show was also largely and well represented, the Grapes being particularly fine. The leading class was for twelve bunches, the first prize, value £10, being won by Mr. J. Roberts, The Gardens, Gunnersbury Park, Acton, with handsome even bunches of eight varieties; the majority being well ripened and coloured. The second prize was secured by Mr. Austen, The Gardens, Ashton Court, Bristol, with fine bunches of fewer varieties. In several classes for Grapes the exhibits were very good. Apples and Pears were a show in themselves, about 300 dishes being staged; the majority of the specimens extremely fine. Vegetables were extensively shown, the collection in competition for the special prizes being of admirable quality. Potatoes were strongly represented.

— THE FIRST SHARP FROST of the season in the metropolitan district occurred on the morning of the 13th inst., when Dahlias and similar tender plants were blackened; until that date they had been growing and flowering freely.

— MR. WM. DEAN writes:—"FANCY PANSY BUCCLEUCH is one of the finest and most distinct we have yet seen, flowers of which have been sent at various times for our opinion by Messrs. Thos. McDougal and

Son, Florists, Musselburgh. It bears some resemblance to Mrs. Crawley in colours, and is of large size, very fine form and substance, and is a grand flower to be sent out in the spring."

— IN an account of a tour by Governor Weld in Selangor, CAMPHOR TREES IN THE MALAY PENINSULA are thus noticed:—"At Kanching, about fifteen miles north of Kuala Lumpur, His Excellency passed through a large forest of Camphor trees, many of which were over 200 feet high. As this forest must become of enormous value, the Governor gave directions that it should be reserved to the State and preserved, single trees only being permitted to be sold when required."—(*Ceylon Observer*.)

— AT the ordinary meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held by kind permission of the Council of the Institution of Civil Engineers at 25, Great George Street, Westminster, on Wednesday, the 21st instant, at 7 P.M., the following papers will be read:—"Report on Temperatures in different patterns of Stevenson Screens," by Edward Mawley, F.R.Met.Soc., F.R.H.S. "On the Storm which crossed the British Islands between September 1st and 3rd, 1883, and its track over the North Atlantic," by Charles Harding, F.R.Met.Soc. "On the Influence of the Moon on the height of the Barometer within the Tropics," by Robert Lawson, Inspector General of Hospitals. "The Ice Storm of July 3rd, 1883, in North Lincolnshire," by John Gordeaux.

— MR. J. LANSDELL writes:—"The plan of CUTTING DOWN CHRYSANTHEMUMS, recommended in your Journal of June 28th, has proved a failure in this neighbourhood as regards exhibition blooms. Those that have bloomed are inferior to those not cut down, and most of them are too late for any of the shows. The plants are much dwarfed, and are more useful for decorative purposes; but I think now, as I thought then, that it was a little too late at least for this district (Leicestershire). The first week in June would be a more suitable time for the late-flowering kinds here."

— "W. L." writes:—"I have been informed that large numbers of TOADS are now being 'raised' in Australia for exportation to England, where they are sold at £3 to £4 per hundred to farmers and gardeners. Can any of your correspondents corroborate this statement, and give any particulars as to where the toads are obtainable?"

— JUST on the eve of going to press we learn that the prizewinners in the chief classes at the BRIGHTON CHRYSANTHEMUM SHOW were as follows—For plants, Mr. Miles, West Brighton; Mr. Spottiswoode, gardener to G. Duddell, Esq.; Mr. J. Bunney; Mr. Hyde, gardener to R. Bacon, Esq., and Mr. E. Meachen, gardener to C. Armstrong, Esq., Woodside, Witheane. For incurved blooms, Mr. C. Gibson, gardener to J. Wormald, Esq., Mitcham; Mr. J. Ridout, gardener to J. B. Haywood, Esq., Woodhatch, Reigate; Mr. Elphinstone, gardener to J. Chalton, Esq., The Orchard, Reigate. For Japanese blooms, Messrs. Gibson, Ridout, Dixon and Co., Hackney, and W. Jupp, gardener to G. Boulton, Esq., Eastbourne. The best Anemones were from Mr. Duncan, gardener to J. Lucas, Esq., Warnham Court, Horsham. Groups of miscellaneous plants and fruit were also well shown, Mr. Balchin having a fine group not for competition.

— "A. M." writes:—"On calling at Hopewood Hall in Lancashire a few days ago I was much struck with a young GROS COLMAN VINE, planted in February, 1882, bearing six bunches, averaging 3 lbs. each, with splendid berries, some of which measured within a tenth of 4 inches in circumference. They were beautifully finished with one exception—the undermost bunch being scarcely up; but I thought considering the season and that they are grown in the neighbourhood of Manchester they reflected very great credit on Mr. Strickland, who grows other things in the gardens so well that I may trouble you with a few more notes about them by-and-by."

— MR. J. NUNNS writes:—"In the Orchid house at Penllergare VANDA CÆRULEA is most beautifully in flower. The plant is bearing four spikes of flower—two spikes with seventeen flowers each, and two smaller spikes with fifteen blooms each. The largest spike measures 2 feet long. Most of the flowers are 3½ inches in diameter."

— THE *Medical Record* furnishes the following particulars, setting forth the MEDICINAL PROPERTIES OF CULINARY VEGETABLES. Asparagus is a strong diuretic, and forms part of the cure for rheumatic patients at

such health resorts as Aix-les-Bains. Sorrel is cooling, and forms the staple of that soupe aux herbes which a French lady will order for herself after a long and tiring journey. Carrots, as containing a quantity of sugar, are avoided by some people, while others complain of them as indigestible; it may be remarked, in passing, that it is the yellow core of the Carrot that is difficult of digestion, the outer, a red layer, is tender enough; in Savoy the peasants have recourse to an infusion of Carrots as a specific for jaundice. The large sweet Onion is very rich in those alkaline elements which counteract the poison of rheumatic gout; if slowly stewed in weak broth, and eaten with a little Nepal pepper, it will be found to be an admirable article of diet for patients of studious and sedentary habits. The stalks of Cauliflower have the same sort of value, only too often the stalk of a Cauliflower is so ill boiled and unpalatable that few persons would thank you for proposing to them to make part of their meal consist of so uninviting an article. Turnips, in the same way, are often thought to be indigestible, and better suited for cows and sheep than for delicate people. But here the fault lies with the cook quite as much as with the root; the cook boils the Turnip badly, and then pours butter over it, and the eater of such dish is sure to be the worse for it. Try a better way.

— AN exceedingly rare and useful plant is GILIA BRANDEGLI, which adds much to the effect of rockwork at this dull season. It is found growing along the face of perpendicular rocks in south-west of Colorado. The flower stalk, which is nearly a foot high, produces from fifteen to twenty long Primrose-looking tubular flowers, upwards of an inch across, and half as broad. The leaves are small, produced nearly always in a whorl, brittle, and not unlike the common Galium erectum, quite hairy, and glandular all over. It is now flowering for the second time this season on the new rockery at Kew, and although many cultivators have quite failed to grow it in the open, it has, we believe, stood there without protection for two years. The failures may be due to the sudden change when planted in a too exposed situation, and might be considerably lessened by selecting a dry and rather sheltered position.

NEW CHRYSANTHEMUMS AT PUTNEY.

AT two establishments in Putney Chrysanthemums are very largely grown, not only the most approved exhibition and decorative varieties, but also a selection of the newest as they are obtained each year from the Continent. Seedlings, too, are occasionally raised, and though necessarily many are found to be inferior to the older varieties, it gives an opportunity of sometimes selecting a striking or useful departure from the ordinary types. The two nurseries in question are both well known in the Chrysanthemum-growing world—namely, Messrs. Mahood & Sons, and Mr. J. Stevens, the former in the Lower and the latter in the Upper Richmond Roads, and both firms have gained considerable fame at the local and other shows, but especially at the Royal Aquarium, for the handsome groups of plants they invariably exhibit. It will, therefore, be interesting to many to learn what are the chief specialities at each place.

MESSRS. MAHOOD & SONS.

The space being somewhat limited in their present nursery, the principal object pursued by this firm has been to secure a collection of only the best and most reliable varieties in the different sections. Numbers of varieties that were found to be insufficiently distinct or comparatively worthless have been expelled, and the collection now comprises about 200 of the leading forms, incurved, Japanese, Pompons, reflexed, and Anemones. The incurved and Japanese are remarkably well grown. The blooms in the former case being notable for their neatness and substance, while the others are mostly very full and rich in colours. Amongst the incurved the following well-known varieties are especially good—Jardin des Plantes, Prince Alfred, Barbara, Empress Eugénie, Alfred Salter, Queen of England, Mrs. Shipman, and Cherub. No novelty of special merit, however, demands notice in this group.

The Japanese are a strong feature, and amongst them we have some new additions of sterling merit. The best are the following:—

Joseph Mahood.—A seedling raised at Putney, and recently certificated at a meeting of the Hackney Society. The bloom is full, with narrow florets, yellow, curiously dotted and striped with a reddish hue. Very distinct, and sometimes highly coloured.

Mrs. Townsend.—This is also a Putney seedling. Very full handsome bloom, of a rich claret-crimson colour, yellow on the under side of the flat florets.

M. Marouch.—Very handsome, substantial flower, deep warm crimson, flat florets, golden on the under surface. An effective variety.

Thomas Todman.—This is likely to make a fine exhibition variety the blooms being of great substance and distinct in colouring, yellowish with red streaks, florets rather flat.

Triomphe de Chatelet.—A handsome variety, salmon-red, with large

wonderfully substantial blooms. The florets are flat, and at the lower part of the bloom strangely reflexed or drooping, imparting a distinct appearance to the bloom.

M. Burnet.—This, though about two years old, is yet but little known. It is a fine variety, the full blooms having jagged, delicate pink-tinted flat florets. A charming shade of colour.

Many more of the last three or four years' novelties are grown, but the above will suffice to indicate that the Japanese group is receiving much attention at the hands of continental raisers, to whom we are indebted for most of the varieties.

MR. J. STEVENS.

In this nursery a good general collection is grown, over 200 varieties being represented, and the plants generally are in admirable condition, strong in growth, with substantial, handsome, well-furnished blooms that scarcely require the exercise of the dresser's art to fit them for the exhibition board. All the standard varieties are grown, and grown well, but the useful *Elaine* is a feature of great interest. A large house has been filled with plants of these, and blooms were obtained early in October in considerable numbers, while now a second crop of smaller blooms promises another profitable supply for a week or two. *Princess Teck* is another variety grown in large numbers, and is especially valued for its late-flowering habit and the delicate tint of the blooms. It is also very free, and is undoubtedly of great decorative value. Numerous seedlings are being tried, and more will be heard of them in the future; but one that has been well tested deserves notice here, as it is likely to become a general favourite when Mr. Stevens places it in commerce. This is named

Stevens' No. 1.—It is a reflexed flower of a rich crimson maroon or chocolate colour, somewhat like the handsome Japanese *Père Delaux*. The blooms are about 2½ to 3 inches in diameter, the florets flat and slightly incurving in the centre, showing the golden under side. It is very full, and the plant is surprisingly floriferous. This was certificated at Kensington on Tuesday and the name altered by the Committee to "George Stevens."

Chrysanthemums are not the only specialty at St. John's Nursery, as Mr. George's seedling *Abutilons* occupy considerable space, Mr. Stevens having the whole stock of the latest batch. *Clove Carnations* are also grown in great quantities, no less than forty thousand plants being included in the stock.—L. CASTLE.

WINTERING STRAWBERRIES IN POTS.

THE best and most natural way of wintering Strawberries in pots is to plunge them a little below the rims in sifted coal ashes out of doors. In every garden a gravelled space sufficiently high to prevent the lodgement of water should be set apart for this and other purposes, and be enclosed by rough boards 8 or 9 inches deep nailed to short piles (the inner side of the latter) driven into the ground at short intervals, so as to make a sort of shallow frame. A little coal ashes should then be spread over the gravel, and the pots, as already stated, plunged below the rims closely together in the same material, a little of which should be spread over the balls of earth and roots as the work proceeds, thus securing both roots and pots from the frost. But in the event of severe weather it will be advisable to slightly cover the plants with dry fern. This, however, should be removed on every favourable opportunity. The "drying-off system" of wintering Strawberries in pots cannot be too strongly condemned, seeing that it is so thoroughly antagonistic to the condition under which the plant lives and flourishes in its natural state. Those not having the gravel space and boards at command can effectively winter their Strawberry plants on a dry south border by spreading the ashes over the necessary space, standing the pots thereon in a straight line at a certain distance—say 32 feet from the wall, filling in the space between the pots with coal ashes as set forth above, and enclosing them with a bank of the same dust. No time should be lost in attending to this simple though important operation.—H. W. W.

ROSE CUTTINGS—TEA ROSES.

I SEE that Mr. W. Boyes is hardy enough to say that Roses on their own roots do not bloom as freely as when budded on the *Manetti*, *Briar* cuttings, or seedling *Briars*; forgetting, perhaps, how I was "sat upon" by my friendly opponents "A Judge," and Mr. Sanders, some six months ago, for asserting the same.

I was obstinate enough to say I was still unconvinced; but still I could not help thinking, during certain sultry days last August, that if I could have set "A Judge" and Mr. Sanders each in a comfortable chair in the shade, with "something soothing" handy on a neat table, in full view of my struggles and grovelling and perspirings in budding a very thick patch of *Briar* cuttings, their revenge would have been ample, and even tinged with compassion.

Thorns I do not mind, what rosarian does? I am afraid I looked no further into a certain treatise on Roses when I saw a recommendation to provide a pair of thick gloves before budding; and I do not grumble much at the position required in budding dwarfs. Luckily my waist is unchanged during the last twenty years, though that 1½ inch over 6 feet is hard to stow away in a horizontal position without inconvenience or doing damage to something. No; it was the flies which so nearly converted me, and constantly dinned in my ears the weariness and unprofitableness of budding, and the coolness, comfort, and delight of cuttings. No creature, I verily believe, has a keener instinct as to when both a

man's hands are irretrievably engaged than the common summer fly; and whenever an unusually active and pertinacious swarm of them, which flourished at that time, saw me curled and twisted up in thorns in that sunny spot, in the agony of getting the bud in, and not a chance of defence, then into my ear they would get. For some time I wondered, with as much calmness as possible, what on earth should make flies so anxious to get into my ear; but at last I recognised that it was only to din into my brain, "Try cuttings: no flies in October."

I am trying them; and come in, from sticking them in by the score, to read how a gentleman who recommends cuttings admits they do not bloom as freely as budded plants. Well, I have tried both. My cuttings are in, and all the flies of August did not prevent me from finishing my budding. If success is commensurate with toil, I know which will turn out the best.

Unlike "A. M. B.," I find that *Madame Falcot* does stick and damp in wet weather, as does certainly *Marie Van Houtte*. *Madame Falcot* is generally represented as an improved *Safrano*—that is, it is fuller; but *Madame Falcot* is, to my mind, not full enough for a summer *Rose*, and too full for a late autumn one. *Safrano* is very thin, and for that reason is, I think, the best of late autumn yellow *Roses*, because it will open when no other *Rose* will. If, during the first fortnight in November, you want a good yellow bud, you may be thankful if you have a plant of *Safrano* on a wall to go to. Mine never fails me at that season, and for that purpose alone I grow and value it.

I wish our respected Secretary had given a fuller criticism of the new *Rose*, *Her Majesty*, in his review of the past season. I think many would have been glad to know if he considered it might justly be called "coarse."

Will someone be kind enough to give a character to *Madame Cusin*, (*Tea*), a fine bloom of which was exhibited by Mr. G. Paul at South Kensington?

I am sorry no one has set my mind at rest on the subject of *Beech* leaves, on which I wrote a few weeks ago.—A. F. M.

THE DAIRYMAN'S ORCHARD.

NEAR the top of the long straight road that leads to *Uxbridge* there is a small Ivy-covered cottage. The door, painted in two tones of green, has a bright brass knocker; the jambs, window frames, and doorsteps are a spotless white, and on each of the four window-sills in front there is a charming little group of *Fuchsias* and *Geraniums*. A strip of flower garden engirdles the front, and on each side the clean asphalted path there is a large *Hydrangea* in a pot. The cottage itself is a plain little Noah's ark-like structure, but the Ivy is always neatly trimmed, and Ivy is the horticultural charity which cover sometimes a multitude of builders' sins. The little house is always bright and cheerful to look at, comfortable and cozy as a chaffinch's nest among the budding *Hawthorns*.

The dairyman is perhaps sixty, but hale and hearty, and in addition to his milk business he found time to plant and cultivate the acre and a quarter of garden ground adjoining the cottage. It is chiefly on this account that I wish to speak. His special hobby is fruit-growing—orchard fruits. About ten years ago the little estate came into the market, and as the dairyman's family had lived thereon for more than twenty years he was naturally anxious about his business and his trees. "They'll help to keep us, missus," he used to say, "if we can keep the cottage." Honest, industrious, thrifty, however, he hoarded every penny in order to purchase the cottage and garden. A friend who accompanied him to *Tokenhouse Yard* on the day of the sale describes his anxiety when, glancing from one to another with up-lifted hammer, the auctioneer repeated, with what appeared to the dairyman, unnecessary emphasis, "For the third and last time, gentlemen, £375 only! A five-roomed cottage, sheds, and an acre and a quarter of orcharding planted with thriving fruit trees. Why, gentlemen, the crop of fruit is an independence. £375, gentlemen. Have you all done?" The dairyman's heart beat quick and audibly as he thought for a moment on the "thriving fruit trees," every one of them worked by his own hands, and tended almost as carefully as his family of rosy girls and boys. At last the ivory hammer tapped the desk and the torturing suspense was at an end. "It's yours, sir," said the auctioneer. "What name, please?" "William Templer," was the reply. "Are you prepared to pay the deposit?" said the salesman, glancing furtively at the homely corduroys and polished bluchers. "Pay it all," said the dairyman; "here, sir, tek it out of that," and he put into the clerk's hands a roll of notes. "There's £400 there." And then he looked across at his friend, and his honest face came all undone, and something dimmed his eyes for a moment, as he said, with feelings which none but he and his could fathom—"I've saved my trees, Naylor, thank God, I've saved my trees."

"Yes, sir," said he, as I walked round with him the other day under the drooping boughs loaded with clusters of ripening fruit—lemon and russet, green and crimson and gold—a charming feature in the autumn landscape, "I worked 'em all myself." It is more than probable that the impetus given to orchard-fruit culture by the present fruitful season, and the quite wonderful and charming display of Apples brought together at *Chiswick* recently, will result in a considerable extension and increase of orchards. It is to be hoped that it will ere long be no longer necessary to send to the continent and America for over three millions sterling worth of fruit that might be grown at home. "I worked 'em all myself," the dairyman repeated, "but I made a mistake in not buying ready-made trees from the nurseries. I lost, I reckon, ten years by that."

But the orchard itself. Perhaps a few entries from the dairyman's mental note-book may be of service to intending planters. The orchard,

as was said, is an acre and a quarter in area, nearly square in shape, and shaded, unfortunately, on the west by a row of tall Elms. There is a deep ditch by the Elms, cut with a view to intercept the roots, but it has been found impossible to check the incursions of the invaders. They descend the slope, cross the ditch at the bottom, and appear on the other side, sending up, if unchecked, scores of wiry suckers. Some of the roots have been discovered 35 yards from the Elms themselves. The eastern half is comparatively free from Elm roots, and the orchard trees have made, of course, a much more vigorous growth in consequence. The subsoil is London clay, but the surface has been regularly dressed twice a year with stable manure, and at least three times yearly also with liquid manure from the cowsheds. It is mainly owing to this systematic dressing and a careful selection of kinds that Mr. Templer owes his success. The ground under the eastern side has been under regular tillage until a year ago, and crops of vegetables and soft fruit have been grown. It is the owner's intention, however, to lay it down and eat off with sheep. Pigs he believes furnish the best manure, but they are less tidy and more troublesome to manage. His single experiment in the way of root-pruning orchard trees was to his mind conclusive. One tree, a Lemon Pippin, was pruned by opening a trench on one side of it two years ago; the pruned side had not a single fruit, the unpruned half was literally loaded with fruit. There are 160 trees in all, about half of them Apples; a third Plums, chiefly the Victoria and the Purple Gage, the latter a great favourite, bearing handsome medium-sized fruit having a delicious flavour. The only Pear carrying a crop this year is the Winter Nelis; as a rule, however, he has found Pear-growing unprofitable.

The Apples are all grafted on suckers from an old tree which stood at the time in a neighbour's garden. They are planted 7 yards apart in the rows and 6 yards from row to row. This distance is now too close for most of the Apple trees, and careful and systematic pruning is necessary to keep the branches from interlacing. The varieties grown consist of Blenheim Pippin, Cox's Orange Pippin, Fearn's Pippin, Ribston Pippin, which cankers badly, as usual, on a clay soil, and is to be discarded, and Devonshire Quarrenden and Lemon Pippin. Culiary sorts in order of importance are Round Winter Nonesuch, Norfolk Beaufin, Keswick Codlin, Northern Greening, and the Minchall Crab. The Nonesuch produced eleven bushels of fine fruit. "Ye see, sir," said the dairyman, swelling with evident satisfaction as he eyed his trees, "I likes a tree with a good spreading growth—a framework like. Why, measure that tree with your tape." It was a Blenheim Pippin, planted twenty-eight years ago. The girth at 3 feet 6 from the ground was 2 feet 8 inches, and the spread of branches 30 feet 6 inches in diameter. The round Winter Nonesuch was 3 feet 1 inch in girth and 31 feet through; it had borne eleven bushels. Another, Blenheim, was 2 feet 6 inches in girth, with a crop of seven bushels. A Fearn's Pippin, bearing six bushels of handsome fruit highly coloured, was 2 feet in girth and 21 feet through, and next to this a small yellow Apple, much like the old Whiting Pippin. The tree, although of the same age, was only 1 foot 4 inches in girth, and bore a comparatively light crop. This question of girth of boll and spread of branches of Apple trees is an important matter to consider for those who, like my friend, grow for profit and look to their orchards as a source of income. At a moderate estimate this little orchard produces £45 worth of fruit yearly. Several of the trees, notably the Blenheim Pippin and Cox's Orange Pippin, were bearing crops, the value of which at a fair market price was as much as the ground they covered. "But which," I inquired, "is your most regular cropper?" "Well, sir, tek 'em altogether the Minchall Crab. It is a good keeper, a capital sauce Apple, and a good regular cropper. For a kitchen Apple it is most useful, and useable even when quite young or half grown."

I had forgotten to say that the dairyman has lately sold off his stock and employs himself in his orchard and garden. It is not only a source of interest and gratification to him from the time when the rosy petals float away on early summer airs till he climbs the ladder to pick the glowing fruit, but it is also a source of income, and altogether a profitable and delightful occupation for his leisure hours.—T. W., Harrow.

ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 13TH.

A FULL and interesting meeting was held on Tuesday in the conservatory, many novelties being shown, and the Chrysanthemums were in especially strong force, Cyclamens and Carnations also being well represented.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Present—Messrs. H. J. Veitch, S. Lyon, Arthur W. Sutton, John Burnett, James Smith, E. D. Blackmore, and George Paul. Messrs. Veitch & Son, Chelsea, sent collections of Beets and Brussels Sprouts, self-blanching Celery, and Capsicums, the latter being very interesting, and representing nine varieties. Mr. W. Allan, gardener to Lord Suffield, Gunton Park, Norwich, was awarded a bronze medal for three magnificent bunches of Gros Colman Grapes, weighing together 15½ lbs., the largest one being 6¾ lbs. Mr. Allan also sent fruits of Improved Telegraph Cucumber 20 inches long, for which a cultural commendation was awarded. Mr. G. W. Cummins, The Grange, Wallington, showed three bunches of Mrs. Pince's Muscat, large and fairly coloured. Mr. B. S. Williams sent fruit of a new Grape named Winter King, which the Committee required to see again. It was said to have been produced by Gros Colman worked on Raisin de Calabre, but was very distinct from either. The berries are long and deep black. Mr. Thomas Woodford, Atherstone, showed fruits of a seedling Apple named Mrs. Stourton, which was not considered of special merit. Mr. G. R. Allis, gardener to Major Shuttleworth, Old Warden Park, Biggleswade, showed three good bunches of Pearson's Golden Queen Grapes, the berries large and well coloured. Mr. Allis also showed three bunches of Lady Downe's Grapes, large and well ripened. Mr. Horsefield, Heytesbury,

Wiltshire, showed three fine bunches of Chatsworth Seedling Grape, each weighing about 5 lbs., well coloured, and of good sweet flavour. Messrs. J. Dickson and Sons, Chester, showed a fine well-netted fruit of Master Charlie Melon, of which, however, the flavour was not very good.

First-class certificates were awarded for—

Apple, Tyler's Kernel (T. Parker, Moreton Cove, Hereford).—A firm heavy Apple, about 3 inches deep, slightly conical, with an open deep eye, freely streaked, and suffused with crimson on one side.

Apple, The Sandringham (C. Penny).—The certificate previously awarded for this Apple was confirmed.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. Present—Messrs. W. B. Kellock, James Hudson, Harry Turner, John Dominy, James Cutbush, H. Ballantine, G. Duffield, H. W. Ridley, John Wills, W. Bealby, H. Bennett, John Laing, and the Rev. G. Henslow. Messrs. J. Laing & Co., Forest Hill, exhibited a large and choice group of Chrysanthemums, incurved, Japanese, and Pompons, including several novelties, especially amongst the Japanese. L'Ordu Rhin, a golden-yellow Japanese, was very noteworthy for the number of its flowers, the large white M. Astory and the mauve Bouquet Fait were similarly notable. Messrs. James Veitch & Sons, Chelsea, showed a group of new Chrysanthemums, chiefly Japanese, including several excellent varieties. Particularly fine were Salterii and Comet, two of Mr. Salter's varieties, both certificated. Rosea superba, with fluted bright rosy florets, is a handsome variety, and Angèle, purplish mauve, is distinct, the florets being flat at the base, but twisted into a point at the apex. Messrs. J. Veitch also had several novelties, amongst them being Cyathea microphylla, a Peruvian Tree Fern, with finely divided fronds 3 to 4 feet long. Spathiphyllum Minahassæ, from Celebes, has a white broadly lanceolate spathe 6 inches long by 3 broad; the spadix is much shorter and white also; the leaves are elliptical, 8 to 9 inches long by 6 to 8 broad. Zygopetalum crinitum cæruleum was considered to be a variety near intermedium, with a dark violet-purple lip. Some others were shown and certificated. Mr. W. Bull, Chelsea, exhibited a collection of new Sarracenias and other plants, several of which were certificated. Cymbidium giganteum was shown with a spike of six fine chocolate-veined flowers. Adiantum Legrandi, with finely divided and curiously bunched fronds.

Mr. H. B. Smith, Ealing, exhibited a large group of Cyclamens, for which a silver Banksian medal was awarded, the plants being extremely vigorous, with large numbers of massive white and crimson flowers. A bronze Banksian medal was awarded to Messrs. Hooper & Co., Covent Garden, for a choice collection of Carnations, well grown and profusely flowered. The varieties were chiefly Irma, deep rose; Purity, white; Jean Sisley, salmon and red; Zouave, deep scarlet; and Alegatière, rich scarlet.

Messrs. H. Cannell & Sons, Swanley, Kent, had a collection of single Chrysanthemums, which attracted much admiration, the colours being diversified and clear. In each case the central florets are yellow, as in other single Compositæ. The best are Mrs. Wills, large mauve and white; Miss Lingard, white; Mrs. Santley, crimson-purple; Miss E. Terry, large rich crimson; G. A. Sala, small rich crimson; Mrs. Langtry, delicate blush; Arthur Sullivan, crimson and white; Gus Harris, rosy purple; Dr. Kellock, rose, large; Henry Irving, pale pink; and Mr. Toole, clear yellow. Flowers of the white Chrysanthemums Star of Wyke and La Vièrge, both good varieties. Plants of a variegated Libonia floribunda and a gold-variegated Heliotrope named Albert Delaux were also represented. A. R. Kesterton, Esq., Dudley House, Nightingale Lane, Balham, exhibited a plant of Oncidium Schillerianum, with a large panicle of small yellow flowers. A vote of thanks was accorded to Mr. Hudson, The Gardens, Gunnersbury House, for a plant of Celsia cretica, bearing three fine spikes of flowers. Mr. Fry, Virginia Water, showed a sport from Chrysanthemum Golden Empress, which was considered to be Empress. Mr. May, The Gardens, Northau House, Barnet, Hants, showed blooms of Chrysanthemum Wm. Robinson, a buff-coloured Japanese, and Bouquet Fait, unusually fine. A vote of thanks was accorded to H. J. Buehan, Esq., Wilton House, Southampton, for a double spathe of Anthurium Andreanum, the outer spathe 6 inches long, with smaller one growing from the base of the spadix. Mr. B. S. Williams, Upper Holloway, showed a plant of Begonia Madame Henri Guehe as an ornamental-foilage variety, with handsome shining leaves, crimson, green, and silver. A vote of thanks was accorded to Mr. G. W. Cummins, gardener to A. H. Smee, Esq., The Grange, Wallington, for a large-flowered and deeply coloured variety of Oncidium Weltoni. Mr. Ward, gardener to G. Waddell, Esq., Stony Stratford, showed a plant of Dendrobium album with two flowers. A vote of thanks was accorded to Mr. G. Allen, Horthenden Road, Sale, for a plant of Nephrolepis exaltata, which was shown as a seedling. Votes of thanks were accorded to Mr. W. Smythe for a fine flower of Amaryllis reticulata; to Mr. Wallis, The Gardens, Keele Hall, for a flower of a double Eucharis with ten petals; to Mr. W. Parkinson, Birkenhead, for flowers of double white Primula; and to Mr. Odell, Gould Green, Hillingdon, for a group of deep crimson single Primulas. Messrs. T. Jackson & Son, Kingston, exhibited a stand of Chrysanthemums, several of which were certificated. A pretty group of Chrysanthemums was also shown from the Society's Gardens at Chiswick, and included many of the newer varieties, extremely well flowered.

Mr. G. F. Wilson exhibited specimens of the Wilson Digger, an instrument with a trowel-like handle and a long narrow steel blade for lifting plants.

First-class certificates were awarded for the following plants:—

Rhododendron Curtisi (Veitch).—A very distinct species from Sumatra, of compact habit, with lance-shaped thick leaves, 1½ to 2 inches long, quarter to half-inch broad. The flowers are bell-shaped, slightly pendulous, three-quarter inch long, deep shining crimson with a tinge of scarlet, and are borne in heads of three or four.

Zygopetalum Burkei (Veitch).—A pretty species from Guiana; flowers four to six in a spike. Sepals and petals 1 inch long, green, mottled and streaked with chocolate. The lip is white, the projection at the base being purple.

Cymbidium affine (G. N. Wyatt, Esq., Lake House, Cheltenham).—A fine plant with two spikes were shown of this beautiful Orchid. The larger spike contained thirteen flowers; the sepals and petals white, 2 inches long; the lip white stained with purple. It is very fragrant and of sturdy habit.

Sarracenia Swainiana (Bull).—A hybrid between *S. variolaris* and *S. purpurea*, with deep red pitchers, having broad heavily veined lids.

Sarracenia Wilsoniana (Bull).—A cross between *S. Drummondii rubra* and *S. purpurea*, similar in shape to the preceding, but with broad, distinctly marked crimson veins.

Trichosma suavis (Bull).—A pretty Orchid, with spikes of small white flowers, the lip streaked with claret and tipped with yellow. It is very fragrant.

Iresine formosa (Goldsmith).—A sport from *Iresine Lindeni*, with leaves similar in shape, but broader, green veined with yellow, the stems and petioles crimson. It has been tried for three seasons at Hollenden Park for bedding-out, and proved very constant.

Violet Comte Brazzi (Allan).—A double white Neapolitan Violet, with very large flowers, pure white, and shown in contrast with Marie Louise and the old Neapolitan, to both of which it was superior in size.

Chrysanthemum George Stevens (Mr. G. Stevens, Putney).—A charming reflexed variety, shown as Stevens' No. 1. It is a compact bloom, with flat florets, crimson-chocolate, slightly incurved in the centre, showing the gold under surface.

Chrysanthemum Mdle. Darnaud (Laing).—A neat Pompon, with small blooms, deep rosy purple, very free, and distinct.

Chrysanthemum roseum superbum (Laing).—A Japanese variety, with fluted recurving florets deep rosy purple. Very handsome in colour and form.

Chrysanthemum Salteri (Veitch).—Very compact Japanese variety, full bloom, rich scarlet-maroon, the golden under side of the fluted florets.

Chrysanthemum Comet (Veitch).—A Japanese variety, with flattish florets, orange-red, the centre incurving and showing the golden under surface. Very free and attractive.

Chrysanthemum Bendigo (J. Ridout, gardener to T. B. Haywood, Esq., Reigate).—This was shown as a fixed sport from Mrs. Heale, which it much resembles in petal and build of flower, but is of a clear pale yellow tint.

Chrysanthemum Mons. Henri Jacotot (Jackson).—A Japanese with flat florets, the centre incurving and orange-yellow, the outer drooping and deep red.

Chrysanthemum Mdle. Le Croix (Jackson).—A handsome Japanese, with flat irregularly cut florets, the blooms 6 inches in diameter and pure white.

SCIENTIFIC COMMITTEE.—Sir J. D. Hooker in the chair.

Potatoes Protected from Fungus Spores.—The Secretary referred to communications received from Mr. Plowright and M. Jeuser on the subject, the experiments and the results obtained by the latter gentleman being given in the *Gardeners' Chronicle* for July 28th. Mr. G. Murray questioned the possibility of the tubers being infected by the spores directly, as the tuberous tissue would not allow them to germinate; the only method of attack being believed to be by the mycelium penetrating the stem and so reaching the tubers.

Sclerotia in Potato Leaves.—Mr. G. Murray read a report on these bodies, and pronounced them to be oxalate of lime—none of the phenomena of "plasmidiation" or "myceliation," &c., were to be seen. They are soluble in dilute nitric acid, and insoluble in acetic acid. The excess of nitric acid being neutralised by ammonia, crystals of oxalate of lime appeared.

Narcissus viridiflorus.—Specimens of this plant in flower were sent by Mr. G. Moore from Gibraltar, and exhibited by Dr. M. T. Masters.

Convolvulus tricolor.—Mr. G. S. Boulger exhibited an inflorescence of this plant, received from Mr. Gibbs, with a terminal flower bud.

Cephalotaxus Fortunei in Fruit.—Sir J. D. Hooker exhibited a branch with fruit of this plant, received from Rev. T. Goring of Wiston, Sussex.

Ear-cockle in Wheat.—Mr. W. G. Smith forwarded the following communication—"Whilst examining a number of galls of *Tyleuchus Tritici* in Wheat spikes, I observed one gall with both the transparent lodicules present at the base. The idea seems commonly accepted that the galls represent these two lodicules and no other part of the flower. Mr. Carruthers, in a paper recently published in the *Journal of the Royal Agricultural Society*, favours this idea. But no doubt Devaine was right when he said that any of the central parts of the flower were liable to an attack from the *Tyleuchus*, and that the gall might represent the pistil or stamens. Devaine states that he once found one of these galls growing from the base of a leaf."

Isaria fuciformis.—Mr. Smith also sent specimens of this fungus (from Australia) from the site of the model farm at Glasnevin. Mr. Smith described the fungus as British in the *Gardeners' Chronicle*, with illustrations, last year. The fungus is spreading over the country, and generally attacks *Festuca ovina*.

EARLY CHRYSANTHEMUMS.

CHRYSANTHEMUMS are grown for other purposes than publicly exhibiting their blooms; and although many persons who never stage their flowers have pride in growing them of exhibition quality, yet the vast majority of cultivators grow their plants for home-decorative purposes, and thousands who are never heard of grow them well. Some of the most useful varieties are practically not eligible for exhibition as cut blooms, as there is, in fact, no class for them; and doubtless their merits do not consist in the individual excellence of their flowers, but rather for the free-growing and profuse-blooming character of the plants. In this category are the floriferous and useful *Sœur Melanie*, *Julie Lagravère*, and some others that might be named; also varieties that flower naturally early and long before the date of even the earliest *Chrysanthemum* shows. Early *Chrysanthemums* are extremely useful and increasing in favour yearly; new varieties of merit are also being produced.

On page 311 Mr. Piercy of Forest Hill directed attention to several excellent varieties, of some of which he sent flowers. Two of these we have had engraved—Mrs. Cullingford (fig. 80); and Lyon (fig. 81). The former is not one of the earliest, but undoubtedly ranks amongst the best; indeed, it is not improbably the best white variety for flowering in September. It was in fine condition at the National Dahlia Show at the Crystal Palace on August 30th, where it was staged by Mr. Davis of Camberwell, who had also among others the useful Japanese variety *Madame Desgranges*. There also was the little gem, *Petite Marie*, for

which Mr. Ware was awarded a first-class certificate last year, and should be grown everywhere.

Mrs. Cullingford is much taller, larger, and later than the one just mentioned. It is a great improvement on *White Trevenna*, being larger, fuller, with broader florets than that variety, and is also earlier. It appears intermediate both in character of blooms and time of flowering between the small summer varieties and the larger and later reflexed autumn *Chrysanthemums*. Mrs. Cullingford is likely to be useful for early autumn decoration, hence is mentioned here.

Lyon is essentially different. It is evidently most floriferous, and its dark rosy purple clusters are highly effective. It was alluded to as follows by Mr. Piercy:—"One of the best new (early) Pompons is Lyon. It is of French origin; colour, rosy purple, much the tint of *Madame Piccol*, and makes the latter of little value, only that it is rather later. Lyon blooms in September from spring-struck cuttings, and is a superb Pompon in every respect; an admirable plant." The flowers that were sent to us justified that estimate, and were the finest of the colour we

Fig. 80.—Mrs. Cullingford.

have seen so early in the season. All who desire a profusion of rosy purple flowers at the period indicated may safely try this excellent variety.

GARDEN CHEMISTRY.—SOILS.

PEATS, VEGETABLE MOULDS, AND HUMUS.

LIKE the word "loam," peat has an exceedingly indefinite meaning in a gardener's mouth. It generally means anything turfy and black. There are any number of varieties, or rather we might say species were such allowable, of peat, each species including several varieties; but it will, perhaps, be more correct to make such a division as we did in the case of loam, when clay formed one end of the series and sand the other. In the present case we may make moss-peat one end of the series, and soil such as results from the decay of fallen leaves, dead ferns, and grasses the other. Outside this series we still have leaf and vegetable soils and humus, which are not in any sense peat.

First comes moss-peat. Of this there are square miles in our own country; but ignoring the fact, we have begun to buy, and largely too, the bogs of Germany, for peat moss is just the dead, half-decayed, half-preserved sphagnum moss which grows in bogs and is found

many feet thick wherever the circumstances have been favourable to its formation. It is this kind of peat which is used so largely in the cultivation of Orchids, and at one time was used fermented along with stable litter as manure. This kind of peat is to be found in all stages of decomposition from the state in which the moss seems only dead and no more (in which state it is best for Orchids) down to black greasy bog earth, which, when sweetened by exposure or after being long laid dry by draining, is good for mixing with light sandy or gravelly soil in the formation of Rhododendron beds.

Then, also formed in bogs, but either when artificially as by draining, or naturally when the outlet for the water has by any means been lowered, so that not enough moisture is present for maintaining the sphagnum in life, is the peat formed from bog grasses. This essentially differs from the moss-peat, and, though inferior to the former as a fuel, is much superior for cultivating plants in. For all outdoor work it is decidedly better than moss-peat, and when cut in turves from off bogs long laid dry, and the turf kept for a year or two till properly decayed it forms, when mixed with sand, sandstone, and charcoal, a really good soil for almost all Ericaceous plants in pots, though not, perhaps, the best to be got. Still, in such material Heaths, Azaleas, and similar hardwooded plants are often grown to perfection.

Next in order to this is a very similar kind, but which differs from it in so far as it never has been formed in bogs, is never of any great thickness, and is very often found covering the sheerest sands which have never been considered worth cultivating. Often this description is found covering the bare freestone rock, and in such positions it forms the best peat going for fine hair-rooted plants. As the surface generally consists of fibre and black soil mixed with more or less sand it is long in decaying, and requires to be cut a long time before it is wanted. Of course the best kind is that which has just the right proportion of the best sharp silver sand in it, and frequently such is to be found. It is, nevertheless, often of first-rate quality though containing no sand at all, and it is better thus than having a deal of very fine sand mixed with it. As a rule only the turf or upper 3 or 4 inches of such is taken when for pot plants, but for beds the whole depth may be taken. Peat of this kind is very often covered with *Calluna vulgaris*, and when this plant grows freely in it, it may be taken as proof that it is suitable for Heaths and hair-rooted plants in general. But this guide is only general, the *Calluna* often growing in very wet peat. In choosing peat for hardwooded plants the rule should invariably be observed to take it from where water never under any condition lodges if a choice is at all possible.

As no hard-drawn line can be drawn to distinguish one kind of loam or peat from another, so it is no easy task to draw the line between such peat as we have here named grass-peat and the light loam to be found in sandy soil. As a rule the peat is on the poorer bottom. White sand may support grasses that by-and-by will form peat, or rather we ought to call it moor earth. Brown sand is, though very far from rich, yet richer, and supports grasses of quite a different kind—grasses that rot more readily, and do not, therefore, so readily assume a peat-like form; grasses that will yield nourishment to animal life, and out of which what is often called humus is formed; grasses that collect nitrogen and phosphates, potash, lime, &c., and when decayed will grow a corn crop. The one becomes black, the other remains brown; and though the one merges into the other, yet the black is on the peat side of the line, the brown on the loam. Frequently the latter can be had off very poor sandy soils when the other cannot be had. For many purposes it is of great value, and when pretty well decayed and the loose soil shaken out and blended with proper leaf mould, it is perhaps better for strong growing members of peat-loving plants than pure peat. For *Lapagerias*, *Camellias*, and even *Azaleas* and *Rhododendrons* and hardy *Ericas*, we have found it decidedly better than peat proper, especially when the peat was not first-rate.

FERN-PEAT.—This may be said to be the connecting link between peat and vegetable mould. When found in woods, when Oak and other leaves have settled among the decaying fronds, and both have become soil together, bound in one web, of which they form the woof, by the warp of the roots the Ferns produce, it is more vegetable mould than peat. This fibre, from *Lastrea dilatata* or even *Pteris aquilina*, is the best peat by far for Orchid cultivation. Sweet, fresh, nourishing, open, porous, not liable to decay, it is far before the true moss-peat. The fine material shaken from it, half peaty, half leaf mould, is capital for Fern-growing in pots or out of them.

But great tracks of brake may be seen where no trees are, and where for many, many years the stems and fronds and roots have accumulated in decay till some inches of Fern-peat have been formed. This also is a capital article when taken from where no stagnant water sours it, for almost all the purposes named for which the Fern-peat of woods is mentioned, and, in addition, for many of those for which grass-peat is suitable.

LEAF SOIL.—One step further than Fern-peat brings us to leaf

soil. We do not mean vegetable soil made from leaves, but the flaky, peaty-looking, sweet mould which is found after years of accumulation, in woods, especially where Oak and Beech flourish, and add their annual contribution towards the sum total. There is hardly anything for which this is not suited. Peat proper is soil, only a rooting medium, and generally very poor soil. Leaf mould looks almost like peat, but has been formed from very different materials than the sphagnums, *Juncuses*, *Carexes*, and grasses that grow in bogs or moors. These yield very little ash when burned, and the little they do yield is not of the kind which higher plants use. Leaves of Beech and Oak are rich, not only in the ash constituents of the higher orders of plants, but in the matters which form the flesh and bones of animals. Such matters nourish swarms of the minutest creatures, and hence such decay rapidly—they are eaten up, and the resulting mould is rich in animal excreta; and supposing there were animals that could

Fig. 81.—Lyon.

live in peat their excreta would be of no great value. But peat is not thus eaten, does not decay, is permanent, is soil, is not food. Leaf soil is soil and food both.

Leaf soil when it has been made very slowly, where worms did not work it into puddle, nor rapid fermentation and much wet turn it sour, is certainly the leaf soil for use in the cultivation of plants in pots. Years ago we had proved its superiority to ordinary leaf mould. Ordinary soil made from huge heaps of leaves is generally full of acids which corrode young roots as if rusted, and fails to produce results equal to leaf mould. Those who wish to have a clearer insight into what constitutes proper and what improper leaf soil cannot better do than read a remarkable paper by Mr. Wright in the *Journal of Horticulture* for April 26th, 1883, if they do not get a clear idea from what is above.

The use of pure flaky soil cannot be entered into here. We are rather inquiring into the nature of the materials necessary than detailing their use. To do so would necessitate our travelling into the domain more of practice than of theory; and however desirable this might be, would swell these papers to a greater length than is intended.

VEGETABLE SOIL, or, as it is often termed, humus, differs from peat in many particulars. Peat is decidedly vegetable mould in the sense that peat is formed from vegetable matter, but not in the sense that is usually employed, nor as employed by Darwin. The word

"humus" is often employed to denote the soil to which we refer, but the word expresses no exact idea, nor is it, perhaps, possible to make it do so. Perhaps we might say it is the remains of animal and vegetable matter, in which, among other germs, bacteria swarm, and in which earthworms can exist. It may be doubted if bacteria exist in peat, and certainly pure peat sustains no worms; yet from the point where pure peat ends—where bacteria appear and worms live—to the richest garden mould, there is any amount of difference from a soil that is poor and yields little food either to animal germs or plants, to that which is rich and is capable of supplying much to both. It is not merely a question of quantity but of quality. Ten per cent. of humus may exist in soils and represent but little food in reserve; five per cent. may be all the amount, yet contain more than the ten. We suppose humus from Rye straw is humus still, and that from sewage nothing more; but they must be vastly different in many respects. Even when neither are in a condition to yield anything the reserve matter stored in both must differ greatly. For this reason the humus in gardens which results from good manure, or even from vegetable refuse, must differ from that in fields which result only partly from manure and greatly from corn and grass roots, stubbles and dead weeds. The one contains in its organic part much nitrogen, the other not much; the one is rich in phosphates and potash, the other in silica. But we might go on indefinitely enough. Humus is an indefinite term. Like loam, like peat, like the animal and vegetable kingdoms, it begins at 0 and amounts to any sum fancy may fix.

But though the thing itself is indefinite it has certain properties which are definite enough. Like clay, iron oxide, and other soil constituents, humus has the property of keeping manurial matter from being washed from the soil. Of all soil ingredients humus attracts and holds water best. Very light-coloured soils are ill to warm, and part with their heat most readily. When darkened by humus they absorb heat more readily and retain it better. Most of the nitrogen present in soil is in the humus. It also supports a bacterium which not only converts the nitrogenous matter present into nitric acid, but also that of applied manure. When organic matter is absent this change does not take place. In it geic, humic, ulmic, crenic, apocrenic, and other acids, including carbonic, are always present, which not only combine with ammonia to prevent its escape, but continually act as solvents on the mineral plant-food present. It is these that render lime soluble and cause its rapid disappearance from highly manured soil. These, acting on tricalcic phosphate, render it dicalcic, in which state it is easily attacked by the roots of plants. When they reach the iron which binds some subsoils into "pans" it is dissolved, and the pan put an end to.

It is to humus that the fertility of American forest and prairie land, as well as the famous black soil of Russia, is owing. It is the food liberated from the over-abundant humus of old garden soils by the application of lime that causes it to do instead of manuring, so long as the humus holds out. It increases the fertility of very sandy soil almost as much as clay would do; in addition to its manurial effect, and it lightens as well as enriches heavy clay. It is always largely present in rich old pastures, and then misleads those whose ideas of "loam" are vague. It is for want of it at the surface that new-laid-down grass pastures are thin of turf, weedy, and poor. Yet it may be too largely present, as it often is in old garden soils, which then get to be so full of worms that the soil gets greasy, sour, inert; so that Cabbages will not grow in it, Potatoes are bad, fruit trees get rank and unfruitful, their roots die, and the tops canker. Lime will cure all this as has elsewhere been shown. But new soils contain often not enough, and their fertility would be greatly increased by its presence in larger quantity. Ordinary manure and the addition of all sorts of vegetable refuse will secure this end. When artificial manure is used, and indeed in all cases, this could be done by keeping every bare inch covered with vegetation to be dug in. Twelve per cent. may be regarded as a medium amount of humus. If below this, efforts ought to be made to increase the amount, especially in the case of very light or very heavy soils. If much above it its reduction would be no evil, but the reverse, for too much greatly encourages vermin of all sorts in addition to the other evils named.—
SINGLE-HANDED.

GARDENS ABOUT BRISTOL.

OLD SNEYD PARK.

THERE are few more delightful places than this, the summer residence of F. Tagaart, Esq. The landscape is wonderfully varied, and includes Clifton, with its numerous handsome residences, in the background. To the left is the noted Clifton suspension bridge with its romantic surroundings; then there is the valley of the Avon, through which immense quantities of shipping goes to and returns from Bristol; while beyond this valley the glorious expanse of forests known as Leigh Woods are to be seen in all their beauty. The autumn tints this season are unusually bright and good, and many a pleasing picture might easily be painted from the pleasure grounds of Old Sneyd Park. The place, too, is well kept up and proves very attractive to the many visitors who avail

themselves of Mr. Tagaart's kindness in throwing open the place once a week during the time the grounds are at their best. One of the features of the place is the large circular carpet bed disposed near the carriage front entrance, and this at the time of my visit was looking remarkably well. In the centre stands a large handsome vase, but the square base of this rather interferes with the design for planting. Fully 8000 plants are required to fill this bed, these including all the approved sorts of Alternantheras, Iresines, Sedums, and other "carpeting" plants. In some of the panels Tradescantia zebrina was very effective, as was also the creamy variegated Pelargonium-like Tropæolum nanus Warrenii. As "dot" plants Sempervivum arboreum aureum was very attractive, and Chamæpeuce diacantha, American Agaves, Echeverias, and other succulents figured well in this excellently designed and planted bed. Other beds were well planted, and the long mixed borders near the house were gay with Marguerites, single Dahlias, Japanese Anemones, Violas, and other well-known bedding plants. There are also good herbaceous borders near the kitchen garden.

The conservatory adjoining the house contains a good assortment of plants, including a fine specimen of Cibotium spectabile, and a recess with its miniature fountain and banks of Ferns as viewed from the rooms presents a delightfully cool and pleasing appearance. There are a considerable number of plant and fruit-growing houses, but they are rather scattered. Orchids are extensively grown, some of the specimens being exceptionally large, while several choice kinds not always to be seen in a healthy state, notably Cypripedium niveum, in large pans are growing freely. One large basket of Stanhopea grandiflora had recently produced thirteen strong flower spikes, and others had done nearly as well. In order to prolong the duration of the usually short-lived Stanhopea blooms, Mr. Miller, the energetic and practical gardener in charge, stated that he hangs the baskets under a tree on the lawn before the buds have expanded, and here they gradually open and keep fresh and beautiful a much longer time than if bloomed under glass. Several plants of Oncidium macrophyllum were blooming strongly and prove serviceable at a time when Orchid blooms are rather scarce. The back wall of one of the plant stoves was beautifully furnished with a mixture of fine-foliaged Begonias, Tradescantias, Panicum, and Ferns in variety, the soil for these being enclosed by strong wire netting. Among the specimen plants were large highly coloured Crotons; Dracenas, and such Ferns as Gymnogrammas, Adiantums, and Davallias are in fine condition. Rondeletia speciosa is largely grown, and its bright orange-red flowers are very showy and serviceable, while two very large specimens of Abutilon Boule de Nieve in an intermediate temperature yield a profusion of white flowers all the year round. When allowed to grow to their full extent as at Old Sneyd this and other Abutilons, such as Fire King, Fire Fly, and Golden Gem, are wonderfully floriferous, and are particularly well adapted for planting in large conservatories.

The most serviceable range of houses are in the kitchen garden. One compartment devoted to heat-loving plants was quite a treat to me, so healthy and cleanly grown were all such kinds as Poinsettias, Eucharis, Pancratiums, Crotons, Gardenias, Allamandas, and Dipladenias. On the back wall and roof the Allamanda Schottii, Bougainvillea glabra, and Dipladenia boliviense—the flowers of the latter being the finest I have yet seen—were charming. Dipladenias, including the richly coloured D. Brearleyana, were also flowering freely. Poinsettias planted out and trained over a wall were growing luxuriantly, and from these last season were cut whorls of floral leaves 23 inches in diameter. Eucharis amazonica are exceptionally well grown, one pot alone having produced 120 flower scapes this season. It was here that the magnificent specimen pot of Eucharis that proved so attractive at the grand show held at Manchester in 1880 was grown. The monster specimen of Latania borbonica is also noteworthy. Soot is Mr. Miller's favourite stimulant or fertiliser, and I noticed it had been employed when watering a great variety of plants, including the Eucharis, Gardenias, and Poinsettias. It is most easily applied when kept mixed in the form of paste and stored in a flower pot. A small piece only should be used, or just sufficient to blacken the water.

Grapes are well grown in the various houses, and a few days prior to my visit a considerable quantity of half-ripened late sorts had been stolen. The thieves, however, overlooked a fine crop of Muscats in the next house, among which much the best in point of weight and appearance of crop is a seedling Muscat, said to be the result of a cross between Canon Hall Muscat and Golden Champion. It much resembles the Canon Hall in its general appearance, but apparently is a better setter, and it seemed to me to have a less pronounced Muscat flavour. The Peach house is being re-arranged, and will eventually produce a much greater number of fruits than heretofore. The wire trellises are now arranged across the house at right angles with the front, and about 5 feet apart. A coarse-mesh strong wire network is employed, and arranged so as to admit of the trees being planted in pairs back to back and yet clear of each other. This profitable method of training Peach and Nectarine trees, which appears to be fast gaining ground, does not interfere with the cropping of the back wall, and in this case, the house being high and light, there will be no necessity to unduly restrict the growth of the trees.

Peaches succeed admirably on the open wall in the neighbourhood of Bristol, and at Old Sneyd I saw a quantity of fine fruit on Lord Palmerston Peach, and Victoria Nectarine and other varieties had done well. Two immense Fig trees yield great numbers of fine fruit. They receive the benefit of the shelter of a high stone wall, but are not closely trained and in this free state the growth is short-jointed, hardy, and fruitful. The more Figs are pruned and nailed-in, the more gross and delicate the

shoots will be. On this same high stone wall I noticed an extraordinary crop of Trophy Tomato, and in this garden Tomatoes, I am informed, seldom fail to ripen heavy crops. The soil of the garden seems extremely fertile, and nearly everything in the way of vegetables, hardy fruits, and flowers succeeds admirably in this highly favoured spot.—W. IGGULDEN.

THE INSECT ENEMIES OF OUR GARDEN CROPS.

No. 9.

IN consequence of its mode of growth the Strawberry is a plant peculiarly exposed to the attacks of insects that are accustomed to secrete themselves, when not feeding, beneath the soil or under the shelter of chance objects. Much injury may be done, and the cause escape detection, if the rows are not examined both by day and night. Washing and syringing cannot always be carried out, even if this were of proved utility in the case of some insect pest, nor can the plants be beaten or shaken with advantage, and searching for small species is tedious work, yielding unsatisfactory results. Something may be done in the way of trapping certain insects whose habits are known, but the destroyers at the roots are apt to escape notice until the injuries are well-nigh fatal to the plant. We have an advantage over these subterranean species with those crops that can be shifted from place to place in a way that is not possible with the Strawberry. It is one of those plants occasionally attacked by the grub of the crane fly (*Tipula* sp.). We had an instance reported to us this summer, and so numerous were the enemies that it was found necessary to destroy the bed, no remedial measures answering.

We proceed to notice the beetles that are hurtful to the Strawberry in various stages of its growth, and begin with those species which have been mentioned in this Journal of late as decidedly mischievous to the ripe or unripe fruit, but which, if previously enemies, had somehow been overlooked. Indeed, when the circumstance was first reported to me, I replied unhesitatingly that I believed there was an error, and that the beetles in question had visited the Strawberry rows to devour smaller insects and molluscs. But one lives and learns. Both in Britain and in America observations in several localities prove that more than one species belonging to the family of the Carabidæ, carnivorous by habit, and reputed formerly to be friends and not foes, will destroy quantities of Strawberries. One of the conspicuous species has been identified as *Harpalus ruficornis*, fig. 82, and it is most probable some others in that genus act similarly when they have opportunity. The beetles of the genus are variable in size and colour even in the same species, and are therefore difficult to classify. The "tarsi" or feet of the males have the basal joints dilated, and the wing-cases are generally dotted over with numerous punctures. During the day they hide under any convenient object, or, should the weather and soil be dry, they will get into cracks of the earth. After dark they come forth, perhaps by hundreds, where they have established a colony in a Strawberry

Fig. 82.

bed, and feast upon the fruit much to its damage. Why they should devour this instead of, or in addition to, their natural food is at present unexplainable, the chief point with the gardener is to put a stop to their proceedings. Trapping them has answered well. At first putting down pieces of board and slates was tried; the beetles concealed themselves under these, but their agility enabled them to escape frequently when they were turned over. It was found an improvement to lay in suitable spots drain pipes filled with hay, which served to attract the beetles, and from which they could readily be shaken and killed.

Samples of beetles belonging to another genus, *Amara*, have also been forwarded, accompanied by the statement that they were caught in the act of feeding upon the fruit. These, like the *Harpali*, are predatory and combative, so much so indeed, that several of them cannot be kept together in a box without a skirmish speedily commencing amongst them. Popularly they are called Sunshiners, because they love the sunshine, and therefore differ from the preceding in appearing by day and only hiding when alarmed. An old superstition is that ill luck or misfortune will befall the person who kills a Sunshiner; but in spite of this the gardener must protect his Strawberries from beetles of such an eccentric taste if he can. Trapping might be tried with these also, as they are supposed to hide at night. Having wings of good size, which they readily put into use, they are not always to be caught by day when they are seen. In form they are somewhat squat, with the thorax broad behind, and the wing-cases striated, are small in size, colour mostly blue or bluish green; some individuals are bronzy, or even black. The larvæ of all these species are supposed to be feeders upon other insects of subterranean habit, and therefore they may help to check some of those which damage roots.

Miss Ormerod, in her excellent "Manual," gives a prominent place to the green or rose chafer, *Cetonia aurata* (fig. 83), as a foe to the Strawberry, but I do not think it has been often complained of by

the cultivators of this fruit. The mature insect is said to injure the blossom, and from its size and appearance could hardly fail to attract notice where abundant, as I have sometimes seen it hovering in parties about Privet bloom or Roses in full flower. From its underground life, however, the larva or grub might escape observation easily, or be unrecognised if turned up with sundry creatures of similar habit. June is the month in which the beetle usually emerges. On the upper side the colour is metallic green with whitish streaks resembling cracks across the wing-cases; the under side is coppery, tending to a rosy hue. The structure of the thorax prevents the wing-cases from opening widely, so that although the insects fly well they cannot raise these when on the wing in the manner beetles commonly do. The clubs of the antennæ are composed of tiny flat plates, which are moveable like the divisions of a fan. All the older entomological works state that the larva feeds upon wood; in reality it is, as noted above, very commonly a destroyer of the roots of low

Fig. 83.

plants or shrubs, but lives also in decayed wood or wood soil. Resembling somewhat the grub of the cockchafer, it is rather thicker than that insect, and clothed with short hairs. It is usually discovered lying in a curved position, the hinder part of the body being thicker than the head; their life as larvæ is reckoned to last about two years. Rooks are reported to hunt them eagerly, and the application of diluted gas lime or a weak solution of paraffin has been recommended where their presence is suspected. There is no great difficulty in securing the beetles by a hand net.

When killing beetles amongst our Strawberries we must avoid injuring any species that is beneficial. *Carabus auratus*, for instance, one of the ground beetles, we are likely to see running eagerly about in search of its prey; it seizes caterpillars, snails, and other beetles, fearlessly laying hold even of the bulky cockchafer. This insect is golden-green, with a larger body than the rosechafer, and we at once distinguish it from that species by the three sculptured ribs on the wing-cases. The blackish larva or grub is also a killer of insects. This only comes forth at dusk to hunt. There are, however, other beetles that are now and then foes to the Strawberry, but which I merely name here, as their history belongs to that of other plants they visit more habitually. One of these is the bracken dock or June bug, *Phyllopertha horticola* (fig. 84), an enemy of fruit trees; but the beetle has in some

Fig. 84.

seasons stripped Strawberries of their blossoms. Then *Otiorynchus sulcatus*, also called the black or Vine weevil, has been taken on the fruit of Strawberries; and the grub of another, the red-legged weevil, *O. tenebricosus*, occasionally infests its roots. The particular aphid of this plant is named from it *Siphonophora Fragariæ*. It is a shining green with long antennæ and red eyes, very like the aphid of the Rose. Some years few are to be perceived, in others they cluster on the fruitstalks during May.—ENTOMOLOGIST.

PANSIES AND VIOLAS.

I MUST thank "H., Notts," and Mr. H. Cannell, jun., for their excellent endeavours to answer my query—namely, What is the difference between a Pansy and a Viola as at present grown, sold, and exhibited? I emphatically disclaim any intention of throwing discredit upon our so-called Violas as bedding plants; on the contrary, I grow them largely, but as Pansies and Violas have of late years occupied a place in almost

all the spring flower shows, and have been allotted separate classes, it is obvious there should be some rule to distinguish one from the other, such as there are in Carnations, Picotees, and Pinks.

I have seen exhibited in a class for twenty pots of Pansies (nursery-men) some of the same varieties that the same exhibitor staged in the class for twenty pots of Violas, and gained prizes in each case. There is no rule by which a judge can disqualify them. It is very easy to see the difference in the case of such varieties as Blue Bell, which is only removed one step from its parent, *Viola cornuta*. But raisers have not been satisfied to stop at the first cross; they have continued crossing until the bulk of the so-called Violas resemble Pansies more than they do their parents on the cornuta side.

I enclose a copy of a group of Pansies grown by Mr. Hogg, florist, Paddington, 1834, considered the best then in cultivation; and I think if Mr. H. Cannell, jun., could see it he would be convinced that the Pansies grown by his great grandfather a hundred years ago were not nearly so good as some of those called Violas at the present time. One of the group named Lucy seems to me exactly like *Viola lutea* Grievii. Now compare *Viola* Sovereign, Holyrood, and many others with the enclosed copy, and it will be seen at a glance that the best Pansies of 1834 were only poor Violas of the present day; and if separate classes for Pansies and Violas are not to become a farce it is time there was some distinguishing rule by which judges may be guided. I have often thought that a rule something like that suggested by Mr. W. J. Murphy, if it could be carried out, would be a move in the right direction—that a *Viola* shall have distinct lines radiating from the centre, all those having a solid blotch of colour would then have to be classed with the Pansies; but the difficulty is, Who are the authorities to carry out any rule, as I am not aware of any Pansy Society such as the Rose Society, the Auricula Society, &c.—WM. PLANT.

[There is a Scottish Pansy Society, and the matter in question is well deserving of consideration by the Committee. The group of flowers referred to shall be seen by Mr. Cannell.]

CHRYSANTHEMUM SHOWS.

EASTBOURNE, NOVEMBER 7TH.

THE first Show of this new Society was held in the Floral Hall, Devonshire Park, Eastbourne, an excellent place for an exhibition—large, light, and lofty; and being illuminated with the electric light in the evening made the Show very effective. The exhibits generally were very satisfactory, and gave good hopes that the Exhibition will be repeated another season.

Cut Blooms.—These were very fair, of good substance, though the Show was early. Mr. J. Ridout, Reigate, was first with twenty-four incurved, having blooms of good size, excellently finished, very fresh, and even, though there was an absence of monster "back rowers," as some call them. The varieties were Lady Hardinge, Beauty of Stoke, Mr. Brunlees, Emily Dale, Mrs. W. Shipman (fine), Mrs. Heale, Lady Slade, Prince of Wales, Gloria Mundi, John Salter, White Venus, Cherub, Golden Eagle, Novelty, Nil Desperandum, Geo. Glenny, Venus, Mrs. Dixon, Antonelli, Beverley, Mrs. G. Rundle, Miss Hope, Aurea Multiflora, and Bendigo—a new sport from Mrs. Heale, the colour something like Angelina, only lighter in the centre; this was the finest bloom in the Show, and was awarded a first-class certificate. Mr. Jupp, Torfield Gardens, Eastbourne, was a fair second with similar varieties. Mr. J. Ridout was again first with twenty-four Japanese blooms, very highly coloured flowers of good size and substance. The best were Peter the Great, Elaine, Triomphe du Nord (grand), Bertie Rendatler, Soleil Levant, Madame C. Audiguier (not very good for this variety), Fair Maid of Guernsey, Chang, Erecta Superba, Bouquet Fait, Etoile Toulousaine, Fulgore (very fine), Albert, Nuit d'Hiver, Comte de Germiny, Chinaman (good), Source d'Or, James Salter, La France, Lady Selborne, and L'Incomparable; Mr. Jupp was second some distance behind; and R. Russell, Esq., Lewes, third. In the class for thirty-six Japanese in twenty-four varieties the blooms were very uneven—indeed, it was too large a class for so young a Society, as the result showed, the number having to be made up with exceedingly small blooms. Mr. Ridout again took the premier prize; Mr. Jupp was second; while for twelve large Anemones, twelve incurved, twelve Japanese, and twelve triplets (Pompons) Mr. Jupp carried off all the first prizes.

Plants.—The best group in the Show was from Messrs. Scott & Co. of Ceylon Nursery, Eastbourne, covering a space of some 600 square feet, and most artistically arranged under Tree Ferns—not for competition. There were seven other groups of 75 feet, besides numerous well-filled classes for pot plants. A very artistic arrangement for a dinner-table was put up by a bashful young lady, who would not let her name be known. This consisted entirely of Japanese flowers. Messrs. Cannell & Sons, Swanley, brightened the Show with their usual fine collection of double and single Pelargoniums and select Primulas. Mr. Davis of Camberwell, who officiated with Mr. Cannell as Judge, exhibited a stand of superb blooms of miscellaneous Chrysanthemums, including the beautiful Mary Major.

A first-class certificate was awarded to Mr. Ridout for *Chrysanthemum Bendigo*, a sport from Mrs. Heale, which is described in the report of the Royal Horticultural Society's meeting.

BRIXTON, NOVEMBER 9TH.

A VERY attractive display of blooms, specimen Chrysanthemums, and miscellaneous plants was provided at Brixton as the commencement of the exhibition season in the metropolitan district. Several very good stands of incurved and Japanese blooms were staged, all that could be desired in finish, though in some instances a little wanting in size. The specimen plants were not quite so numerous, and the fine examples that were once the ornament of the Show are still missed, but those staged showed an improvement generally. Orchids were remarkably good, and formed quite a little exhibition in themselves. All the exhibits were well arranged, and the general system of management is creditable alike to the Secretary Mr. Hall, and the Committee which aid him so well in his work. As usual the lecture

hall adjoining the Congregational Church, Brixton Hill, was the site chosen, and it was satisfactorily filled. One of the principal features of the Show was a charming group of Orchids and Ferns from Mr. Salter, which were tastefully arranged at one end of the hall to form a bank of rich green foliage and bright flowers of great beauty. Amongst the most notable plants were *Cypripedium Harrisianum*, several good *Phalænopses*, and *Cymbidium giganteum* with a long handsome spike. The Judges signified their appreciation of this fine group by awarding Mr. Salter a first-class certificate for it, an honour which was well deserved. Another contribution not in competition was a large and choice collection of single Dahlias from Mr. T. S. Ware, Tottenham, which attracted much attention owing to the lateness of the season for such flowers. They were, however, as fresh and brightly coloured as some were a month ago.

Cut Blooms.—Collections of twenty-four incurved blooms were staged by four competitors, the best being that from Mr. C. J. Salter, gardener to J. Southgate, Esq., Selborne, Leigham Court, and though of medium size they were very neat, fresh, and of good colour. The varieties were Prince of Wales, John Salter, Beauty of Stoke, Empress of India, Mrs. Shipman, Lady Hardinge, Golden Emperor, Refulgence, Barbara, Beethoven, Jardin des Plantes, Rev. J. Dix, White Globe, Caractacus, Isabella Bott, Nil Desperandum, Mrs. J. Rundle, Lady Slade, Queen of England, Lord Derby, George Glenny, Prince Alfred, Mrs. Dixon, and Baron Beust. The second position was assigned to Mr. J. Holmes, gardener to M. Storey, Esq., Nightingale Lane, who had smaller blooms of similar varieties. Mr. T. Sadler, gardener to C. Lambert, Esq., Leigham Court Road, took the third place, his position being due to the comparative want of substance in the blooms. Five stands of twelve incurved blooms were entered, all of average merit. Mr. W. Slade, gardener to J. Wilson, Esq., Upper Tooting, won first honours, closely followed by Mr. E. Cherry, gardener to Mrs. Gabriel, Streatham, and Mr. T. Sadler. For six incurved blooms Messrs. Salter, Sadler, and Green were the prizetakers. A maiden class was provided for twelve incurved blooms, for which much the best samples were staged by Arthur Margetson, Esq., Leigham Court Road, who was awarded the first prize; but the second and third collections from Messrs. Lynch, gardener to Spencer Wicks, Esq., Streatham Hill, and W. Clarke, gardener to T. Bass, Esq., Christ Church Road, were rather weak.

The class for twenty-four Japanese was a good one, the exhibits being very close in merit. Mr. J. Holmes, gardener to G. M. Storey, Esq., Nightingale Lane, was adjudged the premier prize for blooms of good size, fresh, and bright. The varieties were Baronne de Prailly, James Townsend (seedling), Tendresse, Alba Plena, Dr. Macary, Triomphe du Nord, Madam Burnet, Criterion, Rosa Bonheur, Countess Beuregarde, Chang, Elaine, Curiosity, Hiver Fleur, Elegance, Bouquet Fait, Thunberg, L'Incomparable, Comte de Germany, Père Delaux, Gloire de Toulouse, The Sultan, Peter the Great, and Magnum Bonum. Mr. A. Holmes, gardener to A. B. Hill, Esq., Clapham Park, was close second, and Mr. J. Young, gardener to T. Hicks, Esq., Streatham Hill, was third with blooms but little inferior to the preceding. The competition with twelve Japanese blooms was keen, no less than six stands being entered. Mr. Salter was first with very good, fresh, and substantial blooms, Messrs. W. Glide, Cherry, and Sadler following closely in the order of the names. Stands of six reflexed blooms were contributed by Messrs. T. Sadler and J. Holmes, who were placed first and second respectively, their blooms being fairly good, not large, but substantial and richly coloured. Three good collections of twelve large Anemone varieties were contributed by Messrs. J. Young, Swain, and Salter, one creditable stand of Pompon Anemones securing Mr. Livermore the first prize in that class.

Specimen Plants.—The principal class for plants was for six incurved varieties, and in this Mr. Cherry took the lead with moderate-sized specimens, but neatly trained and well grown. The varieties were Beethoven, Mrs. Dixon, Prince of Wales, Venus, fine; John Salter, and Mrs. G. Rundle. Mr. Clarke followed with rather poor examples. For three plants Messrs. Cherry, Clark, Gates were the prizetakers. A maiden class was provided for three plants, incurved varieties; Mr. J. T. Salter, gardener to M. Shepherd, Esq., Roupell Park, taking the chief prize with moderately good plants, the blooms not very large but neat in form. For six Pompons, not pyramids, the leading position was assigned to Mr. Cherry, who had well-flowered, neatly but not formally trained examples of Brilliant, Calliope, Sunset, La Vogue, Perle, and White Cedo Nulli. Mr. J. Weston, gardener to D. Martineau, Esq., Clapham Park, was second; and Mr. J. Howes third, both showing well. Mr. J. Weston also had the best three Pompons, fairly well-grown plants, Mr. Cherry and Mr. W. Clarke following closely. Six beautiful pyramid Pompons gained Mr. E. Cherry the premier honours in that class, as they were freely flowered but not formally trained, contrasting very favourably with some of the others which had the shoots tied in very closely. Mr. C. Livermore took the second prize with less well-flowered examples. The best three standard Pompons were shown by Mr. W. Clarke, neatly trained specimens of Madame Marthe, Calliope, and St. Michael. Messrs. R. Clarke and C. Livermore were the other prizetakers in this class with similar plants but not quite so freely flowered.

Miscellaneous Plants.—Orchids constituted a decided attraction in the Show, and for the time of year were extremely good. The principal class was for six plants, in which Mr. Salter won leading honours with healthy freely flowered examples, such as he invariably stages. *Cypripedium Spicerianum* had seven fine flowers; *Cattleya gigas* three flowers of a good variety; *Vanda cærulea* a fine spike of thirteen flowers; and *Oncidium crispum* had a large panicle of flowers. Mr. Luff was second, his most noteworthy plants being the creamy white-flowered *Lycaste lanipes* with three blooms, *Dendrobium superbiens* with a spike of thirteen flowers, and *Masdevallia tovarensis* in a pan with sixteen flowers. With three Orchids Mr. Salter was again first, showing *Cattleya gigas*, *Vanda cærulea* of good colour, and *Lycaste Skinneri*. Mr. C. Livermore followed with *Vanda suavis*, *Zygopetalum Mackayi*, and *Cattleya Acklandiæ*, Mr. J. Young being third with *Dendrobium nobile*, *Lycaste lanipes* having six flowers, and *Oncidium Papilio*, while an equal third was adjudged to Mr. Weston, who had *Maxillaria picta* very well flowered. For a single specimen Orchid Mr. Salter won first honours with *Cypripedium Harrisianum* in beautiful condition, and bearing twelve handsome flowers.

Fine-foliage plants were well shown by several exhibitors, Mr. W. Clarke winning first honours with four specimen Crotons, Weismanni and Veitchi being very notable for their size and health. Mr. E. Cherry was placed

second, his best plant being *Dracæna Baptisti* in first-rate condition, large, finely coloured. Mr. H. Luff, gardener to R. R. Hyatt, Esq., Streatham, was third, having a good *Asparagus plumosus nanus*. For four Ferns Mr. Luff was first, having fresh vigorous examples of *Platycerium grande*, *Adiantum farleyense*, *A. cardiochæna*, and *A. cuneatum*. Mr. Young was second, and Mr. W. Clarke third, his *Adiantum gracillimum* being extremely good. Table plants were shown by Mr. F. Sandy, who was first with *Cocos Weddelliana*, *Aralia Veitchi*, and *Pandanus Veitchi*, neat and graceful. A graceful ornament for a dinner table secured Mr. J. Weston the first prize in that class. A charmingly simple combination of *Nerine crispa*, *Eucharis*, and *Bouvardia* blooms with Ferns, in a stand of unpretentious appearance, showed how tastefully a few materials may be utilised. In addition to these small Ferns single and double *Primulas* were excellently shown, some of the latter being remarkably well flowered.

Fruit.—Grapes were not largely shown, but were fairly good. For three bunches of white Grape Mr. W. Howe was first with Muscat of Alexandria well ripened; Mr. C. J. Salter second with good bunches of Trebbiano; and Mr. J. Rockell, gardener to Mrs. Falconer, Clapham Park, third with small Muscats. For three bunches of black Grapes Mr. W. Howe was again first with Alicante of good size and bearing excellent bloom. Mr. R. Holmes and Mr. C. J. Salter followed with the same variety in good condition. Apples were staged in good condition by Messrs. J. Rooney, gardener to W. J. Manning, Esq., New Park Road; J. Sadler, and A. Sandy, gardener to George Coles, Esq., St. Julien's Road, Streatham. The best Pears being from Messrs. W. Hall, gardener to W. Stevens, Esq., Lower Tulse Hill, and A. Sandy.

Collections of vegetables were well represented, Messrs. J. Young, Cherry, and J. Swain securing the prizes for fifteen kinds; while for a collection, the number of kinds not stipulated, Messrs. T. Sadler, Gates, and Andrews, Upper Tulse Hill, won the awards with very clean and good-sized produce. Cucumbers were staged by several exhibitors, Mr. W. Howe being first with Rollisson's Telegraph, Mr. J. Young second, and Mr. W. Collins third.

STOKE NEWINGTON, NOVEMBER 12TH AND 13TH.

THE annual Show of this old-established Society is always looked for with much pleasure by Chrysanthemum exhibitors and growers in the north of London; and the Exhibition this year, though not quite so well filled as some of its predecessors, well maintained the credit of the Society for handsome blooms and strongly grown freely flowered plants. Competitors were not, it is true, so numerous as might have been desired, and in some cases there was noticeable a deficiency of substance in the blooms that was not at all in accordance with the traditions of the Society, but taking the exhibits generally the Show was a satisfactory one. It was effectively arranged, the care and energy of the courteous Secretary, Mr. Goldsmith, being manifest in every direction. The competition for the silver cup was the great centre of attraction, and the Sheffield blooms, which so severely tried Mr. Gilbey's strength, were much admired by local and other growers; indeed, the district very nearly lost the honour of retaining the much-prized cup. The Show was, as usual, held in the Assembly Rooms, Defoe Road, Church Street, and was well attended by visitors on both days.

Plants.—Specimen plants are invariably well shown at Stoke Newington, and the present season is not an exception to the rule, for vigorous and profusely bloomed examples of the best varieties were numerous exhibited. The principal class is that for ten plants, but only two collections were entered. Mr. Monk, gardener to W. Fowler, Esq., Forest House, Leytonstone, won the leading position with dwarf and pyramidal-trained plants of Mrs. G. Rundle, Golden George Glenny, Venus, The Cossack, Mr. George Glenny, Dr. Sharp, Sœur Melanie, and others. Mr. R. Payne, gardener to C. Paine, Esq., Cedar House, Stamford Hill, was placed second, his dwarf plants of Rosinante and Cendrillon being the most noteworthy in the group. Standard Pompons were admirably shown; Mr. Gilbey, gardener to R. Booth, Esq., The Cazenoves, Upper Clapton, winning first honours with four beautiful examples of the White and Lilac Cedo Nulli, Marie Stuart, and Sunset, evenly trained and profusely flowered. Mr. Payne, was a close second, Sœur Melanie and Antonius being very fine. Mr. Langford, gardener to J. Barnet, Esq., Coleraine House, Stamford Hill, was third. Mr. Gilbey was also first with four dwarf Pompons, similar varieties to his other plants, and equally well flowered. Mr. Langford followed closely; and Mr. Dymond, gardener to S. Wright, Esq., Rosslyn, Stamford Hill, was third. The premier honours for six Pompons was awarded to Mr. Payne for freely flowered specimens of Sœur Melanie, Cendrillon, Antonius, Lilac Cedo Nulli, Madame Marthe, and Prince Victor.

Mr. Payne had the best four standard large-flowering varieties, The Cossack, beautifully flowered, Venus, Elaine, and Prince of Wales. Mr. Gilbey was second with rather more formal specimens; and Mr. Archer, gardener to J. Griffith, Esq., Highbury Grange, took the third position. For four plants, large-flowered varieties, Mr. Gilbey was first with Barbara; Mrs. G. Rundle, Mrs. Dixon, and Lady Hardinge being fine blooms. Mr. R. Payne and Mr. Langford were awarded each second prizes for rather smaller specimens. Mr. Monk had the only collection of six large-flowered varieties, taking the first prize with fair specimens.

Cut Blooms.—A table in the centre of the room was occupied with the blooms in competition, a row of table plants being placed between the stands. Taking the classes in the order of the schedule the first six are confined to nurserymen, gardeners, and amateurs of the district. In the class for twenty-four incurved blooms there were three entries, Mr. Gilbey being first with even, neat, compact, and handsome blooms of the following varieties:—Back row: Empress of India, John Salter, Golden Empress, Prince of Wales, Mr. Bunn, White Beverley, Alfred Salter, and Queen of England. Second row: Barbara, Princess of Teck, Bronze Jardin des Plantes, Mrs. Heale, Hero of Stoke Newington, Prince Alfred, Golden Beverley, and Princess of Wales. Front row: Princess Beatrice, Rev. J. Dix, Isabella Bott, Venus, Guernsey Nugget, Mr. Brunlees, Lady Hardinge, and Cherub. For this collection the four-guinea silver cup was awarded as the best twenty-four in the Show, the clean neat appearance of the blooms gaining Mr. Gilbey this honour. This is the third season he has won the cup—an unusual feat. Mr. Martin, The Gardens, Woodberry Down, was second with smaller but very neat blooms, the back row including some fine samples of Queen of England, Hero of Stoke Newington, and John Salter. Mr. R. Payne was third with still

smaller blooms, but Prince Alfred, Empress of India, and Queen of England were well represented. In the classes for twelve and six blooms in the same section the first-prize lot of twelve from Mr. W. Cooper, gardener to J. Johnson, Esq., Elmfield, Upper Clapton, included fine blooms of Queen of England, Empress of India, Golden Empress, and John Salter. Most of the others were rather small, the chief prizes being secured by Mr. R. Payne and Mr. Jones. Mr. Gilbey was first with a beautiful six, Queen of England, Empress of India, Golden Empress, John Salter, Prince of Wales, and Hero of Stoke Newington, very even and of good substance. Messrs. R. Payne, W. Cooper, and W. Martin were the other prizetakers.

In the Borough of Hackney amateur classes Mr. F. Bingham, 22, Manor Road, was first with twelve incurved symmetrical handsome blooms, not large but excellent in form and substance. Queen of England, Mrs. G. Rundle, Empress of India, Barbara, and Nil Desperandum were particularly good. Messrs. W. Goldsmith and R. Wright, 42, Darnley Road, followed closely. Six incurved were rather small, the prizes being secured by Messrs. F. Bingham and R. Wright. Two stands of six Japanese were entered, Mr. W. Goldsmith taking the first position with Fair Maid of Guernsey, Grand Turk, and Comte de Germiny very fine amongst others. Mr. W. Wright was second.

In the open class for twenty-four incurved blooms Mr. J. Udale, The Gardens, Shirecliffe Hall, Sheffield, was placed first with substantial handsome blooms, the back row being extremely fine. This collection was very carefully compared with the best twenty-four in the local class for the cup prize, and lost it by only a few points, three blooms being rather old. The blooms were Queen of England, Golden Empress of India, Princess of Wales, Hetty Barker, Bronze Jardin des Plantes, White Queen, Alfred Salter, and Empress of India in the back row. The second row comprised Mr. Howe, Blonde Beauty, Prince Alfred, Mr. Bunn, Princess of Teck, Cherub, Mrs. Heale, and Lady Hardinge. The front row included Jardin des Plantes, Prince of Wales, Barbara, Princess Beatrice, George Glenny, Venus, Mrs. G. Rundle, and Mrs. Dixon. The second-prize stand in this class contained much smaller blooms. Mr. J. Udale also secured premier honours with twelve incurved blooms, massive examples of Golden Empress, Queen of England, Empress of India, and Alfred Salter forming the back row. Mrs. Heale, Princess of Teck, Princess of Wales, and Cherub were in the second row; and Princess Beatrice, Barbara, White Venus, and George Glenny in the front row. This stand was much admired. Messrs. W. Monk and G. Chalkley, gardener to J. R. Droop, Esq., Stamford Hill, were second and third with smaller blooms.

In the maiden class for six incurved the prizes were secured by Messrs. F. Bingham and J. Hicks, all staging medium-size but even neat blooms. Anemone varieties were represented by two stands, large and Pompons respectively, the latter being much the better of the two, including Cedo Nulli, Firefly, Jornette, Perle, Marie Stuart, Astræa, and Calliope, very good. Mr. R. W. Wright was the only exhibitor in both classes. Two collections of twelve Japanese blooms were entered, Mr. W. Monk taking the first position with good blooms of Flambeau, Fair Maid of Guernsey, Gloire de Toulouse, Peter the Great, La Nympe, Chang, Mdle. Moulise, M. Castel, M. Charles Huber, L'Incomparable, and Thunberg. Mr. R. W. Wright was second with looser and smaller examples. Five stands of six Japanese were staged, Mr. W. Monk being adjudged the first position with Peter the Great, Fair Maid of Guernsey, M. Castel, Triomphe du Nord, La Frissure, and Flambeau, very bright, fresh, and of good substance. Messrs. A. Dymond and W. Martin were awarded the remaining prizes.

Table plants were well shown, neat, graceful, little specimens of Crotons, *Dracænas*, *Aralias*, and Palms being selected. The prizes were secured by Mr. Jones, gardener to W. P. Reynolds, Esq., Stamford Hill, and Messrs. Gilbey and Archer. Mr. Archer also had the best foliage plants, followed by Mr. Payne, the two collections forming a good bank at the end of the room. Mrs. G. Davis, 3, Stamford Road, Page Green, Tottenham (a cottager), showed two neat bouquets and table decorations, both tasteful and unpretentious. Mr. Cochrane, Superintendent, Finsbury Park, sent a handsome collection of twenty-four incurved blooms, substantial, compact, and clean. Mr. W. J. Smith of the Covent Garden Supply, 128, High Street, Stoke Newington, contributed a handsome collection of fruits, wreaths, bouquets, &c., the first-named comprising some particularly fine Pears, Apples, Pine Apples, and Grapes. This exhibit added greatly to the beauty of the Show.

LAMBETH, NOVEMBER 12TH, 13TH, AND 14TH.

THE ninth Exhibition of this interesting amateur Society, held as usual in the Borough Road Lecture Hall, proved one of the best that they have yet had. Both plants and blooms would not have disgraced the shows of much more pretentious societies. Incurved and Japanese blooms were admirably represented, and though the plants did not possess that finish which denotes trained specimens at large shows, they were in several cases extremely healthy and profusely flowered. This was particularly so in the class for a group of plants, which brought several good collections, and furnished a bright display on one side of the Hall. At one end, too, was a fine bank of foliage and other plants kindly contributed by Mr. Richards, one of the honorary members, who also staged some handsome blooms in the classes devoted to them. Indeed the honorary members' classes formed quite an important feature, and such a successful innovation might be advantageously followed up another season. It is also proposed, and we consider the proposition a wise one, to extend the radius of the Society to two miles from the Elephant and Castle. This will bring in a much larger number of growers, and may be expected to result in the production of a really first-rate Show, such as is wanted in this part of London. The Honorary Secretary, Mr. G. S. Addison, is energetically endeavouring to improve the position and usefulness of the Society, and the success attending his first year of office gives abundant promise of still better results in the future.

Plants.—One of the most important classes for plants was that for a group of twelve, not less than six varieties. Mr. Clarke won first honours (a silver cup) with freely flowered informally trained specimens, comprising beautiful examples of The Cossack, Chevalier Domage, James Salter, Elaine, and several Pompons. Mr. Mills was second, and Mr. Howett third, both showing good and effective groups. For six standard large-flowered varieties Mr. Tracy was first with very well grown and freely flowered examples of Mr. G. Glenny, Phidias, Mrs. G. Rundle, and Arigena, and Mr. Williams was second with rather more roughly trained, but with several good blooms. Mr.

Tracy staged the best twelve plants of six varieties, and Mr. Williams followed closely, both contributing bright and pretty groups. Mr. H. Ellis was first with six untrained bush Pompons, free and pretty plants, the varieties Antonius, Mr. Astie, and the Cedo Nullis being notable. Mr. Davis, who was second, also had the Cedo Nullis very attractively flowered, and Mr. Hadden was third with similar plants. Mr. Tracy took the lead with six pyramid Pompons, neatly trained but rather sparse of flower. Mr. Child had six neat standard Pompons, which secured him the first prize in the class, while Mr. Tracy showed the best three standards, followed by Mr. J. W. Addison, both showing moderately good plants.

Cut Blooms.—There was keen competition in nearly all the bloom classes. Incurved varieties were numerous and good, especially in the class for twelve blooms, in which the first prize was a silver cup. This was won by Mr. Child, who had small but fresh and neat blooms, the most noteworthy being Barbara, Princess Teck, and Nil Desperandum. Messrs. Ball and R. Ellis followed amongst five competitors. Of six incurved blooms eight stands were entered, and Mr. Ball was first with good blooms, the best being Princess Teck and Prince of Wales. Mr. Child took the second position, and Mr. Howett was third. In the class for six blooms of one variety Mr. Howett won the first place with handsome flowers of Mr. Bunn. Japanese blooms were largely represented, one of the leading collections being twelve fine blooms from Mr. Child, which gained him the first prize. The varieties were Japon Fleuri, Mons. Ardene, Fanny Boucharlet, Père Delaux, Triomphe de la Rue des Châlets, R. Pallantino, James Salter, Madame B. Reudatler, Mdle. Moulise, Etoile du Midi, Peter the Great, and Nuit d'Automne, very fresh and good. Messrs. H. Ellis and C. H. Payne followed amongst six competitors. Mr. Child also had the best six blooms in a class of nine competitors, winning first prize with good blooms of Triomphe de la Rue des Châlets, Fair Maid of Guernsey, Japan Fleuri, The Cossack, Madame C. Audiguier, and Peter the Great. Other prizetakers in this class were Messrs. H. Ball and Hadden. For six blooms of one variety Mr. G. S. Addison led with James Salter, very clean and fresh; Mr. J. W. Addison followed with Fair Maid of Guernsey, and Mr. Davison was third with James Salter. Mr. Child secured the first prize for twelve trusses of Anemone Pompons with a beautiful collection, comprising Mr. Astie, Regulus, Miss Nightingale, Astrea, Marie Stuart, Perle, Madame Montels, Firefly, and Antonius. Mr. Ellis was a very close second with similar blooms.

The honorary members' classes for blooms brought some excellent contributions. Mr. Richards won first honours with twelve incurved blooms, good even, neat and substantial blossoms of the following varieties:—White Beverley, Prince of Wales, Nil Desperandum, Mr. Corbay, White Venus, Golden Beverley. Messrs. Fraser and J. R. Crisp followed. Mr. Richards was also first with twelve large Anemone blooms, a very beautiful collection, and he gained the same position with Pompon Anemones, a similar attractive collection. For twelve Japanese Mr. Fraser secured chief honours with finely coloured substantial blooms. The varieties were Elaine, Red Gauntlet, Madame C. Audiguier, Fair Maid of Guernsey, Kämpfer, Soleil Levant, Rosa Bonheur, Marquis of Lorne, Rubra Striata, Triomphe du Nord Cry Kang, and Peter the Great. Mr. Richards followed closely, and Mr. J. R. Crisp was a good third.

PUTNEY.

SIX years have elapsed since the Putney and District Chrysanthemum Society was established, and each year the shows have increased in extent and excellence. For the Exhibition under notice, that was held on the 13th inst., there were nearly 200 entries, and although an annexe was opened at the end of the large Assembly Rooms the space was quite inadequate for the accommodation of plants, blooms, and visitors. We can only give a brief report of the Show, indicating its general character.

Groups of Plants.—These invariably form the commanding feature of the Putney Shows. The conditions are the best collection of Chrysanthemums in not less than twenty varieties, quality and general effect to be the leading features in this class, the space occupied by the plants not to exceed 40 superficial feet. The first prize is a silver cup. On this occasion six splendid groups were placed in competition, such that have not been excelled at any previous show held in England, if equalled. The Judges were nearly an hour in determining the relative merits of the collections, in consequence of the conflict between quality of the blooms on the one hand, and effective arrangement on the other. Eventually they awarded the cup to the collection they considered the best adapted for the embellishment of a high-class conservatory. The coveted honour was won by Mr. Newell, gardener to Sir Edwin Saunders, Wimbledon Common. His plants were remarkable for their sturdiness and fine foliage, which displayed to advantage the large blooms. The plants were grown in a natural manner, from 2½ to 6 feet high, and the arrangement was good without being crowded, and the colours admirably blended. Mr. Knowles, gardener to G. M. Allender, Esq., Putney Park Lane, was second with larger blooms, but rather too thinly arranged. Messrs. Mahood & Sons third with a beautiful and too-closely-packed collection; and Mr. Carter, gardener to H. J. Perry, Esq., Heathside, Wimbledon Common, fourth; the two unnoticed groups closely following in merit, but were a little too stiff and formal in arrangement.

Specimen Plants.—In the class for four large-flowered varieties Mr. Tyte, gardener to Mrs. Reid, Putney Heath, was first with admirably trained examples 2½ feet high and 4 feet in diameter, scarcely any sticks or bent stems being visible. Mr. J. Bentley, gardener to Sir Thomas Gabriel, Wimbledon Park, and Messrs. Tigwell & Sons, Mortlake, had the remaining prizes in this class. Messrs. Mahood & Sons won the premier prize in the single-specimen class with a fresh and good example of Mrs. G. Rundle, Mr. Knowles being second with a much larger plant of Christine, but over-trained, Mr. Bentley being third. Mr. Stacey was placed first in the single-specimen Japanese class with a neat and bright example of Dr. Masters, Mr. Bentley second with Elaine, and Mr. Pepper third with James Salter. Pompons were still better exhibited, the specimens staged by Messrs. Tyte, Mahood, and Hopkins being finer than have been seen before at Putney. The prizes were awarded in the order named. Eleanor, staged by Mr. Tyte, and Golden Mdle. Marthe by Messrs. Mahood, deservedly attracted much attention. They were not flattened by close training, but were full and free—about 4 feet in diameter.

Cut Blooms, Incurved.—In the class for twenty-four blooms only two

collections were staged—namely, by Mr. Carter in a garden to D. T. Galpin, Esq., and Mr. J. Holmes, gardener to G. M. Story, Esq., Balham, who were awarded the prizes respectively. Both collections were highly creditable to the cultivators, but the blooms in the first-prize stands somewhat over-weighted the others, which, however, were extremely neat. The champion bloom in the Show was in Mr. Harding's stand, a magnificent Empress of India; it was, however, run exceedingly close by Queen of England staged by Mr. Holmes.

In Mr. Harding's stand a bloom of a new variety not yet in commerce deserves special mention—namely, Jeanne d'Arc. It is a good-sized, symmetrical, perfectly incurved flower, silvery white, with pink-tinted florets, and was obtained, we believe, from Messrs. Jackson of Kingston; it is a variety of promise. For six blooms Mr. J. Bentley was first with superior examples of Golden Empress, Alfred Salter, Queen of England, Prince Alfred, Baron Beust, and Mrs. Heales. In the class for twelve blooms five stands were placed in competition. Messrs. Mahood & Sons secured the first position with handsome well-developed flowers; Mr. Harding being second also with good examples, and Mr. Sullivan, gardener to D. B. Chapman, Esq., Roehampton, third with neat blooms.

Anemone Varieties.—Several stands of these were placed in competition. In the class for six blooms Messrs. Mahood & Sons secured the chief position with Lady Margaret, Mrs. Pethers, Prince of Anemones, Gluck, Fleur de Maric, and George Sands, Mr. Charles Bentley being a good second, and Mr. J. Lee, gardener to E. R. Stephenson, Esq., Albermarle Lodge, Putney, a close third. The champion bloom in this section was George Sands, staged by the last-named exhibitor.

Japanese Blooms.—There was excellent competition in the class for twelve blooms, Messrs. Mahood being once again to the fore with fine and beautifully fresh examples. The most striking bloom was a new variety, Joseph Mahood, with round, erect, wire-like florets of a reddish gold colour, very bright; Mrs. J. Mahood, white, in the same stand, also Mrs. Townsend, dark chestnut, were very good, and M. Marouch, the latter with flat crimson florets, very fine. Mr. Sullivan was a close second with large blooms, and Mr. Lee third with very fresh examples, alba striata and Thunberg extra fine. In the class for six blooms Mr. J. Bentley, Mr. Sullivan, and Mr. G. Stevens were awarded the prizes in the order named, with stands very close in point of merit. Comte de Germany, staged by Mr. Bentley, was very grand, the contest for the championship resting between it and Meg Merrilees, staged in another class by Messrs. Mahood, which won the coveted honour.

Mixed Stands.—The prizes offered by Mr. Stevens for twelve blooms, four each of incurved, Japanese, and Anemones, staged 6 inches high, with the foliage attached, brought out three effective stands by Messrs. Mahood, Harding, and Bentley, who respectively secured the prizes.

Stove and Greenhouse Plants.—In the class for four specimens Mr. Stevens distanced all competitors, and secured the first prize with excellent specimens, Mr. Knowles and Mr. Woodhams following creditably. Primulas were well shown by Messrs. Woodhams, Newell, and Lee, who received the prizes in the order named for six plants. Mr. Pitts, a valued supporter of the Society, offered prizes for miscellaneous groups of stove and greenhouse plants, which were won by Messrs. Hoskins, C. Bentley, and F. Bush with neat arrangements.

Bouquets were good. For Messrs. Mahood's prizes the successful competitors were Messrs. Lee, Stevens, and Harding; the winners with Chrysanthemums being Messrs. Lee, Lacy, and Stevens.

Fruit.—The prizes for black Grapes were won—first by Mr. Holmes, Sisters House, Clapham Common, with fine Alicantes; second Mr. Richardson, Springfield Lodge, with Black Hamburg; third Mr. Bradford, gardener to S. Howards, Esq., Wimbledon, with Alicante. In the class for white Grapes the first prize was won by Mr. Freeman, Oak Lodge, Putney, with neat bunches of Golden Queen.

Vegetables.—Six splendid collections were staged, the prizes falling to Messrs. Tigwell, Campbell (The Priory, Roehampton), and Knowles in the order of their names. The Mushrooms in the first-prize stand and the Leeks in the second were of commanding excellence.

Prizes were also awarded for table plants, berried plants, Ferns, and Apples, all the winners showing most creditably; but we failed to obtain their names, owing to the press of visitors in the afternoon. The Show was well managed by Mr. Moore, who, with all the officials, laboured to make it what it was—a great success.

POTTING LILIES.

I HAVE been doing this during the last few days, and as Lilies are particular favourites of mine a few considerations in reference thereto may be of interest. First as to the time of potting. Some recommend January and February. I must respectfully maintain that, except for those imported later on or for the last potting, this is too late. (I have now in view those intended for indoor and conservatory decoration; those planted in Azalea Rhododendron beds take care of themselves.) I have had imported bulbs of *L. auratum* from Japan potted at the same time, with the same treatment, and with nearly two months between the time of flowering; and not only are those grand Lilies peculiar in the time of flowering, but they differ in colour, spots, lines, and markings more or less, and, still further, I have found the smaller bulb having the greater number of blooms. I mention the time of blooming for the purpose of saying that it is upon that the time of potting depends more than upon any stipulated date. This point is very important, for it is to my mind the secret of the reputed "failures" often heard of.

Nothing is so common as to remove potted Lilies when their floral beauty is past, outdoors, perhaps, to leave them uncared full in the sun; or worse, to the back of a house, where they get waterlogged and the sun never shines, instead of regularly feeding them with liquid manure if the pots are small or medium-sized, removing seed pods, and allowing them to regularly ripen full in the sun. I have not the least doubt, if satisfactory results are looked for next year, full ripening and full sunshine are necessary, though I am aware greater authorities than I am, such as

Mr. G. F. Wilson, have had fine blooms in the shade. No wonder there is failure in either of the neglected cases referred to, and that when you come to repot a half-decayed bulb only a few shrivelled scales are left. This is the explanation of why so many say they find Lilies do best outside. But I must maintain, where time can be had for looking after their post-floral treatment, there are few Lilies undeserving of a place indoors if it can be at all spared for them. No Lily lover would care to see his beauties destroyed by the storms peculiar to our climate, or splashed with a fierce driving rain.

As to why I think January and February is too late, when the stalk has withered to the surface of the pot and the leaves have fallen they should be shaken out. Most of my *L. auratum*, all *L. speciosum*, various (*lancifolium*), and with two exceptions my *L. longiflorum* and *L. Krameri* were withered thus, and presented a curious appearance when the clay was removed. Above the bulb was a large mop-like head of innumerable feeding roots; these should be withered and removed with the old stem. On the contrary, the roots at the base are fleshy, sound, and healthy, and ready to commence action immediately. The pots should be in proportion to the size of the bulb, leaving fully an inch free at the top of an 8-inch pot. I find a mixture of two-year-old loam, some peat, old rotten frame manure pulverised, and a small quantity of sand to give stamina, the best. No water for the present.—W. J. MURPHY, *Clonmel*.

REVIEW OF BOOK.

The Culture of Vegetables and Flowers from Seeds and Roots. By SUTTON & SONS, Reading. London: Hamilton, Adams & Co., 32, Paternoster Row.

As the title indicates this work is not devoted to the propagation and culture of plants that are usually raised from cuttings, but to those that are raised from seed and by roots, tubers, and bulbs. With the above limitation the field is wide, as it includes all the most useful crops for the kitchen garden, and most of the popular flowers that are grown for greenhouse, conservatory, and room decoration. The culture of them is detailed clearly and well, the result being a sound, substantial, well-printed volume of 300 pages, which also include chapters on the formation of lawns from seed, the insect pests of garden crops, and the fungus pests of certain flowers, these two latter chapters being illustrated.

In glancing through the chapters it is apparent that they have been written by competent cultivators, and no one can err in carrying out the instructions, except, perhaps, growers of Broccoli in cold northerly districts. On page 27 it is advised that "Broccoli should always be planted in freshly made ground, and if it is in some degree rank with green manure the crop will be none the worse for it. But rank manure is not needful; a deep, well-dug, sweet loam will produce a healthy growth and neat handsome heads." Rank manure and deep digging inevitably lead to succulent growth, and just in proportion as this is encouraged exactly in the same proportion is the destruction of the crops endangered by severe frost. When this destruction occurs, as it has occurred over miles of country, varieties get a bad character for being tender; but the cultivators in innumerable instances have made them so by treating the plants too generously. They will pass the winter far more safely in the firm moderately fertile soil of an open field than in the rich deeply dug ground of a sheltered garden. With this qualification—and we deem it important—we commend this work strongly as one of the most practical that has recently been issued on the cultivation of the garden crops and popular flowers on which it treats. It will be well, however, to let the volume speak for itself in the form of one or two extracts, selected not because they embody the best teaching of the pages, but because the subjects happen to be seasonable.

MAKING ASPARAGUS BEDS.

After describing what is alluded to as the "costly character routine" of repeatedly trenching the ground for beds, the author goes on to say:—

"But we are bound to say that a capital supply for a moderate table may be obtained by preparing a piece of good ground in an open situation in a quite ordinary manner with one good digging in winter, adding at the time some 6 inches or so of fat stable dung, and leaving it thus until the time arrives for sowing the seed. Then it will be well to level down and point-in half a spade deep a thin coat of quite rotten dung to make a nice kindly seed bed.

"At this point another grave question arises, which is not for the men of taste, but the men of practice to determine. It is the question of distance, for there are advocates of a space of a square yard, or even more, for each individual plant, for which, of course, the plant will make some return. But a really profitable crop is of more consequence than a smallish supply of monster sticks, for even if these are valued at £3 or £4 per hundred, as they sometimes have been, there are not many buyers to be found, and they are not wanted, even as home produce, on many tables. There is another question, too, as to the width of the beds, and this, of course, in part depends on the distance between the plants. But having tried many plans, we have come to the conclusion that the best to insure a great bulk of good produce with the least expenditure of labour, is to lay out the land in 3-foot beds, with 2-foot alleys between. The line is put down along the centre of the bed, and the seeds are dropped two or three in each hole at a distance of 15 inches. This is repeated at 6 inches from the alleys, and the result is three rows of plants, 1 foot distance between the inner rows, and 3 feet (including the alleys) between the outer rows. In very strong land, heavily manured, a distance of 18 inches in the row would be better than 15. For special circumstances a few beds may be sown with two rows only, and at 18 to 20 inches distance in the row. But the beds should never be more than 3 feet wide, for if that measure is

exceeded there will often arise an excuse for putting a foot on the bed, which is certainly injurious to Asparagus. April is the best month for sowing.

"When the grass from seeds has grown about 6 inches will be the time for thinning to one plant at every station of 15 or 18 inches in the row. On this point a remark is needful to this effect—much of the injury reported to result from close planting has been the result rather of carelessness in thinning. The young plant is such a slender delicate thing that, to the thoughtless operator, it seems a folly to thin down certainly to one only. The consequence is that two or three, or perhaps half a dozen, plants are left at each station to 'fight it out,' and these become so intermixed as to appear as one, though made of many, and of course amongst them they produce more shoots than they can feed properly by the limited range of their roots, and all drawing nourishment from the same limited tract of ground. Severe, or we may say mathematical thinning, is a *sine qua non*, and it requires sharp eyes and careful fingers, but it must be done if the Asparagus beds are to become, as they should be, the pride of the kitchen garden."

That is excellent advice, as anyone may prove who has fairly good soil to begin with, and will carry out the instructions in an intelligent manner. We pass to an example of the matter relating to flower culture, and the accuracy of the teaching may now or shortly be tested by those who have the means for doing so.

THE CULTURE OF CYCLAMENS.

"Cyclamens afford a striking example of the advantages of the rapid system of cultivation. Seed may be sown at any time of the year, and the plants will not only flower within twelve months, but if properly grown will produce more bloom than can be obtained from old bulbs. But we do not advise more than two or three sowings. The first and most important should be made in October or the beginning of November, and to obtain a succession of plants sow again in January or February. The best soil for the purpose is a rich sound loam, with a liberal admixture of leaf mould, and sufficient silver sand to insure free drainage. Press this mixture firmly into pots or seed pans, and dibble the seed about an inch apart and a quarter-inch deep. It is a good plan to cover the surface with a thin layer of sifted cocoa-nut fibre; this checks rapid evaporation, and keeps the surface free from moss. The autumn sowings may at first be placed in a frame having a temperature of not less than 45°. At the end of a fortnight transfer the pans to any position in the greenhouse or propagating house that is warm and moist. The January sowing should be placed in heat at once.

"Although the Cyclamen is a tender plant it does not need a strong heat, and will not endure extremes of any kind. Sudden changes are always fatal to its growth. In winter the temperature should not be allowed to fall below 56°, or to rise above 70° at any time. The more evenly the heat can be maintained the better, and give all the light possible. In summer, however, although a warm and humid atmosphere is still necessary, the light may with advantage be somewhat subdued, but this must not be overdone, or the constitution of the plant will suffer.

"The seed not only germinates slowly, but it also grows in the most irregular manner. Sometimes a plant comes up long after others have made a good start. Do not be impatient of their appearance, but when some of the seedlings are large enough for removal transfer to thumb pots, taking care not to insert them too deeply. As the plants develop shift into larger pots, ending finally in the 48-size. In the later stages mix less sand with the soil, and when potting always leave the crown of the eorn clear. Keep the plants as near the glass as possible, and when the sun becomes powerful it will require attention to provide shade and prevent excess of heat. Never allow the seedlings to suffer from want of water, or to become a prey to aphid. To avoid the latter, occasional, or it may be frequent, fumigations must be resorted to. About the end of May should find the most forward plants ready for shifting into 60-size pots. Give all the air possible to promote a sturdy growth, bearing in mind that fine healthy foliage is the precursor of a grand bloom. In doing this, however, avoid draughts of cold air. From the end of June to the middle of July the finest plants should be ready for their final shift into 48-pots, in which they will flower admirably. The growth during August and September will be very free, and then occasional assistance with weak manure water will add to the size and colour of the flowers. As the evenings shorten save the plants from chills, which result in deformed blossoms.

"The whole secret of successful Cyclamen culture may be summed up in a few words: constant and unvarying heat, a moist atmosphere, and abundant supplies of water without stagnation; free circulation of air, avoiding cold draughts; light in winter, and shade in summer, with freedom from insect pests. These conditions will keep the plants in vigorous growth from first to last, and will produce specimens of which the grower may be proud. The result will be so bountiful a bloom as to prove the soundness of the rapid system of cultivation. This routine may be varied by the experienced cultivator, but the principles will remain the same in all cases, because the natural constitution of the plant gives the key to the management required."

The above is, we presume, the method that is adopted in growing Cyclamens at Reading, where they are annually produced in splendid condition. The extracts given are fairly representative of the matter of the very practical, reliable, and serviceable volume before us, which is sure to be widely read, and highly useful as a work of reference by all who desire information on the culture of the most important crops of the garden and favourite flowering plants.

EARLY PURPLE-TOP MUNICH TURNIP.—Will any of your readers who have grown this variety give us their experience of it? I did not try it until late in the summer, when I sowed a row or two of it against other kinds, and it beat all for earliness. It has a short top, is of medium size, and has a bright rosy purple colour on the top of the bulb, but the flesh is white. So far as I can see of this variety we shall find it very desirable in gardens.—W. D. W.

HARDY FRUIT GARDEN.

Supplementary Fruit Lists.—In the lists of fruit given in the last two calendars for large and small gardens and for market, especial care was taken to give only sorts suitable for the ordinary fruit-grower; we now add lists of certain sorts of Pears and Apples which we have proved to possess such high merit that the connoisseur may well try to afford space for them. It cannot, however, be said that all the Pears will be found alike excellent, for they are much affected by soil and situation. None of them should be condemned at the first trial, for a good Pear is often an outcome of a season of favourable weather as well as of age in the tree. Try if possible to afford space for one or two cordons of each of them against a wall or building; 18 inches apart is the best distance for single cordons, so that a considerable number of them may be planted in a comparatively confined space, and wall cordons once brought into fruiting rarely fail of a crop afterwards.

Pears.—Doyenné Defaise, Red Doyenné, Duchesse d'Orleans, Passe Colmar, Deux Sœurs, Désiré Cornelis, Napoleon, Dr. Trouseau, Gansel's Bergamot, Duchesse de Mars, Alexander Bivort, Bergamotte Esperen, Beurré d'Anjou, General Todleben, Emile d'Heyst, Durondeau, Beurré de Jonghe, Huyshe's Prince Consort, Huyshe's Prince of Wales, Pitmaston Duchesse, and Beurré d'Aremberg.

Apples.—Coe's Golden Drop, Pearson's Plate, Beauty of Kent, Brabant Bellefleur, Lord Burghley, Reinette de Canada, Golden Pippin, Cockle's Pippin, Reinette Van Mons, Ross Nonpareil, Bess Pool, Scarlet Nonpareil, Barcelona Pearmain, Lodgemore Nonpareil, Ashmead's Kernel, Mannington's Pearmain, Pomme d'Api, Cobham, Mère de Ménage, Golden Reinette.

Planting Bush Fruits.—Distance apart:—Black Currants, 6 feet; Red and White Currants and Gooseberries, 5 feet; Raspberries, 15 inches in the row and 5 feet between the rows. Soil, a deep, rich loam, well drained, and when this can be had careful planting is all that is necessary. But in thin poor soil recourse must be had to special treatment, or failure will be inevitable; with a command of ample materials trenches 2 feet wide and 18 inches deep should be made and filled with top-spit soil thoroughly enriched with old decayed manure, and a liberal mixture of mortar rubbish or coal ashes, taking care to raise the surface sufficiently to allow for its gradual subsidence to the common level. Failing the requisite material for trenches the next best thing is to dig in a heavy dressing of manure, to plant the bushes, and at once mulch with manure and subsequently to apply a surface dressing 3 or 4 inches of manure, by means of which the bushes may be kept in a healthy fruitful condition, but without it they will soon deteriorate and die. Shorten Raspberry canes to 18 inches, and prune the Gooseberries and Currants sufficiently close to obtain abundant growth for main branches. Never plant Black Currants with stems, but let the branches spring direct from the ground.

FRUIT-FORCING.

FIGS.—Early-forced Pot Trees.—The house containing the trees to give ripe fruit at the close of April or early in May should now be closed. The pots, it is presumed, have been placed on pedestals of open brick-work, to bring the plants up to the light and prevent the pots sinking with the fermenting material, of which some thoroughly sweetened fermenting Oak or Beech leaves should be introduced, placing them loosely at the beginning round the pots, as only gentle excitement at the roots must be given at first, the heat not being allowed to exceed 70° or 75°. Syringe the trees and walls every morning and again in the afternoon, but not later than 2 P.M., as it is important the trees become fairly dry before night. In dull, wet, and cold weather syringing will hardly be necessary—the afternoon syringing in such weather should certainly be dispensed with. Apply tepid water to the roots at frequent intervals until every portion of the soil is well moistened. The temperature to commence with should be 50° minimum at night and 5° to 10° more by day in mild weather; but avoid a close vitiated atmosphere, ventilating a little at 55°, which should be the maximum from fire heat in the daytime in cold dull weather, and 65° from sun heat, closing the house when the heat from solar influences begins to decline. Undue haste in the early stages of forcing causes much and often irreparable mischief. The glass should be kept clean, and clear of condensed moisture by the admission of a little air in mild weather.

Earliest-forced Trees.—The house should be closed by the early part of December if ripe fruit is to be gathered from the trees early in May, therefore anything that requires to be done in respect of cleansing the house, and dressing the trees, and securing them to the trellis must be completed at once. Examine the borders, and if found very dry give a slight mulching with short manure, and afterwards water with that a few degrees warmer than that of the house, repeating at intervals until the whole mass of soil is rendered thoroughly moist.

Young Trees for Forcing next Season.—Young plants ought now to be shaken out and repotted. To prepare them for forcing they should be grown on with the forced plants, so that they make an early growth and have time to rest after they have matured their growth. Brown

Turkey, Negro Largo, and White Marseilles are fine varieties for early forcing, having large well-flavoured fruit.

VINES.—Early Vines in Pots.—These are now moving freely, and will need to be disbudded when more than one shoot start from an eye or joint, leaving the strongest and most promising; and it is advisable to leave more shoots than will be allowed to carry fruit, as these aid in maintaining a good root-action, consequently a supply of nutriment is maintained in the canes for the bunches to draw upon as occasion demands. Six to eight bunches are mostly sufficient for a Vine in a pot to carry, but everything depends on the strength of the canes and the means of support. Those numbers are quite sufficient for a Vine with the roots confined to the pot, but where the roots are allowed the run of a bed of fermenting materials we have seen a dozen bunches brought to much finer size of berry and finish. With the shoots about an inch long the temperature should be increased to 60° at night, or 5° more in mild weather, and 65° by day, advancing 5° to 10° from sun heat. Ventilate from 70°, and close at 75° when the sun heat begins to decline. Syringe morning and afternoon, but in dull weather the afternoon syringing should be omitted, especially where there is the advantage of a fermenting bed, the materials of which should be added to and turned over so as to keep the heat steady at 70° to 75°. Water as necessary with tepid water. Secure the canes in position after they have broken well throughout.

Late Grapes.—Those that were forwarded by a judicious application of fire heat in spring are quite promising as to keeping, being fresh and plump, and, the foliage having fallen, the most critical stage in the treatment of late Grapes has passed. We allude, of course, to Grapes that have been ripened by the end of September under conditions so frequently advised in these columns. One of the most fatal mistakes with late Grapes, or those for spring use, is that they should be allowed to come on naturally and ripen their fruit some time before Christmas, or with fire heat in the dull autumn months. The wood in this case never ripens perfectly, and the bunches are loose and wanting in berries; the foliage hangs until December, and generally ripened off by cold, and if the berries escape damp they shrivel when the foliage is gone or the fruit is removed to the Grape-room, which becomes a very important compartment, especially where late vineries have to be occupied with plants. In the Grape-room cleanliness and perfect ventilation are essential, as too dry an atmosphere is quite as fatal to the Grapes keeping as a stagnant moist atmosphere. Grapes keep best in a room having thick dry walls, and therefore not subject to sudden fluctuations in temperature, hollow walls being unquestionably the best, and with sufficient heating power to expel damp, or not allowing the temperature to fall below 45° in the severest weather. The house should be thoroughly cleansed and white-washed; the bottles also must be clean and filled with clear rain water, adding a small lump of charcoal to each, and placing in the racks ready for use. The Grapes should be cut on a dry day, and no portion of the wood above the bunches should be cut, or if it be cut must be dressed with styptic to prevent the escape of moisture from the wood. The Vines may then be pruned, and a long season of rest will then be secured to them. Any additions to the inside borders should have immediate attention, and surface-dress them after removing the loose inert surface soil, giving, if the border be dry, a good watering prior to the top-dressing of turf, crushed bones and charred refuse.

PLANT HOUSES.

French and Fancy Pelargoniums.—Every attention must be paid to these plants, especially the early batch, for if kept in a close atmosphere they will soon draw up weakly and their foliage become spotted. They must be kept close to the glass and in a temperature that will not fall below 45° at night, and every favourable opportunity they should have air admitted to them freely. No attempt must be made to push them forward now the days are short and sunless, but, on the contrary, keep them moving slowly, so that the growth they make will be dwarf and sturdy, which early in the season will be capable of supplying abundance of bloom. Watering must be done carefully and judiciously, only giving sufficient to keep their roots in an active healthy condition. After watering, if the day is fine apply a little fire heat for the purpose of expelling the damp.

Chrysanthemums.—These plants are early this year, and where they have been disbudded they will be unfolding their blooms rapidly. These large blooms are very liable to damp during dull sunless weather, and the only means of prevention is the application of heat and abundance of air. The flowers will need daily inspection during such weather, and any petals that show signs of damping must be instantly removed, or a number will soon suffer and the flower in a few days will be spoiled. There is not so much fear of flowers of a smaller size suffering from this cause. The late batches now they are indoors must be watched, and if mildew appear, which it is very likely to do, it must be destroyed at once, for if allowed to spread the foliage will be injured. For this purpose use a solution of soft soap and water, in which a little sulphur has been mixed, lay the plants down and give them a good washing, and after the mildew has been destroyed wash off the remains of the sulphur with clear water. Do not neglect supplying the late batches that have only just formed their buds, for in this stage they require liberal feeding if the best results are expected. Ventilate freely day and night while the weather is mild, and only close the ventilators in stormy weather and on frosty nights.

THE FLOWER GARDEN AND PLEASURE GROUND.

Glaucoli.—Unless frosts intervene the foliage of most of these will remain green till near the end of the month, when they may be lifted

and stored. Should severe frosts, however, be anticipated, the corms should either be lifted at once or protected with rough litter or leaves. They may be packed thinly in boxes of dry soil, and stored during the winter in a cool dry shed where they can be protected from frosts. The tiny corms, which in some cases are formed about the old corms, should not be overlooked, as these, if preserved in slightly moist sandy soil, and be properly replanted the following spring will, in the course of one or two seasons, grow into flowering corms. In some gardens, where the soil is light and dry, it is not absolutely necessary to lift them, but they should be protected from severe frosts. The commoner sorts frequently spread rapidly and flower freely under this treatment.

Dahlias.—These have held out unusually late this season, and have been particularly good. The beautiful Constance, Ariel, or White Cactus Dahlia, as it is variously termed, and the brilliant Juarezi or Cactus Dahlia, have been exceptionally fine this autumn, and are certain to remain popular long after numbers of the single varieties are discarded. Scarlet Glare of the Garden and its crimson form have been wonderfully effective, and these, with some of the Pompons—notably the white Guiding Star—are especially good for furnishing cut blooms, and may well receive the preference to many of the singles. At least nine-tenths of seedling single Dahlias ought to be destroyed. Better preserve a few really distinct and brightly coloured sorts and throw away all those that are poor both in form and colour. Directly the frosts have injured the leaves and flowers of all the Dahlias, the stems of those selected should be cut down to within 9 inches of the tubers, and either lift at once or protect from a second frost. The labels bearing the registered numbers, name, or brief description of each should be strongly tied to the stem, or otherwise much confusion may easily ensue. After the tubers have stood for a few days in a shed to dry they should be packed in a single layer on a dry floor, and be covered with fine nearly dry soil. They must be carefully protected from frost. When the tubers are stored under a staging in a greenhouse they are either injured by excessive moisture or induced to commence growth much too early.

Salvia patens and Verbena venosa.—The former may be treated similarly to the Dahlias, but in this case, the tubers being smaller, they may well be enclosed in boxes of good soil. The long fleshy roots of the Verbena are quite hardy, and from these any number of plants may be obtained in the spring; but as they interfere with the digging and manuring of the beds, a quantity of trimmed plants and their roots entire should be lifted and stored thickly in boxes of moist soil. A cold frame is the best position in which to winter them.

Herbaceous Lobelias.—These brilliant tall-growing species, of which *L. cardinalis* and *fulgens* are the oldest types, should be lifted and stored in boxes or pots of good soil, and be wintered in a pit, frame, or a greenhouse. They ought not to become dust-dry at the roots, the aim being to encourage them to push up strong suckers for division in the spring.

Polemonium caruleum variegatum.—This has again proved a very effective bedding plant, and should be lifted and treated similarly to the Lobelias. The less fire heat they receive the better. The beautifully variegated Tussilago Farfara is quite hardy, and is best left undisturbed till the spring, when numbers of strong suckers will spring up in all directions.

Chrysanthemums.—It is seldom we have these good in the open air, especially the easily disfigured white sorts. Where they are wisely planted near a wall, a mat should be carefully and securely suspended over them nightly, both as a protection from frosts and rain. If they are situated in such a position as to prevent any protection being given we should strongly advise that many of the best be lifted with a large ball of earth about the roots, and either be placed in large pots or tubs, or, failing these, be bedded in a heap of good soil somewhere in a vinery or Peach house. Such plants, providing they are in a moist state at the roots when lifted, and subsequently maintained in that state, will furnish surprisingly large quantities of blooms. They may perhaps lose much of their lower foliage, but better lose this than have the whole of the blooms spoilt by rains and frosts.

THE BEE-KEEPER.

HIVE-CONSTRUCTION—COVERING FOR TOPS OF FRAMES, QUILTS—TWO TROUBLES.

Two troubles usually beset the bee-keeper who is desirous of preserving the covering of his hive in good order—First, the persistency with which bees will gnaw holes in the material which goes immediately on the tops of the frames; and second, the disagreeable effects of propolis on the carpet covering, or whatever may be laid for warmth over the bees.

We have tried hair cloth, Indian grass matting, and American cloth, all of which were discarded as faulty and not answering the purpose. In casting about for a more suitable covering we came across a very simple article which we venture to say is the best yet introduced; very cheap, durable and indestructible so far as the bees are concerned. It is made of round German match-wood, and is used for various domestic purposes, such as splashes for washstands. This material when woven together with strong

thread is everything that can be desired. We had some difficulty in obtaining the article we required undisfigured by paint, but eventually succeeded, and if the manufacturers can be induced to make them of a suitable size for bee-keepers they will, we believe, be generally adopted. In use they are so light that one may be laid on the tops of the frames, while the latter are thickly covered by bees; not one will be crushed, and the bees can creep from under the covering without difficulty. When uncovering the frames the wood quilt is so pliable than when folded back it lies in a roll out of the way, while only just so much of the frames are uncovered as is necessary. Of course bees will propolis these as they will any other form of quilt, and we have to take the usual steps to remove the propolis when cleaning them once a year.

These wood quilts are made in two parts each 16 by 15½ inches; a small hole is cut in each to admit the bees to the feeding stage. An excellent covering for warmth is made from cow hair felt, used by engineers for the purpose of maintaining heat in boilers; it is about 1 inch thick, light, soft, and very porous, so that when sewn into calico coverings for durability one set of these quilts will last a lifetime. We make them in four parts two of which are 15½ by 9 inches, and two 15½ by 6 inches. A circular hole is cut in each wide piece for feeding.

We have now completed the description of our hive, and the diagram below will assist in making plain its construction as well as showing its relative proportions. We cannot well show the method

Fig. 85. DIAGRAM OF HIVE.

of fixing the legs without confusing the diagram, but they are cut with a shoulder on which the hive body rests, and screwed on at the front and back respectively.

Objections may be taken to this hive on the score of cost or trouble in making; but we would remind our readers that the hive which has been described is devised as the best that could be made regardless to an extent of one or the other. The timber, &c., used in its construction costs about 9s. All really first-class hives are rather costly, but a good article is cheap in the end, and the rubbishy packing-case affairs so frequently sent out now-a-days are dear at any price.

A cheaper form of the same hive for use in a bee house can be made by using inch stuff for the hive body, dispensing entirely with double walls, roof, legs, &c. At each end is screwed on a piece of inch stuff 4 inches wide. On the insides of these the inclined runners are fixed in such a position that the floorboard will fit close up at the back when pushed home, and allow half an inch fall in the front before it is wedged up. Two small wedges 3 inches long, tapering down to three-eighths of an inch, and fastened by a small chain or string to the hive, are used for this purpose. A strip of half-inch wood along the front and back, fixed level with the tops of the frames, keeps them in position; thus we have all the working parts of the hive the same as in the larger one at a cost of labour and material not exceeding that of the cheap hives now in use.—W. B. C., Higher Bebington.

[We regret to learn that our correspondent, also writers on gardening, are troubled with a number of letters that readers are not

justified in sending, and asking for information by post; and we trust that our request to correspondents in this column will be complied with.]

THE BEST TIME TO SLING HONEY

WHILE bees are gathering honey daily the only proper time to sling it from the combs is in the morning before they begin the work for the day. If the work of slinging be not attended to, then the honey extracted will be inferior—in fact, it will remain thin and soon sour. This fact has been repeated so often during the last ten years that I have not deemed it wise to repeat the old story for some years. About ten days ago I met Mr. Hewett of High Leigh, near Lymm or Warrington, a clever, experienced, and successful bee-keeper, when he told me that he had found in his practice that honey gathered in the fields during the day had to be re-swallowed at nights, and thus made into proper honey. Some ten or twelve years ago it did appear strange to me that so many of the leading bee-keepers of Great Britain should be ignorant of lessons that could be learned every day when bees are at work. Mr. Woodbury, unlike most of the leading apiarians of his time, did not venture to contradict or dispute the statement then made, but said he "did not know." It will be well if all bee-keepers who use extractors now learn that honey proper cannot be extracted from combs till the second day after it is gathered; in other words, that bees first gather honey in a crude state, and convert it at home into real honey. This is a lesson of far more importance than some advanced apiarians are now disposed to admit. The treasures of all true science are gathered from facts, and the facts of this case are open to all who look for them.—A. PETTIGREW.

TRADE CATALOGUES RECEIVED.

Dickson & Robinson, 12, Old Millgate, Manchester.—*Catalogue of Forest and Ornamental Trees.*

Alex. E. Campbell, Cove Gardens, Gourcock.—*Catalogue of Gladioli.*

James Dickson & Sons, Newton Nurseries, Chester.—*Catalogue of Forest Trees and Roses.*

Francis and Arthur Dickson & Sons, Chester.—*Catalogue of Forest Trees, Conifers, and Shrubs.*

Hogg & Robertson, 22, Mary Street, Dublin.—*Catalogue of Forest and Ornamental Trees, Conifers, and Roses.*

P. E. Francken, Steenbrugge-Bruges, Belgium.—*Catalogue of Shrubs and Trees.*

Robert Jenkins & Co., Rotherham.—*Catalogue of Boilers (Illustrated).*

Constant Kerkvooide, Wetteren, Belgium.—*Catalogue of Fruit Trees and Roses.*

D. Cannon & E. Brace, Les Vaux, Salbin, Loir-et-Cher.—*Catalogue of Trees, Shrubs, Potatoes, and Strawberries.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Book (*B. J. C.*).—Mr. A. F. Barron's work on "Vines and Vine Culture" can be obtained from this office, price 10s., post free 10s. 6d.

"Mushrooms for the Million" (*C. F. T.*).—The above is the title of the treatise that was alluded to in the article that you have read. The second edition of the work is now being issued from this office, price 1s., post free 1s. 2d.

Greenhouse Rhododendrons (*A. T.*).—In addition to those you have, the following will no doubt suit you, as they are of compact habit with fine flowers—*R. Veitchianum*, *R. exoniense*, *R. formosum*, *R. ciliatum*, *R. barbatum*, and *R. Taylori*. Most of the highly coloured forms are of rather straggling habit, as *R. javanicum* is the species which has been chiefly employed in raising them.

Double Lapageria (*W. W.*).—Examples of the double Lapageria rosea, also of the white variety, have been previously obtained, notably by Mr. G. Duffield of Winchmore Hill, London, N., who has had both forms. The double white variety has much larger flowers, but the red one sent by you is very similar to that he had. It is a distinctly double flower and interesting, but it is a matter of opinion whether it is more beautiful than the single form.

Vine not Thriving (*H. S.*).—There are no signs of the phylloxera on the specimens you have sent, but the Vine is evidently in an unsatisfactory condition. If the others in the house are doing well we should remove the one that is unhealthy, and either plant another, using fresh soil, or train an additional cane from an established Vine. We are not able to determine the reason why your Vine refuses to flourish. It is probably inherently weak.

Insecticide (*J. C.*).—We are obliged by the sample you have sent, and will try it. In the meantime your best plan will be to have it fully tested by good local gardeners of repute. We are not able to send the addresses of gardeners on the terms you propose. The action of the material appears similar to that of gas lime.

Rose Garden (*Mrs. S.*).—We cannot give you more practical assistance than referring you to page 82, vol. xxxvi., January 30th, 1879, where a plan will be found of the Rose garden at Mentmore, and the varieties enumerated for planting the beds. If you do not possess that number of the Journal it can be had by sending 3½d. in postage stamps to the publisher, with a request that he send you No. 931.

Pruning Vines (*J. W. H.*).—Everything depends on the condition of the leaves. If most of them are changing you may prune as you propose, as the wood you have sent is fairly well matured, dressing the wounds with knotting or styptic as the pruning proceeds. Not knowing the exact state of the Vines we are unable to give a categorical reply to your question, but we think you would lose nothing by firing briskly for a week or ten days, making the pipes quite hot, and at the same time giving abundance of air, and so producing a warm dry atmosphere. After that you might safely prune. The retention of the foliage longer than usual will be no detriment, but more probably an advantage to the cropping of the Vines.

Raising Thorns and Briars from Seed (*Oxfordshire*).—The present is the time for gathering the seed. The usual practice is to mix the haws in damp sand and let them remain through the winter, then sow in drills in the open ground in the spring, and transplant the seedlings when they are large enough to be handled conveniently. Briars may be raised in the same way; but if a few only are wanted as quickly as possible they may be had by sowing the seed in a frame placed over a gentle hotbed, the manure being covered with 9 inches of soil.

Order not Acknowledged (*W. T., Quebec*).—We have received a letter from the florist to whom you referred in your post card, in which he states: "I was sold out of some of the things named, and the parcels post to Canada being so precarious the money (10s.) was remitted, as requested, to Mr. T.'s sister in Surrey. I am surprised she has not communicated this fact to her brother." Our correspondent has sent us your name, also the full address of your sister, and you will now probably admit that you have no grounds for complaint against him. He is a thoroughly respectable man.

Various (*Park Hill*).—The Fuchsias in question are shaken out of the pots just when they are starting to grow in spring, and carefully repotted in rich loamy yet gritty soil, and when the pots are crowded with roots rich top-dressings are given and copious supplies of liquid manure. If the Primulas are placed on inverted pots they will succeed very well provided the temperature of the house and its atmospheric condition are favourable. The finest of plants are so grown, the pots being inverted on a stage covered with ashes or cocoa-nut fibre refuse. Your letter on cropping a garden is too vague, as it implies you only desire to grow one crop only. You will find an article on the culture of Asparagus in another column, but to have produce as soon as possible you should plant two-year-old crowns in April.

Propagating Chrysanthemums (*R. S.*).—Many excellent cultivators find that stout suckers inserted early in the spring and grown without check give as fine exhibition blooms as plants do that are raised from cuttings in the autumn; but if very large specimen plants are required an advantage is gained by starting in the autumn and keeping the plants steadily growing under favourable conditions through the winter. Plants for ordinary decorative purposes may be safely raised from cuttings in the spring. Some persons insert cuttings in November because their whole stock can thus be wintered in a tenth part of the space that would be needed for preserving the old plants in frames. If you have no room in frames for wintering your old plants, you may preserve them by placing the pots near a south wall or fence, packing leaves or litter closely round them, and protecting with mats in severe weather. If you have space in frames you may prevent the growths becoming tall and wiry by abundance of ventilation, removing the lights entirely on all favourable occasions. Cuttings made of tall weak shoots cannot be expected to make good plants and produce fine blooms. If you plant one each of your varieties on a sheltered border, inserting young plants in spring, growing them there and allowing them to remain through the winter, they will probably give you the best of cuttings in the spring. Very highly fed plants that have given grand exhibition blooms often fail to produce strong healthy suckers, better cuttings being almost invariably afforded by plants that have been grown in a more natural manner and not forced by stimulants.

Flowers in Rose Bed (*Irish Subscriber*).—Dwarf Roses planted nearly a foot apart ought to occupy all the bed, and there would not be any "spaces" between them if you had not made them—that is, prevented the free growth of the Roses by planting amongst them Pelargoniums, Calceolarias, and other bedding plants. The only way we can suggest of rendering the beds attractive otherwise than with Roses is to plant such bulbs as Snowdrops, Crocuses, and Hyacinths, and let them remain. These would have a cheerful effect in the spring, and in the summer the beds should be quite a mass of Roses, with no spaces between them for anything; still, if there are blanks, such plants as Gladioli and Lilliums would fill them without greatly overcrowding the Roses.

Cucumbers and Tomatoes (*Old Subscriber*).—A temperature of 55° at night is too low for winter Cucumbers. Occasionally in severe weather, and when the pipes are very hot, we have known the thermometer to register as low as that in the Cucumber house without strong well-established plants receiving any serious check; but for growing Cucumbers successfully in winter there ought to be a command of temperature of from 60° to 65°. Tomatoes will succeed in the temperature named.

Grapes not Keeping (*The Lodge*).—Grapes do not keep so well during some seasons as they do in others, and the decay of Black Hamburg is accelerated by too much moisture at the roots. Perhaps your border has been saturated by heavy rains. Your Vines, too, may have been rather heavily cropped, in which case the skin of the Grapes would be thin and the keeping properties of the fruit thereby impaired. The fruit might perhaps have kept better on the Vines; still we presume you had some reason for removing the bunches. Five weeks is not long enough for Grapes to hang after the commencement of colouring, and to cut them at that time is to cut them too soon for purposes of keeping. Is the room in which you have them too cold and damp, or liable to extreme fluctuations of temperature? The temperature ought to be equable—about 45°. Lady Downe's is a good keeper, but does not succeed well in all places. We have grown it equally well on its own roots and on the Black Hamburg stock. The easiest to grow and certain to bear of late Grapes is the Black Alicante, but its quality is not equal to that of Mrs. Pince. Duchess of Buccleuch is not a late keeper. It is a small but very rich Grape, and not likely to suit you in anything but flavour. One of the most useful white Grapes for keeping is the Trebbiano; it is a strong grower, but not particularly rich in flavour.

Thorn Apple, Datura Stramonium (*Twenty-five-years Subscriber*).—The plant of which you send a fruit bears the above popular and scientific names. It is found wild in Britain, having escaped from the gardens, and its habitat is generally among rubbish and on dunghills. It is easily known by its large oval seed-vessels, thickly covered over with stout sharp spines. The whole plant has a disagreeable, nauseous, and heavy odour, particularly when bruised, and an acrid bitter taste. It loses much of its odour by drying, but retains its properties. When taken internally, in moderate doses, it causes numbness, vertigo, dimness of vision, dilation of the pupils, produces a slight delirium, intoxication, and forgetfulness, and these effects pass off in five or six hours; but if the quantity taken be large, then all the symptoms of poisoning are presented, as heartburn, intense thirst, a feeling of strangulation, delirium, madness, convulsive movements, and paralysis; congestion of the brain ensues, symptoms of inflammation are manifested, and death follows in twelve or fifteen hours. M. Orfila states that Stramonium acts with more force on the brain than Belladonna, and produces more furious delirium. Stramonium, smoked like tobacco, is a popular remedy for the cure of asthma. Its use in this way has been derived from the East Indies, where other species are used for this purpose. It is the root and lower parts of the stem which are so employed, and the smoke excites a sense of heat in the chest, followed by copious expectoration, and sometimes attended by temporary vertigo and drowsiness. The seeds have the same nauseous bitter taste as the leaves, and in them Brandes discovered an alkaline principle called *Daturia*, combined with an excess of malic acid. It is in the form of colourless crystals, inodorous, and when first applied to the tongue is bitterish, but afterwards of the taste of tobacco; its action is poisonous.

Fruit Trees in Pots (*H. S.*).—The following extract from a description of Col. Turberville's garden at Ewenny Priory will answer your inquiry relative to the trees grown by Mr. Hawkins:—One large span-roofed house and another lean-to are filled with fruit trees in pots, and these were just at their best at the time of our visit. The trees are chiefly Nectarines, Peaches, Plums, and Pears. They are mostly about 5 feet high. The pots are from 10 to 15 inches in diameter, and they altogether number about fifty. The first glance at the trees proves them to be in excellent health—not a spotted leaf or an insect being visible, and the crops are surprising. On a small tree of Rivers' Early Alfred Peach there were six dozen of good fruits, and Mr. Hawkins, the skilled grower, speaks highly of the variety as a sure cropper. Next to this there was one of Rivers' Purple Gage Plums which had sixteen dozen fine fruit on it last year, and this season they number ten dozen. This is considered the finest flavoured of all Plums. Pears were equally fine, a small sprig of a tree of Brockworth Park bearing fourteen fruit, each more than 8 inches in circumference; Louise Bonne of Jersey had forty fine fruits. These are finer than we have seen in the open air against walls or in any other position. Some samples of Pears were extremely fine. Three varieties were especially noteworthy—Doyenné du Comice, five fruits of which weighed 4 lbs. 3 ozs.; Pitmaston Duchess, and Duchesse d'Angoulême, one fruit of each weighing 1 lb. 15 ozs.; and Beurré Diel, five fruits making a total of 4 lbs. 12 ozs. The trees from which these were gathered are very small, but, like all the others, they are in excellent health. Beurré Hardy was also fine in pots, the fruits being remarkably clean. We may look in vain for such fruit out of doors in our walled gardens; and yet these trees are not expensive to grow, as they have little fire heat and they do not need much training, supplying water at this time being the heaviest part of the labour. After the fruit has been gathered the trees are moved out to the open air, and any which require potting are shifted a little time before the leaves fall. Gritty soil from the roadside is employed, and one barrowload of horse droppings is added to every four of soil. Old bones from the house are broken up and used as drainage. The trees in pots are not forced, but start into growth naturally under glass. In this system of growing trees Mr. Hawkins has the very highest confidence, and well he may, as everyone must envy those in his position with such large crops from small trees in a fruitless season out of doors. The same trees have been fruiting for fourteen years, and they have no appearance of being exhausted. Perhaps your trees are shaded or kept too close and warm during the blossoming period. Apricots do not usually succeed so well under glass as Peaches; but with healthy Pear trees you ought to succeed by carrying out the practice described by Mr. Rivers.

Names of Fruits (*J. Burn*).—1, Warner's King; 2, not known; 3, Syke-house Russet. (*G. Snow*).—1, Golden Noble; 2, Beauty of Kent; 3, Dumelow's Seedling; 4, Golden Winter Pearmain; 5, Court Pendu Plat; 6, not known. (*R. Ogston*).—1, Alfriston; 2, Autumn Red Calville; 3, Tower of Glamis; 4, Lemon Pippin; 5, Keswick Codlin; 6, Winter Greening. (*J. L., Newport*).—1, Mère de Ménage; 2, Blenheim Pippin; 3, Red Doyenné; 4, Bergamotte Cadette; 5, Winter Peach; 6, Claygate Pearmain. (*R. J. Lynch*).—1, not known; 2, White Nonpareil; 3, Doctor Harvey; 4, Cox's Pomona; 5, Cox's Orange Pippin; 6, Dumelow's Seedling.

Names of Plants (*Twenty-five-years Subscriber*).—Datura Stramonium. see reply above. (*A Subscriber*).—It is impossible for anyone to name such fragmentary specimens, crushed and dried as they are beyond recognition. Good specimens that arrive in a fresh state will be named if possible but

sprays of flowering plants should be sent with flowers attached, this being the only certain mode of getting them named correctly. (*C. S. R.*).—1, *Æschynanthus fulgens*; 2, *Sedum Sieboldi*; 3, *Cassia corymbosa*. The *Begonia* and *Primula* were quite shrivelled on arrival from being packed in dry paper.

Comb-making (*A Bee-keeper*).—Wax is made from syrup as well as from honey, but is not considered so good, as the combs are more brittle than those made from honey.

COVENT GARDEN MARKET.—NOVEMBER 14TH.

IMPROVED DAIRY CATTLE.

(Continued from page 412.)

HAVING furnished ample prefatory remarks in connection with this subject we shall now consider the minute and somewhat difficult particulars. We hope that some breeder of experience will undertake the task which we would have gladly done twenty or thirty years ago with a prospect of having attained our object at the end of ten years from its commencement. Select first half a dozen heifers at the age of twelve months of the pure-bred Shorthorn type, celebrated for having descended from animals which shall have been notoriously great or deep milkers, and whose ancestors for a long period have been of a light brown, or patched light brown and white colour. At the same time it is of the utmost consequence they should in their generations on both the male and female side be known by tradition or pedigree to be the representatives and the descendants of a type and character celebrated for their milking characteristics, and possessing also capacious and well-shaped udders and a disposition to fatten quickly when out of use for milking. They should be noted for their perfect form and symmetry, excepting the light and bare shoulder top which we have previously stated as being of the greatest consequence as representing any tribe of full milking capacity. In order to be sure of the future generations being possessed of well-shaped capacious udders we must know the blood from which we select our heifers to have been carefully treated and managed by the dairymen and their owners. Unless this can be guaranteed there must always be a doubt as to the capacity of future generations to furnish us with animals possessing the shape of udders which we deem indispensable towards attaining the object we have in view.

To show the management necessary for this purpose, let us see what Mr. William Houseman, the greatest authority of the day upon such matters, has said in his excellent essay upon "The Management of a Shorthorn Herd" in the Journal of the Royal Agricultural Society of England, published in the year 1880. He says—"In the belief that without losing in the smallest degree the Shorthorn's usefulness as a grazing animal we may largely increase its yield of milk, I am supported by the carefully founded opinion of some of the most practical and successful breeders of grazing stock. In all probability the three-

times-a-day milking would greatly tend to cause an increased flow of milk; and a great deal, I believe, might be done by attention to the bag. In hand-milking a lazy milker goes to the hind quarters of the bag first because they are easiest to draw, and for the same reason he sticks to them longest, so that eventually they increase, while the fore quarters diminish, and a "can-bag," all down behind and shallow and shrunk in front, is the necessary consequence. Eventually the fore quarters become almost useless, not in the first cow that is so treated, but by gradual deterioration through successively mismanaged generations of cows, bred until in a great part of the stock, common as well as highly bred, which should be the dairy stock of the country, the capability of the udder is seriously impaired. More attention to this on the part of the owners of Shorthorn herds is urgently needed, not only on the part of herds kept for the dairy, but more especially of the owners of bull-breeding herds; for it is the bulls bred from cows with no fore-bags that do the mischief all over the country."

Thus we must admit how desirable it is in selecting our young heifers to make a searching inquiry, and it should be minute examination, or by our knowledge of the parents of the animals we may choose for the purpose of breeding from. We have been particular in naming heifers of the class and character described, because most practical men know the result of breeding from cows which have been mated with bulls of various colours as well as points not desirable for the object we have in view. As we have previously said and quoted from the opinions of various practical men, that with all our skill in cattle management and breeding we cannot combine in the same individual animal extraordinary fattening and extraordinary milking qualities. This leads up to the point or question of feeding of our selected stock heifers; and in order that no unforeseen obstacles may appear we advise that our heifers from infancy should be kept without artificial food, like cake, &c., but as soon as they would graze upon good pasturage in summer, and in bad weather in winter when the grass fails they should be fed upon cabbage or roots, with sweet pasture hay *ad libitum*, within littered yards and sheltered sheds. When being brought up in this way we may expect the animals will not only be healthy, but in that condition from which we may expect sound and well-conditioned calves, well calculated to answer every purpose we have sought on arriving at the breeding period. By this we mean that they should never be mated until they are fifteen or sixteen months old, so that no heifer drop her calf until she has reached two years of age; for heifers are not only surest to breed at that period, but usually prove the best milkers after calving at that age.

We must now turn our attention to the selection of a bull to mate with these heifers; and in fact it may be well to have two of the best Guernsey bulls of about two and a half years old, which shall afford reasonable hope of furnishing us with calves such as we desire. All possible care must therefore be used, not only through the good character of the parents from whence the bulls were derived, but we must especially make a searching examination into the style, type, and character of them, not only by our own experience, but also to obtain assistance from some of the best judges of cattle to assist us in our selection of the Guernsey bulls we may require. Still, let us be first assured, and accept some of the facts well known to experienced breeders as to the potency of the male in securing the quality we require in the highest degree of a butter-yielding stock, for there are various instances to adduce, both from America and Guernsey Island also, which alleges that the quality of the milk is determined by the sire, and the quantity by the dam. Let us see what Mr. Ledyard has said in his Lecture, and from which we have previously quoted, and in conclusion by the following observations—"If the purpose of the farmer is to produce butter that will meet the demand of critical consumers, he will attain the best results by using Guernsey males, thus availing himself at once of the centuries of careful breeding that have been carried on in the Channel Islands. Accidental breeding often produces cattle of great individual excellence—animals that in beauty and usefulness will compare favourably with any; but a breeder who relies upon the power of such to transmit these traits will be very likely to learn to his cost that the tendency in stock animals is to impress upon their get some of the mongrel strains that they are descended from. In the Guernsey this prepotent power of transmitting the traits inherited through a long line of pure breeding is very remarkable."

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—As the harvest was late a heavy burden of horse labour has accumulated in consequence; in fact, the preparation and seeding of the land for Wheat has been in most cases on farms in various parts of the kingdom much delayed, especially as so much rain fell in

the end of September and early part of October. This matter has been more felt on those farms where steam power is not available, for it is generally admitted that in consequence of adverse seasons for fallowing the land for five or six years past, that the land upon the mixed-soiled farms is more foul with the Couch or Twitch than formerly. The difficulty of cleaning the land during the late autumn months has been great, and has tended to delay the dung-carting on the Clover leas for Wheat, as well as preparations of any kind for Wheat on fallowed land, and also the storing of Mangolds, Carrots, and lifting Potatoes, has suffered delay, and has induced great pressure upon the horse labour as well as hand labour up to this date. If November weather occurs and prevails—viz., alternate rains and frosty mornings, it will make further delay inevitable in sowing Wheat after roots, whether they have been fed off by sheep or chopped and ploughed in for Wheat. The latter usage for Turnips and green crops is increasing in favour with the farmers because the land does not suffer as by the treading of the sheep, and the Wheat may be sown anywhen on most soils, for requiring no other manure there is no hindrance to the seed in any respect if the land is ploughed and seeded simultaneously. When this is done every ridge is seeded immediately after ploughing, so that in case of a sudden change of weather, either from rain or snow, the seeding may be completed in a satisfactory manner. However advantageously this may be done upon good and friable loams, yet it should be remembered that upon flat soils of strong land the November seed-time should not be selected or waited for. It is therefore indispensable on strong land that the last week of September or first fortnight of October should be made the seed-time on such land, and should be arranged for by the manuring in anticipation of this period for sowing Wheat with more safety, and certainty in our fickle climate, especially in the finishing off the land in the best form. On those farms where Wheat has been sown and finished it becomes a question whether the land should be ploughed up deep to be benefited by frost during the winter, or whether it should be sown by Vetches, Trifolium, and Rye. Sir J. B. Lawes continues to write upon this subject, stating that a bare fallow loses a certain amount of fertility during the rainy period; in fact he goes so far as to state that totally opposite opinions may be held upon the same subject. It must be considered whether the green crops are intended for feeding by sheep or ploughing in as manure, and this in a great measure will depend upon whether there is couch or not on the land; for although the land under green crop would lose less in fertility, yet the chances of cleaning the fallow are greatly improved as compared with the short summer tillage after disposing of the green crops.

Hand Labour.—Men have been lately employed in filling and spreading dung on the Clover leas or Peas eddishes for Wheat. The preparing of the corn for sale after having been thrashed by the steam power has employed some men both for the Wheat and White Oats, which we have been threshing lately. Men and lads have also been employed in chopping and preparing the abundant root crops for ploughing under as manure for Wheat, and we have much to do in this way yet; for where the Turnips have been sown late so much the better, when thick in plant, for no labour of breaking down is required, the crop being ploughed under without any labour of chopping or labour of hoeing while growing.

Live Stock.—On various farms in the southern districts the horned Dorset and Somerset ewes are preferred, as they bring their lambs very early. Some parties have informed us that the early lambing season has so far been successful, the lambs and ewes both being healthy; and many twins, in some cases amounting to one-half of the ewes in the flock, has been obtained. These ewes are much preferred now the early lambing Down ewes are extinct, they being originally a cross between the Horns and Downs; for although the use of the Down ram only having been continued for many years, the horned blood still existed to some extent in certain flocks, which enabled the Down ewes to lamb early, with better milking capacity, and producing more twins. These breeds of ewes are now gone, and their successors are settled down into stock of the ordinary down type and character.

REMARKS.

4th.—Fine at first; rain from 11.15 A.M. till 5 P.M.
5th.—Fine bright morning; very wet evening.
6th.—Wet morning; fine afternoon and evening.
7th.—Thick fog at first; fair day; fog again in evening with rain.
8th.—Fine day, with some bright sunshine; rain at 8.30 P.M.
9th.—Fine pleasant day; brilliant sunset.
10th.—Slight rain in early morning; bright cold day.
Temperature still falling, and rather below the average. Squally, with sharp rain on Sunday. Several exceptionally fine sunsets.—G. J. SYMONS.

NOTES FROM THE NORTH.

ODONTOGLOSSUMS.—We have recently been cutting for room-decoration some very fine spikes of *Odontoglossum Alexandræ*. One spike with two branches measured from the bulb to its top over 3 feet, and bore thirty-nine blooms each 3 inches across. Another and very superb variety had twenty-seven blooms on a spike. One had twenty-three and another twenty-one blooms, all fine varieties. To support these when placed in glasses very slender green stakes are used, to which the spikes are attached, for the weight of bloom is such that light glasses would be upset unless the spikes were kept almost erect. A bulb of *O. Wilckeanum* (a most charming flower) gave two spikes, one with fifteen and the other with twelve of its elegant and beautifully spotted and barred blooms. These are plants grown in glazed pots filled to within 2 inches of the top with rough pieces of charcoal. Very little peat is used for potting—next to none, in fact; and what is used has every particle of soil taken out of it, and the hairy or fibry part only is used. The cone of sphagnum gets entirely matted with white healthy roots, and they hang down among the interstices of the charcoal in beautiful luxuriance and freshness. At one time the charcoal was covered with a layer of finer crocks, but this practice has been discontinued with marked improvement in the condition of the roots. The material is annually cleanly washed from the roots by rinsing them in a pail of water, so that the sphagnum is always fresh and living. There seems very little fear that this charming and useful Orchid will degenerate in this country, for each year the bulbs gain in size and the spikes in vigour.

CYPRIPEDIUM SPICERIANUM.—What a charming and useful flower is *Cypripedium Spicerianum*! The smallest morsel of it produces flowers, and, like *C. Harrisianum* and some others, it seems to be a perpetual bloomer, and with the heat of the East Indian house it grows freely. It is found that a very thin layer of sphagnum over plenty of rough drainage suits it best. Its roots cling most tenaciously to charcoal and the sides of the pot, indicative of the position in which it is said to grow in its native habitat—namely, the face of damp moss-covered rocks. Speaking of roots clinging to the sides of the pots, this may be all very desirable while the plant remains undisturbed; but when shifting time comes it is a disadvantage, for it is scarcely possible to shift this and many other Orchids without considerable breakage of roots. Could pots be invented to the which the roots would not adhere, but only to the charcoal lumps, the evil might be so far obviated. We fear glazing inside as well as outside of the pots would only partially accomplish this object. As to glazed pots for some Orchids, we find them a very great advantage, in as far as they never require scrubbing; and in the case of all Orchids as require to be kept constantly on the wet side, such as *Cypripediums* and *Odontoglossums*, they are a decided advantage.

GROS COLMAN GRAPE.—A recent writer pronounced Gros Colman Grape not fit to eat, and no doubt that is his own

experience of it. Along with this I send you a small bunch of it, and leave you to tell your readers whether the above verdict be correct, and also what you think it might prove to be in flavour if allowed to hang on the Vine for two months longer. My employers are very fastidious, or rather choice, as to the varieties of Grapes placed on their table, and they have made me discard all but Black Hamburgh, Duke of Buccleuch, Muscats, and Gros Colman, and much prefer the last-named as submitted to you to any other of the late blacks in December and January. When treated on the cool system it is admitted that it is not agreeably flavoured, but when treated to the same temperature as those who grow first-class Muscats treat that Grape it has always been pronounced an agreeable Grape here.

NECTARINES.—Have any of your readers found that the Victoria Nectarine cracks in a cool orchard house in October? With us it cracks so much as to quite disfigure the majority of the fruits. This applies to a tree with all its roots inside, and to another with a portion only of its roots inside. It bears most abundantly, as all admit. Under exactly the same treatment such varieties as Pine Apple, Humboldt, Albert Victor, Elruge, Pitmaston Orange, &c., do not crack. Growing side by side we find that Victoria is only eight or ten days later than Pine Apple, while the latter is finer in appearance and flavour. Humboldt is also a splendid Nectarine, about a week earlier than Pine Apple and of the same type but larger, and well worthy of all that has been said in its praise. With great reluctance we had to banish Lord Napier from cool quarters, for, excepting the one bright warm summer that we have had these five or six years, when it was grand, it was not satisfactory.

LADY BEATRICE LAMBTON PINE APPLE.—Another year's experience of this noble-looking Pine fully confirms the high opinion I had formerly held of its superior quality as a winter Pine. About twenty fruits of it have been ripened here this autumn, and the very highest estimate of its flavour has been formed by all who have partaken of it, and I have been asked if it was Black Jamaica that was handed round. Personally I consider that Black Jamaica is the only Pine to be compared to this much finer-looking fruit, the flavour of which is superb. The juice follows the knife in a stream, and I know of no Pine more free from stringiness (if I may coin a word). It melts in the mouth like marrow. It has been grown to 9 lbs. here, and I consider it can be raised to 11 lbs. One peculiarity in its successful management is that it requires to be kept drier at the root than any other Pine after it shows signs of ripening, because it is so deep or high a fruit, and so full of juice, that if kept moist the juice oozes from its base before it is ready to cut. It should also be cut with a green tinge upon it, and this is the stage in which all Pines are best flavoured in autumn and winter.

CALANTHE VEITCHII.—A few years since I called attention to the fact that there are two, if not more, quite distinct varieties of this grand *Calanthe*. In referring to this fact in a private letter to Mr. Speed of Chatsworth, he said, in reply, that he never knew there was more than one variety, and I sent him what I consider the best one, and he tells me this season the distinction is most marked. A similar correspondence with Mr. Wescott at Raby has led to the same result. The one most generally in cultivation has the middle of its bulb very much contracted, just like the waist of a fashionable lady. The other variety has no contraction, and tapers gradually from base to apex. The flower of this later variety is of a much deeper, and, as I consider, finer colour. Mr. Speed says he fancies the narrow-waisted bulb produces larger spikes, but I have not found it so. Several years since we discontinued growing the bulbs with the contraction because I considered the other so much finer than it. Those who have not this deep-coloured sort should certainly procure it.

SINGLE FLOWERS.—Those who have a fancy for single flowers—and who has not?—and want them in plenty after single Dahlias, yellow and white Marguerites, &c., are de-

stroyed with frost, should grow *Pyrethrum serotinum* and *Chrysanthemum lacustre* for whites. We find the former of these especially stands 10° of frost without the flowers being injured in the least. For yellow there is nothing more effective or hardy than *Rudbeckia Newmanni*, and for purples *Asters amellus* and *bessarabicus* are excellent among the dwarf and larger-flowering *Asters*. Then for another shade of colour—what shall we call it?—a reddish violet—there is *Senecio pulcher*. These for cut flowers and for furnishing large glasses or bowls are invaluable, and should be grown by the hundred for cutting late in autumn, and particularly in cool damp soils and climates like this.—DAVID THOMSON, *Drumlanrig*.

[The quality of the Gros Colman Grape above referred to is excellent, and such fruit is quite fit for the table of a Duke, however great a Grape connoisseur he may be. We have never tasted this Grape half so good when grown and ripened in a very low temperature.]

ANEMONE JAPONICA ALBA IN POTS— PROPAGATING.

THIS plant deserves the post of honour amongst hardy plants for flowering in the autumn. It has lately been much the most effective plant outside, and there is no question about its usefulness for decoration and for cutting. Some attention is needed when planting in order to extend the flowering period of this plant. Those placed in warm positions will bloom much earlier than those in less favourable situations, and the batch for late flowering should occupy a place on a north border. Those planted in this position should be so arranged that slight protection could with ease be applied to them during cold nights when the temperature is likely to fall below the freezing point. All that is needed is a light temporary framework of wood over which mats could be secured, or, better still, if the framework is sufficiently strong to support old or spare lights. Sooner than allow a fine late batch of this useful *Anemone* to be cut off by a few untimely frosts, we would recommend the plants to be lifted and potted.

It is an excellent plan to prepare a batch of plants in pots for flowering indoors late in the season, and nothing when well grown can surpass them for effect or beauty in the conservatory or greenhouse. After the plants have been raised for outside planting they should be potted in rich soil in 6-inch pots. After the completion of this operation they should be plunged outside on a north border, or in any position not fully exposed to the sun. To produce the plants that will flower late in the season when required indoors is the object to be attained, for seldom are hardy plants considered choice or much appreciated indoors when their flowers can be gathered outside in abundance.

The pots should be plunged for the purpose of saving labour in watering; in fact, they may be entirely covered with the plunging material or with soil. Stimulants will be found very beneficial to the plants after their flower spikes are visible. If worms take possession of the pots while they are plunged, a good soaking of lime or soot water will quickly eradicate them, and the soil can be pressed again afterwards firmly into the pots, and the plants top-dressed with fresh compost. Although this plant will bear lifting well, and will open its flowers freely afterwards, it is decidedly preferable to establish a batch in pots for late flowering.

I had thought that the old system of propagating this plant by division of the crowns had been discontinued, but I find to the contrary that it is still practised; and I am inclined to believe from the many inquiries that have been made during the past year or two that the method of root-propagation is not generally known. Some seven or eight years ago I first saw the root-system practised on a large scale in a nursery. A small portion of root was placed in the centre of 2 and 3-inch pots, which were afterwards stood in frames, and in a short space of time to my surprise hundreds of small, healthy, vigorous, saleable plants were the result. There is no risk to be incurred by the root form of propagation, and anyone anxious to increase their stock may safely lift the whole, or greater portion of the plants they possess, as the case may be, remove their roots, and convey their crowns to the rubbish heap. The roots should be cut into lengths, and every portion, if only half an inch in length, will produce a plant which, if well cared for, will make a strong flowering plant by autumn. None need fail with this quick and

ready system of propagation. If plants have to be purchased for a start obtain them as strong as possible (even if a larger price is required for them), so that they will possess good roots, from which a stock can be obtained. The whole of the roots can be taken and cut up, and the tops thrown away; this I should do if I wanted as many as possible. After the roots are cut into lengths they can be laid thickly together in pans or boxes filled with old potting soil amongst which has been intermixed a fair per-centage of leaf soil. After the roots are laid in scatter over them a little coarse sand, and cover them with about half an inch depth of fine soil. If strong plants are wanted a start may be made as soon as roots can be obtained, and the boxes containing them placed in an early vinery or Peach house that has to be started next month. In this position they will soon commence growing, and if placed thickly in the boxes will need to be transferred to others, as soon as they commence rooting, a certain distance apart, so that they will have room to grow until it is deemed safe to plant them outside. It is better to start the roots during the month of December even if they can be obtained at once, for they can be kept perfectly fresh amongst cocoa-nut fibre or even in the soil outside, until they are wanted. When started a little later they can be placed in cold frames, after they are well started or planted out of the boxes, on to a slight hotbed that has been prepared for them, with about 3 inches of old soil on the surface. The hotbed is by no means necessary, the other houses are free of them, and the boxes set at liberty; and the frame, if a moveable one, can be removed from protecting the young plants after they are well hardened, and used for other purposes. We prefer planting them out in frames to either keeping them in small pots or boxes until they can be finally planted outside; they can be lifted with good roots, and do not become so crowded as is the case when confined in boxes. When the time arrives for planting them outside the smallest can be retained for placing in pots for late flowering, and the remainder planted in various positions in moderately rich soil.

This plant should be grown in quantity, for it is at home in almost any position, and is invaluable for the neighbourhood of smoky towns, where it appears to grow as luxuriantly and flower as profusely as it does in the pure atmosphere of the country.—W. B.

MANURE AND MOULD FROM BEECH LEAVES.

"A. F. M.," at page 292, in a few remarks headed "Beech Leaves and Fungus," in which he refers to the fact that mould or manure made from Beech leaves are often (he seems to think always) hurtful, because of the fungus so liable to form where Beech leaves are. There can be no doubt of the correctness of what your correspondent states *so far*, but at the same time, while having seen all that he describes, we think it is only under certain conditions that mould or manure from Beech leaves is so infested, and have used quantities that was perfectly free, and seen them largely employed by themselves and in mixture with no evil result. At the same time I do not profess to quite understand the matter, and was in hopes someone thoroughly familiar with the subject in all its aspects would have done so. The present is only a contribution to the subject, and it is hoped some others may benefit your readers with their experience.

In different situations it has been my experience to see Beech leaves collected in quantities in autumn and stored in pits, sheds, and otherwise as dry and as firmly as possible for use in spring, liberally mixed with stableyard litter, in the formation of hotbeds. After serving this purpose during the spring and summer months, the beds in some cases being made up more than once with the addition of some fresh material, the best of the resulting mould we have seen used for all purposes, but especially for mixing with loam in which to keep bedding stuff over winter, and also for raising seedlings of all descriptions in the following spring, as well as for potting up numbers of plants. Many gardeners prefer this to pure leaf mould, as it is always richer, often because of the careful preparation to which it had been subjected, sweeter, and generally drier and more workable. We do not remember a case of this kind where fungus proved troublesome.

Again, about large places where Beeches thrive it is no uncommon thing for the leaves to be largely collected, mixed with road-rakings, ditch-clearings, and sometimes, sometimes not, mixed with lime and used as manure in the farm or in the garden. Under such conditions it never (or seldom) generates fungus to an observable extent.

In one district where we are very well acquainted there is a large wood of very fine Beeches. The villagers close by in winter gather the leaves from this wood largely for littering their pigs and making manure, which they put out for growing Potatoes with the farmers (the latter giving the land free, in return for getting their land cleaned and enriched), and though we have often seen these cottagers' plots, we never saw anything but the finest Potato crops. Neither do the rakings, partly mud but mostly leaves, gathered from a public road that traverses the wood have other than a beneficial effect.

There remains the other side of the picture. Some years since a few miles from where we then lived a new-come gardener, in his anxiety to improve the Vines, lifted and treated the roots as Mr. Iggulden did his

with so much success, but with, not successful—disastrous results. Correctly or not I cannot say, but having employed Beech leaf mould, he attributed his failure to that. Sure enough the Vines were destroyed with fungus in their roots.

Repeatedly have we employed Beech leaves, and leaves where Beech were largely present pure and simple, for forcing Seakale and Rhubarb where it grew, and afterwards used the leaves partly to form mould, partly to form manure, and never saw fungus in them. But we know one place at least where the leaves so employed go into one grey mass that cannot be used for anything afterwards. In both cases boxes were used.

Again, at the very place where the cottagers employ Beech leaves with so much success to make manure, the farmer dare not do so. With them the resulting manure is overrun with fungus. In this case we are inclined to think that the drier state of the stable manure, partly securing a high temperature, partly because of the comfortable state of the medium as regards moisture, produces the fungus. Mixed with mud, as in the case of road-rakings, with earth as in other cases, or much too wet and cold, as when used to litter pigs, the leaves get past the fungus-producing period before it finds thermal and other conditions favourable. But this by no means accounts for the sweet fungus-free mould produced by well-made hotbeds. At the same time gardeners well know how apt ill-prepared manure is to produce an evil crop of fungus and that well-sweetened does not.

At one large country domain where the leaves are collected into heaps, the masses become one mass of fungus. For this reason they are now, we believe, burnt. But again and again we have collected the best of leaf mould from where the leaves had drifted. Collected leaves we have thought have a tendency to produce fungus, and the sticks collected with them may be one cause of this. Another may be that, when collected dry they are with difficulty properly wetted afterwards by natural means. It is only slowly that the damp penetrates. But as it gradually creeps to the centre does not the favourable condition follow or accompany it for producing fungus?

Drifted leaves are generally free of sticks and of mast husks. Moreover they are not in such large heaps, and, therefore, become readily damp and of too low a temperature to encourage the crop that the collected heap encourages. That leaves dug in dry in spring will turn out dry and undecayed in autumn is very true, and this points to the necessity for thoroughly preparing such before applying.

That pure mould, free from fungus or anything hurtful, may be made from Beech leaves, and is, in fact, plentiful, is undoubted. That other Beech leaf mould exists full of fungus and poisonous is also undoubted. That both are found under the same conditions may be doubted. We may end with the confession that we cannot tell exactly what these conditions are, though we have endeavoured to indicate them. If anyone can tell us more clearly the information will be welcome.—SINGLE-HANDED.

GROS MAROC v. GROS COLMAN.

THIS Grape, which some seem to think will in a measure supplant Gros Colman has not, in the experience of the writer, proved such a fine variety as some persons assert it is. The berries of such samples as I have grown and seen do not approach Gros Colman in size, and the general appearance of the bunch is not so massive and handsome as Gros Colman. Undoubtedly the bloom of Gros Maroc is fine; in this respect it excels Gros Colman, though not by much.

The keeping qualities of Gros Maroc are not better if as good as Gros Colman; the flavour is not so good, the skin thicker, and the flesh less firm. Taking everything into account, Gros Colman must in my opinion still maintain the premier place as a noble-looking, prolific, long-keeping black Grape, possessed of fair flavour and of a splendid constitution. Whether Gros Maroc will keep better than Gros Colman when bottled has not yet been proved, but if it does it will be almost the only point in which it has the advantage of its noble rival.

Gros Maroc may, perhaps, be said to colour quicker and with less heat than Gros Colman, but the latter when well finished, as it can easily be when not too heavily cropped, amply repays its cultivator for any little extra heat expended on it.—S.

POLYGONUMS.

THE genus Polygonum is generally designated "the weedy genus," but there are nevertheless amongst its members many useful and exceedingly ornamental for the rockwork, the flower border, and for isolating in woods, &c. They are widely distributed in this and other countries, and seem suited to almost every condition of soil and climate.

Polygonum orientale.—This is represented in the woodcut, fig. 86. Although introduced to this country nearly two centuries ago it does not seem to be so well known in gardens as its merits deserve. It is a native of the eastern parts of India and the Levant, and was first sent to this country by Tournefort, who found it growing in the monks' garden near Mount Ararat, and where it was cultivated principally for the brilliancy of its flowers. It is seen to the best advantage when grown in a rich moist soil, where it often reaches from 8 to 10 feet in height, and has a most charming effect against a dark green background. The leaves are oval-shaped, slightly pointed, of a dark green colour, and covered with

soft hairs. The flowers, which are of a fine lively red, are borne on close terminal spikes 7 or 8 inches long, and often hanging downwards. It flowers from the beginning of July until cut down by the frost, and although only an annual the seeds are produced so plenteously that there is no fear of losing it. It is usually sown in spring along with the other annuals, simply thinning the seedlings to about a foot apart.

P. sachalinense.—For isolating in pleasure grounds or woods this is the noblest species of the genus. It forms clumps from 10 to 12 feet high and half as broad. The stems droop gracefully all round, and are well clothed with large and beautifully veined leaves, bright green, and undulated at the margins. It is, however, herbaceous, and care must be

Fig. 86.—*Polygonum orientale*.

taken to plant it only in places where it will not leave a gap or appear unsightly during the winter and early spring. The roots have a tendency to run, and unless allowed plenty of room will be rather troublesome. The flowers are inconspicuous.

P. cuspidatum.—A species introduced from Japan about 1824 by Siebold, and generally known in gardens under the name of *P. Sieboldii*. The leaves are broadly oval, having marked red margins, and the flowers, which are borne in bunches, are pure white or tinted, very numerous and effective. It forms a compact bush 6 to 8 feet high, and is admirably adapted for making a screen or planted in company with the above.

P. vacciniifolium and *P. affine* are both very useful for rockwork when planted with a view to hang over ledges or for covering bare slopes facing south or west. Flowers pink.

P. molle.—A half-shrubby species of North India, having dense panicles of small white flowers. *P. amplexicaule* and its varieties *P. Weyreichii*, *P. polystachum*, &c., are all very useful and effective for backing up rockwork.—W.

POTATOES FROM SEED—AMERICAN EARLY.

I HAVE been reading with great interest the various articles which have appeared for some time back in the Journal, but should have benefited more if the writers had mentioned the part of the country wherein they reside, and the nature of the soil experimented upon. Irrespective of the Potato question, might it not be a good rule for your contributors to state the country where their experience has been gained, also the height above sea level and the kind of soil? The average rainfall would be useful if obtainable. With these data much information could be gleaned which is otherwise lost or thrown away.

It appears to be generally admitted that the best way to eradicate the Potato disease is to raise new varieties from seed, and thus get a more vigorous race of plants. My own experience leads me to differ from this theory, inasmuch as that a number of years ago I began to raise seedlings, but could rarely save them over the first season in consequence of disease, and after four or five years' trial the attempt was given up in despair.

There is a Potato which has been cultivated hereabout for over half a century, known as the American Early. I have grown it in the same garden for more than twenty years, saving my own sets, and consider it less subject to disease than any of the new varieties which have recently been sent out. It is only about a fortnight later than the earliest of the other round varieties, is a fair cropper, and of first-rate quality for the table, besides being as handsome to look at as most kinds. I am aware that there is a Potato in the market of the same name, but it is an inferior strain, and I have never been able to purchase it true. I enclose three tubers taken at random from the seed bag, much handsomer ones could be selected. The soil here is sandy loam, 500 feet above sea level.—M. G. F., *Berwickshire*.

[We have grown the American Early for years, and it was one of the few that escaped the virulent attacks of the murrain with us in 1845 and 1846. It is an excellent second early variety.]

ORCHIDS AT BRIDGE OF ALLAN.

I LATELY enjoyed another visit to Fernfield. Dr. Paterson's cool treatment of his Orchids—not of his visitors—is vindicated by the splendid health of the whole stock, which quite fills without overcrowding the houses. I found the subjoined in flower or about to bloom:—

Cattleya maxima, *C. marginata*.
Cypripedium Spicrianum, *C. Sedenii*, *C. Roezli*, *C. Maulei*, *C. insigne*, *C. Harrisonianum*, *C. venustum*, *C. javanicum*, *C. longifolium*.
Cymbidium giganteum, *C. Lowii*.
Calanthe veratrifolia, *C. Veitchii*, *C. lutea*.
Cœlogyne Gardneriana, *C. speciosa*, *C. ocellata maxima*.
Dendrobium album.
Dendrochilum filiforme.
Epidendrum ciliare, *E. latifolia*.
Lælia purpurata, *L. superbiens*, *L. Perrini*, *L. autumnalis*, *L. anceps Barkeri*.
Lycaste Skinnerii.
Maxillaria lepidota.
Masdevallia tovarensis, *M. amabilis*, *M. maculata*, *M. aurea*, *M. melanopus*, *M. ichtbodes*, *M. Veitchiana*, *M. Davisii*, *M. ignea*.
Miltonia spectabilis, *M. Clowesii majus*, *M. Moreliana*, *M. atro-rubens*, *M. candida*.

Oncidium tigrinum, *O. tigrinum Barkerii*, *O. macranthum*, *O. Kramerii*, *O. Rogersii*, *O. linguiforme*, *O. serratum*, *O. cheirophorum*, *O. Schlimii*, *O. aureum*, *O. incurvum*, *O. ornithorhynchum*.
Odontoglossum Londesboroughianum, *O. pulchellum*, *O. Alexandrae*, *O. Pescatorei*, *O. bictonense*, *O. grande*, *O. Lindleyanum*, *O. nebulosum*, *O. candidulum*, *O. Hallii*, *O. cordatum*, *O. cirrhosum*, *O. Uro-Skinneri*, *O. Rossi majus*.
Phalenopsis Schilleriana, *P. grandiflora*, *P. Lowii*.
Plicone maculata, *P. Reichenbachiana*, *P. Lagcnaria*, *P. Wallichiana*, *P. præcox*.
Sophronites grandiflora, *S. cernua*.
Saccolabium giganteum, *S. gemmatum*.
Sarcanthus crotifolius.
Stenia fimbriata.
Vanda Cathcartii, *V. cœrulea*, *V. multiflora*.
Zygopetalum Mackayi, *Z. M. Patersoni*.

There are also in flower in the Orchid houses Amaryllis in variety with Nerines.—A NORTHERN AMATEUR.

STORED-UP SAP IN VINES.

A CORRESPONDENT (see page 396) signing himself "A Non-Believer" asks some pertinent questions respecting my physiological creed, which I shall have much pleasure in answering to the best of my ability, but at the same time I must tell him plainly he has no right to assume that most "experienced gardeners" are as far behind as he represents them to be. Let your correspondent be content to know that he has represented clearly the state of his own knowledge, and as he is anxious to learn he will doubtless find others more capable than myself willing to help him forward. Your correspondent says, "What is meant by root-action is the absorption of food from the soil." Well, this is part of its meaning, but not all. But he proceeds, "and this begins as soon as the Vines are started." We will see.

Those parts of a plant which are underground have in many respects their corresponding parts above. Thus, the main roots or "underground

stems" are analogous to the stem proper. The divisions and ramifications of the main roots have their corresponding parts in the branches, and both act mainly as channels for the conveyance of material from one part of the plant to another. These parts are all perennial—i.e., lasting several years.

Then we have the soft spear-pointed roots, darting about in all directions and seeming to be endowed with something like instinct, enabling them to travel the shortest way to obtain the plant's necessities. These we may, if we like, compare to the green growing shoots above, for, like them, they take up less room the second year than they do the first. And lastly we come to the real workers, the root-hairs and the leaves, and both of these are only of annual duration. All the good the plant receives from the soil, with perhaps the exception of water, passes through these root-hairs, and they are only formed on *new* growth. The part of the root which bears them is soft, and varies in size from that of a small pin to a goose-quill. Some time in the following winter the hairs and the epidermis of the root which bears them will decay, leaving only a small wire-like root, which will in turn emit other hair-bearing roots, and become itself, like its predecessors, only a channel of communication. Then your correspondent will see that one reason why the Vine does not begin to feed at the root at the same time it starts at the top is that it has no roots to feed with. Plums and most other fruit trees start at the root first. Why they do so I will not enter into here, and only mention the fact to show that the Vine, as far as I know, is unique in this respect.

A little further on your correspondent laudably endeavours to correct us by saying that "some people wrongly apply the term root-action to root-growth or extension." I confess to being in this company myself, and need hardly add to what I have already said, that root-action and root-extension are, for all practical purposes, synonymous terms.

To keep the point clearly before your readers I must again quote your correspondent's words. He says, "What is meant by root-action is the absorption of food from the soil, and this begins as soon as the Vines are started. If this is not so, will Mr. Taylor explain the well-ascertained fact that a Vine cut off at the root does barely more than burst its scale buds before it dies?" Whether such a Vine lived or died would depend entirely on its treatment. If it was cut off early in autumn and the greater portion of its stem buried, with a few inches of suitable soil above it, and kept where it would neither lack a suitable temperature, sufficient moisture, nor sufficient light, it would not only live, but, making allowance for the time it would take to emit roots where there had been none before, it would produce some fairly good fruit the first season. It probably contains in itself all that is necessary for the first stages of development, but as when above ground it is subject to evaporation, a certain quantity of water is necessary to make up the deficiency; and as a log of wood or even a brickbat is capable of absorbing water to its full length when one end only is placed in a moist medium, we cannot wonder that a living plant should do the same, even when it has no working roots.

The liquid which comes from a Vine stem when it is pruned too late in the season is, I believe, very little if anything more than water. It is perfectly tasteless, and beyond keeping the wound open probably does no harm. There are some Vines which have been so starved and badly managed that they will scarcely bleed with any amount of amputation; and again there are some—I had the manipulation of some such last spring—which bleed, as it is called, at every berry stalk when the Grapes are thinned. The growth of foliage will not always stop the bleeding; it is simply a question of degree. If the Vines are very vigorous they contain a great quantity of water, and some of it will exude. If they have been starved and stunted their cells are probably barely sufficiently large to draw up even the necessary quantity.

There is one sentence towards the end of your correspondent's communication, which although correct in this instance might mislead some readers who have not followed what I have written before on the subject of watering. I never allow the soil of a Vine border to become dry. Although it does not require as much water in winter and spring, and it is worse than useless to water it when it is already wet, it must never even approach dryness except on the surface.—WM. TAYLOR.

CAULIFLOWER AND BROCCOLI ALL THE YEAR ROUND.

THE subjoined directions are intended to supply general information, and must of course be adapted to the peculiar circumstances of each locality. The dates are transcribed from a diary in which the records of culture were carefully entered.

A continuous supply of Cauliflower and Broccoli can be maintained in the following manner:—Sow Walcheren Cauliflower the last week in August, plant out the 24th of October on a warm border, as thick again as wanted for a crop; leave the small plants on the seed bed until March; in that month thin out the crop planted in October to the proper distance, filling up the vacancies caused by the frost; then plant out a good batch in March of the plants left on the seed bed in October; they will come in May, June, and July.

The first week in February sow Walcheren, or any sort of similar constitution, in a warm quarter; then sow a little more the first week in March at the foot of a wall in case the February sowing fails. In the third week of April plant out two good batches of those on a

quarter of the kitchen garden ; they will come in July, August, September, and October.

In the middle of April sow Veitch's Autumn Giant and Walcheren ; the latter is useful, as the leaves cover the heads, keeping them dry and from being spoiled by the autumn frosts. This is the sowing that produces heads in November, December, and January. The plants must be protected in frosty weather. If they are taken up with good heads and laid in soil out of the frost they will keep a month or six weeks, and be none the worse for table use. Those with small heads ought to be placed in soil in frames, and covered with mats to protect them ; they will grow and produce good heads in January.

A small pinch of seed is sufficient to sow at a time, and 2 or 3 ozs. will be ample for all the sowings mentioned, unless the garden is extensive. Cauliflowers like plenty of manure and the ground well trenched, but some soils are poor, and will not do trenched ; in that case it is best to dig deep, and place the manure at the bottom of the trench. Always plant 2 feet apart when planting for a crop.

BROCCOLI.—For insuring Broccoli for the kitchen in January, February, and March precautionary measures should now be resorted to for Broccoli as well as Cauliflowers. The first batch that require protection now should be sown on a warm border the first week in March. Snow's Winter White Broccoli sown then will come in for cutting in January, February, and March, after the Walcheren Cauliflower ; plant out as soon as the ground is ready ; it should be well mulched, and trenched 2 feet deep. The end of October lift the plants with earth attached to the roots, and lay them in up to their leaves in a frame or some place where they can be protected with mats, straw, or Fir boughs in frosty weather. Snow's is by far the best Broccoli, as it come in at a time when most useful. There are perhaps other sorts that will come in the same time as Snow's if treated the same, but I have not seen them.

For succession sow on a border during the first week of April a little of about three sorts to stand in the ground all the winter. Snow's Winter White will come in in March and April ; also Adams' Early and White Malta. Though these are winter sorts they are rather tender. Plant out in June. In October or November lay them on their sides, facing north or westward. The way to do this is to dig out a trench before the first row, put the spade the opposite side, prise them ; dig out another trench for the next row, and place the soil on the first, and cover them up to their leaves. If not protected in this way and a sharp winter follow this batch is sure to suffer.

Again, sow three sorts during the last week of April. These will come in for cutting in April and May. Dilcock's Bride, Dalmeny Park, Salter's Imperial, with any other approved late sorts, are good for this sowing. During the third week of May sow two or three of the latest kinds. Cattell's Eclipse, Barr's Champion, also Late Mammoth and Dwarf Russian are suitable. I have seen a splendid lot of these in May and June, when there were plenty of Walcheren Cauliflowers from the autumn sowing ; thus by attention to sowing and treating Broccoli and Cauliflower heads may be cut all the year round, unless the winter is unusually severe. There are several other old and new sorts that will come in at specified times.—A FOREMAN.

WATERING PLANTS—CHRYSANTHEMUMS.

By the reference to the above subject at page 218 of the *Journal of Horticulture* the full meaning of my previous paper is obscured. With regard to watering, the remarks were intended generally. As there is no rule the guide I should take would be the plant. If it is a Chrysanthemum, water should be given to keep the plant fresh and vigorous. To the inexperienced an examination of the soil will be necessary to ascertain its condition of dryness. The opposite is to be avoided, as upon the solidity of the plant the character of the bloom depends. Perhaps there is no plant so easy to keep in bounds as the Camellia by limiting the supply of water. I refer to those inclined to produce second growth. I should not think of deluging such a plant, or to keep a starting Strawberry plant soaked with water, or a sickly Azalea recently potted watered on the principle of giving the supply to-day which it may require some future day. Such treatment consigns numbers of plants to the rubbish heap. The Cineraria so treated flags with the first bright sun in spring and soon dies.

The chemical constituents of the Chrysanthemum were, to the best of my belief, correctly given. The experiment was made several years since, and I have not at hand the notes for reference. If it serves no other purpose it will assist the gardener in his selection of compost to suit the individual plant, and stand in good stead of an array of figures which look so well on paper.

The Hyacinth, as an example, is built up strong in ammonia and potash? The question is, When does the Hyacinth require those substances? We cultivate the Hyacinth to develop the spike of flowers within the bulb, and from the conditions under which the bulbs are placed after potting decomposition of carbonic acid cannot be effected. We may therefore rest assured the safest compost to use is an almost insoluble one—pure silica with a little vegetable matter.

Next in order comes the Liliium. The ash obtained from the bulb

is not easily reduced. I suspect silica and iron are present, but silica dominates. Why does the Liliium bulb gradually become less in some soils and disappear? Silica is acted upon by lime (bones), ammonia, and carbonic acid, hence the benefit of preparing composts in a moist condition free from drenching rains some time previous to being required, allowing plant food to digest and become soluble.

In the use of manures blood, bones, guano, and preparations from slaughter houses never fail with myself to produce mildew on Roses and Chrysanthemums, especially in the latter stages of growth. Amies' chemical manure prevents mildew, and has given the most satisfactory results in the cultivation of the Rose and Chrysanthemum, washing the substance into the soil of the pot. The first-mentioned manures are used variously, solid and in solutions, and applied during the period of growth to many plants, including Ferns and Orchids.—C. PRINSEP, *Hammerwich*

GARDENERS' BENEFIT SOCIETY.

DOUBTLESS there are many like myself anxious to tender their thanks to Mr. Heale for his letter on page 339 ; also to our good Editor for his able article on page 349. I was previously quite ignorant of the existence of the United Horticultural Benefit Society, and I was, therefore, agreeably surprised to read Mr. Heale's letter. I now see no need of carrying out my suggestion (page 332), as this meets my ideas of a Gardeners' Benefit Society better than I could have expressed them myself. The chief thing that I see wanting now is for us all to unite and make it truly a Gardeners' United Benefit Society ; then we may hope soon to see "A Sussex Gardener's" (page 374) suggestion carried out, and have country branches established (but as he rightly says not at public-houses), with a horticultural library attached to each, always keeping one grand centre for all to look to for advice, &c., as I think it is always best when the younger know who is the head of the family. I think Mr. Divers has spoken very truly on page 402, when he says by joining such a society we are helping our brethren whose occupation is far more healthy, and their social life and morals are better than many mechanics. I think "J. B." (page 403) has offered a capital suggestion—namely, that your article on page 349 be reprinted and a copy sent to every gardener. I hope the Society will take the hint, though I suspect Mr. McElroy has found nearly all his spare time occupied of late ; but I will not encroach upon your kindness farther only to express my thanks (and I hope every gardener joins with me) for your kindness in giving publication to letters on this very important subject.—J. SMITH, *Hampstead*.

MUCH good has doubtless resulted from the publicity given in your columns to the "United Horticultural Benefit and Provident Society," and with the object of bringing its claims prominently before the gardening fraternity "J. B.'s" suggestion (page 403) deserves the notice of the Committee.

I would also offer two suggestions that may prove worthy of their attention.

In the first place, that printed forms be circulated amongst gardeners for the purpose of obtaining subscriptions from employers and others towards its funds ; also that the standard of age for members withdrawing their moneys be reduced at least five years. Surely if needed at all it is needed before attaining to the mature age of seventy, for, healthy as our calling is, comparatively few are able to cope with a day's work after sixty years of age ; and still fewer employers are generous enough to retain men in their service who cannot fully earn their pay.—T. L.

[This point was strongly urged when the Society was founded ; but the Government actuary did not feel himself justified in admitting it, and the proposal, we believe, had to be withdrawn to insure the enrolment of the Society].

I HAD no idea there was such an institution in existence as the United Horticultural Benefit Society until October 25th. I have written for the book of rules of the Society, as I hope to become a member. I think it ought to be advertised as a means of inducing others to join, also to have branches in different parts of the country the same as other benefit clubs, for I am confident it would be well supported in time. I have watched the various articles in your columns concerning the Gardeners' Royal Benevolent Institution, and I was in hopes the Secretary would answer them, but they appear to be unnoticed. When I have looked over the rules of the Benefit Society, with your permission I shall, perhaps, say more about it.—J. S.

WILL you kindly allow me a brief space in your columns for a word or two of explanation? I regret that the introduction of a single word—harmless as I certainly intended it to be—should have been misunderstood by your correspondent Mr. Coates ; but it seemed to me not inappropriate in a matter affecting gardeners to call a spade a spade.

Nothing could have been further from my thoughts than to cause the slightest breath of suspicion to rest on the management of this excellent institution ; the men who have the direction of its affairs in their hands merit the confidence and thanks of all true horticulturists for their laudable endeavours to stretch out a helping hand to their fellows in the craft in the hour of need ; and it appears from your editorial note that their "light" would not have been "hid under a bushel" had adequate funds existed for making the Society and its objects widely known. It remains, then, with every British gardener to help himself and the executive of this worthy institution by becoming subscribers,

and make it really a "united" society. Then will it possess that strength which we are truly told is the result of unity. I have joined the Society, so that my preaching has been reduced to practice, and to this, I presume, your correspondent will have no serious objection.—J. B.

YOUR excellent article on this Society, I am very pleased to say, has already borne fruit, several gardeners having informed me they have joined the Society or are about to do so. In my letter using the word "lukewarmness," I did not intend to wound anyone's feelings, but those who, like myself, are aware that the Society was originally advertised and made public in the gardening periodicals will thoroughly understand my using the term; and I trust, now the Society has been brought prominently before the gardening community, that they will not take notice of phrases to which probably the writers attach only a harmless meaning, but endeavour to make the Society known amongst their friends and neighbours; and I hope at the annual meeting (the second Monday in February) to see a goodly gathering of both old and new members, and no doubt the Committee would be pleased to see anyone who was not a member, but wished to observe how the business is conducted.

Having drawn up the rules of the Society and passed them through the "Registrar of Friendly Societies and the Government Actuary's hands," I have naturally felt great interest in the welfare of the Society, and I can fully endorse all that has been said about the good management and the most satisfactory manner in which the Committee carry out the rules. I have probably tried them (*i.e.*, the Committee) more than anyone else when residing in Scotland, and always found them to carry out in every case the intentions of the founders in a thoroughly business-like manner. Referring to holding meetings at hotels or public-houses, this has been unavoidable. The Committee pay for their room for the monthly meetings, and nothing more is required. If gardeners will now muster as they should do, and join in large numbers, the Society may some day be able to afford offices of their own.

"J. B.'s" suggestion that the Committee would do well to have your excellent article reprinted and a copy sent to every gardener is a step in the right direction, and if the Committee do not see their way to do it before, it will be brought forward at the annual meeting.

I hope the time has now come and the tide has turned, and gardeners will join the "United" and make it one of the strongest societies in the kingdom. The more members join the greater will be the benefits in their old age. The motto of the Society is "Union is Strength."—WILLIAM HEALE, *Messrs. Chvals', Lomfield Nurseries, Crawley, Essex.*

STORING GLADIOLI.

A FEW hints respecting these may be of service to many at the present time. It will be necessary to lift the corms and store them in a frost-proof place, but do not dig them up till it is absolutely necessary, in order to save them without running undue risk. This is of importance in more than one respect, but more especially to thorough maturation. If any seed pods are on the stems collect them as soon as they begin to burst, as the varieties raised from this seed may be as good as those that produced it. Whenever the corms are lifted they should be laid in an airy place, leaving the stems upon them till quite dry, when they may be removed with the withered roots, and the corms cleaned ready for storing. A very good plan is to keep them in small flower pots or boxes filled with dry sand, just covering the corms, and place them in as cool a place as possible to the exclusion of frost. Whatever temperature protects Dablias and Potatoes will answer equally well for the preservation of Gladioli, and there they can remain with their tallies till the middle or end of March, when the first batch may be planted, planting the remainder about the middle of April. It is preferable to plant in two or more batches, as the flowering period is greatly extended, and no plants are more effective in the borders, while for certain decorative purposes spikes are unique. At harvest festivals they are indispensable, especially the rich-coloured selfs, than which no variety is more appreciated than the old *brenchleyensis*. This, too, has the advantage of being almost ridiculously cheap. Good corms may be purchased at 1s. per dozen, whereas no florist thinks of charging less than 4d. per spike for them in flower; thus a good investment offers itself to those requiring such flowers during the late summer and early autumn months.

When raising the corms a quantity of small bulbils will be found attached to the base, which are called in the trade "spawn," and by means of which the stock of the named varieties is augmented. Presuming the amateur feels disposed to increase the stock by that means, the spawn should all be carefully removed, each kind being labelled and placed in small boxes or pots and slightly dried, then covered with dry sand until the spring, when they should be planted thickly in rich sandy soil in a sheltered corner. They will increase greatly in size the first year, and will ultimately produce corms equal in size to the parents. The process requires time and patience, but the reward is sure. We would encourage the raising of seedling Gladioli on a much more extended scale than is at present accomplished, because the stock is much more vigorous, and a great diversity of colour reveals itself.

A hint now as to the selection of Gladioli. The majority of purchasers—for the simple reason, I suppose, that they are not planted till the spring—do not order their bulbs before the new year, usually with the garden seeds. This is a mistake, because they are very likely to get poor corms, for the few that send their orders in with the ordinary

bulb order certainly stand a chance of securing finer examples. I advise all who intend growing these charming plants to fill up their desiderata lists at once, and put up with the small amount of trouble incurred in keeping the corms through the winter.—R.

THE BIRMINGHAM CHRYSANTHEMUM SHOW, opened in the Town Hall yesterday and continued to-day (Thursday), is the finest that has been yet seen in that town, both specimen plants and cut blooms being of exceedingly good quality. Mr. W. H. Dyer, gardener to T. W. Webley, Esq., Selly Oak, secured the £5 silver cup offered for the best nine Chrysanthemums in pots, a position he has previously obtained with similarly well-grown and neatly trained specimens. The chief interest however, centred in the class for forty-eight blooms, twenty-four incurved and twenty-four Japanese, distinct varieties, and in this Mr. Tunnington, The Gardens, Calderstone, Liverpool, won premier honours, the substantial prize of £10, with handsome blooms of the best varieties. He was followed by Messrs. Jellicoe, Comfort, and Neal, who all showed good blooms. Mr. Tunnington was also first with twenty-four blooms, twelve incurved and twelve Japanese, and again with eighteen incurved. Mr. Jellicoe was also the most successful exhibitor of twelve reflexed and twelve Anemone varieties. These brief details, which we received by telegram on the eve of going to press, will be supplemented by a full report next week.

— MR. DERRY, for some time past foreman of the extensive collection of Ferns in the Royal Gardens, Kew, has obtained an appointment in one of the Government experimental gardens, under Mr. Jenman, in British Guiana. We understand that the garden is a new one, and is to be devoted chiefly to the trial and acclimatisation of plants likely to be useful in that colony.

— THE CHRYSANTHEMUM EXHIBITING SEASON is now fast drawing to a close, and about half a dozen more shows will conclude the displays. Up to the present between thirty and forty exhibitions have been held since the 7th inst. For to-day the following are announced—Reading, Aylesbury, Tunbridge Wells, Taunton, and Ipswich; while on next Tuesday the two last events, Liverpool and Malton, will, with a few other local shows, bring the total up to fifty or more, all within the space of three weeks. This is convincing evidence of how fast the popularity, of the Chrysanthemum is extending.

— MR. E. R. CUTLER, Secretary of the Gardeners' Royal Benevolent Institution, writes:—"I beg to inform you that at the Committee held on the 15th inst. it was decided to add twelve pensioners to the list on the 10th January; two of whom will be placed on the list without election in conformity with rule No. 6; and they also ordered the sum of £350 to be purchased on account of the trustees, making the total amount of stock in the 3 per cent. consols £15,100."

— "R. I. L." writes:—"In the west of England an Apple called 'TOMMY KNIGHT' is very much valued for dessert, and it is an excellent kind which I do not remember to have seen elsewhere. Is it described or referred to in books? I do not find it in those I have." It is probably a local variety, and has not been described under its name in any work.

— "AMONGST the tall-growing Sunflowers none," writes a correspondent "can be compared to HELIANTHUS LENTICULARIS. It grows from 10 to 12 feet high, and the flower heads, although not so large as *H. annuus*, are much showier, owing to the brighter colour of the ray florets, more compact form, and darker disk; they are about 4 inches across. Seeds, I believe, of this species were received at Kew from America to try if possible and turn it into *H. annuus*, doubts having arisen as the probability of *H. annuus* being the parent; but so far from this, the plant after two years' cultivation still keeps its distinct character, which is well represented in the 'Bot. Reg.' tab. 1265."

— WE have received a parcel of CHRISTMAS CARDS of a very superior kind, and which exhibit a wonderful advance in the art of

chromo-lithography. They are from the works of Messrs. Meissner and Buch, chromo-lithographic printers of Leipsig, and most of them are equal, if not superior, to the most artistic productions by hand. They consist chiefly of flowers, and we are sure will commend themselves to the great mass of our readers.

— MR. T. PARKER writes:—"In your report of my APPLE, TYLER'S KERNEL, which gained a first-class certificate at the Committee meeting of the Royal Horticultural Society, you gave my address as Moreton Cove; it should be Moreton Court."

— THE "Journal des Roses" gives a coloured plate of ROSE SECRETAIRE J. NICHOLAS, a Hybrid Perpetual raised by M. J. Swartz of Lyons, and sent out at the commencement of the present month. It has a full, well-formed, and apparently substantial bloom of a very dark crimson-scarlet colour, and the variety is described as very vigorous and free.

— "A YOUNG GROWER" writes:—"We have Rose, Chrysanthemum, and Apple elections, why should there not be an ELECTION OF CARNATIONS AND PICOTEES? I am sure if one of the great growers, say Mr. Dodwell, Mr. Turner, Mr. Douglas, or Mr. Rudd, were to take it up all growers would be pleased to give their assistance and send in lists of the best varieties. If each elector sent in a list of the best twenty-four Carnations and the best twenty-four Picotees, the result could be published in the Journal, and with the co-operation of the exhibitors of these popular flowers I think it would be a decided success."

— THE forty-fourth ordinary meeting of the ESSEX FIELD CLUB will be held at the head quarters, 3, St. John's Terrace, Buckhurst Hill (opposite the church), on Saturday, November 24th, 1883, at seven o'clock p.m. The following papers will be read:—1, "On the use of the Hygro-Spectroscope in Meteorology, and the Observation of the 'Rain-band' Spectrum as a Weather Prognostic," by F. W. Cory, M.R.C.S., F.R.Met.Soc., &c. 2, "A Note on the Occurrence of the Beech Marten (*Martes foina*, L.) in Epping Forest," by James English. 3, "On a Proposed Catalogue of the Pre-historic Remains in Essex," by R. Meldola, F.C.S., F.R.A.S., &c., Vice-President. The rooms will be open at six o'clock for the exchange of books, and for the convenience of exhibitors at the meeting and conversation. During the winter session the library will be open on Thursday evenings from seven to nine o'clock. The Secretary, Mr. W. Cole, will be glad to have notice of any communications intended to be brought before the Club during the winter session.

— THE *American Journal of Forestry* records an instance of handsome PROFITS ON TREE-PLANTING received for ten acres purchased ten years ago in Logan Valley in Nebraska, and planted with Black Walnuts, by Col. Van. He gave 1 dollar 25 cents per acre for the land, and after it was handsomely covered with a dense growth of thrifty Black Walnuts ten years old, he sold ten acres for 3000 dollars. The time will certainly come when all this timber will be wanted at an advanced and handsome price, and there is nothing for which there will be a more extensive demand than the best, large, second-growth selected timber."

— AT the first meeting of the Manchester Horticultural Mutual Improvement Society recently, Mr. Leo H. Grindon delivered an interesting lecture on POISONOUS AND MEDICINAL PLANTS. He also exhibited two curiosities, one a specimen of a Japanese Chrysanthemum, in which, intermingled with the bracts forming the involucre, were developed a number of leafy branches, so that the flower was enclosed, as it were, in a little arbour of green foliage. The object, he remarked, was a monstrosity, and one might have to wait many years before meeting with anything like it. He had received from the Isle of Wight a specimen, the first he had seen in Manchester, of the fruit of the *Benthamia fragifera*, from the far East. The tree from which the branch was taken was sent to the Isle of Wight some twenty or thirty years ago. Proceeding with his lecture, he said that botanists had ascertained through the medium of living specimens in the country, and more particularly through the medium of dry specimens brought from foreign countries, that there are no fewer than about 100,000 different flower-bearing plants. At a liberal estimate the number of plants which could be said to be of direct service to mankind would not amount to more than 10,000. There would be 500 different kinds of fruit trees, then all sorts of vegetables, trees supplying timber, and plants which give material for the manufacture of clothing—cotton, hemp, flax, and so on. The greater portion of the remainder of the plants were simply

ornamental, but to his mind every bit as useful as the economic ones. As nearly as he could estimate there might be some 5000 plants which were more or less poisonous and hurtful, some of them very much and others only moderately so. The most important fact of all was that a large proportion of the deadly plants with which we are acquainted are admirable medicines in the hands of a clever physician who knows how to administer them in proper quantities and at proper times. We may, therefore, look upon poisonous plants and accept them as the good gifts of Providence intended to be applied to certain purposes.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE attention of the Committee of this Institution has been drawn to a letter in your Journal of the 8th inst., signed by Mr. W. H. Divers, of Burghley Gardens, Stamford, stating "that a friend of his had paid ten guineas to the fund of the Society, thinking thereby to provide for a rainy day; that he became seventy years of age and unable to pursue his calling any longer, and that upon applying to be placed on the pension list was told that he had paid the ten guineas as a donation, and consequently was not eligible for the pension."

As this statement is so extraordinary and one calculated to inspire a want of confidence in the management of the Institution, I am instructed by the Committee to request that Mr. Divers will kindly favour me with the name and address of the subscriber in question, and if possible with the date of his application to be placed on the pension list, and the name of the person who told him he was not eligible. Upon receiving these particulars the Committee will cause the subject to be investigated.—EDW. R. CUTLER.

I DID not intend entering into any of the discussions which have taken place in our Journal in relation to this Institution, for I agree with others who have written that the Secretary is the proper person to give any information that may be sought. If tendered privately, as appears to be the whim of the "Royal," it benefits only the person who makes the inquiry, but when given publicly it imparts information to others who are interested besides the inquirer. I cannot tolerate this "stand off" principle, and think the questions asked in the first instance were only reasonable, and should have been as freely and willingly replied to. In reference to the letter from Mr. Divers respecting life subscribers, I fail to find the rules satisfactory on this point. Before I became a life subscriber I asked a similar question, and the answer received must have been satisfactory. I have again written, and I will give extracts that bear upon the point from the letter received. "Any person subscribing the sum of £10 10s. to this Institution becomes a life subscriber of it and is free from all further payment, and as such is entitled to vote at all elections of pensioners." "Should such a subscriber be a gardener, or other coming under rule No. 3, when he has been on the books fifteen years and upwards he would (should he be in need and in every way complying with the rules), in the event of an addition to the pension list, be placed upon it without any election in preference to all others who may not have subscribed so long or not at all. This rule also applies to the widows of such person. It is the fundamental rule of the Institution and has never been departed from. At the present time we have one pensioner who subscribed £10 10s. in the year 1846. In the year 1879 he fell into distress and applied for the pension, and in January, 1880, he was placed on the list without any election. Should he at his death leave a widow, she, upon showing her credentials, would be placed on the list in his place without election." "Life subscriptions are not treated as income, a portion of them being invested yearly in Government securities."

If this information prove of any service to any of your many readers, then I shall be abundantly repaid in obtaining it and forwarding it to you. I am afraid we are too apt to look upon what we contribute from a selfish standpoint. I sincerely hope I shall never need the assistance of the Institution, and am gratified to think that the mite I have subscribed may be the means with others of helping those who may be so unfortunate to need assistance.—WM. BARDNEY.

BOUVDIAS IN WINTER.

BOUVDIAS are amongst the most beautiful and useful of all our winter-blooming plants. When propagated from cuttings in spring they may be grown into bushy plants by the end of September, and they will begin flowering then and continue until the winter is nearly over. Most useful plants may be grown in 6-inch pots, and for general purposes these are to be recommended. Some growers turn their plants out into the open borders in summer and lift and pot them in the autumn; but this I never do, as some years ago I proved to my satisfaction that plants grown wholly in pots were the best during the winter. The lovely flowers of the Bouvardias are acceptable at all times, but they are most pleasing during the winter, and it is no difficult matter to grow the plants so as to make them bloom profusely now. A cold frame suits them well throughout the summer, and here the leading shoots should be frequently stopped to cause the production of side shoots and make the plants dwarf and bushy. By September they should be a mass of healthy young shoots, and these, when introduced to a temperature of 65° or so, will produce a fine cluster of bloom. As soon as these are open they should be cut off, and this will induce more young growths to come. These will flower in their turn and

form a good succession to the first flowers. They will do well at this season in a temperature of 65°, and 70° will bring them on faster, but they will not grow and bloom successfully in less heat than this during the winter. Frequent syringings and copious supplies of liquid manure also help greatly to bring them to perfection, and they are well worth all the labour which is required to bring them out to the fullest, as they are really the best and choicest of our winter flowers. The new double-flowering varieties recently introduced are very handsome, and are as easily grown and bloom as freely in winter as the single ones; but with many others I prefer the single flowers to the double ones.—J. MUIR.

LANE'S PRINCE ALBERT APPLE.

SINCE the favourable reference to this Apple in articles that have recently appeared we have been requested to describe its character; and though an outline of the fruit was published in this Journal a few years ago, we have prepared a more complete representation of the fruit.

We may remind our readers that there are two Prince Albert Apples in commerce; but the best known, and we believe the first to bear the name of Prince Albert, was that raised by Mr. John Lane of Berkhamstead from Russet Nonpareil fertilised by Dumelow's Seedling. It received its name on the occasion of Her Majesty and Prince Albert visiting Berkhamstead.

Lane's Prince Albert (fig. 87) is a large handsome Apple, and the tree is an immense bearer. The shape of the fruit is short, conical, or ovate, even and regular in its outline, with broad ribs round the crown

Fig. 87.—Lane's Prince Albert.

Skin smooth, bright grass green at first, but changing to clear pale yellow as it ripens, and sometimes with faint broken streaks of red on the side next the sun. Eye rather small, closed, with erect pointed segments, which are reflexed at the tips and set in a deep rather angular basin. Tube funnel-shaped; stamens basal. Stalk over half an inch long, inserted in a deep round cavity. Flesh very tender, juicy, briskly acid, and agreeably flavoured. Cells wide open. A very excellent kitchen Apple, in use from October till March.

In all probability this Apple will be largely planted both in gardens and orchards, as it bears freely in a dwarf state on the Paradise stock and as a standard on the Crab. It, moreover, appears to be hardy during the blossoming period, as trees of it produced fine crops during the first few almost appleless years.

The other Prince Albert, Smart's, is a very good conical dessert Apple grown in Kent, and is now called Smart's Prince Arthur.

PELARGONIUM v. GERANIUM.

To botanists like Mr. Percival the difference between the Pelargonium and the Geranium may be as "clear and distinct" as he says it is. To ordinary observers there is great confusion and disorder, with the usual accompaniment—bewilderment. To begin at the very beginning, confusion meets us in the very names and their derivations. Take them as they are given in the "Cottage Gardener's Dictionary":—"Pelargonium,

Stork's-bill (from *pelargos*, a stork, referring to the beak-like formation of the ripe seed-pod). Geranium, Crane's-bill (from *geranos*, a crane, referring to the beak-like torus, or projection beyond the seeds)." What is the difference here? Are not Cæsar and Pompey very much alike, especially Pompey.

I accept Mr. Percival's explanation as one more addition to those clearing-up of differences already given; but I beg to point out to him that his explanation is not clear enough to the lay understanding, and that the contention begun here as to the difference between the Pelargonium and the Geranium does not lie in matters of nice botanical distinctions, but in those broad and clear lines of judgment that are required for the ordinary observer to decide which is which. For instance, the Show and Fancy Pelargoniums are called Pelargoniums rightly; there is no confusion here except amongst the hybrids as to what family or families of Pelargonium have been married to produce such a wide variety of form and colour; but then the bedding Geraniums are Pelargoniums proper, and yet who ever thinks of calling them Pelargoniums? It was this confusion that was referred to by me in quoting the curiosities of the styling of Pansies and Violas. That confusion lies on precisely the same lines as the other; so it appears to me, and the sooner we reconcile the differences the sooner we shall get order where at present there is disorder. It is calling things by first, and often ignorant but conventional, names that does the mischief, and it is only in the pages of the gardening press where we may thresh the matter out and bring about a right way of speaking of things.

It may be said, and I admit the force of such a speech, that it is easier to point out an evil than it is to suggest a remedy that shall effectually right the evil. My own contribution is, I own, a very feeble one, and is more in the form of a suggestion of a remedy than a remedy itself. I would have the botanists and other plant-namers in their classification of plants not to make families of plants from small and hidden peculiarities, but to classify on broad lines, and on lines that can be seen at a glance. This, with a correct way of speaking of plants by their real names rather than their local or conventional ones, would, I think, clear the ground a little of some of the differences that now exist. Anyhow this is what occurs to me, and I throw it out for what it is worth.—H., Notts.

FORCING RHUBARB AND SEAKALE.

THE time of the year being at hand for the above work, a few remarks as to the best and most economical way of proceeding may not be out of place in your widely read journal. Undoubtedly the best place for such a purpose is a Mushroom house, as it curtails labour, which is a great consideration to many gardeners, but all do not possess such a structure. Failing this the next most suitable place, if it is wanted early and good, is a heap of thoroughly prepared manure and leaves.

The manure and leaves, about half and half of each, should be well mixed before using them, for by so doing most of the rank heat will have escaped, the object aimed at being a steady lasting heat. The manure being properly prepared, a suitable position in which to make the bed must next be decided upon. I may here state that we have for some considerable time now dispensed with Rhubarb and Seakale pots, and the generally practised method of putting hot manure around them, such a practice proving not only less satisfactory, but causing much unnecessary labour.

The bed may be made in any corner as near the heap of prepared manure as possible, but if against a south or east wall so much the better. All being ready, lift the desired quantity of Rhubarb roots carefully, and place them in a line 4 feet from the wall and as close together as the balls of soil will allow. Next drive some stout stakes about 4 feet in length into the ground, allowing about 3 feet above ground on each side of the roots, equidistant 2 feet. It will thus be 4 feet wide inside the bed. To the outside of these stakes nail boards along both sides and the ends to the desired height, 3 feet. This done, put in what soil is necessary. Any good garden soil will do well for this purpose. The Seakale may now be planted. Lift carefully as many roots as will meet the demand, and plant them on each side of the Rhubarb, introducing more roots from time to time as required. Place the manure 2½ to 3 feet wide around the whole, shaking it well and treading it firm during the operation. Some boards should now be placed on the top, and on these a few barrowloads of rather long manure. Water may be occasionally given with advantage if the soil gets at all dry.—J. RICHARDSON.

GARDEN CHEMISTRY.

THE PREPARATION AND MANAGEMENT OF SOILS.

HAVING made up our mind in the choice of soil it depends on the purpose to which it is to be put, how it should be collected, and how prepared. In the case of pot plants much depends on whether the plants are large permanent specimens, or only decorative stuff destined to live one season only. For large plants it is necessary to cut the turf so that only soil full of fibre be taken; for decorative plants much more may be taken, and indeed it may do very well though it be devoid of fibre. For years we were in the habit of using loam that once had been weeds, but had, after years of decay, become plain soil. When we say weeds it is wrack grass, weeds from fields that is referred to, not the weeds from gardens.

After turf is cut it requires to be kept till it is more or less decayed, and for this purpose it is stacked in ridges so formed as to shed most of the rain that falls on the heap. For permanent plants it is best if the fibre is little more than dead; for small plants it must be so decayed as to be easily broken in pieces—must be far on the way to mould, in fact. In the case of small plants it is almost invariably mixed with manure and leaf mould at potting time. A better way is to build the manure along with the turf at stacking time. For this purpose cowdung should have the preference over that from horses, as horse manure is apt to cause a growth of fungus, which is frequently very injurious, especially in light soil. Put up with the soil, cowdung in a few months becomes fine sweet mould—much sweeter and better than the same decayed in a heap by itself would; indeed, it is in no way behind the best leaf mould, and is richer. In the case of rich loam a good dressing of this manure may make the soil quite rich enough; but if it is poor, rather than overdo the proper quantity of mould it is far better to be at some trouble to get urine from stables and to give that. Weight for weight this will enrich the loam more than the solids; but, unlike them, will make no mechanical alteration. Many gardeners stack and rot their materials separately, and for some purposes it may be necessary to have the loam pure; but for nearly all purposes the plan of preparing them all together is very much to be preferred. It is only in the soil that plant foods are properly cooked and digested, so to speak, and if those who have hitherto held to the older method will try the plan advocated here they will be convinced.

Failing turf, as we have said, much may be done—indeed, the best success secured—with loam in which no fibre forms a part, at least with plants the existence of which is short. The only peculiar care necessary with such is to rather under than over-pot, and to use more gritty opening material than when fibre performs this office. In the case of very heavy loam a little hot lime may be sprinkled over and thoroughly incorporated with the whole some time before using; but wood ashes, especially when much small charcoal is present, is decidedly better, and may be applied when the soil is used. Failing wood ashes burnt clay soil is a capital substitute, and, indeed, both may be used together. For opening purposes charcoal is very valuable, as it sweetens soils and holds stores of nutriment, gradually yielding them up. Even pieces of sandstone are by no means to be despised, and the use of sand is well known as an opener, although it is, not unseldom, too plentifully applied, especially by those who are in the habit of giving large shifts. For a very large number of plants an addition at potting time of phosphates is advisable, and no better way of giving them exists than as very fine bonemeal for small plants, and crushed bones for large. Light soil will be improved if mixed with soil which by itself would be much too heavy. Mr. Thomson of Drumlanrig recommends watering-in clay into sandy soils in order to convert them into loam. We commend the idea.

In preparing peat it is not usual to put up manure of any kind with it, but for some plants, Azaleas and Camellias for instance, when really good leaf mould cannot very well be had, it certainly improves it and secures much finer growth. For the majority of plants grown in pure peat, however, anything beyond sand, charcoal, sandstone, and, in certain cases, good leaf mould, would be an evil rather than otherwise. When very fresh it requires a long time to prepare, and when allowed to become too dry it does not prepare very rapidly. As a consequence it may often require to be turned over and damped, but it will be ruined if kept wet.

In taking soil for making borders it is far better to take a good few inches, unless the under soil is very unsuitable, than merely to skim the surface turf off, if the turf, that is, really is turf. The habit of making up borders of clean turf has led many astray; besides, it is frequently easy to find enough material when 6 inches are taken, and the opposite when only the merest surface is skimmed. Then, when only turf is taken, it requires much chopping and turning and mixing, and even then the borders are hollow and sink much, carrying the roots found downwards as they sink. If soil be taken as well as turf the borders may be made at once, and made firm and un-sinkable too. Into this subject we cannot go in detail here, but must refer the reader to the books treating of different subjects for the details; but we ought to warn against the very wide and very deep borders recommended by many. Gardeners are now in favour of very much more restricted borders for all sorts of trees than they were only a decade ago; and there can be no doubt that as gardeners get impressed with the idea that it is better to have small shallow borders filled well with roots, than large deep ones unfilled, the borders of the future will be shallower and narrower still, for in narrow borders when the roots are near

the surface, exactly what is wanted can be plentifully supplied exactly when it is needed. Big borders were perhaps the proper thing before men had learned exactly what to supply and when to supply it. Now the case is altogether altered.

In the making-up of borders the same rules apply for the lightening of heavy clays as in the case of potting soils, but lime rubbish and burnt clay are of more value in Vine and other borders than even charcoal, and are much cheaper, unless when it can be made at home from brush or other otherwise useless wood. Wood ashes, which have been produced by smother-burning, are also of extreme value for such purposes. Even broken stones and brickbats are of value. It is not so easy dealing with very light soils, but roadside turf, and even well-sweetened serapings from off public roads, materials which are generally of a heavy nature, the writer has employed with great advantage. Mixing-in very heavy clay loam, if thoroughly done, is also of advantage, but the evil influence of light gravelly or sandy soil may be best combated by the plentiful use of water, proper feeding, mulehng, and other mitigative treatment. Keeping the soils well firmed is also a very good plan. As all roots of all kinds of fruit trees are best when very near the surface, in order to keep them there all manurial applications should be over the surface; and as much humus is not conducive to fruitfulness, the use of artificials rather than ordinary manure may be advised. The digging of all such borders is, of course, a blunder. Digging borders often does no harm, because matters are so bad neither digging nor anything else could make them worse.

In the matter of potting soils, and even in those with which Vine, Peach, and other fruit-tree borders are made, there is generally a choice, and that which is considered unsuitable may be rejected. It is quite different with the soil of gardens which have been formed. Even with most which are not formed no choice of soils exist. The garden must be on a given spot, no matter whether the soil or site be good or bad. Even when a choice has been afforded, by some strange fatality the worst site and soil have often been chosen. A very large number of gardens have been made on the lowest spot, where spring frosts linger and winter ones are hardest; where the soil was wettest, most clayey, and most difficult to drain; where the beams of the early sun ever will be utilised, not in warming the soil, but in evaporating dampness; and where heavy mists shut the sun out altogether at times, and breed and nourish mildews against which labour fights nearly in vain. But no matter what or where the soil is, if it is too heavy or too light, too thin or too poor, it can be improved if not made very good. In some respects clay soils are worst to deal with, especially when the rainfall is great. Light soils, especially when thin, are worst when the rainfall is small.—SINGLE-HANDED.

ROSE CUTTINGS—TEA ROSES.

"A. F. M." and Mr. W. Boyes are agreed that Rose cuttings do not bloom as freely as the budded plants. "A. F. M." recalls how he was "sat upon" some weeks back for venturing such an opinion by "A Judge" and Mr. Sanders. Perhaps we are all disposed, and not unnaturally, to value our own experience beyond that of other observers; yet it seems to me that in this matter both the contending parties may be right, and season and locality may explain why one observer sees no difference between budded plants and cuttings, whilst another pins his faith for blooming purposes entirely on the former. What Rose exhibitors would rather learn is, whether, other things being equal, the blooms are as good from plants raised from cuttings as those established on stocks. I scarcely think they are. Probably here I am in error, as to make a just comparison a certain number of the same varieties need to be tried under similar conditions. Certainly, from cuttings I have had very satisfactory blooms, and when I reflect that my cuttings are in proportion but as 1 to 15 or 20 I am content still to strike cuttings. Personally I am now forced to depend on cuttings, for whether flies have the same predilection for me as for "A. F. M.," or the reverse, my back now positively refuses the doubled-up position requisite for budding dwarfs. My old plan used to be standing over the stock and stooping down to place the bud. This position entails a tightening of neck collar, which is not advisable as years increase. I confess that there is a greater pleasure in the success of a bud than of a cutting, at least to myself. I think the bud requires more attention, "A. F. M." calls it "toil," but with such a queen to serve, attention, toil, or whatever it may be called, becomes a pleasure.

In any comparison between the two sets of plants, those raised from cuttings and those from buds, it strikes me that their first season is not the date for comparison. The budded plant is perhaps at its best, at least with the great number of varieties, as far as "exhibition" blooms are concerned; while many of the cuttings, not being placed in circumstances calculated to bring them to perfection, being probably in very close quarters, would not be fit to enter the lists until well settled in their proper site, with room both to breathe and grow. If, therefore, the following season after budding or striking is taken as the test period,

budded plants must win. I do not like to speak positively, but I fancy that it is during the year after striking that the plants do not bloom so freely. I have two or three-year-old plants from cuttings that appear to me just as floriferous as the budded plants whether on the Briar or Manetti.

For "garden Roses" I certainly think the palm must be given to cuttings, and for this reason, that so long as the plant lives you will have the Rose itself and not the stock cultivated. It may be said that this accident should not occur. Granted, but nevertheless it does. Ordinary working gardeners are as a rule not sufficiently acquainted with the Manetti, for instance, to detect it, and as it is a grand grower its shoots are often carefully preserved, and the bud, the Rose *par excellence*, of the plant is a thing of the past. This every Rose-grower, I fancy, must have noticed. It rarely falls to my lot to go round a flower garden without spotting a Manetti shoot if there are two or three dozen Roses grown, and on one occasion a friend complained to me that her Rose trees never bloomed. I found there were large rampant bushes of Manetti, and scarcely a plant with any of the budded portion left. Such a condition could not exist with plants grown from cuttings.

"A. M. B." endorses the opinion promulgated during the last two or three years, that the Tea varieties are far less tender than was supposed. There is no question in my mind that many of the Teas are as hardy, if not more so than some of the Hybrid Perpetuals. Last season, February was so forcing that my Teas were throwing up young shoots through their protection. To harden off these I removed the protection; then comes March, bitter, biting, and for ten days or a fortnight we had continuous frost of 10° to 20° below freezing. I feared the Teas would suffer, but the only plants that I saw injured, and I do not feel certain this was frost, were a Climbing Devonensis and a Triomphe de Rennes. Of their extreme elegance and beauty one cannot say too much. They are the cream of Roses, not alluding at all to their colour, whilst for continuous blooming the H.P.'s cannot approach them. With all my intense admiration for them I must allow that a great number of them do not like wet, and if caught in the bud decline to open. The fuller they are the more probable is this to occur, but the blooms are worth a little protection then, they well repay it. Safrano merits all that "A. F. M." writes. I would say more. "A. F. M." remarks that in November he can always find a bud, and I would add that in many Februarys he might find the same, at least it is one of the earliest bloomers bar Gloire de Dijon, which our old friend "C. P. P." maintains is not a true Tea, as it is one of the latest; and although it may have but a dozen petals, how exquisitely are they folded and tinted in the bud! and in that stage how beautifully the poverty of petals is hidden!—Y. B. A. Z.

VIOLAS.

In the Journal of November 8th there is a further correspondence respecting Violas and Pansies. To those who have grown these plants for years there is really no difficulty in classifying them so far as trade lists are concerned. Holyrood and Blue Stone, as well as Blue King and others, are Pansies, but then the Pansy is a Viola, and is Viola tricolor. Such varieties as Blue Bell, Crown Jewel, Countess of Kintore, Mrs. Gray, and all the small-flowering kinds, are safely classed as Violas to distinguish them from Pansies, both Show and Fancy, for as a rule the bedding Violas have stronger constitutions than Pansies, stand bad weather better, and are much better bedders. It is quite true that Pilrig Park comes very near to the Pansy in growth, still, as it is a capital bedding variety, and not of the slightest use as a show Pansy, I should place it amongst the Violas. Mr. Percival refers to the perfume of Miss Darling Pansy. In Mrs. Gray Viola we have a strong, delicious, Violet perfume, and this, added to the snowy white colour of the flower, and its robust habit and freedom of blooming, makes this a most desirable bedding plant for spring and summer.

Mr. Murphy's solution of the problem as to considering "all those with radiating distinctly marked lines from the eye as Violas" is altogether wrong. I have held for years past that we should aim at getting pure self-coloured Violas entirely free from any blotch or lines whatever, and in Golden Queen of Spring, Yellow Beauty, Yellow Dwarf, all seedlings of mine, we have it. Mrs. Gray and Countess of Polwarth are almost free from markings. In the midland and northern districts thousands of Violas are now grown where only dozens were cultivated a few years since. One of our very best and most distinct varieties is elegans, by no means a new kind, an abundant and continuous bloomer of a pleasing pale lilac colour. Mrs. Gray is a grand white, and True Blue by far the best and most useful blue I know.—W. DEAN, *Florist, Walsall*.

CHRYSANTHEMUMS.

NEW VARIETIES.

It appears that increased attention is now being paid to raising Chrysanthemums from seed, and as a consequence the new varieties are rapidly becoming more numerous; indeed there is just a possibility that the demand for novelties may cause the market to be flooded with many that are inferior to older and proved sorts. This is one evil which it is to be hoped will be avoided, and most of the leading nurserymen who trade in these plants will undoubtedly be careful in recommending their new productions until their merits have been tried or submitted to the test of examination by a competent tribunal, such as the Floral Committee of the Royal Horticultural Society. Without some guarantee the public are likely to become the unhappy possessors of worthless additions

to their stock at prices greatly in advance of those for which they could obtain really useful and beautiful forms. It seems that some of those who devote themselves to raising new Chrysanthemums on the continent must do so in a very haphazard manner, no definite attempts at systematic crossing being made, and the chief object is apparently to get all the seed possible, and nearly every plant so raised which differs at its first flowering in the slightest perceptible degree is honoured with a name and sent out with a magniloquent description. Fortunately, however, this is not a general practice, and there are some continental firms who have distinguished themselves by the high quality of the varieties they have contributed to commerce. The same remark applies to all the best home growers, who are very careful in introducing to their lists those alone which possess sterling merit, and it is only by acting on this principle that they can gain the confidence of the public. Still selection becomes of greater importance as the numbers increase to preserve the character and high quality of the different sections in general estimation.

It is strange that so few additions are made to the incurved group. We still need brighter and more diversified colours amongst these; yet the three best novelties of the present season—namely, Lord Alcester, Bendigo, and Jeanne d'Arc are all light-coloured. Two of these are sports, and seedlings are of very infrequent occurrence. The Japanese produce seed more freely, and there seems to be no difficulty in getting a supply from France and some other districts in South Europe where the autumn temperature is sufficient to mature the seeds. Some English seedsmen now offer seed at moderate prices, and those who wish to indulge in the agreeable excitement of raising new varieties can readily do so, as the seed usually germinates very readily in a little heat, young plants being obtained within a fortnight if the seed is good. It is rather surprising that more efforts are not made in crossing Chrysanthemums in England, as there is every probability that with a moderate amount of perseverance and study of the peculiarities of the floral structure in these plants satisfactory results could soon be insured. Mr. Broome of the Temple Gardens, one of the most noted of the earlier growers of Chrysanthemums, tried experiments of this character more than twenty years ago, and his efforts were sufficiently successful to encourage others in the same path. In a lecture delivered in 1863 the above grower thus describes the method adopted:—

"The following mode I saw practised in Guernsey, where I went twenty years ago, at Christmas, to look after some new varieties. At the town of St. Peter's, which is built on a rock a considerable height above the sea, I found the Chrysanthemum seeded freely, and that many of our newest and best varieties were raised in an alcove on the top of a rock. About one hundred pots were crowded together in the dry, and all the late blooms of the season were full of seed half ripe. I saw the petals had been carefully cut off with a sharp pair of scissors close to the florets, avoiding disturbing the pollen. The buds were quite firm with the seed. I have practised the same mode myself with perfect success. Mr. Wyness of Buckingham Palace has also raised a great number of very good varieties. He takes the seed off in February, and puts it into his pocket to dry for a week or two, and then sows it in a sharp heat in silver sand, and it comes up in nine days. I am persuaded that anyone can seed them in the greenhouses or dry stoves in this country if kept free from damp."

The structure of the florets should be carefully observed, and where, as is usually the case in the incurved as well as other varieties, the florets contain a pistil only, pollen could be gathered from the central tubular florets of the best single or semi-double varieties if it could not be otherwise obtained, and by this means it is very probable that seed might often be secured if the plants were grown in a light, dry, and warm position after the crossing had been effected. Should anyone be induced to undertake the task they should by all means direct their efforts to improving the colour of the incurved; and if it were possible to get a cross between some of the highly coloured Japanese and the superbly formed varieties of the former type, a beautiful race would probably be originated.

It should be observed that Mr. John Salter, who did so much to improve the Chrysanthemum and added so many fine varieties to those in cultivation at that time, once expressed an opinion that on an average not more than one out of every 2000 seedlings raised were worth naming as distinct. This was the result of long experience, and if it were true twenty years ago, the probability of obtaining meritorious novelties must be even less at the present time.

Some of the best of the varieties that have been recently honoured with certificates are the following:—

Lord Alcester.—A grand substantial bloom, pale creamy yellow, quite of the Empress of India type, from the golden form of which it was described at Southampton as being a sport, though it was stated at Kingston to have been obtained from Golden Queen of England. The former is the more probable, and some doubts were expressed at Kingston respecting the correctness of the information. It is, however, a superb bloom, and is likely to become a great favourite for the back rows of exhibition stands.

Jeanne d'Arc.—This, also an incurved variety, will undoubtedly become a favourite if it retains the character which distinguished the blooms shown at Kingston by Messrs. Jackson & Son. The petals are broad, strongly incurved, the bloom substantial and full, while the pure white tipped with pale purple has a very distinct effect.

M. Astory.—A magnificent Elaine, with much broader petals and extremely full handsome blooms, pure white. This may be expected to prove a fine exhibition variety.

Roseum superbum.—Both Messrs. Laing and Messrs. Jackson have

secured certificates for this variety, which was much admired at Kensington and Kingston. It is one of the fluted-floret section, the florets recurving slightly and of a peculiarly rich and distinct shade of rosy purple. Very telling and attractive.—L. CASTLE.

VERSCHAFFELTIA SPLENDIDA.

A GARDENER writes us that he "is in a fix and hopes we may be able to help him out of it." His case is that he is "likely to lose his situation, because he cannot help the old leaves of the above Palm decaying," but is expected to keep it "feathered to the ground," the plant being 9 feet high.

The owner of the Palm in question expects a practical impossibility, and not until he can grow an Oak tree to a large size and keep it "feathered to the ground" ought he to expect his gardener to achieve this phenomenon with a Palm. It is the nature of these handsome

completely envelopes the stem, the latter portion being abundantly armed with long black spines, whilst the footstalk is only about 6 inches long and perfectly smooth. The leaves are entire, broad, somewhat serrate at the edges, and deeply bifid at the apex; they are of a rich bright green in colour, and in a plant of some 3 or 4 feet high the blade will measure from 3 to 4 feet in length and nearly as much across. One of the peculiar features of this plant is its broad entire leaves, which is one of the distinguishing characteristics of the genus. This will satisfy every reasonable person who has hitherto not been familiar with the habit of this plant, and we are convinced will help our correspondent in his difficulty.

EUCHARIS AMAZONICA.

I SEND for your notice a very extraordinary flower scape of *Eucharis amazonica*. It has nine flowers upon it. This is more than I ever re-

Fig. 88.—VERSCHAFFELTIA SPLENDIDA.

plants to cast their lower leaves as others unfold, and the charm of Palms consists in their tall straight stems and crown of handsome foliage.

A developed specimen of this Palm is represented in the engraving. It is a native of the Seychelle Islands, belonging to the dependencies of the Mauritius, and when first introduced to our gardens, in 1864 was known by the provisional name of *Regelia majestica*. The stem is slender and of somewhat quick growth; as it increases in size it sends down adventitious roots, which in the form of an inverted cone ultimately serve to support the tree after the manner of the genus *Iriarteia* of the American continent, and give to the plant a most singular and picturesque appearance. The stem is profusely clothed with very long black needle-like spines, which spread around it in a fanlike manner. The petiole is short, with the exception of the large, broad, sheathing base, which

member having seen upon one head; but the most noticeable part is the extra development of one of the flowers. You will see that instead of the usual number of six petals in the flower it has ten. It has also ten stamens set along the edge of the corona. We have just had in flower a pot of *Eucharis amazonica* with sixty-seven spikes of flowers. These opened in a temperature of an intermediate house, and were remarkable for the size of the flowers.—ROBERT MACKELLAR.

[The spike sent is very fine, and the flower referred to extremely handsome. A similar one was exhibited last week at South Kensington by Mr. Wallis of Keele Hall. If a flower of this character were fertilised with its own pollen there would be a chance of a double variety being raised; but whether this would be more beautiful than the normal form is a question of taste. The experiment is worth trying.]

CRICKETS AND COCKROACHES.—I should be glad if any of your readers could tell me what will rid my houses of crickets and cockroaches. They eat everything, and the loss I have sustained is very

great, and I find toads so scarce, or they are very useful. I know plenty like myself who would be glad of some remedy that would destroy them quick.—J. W. R.

ROSE NIPHETOS.

I AM glad to see the Niphetos Rose being brought to notice. I have often wondered why it is not more generally grown. I quite agree with your correspondent that it is the best white Rose. About eight years ago, having decided to build a Rose house, I purchased two Niphetos Roses and planted them at the foot of wire pillars, and ever since we have not been short of white Roses. I consider Niphetos and Safrano two of the most useful varieties anyone can grow. They are both in bloom most of the year. Very little pruning is needed, simply cutting out the weakest wood and thinning the rest. I put a little heat on at the beginning of October simply to expel any damp, increasing it about the beginning of February, and by the middle of March we are rewarded with plenty of blooms. Besides Nephetos we have planted out Maréchal Niel, Adam, Marcellin Rhoda, Gloire de Dijon, Safrano, and David Pradel. The last I consider very poor, and would be glad if anyone can recommend a good red climber. Perle des Jardins I consider a splendid Rose, but not so free as Safrano. I enclose three Nephetos blooms; they are not quite so good as in April, but not to be despised.—F. B., *North Wales*.

[The blooms were very fine, and indicate excellent culture.]

PROPAGATING REIDIA GLAUCESCENS.

I HAVE been a reader of your Journal for more than a dozen years, and have derived much benefit from its perusal. Your answers to correspondents have always been a source of interest to me, containing a wonderful amount of information in a single number. In your issue of November 8th, in answer to "J. G." regarding the propagation of *Reidia glaucescens*, you say, Insert cuttings of half-ripe wood under a bellglass. This does very well, but it takes some time to get up a stock unless there is a number of plants to commence with. I grow this plant very largely, and find the best way to increase it quickly is to turn out a plant that is rootbound, cut the ball right through the middle, using the roots cut off as cuttings. We cut these in pieces an inch long, and insert in seed pans. This is done in early spring, and they make handsome plants for table use by the autumn. They strike readily from the leaves, but I much prefer the roots. This elegant plant has done so well with me treated in this manner that I trouble you with this note.—G. R.

[We shall be glad to be "troubled" with other notes similarly useful. We know the system of propagation described is good, but when letters arrive late we are only able to give brief answers, and are always glad for them to be supplemented, as in this case, by competent cultivators.]

CHRYSANTHEMUM SHOWS.

SOUTHAMPTON, NOV. 13TH AND 14TH.

THE sixth annual autumn Exhibition of this important Society was, as usual, held in the Victoria Skating Rink. The entries in all the classes were very numerous, far surpassing both in quality and general excellence any of the kind exhibited in Southampton before. The plant classes made a grand feature, occupying a large portion of the body of the great hall, and most of the plants would have done honour to the metropolitan exhibitions. The cut-bloom classes each contained seven entries and upwards, and the quality throughout was very marked. The fruit and vegetable classes were magnificent, and not only occupied the whole of the table room allotted to them, but a gallery some 50 feet in length had to be extemporised to receive them. Nearly twenty collections were staged in each of the five classes provided for Apples and Pears, which in the aggregate amounted to about 400 dishes.

Plants.—In the class for a group arranged in a space 8 feet by 5 feet there was only one exhibitor, Mr. Osborne, gardener to H. J. Buchan Esq., Wilton House, Southampton, who staged a very creditable collection, and well deserved the first prize awarded to him. For nine plants, distinct, Mr. Wills, gardener to Mrs. Pearce, The Firs, Bassett, was awarded first honours for a magnificent collection, consisting of Hiver Fleur with about 100 very fine flowers, Mdle. Bertie Rendatler, Fair Maid of Guernsey, and La Nympe of the Japanese varieties. This last variety was a perfect monster bouquet, the plants being from 3 to 4 feet in diameter, and carried upwards of 170 well-finished flowers of a delicate pale pink, showing how well this variety is adapted for specimens. The other plants were Golden Christine (good), Mrs. Forsyth and Dr. Sharp of the reflexed varieties, and Mrs. Dixon and Hero of Stoke Newington of the incurved varieties. This was altogether a very fine and well-finished collection, the plants were globular-trained, and well clothed with foliage almost to the rim of the pots. Mr. J. Allen, gardener to J. Bailey, Esq., Elmfield Hill, Southampton, was placed second for a collection larger than those to which the first prize was awarded, but not so fine in flower and finish. Mr. Osborne was placed third, also with an excellent collection. For six plants Mr. J. Thomas, gardener to R. R. Scott, Esq., Shirley Lodge, Shirley, and Mr. H. D. Hunt, gardener to R. Moss, Esq., M.P., Woolston, were placed first and second respectively for good collections. In the maiden class for four plants first honours fell to Mr. W. Joy, Shirley, the second to Mr. Hunt, and the third to Mr. N. Blandford, gardener to Mrs. Hazlefoot, Moorhills, West End. Classes were provided exclusively for Japanese-trained plants. In the class for six, Mr. Allen was well to the front with Hiver Fleur, Sultani, Mdle. Bertie Rendatler, Triomphe du Nord, Nuit d'Hiver, and Alba Plena, Mr. Osborne occupying the second position. For four plants Mr. Wills took the first place with plants nearly 5 feet in diameter of Fulgore, Sultani, Fair Maid of Guernsey, and Hiver Fleur, Mr. Hunt taking second honours. For a single specimen Japanese Mr. Wills and Mr. Allen shared the honours, the former with La Nympe, the latter

with Alba Plena, both very fine examples of culture; and for a single specimen, incurved or reflexed, Messrs. Wills and Osborne were first and second respectively, Mr. Wills showing Mrs. Sharp, and Mr. Osborne a good plant of Golden Christine. In the class for six plants, distinct (amateurs), Captain Gibbs staged a very good collection, and worthily deserved the position awarded to him. Mr. W. Reeves, 33, Brintons Road, received the second prize; and in the class for single specimen (amateurs) Captain Gibbs and Mr. Reeves were again placed first and second respectively, while the third position was gained by Mrs. Brodie, Belmont Inn, Portswood.

Cut Blooms.—For twenty-four cut blooms distinct, sixteen incurved or reflexed and eight Japanese, Mr. E. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishops Waltham, was awarded the first position with a magnificent collection. The back row in this collection consisted of Comte de Germiny, Fair Maid of Guernsey, Boule d'Or, Mad. C. Audiguier, Meg Merrilees, Marguerite Marrouch, Japonais, Baronne de Prailly; while the other two rows consisted of King of the Crimson, Incognita, Mr. Bunn, Queen of England, Golden Empress of India, Mrs. Heales, Dr. Sharpe, Princess of Wales, Lord Wolseley, Princess Teck, Barbara, Cherub, Prince Alfred, Venus, Empress of India, and Alfred Salter. Mr. Wills was a very good second, in fact some of the blooms were even larger than the same varieties in Mr. Molyneux's collection. Mr. Allen also exhibited a superb collection for third position, and in which was a fine bloom of Gabriel Delaux. Mr. Osborne was a good fourth.

For twenty-four cut blooms, not less than eighteen varieties, Mr. Molyneux was again first with handsome blooms. Mr. Wills was also here a good second, and having amongst others monster blooms of Snowball, Golden Empress of India, Comtesse de Beauregard, Madame C. Audiguier, and Lord Alcester. Mr. Allen again is awarded the third place. For twelve cut blooms, incurved, Mr. Molyneux was awarded the first place with another magnificent collection, Messrs. Wills, Allen, and Osborne following in the order of their names. In twelve Japanese, distinct, Mr. Molyneux was once more to the front with Meg Merrilees, Baronne de Prailly, Comte de Germiny, Elaine, Balmorean, Boule d'Or, Japonais, Khedive, Peter the Great, Madame C. Audiguier, Marguerite Marrouch, and Bend Or; Mr. Allen second, Mr. Wills third, and Mr. Moorman fourth.

Twelve cut blooms, Anemone-flowered. Mr. Molyneux here out-champions all with a grand stand of blooms, comprising Mdle. Cabrol, a new variety departing from the usual style of an Anemone flower, the guard petals being much longer and partaking much of the Japanese character—a most pleasing and promising variety; Mrs. Pithers, Lady Margaret, Princess Louise, Madame Godereau, Fleur de Marie, Gluck, and Empress. The other four were duplicates of the above-named. Messrs. Wills and West were second and third respectively. For twelve reflexed, eight varieties, Messrs. Molyneux, Wills, Allen, and Osborne were placed in the order of their names. The first-prize collection comprised King of the Crimson, Golden Christine, Mrs. Forsyth, Cloth of Gold, Felicity, Phidias, Christine, and Dr. Sharp; the others were duplicates. This was a remarkably fine collection. Other cut-bloom classes followed, which were well contested, the principal winners being Messrs. Osborne, Cox, Neville, Hammond, Jennings, Ransom, Gibbs, and Carter.

Fruit.—In the fruit classes the competition was very keen. For the heaviest bunches of Grapes Mr. Molyneux was first with a bunch of Barbarossa, weighing nearly 6 lbs. For three distinct varieties Messrs. Hall, Molyneux, Budd, and Miller were placed in the order of their names. For three bunches of black Grapes Messrs. Hall, Wyndham, and Dalgety were first, second, and third respectively, all exhibiting well-finished bunches of Alicante. For three bunches of white Grapes Messrs. Sanders, Molyneux, and Davidson occupied similar positions with Muscat of Alexandria, while the prizes for two bunches of white and two of black were awarded to Messrs. Sharp, Allen, Gates, Osborne, and Dalgety respectively. Apples and Pears formed, as we have before said, a grand feature. The first prize for three dishes of kitchen Apples was awarded to Mr. J. Mair for Blenheim, Alfriston, and Gloria Mundi. The second to Mr. Saunders with Dumelow's Seedling, Mère de Ménage, and Warner's King. The third to Mr. Hall with Bedfordshire Foundling, Wellington, and Flower of Kent. For three dishes of dessert Apples Mr. W. Fowle, gardener to Sir H. Mildmay, Bart., Winchfield, received the first prize for three splendid and highly coloured dishes of Cox's Orange, Blenheim, and Fearn's Pippins. In the class for four dishes of Apples the first and second-prize collections contained Mère de Ménage, Warner's King, Cox's Pomona, and Wellington, all wonderful examples of size and colour. Primulas, berried plants, and vegetables were all numerously exhibited, adding materially to the attractiveness of the display.

The above is but a necessarily brief account of a large and grand Exhibition, admirably managed by Mr. Fuidge, the Secretary, and ably assisted by Capt. Gibbs and others on the executive, whose sole desire is to study the interest of both visitors and exhibitors. The Royal President, General H.S.H. Prince Saxe-Weimar and the Princess honoured the Show with their presence on the first day, and the amount taken at the doors was nearly £150.

A certificate was awarded to Mr. Wills for

Chrysanthemum Lord Alcester.—A cream-coloured sport from Golden Empress of India. It is described in the Kingston report.

HAWKHURST, NOVEMBER 13TH AND 14TH.

THE first Exhibition of the Kentish Society was held in the Hawkhurst Lecture Hall, and, judging from the first attempt, the promoters have every reason to congratulate themselves, and may also safely anticipate still better achievements in the future. The district is notably a highly favoured one, and there is no lack of supporters and exhibitors of all things pertaining to horticulture. Mr. Gilmour, gardener to the Right Hon. J. G. Goschen, Seacox Heath, Hawkhurst, took an active part in establishing the Society as well as in the preliminary arrangements of the Show, and, as will be seen, was also the most successful competitor. Mr. L. Barnes, gardener to Lady Herschel Collingwood, Hawkhurst, and Mr. A. Whetley, gardener to A. Hardcastle, Esq., Hawkhurst, contributed materially to the success of the meeting. A very pleasing group of well-grown plants, comprising among others Chrysanthemums, Ferns, Primulas, were arranged by Mr. Nicholls, gardener to J. C. Fischer, Esq., Highgate, Hawkhurst, and in addition to these a few other plants and fruits were contributed by other growers not for competition.

The premier prize group of plants of Japanese varieties were staged by

Mr. Gilmour, and consisted of handsome flatly trained specimens of Purple King, James Salter, The Cossack, and Lady Selborne. Mr. Whetley followed with creditable specimens of Madame Crousse, Bouquet Fait, L'Isle des Plaisirs, and La Frasure. Mr. T. Barnes was a good third. Mr. Gilmour had the best four plants of incurved varieties, these being well-grown pyramids. Mr. T. Barnes and Mr. G. M. Newman (the latter an amateur) were placed equal second. Mr. Gilmour also staged the best Anemone-flowered and Pompons, Mr. Whetley being second in the former class and Mr. Barnes with Pompons. For a single specimen Mr. Gilmour was first with Mons. C. Hubert in good condition. Mr. Whetley was second with a fine plant of Elaine, and Mr. Barnes third with a good pyramid of Mrs. G. Rundle.

Mr. Gilmour was first in both classes for cut blooms. His stand of Japanese varieties included good blooms of the leading varieties. Mr. Barnes was a good second in both instances. Competition was keen in the classes for table decoration, open to ladies only. Here Mrs. Gilmour distinguished herself, the other successful competitors being Mrs. G. Cooper and Mrs. Pridgeon, and Mrs. Litchfield, who took the prizes in the order named, all giving evidence of good natural taste for the work. Two very fine stands of cut blooms of Chrysanthemums were lent by Mr. Doughty gardener to Mrs. Tomlin, Angley Park, Cranbrook, and these deservedly attracted much attention.

Mr. Gilmour took all the principal prizes for Apples. Messrs. Barnes, Whetley, and R. Titley, gardener to J. Thompson, Esq., also exhibited successfully in the Apple classes. Mr. J. Iggulden, gardener to the Rev. Canon Jeffreys, Hawkhurst, was first for a creditable collection and also for single dishes of Pears, the remaining prizes being taken by above-mentioned exhibitors. Amateurs made a good display in the classes provided for them. Of these the most successful were Messrs. E. T. Rodmell, G. Russel, J. Arnold, C. Boxall, G. M. Newman, Pridgeon, G. Fuller, and G. Feaver, all of Hawkhurst, and Mr. Lester, Ticehurst.

LEWES, NOVEMBER 13TH AND 14TH.

THE second Show of the Lewes Chrysanthemum Society was held in St. Ann's Concert Hall, and although unfortunately clashing with Brighton there was a great improvement on last year in both plants and cut flowers. In the open class for six pyramids Mr. Divall, gardener to A. Russell, Esq., was first, and also for six dwarf-trained plants. For six Japanese Mr. Stedman, gardener to Mrs. Godlee, Lewes, was easily first with meritorious blooms, Mr. Stidworthy being first for six Pompons. In the class open only to gardeners and amateurs within fourteen miles of Lewes Mr. Stedman was again to the fore with six well-grown plants, and also first for a specimen standard, a well-grown plant of Mrs. Dixon. Cut blooms were well shown. In the open class for twenty-four incurved there were six competitors. Mr. Gore, gardener to Capt. Taylor, being first, Mr. Stedman second, and Mr. Barchard, gardener to C. Cornwell, Esq., Uckfield, third. With twelve Japanese Mr. Divall was first, and also for twelve Pompons. Mr. Gore was again first in the restricted class for twenty-four incurved varieties. Mr. Barchard being second. For twelve incurved Mr. Hopkins, gardener to R. Thornton, Esq., Framfield, was first, and also for six Japanese; Mr. Divall being first for twelve Japanese.

The amateurs' exhibits of both plants and flowers were very creditable. Primulas and table plants were not very good, Mr. Stroud, gardener to F. Verral, Esq., taking first for the former, and Mr. Gore for the latter. There was a prize of two guineas offered for the best single flower of Chrysanthemum indicum, which was withheld, and rightly so, for if those that were staged were single flowers it will be a difficult matter to draw a line between single and doubles. A large quantity of Grapes, Pears, and Apples was shown not for competition, Mrs. Woollard of Cocksbridge being the principal exhibitor.

BATH, NOVEMBER 14TH AND 15TH.

THE fourth annual Exhibition of this Society was in every respect a great success. A decided improvement was evident in nearly all the classes, this being most marked both in the groups composed entirely of Chrysanthemums and also flowering and fine-foliage plants; these, in fact, rightly engrossing more attention than the various trained specimens. It was generally admitted that the arrangement was most satisfactory, and creditable alike to the Committee and Mr. Pearson, the able Honorary Secretary. No precaution, however, was taken to prevent damage being done to the front rows of plants and cut flowers, as well as the tables of tempting fruit. The Assembly Rooms, commodious and otherwise suitable as they are, were still uncomfortably thronged with visitors; and if ropes had been provided, and policemen stationed inside with instructions to keep the visitors moving, no damage would have been done and the Exhibition rendered more enjoyable.

Plants.—With six large-flowered specimens Mr. J. Bradner, nurseryman, Bristol, was easily first, his plants measuring about 4 feet across and carrying on an average about ninety well-formed blooms. The varieties were Mrs. Corbay, Mrs. Dixon, Alma, Mrs. Rundle, Lady Hardinge, and Prince of Wales. Mr. H. Scott, Bath, was a good second, his most noteworthy specimens being of Mrs. Glenny, Sir S. Northcote, and Mrs. Forsyth. Mr. M. Cole, gardener to R. B. Cater, Esq., was third with larger but rather shabby specimens. The best four specimens were staged by Mr. G. Tucker, gardener to Major W. P. Clarke; the second prize going to Mr. H. Gay, gardener to L. Danberry, Esq.; and the third to Mr. A. Hawkins, gardener to T. Jolly, Esq., the exhibits in each instance being most creditable. In the class for Japanese varieties Mr. Tucker took the lead with admirable examples of Elaine, Peter the Great, Nympe, Bertie Rendatler, Soleil Levant, and James Salter; Mr. M. Cole following with, among others, fairly good specimens of Fulgore, Elaine, and Peter the Great. The best six trained Pompons were staged by Mr. Bradner, and consisted of freely flowered specimens of Bob, Golden Circle, Mustapha, Calliope, Andromeda, and St. Michael. Mr. Clarke was a good second. Messrs. Scott, M. Cole, and G. Cooling & Son were also successful exhibitors of Pompons.

In the single specimen classes Mr. Bradner was first for a large-flowered variety, Mr. Tucker for a Pompon, Mr. Bradner Anemone-flowered, and Mr. M. Cole for a large-flowered variety not a pyramid. The latter won with an immense plant of Peter the Great, fully 7 feet across, and carrying hundreds of well-developed blooms. There were but few good standard-trained specimens shown. The best came from Mr. Bradner, and consisted of

Guernsey Nugget, White Globe, and Prince of Wales. Small trained conservatory plants were well shown by Messrs. Bradner, Cooling & Son, and H. Scott. There were seven excellent groups of Chrysanthemums arranged, the plants in most cases being in small pots, and were tall, freely bloomed, and bright in colour. The group of best-grown plants were unplaced, owing to lack of variety and damage from frost during transit. The successful exhibitors were Messrs. H. Gay, Mr. S. P. Budd, gardener to W. Taylor, Esq., and Mr. J. W. Brown.

Fine specimen Crotons and Palms were well and successfully shown by Mr. J. Mould, gardener to E. E. Bryant, Esq., Mr. M. Cole, Mr. W. C. Drummond, Mr. Hawkins, and Mrs. Grace Tiley. The groups of fine-foliaged and flowering plants with which Messrs. G. Cooling & Son took the lead was particularly attractive. It was sufficiently heavy without being crowded, and was a good example of what may be done with an abundance of good materials. It was largely composed of Crotons and Dracenas in rich variety, Bouvardias Alfred Neuner, Vreelandii and elegans, Roman Hyacinths, Erica hyemalis, and Adiantum cuneatum farleyense. Mr. J. Mould followed with a choice and neat, but rather too thin group, the third prize going to Mr. W. C. Drummond. Primulas in the different classes were well shown by Messrs. F. J. Walker, T. Channing, E. F. Pocock, and Mrs. Counsell. The four double white Primulas staged by Mr. Pocock were the best we have yet seen. The variety is vigorous, has dark leafstalks, and the trusses of very double pure white blooms are very attractive. Mr. W. K. Wait had the best Poinsettias, Messrs. Cooling & Sons the best Cyclamens; and pans of white Roman Hyacinths were well shown by Messrs. Bryant and Mr. Howe gardener to Lewis Fry, Esq., M.P.

Cut Blooms.—These were shown in good numbers, and in some instances were very fine, notably those shown by Mr. J. Baylis, a quarryman living at Winterbourne near Bristol, and Mr. E. S. Cole, gardener to E. S. Pethick, Esq., Clifton. The former staged the best twenty-four blooms in twelve varieties, these consisting of perfect examples of Empress of India, Bronze Jardin des Plantes, Prince Alfred, Princess of Wales, Mrs. Heale, Prince of Wales, Miss M. Morgan, White Venus, Baron Beust, Jardin des Plantes, St. Patrick, and Barbara. T. Hobbs, Esq., was a good second, and had excellent blooms of Beverley, Novelty, Isabella Bott, Mr. Corbay, and Barbara. Mr. D. C. Powell was third with smaller but fairly good blooms. Mr. E. S. Cole had the best twelve blooms in twelve distinct varieties, these consisting of large, though not coarse, examples of White Globe, Lady St. Clair, Empress of India, Mr. Bunn, Cherub, Golden Empress of India, Princess of Wales, Jardin des Plantes, Mrs. Nash, John Salter, and Venus. Mr. J. Waite followed with smaller but otherwise good blooms, among which were good Empress of India, Mrs. Rundle, and G. Glenny. The third prize was awarded to Mr. W. Fox, who also staged creditably. Mr. H. Scott had the best six blooms. The best bunches of

Pompons were staged by Messrs. Hawkins and H. Scott. The first-prize stand of large-flowered Anemones by Mr. E. S. Cole was remarkably good, and included splendid blooms of Empress, Lady Margaret, Gluck, Acquisition, Fleur de Marie, and Louis Bonamy. Mr. Baylis followed with similar varieties, and T. Hobbs, Esq., was a good third. The Japanese varieties were well represented, and naturally delighted the visitors. Mr. D. C. Powell took the lead with very fine blooms of Fair Maid of Guernsey, Daimio, Hiver Fleur, Cossack, Album plenum, Meg Merrilees, Madame C. Audiguier, and Soleil Levant. Mr. E. S. Cole was second with rather small but stouter blooms of such sorts as Golden Dragon, Rosa Bonheur, Flambeau, and Madame Clemence Audiguier. Mr. J. Baylis was third, in his stand being a fine bloom of Madame Berthe Rendatler. With twelve blooms in four distinct colours and varieties Mr. Baylis won first prize, staging good-sized blooms of Barbara, Prince Alfred, Golden Empress of India, and Mrs. Cunningham. Mr. E. S. Cole was second, and was followed by Mr. J. Waite. Messrs. Baylis and D. C. Powell were the successful exhibitors of eighteen blooms with long stems and foliage. Vases of cut flowers as shown by Mr. M. Hookings, Miss Turner, and Mr. Drummond; bouquets by Messrs. W. H. Mould, Hookings, and A. George; and baskets of autumn foliage and berries by Miss Pearce, Mr. H. Lord, and Miss Martin, were all highly meritorious.

Fruit.—There was a fairly good number of Grapes staged, while Pears and Apples were most abundant and good. Four collections of six varieties of fruit were shown, Mr. W. Nash, gardener to the Duke of Beaufort, taking the lead with very good Black Alicante and fairly good Muscat of Alexandria Grapes, a Melon, Beurré Diel Pears, good Ross Nonpareil Apples, and Medlars. Mr. W. Bannister, gardener to H. St. Vincent Ames, Esq., was a very close second, his collection consisting of good Black Hamburgh and Muscat of Alexandria Grapes, a faulty Melon, very fine Marie Louise Pears, Worcester Pearmain Apples, and Medlars. The third prize was awarded to Mr. J. T. Holmes. Mr. Nash was first for four bunches of Grapes in two varieties with perfect examples of Black Alicante and creditable Muscat of Alexandria, Mr. Bannister again following closely with good Black Hamburgh and Bowood Muscat. Mr. G. Shelton had fairly good Lady Downe's and Black Alicante, and was awarded the third prize. In the class for three bunches of any black variety Mr. Nash staged three large grandly finished bunches of Black Alicante, and was followed by Messrs. G. Shelton and W. K. Wait, both staging Black Alicante in good condition. Mr. H. Jones, gardener to General Doherty, was the only exhibitor of white Grapes, and received a second prize for rather poor Muscat of Alexandria.

There were twelve entries of six varieties of Pears, Mr. A. George being first with fine dishes of Beurré de Rance, General Todtleben, Beurré Bachelier, Beurré Clairegeau, and Duchesse d'Angoulême. Mr. F. R. Smith was a good second, and Mr. H. Beavis third. The best four varieties were staged by Mr. E. Jones, and consisted of General Todtleben, Beurré Bachelier, Duchesse d'Angoulême, and Durondeau. Mr. M. Cole was a good second, and Mr. W. Hall third. There were thirty exhibits of a single dish of Pears, Mr. F. Rice winning with Marie Louise, and was followed by Mr. C. H. Gabriel with the same variety, and the third prize was won by Mr. W. Mead, who staged Glou Morceau.

Twenty lots of six varieties of dessert Apples were staged, Mrs. Pinder taking the lead with highly coloured medium-sized fruit of King of the Pippins, Cox's Orange Pippin, Royal Russet, Newtown Pippin, and Blenheim Orange. Messrs. H. Beavis and W. Bannerman took the remaining prizes. There were twelve exhibitors of four varieties, Mr. E. Hall winning the first prize with Jackson's Pippin, Ribston Pippin, Blenheim Orange, and King of the Pippins in good condition, the other prizes going to Messrs. H. Taylor

and J. Horsell. No less than forty-nine single dishes were exhibited, the Judges eventually awarding the first prize to beautifully flavoured Cox's Orange Pippin, staged by Mrs. Phayre, the second prize going to Mr. Fisher for Ribston Pippin, and with the same variety Mr. A. Beavis was third. Kitchen Apples were also numerous and well shown. Mr. S. Butler staged the best six varieties, these including fine fruit of Warner's King and Blenheim Orange. Mr. A. Beavis was second, and Mrs. Pinder third, both staging fine produce. There were thirty single dishes shown, Col. Grant taking the first prize with very fine Warner's King. Mr. S. Butler was second with the same variety, while the third went to Mr. W. Ashman for very good Blenheim Pippin.

CROYDON, NOVEMBER 14TH AND 15TH.

THE seventh annual Exhibition of Chrysanthemums, &c., was held in the Public Hall, George Street, and in spite of the clashing with other shows the result was highly satisfactory, the exhibits showing a marked improvement as a whole. There was better quality running through the whole classes, the rear rank in the cut blooms showing up much better than usual—a sure indication that the Society is doing the good work it intended in advancing the cultivation of the Chrysanthemum.

The groups were very effective in the trade class. Mr. Curd, florist, Addiscombe, was first with a fine collection, and Mr. Coppin second. In the amateurs' division Mr. Bowman was first with well-grown plants and of fair average quality. Mr. Lewis, gardener to H. Goschen, Esq., Addington, and Mr. Salter were the principal prizetakers for trained plants, the exhibits showing good cultivation, but some of them badly finished, the sticks in some of the standards being very objectionable.

In the open division for cut blooms Mr. Gibson, gardener to E. Wormold, Esq., Mordam Park, as usual, showed some fine blooms, as he was awarded the silver cup for twenty-four incurved, distinct, and also the silver cup for the corresponding class for Japanese; Mr. J. Holmes, gardener to C. M. Storey, Esq., Nightingale Lodge, Balham, being second in both classes with good well-finished blooms, and Mr. Elsey, gardener to D. Cornish, Esq., Selhurst, third in both classes. The other classes for cut blooms confined to the district were well filled, the principal prizetakers for incurved blooms being Messrs. Sadler, Elsey, Reed, and Rodbourn; and for Japanese Mr. Alderman, gardener to C. Czarnikow, Esq., Mitcham; Mr. J. Staines, gardener to J. Newton, Esq., Park Hill; and Mr. Reed. The large Anemones were well represented, but, unfortunately, some of them were not distinct, which led to disqualification, and the Committee would do well another year to allow eight varieties to be shown, which would lead to greater competition. All the classes in the amateurs' and single-handed gardeners' division were well filled, Messrs. Reed, Bowman, Brice, Welstead, Staines, Dobson, and Elsey taking the chief prizes. The competition in the fruit classes was very keen, and rendered especially interesting by the splendid collection of Apples from Mr. Cummings, gardener to A. Smee, Esq., Carshalton, who staged over a hundred dishes of handsome clean fruit, and was awarded first prize for a collection; Mr. Penfold, gardener to Canon Bridges, second; and Mr. Rodbourn third. Mr. Cummings was also first for black Grapes with Mrs. Pince, and Mr. Alderman first for white Grapes with Muscat of Alexandria. The baskets of vegetables were exceedingly good, Messrs. Cooper, Rodbourn, and Welstead being the chief prizetakers. For a single stand for dinner-table decoration Mrs. Bishop was awarded first prize and Mrs. Cross second. Mr. Chaff, florist, was awarded an extra prize for a splendid box of cut flowers of stove and greenhouse plants, which was a great attraction, and extra prizes and commendations were also awarded to Messrs. Roffey, Curd, Gibson, for various plants and cut flowers.

BOROUGH OF HACKNEY, NOVEMBER 14TH AND 15TH.

THE finest Exhibition yet held by this Society was that at the Royal Aquarium, Westminster, on Wednesday and Thursday last week, as the number of competitors was larger than usual, the general quality of the exhibits was admirable. Blooms, specimen plants, fruit, and vegetables were all in strong force, and in many respects superior to any that have yet been staged at previous Aquarium shows. It has been customary to place the vegetable and fruit exhibits in the gallery, but on this occasion they were all with the blooms and plants in the large hall, and produced a fine effect, though this was somewhat marred by their being rather scattered owing to the arrangements for the entertainment. If the whole body of the hall could have been devoted to the Show it would have been much more imposing and convenient for the visitors. The general system of arrangement and affixing the prize cards was all that could be desired, and though a little delay occurred in the judging, the general details were well managed and very creditable to the Hon. Secretary, Mr. William Holmes, and his coadjutors.

Plants.—A most important class in this section was for a group of Chrysanthemums arranged for effect in a space of 100 square feet. Three competitors entered, and though all their contributions were good there was considerable difference in their merits, and the awards occasioned much discussion and some dissatisfaction. It was stated that "general effect would be the leading feature," and it would seem the positions taken by the groups was not in strict accordance with this rule. Messrs. Mahood & Sons, Putney, won the silver cup offered by the Royal Aquarium Company with handsome well-grown plants bearing substantial and beautiful blooms, but the arrangement was a little too crowded and not quite well enough finished in front. Mr. G. Stevens, Putney, was placed second also with good plants and blooms, but in this case rather too loosely arranged, and the front plants were too tall. Mr. N. Davis, Camberwell, took the third position with a group that was well entitled to second honours, and it was a matter of opinion if it was not more effective than the first. The plants were strong, bearing handsome blooms with a good diversity of colours, and freely arranged without being either loose or crowded, and having a neat margin of dwarf plants. For six specimens of large-flowered varieties in 12-inch pots Mr. E. Cherry, The Gardens, Norfolk House, Streatham, was the leading exhibitor, taking first honours with even freely flowered examples of Mrs. G. Rundle, Barbara, Mrs. Haliburton, Prince of Wales, Mrs. Dixon, and Beethoven. The best six Pompons were staged by Mr. R. E. Reeve, Hadley Green, Barnet; dwarf beautiful specimens about 4 feet in diameter, excellently flowered; Defiance, Antonius, Fanny, White, Golden, and Lilac Cedo Nulli being the varieties. In the borough classes Messrs. Drain won the silver

cup for the best ten specimens with handsome dwarf plants, some of the best in the Show. They were all freely flowered; Gloire de Toulouse, Elaine, Peter the Great, and Bouquet Fait being particularly good. Messrs. S. Gilbey and R. Payne followed closely in this class, both showing freely flowered examples. In the other borough classes the same exhibitors secured the leading prizes.

Cut Blooms.—Principal interest centred in the class for forty-eight blooms, equal numbers of incurved and Japanese, not less than eighteen varieties of each, or more than two blooms of one variety. The prizes of £10, £3, and £1 have usually brought a number of competitors, but this year only three staged, the first two being close in merit. Messrs. Dixon & Co., Hackney, won first honours with substantial beautiful blooms of great depth, clean and fresh. The incurved blooms comprised the following varieties—Golden Empress, Queen of England, Golden Queen, Empress of India, a grand bloom, about 4½ inches deep, which was awarded a prize as the best bloom in the Show; Prince Alfred, Cherub, Refulgence, White Globe, Venus, John Salter, Mrs. Shipman, and Princess of Wales, Lady Slade, White Venus, Jardin des Plantes, Barbara, Princess Beatrice, Hero of Stoke Newington, and Eve. The Japanese varieties were Fair Maid of Guernsey, Mons. Ardene, Madame Moulise, Baronne de Prailly, Meg Merrilees, Alba Plena, Madame C. Audiguier, The Daimio, Comte de Germiny, Soleil Levant, Dr. Macary, Criterion, Sarnia, Thunberg, Fanny Bouchardat, Bronze Dragon, Alba Plena, Triomphe des Châtelets, Agremens de la Nature, Parasol, and Cry Kang. Mr. C. Herrin, The Gardens, Chalfont Park, Gerrard's Cross, followed very closely, most of his Japanese being equally as good as those in the premier stand, and some were superior in size and substance; but the incurved, though neat and fresh, were a little wanting in size. Messrs. Mahood & Sons were third with smaller blooms, but bright.

The class for twenty-four incurved blooms was a good and interesting one, eight collections being staged, mostly very even in quality. The silver cup was, however, well won by E. Sanderson, Esq., St. Mary's Road, Harlesden, the President of the Society, and one of the oldest Chrysanthemum growers in the metropolis. His blooms were throughout distinguished by their symmetry and substance, clean, even and perfect. The varieties were, in the back row, Empress of India, Alfred Salter, Emily Dale, John Salter, Queen of England, Barbara, Hero of Stoke Newington, and Golden Empress of India. Second row: Empress Eugénie, Jardin des Plantes, Lady Hardinge, Princess Teck, Le Grand, Guernsey Nugget, Venus, and Mrs. Heales. Front row: Princess of Wales, Abbé Passaglia, Golden Eagle, White Venus, Cherub, Nil Desperandum, and Mrs. W. Shipman. The second and third prizes were secured by Mr. C. J. Salter, The Gardens, Selborne, Streatham, and Mr. J. Clark, gardener to Mrs. Joad, Patching House, Worthing, Sussex, both showing good collections. For eighteen incurved Mr. Sanderson again took the lead, followed by Mr. J. Major, gardener to G. J. P. Kidstone, Esq., Nyn Park, Potters' Bar, and Messrs. Saltmarsh & Son, Chelmsford.

Competition in the class for twelve incurved blooms was extraordinarily keen, seventeen stands being entered. Mr. J. Udale, gardener to J. Watson, Esq., Shirecliffe Hall, Sheffield, won first honours with large, even, and handsome blooms of Queen of England, Alfred Salter, Empress of India, Golden Empress, Princess of Wales, Mrs. Heale, Cherub, Isabella Bott, Jardin des Plantes, Prince of Wales, Princess Teck, and Barbara. This stand well deserved its position, as the blooms were much superior to the majority of others in the same class. Mr. C. Herrin was second with smaller but very neat and well-finished blooms; Mr. J. Spreckley, Worplesdon, Guildford, being third. Six incurved were also strongly shown, sixteen competitors staging, Mr. H. Prickett, gardener to J. Gribble, Esq., East Barnet, taking the lead. Mr. Berry, gardener to the Countess of Leven and Melville, Roehampton, had the best twelve large Anemone-flowered varieties—very fine blooms of Lady Marguerite, George Sands, Fleur à Marie, Mrs. Pithers, Marginatum, St. Margaret, Acquisition, Prince of Anemones, Gluck, and Louis Bonamy. E. C. Jukes, Esq., Hope House, Winchmore Hill, N., and Messrs. Mahood & Sons secured the second and third prizes. Mr. H. Butcher, Hadley, Barnet, staged the finest twelve Anemone Pompons—a very beautiful collection. Mr. Ridout, gardener to T. B. Haywood, Esq., Reigate, was awarded premier honours for twenty-four Japanese, a grand lot of blooms of the best varieties. Mr. E. Maxted, gardener to the Marquis of Ely, Kearnsey Abbey, Dover, was a good first in the class for twelve Japanese blooms amongst thirteen competitors. The same exhibitor had the finest collection of twelve Pompons, extremely beautiful blooms. The special prize offered by Messrs. Dixon for twelve new Japanese varieties sent out by that firm was secured by Mr. J. J. Hillier, with Chinaman, Beauté de Toulouse, François Delaux, Mdle. Louise Sabatie, J. Delaux, Venus, Source d'Or, Mr. Starling, J. Hillier, Petit Frise, Petit Norbont, and General Lartique. In the one-variety classes Mr. Herrin was first for large Anemones with six handsome blooms of Lady Margaret; Messrs. Mahood first for Japanese with Triomphe de la Rue des Châtelets, large and full; closely followed by Mr. Herrin with Baronne de Prailly. In some of the local classes Messrs. S. Gilbey, Martin, P. Payne, G. Laughton, and Nichols were the chief prizetakers.

Fruit.—Grapes, Apples, and Pears formed an interesting portion of the Show, as they were both largely and well represented. The most important Grape class was that for twelve bunches, number of varieties not stipulated, and in which the prizes—viz., £10, £3, and £1 10s., were offered by the Royal Aquarium Company. Eight collections were entered, some comprising black Grapes alone, and some had twelve bunches of one variety; there was thus evidently some little confusion respecting the meaning of the schedule. Mr. J. Roberts, gardener to the Baroness Rothschild, Gunnersbury Park, Acton, was adjudged first honours for a fine collection, the bunches being even, and including handsome examples of West's St. Peter's, unusually good for that variety, Alnwick Seedling very well coloured, Alicante, Gros Guillaume, Mrs. Pince, large in bunch and berry but not highly coloured, Black Hamburgh, Muscat of Alexandria, and White Tokay. Mr. Austen, The Gardens, Ashton Court, Bristol, secured the second place with even bunches that were considered by some as equal in merit to the first, but only three varieties were represented—namely, Black Alicante, good, Mrs. Pince, and Muscat of Alexandria, first-rate in colour and size. Mr. Findlay, The Gardens, Wroxton Abbey, Banbury, was third, all his specimens being black Grapes—Gros Colman, beautifully finished, of medium size, Gros Guillaume Alicante, Lady Downe's, and Mrs. Pince. Messrs. Goodacre, Elvaston Castle Gardens Church, Bradsworth; W. Howe, Park Hill, Streatham; Holmes Clapham

Park; and S. Castle of Lynn, also competed in this class. Mr. Allan, The Gardens, Gunton Park, was first with three bunches of black Grapes in a class of eight competitors with the grand examples of Gros Colman staged at Kensington on the previous day; Mr. S. Castle was second with Alicante; and Mr. W. Howe third with the same variety. Mr. A. Smith, gardener to H. Sewell, Esq., Loughton, was first with three bunches of white Grapes with Muscat of Alexandria, followed by Mr. Austen and Mr. C. Herrin with the same variety, seven lots being entered.

Apples were remarkably good, one of the finest displays we have seen this season. Twenty-two collections of six dishes of dessert varieties were staged. Mr. Allis, gardener to Major Shuttleworth, Old Warden Park, Biggleswade, being first with even and handsome examples of Reinette Grise, Aromatic Russet, Sykehouse Russet, Court of Wick, Court Pendu Plat, and Cox's Orange Pippin—a very fine collection. Messrs. Goldsmith and Austen followed closely. For six dishes of culinary Apples there were sixteen entries, Mr. Haycock, The Gardens, Barham Court, Maidstone, winning premier honours with superb fruit of Gloria Mundi, Emperor Alexander, Peasgood's Nonesuch, Bedfordshire Foundling, and Mère de Ménage. Mr. Ross, The Gardens, Welford Park, Newbury, and Mr. Austen were second and third respectively. Fifteen collections of six dessert Pears were staged, Mr. Haycock securing first honours with magnificent fruit of Duchesse d'Angoulême, Doyenné du Comice, Conseiller du Cour, Beurré Diel, Easter Beurré, and Triomphe de Jodoigne. Mr. Fowler, gardener to Sir H. Mildmay, Bart., Dogmersfield Park, Winchfield, and Mr. Goldsmith followed with smaller but good fruits.

Vegetables.—A large and good display of these was provided. Eight collections were staged in the general class, the number of sorts not stipulated; and Mr. May, Nortbau Home, Barnet, won the premier prize with a most excellent collection of nineteen varieties, all in first-rate condition. Mr. J. Austen and G. Hanes, Highworth, followed. Messrs. Webb & Sons' prizes for a collection of six varieties Mr. Austen took the lead, followed by Messrs. May and Findlay, all the specimens being of great merit. Of Potatoes about 130 dishes were entered, Mr. R. Dean, Ealing, securing the premier prizes in both classes; Messrs. Osman, Prangnell, and Ross following.

Miscellaneous exhibits comprised an extensive and beautiful collection of Zonal Pelargoniums, Salvias, single Chrysanthemums, Primulas, and Cyclamens from Messrs. H. Cannell & Sons, Swanley; a fine group of Chrysanthemums from Mr. N. Davis, Camberwell; a group of well-grown Chrysanthemums from Mr. J. Lewry, gardener to James McAnderson, Esq., Belmont, Mill Hill; and a large collection of Potatoes from Messrs. Sutton and Sons. A first-class certificate was awarded to Mr. Ridout for

Chrysanthemum Bendigo, a yellow sport from Mrs. Heale which has been already described.

STAINES AND EGHAM DISTRICT.

THE second annual Exhibition of this young Society was held in the Literary Institute, situate in the High Street, Egham, on the 15th inst. Unfortunately a capital display of plants, cut flowers, fruits, &c., was much marred by the darkness of the rooms in which the Show was held and the very limited space at disposal, contrasting indifferently with the ample light and space seen in the Staines Town Hall last year. During the afternoon the Show became so crowded with visitors that locomotion was almost impossible, and seeing the exhibits was out of the question. The groups of decorative plants were a telling feature in the Show, not less than eight being in competition. Mr. Thatcher, Tborpe, had the best—a very admirable arrangement, and Mr. Springthorpe's was a capital lot of flowers. Trained plants were not largely shown, but some very good standards came from Mr. Riddish and Mr. Jannett, both of Egham. The open classes for twenty-four incurved blooms and the same of Japanese flowers were the chief features in cut flowers. In the former Mr. Hill, gardener to A. Savory, Esq., Chertsey, was a good first with capital blooms well displayed, and Mr. Strong, Wellington College, Berks, had some fine blooms in his second-prize lot; Mr. J. Strong, gardener to H. Sweet, Esq., Weybridge, came third. Messrs. Hill and Strong occupied the same positions in the Japanese class, both having beautiful blooms. The classes limited to the district brought fair quality and good competition, some specially good blooms being put up in the class for six incurved one kind, and six Japanese one kind, the prizes offered by the Secretary, Mr. Rawlins of Chertsey. Princess of Wales and Fair Maid of Guernsey was first, and Empress of India and Soleil Levant second. Zonal Pelargoniums, Solanums, Chinese Primroses, Mignonette, &c., were all well shown, and there were also some splendid Lady Downe's, Gros Colman, and Muscat of Alexandria Grapes sent by Mr. Robinson, gardener, Cooper's Hill, and some fine Alicantes from Mr. Peckham of Tborpe. The best two bunches were first-rate Madresfield Courts from Mr. Craill, gardener to F. Yeo, Esq., Staines. Apples and vegetables were of a high order, and merit the warmest commendation.

KINGSTON, NOVEMBER 15TH AND 16TH.

THE seventh great southern Chrysanthemum Exhibition has come and past, and has raised the fame of the Society to a still higher level, for in it was represented some of the most handsome blooms, both incurved and Japanese, that have ever been staged in the south. The number of blooms were rather less than last year, owing to the fact that then there were two challenge vase classes, the conclusion of the competition for the first, and the commencement of that for the second. This not only increased the number of exhibits, but also added greatly to the interest of the Show. However, taking the blooms, plants, and groups all through, the Exhibition just concluded would bear favourable comparison with any that the Society has previously held. In one respect it was remarkable—i.e., for the general success of Mr. Molyneux, who was undeniably the premier exhibitor, gaining first honours in six of the principal classes, besides the crowning achievement of winning the second challenge vase, in itself sufficiently creditable.

The Drill Hall was as usual chosen for the Exhibition, and the arrangements being judiciously supervised, the result was a very satisfactory display, bright, varied, and attractive. The weather proved very favourable, and a large number of visitors assembled on the first day, the Princess Frederica honouring the Show with her presence.

Cut Blooms.—These formed by far the most important portion of the Show, and the challenge vase class was the great feature of interest. This, it will be remembered, is the second vase, and was first offered last year for

twenty-four incurved and the same number of Japanese; Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishop's Waltham, being the successful exhibitor. According to the terms under which it was offered winning the vase twice renders it the property of the exhibitor, and this has been accomplished by Mr. Molyneux this time easily, for his blooms were much superior to all the others staged. Only three collections were entered, the Swanmore Park blooms, both incurved and Japanese, being remarkable alike for their size, substance, and freshness. The incurved were beautifully finished with few exceptions. The varieties were as follows:—Back row—Empress of India, Hero of Stoke Newington, Golden Empress, Alfred Salter, very fine; Mrs. Howe, Princess of Wales, handsome; Jardin des Plantes, and Queen of England, grand. Second row—Beauty, Mrs. W. Shipman, Prince Alfred, Cherub, Mrs. Heale, Barbara, fine; Pink Venus, and Refulgence. Front row—Mr. Bunn, Incognito, Bronze Jardin des Plantes, Princess Teck, Baron Beust, Le Grand, Orange Perfection, and Lady Hardinge.

The Japanese were similarly handsome, the colours being exceedingly rich. The varieties were in the back row—Mad. C. Audiguier, Fair Maid of Guernsey, Marguerite Marrouch, Dolores, Meg Merilees, M. Ardene, Peter the Great, and Baronne de Prailly. Second row—Père Delaux, Criterion, handsome; Balmorean, Soleil Levant, Khedive, Boule d'Or, grand; Comte de Germany, and Elaine. Front row—Triomphe du Nord, Hiver Fleur, Grandiflora, Sarnia, Japonais, R. Ballantine, Aiba Plena, and Thunberg. Mr. G. Harding, gardener to T. D. Galpin, Esq., Bristol House, Putney, was second, both the incurved and Japanese being smaller, though neat and fresh. In the former class he had some good blooms of Golden Empress, Empress Eugénie, Empress of India, Emily Dale, and Yellow Perfection. In the Japanese Père Delaux was extremely good; La Nymphé, Criterion, and Fanny Bouchardat being similar in size and substance. Mr. J. Hennell, gardener to F. A. Davis, Esq., Anglesea House, Surbiton, was third with good Japanese, but small incurved blooms.

Six good stands of twenty-four incurved blooms were entered, and Mr. Molyneux was again the premier exhibitor, having substantial blooms of the following varieties—in the back row, Queen of England, Golden Empress, Princess of Wales, Jardin des Plantes, Prince Alfred, Empress of India, Mrs. Howe, and Alfred Salter; second row, Baron Beust, Beauty, Cherub, Incognito, Mrs. Heale, Mr. Bunn, Pink Venus, Mrs. W. Shipman; front row, Le Grand, Dupont de l'Eure, Alma, Princess Teck, Barbara, Refulgence, Lord Wolseley, and Hero of Stoke Newington. Mr. Harding was a close second; Mr. G. Woodgate, Warren House, Kingston Hill, and Mr. J. Macpherson, gardener to S. Page, Esq., St. Leonard's Lodge, Surbiton, third. The class for twelve incurved blooms was well filled, six good stands being entered. Mr. E. Coombe, gardener to F. A. Brown, Esq., Lawn Bank, Teddington, took the lead with neat blooms, not large but of good substance. Mr. Lync, The Gardens, Belvedere House, Wimbledon, followed, Messrs. Fyfe and Watson being third and fourth with smaller blooms. One fine collection was disqualified for containing three blooms of one variety. Messrs. Strong, Benson, and Orchard secured the prizes for six incurved blooms with good stands. For six incurved blooms of one variety Mr. Molyneux was first with Princess of Wales, charming in substance and form; Mr. Benson third with Golden Empress, rather small for this variety, but full and of good form.

Japanese varieties were shown in large numbers, the majority of the blooms being of fine quality. Mr. E. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esber, had the best collection of twenty-four, and gained premier honours amongst six competitors with large richly coloured blooms of the following varieties:—Back row—Mad. C. Audiguier, Mr. Burnet, Boule d'Or, very large; Fair Maid of Guernsey, M. Delaux, M. Plancheron, Bronze Dragon, and Baronne de Prailly. Second row—Alba Plena, F. A. Davis, Mr. J. Mahood, The Sultan, Criterion, Marguerite Marrouch, Meg Merilees, and Soleil Levant. First row—Chang, Fanny Bouchardat, Magnum Bonum, Thunberg, Comte de Germany, M. Ardene, L'Incomparable, and Sarnia. Mr. J. King was a close second with similar blooms, but a few points behind. Mr. C. Herrin, Chalfont Park, and Mr. G. Woodgate were third and fourth respectively. Eight stands of twelve Japanese were in competition, Mr. Molyneux following up his remarkable success by taking the first prize with very beautiful blooms; Comte de Germany, Mad. C. Audiguier, and Criterion were especially fine. Mr. J. Child was placed second, and Mr. W. Fyfe, gardener to W. W. F. Dick, Esq., Thames Ditton House, was third, but in the opinion of many the adjudication here was far from satisfactory, as the third-prize lot was superior to the second in substance and colour, and indeed ran the first very closely. Competition was exceedingly keen in the class for six Japanese, ten stands being entered. Mr. Orchard was adjudged the premier award for substantial richly coloured blooms of Triomphe de Chatelet, Mad. C. Audiguier, M. Ardene, Criterion, Père Delaux, and Madame Le Croix. Mr. T. H. Benson, gardener to W. H. Roots, Esq., Kingston, was placed second with smaller examples, and Mr. Gibbons was third. For six blooms of one variety, Japanese, Mr. Molyneux was first with Mad. C. Audiguier, magnificent in size and colour, quite 6 inches in diameter, and nearly as much in depth. Mr. Beckett was second with Boule d'Or, also very fine, 7 to 8 inches in diameter; and Mr. Woodgate was third with Mad. B. Rendatler.

Five lots of twelve reflexed blooms were staged, Mr. Molyneux taking the first place with beautiful blooms of Golden Christine, King of Crimson, Pink Christine, Clot of Gold, Dr. Sharpe, Phidias, and Mrs. Forsyth. Messrs. Gibbon and Child were second and third. Mr. Molyneux also had the finest twelve large Anemone varieties amongst the same number of competitors, showing fine blooms of Lady Marguerite, Mrs. Pithers, Gluck, Madlle. Cabrol, and Fleur de Marie. Mr. Lync was a close and good second, Mr. Woodfall being third. Four fine stands of twelve Anemone Pompons were entered, Mr. Beckett securing the first place with Miss Nightingale, Perle, Marie Stuart, Mr. Astie, Antonius, Marguerite de Coix, Firefly, and Calliope. Messrs. Benson and Moorman were second and third. Mr. W. Clark, gardener to A. Nagle, Esq., Bijou Cottage, Kingston, was awarded premier honours for twelve bunches of Pompons amongst five competitors, his best blooms being Golden Aurora, Bronze Aurora, Phidias, Pericles, Bijou d'Horticulture, Cendrillon, Model of Perfection, and Marabout. Messrs. Lync and Beckett followed. Maiden classes were provided for six incurved and six Japanese blooms. In the former Mr. Bates took the lead, and in the latter Mr. J. Munro, both showing well. Several amateurs' and cottagers' classes were also well filled and interesting.

Plants.—The leading class for Chrysanthemum plants was for a group in which quality and effect were to be combined, and this stipulation caused the Judges some difficulty, for though the group selected for the premier shown by Mr. J. Bass, gardener to A. S. Price, Esq., Parkside, Ewell, included the finest blooms it was decidedly surpassed in gracefulness of arrangement, diversity and brightness of colour, by that from Mr. C. Orchard, gardener to J. Galsworthy, Esq., Coombe Leigh, Kingston Hill, which was placed second. In classes of this character it is far better to let the one quality of effectiveness stand alone, as that is the principal requirement in a group. Mr. D. Gibbons, gardener to Mrs. Beckford, Orford House, Ham, was third, his front plants being too tall; but the group was bright and contained some fine blooms. For six specimen large-flowered varieties Mr. G. King, The Gardens, Wolsey Grange, Esher, took the lead with good plants about 5 feet in diameter and well flowered. John Salter, Mrs. G. Rundle, G. Glenny, Mrs. Dixon, Prince of Wales, and Lady Hardinge were the varieties. Decidedly the finest plants in the Show were the three standards from Mr. J. Trussler, gardener to J. Strand, Esq., Fullbrooks, Old Malden. These were about 4 feet high, with finely trained conical heads of seven concentric rings of about 120 blooms, the centre one being as true as possible, and all the others arranged with geometrical precision. Mr. Sallows was a good second. For three large-flowered trained specimens Mr. Sallows was first with good plants, L'Isle des Plaisirs being about 4 feet across and profusely bloomed. Hiver Fleur was also very good. Mr. Hoskins, gardener to S. Williams, Esq., The Laurels, Putney, followed. Mr. J. Lyne had the finest six Pompons, freely trained and well-flowered examples of the Cedo Nullis and Dick Turpin being very noteworthy. Mr. King had the finest single specimen, John Salter, about 5 feet in diameter with over a hundred blooms. Mr. Sallows was second with Mrs. Dixon, having small blooms but numerous.

Miscellaneous Plants.—A class was provided for a group of miscellaneous plants arranged for effect, and three tasteful collections were contributed; that, however, from Mr. T. Glover, gardener to W. Evill, Esq., Worcester Court, Worcester Park, which gained the premier prize, was so light and graceful, so unpretentious and yet so extremely attractive, that was greatly admired by all the visitors. A few well-grown Palms, such as *Cocos Weddelliana*, *Areca lutescens*, *Dracænas*, and *Cordylines* were employed with a groundwork of small Ferns, *Primulas*, *Crotons*, and a free margin of *Panicum variegatum*, while from the body of the group numerous spikes of *Calanthe vestita* and *Veitchi* elegantly arched, giving it a most pleasing appearance. Mr. Martin, gardener to J. Ford, Esq., Elm Lodge, Surbiton, was second, and Mr. C. Attrill, Bank Grove, Kingston, a good third. Table plants were well shown by Messrs. Beckett, Lync, Buss, King, and Hoskins; *Cyclamens* by Messrs. Beckett, Bate, and Russ; while Mr. King had the best collection of "berried" plants, fine plants of *Capsicum Princess of Wales* with abundant large golden fruits.

Fruit.—There was a fairly good display of fruits, Apples and Pears. Mr. Bates had the premier collection of six dishes, which included a well-grown Smooth Cayenne Pine Apple, Blenheim Pippin Apples, Alicante and Muscat of Alexandria Grapes, both well coloured, with neat examples of Glou Morceau and Chaumontel Pears. Mr. Munro, who was second, had Alicante Grapes well coloured, and fine King of the Pippins Apples, Mr. Beckett being third with good Alwick Seedling Grapes and Beurré Diel Pears. Mr. King staged the best four dishes of dessert Pears, Beurré Diel and Duchesse d'Angoulême being very fine. Messrs. T. Glover and Beckett followed. Thirteen collections of four dishes of Apples were staged, Mr. C. Attrill taking first position with fine fruits of Beauty of Kent, Mère de Ménage, King of the Pippins, and Cox's Orange Pippin. Mr. Orchard was a close second, and Mr. J. Child third.

Special prizes were offered for buttonhole bouquets and stands of flowers and foliage, and the competition was keen in each class. Unfortunately, however, as on previous occasions, the judging gave much dissatisfaction, and it would be well if the Committee could make different arrangements for these classes. In the buttonhole class decidedly the best examples, those from Mrs. Brown of Richmond, did not receive any award, while in the stand of autumn foliage and berries the most tasteful from Mrs. Drewett was placed second.

Not for competition were some good bunches of Grapes from Messrs. T. Jackson & Son, Kingston; a group of pretty Carnations from Messrs. Hooper & Co, Covent Garden, and a number of well-grown *Primulas* of a new rich crimson-coloured variety from Mr. Wiggins, gardener to W. Clay, Esq., Kingston.

Certificates were awarded for the following Chrysanthemums:—

Roseum superbum and *Madlle. Le Croix* (Jackson), which were certificated at Kensington on the previous Tuesday.

M. Astory (Jackson).—A very handsome Japanese variety of the Elaine type, with much broader petals and more substantial pure white blooms.

Jeanne d'Arc (Jackson).—An incurved variety with deep well-built blooms; the petals broad, white tipped with pale purple. Very pretty.

Lord Alcester (Mr. E. Wills, gardener to Mrs. Pearce, The Firs, Basset, Southampton).—A fine incurved variety, a sport from Golden Empress of India. The bloom shown was 5 inches in diameter and nearly as much in depth, beautifully formed, with broad petals pale creamy yellow in colour. It has also been certificated at Southampton.

LINDFIELD, SUSSEX, NOVEMBER 15TH AND 16TH.

AN interesting Exhibition of Chrysanthemums, fruit, and flowers was held in this village on Thursday and Friday last, and ended in a complete success. The Exhibition was organised by the Committee of the Assembly Rooms, assisted by the gardeners of the neighbourhood. The principal contributors to the Show were Mr. A. J. Brown, gardener to J. Proctor, Esq. (the majority of this gardener's exhibits was in advance of the other exhibitors, as will be seen by the prize list, the group especially is worthy of commendation for the tasty arrangement and good flowers which was very much admired). Mr. Venn, gardener to W. Sturdy, Esq.; Mr. Horscroft, gardener to J. Potter, Esq., Ardingley; Mr. Hodges, gardener to W. Gibbons, Esq., and smaller group from other gardeners in the neighbourhood. The principal prize-takers were as follows:—For the best group staged for effect in a space of 39 square feet (eight entries). First, Mr. Brown, gardener to J. Proctor, Esq.; second, Mr. Horscroft, gardener to H. Potter, Esq.; third, Mr. Hodges; highly commended, Mr. Venn, gardener to W. Sturdy, Esq. For the

best two plants (Japanese), Messrs. Hodges, Brown, and Horscroft. Incurved (two plants), Messrs. Horscroft, Hodges, and Brown. For Pompons, Mr. Brookes had the best specimen plant; Messrs. Hodges and Plummer. For cut blooms (twelve Japanese), Messrs. Brown, Hodges, and Mr. Venn. For twelve incurved, Messrs. Brown, Horscroft, and Venn. For six *Poinsettias* there was one exhibit, which was deservedly awarded the first prize—namely, from Mr. Brown; the foliage was in good condition from the surface of the pots upwards, some of the bracts being nearly 14 inches across. Plants suitable for table decoration were shown by exhibitors previously mentioned, as were also Apples, collections of fruits and flowers. A fine collection of fruit, plants, and cut Chrysanthemums was exhibited by Mr. Balchin of Brighton, and was highly commended, and a collection from Messrs. Cheale & Son of Lowfield, was also highly commended. Mr. Russell, gardener to Dr. F. Descou of Henfield was awarded an extra first prize for a splendid collection of cut blooms. Some elegant table decorations were shown by Miss H. Catt and Miss Dixon, and the bouquets exhibited by Mrs. Warre were highly commended.

WINCHESTER, NOVEMBER, 19TH AND 20TH.

WINCHESTER is a city of more than ordinary historical importance, but to ourselves and our readers it possesses a special interest as being the birth-place of the *Cottage Gardener* some thirty-five years since, and which has now developed into lusty manhood as the *Journal of Horticulture*. It was in this ancient city, too, that originated the fable of forty days' rain falling after July 15th, if rain happen to fall on that day (St. Swithin's). On the occasion of a new dedication of the Cathedral some 800 years ago, St. Swithin was included as a patron Saint, and his remains exhumed from the churchyard to be placed within the sacred edifice; this removal being delayed by heavy and continuous rains gave rise to the adage which is familiar to all, but of the origin of which all may not be familiar. But we must leave the past and glance hurriedly at the latest event of importance in our sphere that has occurred in the Hampshire capital—the first Chrysanthemum Show.

This was held on the dates above mentioned in the new and handsome Guildhall, and as a first show must be pronounced highly satisfactory; indeed it is a question if any such plants and blooms have been staged at a first show anywhere as the grand-trained specimens of Mr. Wills, and the magnificent blooms of the redoubtable Mr. Molyneux. A compact well-arranged schedule was prepared, very good prizes offered, and the competition was good throughout, not a few of the exhibits being of superior quality. We can do little more than glance at the successful exhibits, and record the names of the winners of the chief prizes.

In Class 1, collection of plants arranged for effect, in space 8 by 6 feet, there was the usual conflict between quality of blooms and effective grouping; but quality having precedence in the schedule had apparently the greatest influence in the determination of the awards. The premier position was won by Mr. Neville, gardener to F. W. Flight, Esq., Twyford, Winchester, with undoubtedly the finest blooms, and equally most imposing group. Mr. Goodchild, gardener to W. Colson, Esq., Colden Common, was an excellent second with very fresh and good examples. The remaining prizes going in the order named to Mr. W. Wareham, gardener to H. Goodhall, Esq., and Mr. Prouting, gardener to Miss Butler, with pretty groups of dwarf plants, which had not been grown for the production of a limited number of blooms. Though these groups did not equal those at Putney, Kingston, and the Westminster Aquarium, they were creditable to the exhibitors at a new show.

In the open class for six specimen plants Mr. Wills, gardener to Mrs. Pearce, Southampton, easily won the chief position with grand convex examples, about 5 feet in diameter, and admirably trained, no bending of the stems being visible, and the blooms relieved by excellent foliage. The varieties Madame Berthe Rendatler, La Nympe, and Hiver Fleur were magnificent. The second prize went to Mr. Hunt, gardener to R. Moss, Esq., M.P., Weston, with tinner plants; Mr. Joy, Shirley, being third with smaller examples, but more compact, running the others very closely. There was only one entry in the class for six specimen Japanese, and a second prize awarded to Mr. Hunt. Mr. Wynyard, gardener to Mrs. Hursley, won the first prize for a single specimen Japanese with a handsome well-bloomed dwarf plant of La Nympe, 4½ feet in diameter. Mr. J. Wareham, gardener to Mrs. T. Gunner, and Mr. Hunt securing the remaining prizes with free informal plants, but not of high-class merit. In the class for a single specimen incurved Mr. Astride, gardener to W. B. Simonds, Esq., distanced all competitors with Dr. Sharpe, admirably grown, flowered, and trained; Messrs. Hunt and Joy following. In the amateurs' classes for plants the prizes were awarded to Mrs. Rembery and General Sir A. Beechen, C.B., and considering the small pots the plants were grown in they were very good, each bearing six to ten blooms of good quality.

Cut Blooms.—In the class for twenty-four blooms, sixteen incurved or reflexed and eight Japanese, Mr. Molyneux, gardener to W. H. Myers, Esq., Swanmore Park, Bishops Waltham, was in his usual position with large, fresh, and splendidly finished examples. Amongst the Japanese, Meg Merrilees, La Boule d'Or, Criterion, Balmorean, Baron de Prailly, Madame C. Audiguier, and Margaret Marrouch were prominent; the most remarkable of the others being Empress of India and the golden variety, grand; Queen of England, Jardin des Plantes, Barbara, Mrs. Heales, King of the Crimson, Princess of Wales, and Pink Venus being little inferior. Messrs. Dixon and Sons, Hackney, followed with excellent stands, Empress of India being of remarkable excellence; the third prize going to Mr. Wills with generally larger but rather rougher blooms. Mr. Molyneux was also first in the class for twelve blooms, incurved, with an exceedingly neat stand, Mr. Wills following; and again in the twelve Japanese class Mr. Molyneux was to the fore with beautiful blooms, followed by Messrs. Wills and Neville with admirable contributions. In the twenty-four blooms in not less than eighteen varieties the prizes went to Mr. Molyneux. The class for twelve blooms in not less than eight varieties brought out several imposing stands; Messrs. Molyneux, Cox (gardener to R. King-Wyndham, Esq., Corhampton, Bishops Waltham), and Mr. Remsbury; and in the amateurs' classes for cut blooms the last-named exhibitor and Mr. H. Guillaume were the successful exhibitors.

A noteworthy group of plants sent by Mr. Molyneux was highly commended. Several of them were in 2½-inch pots, the plants ranging from 6 inches to a foot high, with fine foliage and excellent blooms, one on each plant 3 inches in diameter.

Fruit.—Very good Grapes, Apples, and Pears were staged. In the class for three bunches of Grapes Mr. Wildsmith, gardener to Lord Eversley, Heckfield, was first with Gros Colman, Gros Guillaume, and Muscat of Alexandria, all good; Mr. Weaver, gardener to W. Beach, Esq., M.P., second, and Mr. Cox third. Mr. Wildsmith was also an easy first with two bunches of black Grapes, Gros Guillaume and Gros Colman; Mr. Dauncey, gardener to B. Staive, Esq., Basingstoke, second; and Mr. Hillier, Winchester, third. For white Grapes the prizes went to Messrs. Wildsmith and Weaver for Muscats, the former having admirably finished bunches, the latter larger examples. In the heaviest bunch class Mr. Molyneux was first with Gros Guillaume, 5 lbs. 14 ozs.; Mr. Dauncey second with Alicante, 4 lbs. 5 ozs.

There was an excellent display of both dessert and culinary Apples, several of the collections of three dishes closely approaching each other in merit. Mr. H. Fiford was first in both classes, Mr. Wildsmith being a close second in the dessert, and Mr. Wills in the culinary section. Mr. Gandy, gardener to the Earl of Northbrook, was also a prizetaker. Pears were much less numerous. Mr. Wildsmith was the foremost exhibitor, winning the chief prize with Beurré Gris d'Hiver, very good; Glou Morceau, extra fine; and Beurré Diel. W. T. Cordrey, Esq., St. Cross, and Mr. Wills had the remaining prizes. But by far the most meritorious contribution of fruit in the Show was a collection from Mr. Wildsmith, comprising four splendid Pines, with capital Grapes, Pears, and Apples. A certificate of excellence was awarded, and an extra prize recommended by the Judges. Mr. Hillier also staged a large and excellent collection of Apples.

Miscellaneous Plants for Table Decoration.—Substantial prizes were offered for groups of stove and greenhouse plants arranged for effect. The competition was very good, but as a rule the arrangements were too crowded. Mr. Blackmore, nurseryman, Winchester, was the leading prizetaker, Mr. R. Hunt being second, and Mr. Hillier third. Table plants were very neat and fresh, but some of the collections too heavy; the prizes went to Messrs. Cox, Blackmore, and Wills respectively. Primulas were creditably exhibited, the prizes for doubles going to Messrs. Hurst, Blackmore, and Prouting; and for singles to Messrs. J. Merrit, gardener to Mrs. C. Warner, Axford, and Blackmore. Mr. Axford was the only exhibitor of Poinsettias, and was awarded the first prize for six plants.

Table decorations were quite equal to the average at larger shows than this. The Misses Flight were remarkably successful, taking most of the prizes; but in one class Mrs. F. C. Birch surpassed all other competitors.

Vegetables were very good indeed, and the collections exceedingly close in order of merit, the Judges, after carefully awarding points to every dish, awarding the prizes to Messrs. Cox, Wildsmith, and Dauncey in the order named.

As we were leaving the Show in the afternoon the officials and visitors were on the tiptoe of excitement in expectation of the announcement of the Premier, not the premier Chrysanthemum bloom, but the Prime Minister of England, who was in the neighbourhood, who, if he attended, would no doubt be the chief exhibit.

The Show was admirably managed, the officials discharging their duty like veterans, and we never saw the prize cards so quickly placed when the judging was done under numbers. The promoters of the Show are to be congratulated on its excellence, and it is quite certain that if public support is given some fine autumn shows will be seen in future in the ancient city of Winchester.

LINCOLN, NOVEMBER 20TH.

UNDER most favourable auspices the first Exhibition of the newly formed Lincoln Chrysanthemum Society was held in the Corn Exchange of the old city on the date above named. An excellent and industrious directorate, with Dr. G. M. Lowe as Honorary Secretary, succeeded in enlisting the sympathy of most of the influential families of the city and neighbourhood—very practical sympathy too, in several cases, judging by the various special prizes which adorned the schedule. As a first show weak points were apparent, but the general display was effective, and better quality will come with experience.

Cut Flowers.—In the class for twenty-four incurved, not less than eighteen varieties, Mr. Udale, gardener to W. Watson, Esq., Shirecliffe Hall, Sheffield, was distinctly ahead of all competitors, and was awarded the first prize for excellent blooms; Mr. Couling, gardener to J. Ruston, Esq., Lincoln, second with neat and creditable examples; and Mr. Wipf, gardener to N. Clayton, Esq., third with smaller blooms. In the class for twelve blooms went to the same exhibitors in the order above named, ten collections being staged. For six blooms Mr. Couling was an excellent first, followed by Mr. Radford, gardener to J. Hall, Esq., North Collingham, and M. Reynolds, gardener to Lieut.-Col. Seddon, Waltham Grove, Great Grimsby. Mr. Wipf, Mr. Mitchell, gardener to W. J. Warrener, Esq., Lincoln, and W. Ashley, Esq., Limefield, Brigg, were the prizewinners for reflexed flowers, all the blooms being fresh but small. Very creditable indeed were the first and second stands of twelve Japanese from Messrs. Couling and Wipf, similar to blooms staged at the London shows a few years ago. Mr. Couling also had the premier Japanese bloom in the Show, an excellent Elaine, the corresponding award in the incurved section going to Mr. Udale for a fine example of Empress of India. Stands of Pompons were good, especially the first-prize collection of twelve from Mr. Wipf, Messrs. Warrener and Couling following, the two last-named exhibitors also securing the prizes for Anemone flowers with neat clean examples. The blooms staged in the amateurs' classes were very small. A collection of blooms was sent from the Inner Temple Gardens, London; but by far the finest stand in the Show was staged by one of the Judges not for competition.

Plants.—These were generally wanting in finish and size of blooms, the prizewinners being Messrs. Couling, Woollas (gardener to — Bell, Esq.), S. Lowe, Esq.; Worsdale (gardener to H. K. Hebb, Esq.), for large-flowering varieties, Japanese excluded; for Japanese Mr. Bell and Mr. Lowe; the best Pompons being staged by Messrs. Rowson Brothers, Torrington, but they were poor, and the only standards worth notice were neat miniatures from Mr. Mitchell.

Groups of Chrysanthemums in semicircles 10 by 5 feet had an imposing effect, eight of them being staged down one side of the hall. Mr. Ridsdale, gardener to the Marquis of Ripon, S. Lowe, H. K. Hebb, R. Swan, and J. J. Clarke, Esqs., were awarded the prizes for ordinary untrained conservatory decorative plants, defective in quality of bloom, no disbudding having been done. By far the best plants in the Show were included by Messrs. Pennell

and Sons, nurserymen, in a most effectively arranged group, which certainly excelled all others, and was highly commended, as it was not entered for competition. Mr. Close, gardener to Robert Dawber, Esq., was similarly commended for a group better than any in competition. Messrs. Pennell had also a handsome group of choice Coniferæ worthy of a place at any exhibition in the kingdom. For groups of "Chrysanthemums and other plants" equal first prizes were awarded to Messrs. Mitchell and Wipf for good arrangements. J. Ruston, Esq., had an imposing group not for competition. Mr. Worsdale received the first prize with Peter the Great as a single specimen.

Fruit.—Mr. Wipf staged excellent Grapes, and secured the first prizes for both black and white with Gros Colman and Mrs. Pearson, followed by Messrs. Seddon and Reynolds, gardener to F. J. Clarke, Esq. Apples were very good, Mr. Picker, gardener to A. S. L. Melville, Esq., Messrs. R. Grant, Bracebridge, and Ridsdale being awarded the prizes, the prizes for Pears falling to Mr. Couling; but the finest display of Apples was contributed by Messrs. Pennell, sixty varieties being staged in capital condition.

The prize for vegetables was awarded to Mr. Bentley of the Corporation Sewage Farm for examples of Celery, Potatoes, Brussels Sprouts, Onions, Cauliflowers, and Carrots, such as we have never seen excelled at any exhibition. Mr. Foster, gardener to R. Greenham, Esq., Metheringham Heath, was also worthily granted an extra prize for an excellent collection. Dr. E. M. Lowe and R. J. Ward, Esq., two gentlemen of position in the city, worked zealously throughout the Show, and a large measure of the success that has been achieved is attributable to their laudable efforts in endeavouring to improve the cultivation of the Chrysanthemum in the district, and with good public support they will succeed in their object, affording the citizens rich floral treats.

MANCHESTER, NOVEMBER 20TH.

THE above Society held their annual Show as usual in the Town Hall. The Exhibition on the whole was equal to those of past years, and in some respects superior. The Chrysanthemums in pots were not only more numerous, but on the whole of better quality. The cut blooms were much superior to what we have before seen them at this Society's exhibitions, and more numerous.

Plants.—In the class for nine plants J. Allan, Esq., Altrincham, took the lead with dwarf and fresh specimens. Thomas Statter, Esq., Stand Hall, was placed second with good plants, but the blooms of some were a little past their best. G. Howarth, Esq., Stretford, and G. H. Kenworthy, Esq., Ashton-under-Lyne, were equal thirds. For four plants Mr. G. Allan was again first with even well-grown plants. J. G. Best, Esq., Withington, gained the second place with rather taller examples. John Wild, Esq., Uplands, Stand, was third. The plants of Japanese varieties were not numerous, but of good quality. In the class for six plants G. Cooper, Esq., Timperley Hall, was first, and Mr. J. Allan second. For four Pompons T. Dickens, Esq., Higher Broughton, took the lead with large well-grown plants not too stiffly trained. Mr. J. Wild was second with less neat plants, and Messrs. Cooper and Statter were equal third. In the class for eight plants grown for conservatory decoration without being disbudded Mr. J. Allan took the lead, followed closely by Mr. J. Dickens.

Cut Blooms.—In the class for twenty-four blooms Mr. J. Warrington, gardener to T. Bright, Esq., Aigburth, was placed first with bright substantial blooms. Mr. E. Green, gardener to J. Woolwright, Esq., Mosely Hill, Liverpool, was second, but his blooms were finer in colour, size, and substance. Mr. G. Cooper was placed third with much smaller flowers and very irregular. In the class for twelve blooms Mr. E. Green was first, Mr. J. Warrington second, and Messrs. J. Allan and G. Cooper equal third. In the class for twenty-four miscellaneous blooms twelve lots were staged, which included some good blooms of Japanese, Anemone, incurved, reflexed, and Pompon varieties. Mr. G. Allan took the lead, followed by Messrs. G. Cooper, J. Dickens, and D. McCure, Heaton Mersey.

Table Plants.—Nine or ten lots were staged for the three prizes offered, and the whole were very creditable to the exhibitors. R. P. Gill, Esq., Ashton Mersey, was first with neat well-grown plants. The second award went to O. Schneider, Esq., for a little larger plant but equally well grown. R. A. Farrington was the remaining prizetaker. Primulas were not so good on the whole as I have seen them, and they need no special comment. Mr. G. H. Kenworthy was first, and S. Hazzopulo, Esq., Higher Broughton, second. Mr. T. G. S. Garnett, Bolton, was the remaining prizewinner. Roman Hyacinths were not largely exhibited, but were really fine, especially the first-prize collection staged by Mr. J. Dickens. Messrs. G. Cooper and R. A. Farrington, Wigan, were second and third in the order named. The bouquets and vases for dinner-table decoration need no special mention, the principal prizewinners being Messrs. W. Irvine, G. A. Kenworthy, and Mrs. Shaw.

Miscellaneous Exhibits.—T. W. Tatton, Esq., Wythenshawe, staged a very handsome collection of Pears and Apples grown within seven miles of Manchester on heavy soil with a subsoil of sand. Seventy dishes of the two were staged, the whole collection being most creditable. Messrs. G. and W. Yates, Market Place, Manchester, also staged a magnificent collection of Apples of about 120 dishes, some of them being of remarkable size and colour. At the back of this collection was also staged an assortment of flowering plants. Messrs. Dickson, Brown, & Tait, Corporation Street, Manchester, also contributed largely to the beauty of the Exhibition by staging a collection of Cyclamens and other flowering plants, the former being remarkably fine.

TWICKENHAM, NOVEMBER 20TH AND 21ST.

THE annual autumn Show was held on Tuesday and Wednesday last in the commodious Town Hall, and was one of the most satisfactory displays this thriving and well-conducted Society has yet held. The upper rooms were devoted to the cut blooms, of which several handsome collections were contributed, fruit, vegetables, and miscellaneous plants, all these classes being well filled and good produce staged. The large hall was occupied with the groups and miscellaneous plants, the former being very bright; and with the handsome group of Chrysanthemums and fine-foilage plants exhibited by Mr. Bates, gardener to J. E. Meek, Esq., Poulett Lodge, not for competition, an effective display was formed. Considerable space had, however, to be reserved, as promenade concerts were held each evening which were very largely attended. Mr. H. Allfrey, the Honorary Secretary,

and Mr. Bates deserve much praise for the general arrangement of the Exhibition.

The principal class was that for a collection of Chrysanthemums arranged for effect in a space of 50 square feet, the first prize of £3 being presented by Lady John Chichester. Mr. Munro, gardener to the above-named lady, Cambridge House, Twickenham, was the successful competitor, gaining the premier award with a tasteful group of handsome plants bearing large substantial blooms. Mr. Sallows, gardener to J. J. Flack, Esq., Hampton Wick, was second with taller plants rather more freely arranged; and Mr. G. Parsons, gardener to T. Twining, Esq., Perryn Home, was third with a too loosely arranged group. Mr. Sallows had the best six specimen plants, very well-flowered specimens, L'Isle des Plaisirs being especially notable. Baskets of miscellaneous plants were well shown by Mr. Trussler, The Gardens, Thistleworth, and Mr. Fittell, gardener to J. R. Greaves, Esq., Cambridge Park, who won first and second respectively with graceful combinations of flowering and fine-foliage plants.

In the cut-flower classes the premier awards were secured by Mr. Beckett, gardener to J. P. Currie, Esq., in all the leading classes, and showed some very handsome blooms. He had the best twenty-four incurved and Japanese varieties, the best twelve Japanese, and the best twelve incurved—a fine selection of varieties admirably represented. Messrs. Sallows and Trussler secured the other chief prizes with smaller but bright and fresh blooms.

Fruit was well shown by Mr. Munro, who had some excellent Apples and Grapes, Alicantes being very well coloured; Mr. Trussler also staged some fine Apples. The chief collection of vegetables was from Mr. J. Wild, gardener to G. Macintosh, Esq., Richmond House, who had some very clean well-grown produce.

Miscellaneous collections of fruit, vegetables, and plants were numerous. Some good samples of Apples, Cabbages, Savoys, and other vegetables, with wonderfully fine specimens of Celery, were contributed by Mr. W. Poupard, Twickenham. Mr. Wright, gardener to Sir Charles Freake, Bart., had excellent specimens of Alicante and Gros Colman Grapes, with Apples. Mr. J. Howell sent a number of baskets of highly coloured Apples. Mr. W. Mann, The Warren, Whitton, showed a fine collection of Apples. Mr. J. Walker, Whitton, had a group of well-grown Cyclamens. Messrs. Hooper and Co. had a beautiful group of Carnations in pots. Mr. Bates also contributed, in addition to the central group, two stands of incurved, Japanese, and reflexed, blooms of good quality.

CLONMEL ROOT, FRUIT, AND FLOWER SHOW.

This was held on the 14th inst. in the spacious Skating Rink and adjoining promenade grounds under the management of the President, Lord Lismore, and a special Committee of the local Agricultural Society, but the head and front of the labour, and I may add success, devolved on the respected and energetic Hon. Secretary, Rev. J. R. Millington, rector of an adjoining parish. The number of entries exceeded that of all previous years, and comprised some splendid specimens. There were competitive and non-competitive collections. Take the latter first. A magnificent collection, a show in itself, was sent from Friar's Walk Nursery, Cork, by Mr. Saunders, and consisted of eighty-four different varieties of fruit, principally Apples and Pears, that elicited a "very highly commended" from the Judges, Messrs. Freeman and Benson, assisted by Dr. Hamphill. Seventy-two distinct varieties of Chrysanthemums, some really fine, and fifty cut blooms of Orchids, stove and greenhouse plants—these also received a special prize from the Judges, and right well they deserved it, remembering the time of the year and the distance from Cork, as well as their special merit. Messrs. T. Phelan, Spring Gardens, and F. Clibborn, Anner House, staged some really well-grown Chrysanthemums, incurved and Japanese being specially good; while the writer had specimens of Chou de Burghley, marked "Very highly commended," and deserving of extended culture, and was much noted by vegetable connoisseurs, to whom it was new.

I should require a special number of the Journal to do justice to those entered for competition; but before coming to these exhibits I must refer to the fine collection of some two dozen of the newer varieties of Potatoes sent by Mr. John Hunter from Dumfries, Scotland. Two remarkable varieties were Queen of the South and a coloured kidney, white eye, named Sir Garnet Wolseley, for early; Mammoth Pearl and Adirondack (coloured) for midseason; and he recommends Bresce's Peerless and White Don for the general or late crop. While Mr. Hunter deserves every encouragement, I must say I am certain none of his fine-looking varieties are likely to displace Magnum Bonums and Champions, which won first prizes in the farmers' classes, and deservedly. I grew thirty varieties last year, and for the general crop the two just named are still pre-eminent.

Taking fruit in the competitive section next, from local causes, change of gardeners, planting and transplanting, this was the only department behind other years, in the case of Apples especially. Though Ireland was not represented at Chiswick there was an abundant yield. For collections of fruit Mrs. Thomas Malcomson, Minella (gardener, Mr. John Crehan), took first prize, and had conspicuously good Gros Colman Grape, Doyenné Boussoch Pear, and Hawthornden and Ribston Pippin Apples. Lord Lismore (gardener, Mr. Fraser), Shanbally Castle, was second, and had fine specimens of Catillac Pear and Lord Suffield Apple, and what is rarer at this time of the year, a local seedling Melon. Nearly all the prizes in the sections for black and white Grapes, dessert and baking Pears, not less than two varieties, went to Mrs. Malcomson and her excellent gardener, Mr. Crehan, already mentioned. The next most important entries from a gardening point of view were the collections of garden vegetables. Here the competition was close between Lord Lismore and Capt. Moore, Barne (gardener, Mr. Heneberry), for the silver cup, which ultimately went to the former, and was won last year by the latter. The third prize went to a very select but smaller collection from C. Winston Duggan, Esq., M.A., Adelaide House. Of the thirty varieties in each collection some were admirable. Among the rest, Conover's Asparagus and Orangefield Tomatoes in the first, Carter's Dwarf Red Celery and outdoor Mushrooms in the second, and splendid Scrymgeour's Brussels Sprouts in the third. The collection from local cottagers in Cauliflowers and Onions were said by many to exceed those already referred to, and none was better pleased at this than the gentlemen themselves.

The collections of farm produce contained some things well grown, as Lucerne, Queen of the Valley, and White Elephant Potatoes, and various fine varieties of grain and roots not meet to go into the Journal. The first prize went deservedly to B. P. Phelan, Esq., J.P. The principal prize-winners in the various root classes, farm produce, were Sir John Gough, Knockeven; Capt. Bagwell, Marlfield; Abraham Denny, Tramore; Capt. Barton, Grove; Robert Coke, Kithnain; Capt. Moore, Barne; W. Tennant, Fethard; Thomas Lalor, Cregg; Thomas K. O'Mahony, W. E. Johnston, Esqs., &c. In grain the prizes went to many of the gentlemen named, and so of poultry, which I cannot intrude on your columns here. I may here fitly notice that some of the best-filled classes were for labourers' cottages—plants in flower grown by cottagers, cottagers' fowl, flannel, specimens of mending and darning, needlework, socks, hives of honey, and so on. Prizes for these several objects you will be glad to hear were offered, principally by the Benevolent Irish Peasantry Society of London, and warmly contested. I venture to say you and many of your readers will be pleased at all this good work.—W. J. MURPHY.

KITCHEN GARDEN.

Jerusalem Artichokes.—The stems may now be cut from these close to the ground, and the tubers should be all dug and stored in the same manner as Potatoes. The finest of them may be kept by themselves for use in the kitchen, and the small ones for seed.

Herbs.—These are mostly over for the year. Young Sage, Thyme, and other plants raised from seed sown last spring are dwarf plants requiring no attention at present; but old beds of these, Fennel, and such like, have much old wood about them, and this will never be any good. It should be cut off and thrown away; or if the plants are very old the tops should be cut from them and dried, then throw away the old plants and raise a new stock next spring. Tarragon and Mint should have all the stems cut level with the ground, and then a good dressing of manure should be spread over the surface to feed and shelter the roots.

Autumn-planted Cabbages.—The open weather hitherto experienced has been much in favour of these, and many of the first planted are now strong and established. In many cases weeds will show amongst them, but must be destroyed by hand-weeding or hoeing. All plants which are tall enough to be earthed up should have a quantity of soil drawn firmly up to their stems with a drag hoe. This affords them both support and protection during the winter.

Growing Crops.—Autumn-sown Onions, late Spinach, and all young crops should be kept quite free from weeds at this season, and if the Dutch hoe is run between the rows when the soil is dry it will benefit them considerably.

Salading.—Chicory roots should be lifted, potted, or placed in boxes in a Mushroom house or cellar to produce fresh growth, which is most valuable as a winter salad. Where frost is likely to injure Lettuces, Endive, &c., the plants should be lifted with a good ball of soil attached to each, and planted in frames as close as they can be placed together. The lights must not be put over them until frost comes, and then air must be freely admitted on all favourable occasions. Mustard and Cress will grow readily in any house or pit where the temperature is about 60°. The hardy winter Radish requires no protection, but previous to periods of frosty weather we have had to lift a batch of them and store them in a shed until it thawed.

Cauliflower.—These are turning in well this autumn, and we have frequently large numbers ready for cutting before they are wanted in the kitchen. This is sure to be the case in many instances, but the time may come soon when frost will make them more scarce or stop the supply altogether, and care should be taken of all that can be had now. It is a good plan to cut the heads before they become too large, take the greater part of the leaves from them, and then place them in a dark cool shed with the stem inserted in damp sand or leaf soil. We have frequently a large stock in hand in this way, and we find them most convenient and useful, as they may be kept good for three or four weeks in this way.

Leeks.—These should have more soil placed to them, as they cannot be too much blanched, and should the winter prove severe they may be frequently called for before the spring.

Cucumbers.—The summer plants will now all be cleared out, and the winter plants should have the best of treatment. The day temperature should be kept up to 70°, and at night the heat should never be less than 65° with a bottom heat of 75° or 80°. Steady temperatures are much better than having a great heat at one time and allowing it to fall at another. Weak guano water should be given them whenever they are watered at the roots. Syringe to keep down insects, and as soon as the fruit becomes large enough for use cut them off, as allowing them to hang will prevent more from forming readily.

FRUIT-FORCING.

PEACHES AND NECTARINES.—*Earliest House.*—Attention having been paid to the directions given in former calendars, the house and trees will have been properly cleansed, and the trees tied-in ready for a start by the middle of this month, where fruit is required ripe in April or

early May of such kinds as Alexander, with Hale's Early and Royal George to succeed, all of which are fine in size and excellent in quality. Lord Napier Nectarine is a capital companion. The house being closed at the middle of the month, or if not it must not longer be delayed; but unless the weather be severe no artificial heat need be applied until the buds show signs of moving, when gentle firing for a few hours in the early part of the day may be employed to raise the temperature to 50° or 55°, which should be the day temperature, advancing 5° to 10° from sun heat, maintaining the temperature at from 40° to 45° at night. If the roots are in inside borders, as they certainly ought to be, they should be carefully supplied with tepid water until every part of the border is made thoroughly moist; then a good bed or ridge of thoroughly sweetened fermenting materials being introduced, a moist genial atmosphere of great advantage to the trees will be insured, and found sufficiently exciting in all but very severe weather for the first fortnight or three weeks. Give air on all favourable occasions (*i.e.*, between 50° and 55°) as a means of sweetening the atmosphere and securing a strong vigorous blossom. Syringe the trees, walls, and paths twice a day in favourable weather.

Second House.—The trees in this structure have been exposed to the weather for some time, and the house, trees, and everything put into thorough going order so as to be ready for a start at the proper time, which to have ripe Peaches by the middle of June should not be later for such varieties as Royal George and Grosse Mignonne than the middle of December, the house being closed at that time, and fire heat applied on the 1st of January; but if early varieties are relied upon the house need not be closed until later, as Alexander will come in four to six weeks before Royal George under the same conditions, and so will Early Beatrice, but it is far too small, whilst Hale's Early precedes Royal George by at least three weeks. The lights may be replaced and the house freely ventilated in favourable weather, keeping closed only in severe weather. The inside border should, if at all dry (as may be the case where lights are fixed), be thoroughly watered, and the outside border protected with dry fern or litter, and with a good slope to the front, so that when covered with lights or shutters the wet will be thrown off.

Succession and Late Houses.—Have all the trees pruned, dressed with an insecticide, which to be effectual must be applied in such a manner as to reach every part, and where the trees have been infested with insects they should be attended to at least twice at short intervals. The house being thoroughly cleansed, and the trees secured to the trellis, remove the loose surface soil, and replace with fresh material. Examine the borders, and if there be a deficiency of moisture in the soil give a thorough soaking, for to allow the trees to become dry at the roots when at rest is a certain means of causing the buds to drop when they should be swelling.

Pines.—During the next two months very little aid can be expected from sun heat, consequently the treatment afforded will necessarily be restricted to artificial means almost exclusively, and will demand considerable time and attention to secure and regulate the atmospheric conditions suitable to the plants in the different departments. The winter minimum temperatures should now be in force—*viz.*, 55° for suckers, 60° for succession, and 70° for fruiting plants at night. These temperatures should be regularly enforced in all but very severe weather, when a few degrees less will be better than the harsh condition of the atmosphere resulting from very sharp firing. In the fruiting department the temperature should be raised 5° to 10° higher every day, according to external influences; and successions that are expected to show fruit must be given the treatment advised for fruiting plants, but the other plants need not have the temperature artificially raised by day, or only a few degrees. Great care must be exercised in watering at this season, especially in the case of plants plunged in beds with but a slight degree of heat, and should only be given when absolutely necessary, and then in a tepid state.

PLANT HOUSES.

Allamandas.—Where plants are intended to flower for some time longer they must be in a sufficiently high temperature to keep them growing, or they will soon cease flowering. It is a good plan to top-dress the soil with some rich material, which will soon be taken possession of by the roots, and add much to the vigour of the plants, and their season of flowering will be prolonged. These plants must never be allowed to suffer by an insufficient supply of water as long as their flowers are required, but, on the contrary, should have stimulants given to them every time they require water. Any that are required for early flowering next season must be kept dry at their roots, and in a temperature that does not exceed 55° at night, so that they will receive that complete rest so essential to success. If the wood is hard and well ripened they may be pruned close back, leaving only one or two eyes of the new wood. If the plants have not attained their full size they need not be pruned so close; more of the young wood may be left. Succession plants must gradually be brought to rest by withholding the supply of water at their roots. This must be done with care until the foliage and the wood become ripe and firm, when water for a time can be withheld altogether.

Heaths.—Early-flowering kinds that were cut back late in the season, and have in consequence failed to make a good well-ripened growth, and are only flowering poorly, may now be cut over without further delay, and allowed to start into growth gradually for another year. Plants subject to this treatment at the present time are starting again before the majority are cut, and are ready early next season for placing in cold frames. Plants that flower in conservatories, and other structures that are kept gay, are often checked when they are brought out, cut down, and placed in the greenhouse that is kept several degrees cooler. This is not the case with plants that have been under cool treatment and can be cut down now, for they have every opportunity of making an early growth, which by early

autumn will be well ripened and set with flower buds. We have found it an advantage rather than otherwise when a few of the late-cut-back plants fail to flower, for they have a long season before them, and are in the best possible condition for flowering in early autumn, and seldom they fail, even if the season proves a bad one. A sharp look-out must now be kept for mildew, and directly it is discovered dust the plants or affected parts with sulphur, which must be washed off the plants after this destructive parasite has been destroyed.

THE BEE-KEEPER.

NOTES ON BEES.

PRACTICAL MANAGEMENT.

IN giving our views on bee-management we shall confine ourselves to what we consider the best method of proceeding with the particular hive which has been the subject of these papers, and give as briefly as possible an outline of the plan we pursue, beginning with the time of hiving a swarm into it. We shall presuppose that the reader is already acquainted with the ordinary details necessary for managing bees, and that our province will be merely to explain how to apply that knowledge to the plan of working here advocated.

HIVING BEES.

The hive is supposed to be prepared to receive the swarm (fitted with full sheets of foundation or narrow strips as may be preferred), and on the stand it is intended to occupy permanently. When it is known that a swarm is on the wing, withdraw the wedge front altogether and hook on the large alighting-board to the floorboard; this is all the preparation necessary. When the swarm is hived as usual in a skep, bring the bees to the hive and throw the bulk of them out on to the alighting-board, slip one hand through the cane handle at the top of the skep, and give a sharp rap or two on it with the other; this will dislodge the remainder. In the evening reinsert the wedge front and all is complete. Should the swarm be an unusually large one, or if the weather is very hot at the time, do not wedge up the floorboard till the following morning.

A second method, as follows, is perhaps the most suitable for novices or those inexperienced in handling bees. After taking off one of the four parts of the hair quilt, fold back as much of the wood quilt as is necessary, and remove five frames into the "spare frame box;" set the latter with its side close to the opening thus made, throw the bees in (the side of the box will guide the falling mass into the hive), and replace the frames gently while the swarm is running for shelter under the covered part of the frames. When all the latter are in position push the divider close up to them, lay the wood quilt over the bees, and allow the stragglers to enter by the feedhole. Do not close the roof quite down for an hour or so.

The time occupied in hiving a swarm by either of these methods need not exceed five minutes, and if there is a simpler way we have yet to learn it.

There is just one drawback to the plan of hiving a swarm by tossing it on to the alighting-board in front of the hive, and that is the slight risk of the swarm taking wing and returning to the spot where they first clustered. This will only happen when the bright sunshine glares fiercely on the front of the hive at the time; and if an umbrella is held open for a moment to screen the bees from the sun till they begin to enter, or if the swarm is hived in the evening, all will be well. As experience is gained the bee-keeper will generally practise the quickest and readiest mode.

AFTER MANAGEMENT OF SWARMS.

Natural swarms when hived on full sheets of comb foundation should have completed most of the combs and be ready for supering in about fourteen or sixteen days after hiving, that is supposing fine weather to have continued during the time. When it is seen that the honey is coming in fast, set a grate of sections on, so that they will cover nine frames on one side of the live, remove as many of the end frames as contain honey only to the *outside* of the divider, pushing the latter up towards the sections as the frames are removed. We thus crowd the bees up and make them take to the sections sooner than if the hive had not been contracted. The honey should be carefully slung from these frames, as the combs will be very tender, and they may be replaced in the hive or not, just as the season is more or less advanced, or as the queen requires room for egg-laying. Suppose four or five frames to have been removed in this way, it still leaves a fairly large brood chamber of fourteen frames, so sometimes the extracted frames are not returned at all to the hive from which they were taken, but are used to assist second swarms.

When making artificial swarms three frames of combs are removed with the queen, and eight or nine frames of comb foundation given in addition. In about a week two more frames may be added,

and in a few days, as progress is made, give the remainder. The centre entrance only is used during the first year unless in exceptionally good seasons.

We must suppose that our readers are fully aware of the necessity for feeding swarms for a few days if the weather is at all unfavourable.—W. B. C., *Higher Bebington, Cheshire.*

HOW FAR WILL BEES GO FOR HONEY?

THIS is a question that has been addressed to us by a gardener, who states that bees find their way into his Peach-house every year, and he knows of no hives nearer than one and a half mile. On this subject Mr. Pettigrew has a short chapter in his "Handy Book of Bees," which we cite:—"This question we cannot answer with accuracy. Our experience in this matter goes dead against the wonderful stories that are told in some books. We read of bees flying four, seven, and twelve miles for food! Our bees will perish and die for want of food within three miles of good pasture. Our bees here never find the hundreds of acres of Heather which cover Carrington Moss within three miles of them. In fine sunny weather bees go farther from home than they do in dark cloudy weather. But even in the best and brightest of weather in June and July very few, if any, find their way home to their old stand if removed three miles off. Moreover, the return of some bees does not prove that they travel three miles in search of food. It proves that some of them go a little more than one mile and a half from home, and finding themselves on known pastures within one mile and a half of the old place, they return thither, forgetting, as it were, where they last came from. I am therefore of opinion that very few bees go more than two miles for food.

"It is very desirable to have bees near the pasture on which they work. Short journeys are not only a saving of labour to bees, but also a protection of their lives. When compelled to fly far for honey they are often caught by showers and destroyed. In warm genial weather, with a superabundance of honey in flowers, bees will have it. They go beyond the bounds of safety for it. Gentle showers do not stop outdoor labourers. Black clouds often send them hurriedly home; but they are frequently caught, and die on the altar of their industry. Hives containing 8 lbs. and 10 lbs. of bees have lost two-thirds of their ranks by sudden showers in warm honey weather. Bees driven to the earth by showers do not die at once. If the following day be warm and fair the rays of the sun sometimes reanimate these storm-beaten creatures, and enable them to return to their hives."

TRADE CATALOGUES RECEIVED.

N. Davis, 66, Warner Road, Camberwell.—*Catalogue of New and Old Chrysanthemums.*

Joseph Unthank, 25, Spring Terrace, North Shields.—*List of Dutch Bulbs.*

W. Leighton, 89, Union Street, Glasgow.—*Catalogue of Forest Trees.*

John Downie, Edinburgh.—*Catalogue of Roses, Fruit Trees, and Conifers.*

Louis Van Houtte, Ghent, Belgium.—*Catalogue of Hardy Herbaceous and Alpine Plants.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Vine Roots Unhealthy (B. C.).—We have examined the roots carefully and find no symptoms of the attacks of the phylloxera. They appear to have been grown in a wet border and inert soil. Fresh soil is what they need—good loam with an admixture of bones and wood ashes, with efficient drainage to carry off superfluous water.

Chrysanthemums Sporting (T. Grant).—It is far from common to find a Chrysanthemum two-thirds yellow and one-third pink; but we have seen this more than once. It is not unlikely that your plant may throw a pure yellow sport some time or other. The one you have sent is a very near

approach to that; but the variety, at least as represented by the example before us, appears to possess little merit.

Buck's Scarlet Rhubarb (Cambridge).—We are quite unable to say from whence you can obtain roots of this variety. Those who have the true variety for disposal would do well to advertise it. It is one of the best small early sorts in cultivation.

Planting a Mulberry (E. M. S.).—We have no doubt a Mulberry would grow and fruit in your garden. It thrives quite as well near towns as Apples do. In all probability the Tea Rose Niphetos would succeed fairly well, and it is well worth trying. We had an inquiry for a few volumes of the Journal the other day. What are the dates of those you have for disposal, and the price you require for each volume?

Breeze for Stoking (A. J. S.).—Breeze mixed with coke would answer admirably for your boiler, but can only be had at the price named in or within a short distance of the colliery districts. It will be necessarily much more costly in your locality, yet much below the price of coal. We do not think it would answer in your case if not mixed with coke broken small.

Late Lilliums (H. J. G.).—Lilium auratum is extremely variable in its time of flowering, but it is usual for bulbs planted in March to flower long before November. Yours is an exception to the rule, and perhaps not unwelcome; we have known similar instances of very late flowering. We are not able to answer your other question, as we have no Tasmanian catalogue of hardy plants. You could obtain seeds of many hardy border flowers, and these we should take and raise plants from them. This would be the cheapest and readiest way of establishing a stock, and you do not say you want named varieties.

Writing to Correspondents (C. H., Antwerp).—Every week we publish a request at the head of this column that "no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense." We regret that this request has been so widely ignored that some of the most competent writers have felt compelled to hide their identity under a *nom de plume*. We repeat that all letters of inquiry should be addressed to the Editor, and the information needed will be given sooner than by any other means. We forward such letters as in our judgment should be sent to departmental writers and publish their replies; and we shall be glad if any of our esteemed coadjutors who receive letters from readers will forward the same to us, together with any reply they deem necessary for publication. So far as regards yourself your letter to "Single-handed" will be answered; but your non-compliance with our published request has caused some delay.

Leaf Soil from Oak Leaves (Subscriber).—Some of the best leaf soil we ever used was that from Oak leaves, which formed where the leaves fell. In Oak woods and coppices we have always noticed that where the Oak leaves accumulated as top-dressings among the brake there the brake grew best, and there in time was formed a half peaty-like bed that was unsurpassed for general plant-growing, and more especially Ferns. There is tannic and also some gallic acid in Oak leaves, but it is so small as not to be harmful; and you may satisfy yourself of this by examining the roots of any vegetation near or among the leaves. Moreover, tannic acid is soluble, and when leaves have lain damp in the position, and for the length of time you name, very little tannic acid will be left, even supposing it not to be decomposed, which it readily does under conditions that turn leaves to soil. But a simple way of testing whether a sample of leaf soil is unwholesome or not is to sift some with loam and sand and to strike cuttings of some plants with fleshy roots and examine these. If they root freely and, on examination, are found healthy, all is right. But even if not, it is hardly likely that tannic acid will be the cause of the mischief. Let us know whether you succeed with yours.

Climbing Plants for South-west Aspect (A. M. B.).—A mixture of deciduous and evergreen plants is the most satisfactory both for the charm of variety and for the pleasant clothing of green in winter. Four plants would suffice for your space planted in the following order:—Escallonia macrantha, with handsome glossy evergreen foliage, with deep pink flowers which come abundantly in early summer and again in autumn. We have several plants of it, some of which have still a few perfect spikes of flowers. Next to it plant Jasminum officinale, which is almost hidden beneath its thickly clustering fragrant white flowers in summer; and its free growth spreads quickly, and soon mingles with anything growing near it. Then take Berberidopsis corallina, a perfect gem among evergreen climbers, with deep green foliage and dark red flowers, which come in pendant clusters of miniature rosettes in autumn; and the sweetest of all Honeysuckles, Lonicera flexuosa.

Evergreen Shrubs for a Bank (Rus in Urbe).—If the shrubs were to be altogether under the branches of the trees your choice would be restricted to three or four sorts, but we gather from your letter that they will be partly under and partly near the trees, and therefore you may give a trial to such choice flowering shrubs as Berberis Darwinii, B. stenophylla, B. Wallichiana, Mahonia aquifolia, Diplopappus chrysophyllus, Escallonia macrantha, Garrya elliptica, Ligustrum japonicum, Ulex europæi flore-pleno, Spartium junceum, S. multiflorum, Buddlea globosa, and of Laurustinus the common form, with lucidum and Sieboldii. If the Rhododendrons answer in your soil a large proportion of the best varieties would materially enhance the beauty of your bank, and no shrub answers better than Rhododendron ponticum under the shade of trees. Vases on a wall 14 feet high are so difficult of access that the failure of your Clematis is only what might be expected, for without copious watering twice daily in the heat of summer plants could hardly live, much less thrive, in such a position. Your idea of clothing the wall with Ivy plant in the vases is impracticable. Plant the Ivy in rich soil at the foot of the wall and it will soon mount upwards in rich luxuriance, and a few branches trailing over the vases would have a graceful and picturesque effect.

Culture of the Orange (M. S. P.).—To grow the plants well, and to fruit them freely, they must be treated liberally. We have found the following mixture suit them well:—Two parts good turfy loam, one part of fibrous peat, and about the same quantity of sheep or pigeon's manure, adding to these a good quantity of sharp sand and lumps of charcoal; the whole must

be well and thoroughly mixed together. The peat and loam should be chopped with a spade into moderate-sized pieces, but upon no consideration should it be sifted. Orange trees, when growing, should be kept in a temperature of 60° or 65°, and treated to copious showers from the syringe two or three times in the day; indeed, at any time, saving when they are in flower, occasional syringing is very beneficial, though it must be resorted to in a less degree during the blooming period than in the growing season. These plants can withstand uninjured a very low temperature, but are certainly better if kept at about 48° during winter. The Citrus family must have good exposure to the sun to induce them to flower and fruit freely; yet, as the leaves will become yellow and sickly-looking if fully exposed, they must have a certain amount of shading during the brightest part of the day during summer.

Ranunculuses (J. C.).—The tubers may be safely stored in a mixture of sawdust and cocoa nut fibre refuse, quite dry or in dry sand. The best season for planting is in the early spring, as soon as the most severe frosts have passed and the ground has become tolerably dry. Some time about the end of February or the first week in March, rake the surface of the bed in the morning of the day previous to that fixed upon for planting. Supposing, then, that the weather is propitious, and all things prepared, commence by drawing with a hoe a drill across the end of the bed 1½ inch deep; if deeper the roots will be weakened the succeeding year, by forming a kind of stem nearer the surface; and if shallower, the plants are more liable to be struck with drought. The drill being drawn the right depth, plant the whole of No. 1, and press each tuber slightly down into the ground; plant them, if large, 4 inches apart in the row; if small, 3½ inches will be a sufficient distance. Draw a second drill 5 inches from the first, and so on until the bed is finished. Cover the crowns of each tuber with fine sand. This will cause the tubers, when they are taken up in July, to come out of the ground quite clean for keeping. Then, with a short-toothed rake, draw the soil over the tubers, and when it is level, with the head of the rake gently press the soil pretty closely upon them. The soil should be retentive of moisture. The best kind is the virgin mould of some alluvial soil on the banks of a river or some lowland pasture. It should be of a rather close texture, without any small stones or sand amongst it. If the situation is low, with a wet subsoil, it must be well drained; but if the subsoil is dry there is no necessity for drainage. If the soil should be thought too poor, a small addition of decayed cowdung will be advisable; but it must be so decomposed as to appear like a black powder. Let it be thoroughly mixed with the soil at the present time, and again forked over in the spring before planting.

Culture of Vallota purpurea (W. E.).—An experienced grower has described the following successful practice in these pages:—The compost employed should consist of turfy loam with a little decayed manure and leaf soil, with sufficient coarse sand to keep the soil open. In potting place three bulbs in a well-drained 6-inch pot; if bulbs are scarce have one in a 3-inch pot, but I recommend the former practice where possible, as the plants will flower profusely and make a beautiful display. In potting place some of the roughest of the compost over the drainage, then three parts fill the pots with soil, and press it down gently to prevent it sinking too much. If 6-inch pots are used place the bulbs a little distance apart to allow the growth of offsets. Tie the bulbs to a small stick to keep them steady, give a good watering through the rose of a watering can, and transfer the pots to the greenhouse, assigning them a position near the glass, and the bulbs will soon commence growing. Never permit them to be insufficiently supplied with water, and in the summer months they should be sprinkled overhead. When the pots are quite full of roots and the flower stems appearing, weak guano water may be given twice a week. After flowering remove the flower stems, as they exhaust the bulb; the pots can then be placed in any sunny part of the greenhouse, so as to have the bulbs well ripened. The soil must not be allowed to become dust-dry at any time, not even in the winter months. The Vallota is increased by offsets. The small bulbs can be taken in the spring, and are either potted singly in small well-drained pots, or placed in pans in a compost of half loam and leaf soil with a little sand, and if placed in a warm part of the greenhouse they will soon produce roots. To flower the plants well they must be rootbound, and three bulbs in a 6-inch pot will not require a larger pot for three or four years providing the drainage is open.

Names of Fruits (Arthur T. Clarke).—Very curious. You will see something like it in next week's Journal. If not the Stoup Leadington we do not know what it is. (R. A. Turriff).—1, Devonshire Quarrenden; 2, Gravenstein; 3, not known. Pear, Beurré Diel. (F. M.).—1, Winter Colman; 2, Red Doyenné; 3, Cockle's Pippin; 4, Round Winter Nonesuch; 5, Ashmead's Kernel. (Fifteen-years Subscriber).—1, Beauty of Kent; 2, Yorkshire Greening; 3, Flanders Pippin; 4, Doctor Harvey; 5, Lemon Pippin; 6, Gloria Mundi. (G. B. C. W.).—It certainly is not Fearn's Pippin, and on further examination we should say it is a local variety. We saw nothing like it at the Apple Congress. Several parcels of Apples which arrived late on Wednesday morning will receive attention in the next issue.

Names of Plants (G. Q.).—1, Cestrum aurantiacum; 2, Aspidistra lurida variegata. (J. C.).—Polyporus ajustus, a rather common species in some parts of the country.

COVENT GARDEN MARKET.—NOVEMBER 21ST.

LITTLE alteration to quote this week. Best Apples coming shorter and commanding better prices. Kent Cobs fat. Vegetables in good supply.

IMPROVED DAIRY CATTLE.

(Continued from page 434.)

AFTER having given our experience and confirmed it by undoubted authorities, amongst whom are Mr. W. Houseman, Mr. Ledgard of America, and also Mr. D. E. Wheeler of Lake View Farm, Natick. These gentlemen, together with various eminent breeders of the Guernsey cattle both in the island and in various parts of the kingdom, tell us plainly that without great care in selection of the bulls for use we may not obtain what we require—viz., the assurance of the quality of cream for butter-making as the result of the potency of the male animal in breeding from any animal either of pure blood or partially mixed breed. In selecting our bulls the type and character is of the greatest importance, and to illustrate our model we will speak of a bull shown at the Tunbridge Wells Exhibition of the Bath and West of England Society in 1881, of the pure Guernsey blood, which we find well portrayed in the *Agricultural Gazette* of August 8th, 1881, fig. 13. This animal exhibits great length of body, deep in the fore quarter, with a fine arched neck and crest, which is heavy, and finds its basis near the shoulder-top; we therefore do not expect in the male animal the same bare and narrow shoulder point which we so much value in the cows as one of the indications of true milking capacity. It often, however, that it has a tendency to lower the chine and depress the outline when bulls are the offspring of deep milking cows, but it should be understood also that it is one of the corrections or alterations we require in the conformation of our improved animal, which we have a right to expect may be the result of a cross with the Shorthorns from careful selection, and by keeping steadily in view the objects which we require.

It is now necessary to take up the question of mating the animals, for we have chosen six Shorthorn heifers of fifteen or sixteen months old, as before stated, as to colour, type, and parentage; we have also chosen two pure-bred Guernsey bulls two years of age. We have now the opportunity of mating the animals so as to obtain the advantage of correcting any slight deficiencies of form from either side by mating the animals with this object, and this idea may be carried out with the same animals if mated with judicious variations the second year. In every instance if a heifer does not prove pregnant by the first mating, be sure to change the bull (as we have two for use) in order that we may have if possible no barren or unfruitful animal, for such must be discarded when found. After all the heifers are proved or supposed to be pregnant they should be carefully kept on grass or roots and hay, without cake or artificial feeding stuffs of any kind or quality. The same moderate system of feeding should be adopted with the bulls, although they will not, or should not, be running at liberty on the pastures, as they may be soiled with green fodder, such as Trifolium, Clover, and Rye-grass in their pens.

The construction of pens for all the male animals of the Channel Island cattle requires consideration, because, although the Guernsey bulls are more docile and better tempered than Jerseys or any cross-breeds, yet the benefit to be derived, as well as the security from injury to the animals or their carer, is so great, that we always advise a hovel under cover of about 12 or 14 feet square, and an outer yard adjoining of about 16 or 18 feet square, for service when females are admitted. The plan we adopt in separating the outer part from the inner shed is to

make the severance a moveable panel, which may be drawn or closed by a handle outside the pens to be used by the herdman, in which case any operation, such as littering the pens or feeding the bull, which may be done under cover through a drawing shutter adjoining the feeding trough or rack. This affords the greatest measure of safety, for the herdman need not at any time be in the actual presence of the bull, and when not being fed or expecting company, the outside as well as inside space will be available for the health and exercise of the animal, which is far preferable to the tether. Under this style of pens the herdman is always safe, as he need not be in the company of the bull for any purpose. When, however, not tethered, bulls after two years of age frequently injure the divisions of the outside fences of the apartments with their horns, and we find no fence so suitable as fir or elm slabs or planks like railway sleepers set upon end, well secured with stout iron hoops.

After the heifers have calved their management is of great importance. First we should notice the shape and capacity of the udder, if with full-sized teats so much the better; but it must be remembered that milking them by hand, or partly so, is of the greatest consequence, not only to freeing the udder of milk entirely at each time of milking, but the learning, or so treating, the young animals to stand quietly to be milked, and especially for the first few times after calving. In fact, it is a standing rule of ours to allow the calf to suck during the time of hand-milking for the first few days, and afterwards to hand-milk away a portion of the milk, leaving enough for the calf, which will thoroughly clear out the udder at each milking, so important for various reasons. The calf, too, should always be in the presence of the heifer when milking by hand is commenced, otherwise she will not always give down her milk freely. By adopting these modes of management by a quiet good-tempered milkman, we shall soon learn the capabilities of each animal, and be enabled to reject any unsuitable ones during the first year of breeding.

In the second year of breeding the same bulls may be used, but changed for mating with such individual females as judicious selection may dictate. After the heifers have calved the second time we even then have but a few animals to select from, because some may be bull calves as usual. After selection as well we may have but a few to choose from and decide upon retaining, for in the third year of the experiment, when the first fall of heifers which have been selected for breeding the third time, we must of course mate them with bulls not previously used. This circumstance obliges the obtaining another one or two bulls, but in doing this be sure and go to the best herds in Guernsey, or the best Guernsey herd we can find; for now occurs a critical period which will extend over five or six years, or even longer, because the longer time during which our endeavours to obtain the exact style, type, and capacity is extended, and the same good judgment carefully carried out, the more likely we shall be to succeed in obtaining stock animals capable of transmitting those characteristics which we have endeavoured to secure.

If our readers have followed our statements on this subject they will notice that in addition to the absolute necessity of selecting pure-bred bulls of the Guernsey blood, and then as the offspring increases selection must still be made the only sure grounds on which to proceed, and to save or breed from no animal which has not acquired the form, colour, flesh-making, yet milking capacity, to the extent we require and have sought for. How many years it would take to obtain the desired race of stock cannot be stated, but at any rate it must not be less than seven or eight years before we could use with safety bulls raised from our selected stock of females; but it would be far better to extend the experiment over ten years at least, during which time none but the best bred bulls of the pure Guernsey stock should be used. Now to assist in the completion of our experiment it may be best to secure the help and co-operation of another person with similar objects in view, in order to meet successfully any of the various contingencies of life and position of the experimenters, so that the value of the improved cattle may be assured as much as possible for the future benefit of dairy farmers in general as for the advantages of the original breeders or experimenters.

WORK ON THE HOME FARM.

Horse Labour.—Horses have been almost continually employed up to the present time in preparing land for and seeding with Wheat, but upon anything like strong flat-lying land it has been difficult to use the horses every day, for since the dry weather broke up in October both the land intended for Winter Beans or Wheat has suffered hindrance and delay, unless upon farms where three or more teams of horses are available. In this case the land may be ploughed and worked sufficiently for the drilling of beans to follow in the same way as for Wheat, except that before drilling the beans land requires more working than it does for

broadcast sowing for Wheat, which may be ploughed land after land or ridge after ridge and may be sown and finished off. But in drilling Wheat it is not so safely done as fast as the land is ploughed, because more horse power by numbers is required to finish off the land quickly. Drilling at the wide intervals of 10 or 12 inches between the rows is an actual necessity where the land is subject to such weeds as may be indigenous to the soil, like yellow cress, black bents, onion grass, and couch, because in certain seasons when rainy weather prevails. In the spring, however, a fine interval of only a few days may be sufficient to enable the horse hoes to be used if the drilling has been done of a sufficient width for horse hoes to proceed, for with flat hoes in work they may be advantageously used. In the case, however, of broadcast seeding or close drilling the horse hoes cannot be used with success, nor can the hand hoes, which require much time for a staff of men to accomplish the work be done effectually if followed by showery weather, whereas after the horse hoes if the weeds do not die off they may be hand-picked by women. Those fields which have been steam-cultivated since harvest and have been worked down, and the couch either burned or carted away, may be ploughed to lie for the winter, whether required to be cropped with Potatoes or Lent corn in the spring, or for root crops in the early summer months. It is, however, an important question as to the best mode of ploughing and leaving the land during winter. By different farmers on various soils we shall find advocates for clean ploughing in ridges, or to lie in stetches; some parties, however, advocate the lying of the land to be left rafter-ploughed. Experience and the nature of the soil as well as the next crop required exert some influence on the mode of proceeding, but Mr. Lawes has lately informed us that a bare fallow is often the cause of loss of some fertility when washed by the heavy winter rains. It therefore appears that in case the land is not foul with twitch or couch that it may be sown with catch crops in the autumn, and tilled for roots afterward the green crops are disposed of, but in those cases where the land is foul it may well be rafter-ploughed, in which event the land will not lose much fertility, because the couch will be spindling more or less in open weather. When dry weather commences in the spring the rafters may be reversed with the plough, and cleaning of the land proceed easily so long as favourable weather continues, whether the land is intended for early Potatoes, Lent corn, or Mangold, Carrots, and Cabbage. It is, however, only on friable loamy soils that this latter method can be carried out with benefit, for on strong land if it loses fertility by a long fallow, yet fertility and an ameliorated soil will be the result if the land is lying during winter deeply ploughed in ridges or stetches about 30 inches wide. In case a long fallow is rejected Vetches may be sown and fed off during summer, or, like Mustard, ploughed in with two crops during the summer. The land will then not only be fallowed and cleaned, but will be manured also, a matter of great importance on strong land where dung-carting is not advisable, especially on fields lying away from the farmery.

Live Stock.—The weather peculiar to the month of November varies from frost to rain. Now either of these variations are bad for animals which may have to live and feed in the open fields. This applies principally to sheep, and the pregnant ewes should now be allowed the driest soil on the farm for their night lair, but nearer to lambing time a dead fold well littered. With respect of their food they should have grass only on a dry pasture, but in case of receiving a small quantity of roots some dry fodder is necessary for maintaining their health and condition. All young store cattle, either heifers or steers, will now require dry pasture for their night quarters, feeding the low-lying or water meadows not in flood only during the daytime.

OUR LETTER BOX.

Food for Milch Cows (A. G., Betturbet).—You could not give the cows better food than Cabbages and Parsnips during the winter. Both vegetables are nourishing and wholesome.

REMARKS.

11th.—Fine, bright, cold day; misty towards evening.
 12th.—Bright, fine, and cold; moonlight night.
 13th.—Thick white frost in early morning; fine throughout and cold; moonlight night.
 14th.—Bright sunshiny morning; overcast afternoon; fine evening.
 15th.—Thick white frost and rather foggy early; fine day.
 16th.—Rain in early morning; fair day.
 17th.—Rather dull generally. Squall of wind and rain 1.30 P.M. till 2.30 P.M.; fine afterwards.
 Nights generally very bright, causing great radiation, and therefore sharp frosts on grass. Temperature much below the average.—G. J. SYMONS.

STRAWBERRY FORCING.

IN the majority of places Strawberries are more or less extensively forced, the object, as a rule, being to have ripe fruit as early in the new year as possible, and to maintain the supply until the outdoor crops are ready for gathering. Yet, frequently the forcing of this delicious fruit has to be done upon what for want of a better name may be termed the "makeshift" principle—that is, grown in vineries, Pine stoves, Peach houses, or in any other structure where a shelf or two can be fixed. From the middle to the end of January is as early as ripe Strawberries, with the best accommodation for producing them, can be gathered from plants of Vicomtesse Hericart de Thury, which had been layered into the fruiting (6-inch) pots six months previously, and liberally and judiciously treated during the interval. A good batch of these plants, selecting those having the plumpest crowns, should forthwith be taken to the potting shed to have the bad leaves and a little of the surface soil removed, and some pulverised horse droppings and loam added as a top-dressing. The pots then, having had the drainage made efficient, should be plunged in a bed of new leaves within a few inches of the glass in a pit from which frost can be excluded. They should then have some water to settle the new soil, after which further applications will probably not be needed more than once or twice before their flower stems appear, which they will do in three or four weeks if the pit is kept close and the plants carefully tended. The pots should then be washed and placed on shelves near the glass in a forcing house. One suitable for this purpose would be a low span running east and west, having a pathway down the centre and a couple of shelves suspended on each side near the apex, the air being admitted through the front sashes (about 21 inches deep and 4 feet wide), and a box 10 inches deep and the same width fixed in the ridge, the lid being raised and lowered by means of a crank and piece of sashline. Such is the outline of one of the houses recently erected here in three divisions for growing Strawberries and Melons, and for which purpose it answers admirably. We are thus provided with a good forcing house, and without which gardeners cannot reasonably be expected to produce and maintain supplies of early Strawberries and other fruits.

In order to prevent a blank occurring in the supply of ripe Strawberries from the time the first dish is sent to table until ready for picking out of doors, it will be necessary to start a batch of plants in the manner indicated at intervals of a week or ten days, so that there shall be always a good succession of plants in various stages of growth to fill the shelves as they are vacated by plants from which the ripe fruit has been gathered.

TEMPERATURE.—In the process of forcing plants, fruits, or vegetables it is best for the cultivator to first consider the most favourable conditions under which the finest examples of such are naturally produced out of doors, noting the maximum and minimum temperature prevailing through the various stages of the plant's growth. These temperatures

should be the guide, varying them a little, if need be, to suit the other occupants of the house. Thus a night temperature of from 45° to 50° when the Strawberry plants are in flower, and 10° higher by day with fire, will be sufficient, increasing 5° or 10° by sun; but during the interval from the setting to the ripening of the fruit the night temperature should be gradually increased to 60°, or higher if necessary, with a corresponding rise in the temperature by sun.

CROPPING THE PLANTS.—As the flowers develop pass a small camel's-hair brush over them about midday when dry to assist the work of fructification, repeating the operation daily until a fair crop of fruit is set. But with the advent of spring and an increase of light and sunshine the brush can be dispensed with, as a good "set" can be obtained without its aid—the hand passed lightly over the blossoms, which will then be plentiful and strong, or a gentle spray from the syringe, being sufficient to distribute the pollen. When the fruit is set select ten or twelve of the best (crown) berries of uniform size, so that they may all swell and ripen together, when the fruit can be gathered and the plants removed to a hardening-off pit or house. Having selected the best berries, a few, more or less, according to the strength of the plants, remove the superfluous parts and all flower spikes that show between this and the ripening of the crop should be kept pinched out, otherwise the result will be unsatisfactory.

ATMOSPHERIC MOISTURE AND VENTILATION.—No hard-and-fast line can be laid down in the distribution of moisture in forcing houses, for, like the admission of air, it must be regulated in accordance with the character of the weather and time of year, temperature of the house, and stage of growth at which the plants and fruits may have arrived. However, we may say that Strawberry plants started under the influence of fire heat will require to be syringed once or twice on most days until they come into flower. A somewhat dry and buoyant atmosphere must then be maintained until the fruit is set, when the syringe can again be brought into use, using it, however, with judgment and somewhat sparingly during the dull months of December, January, and February. After the fruits are set and until they commence colouring the plants may be syringed three or four times a day in bright weather, the last time just before dark. By so doing the foliage will remain damp all through the night, and in the morning have the appearance of having been exposed to a heavy dew, which is then their natural condition. When the plants are in flower, and again when the fruit is approaching maturity, it will be necessary, especially so in air-tight houses, to leave a little ventilation at night and to ventilate freely (weather permitting) during the day.

WATERING THE PLANTS.—Give no slight surface watering, but a thorough drenching to the roots when they require it, and from the time the plants throw up their flower scapes until the fruit commences colouring they should have weak liquid manure alternately with clear water. Peruvian guano, about a 3-inch potful to ten gallons of water, is an excellent fertiliser, the use of which imparts perhaps a higher colour to the fruit than any other liquid manure, but it should be used with caution and judgment. Care should be taken in watering the plants not to pour it indiscriminately over the fruit and crowns, but pour it in at the side of the pot.

VARIETIES FOR FORCING.—A knowledge of the varieties of Strawberries most suitable for forcing being almost as necessary as that of their culture, I will give the names of the best and most reliable varieties for this purpose, which should be started in the order in which their names appear—viz., Vicomtesse Hericart de Thury, La Grosse Sucrée, Keens' Seedling, President, Sir Joseph Paxton, and a few of James Veitch, the latter variety more for the size than the quality of its fruit.

INSECTS.—*Red Spider and Green Fly.*—In early forcing establishments red spider is the most troublesome and destructive insect (excepting the three plagues, phylloxera,

mealy bug, and Pine scale) that gardeners have to contend with, and its presence on the Strawberry and other plants should be prevented by judiciously balancing the temperature and atmosphere of the house; but should it attack the plants, it must be repelled by a vigorous and well-directed use of the syringe and clear water. The application of sulphur in a liquid state to the flue or hot-water pipes to arrest the ravages of spider should be the last resort. Respecting fly, a slight fumigation with tobacco paper a couple of evenings in succession before the flowers expand, and again after they have set, will be sufficient, should the syringe not do so, to rid the plants of this pest.—H. W. WARD.

P. S.—In my remarks on wintering Strawberries in pots, in the Journal (p. 420), four lines from the bottom of the note on this subject, for "32 feet" from the wall, read "3 feet."—H. W. W.

LILIUMS.

(Continued from page 414.)

L. Szovitzianum, Fisch.—A very elegant Lily, very frequently met with under the names of *L. colchicum* and *L. monadelphum*, but more generally known by the one here adopted. It grows from 2 to 5 feet high, reaching the maximum height only when established, with stout stems well furnished with lanceolate leaves, and terminated with a raceme of flowers from two to twelve, rarely more in number; perianth nodding, from 2 to 3 inches across, clear sulphur-coloured spotted inside, with a very strong perfume. Native of the Caucasus and Northern Persia, flowering towards the end of June and July. It is a very beautiful species, thriving well planted out in rich loamy soil. I have known it frequently to die away in two or three years when planted in peaty soil, but in loam it will stand and improve much longer; in fact, I know of some clumps which have been in their present position eight years, and they were magnificent this season.

L. testaceum, Lindl.—The Nankeen Lily, often met with under the aliases of *excelsum* and *Isabellinum*. It is one of the most distinct of all the species of *Lilium* as far as colour goes, very much in habit like the old white garden Lily. Stems from 4 to 6 feet high, copiously clothed with dull green foliage. Flowers from three to ten, umbellate or racemose, the perianth 2 to 3 inches across, of a yellowish buff colour, and sweetly scented. Mr. Baker thinks it may be a garden hybrid between *L. candidum* and *chalcedonicum*, and it is said to have been first observed in a bed of seedlings at Erfurt. It is really a charming Lily and greatly appreciated, thriving well in light well-drained soil well enriched with manure, flowering towards the end of July and August.

L. Thunbergianum, Schultes, fil.—Very frequently called *elegans*. It represents a very large series of dwarf extremely showy Japanese Lilies, very serviceable either for pot culture or for beds and borders. It is extremely difficult to describe the normal form, as there is such a diversity even in specified varieties. I will simply enumerate a few of the best varieties now well known in our collections—*alutaceum*, pale apricot, with rather large flowers, very dwarf; *armeniaceum*, flowers bright orange, not dotted; *atrosanguineum*, perianth deep blood red, spotted below, with very broad segments; *fulgens*, deep red, scarcely spotted, very free-flowered; *Van Houttei*, deep red, with a distinct yellow blotch in the centre of each segment, with very open and broad perianth; and there is the duplex variety, which is very dwarf, with deep-coloured semi-double flowers. All these and several others are well worth growing, and as they are most easily managed and very cheap there is no reason why they should not be much more extensively planted than they now are.

L. tigrinum, Gawl. (the Tiger Lily).—A well-known old garden Lily, growing freely under most conditions, and flowering copiously. It is too well known to need description. As well as the typical form, there is a very fine variety under the name of *splendens*, which flowers much later, and the flowers are very much larger, set with larger dots; and there is the double-flowered kind, which is very handsome and lasting when in flower. This should especially be sought and planted.

L. Washingtonianum, Kellogg.—A very noble Lily. It grows from 3 to 5 feet high, with the slightly glaucous leaves in whorls. Flowers numerous, in rather close racemes, large, white when first expanded, some becoming shaded with pink inside; very sweetly scented, with the segments revolute at the top. Native of California, occurring on the western slopes of the Sierra

Nevada. This magnificent species grows freely in rich loam soil in a well-drained position, flowering in July and August.—T.

SEAKALE.

IN the culture of Seakale, like many other things, there is more than one road to success. Your correspondent "B." (page 415), gets his supply by planting out the old stools that have been forced, and forcing them year after year. Like "B.," we have long since abandoned the old plan of forcing in the open ground, but obtain our supply of Seakale by a very different mode of procedure. Your correspondent says—"This is not the time to enter into the preparation of the plants," while we are now (November 19th) preparing our next year's stock. We lift the whole of our crop as soon as the leaves are dead, cut them about 8 inches long, and lay them in in a border where they can be covered with leaves, so that they can be easily obtained when wanted, even in hard frost. The long thong-like roots that have been cut off are then cut into 6-inch lengths, and laid in thickly amongst some light sandy soil in a warm corner, and covered with about 6 inches of leaves. By the 1st of March these will be showing signs of starting, and the leaves must be removed, but in the event of sharp frost they will have to be protected at night. As soon as the land is in good condition after the middle of March, we plant these out in rows 2 feet apart and 8 inches between the plants, and we never fail to have a good supply of roots for forcing. When planted out a little ridge of coal ashes is placed over the rows. This keeps off slugs, and the young growths have rarely to be thinned out, as only one or two of the strongest get through the ashes. Some years ago we used to plant old stools, but never do so now, finding young stock more to be depended on.—R. INGLIS.

PELARGONIUM v. GERANIUM.

I WILL endeavour to help "H." out of his difficulty because many others, perhaps, are in want of an easy distinction between these genera. There need be no confusion whatever. In general terms Pelargoniums are sub-shrubby, while Geraniums are herbaceous, having annual stems, and some species are annual plants, though there are a few exceptions so rare that they need not be regarded. They do not even belong to the same tribe, and the floral differences are extensive enough. Some of the tribal differences are that the flowers of Pelargonium are irregular and have no glands, the flowers of Geranium being regular with glands alternating with the petals. Then there is a difference in the number of fertile stamens, with other generic characters we do not want now for the present purpose, after putting these genera so far apart. The derivation of the names has no bearing whatever upon this question. The broad and clear line of distinction desired by "H." lies for all practical purposes in the difference of habit, that being the difference there is between a Michaelmas Daisy and a Monthly Rose. It is to no great extent a question of what people call things, for popular errors are not very uncommon; but there is some reason for the popularity of speaking of Pelargoniums as Geraniums. It is a survival, I suppose, from the time of Linnæus, who had only his genus Geranium, in which he included the plants since separated by L'Héritier, when knowledge increased, under the title of Pelargonium. This, I believe, without research, is the history.

The "confusion" between Viola and Pansy does not lie on the same lines, because they are all equally Violas. Gardeners used Viola cornuta and V. lutea some years ago for bedding, and the derivatives obtained by crossing with the Pansy they called Viola. They were so called for convenience, and there was no error, but it would be equally correct to call the Pansy Viola. Viola in this application has become a popular name, and it is useful as pointing out the hybrids. If gardeners will hybridise (in doing which they are perfectly right), they can but obliterate original landmarks, and so it has been in this case.

By the way, it is not a bad illustration, when "H." would have botanists classify on broad lines that can be seen at a glance, to point out that in a certain sense the whole of the vegetable kingdom is like these Violas with no lines drawn anywhere. If botanists could do as "H." proposes, what happy men they would be! Had life been created for this to be possible we could never have had a Darwin, and if the systematic botanist existed at all, it is difficult to conceive the kind of man he would be. I do not say that there are no plants which are not separated by broad and clear lines from all other plants. To be understood, let me compare the vegetable kingdom to the land of a continent. There are some plants so different from all others that they stand away like islands, but the majority of plants group together like the countries of a continent. Then the genera are counties if you like, and the species are parishes; but when you come down to hybrids and other forms like these Violas, you can only liken them to fields, which are as like in themselves as they can be. Nature cares nothing about these arbitrary boundaries and frontiers, but, on the contrary, is free as the wind, and cares nothing about the limitation of a species which, in the abstract, is not real but purely imaginary. You had very good lines of demarcation between the original Pansy and the other species of Viola before the hybridist came and levelled them down, but now there are two or three adjoining parishes without hedge or ditch, and you get from one extreme end to the other by insensible gradations. Now in this question of Pelargonium versus Geranium, "H." evidently wants to put the sheep on one side and the goats on the other, but let me ask him, supposing that these genera were more closely related than they are, as many suppose, why there should not be a meeting-point around which

the species might be as correctly referred to one genus as the other. It is not the case here, but it is the case with other genera. If "H." will lay down a broad and clear line between the vegetable and animal kingdoms he will never be forgotten, for Nature has not even done that.—R. I. L.

A NEW GARDEN.

THE KITCHEN GARDEN.

Drainage.—Roughly stated, enough rain falls annually in this country to cover the entire surface of the soil to a depth of 2 feet. What becomes of all this water? In most cases it disappears as it falls, being promptly absorbed by the soil; the plants growing in it take up a certain quantity, but the bulk of it sinks down in undrained soil to a depth determined by the nature of the subsoil, which is generally so compact that it retains much water near the surface, where it becomes stagnant and unwholesome. The baneful effects of such shallow water tables are clear and unmistakable, and may thus be explained:—

- 1, The soil becomes sour and unfit for the food of many plants.
- 2, Its temperature is so low even at midsummer that growth is slow and crops backward.
- 3, This lowness of temperature arises from the accumulation of so much stagnant water near the surface, its temperature at a depth

Fig. 89.

of 2 feet being only 47° in the heat of summer. It chills the soil above it, as it constantly ascends by capillary attraction. It chills the atmosphere by evaporation so much that frosts at midsummer are by no means uncommon. Early frosts in autumn destroy tender vegetables prematurely. The frosts of winter are of exceptional severity, and are proportionately destructive, and with the late frosts of spring hopes of a fruit crop repeatedly vanish.

Soil that is thus, in the words of quaint old Tusser, "with water opprest," is certainly in an unsuitable condition for a kitchen garden, and must be drained before anything else is done. Considerable diversity of opinion exists as to the position and depth of the drains; but it is not at all a matter of mere opinion, for we have the sure evidence of practical results for our guidance. As a general rule the best depth for drains is 4 feet from the surface, because by keeping the water table at this depth we get rid of all hurtful upward spreading of water by capillary attraction, and the attendant mischievous evaporation which I have already explained, and no water can then accumulate in the soil permeated by the roots of vegetables or fruit trees. "How can I have drains 4 feet deep," said a gentleman to me once, "when I have only 3 feet of soil upon a bed of granite?" I know, too, a garden with a shallow soil of less than 2 feet upon chalk. But neither of these nor similar cases at all affect my position. Thirteen years ago the site of the new garden here was drained with 2-inch pipes at a uniform depth of 4 feet, and with the drains 30 feet apart running into a main 4-inch drain. Now, the soil consisted chiefly of silica in such minute particles that its

tenacity closely approached that of pure clay, water passing through it so slowly that much remained upon or near the surface for a considerable length of time after a heavy shower of rain. But then the fact of its certain subsequent improvement for the growth of vegetables and fruit pointed so unmistakably to a radical change in which mechanical division must be so thorough that superfluous water would sink to the drains quickly even at that depth, and no hesitation was felt in doing it. Certainly nothing could be more satisfactory than the result. From the first the drains have acted well and since the soil has been improved it becomes dry so quickly, even, after heavy rain, that successional cropping can always be done in due season. A rich, friable, warm, fertile soil, in which many half-hardy plants pass unscathed through the severity of winter weather now exists where once its cold, sodden, inert, and almost barren condition gave very little promise of successful cultivation, the first and most important step towards which was undoubtedly the drainage.

Warmth and dryness are not, however, the only benefits which the soil derives from thorough drainage. A certain degree of fertility also naturally results from it, for the vacuum made by drains beneath the surface gives admission to air laden with fertilising gases, such as carbonic acid, oxygen, and ammonia; not, it must be owned, in sufficient quantity for the requirements of gross-feeding vegetables, but still in some degree promoting the soil's fertility.

Turning now to the actual details of the work, it will be well to explain them so fully that a beginner may be enabled to see clearly what to do and how to do it. With very few exceptions, then, the drains are to be 4 feet deep and 30 feet apart, and each drain must run from the higher to the lower part of the garden into a main drain. Take, for example, the kitchen garden here, which slopes gently from north to south. The first drain was made 15 feet from the west wall and parallel to it, starting from the foot of the north wall and running down to the main drain 10 feet from and parallel to the south wall. The second drain is 30 feet east of and parallel to the first, and the other drains follow regularly at the same distance throughout the garden, all of them being of ordinary land drain pipes 2 inches in diameter and 1 foot long, except the main drain, which is of similar pipes 4 inches in diameter, without socket or flange of any kind, but quite plain, as shown in B, fig. 90. In digging the trench for the drains three spades are required like A, B, C, fig. 89, the top spit being taken out with A, the next with B, and the bottom with C, thus avoiding all unnecessary removal of soil. The bottom of the trench is then cleaned and hollowed with the scoop, D, fig. 89, and the trench is then carefully examined before a single pipe is put in it in order that any faulty work may be set right. This is important for the drains are usually made by the perch, and unless the workmen are closely looked after the work will not be well done. The pipes are laid with E, fig. 89, and the soil put back again, the drain then being complete as shown in the section A, fig. 90. When the garden has no slope it sometimes proves difficult to give the drains the necessary gradient to carry off the water quickly. A good way of overcoming this difficulty is to make several short diagonal branches emptying into a main drain, so as to secure the few inches of fall without materially lessening the depth of any of them.—EDWARD LUCKHURST.

Fig. 90.

(To be continued.)

CYPRIPEDIUMS.

AMONG *Cypripediums* there are many varieties; and while there are some with nothing particularly beautiful about them, there are others that command much admiration for their striking and beautiful appearance. The old *C. insigne*, though now considered common and therefore not so highly prized as otherwise it would be, has qualities of beauty, freedom of flowering and long-lasting, that entitle it to a place in every collection. Then there are the improved forms of *C. Chantinii*, *C. Maulci*, and *C. punctatum violaceum*, all of which are extremely fine, the last being a real beauty, and still high-priced. *C. Dominionum* and *C. caudatum* present forms both curious and beautiful, and exemplify some of Nature's wonderful versatility. *C. villosum*, and the improved variety *aureum*, are varieties that combine beauty with a certain massive appearance—when large specimens are concerned—that go far to make them striking features in a collection. Turning from these large handsome varieties, *C. niveum* presents an appearance of delicate *petite* beauty that makes it a great contrast to *C. villosum*. A good pan of *C. niveum*, with twelve or eighteen blooms on it, is really an attractive object, and seldom fails to be admired by all who see it. Then we have the bright-flowered *Sedeni*, almost always blooming, and adding much to the colour of a house of Orchids. *C. Spicerianum*, when first introduced

became at once a favourite, and seems to be fast becoming one of the most—if not the most—admired of the family.

The varieties of *Cypripedium* are being added to, either by importations or crossing—some fine forms having been produced by the latter agency—so that those intending to begin forming a collection are sometimes at a loss to know which to select. No one can, however, err in obtaining all the varieties named, and if they possess these kinds they are sure to admire them and seek to add further to their collections.

Most of the *Cypripediums* are of easy culture, and when not in bloom have the advantage, which too few Orchids possess, of handsome foliage. When cut and placed in water the blooms of many last for six weeks or two months, which is another great recommendation. Altogether they form a group of Orchids that have so many good qualities that no praise that can be bestowed is undeserved.—INSIGNE.

CRICKETS AND COCKROACHES.

"J. W. R." should get a box of Hughes' tropical beetle powder, and use as directed—simply to place a little on some pieces of tile or slate, fresh every night, about the floors of his houses. I have used it, and advised others to do so, with good and satisfactory results. Of course it will require repeating, as fresh broods are hatched almost daily. I never found toads interfere with either of them, although very useful for destroying woodlice.—S. TAYLOR, *Acacia Gardens, Leeds*.

In reply to "J. W. R." respecting the above troublesome pests, I find the best thing to get rid of them is to feed them for a few nights with oatmeal, and when they eat it, add a little arsenic to some oatmeal by slightly damping the meal to make the arsenic adhere to the oatmeal; then spread it thinly on small pieces of thin board or slate, and place it of an evening where they abound, removing it in the morning out of the way of cats and dogs. This will soon clear off all crickets and cockroaches.—N. CAMPANY.

In reply to your correspondent, page 445, I have seen a very successful capture of these in a very plain and easy manner. Place a bowl containing a small quantity of sour beer, or any strong-smelling liquid, with two or three pieces of wood to act as bridges or gangways, up which the beetles will crawl in large numbers. They fall into the liquid but cannot get out again, the sides being too smooth to obtain any foothold. I have seen the bowl half filled in one night—at least 200 beetles in it. They may be killed by pouring hot water over them.—JAS. THOMSON, *Kelso*.

WATERING PLANTS.

THERE can be no doubt that watering plants is often done in a most negligent manner, and it is frequently regarded as an easy and trivial operation of minor importance. This is not always the result of ignorance, but is often due to the fact that young men will not take the trouble to carefully examine the plants they have charge of. Watering is a very important operation, and much of the success that attends plant growing is due to a judicious use of the water pot. Those who make themselves masters of this operation are indeed valuable assistants.

Explanations and advice may be given from time to time on this subject, but it is most difficult to lay down any hard-and-fast lines or even to teach the exact time when and how watering should be done; in fact, it is a knowledge that can only be attained by intelligence and experience. To merely tell a man to be careful with a certain class, say of hardwooded plants, or that you are particular about the manner in which they are watered, is insufficient. With remarks similar to these they often allow the plants to become thoroughly dry before they apply water, and more hardwooded plants are sent to the rubbish heap through being kept too dry than from almost all other causes. To water these plants properly the soil in their pots should never be destitute of moisture, or they will be seriously injured, and months of careful watering afterwards will not repair the damage done by neglect on one occasion. Their delicate fine fibry roots are destroyed in a few minutes after the soil has become thoroughly dry. Their leaves soon turn a sickly yellow, eventually fall, and no after treatment can restore the plants.

In watering these plants an intermediate state should be provided as far as possible. It is, I am aware, impossible for them always to be kept in this stage, but overdryness can and must be prevented if any success is to be attained. Water should be applied just before the soil becomes dry, and if this is insufficient they should have a second or even a third application to soak thoroughly the whole mass of firm soil. During summer these plants may with safety be watered before they approach so dry a stage as is necessary at this season of the year. In summer, when examining these plants, they may scarcely be sufficiently dry to need water, but with one or two hours' bright sunshine they would in all probability suffer. These might safely be watered at that season of the year. At the present time plants in the same condition would stand one or two days, and later in the season perhaps for nearly a week, but the weather must be taken into consideration.

During the period when these plants have completed their growth and resting they must never be allowed to suffer by the want of water. Dryness at their roots while at rest is one of the greatest mistakes that can be made in the culture of these plants.—W. B.

PROTECTING OUTDOOR CAULIFLOWER AND BROCCOLIS.—For several years back I have grown Cauliflower plants outside on a sunny border

during winter, and in nine winters out of ten the vast majority of them did better than if grown and coddled in a frame, and of course give no trouble whatever, except the trifle I am going to tell of how the thing is best done. I sowed Carter's Dwarf Mammoth, Early London, and Early Defiance—this last as an experiment, as it is more tender than the others, and of finer quality—on small beds in the end of July. They are now strong, have been dusted with fresh soot to scare away slugs a week since, and yesterday have had what, for want of another better word, I must call a top-dressing of dry loam between the plants. The object of this top-dressing is to cover the stalks, for I find if the generally long stalks are safe the leaves and hearts are secure. I shall pit those now against the most carefully watched and air-given frame plants, and, what is important, I never find them to "button."—W. J. MURPHY, *Clonmel*.

GLADIOLUS THE BRIDE.

It is difficult to say how long this beautiful plant has been known in English gardens: one thing is certain, until very recently its merits were not appreciated. Whether re-christening of the old *G. Colvillii* alba with the attractive designation heading these notes has influenced public taste, is a matter of little moment. Happily it is becoming much better known and very largely employed for its intrinsic value in floral decorations. Wherever white flowers are in great demand this is one of the most useful plants possible to cultivate. There are several reasons why I make this assertion. The colour and substance of the flowers is precisely what is requisite; it can be forced readily, and can be had in bloom over a very lengthened period, and it increases freely even under pot treatment if liberally grown. As large as has been the demand for this *Gladiolus* in some quarters, I am in a position to know that at the present time it is absolutely unknown to a large number of gardeners; and when we take into consideration the multitude of amateurs whose garden is only secondary to the chief business of life, most of whom are unacquainted with it, there is ample reason why the pages of the Journal should be the medium of bringing it at the present very opportune season before the notice of the flower-loving community. Of course, at the very mention of *Gladiolus*, more than half the world think you are referring to some half-hardy plant which requires to be coddled in some warm cupboard during the winter, and ever carefully watched after being planted in the spring; whereas this variety is perfectly hardy, increasing rapidly in the open ground, and should be planted or potted in autumn in preference to the spring, as they are subjected to unnecessary and most prejudicial drying if bottled up through the winter out of the ground. What few corms I have out of the ground or pots will be speedily transferred to their permanent quarters, and I recommend all the readers of the Journal desirous of trying it to secure their stock without delay, either for pot or border culture. Several clumps of bulbs which were not raised in early autumn are pushing up the narrow leaves through the soil, and will be able to hold their own against winter's cold. If required for forcing several corms should be put in a pot, when they should be placed in a cold frame or plunged outside in ashes of cocoa fibre until root-action is fully resumed, when they may be subjected to a higher temperature, finally placing them in the forcing pit as required to be in flower. No plant is more easily managed in this respect. During this year I had them in flower from March until September, and they were greatly admired when employed with other plants for decorative purposes, while the flowers were equally appreciated, and constantly being asked for. Yes, The Bride was really a general favourite. I hope these remarks will secure for her a wider circle of friends.—T.

SIX MONTHS IN A VINERY.

THE principal leaves are larger than when I made my last note. Many of them now measure 11 to 12 inches across and 12 to 13½ long. The side shoots or laterals have extended too—*i.e.*, the stems measure further from leaf to leaf, so that they overlap slightly where the rods are not more than 4 feet apart. Most of the sub-laterals have been stopped once, and in some instances where they made a second start the second bud has been taken clean out with the thumb-nail, for although the roof is not yet entirely covered it will be as much so as is desirable by the time the growths already allowed have stretched out to their fullest extent.

Tying down has now been completed, not from choice, but from necessity, as the space above the trellis is too limited. The bunches, which are fast approaching the flowering stage, have strengthened satisfactorily, and are rebelling against their unnatural pendent position, which the horizontal tying of the laterals has brought about by turning up their points to the light. These will come down again when the fruit has grown sufficiently heavy to bring them down naturally by its own weight.

On the 25th February we had a bright, clear, and mild morning. A little air was given by sliding down four of the lights a couple of inches each at 8.30, increasing to double that amount at 9 o'clock and closing at 1 p.m. No more air was needed till the 1st of March, when the management was about the same. The next day we had some sunshine with a bracing east wind—too bracing, we thought, to admit more into our vinery than could go through the laps. On the 3rd and 4th, although there was a little frost, the air was not quite so

harsh, and we again admitted some of it at 8.30, closing at 1 o'clock. No air was given on the 5th, as it was not bright long at a time.

The morning of the 6th opening brightly, we gave a little ventilation at 8 A.M., and closed the house again at 10 on the appearance of clouds.

The 7th was the beginning of a very cold spell of weather. Our minimum thermometer outside registered 26° at 4 feet from the ground, and the one on the grass 24°; not a great amount of frost certainly, but the wind was brisk, and coming as it did after so much mild weather it was very trying.

There were occasional glimpses of the sun to warm up our house, and yet not sufficient to make it necessary to open the ventilators, so that altogether as far as foreing was concerned it was a beautiful day.

The next day was very much like it, only with the minimum temperature one degree lower, and on the 9th it was one degree lower still—viz., 24°, while that on the grass was down to 21°, and the wind was bitterly cold. Outside vegetation is very much cut up, but happily we have not been obliged to open our ventilators since the 6th.

This morning (the 10th) it is to be hoped the weather has reached the climax. Our minimum thermometer registered 17½°, or 14½° below the freezing point, and that on the grass has been down to 11°. There is ice inside the glass of all our houses, and in the vinery a few of the leaves which press up against the glass are frozen to it. The lowest temperature as indicated by a registering thermometer in this house was 54°, which is within one degree of the present regulation temperature, and is quite high enough for such severe weather. The mischief is owing to the trellis being too near the glass; it never ought to be less than 18 inches, and I much prefer a space of at least 2 feet. The sun unfortunately came out brightly as soon as it rose, and touching the leaves while they were still frozen, a few of them show the effects of these sudden changes, portions of them being reduced in appearance to tinder, but on the whole we have escaped apparently without much damage. We gave a little air at 7.50, or almost immediately the sun touched the house, and increased it at 8.30, it being very bright and calm at this time. About 10.30 some pieces of broken cloud appeared and the wind was a little brisk; we therefore reduced the ventilation, although the temperature of the house was about 80° and rose a little afterwards, and at 12 o'clock we closed it altogether with the mercury at 78°, which figure was maintained for a couple of hours later.

As there is every appearance of the frost continuing we decide to put a little litter on the outside border, which hitherto, owing to the winter being mild, has had no covering. A little of the driest litter we can procure is now spread lightly over the border, which has become quite hard on the surface, and ought certainly to have been covered before last night's frost. We shall remove this litter during sunny days and take it away altogether as soon as the weather changes.

The inside border was watered on the 7th and 8th, the area is about equal to a perch, and this received 840 gallons. 3 lbs. of two star crown manure, which is supposed to contain a considerable quantity of potash, was applied after it had received half the quantity of water, and the water was used at about 60°.—WM. TAYLOR.

SWEET PEAS.

As free-growing, profuse-flowering, pleasing-coloured and deliciously fragrant plants Sweet Peas will always command a place in our gardens, but considering their great value it is rather surprising that they are not cultivated to bloom much longer in the year than is generally the case. In an ordinary way when the seed is sown in the open ground in March the plants will bloom in June and continue until October, but later in the autumn and earlier in the spring they are not to be seen, and it is in this respect there is so much room for improvement. By sowing the seed in pots we have had them flowering freely until Christmas, and by sowing again in January they have bloomed in April, and at all times they are most acceptable. They do not require much heat to bring out the flowers; and for late blooming they should be specially prepared by sowing the seed in August, and not allowing the plants to bloom until October; and for conservatory decoration at this time they have few equals. There is yet another mode of growing them which I will point out for the benefit of those who have no glass houses. This is to sow the seed at once in the open ground, and grow the plants so obtained on as we might do the Peas for the kitchen. Seed sown in good soil in drills 3 inches deep now will soon germinate and produce plants which will flower well in May next, or before that time if the winter and spring are mild.—A KITCHEN GARDENER.

MEALY BUG AND SCALE ON VINES.

PERMIT me to say a few words respecting these, as the time is now commencing for cradicating this great pest. I should like to know if any reader of the Journal has tried Murray's Vine Composition for bug and scale on Vines and Peaches. It is the best I have ever used. I saw it last winter applied to some Vines which were very badly affected

with these insects and they are now perfectly clean, although the same had in previous years been dressed with various compositions without effect. I find it a first-class dressing for Peaches affected with scale, being quite harmless to the buds and a most effectual exterminator, and one which should be in every Vine and Peach-grower's hands, as we all experience enough trouble with these pests.—M. A. S.

CHRYSANTHEMUMS AT THE SLOUGH NURSERY.

ALL lovers of the Chrysanthemum, where the possibility exists, should visit the magnificent display Mr. Turner has provided for all comers. Having seen the annual display of Chrysanthemums at Slough for some years past, I think it safe to say the present Show has never been equalled. Certain it is the exhibitions at the Temple and other metropolitan centres do not reach the high quality to be found there. Three houses are filled with the plants, the square conservatory containing Japanese varieties only; a span house, over 100 feet long, with central path, being filled chiefly with large-flowering incurved varieties, forming sloping banks on either side of the pathway. The front lines are finely finished off with dwarf plants of the rich crimson Julie Lagravère and pure white Sœur Melanie in quantity, which has a very pretty effect. Another house, 50 feet long, contains more incurved varieties, and there are some of the largest flowers. Among these I noticed as being particularly fine, Jardin des Plantes, Bronze ditto, Barbara, Mr. Bunn (very fine), Refulgence, Beethoven, Beauty of Stoke, Prince Alfred, Princess Beatrice, Queen of England, Empress of India, Golden Empress of India, Mrs. Heale, Lady Hardinge, Beauty, the Rundle trio, Nil Desperandum, Novelty (fine), Yellow Formosa, and Jeanne d'Arc, a pretty variety having the waxy petals of White Venus faintly striped with violet, and finely incurved.

Among the Japanese extremely good were Madame C. Audiguier, large deep pink, of exquisite form, Fair Maid of Guernsey, Hiver Fleur, Madame Rendatler, Peter the Great, Comte de Germiny, La Nympe, Bouquet Fait, Criterion, Triomphe de Chatelet, Lady Selborne, Oracle, The Daimio, Royal Soleil, Meteor, and Duchess de Gerolstein.

A few very effective new varieties were M. Desbreaux; Safrano, pale primrose with yellow centre; F. A. Davis, fine crimson-red; Japon Fleuric very dark crimson, and Duchess of Albany. All the above varieties are well adapted for conservatory decoration, also for exhibition blooms. The collection throughout is in fine health, with foliage to the pot's rim, and promises to be in good condition for another fortnight.—C. H.

EARLY PURPLE-TOP MUNICH TURNIP

IN reply to the inquiry of "W. D. W." respecting this Turnip at page 429, I beg to say that it is the earliest and handsomest variety I am acquainted with, and on this account it is invariably grown by exhibitors of vegetables at the metropolitan and provincial early summer shows. It is, however, inferior in other respects to the Early Snowball and other early varieties, being tough and wanting in flavour.—H. W. WARD.

IN your issue of November 15th, "W. D. W." writes for others' experience of the above-named Turnip. I have grown this variety for three seasons. It is the earliest Turnip I am acquainted with, and it requires to be used in a very young state, or it loses its flavour and becomes pithy. The first season I grew it I made several successive sowings on a north-east border during spring and summer, but as I found the flavour of it inferior to many other varieties, I now only grow one small batch of it for early work. The best Turnip I am acquainted with for general crop is Veitch's Red Globe. It is of good flavour, handsome shape, remains a very long time fit for use, and stands the winter well.—N. CAMPANY, *The Gardens, Thedden Grange, Alton.*

PANSIES AND VIOLAS.

ABOUT the year 1874 Mr. Williams of London raised a true cross between a Pansy named Imperial Blue or Prince and the common Viola cornuta, which I believe was named Perfection, and is well known. Interested as I was at the time by his success, I repeated the cross, and obtained a pod of seed, from which I raised twelve plants which flowered the next season, the produce resembling Perfection, but the plants were rather dwarfer than that variety, but as regarded flowers were precisely similar. I crossed this hybrid, which I named at the time Viola "True Blue," with the pollen from various coloured Pansies, and had a considerable number of seedlings to bloom the following season. From the seeds so raised Violas became the fashionable flower, and the Floral Committee of the Royal Horticultural Society of London invited raisers to send their seedlings to be bedded out at Chiswick. When the beds were in their best state in June the Floral Committee went round and awarded certificates to the most meritorious. Of course the members had no knowledge of the raisers, as the beds were numbered. Messrs. Dean of London, Dickson & Co. of Edinburgh, Fromow, Robertson & Galloway, and myself competed. Five first-class certificates were awarded to Mr. Dean, four to Messrs. Dickson & Co., I was awarded six, and the other raisers also had several.

Great diversity of opinion existed at this time as to what were the distinguishing features of a true Viola, and the same difference of opinion seems to exist still. I have described exactly how my strain was obtained. They are true hybrid cornutas, rather long in shape, with the long spur or horn projecting behind the footstalk. Many of

the so-called Violas of the present day are simply bedding Pansies selected for their floriferous character and bright telling colours. I am not sure but those of my friend, Mr. Grieve of Messrs. Dickson & Co., in these respects excel any I have ever raised as hybrids. For dwarf habit and continuous flowering the hybrids are difficult to treat. In the months of June and July, however, few plants of any kind can equal the grand mass of blue seen in Messrs. Dickson's Tory, or the golden yellow of their Sovereign. These varieties have more of the character of the Pansy than the Viola, and most of their strains are of a similar character. Mr. Grieve and I have had many discussions on the subject, and I do not suppose he even maintains that there is much of the cornuta character in his Violas. In order to prevent my Violas becoming like Pansies I grow no Pansies in the same garden, and in that way have succeeded in perpetuating a true and distinct strain of dwarf, hardy, free-flowering bedders, which resist our harsh climate better than any plants I am acquainted with.—CHARLES STUART, M.D., *Hillside, Chirnside, N.B.*

WINTER KING GRAPE.

I SEE in the report of the Fruit Committee held at Kensington on the 13th, that Mr. B. S. Williams exhibited a Grape called the Winter King, but that confirmatory evidence was required of the way in which it was obtained. I am pleased to be able to confirm the account given of it, as I saw the bunches on the Vine a fortnight before it was exhibited, and must say that a finer Grape for winter could not well be seen. Fancy a Grape with the colour of an Ickworth Impératrice Plum, and with every quality which a winter Grape ought to possess, and we have that which has long been wanted.

For bold and striking individuality Winter King Grape is the most handsome in cultivation; in colour it is deep blue-black, which makes it stand out conspicuous from any other Grape known, and gives it a rich appearance hanging on the Vine. It is of robust constitution, a free setter, colours freely, rich, juicy, with a slight aroma similar to a well-finished Black Hamburgh. The way in which it was stated it was obtained was correct in every particular. A more striking effect of the stock upon the scion could not well be conceived.—J. GADD, *Gardener to Sir T. B. Lennard, Bart., Belhus, Aveley.*

WE regret to announce the death of MR. JAMES GRAY, the well-known hothouse builder of Chelsea, which occurred on the 24th inst., at the age of 73. Mr. Gray caught a cold last Thursday week, when returning from a meeting of the Committee of the Gardeners' Royal Benevolent Institution, with which he had for many years been associated, and this turning to bronchitis resulted in his death. Mr. Gray, originally a gardener, was a native of East Lothian, and being a good draughtsman and designer he, after practising his art, entered the works of the late Mr. John Weeks of Chelsea, where he was engaged for some years. Eventually he began business on his own account, along with Mr. Ormson, and they for many years carried on a very successful business, and afterwards they parted, each of them being the heads of large establishments. We are glad to know that Mr. Gray's works will be continued by his son, Mr. Alfred Gray, to whom we wish every success. Mr. Gray was grandnephew to the celebrated Johnnie Dowie, immortalised by the poet Burns and the Edinburgh literati of the last century as the keeper of that tavern which was their social haunt, and who was himself a man of no indifferent attainments. His funeral takes place this day (Thursday) at the Brompton Cemetery at 3 P.M.

— A LECTURE was delivered in the Parkes Museum, Margaret Street, Regent Street, on Thursday evening last, by Mr. Murray, on the POTATO DISEASE. The lecturer treated the subject in an able and practical manner, giving a life history both of the Potato and the disease. The lecture was illustrated by eleven diagrams. No hopes were given of exterminating the disease, but the introduction of a new species of Potato was favourably spoken of. Mr. Murray seemed to give most favour to the unpopular system of consuming or destroying all the Potatoes of one season, and obtaining seed from another locality and introducing them from a locality or country where they were free from disease. The lecture was followed by a short discussion.

— A LARGE sale of ORCHIDS IN FLOWER was held in Messrs. Protheroe & Morris's Auction Rooms, Cheapside, and a number of Orchid growers were present. Quite a bright display was produced by the number of flowers, *O. ontoglossum Alexandræ* being especially

notable, one splendid variety of which was sold for nine guineas, and a small plant in a 60-size pot of a dark-coloured form of *O. punctatum* was purchased for fifteen guineas. Some fine *Oncidium*s and *Phalænopsis*s were included, together with a large number of the distinct *Eucharis Sanderi*, which was flowering very freely.

— IN the pleasure grounds at Kew the common Strawberry Tree, *ARBUTUS UNEDO*, and its varieties, notably *A. Unedo Croomii*, are well worth notice at this dull season. When grown in sheltered positions, which is almost essential to the production of fruit in quantity in this country, the contrast between the creamy white flowers and the rich scarlet fruits is very attractive.

— THE lakes in the same establishment, which are always a source of much enjoyment to visitors, have within the past few weeks undergone a much-needed alteration. The end nearest the Palm house, which was hitherto inconveniently narrow, has been considerably widened and the edges made more irregular. The bed, too, has been cleared of the *Potamogetons*, *Myriophyllums*, &c., with which it was infested, with, we believe, a view to introducing Water Lilies and other aquatics of a more ornamental character.

— THE EALING AND DISTRICT CHRYSANTHEMUM SHOW, held on the 21st inst., was a great success in the number and quality of the exhibits; plants, blooms, fruit, and vegetables being well represented. An interesting class was provided for cooked Potatoes, and the competition was very keen, about two dozen dishes being staged. An excellent collection of Apples and Potatoes was exhibited by Mr. R. Dean, Ealing, and Messrs. Lee & Son, Hammersmith, contributed a large and beautiful group of Chrysanthemums.

— MR. ROBT. D. LONG, Cranbourne Court, Winkfield, Windsor, writes respecting *CHOU DE BURGHELY* as follows:—"As much has been written from time to time in favour of the above, we were induced to give it a trial. We commenced cutting it a month ago, and after repeated trials in cooking do not find it in any way superior to the ordinary Cabbage. We shall leave a portion of the plants to stand through the winter, for if they will form heads of Broccoli later on, will be most useful in that way."

— A CORRESPONDENT writes—"In your report of the LLWES CHRYSANTHEMUM SHOW in last week's Journal a slight error has occurred owing to a transposition of names. In the open class for twenty-four cut blooms you state that Mr. Barchard, gardener to C. Cornwell, Esq., was third. It should read—Mr. C. Cornwell, gardener to F. Barchard, Esq. I know the latter gentleman, who is locally famed for his skill in Chrysanthemum culture."

— THE second number of the "SCIENCE MONTHLY" contains several interesting and instructive articles, and if this periodical is continued as well as it has been commenced it will undoubtedly become very popular. The principal subjects are "The Aurora," "Disease Germs," "Some Account of New Guinea," a paper read before the British Association this year by Mr. Coutts Trotter; "The Transmission of Energy," "Lessons from Common Plants," and the Biography of Sir John Lubbock, Bart., with a portrait.

— RELATIVE to the LINCOLN CHRYSANTHEMUM SHOW, reported in our last issue, Mr. Wipf informs us that the first prize for six incurved blooms was awarded to him, also the second prize for twelve blooms, and not to Mr. Coulling. The errors occurred through some of the prize cards being accidentally placed on the wrong stands, but afterwards rectified. The collection of blooms shown at this Exhibition, and stated in our report, page 451, to be from the Inner Temple Gardens, London, were, we are informed, shown by Mr. Wright, gardener at the Middle Temple. Mr. J. J. Lowry writes:—"In your report of the Borough of Hackney Chrysanthemum Exhibition, James Macanderson, Esq., and J. Lewry, gardener, should be read James Macandrew, Esq., and J. J. Lowry, gardener."

— "YORKSHIRE" writes—"I notice there has been some correspondence in the Journal lately respecting FUEL FOR HEATING BOILERS. I have the last month been using breeze coke, which I procured from a colliery through a friend of mine, and which cost me 11s. 6d. per ton, carriage paid to any station in the East Riding of Yorkshire. As gas coke with me is very dear, I find this breeze coke comes in at about the same price, while the pieces are about the right size for use, thus saving the labour of breaking, and occupying less room. It is also harder and

more solid, and lasts longer than the ordinary gas coke, so that I really believe it is much cheaper."

— THE GLASGOW AND WEST OF SCOTLAND HORTICULTURAL EXHIBITION next year will be held in the City Hall. The Spring Show on Wednesday, 26th March, 1884, and the Autumn Show on Wednesday, 3rd September, 1884.

— OUR correspondent, "W. J. M., *Clonmel*," urges the desirability of growing CHRYSANTHEMUMS OUTDOORS more generally for supplying flowers, cutting in October and November, and sends us specimens of Golden Christine and Fingal, under the impression that we have seen few finer blooms. They are attractive, but we have seen many far superior from plants grown in the open air; indeed really fine blooms can be had, especially when the plants are generously treated and judiciously disbudded, and the growths trained to walls and fences. We doubt if the variety sent as Fingal is correctly named.

— THE same correspondent sends us sprays of FUCHSIA CORALLINA from "a plant grown in the open bed, where it has had no protection, except a mound of coal ash in December, and has been blooming since July. These blooms are but a mere fraction of the size of those cut hitherto." They are as good as from plants grown under glass.

— REFERRING to a class in the schedule of the SOUTHAMPTON CHRYSANTHEMUM SHOW, which was provided for twenty-four blooms, sixteen incurved or reflexed and eight Japanese, Mr. Moorman remarks that it is advantageous, as by "placing the eight Japanese in the back row the other two rows of a stand are filled with flowers that are larger in size than if the whole twenty-four were all to be incurved. The effect is materially improved also, as the Japanese row at the back are set higher and are larger in themselves than the incurved varieties. Further, it is easier for an exhibitor to fill a stand with good blooms, for all exhibitors well know the strain it is to sometimes procure twenty-four good blooms, while from sixteen to twenty can readily be found. This class has been a leading feature in the Southampton shows for several years, and I strongly recommend its adoption in societies of smaller pretensions, especially in new societies."

— No. 86 of the third edition of the "ENGLISH BOTANY" continues the description and plates of the Ferns, the species and varieties of Cystopteris and Asplenium occupying the chief portion of the space. The plates are beautifully executed, life-like in the minutest details. The descriptions are also very full and accurate.

— MESSRS. J. CARTER & CO. have had for some time past a very extensive display of CHRYSANTHEMUMS at PERRY HILL. Some hundreds of plants are grown, representing all the leading varieties, many new, and some of the old and rare sorts that are now seldom seen. They have been well grown and have a great number of blooms, some being large and bright in colour. Incurved, Japanese, Anemones, and Pompons are all in strong force and produce a very pleasing show.

— THE CHELMSFORD CHRYSANTHEMUM EXHIBITION was held on the 21st inst. in the Corn Exchange of that town, all the classes being well filled. Specimen Chrysanthemum plants were well shown by Messrs. Saltmarsh & Son; J. Burrell, gardener to W. W. Duffield, Esq.; J. Tunbridge, gardener to Wm. Bott, Esq., Broomfield; and cut blooms were similarly well staged by the same exhibitors, with Mr. J. Clark of Writtle. In the fruit class Mr. Henry Lister, gardener to Lord Brooke, Easton Lodge, Dunmow, was very successful, staging some handsome Apples. Mr. Smale, gardener to R. Woodhouse, Esq., and Mr. W. Green, Romford, were also prizetakers in these classes. Miscellaneous exhibits were largely contributed, and added much to the attraction of the Show.

— THE second meeting of the MANCHESTER HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY was held on Thursday evening, the 22nd inst., in one of the rooms of the Old Town Hall, King Street, when Mr. Abraham Stansfield read a paper on the mode of reproduction in Ferns. Mr. B. S. W. Williams was voted to the chair; the room was crowded with members. Mr. Stansfield pointed out in his paper that the secret of the reproduction in Ferns was discovered by an amateur. He described some of the phenomena of reproduction in the Fern, and in some general remarks said the botanist and horticulturist were inseparably connected with each other, and no horticulturist without some knowledge of botany would proceed clearly in his work. On the other hand, a botanist could derive many hints from a horticulturist. He believed thoroughly in a practical acquaintance with things, and in

nothing that was not capable of demonstration. A botanist was a man who had helped gardeners in their business. We knew what a Cabbage was, a Turnip, a Pear, an Apple, and a Gooseberry; but a botanist could tell us what they had been. He searched and ransacked the world for new species, and the gardener cultivated them. With reference to Ferns, the number of varieties, especially British, had multiplied amazingly; nothing like it was known, and he thought that one principle ought to be laid down with regard to naming new varieties, which was that the name given should be in some way descriptive of the plant itself, not a simple laudation of some individual. He urged upon his audience the importance of studying the different varieties of Ferns and how they developed. The Chairman, Mr. W. Swan (Honorary Secretary), Mr. R. Astley, Mr. Lunt (Stamford Park), Mr. Birkenhead (Sale), Mr. W. Plant (Sale), and Mr. T. Rogers joined in the discussion which took place, and a vote of thanks was passed to Mr. Stansfield for his paper.

— THE CHRYSANTHEMUM SHOW of the Royal Jersey Agricultural and Horticultural Society, held in the Odd Fellows' Hall, Don Street, St. Helier's, on November 14th, was a great success, and one of the best the Society has held for some years past, both plants and cut blooms being remarkably good. The following were some of the principal prizetakers:—In the "silver eup" class for twelve plants, four each of large-flowered, Japanese, and Pompons, Dr. Hooper (R. Thorne, gardener), was a good first with medium-sized plants, well flowered, and fresh alike in foliage and bloom, Judge Falle (Mr. Allix, gardener) was second, and Captain J. F. De Carteret's (Mr. Druce, gardener) third. For eight Japanese Mr. G. Ereaut obtained first and the bronze medal; they were handsome, fresh, and well-bloomed plants. For a single specimen Japanese Mr. G. Ereaut was first with Fair Maid of Guernsey, a very fine plant; Mr. G. De Quetteville second with La Nympe, a fine large plant; equal second Judge Falle with a fine plant of Early Red Dragon; third, Dr. Hooper. Judge Falle, Mr. Morris, Captain J. F. De Carteret, Mr. G. De Quetteville, Mr. G. Ereaut, and Dr. Hooper were the chief prizewinners for Pompons. The cut-flower classes were good. For eighteen pairs, twelve large flowers and six Japanese, Mr. G. De Quetteville was awarded first and the bronze medal for superior blooms; Mrs. Fothergill (gardener, Mr. Beckford), was a good second with a well-matched even set of blooms; Mr. G. Thorne was third. Twelve Japanese, one variety, first Mr. Morris with extraordinary blooms of Madame C. Audiguier; second, Mr. G. De Quetteville with wonderfully fine Peter the Great; third, Miss Ainge, very good. For twenty-four bunches of Pompons Mr. E. Collas (gardener, Mr. Dingle) was first with very clean handsome bloom, second Mrs. Fothergill. Twelve bunches Pompons, first Mr. R. Robin (gardener, Mr. Randell), second Captain J. F. De Carteret, third Miss Ainge. Extra prizes were awarded to Dr. Hooper for a small but very fresh, healthy, and well-flowered piece of Ixora; to Mr. Morris, Anemone-flowered Chrysanthemum, and to Mr. G. Ereaut for twenty-four Japanese cut blooms. Mr. Morris also showed some fine-foliage plants and Ferns, and Mr. G. De Quetteville specimen trained Chrysanthemums, not for competition.

FRUIT TREES IN POTS AT EWENNY PRIORY GARDENS.

IN the remarks concerning these trees, page 433, there was a slight error regarding the number, and it may be well to give the exact number, also the size of our orchard houses. Our lean-to house is 40 feet long by 14 wide, 6 feet high at the front, and 13 feet at the back. Trees are planted and trained against the back 1 foot from the wall. A trellis path 3 feet wide runs lengthways; in front of this are the trees in pots. This being the early house it has a flow and return pipe along the front. All the trees in pots are taken out in autumn, and the house filled with Chrysanthemums. Two Vines are also trained up the rafters, and there is a shelf running the whole length at the back for Strawberries. The span-roof house is 45 feet long by 12 feet wide, 5 feet 6 inches high at the front, and 8 feet high in the centre. A 3-foot walk runs through the middle of this house, which has no artificial heat. Late Peaches and Nectarines are grown there, Pears, Plums, Cherries, and Apricots. All the trees in pots grown in both houses are placed in this one during winter, and they now amount to over eighty. The pots, when placed in this house in winter, are covered with straw to prevent frost breaking them. In spring, when the early Peaches and Nectarines commence blooming, I remove a sufficient number of the earliest to fill the lean-to house. I should advise every lover of trees in pots to obtain Mr. Rivers' book, which is full of sound instruction. I syringe more than many do when the trees are in bloom instead of using insecticides for green fly. My system of pruning also differs from that some practise, but I may write on this subject some other time.

The following is a list of some of the best varieties grown here in pots:—

Pears.—Beurré de l'Assomption, Beurré Diel, Beurré Easter, Beurré Superfin, Doyenné du Comice, Durondeau, Duchesse d'Angoulême, Marie Louise, Louise Bonne of Jersey, Pitmaston Duchess, Souvenir du Congrès, and Brockworth Park.

Peaches.—Barrington, Conkling, Bellegarde, Hales' Early, Grosse Mignonne, Noblesse, Royal George, Waterloo, Alexandra Noblesse, Crimson Galande, Dagmar, Early Louise, Early York, Gladstone, Osprey, Lady Palmerston, Princess of Wales, Rivers' Early York.

Nectarines.—Downton, Elruge, Hardwick Seedling, Pitmaston Orange, Violette Hative, Albert Victor, Newton, Pine Apple, Rivers' Orange.

Plums.—Belgian Purple, Coe's Golden Drop, Green Gage, Denniston's Superb, Reine Claude de Bavay, Transparent Gage, Lawrence's Gage, Prince Engelbert.

Cherries.—Governor Wood, May Duke, and Bigarreau.

Apricots.—Moor Park and Peach.

Some other sorts are grown, but those I can rely on as sure croppers, and they are good-flavoured.—GEORGE HAWKINS.

STOUP LEADINGTON APPLE.

ONE of the most curious-looking Apples shown at the National Apple Congress at Chiswick was the Stoup Leadington, a Scotch variety of

Fig. 91.—Stoup Leadington Apple.

ancient reputation, and we have thought that an illustration of it would be acceptable to our readers.

The fruit is medium-sized, about $2\frac{1}{2}$ inches wide and 3 inches high; tall and angular like the Catshead. It is distinctly five-sided, with five corresponding angles. Skin dark grass-green, becoming yellowish after being kept for some time. Eye with divergent segments, set in a deep angular and plaited basin. Stamens median; tube conical, very wide and deep. Stalk short, inserted by the side of a large and prominent growth, which projects from the fruit in the form of the lip of a jug. Flesh greenish, juicy, very acid; cells elliptical, abaxile.

A kitchen Apple of good quality, in use from November till January. It receives its name from the likeness of the fruit to a stoup or pitcher for holding liquids, which it certainly resembles when stood upon the eye, the stalk being upwards.

ANEMONE JAPONICA ALBA IN POTS.

"W. B." (page 436) writes interestingly on this plant, but his remarks would have been more valuable had he named the time his early and late plants flowered. There is no word of this, and we cannot tell whether his early plants may bloom in October and November, and the late ones in December and January, or when his treatment results in this. Indeed, this is one of the most interesting facts we could have been told on the subject, and probably your correspondent may be induced to give us dates. Apart from this, however, I have to confirm his observations respecting the value of this plant. It is one of

the best anyone can possess. I grow it both out of doors and under glass, and it does admirably in both positions. The open air plants are grown like Phloxes, but the heavy rains we frequently have in October spoil the flowers on these so much that it is mainly on this account I was induced to plant it under glass, and the result is a great success. They are planted in a border in an old-fashioned cool conservatory. In June the leaves are produced in profusion, and about the end of August the flowers begin to appear, and from then until now there is a constant succession.

The advantages of having them under glass are very apparent, as they bloom much more freely than in the open, and for a longer time, and the blooms are vastly superior to any we can get outside. We never trouble very much about its propagation, as under glass the roots extend like those of Mint, and when we wish to increase our stock these are cut off and planted elsewhere.—M. M.

ARTIFICIAL v. STABLE MANURES.

M. VILLE'S THEORIES EXAMINED.

I MUST suppose that you know M. J. Ville's celebrated work on artificial manures. He professes that stable manure can altogether be dispensed with and chemical agents be substituted. Do you share this opinion? or at least do you think that for the managing and manuring of a plantation of Red and Black Currants, Gooseberries, and Morellos, this would do?

I am just now preparing some twenty-five acres of land for making a culture such as I mention. The question of manure is all-important, and I try hard to get every possible information. If chemical manure would be available for such a purpose another question arises, which is for each of the trees planted the "dominant" (the principal required agent)? Has this been studied already, or should experiments be made?

A gentleman near Antwerp has succeeded in using chemical manure to bring to a successful issue the rearing of Pine trees in the sands of the Campine, whilst all his neighbours failed. The use of chemical manure would be such an economy of transport and saving of trouble on ordinary manures, such as blood, liquid manure, cow and horse droppings, &c., that it would be highly desirable. Only, can it well be done, has it been tried before, and are the formulas known?—C. HAVENITH, *Antwerp*.

[The above letter, by request of the writer of it, was sent to our correspondent "Single-handed," who has sent the following reply:—

Although M. Ville maintains that with artificial manure alone equal, nay superior, results may be obtained compared to what ordinary manure will yield, it should be remembered that he is only one, and by no means the greatest, of modern experimenters, who maintain anything so extreme. All the evidence goes to prove that the proper place for artificial manure is as a supplement when other manure is scarce. M. Ville has made a large book by reiterating his fallacy again and again; but though his iterations are strong his evidence is weak, for he fails to recognise some of the most potent factors that secured the results which he attributes wholly to the ingredients supplied. Decayed vegetable matter he considers valueless, hence his sneers at common manure. Others, of a much higher authority than he, give it a high place, and that in countries where it disappears much less rapidly from the soil than in France. If you have read what I have said on this subject there will be no need for me to repeat it here.

As for a "formula" being wanted in any case, it really is all nonsense. If anything has been proved at all, it is that what is absolutely necessary in one spot may be altogether superfluous in another, M. Ville, with all his exact and many multiplied "formulas" to the opposite notwithstanding. It is impossible to prescribe for this, that, or the other crop without knowing something more than the names of the plants. The state of the soil is of far more importance. You may trust M. Ville's formulas—any one of them. He takes care that a very great deal more shall always be present than enough. But if your soil is like some here in England it would be sheer waste of money to give plaster of Paris (calcic sulphate). If like some soils we know of in this country, it would be equally foolish to give potash. Even supposing it were necessary, if you keep dairy stock (as we presume you do, seeing you mention "liquid manure"), the liquid from the stables would supply a rich source which it would be a mistake to neglect in favour of artificials. The question thus is not so simple as M. Ville would put it, and his formula for "garden stuff" is only a wild guess.

Doubtless artificial manure, especially for the trees named, might almost wholly take the place of ordinary manure, especially if every leaf, every bit of vegetation (and you might raise a crop on purpose by sowing Rape and digging it in) be used. You can hardly go wrong in giving a good dressing (such as Ville recommends, so far as quantity is concerned) of super-

phosphate now, and such dressings of sulphate of ammonia and nitrate of soda as he recommends early in summer, after growth has commenced, and just before rain if possible. This, if the soil be otherwise good, especially if there be enough lime in it, will almost certainly cause luxuriant growth followed by the best crops. But possibly potash may be needed too—it may be absent from the soil; but dressing a portion of the land only will tell you that. If an addition causes more luxuriant growth, it is necessary; if it makes no difference, it is not. There is one thing, potash and nitrogen have a very favourable influence on Currants. Always apply dressings right over the roots, where they will be sure to find it. We should very much prefer to give one spade of ordinary well-decayed manure to each plant to secure a thorough start.—SINGLE-HANDED.]

WHITE ELEPHANT POTATO.

SOME speak well of this Potato, but many have been disappointed in it. It is certainly a wonderful variety to produce a heavy crop of large tubers, but this is all that can be said in its favour. We have grown it two seasons, and each time it has been very prolific. The finest of the tubers have weighed 22 ozs., but the quality when cooked might be termed sixth-rate. In flesh they are not white when boiled nor yet are they mealy, but a dull unattractive colour, and altogether disagreeable when compared with other varieties, such as the Queen, Paterson's Victoria, and Schoolmaster. I consider many advertisements I have seen in favour of this sort quite misleading, as, although it may excite curiosity in the way of producing a heavy crop, the quality will never give satisfaction. As to its being a good poor man's Potato, I would not class it as such. If it could be boiled and relished with salt alone, as all good Potatoes can, then it would have every quality to recommend it to the poorest of cottagers, but there is no hope of seeing it in this condition. Respecting disease, it must be named with those varieties very liable to be affected in its worst forms.—J. MUIR.

ROYAL METEOROLOGICAL SOCIETY.

THE first meeting of the present session was held last Friday evening at the Institution of Civil Engineers, Mr. J. K. Laughton, M.A., F.R.A.S., President, in the chair. The Earl of Dalhousie, K.T., T. H. Davis, D. E. Embleton, M.R.C.S., J. Hargreaves, and T. L. Lewington, were elected Fellows of the Society.

The following papers were read:—

1, "Report on Temperatures in two Different Patterns of Stevenson Screens," by E. Mawley, F.R.Met.Soc. The screens employed were an ordinary Stevenson screen obtained from Casella, and a new Stevenson screen made in accordance with the recommendations of a Committee appointed by the Council of the Society. The new screen is 2 inches wider and deeper than the old screen. It has also an upper sloping roof, and, at a little distance below, a flat inner roof pierced with holes for ventilation; while the old screen has a single flat roof with only a narrow slit beneath on each side for ventilation. Observations were made during the three months, July to September, and the results are given in the paper. From these it appears that the new screen is, of the two, slightly cooler and better ventilated, and retains the heat of the sun for a less time than the old screen; also, having a double roof and overlapping boards below, it is better suited for extreme climates.

2, "On the Storm which Crossed the British Islands between September 1st and 3rd, 1883, and its track over the North Atlantic," by C. Harding, F.R.Met.Soc., of the Meteorological Office. This storm caused considerable havoc in the south-west and south of England, owing not only to its exceptional violence, but also to its occurrence before the completion of the harvest. The storm is traceable in the first instance to two centres of disturbance, one being first shown at about 450 miles to the south of Bermuda on the 26th of August, and the other to the east of the Rocky Mountains on the 27th; these two disturbances afterwards merged on the 29th at about 300 miles to the north of Bermuda, and formed one great and destructive gale, which continued to grow in violence as it crossed the Atlantic until it reached the coast of the British Islands. The average speed at which this storm crossed the Atlantic was fully forty miles an hour, which is more than double the usual speed of storms which traverse that ocean.

3, "On the Influence of the Moon on the Height of the Barometer within the Tropics," by Robert Lawson, Inspector-General of Hospitals.

4, "The Great Ice-storm of July 3rd, 1883, in North Lincolnshire," by J. Cordeaux. The direction of the storm was nearly south-east to north-west, and travelled from Caistor along the higher ridges of the hills to Barton-on-Humber. The storm commenced at about 9.20 P.M. with heavy drops of rain, and increasing to a downpour, speedily followed—amidst the blaze of lightning and the constant roll of thunder—by the rush of hail or rather lumps of ice. An eye-witness remarked that they were not like hailstones but "salt-cellar;" another that they resembled "duck's eggs;" in fact, they were solid lumps of ice of every shape and size, weighing from 2 ozs. to 6 ozs., and some were measured 6 inches in circumference. The injury done to the growing crops cannot be estimated at less than £20,000.

STORED-UP SAP IN VINES.

MR. TAYLOR'S attempt (page 438) to explain and reconcile things, which he confidently asserted as facts, to "the best of his ability," is very unsatisfactory. He ought to be ready with his reasons as well, and give them plainly. I decline entirely to accept his own unsupported explanations of the "analogous" functions of the roots and stems; but he clears the ground a little when he says he regards "root-extension and

root-action as synonymous terms." He is in error there, however, for root-action no more means root-extension than "leaf-action" means leaf-growth. But, accepting his meaning as he gives it, will he tell us what he meant by implying that his Vines were "dependent" on the stored-up sap of the previous autumn till the shoots were long and had leaves 5 inches broad? In the meantime what became of the sap coming up daily and hourly from the roots? How came it also that those dark patches of colour did not begin sooner under these circumstances? The fact is, the "root-extension" explanation seems to present a ready loophole for your correspondent to escape from an untenable position.

There is really no such thing as storing up sap in the sense Mr. Taylor states in plants like the Vine. Only bulbs and tuberous roots store food, for reasons apparent to anyone. I still assume that few or no experienced gardeners believe that Vines are dependent on the stored-up sap of the previous autumn till they reach the stage Mr. Taylor says, but if there be any will he produce them, and their reasons for such belief? It does not seem to have occurred to your correspondent that the darker colour in the Vine leaves was due to their advancing growth and the more light they were receiving.

Dr. Lindley's explanation of the phenomena of the sap is the right one, and is still accepted by all. He says, pages 26 and 52 of his "Theory and Practice," "There is no period of the year when the roots become altogether inactive except when they are actually frozen. At all other times during the winter they are perpetually attracting food from the earth. . . . The tubes are nearly empty at the fall of the leaf (this is the period, according to Mr. Taylor, when they have completed their store of sap). During winter the roots absorb water from the soil and fill the tubes again. By the arrival of spring they are filled almost to bursting, and then if the stem is cut it bleeds." This is a clear statement, and I commend it to Mr. Taylor, especially the statement that there is no period of the year in which the roots are "inactive"—i.e., not "in action," and that it is "food" they are drawing up. For fuller corroboration I refer him to the book itself.

If Mr. Taylor would put his theory on the subject into plain language, or give us facts instead of surmises in proof of it, I would accept his opinions as readily as any other person's; but that is exactly what he has not done, while his replies are full of invidious and imaginary references to those who venture to differ from him. Will he, in as few words as possible, tell us clearly what he does mean by "stored-up sap" in the Vine, when the Vine stores it, where it is stored, and what the difference is between this stored-up sap and that which is continually rising from the roots? His teaching on this subject is very loose indeed. It is an old and excellent maxim, recognised as fair and honourable by all scientific and educated authorities since the time of Bacon, that a man is bound to substantiate, what he advances as facts, with proofs, and to meet all fair questions in the same spirit. I therefore ask Mr. Taylor to do this, and above all to keep to the point, take up the questions one by one as they are put, and answer them in as few words as possible. I want to take up your space and his time as little as possible.—A NON-BELIEVER.

HISTORICAL JOTTINGS ON VEGETABLES.—No. 10. THE TURNIP.

DR. TANNER of fasting notoriety, if the American press is to be believed, has experimented with some vegetables to ascertain the effect they had upon the disposition of those who ate them. Turnips, he believes, induce amiability, for instance, and French Beans considerable sharpness of temper; having given the latter vegetable to an individual in his household, when he found irritability so decidedly developed that this person "threw a jug at his head." He then hastened to administer Turnips, but found it took some time to overcome the unpleasant influences of the Bean. The amount of nutritive matter Turnips contain is certainly less than that in any variety of Bean. According to Dr. Lyon Playfair, 90 per cent. in an average Turnip consists of water, and therefore, where the vegetable is largely consumed, we might suppose irritative matter would be washed out of the system! The Greeks, who first grew the Turnip, appear to have thought the best use of this vegetable was as a cataplasm or outward application to relieve pains and lessen swellings, but the Romans appreciated the somewhat insipid root, and, being fond of tasty dishes, they devised a variety of modes of dressing it, which have not been rediscovered by our modern cooks. Pliny and Columella agree that as a vegetable the Turnip should be placed next to the cereals, and feeding cattle with the roots, though occasionally practised, was secondary to their use amongst mankind. A choice Turnip grown in the land of the Sabines was worth a sestertius—say 2d. or 3d., at one period.

Fields, waste lands, and roadsides in Europe and the temperate districts of Asia afford samples of the Turnip (*Brassica Rapa*) growing wild, with rough, dark green radical leaves, and if two years old, a flower-stalk, surrounded by smooth leaves exceedingly like that of the Cabbage. Ancient Gaul is said to have supplied to Greece and Italy the first Turnips grown in those countries, but in fact nobody knows. The Romans were accustomed to manure the ground thoroughly before sowing

their crops; the best time, the older naturalists state, is the end of July and the first half of August, but Turnips were also sown by them in spring where warm and moist positions could be found for them. When we remember how long the Roman occupation of Britain lasted, and the ease with which suitable spots for planting this and other vegetables might be obtained by the Romans near London and at various stations of theirs, I think there can be little doubt they were the first to grow Turnips on the soil of England. That the vegetable subsequently died out here is also evident, nor did Saxon, Dane, or Norman bring it over again; probably we owe its reintroduction to the Flemings or Walloons, who came over in parties at different times during the sixteenth century. By the reign of Elizabeth both gentle and simple had become acquainted with the Turnip, cooked by boiling or roasted in the ashes upon the hearth. It would seem, also, from a passing remark in Shakspeare's "Merry Wives of Windsor," that when balls were not at hand Turnips served as a substitute in some popular games, for Mistress Anne Page sincerely declares that rather than be mated to a fool she would be willing to be bowled to death with Turnips! The name in our vernacular has undergone no change; "nip" is the Saxon *næpc*, in fact the representative of the Latin *napa*, but no maker of dictionaries has been able to discover the origin of the "tur."

From old Gerard's comments upon this vegetable it may be surmised he did not grow Turnips himself; he speaks of having purchased them at the Cross in Cheapside of the women who brought them from their gardens near Hackney village. Although much of the land thereabout was low and marshy in Gerard's day, as in ours, there were some hills of gravel and sand, since levelled to some extent, upon which nobles, citizens, and others had gardens yielding choice fruit and vegetables. Here were the nursery and orchards of the famous Lord Zouch, who astonished his contemporaries by his skill in transplanting trees; and the repute of Hackney as a locality for horticulture centuries ago is proved by an antique silver token, which has on one side a figure of Time, with a pile of books on his right and a garden plot on his left. Besides Hackney, such suburbs as Hoxton, Islington, and Stepney probably had some Turnip fields before the outbreak of the Civil Wars, and after the Restoration there was an increased demand for the vegetable, as cattle were fed with the roots, at least partially, during the winter months. Also in some years, when the supply of corn was insufficient, Turnips were used as an admixture with the flour. After they were boiled the water was removed by pressure, or most of it, and an equal bulk of flour worked in. This Turnip-bread, however, had few admirers, if many had to submit to eat it. As Gerard observes—that the peasantry in Wales ate the Turnip uncooked, we have proof that it was grown commonly about the western districts of England while he was living, though Parkinson hints that it was only here and there Turnips were cultivated in 1629; but he may have had a prejudice against them. For some fancy or other they were not unfrequently planted in vineyards or between the rows of Hops. As Westminster increased its population; the gardeners of Pimlico, Chelsea, and Knightsbridge began to cultivate Turnips, and in the Georgian era they might have been seen growing upon what was then the "Five Fields," now an aristocratic suburb, or along the sides of the road leading to courtly Kensington. But one great objection to this plant, in the estimation of the London market gardeners, was the time it occupied the ground; a rapid succession of crops has always been a desideratum with them because it pays best.

But although Sir R. Weston had recommended the British farmer to grow Turnips extensively, little was done in this direction till late in the reign of George I., the practical prompter being Lord Townshend. As a natural consequence he became the butt of an abundance of jokes, for the small wits of that day called him "Turnip Townshend," and there may have been a ludicrous element in his enthusiasm about his favourite topic. When in Hanover he observed that much land there, resembling some upon his own estate at Rainham, yielded an abundant crop of Turnips, and he procured a supply of the seed, which he distributed amongst his tenants and other persons. The result was more important than could have been anticipated. A great change came over the agriculture of the county, and not only Turnips, but other valuable produce was raised upon land that had previously been left waste. So great was the prejudice against the Turnip as a food for sheep, that many farmers declared, in the teeth of facts, either that the animals would not eat the vegetable, or, that when they did, it had an unwholesome effect upon them. Swedes are stated to have been introduced to this country by a Mr. Knox of East Lothian, who removed to Gottenburg, from whence he sent the

seeds to Scotland. It was soon perceived that the Swede was valuable on account of its hardiness, and the tops, eaten as greens, came to be much in request, as offering an agreeable variety. In our time it is rumoured one use to which Swedes are put is the furnishing a certain proportion of the so-called orange marmalade sent into the markets. Sugar is contained in the Turnip, and it has been separated therefrom, but rather for experiment than with the expectation of profitable results.

Big Turnips, like gigantic Gooseberries, have served to furnish paragraphs for our newspapers in the dearth of items more important and more novel. It was thought a remarkable thing in October, 1828, to produce a Turnip weighing about 20 lbs., but this has been outdone since, for roots of the Purple-top Mammoth have been shown weighing just upon 30; yet Pliny tells us the Romans grew Turnips still larger, and describes single roots that weighed 40 lbs., a statement open to doubt, unless that people had some huge kind of Turnip we do not possess, or had a special skill in its culture surpassing ours. Miller, in enumerating Turnips, mentions a long yellow sort approaching the Parsnip in shape, which appears to have lost favour, though once much liked.—J. R. S. C.

WEBB'S NEW NUT, DUKE OF EDINBURGH.

ONE of the finest Nuts we have ever seen has been sent us by Mr. T. O. Cooper of Calcot near Reading. We believe it is one of the many

Fig. 92.—Nut Duke of Edinburgh.

seedlings raised by the late Mr. Webb, Mr. Cooper's father-in-law, and 't adds to Mr. Webb's reputation both as a raiser and a cultivator. This and Davianum, another of his seedlings, are possessed of high merit. Husk finely downy, but not hairy, about one-fourth longer than the nut; in some cases entire, but generally coarsely though not deeply cut. Nut large, the largest seven-eighths of an inch wide and $1\frac{1}{2}$ inch high; ovate. Shell not so thin as in Davianum, rather dark brown—approaching mahogany colour, faintly striated. Kernel full, covered with a pale brown pellicle, firm, and well flavoured.

This is a very excellent Nut, and ought to be cultivated wherever Nuts are grown. It was awarded a first-class certificate by the Royal Horticultural Society, October 9th, 1883.

There are several other of Mr. Webb's seedlings that are cultivated by Mr. Cooper for sale, some of which we have not seen, but which are described in a "Descriptive List of Prize Cob Filberts and other Nuts Grown at Calcot Gardens, near Reading," in which are instructions for the cultivation and management of the Filbert.

Mr. Cooper, who has succeeded his father-in-law, Mr. Webb, makes a speciality of the culture of Nuts, and he informs us that he has added nine acres to the original gardens for extending the cultivation of the plants, which are exported to all parts of the world, even to Manitoba and Germany.

CAMELLIAS IN WINTER.

FROM now onwards for the next four or five months there will be no flowers which can be produced in a greenhouse or conservatory more valued than a constant and good supply of Camellias. They are highly

attractive when seen on the bushes, and when cut and placed in glasses in sitting-rooms or on the dinner table they have always a charming appearance. By starting the plants into growth early in the season there is no difficulty in having them in bloom in August and September; but unless there is some very special object in having them then it is best not to flower them quite so early, as Camellias are undoubtedly more winter than autumn flowers, and their value at that season cannot be over-estimated. A few of our blooms have opened during October, but the bulk of them are to come, and we will now induce them to open as well and regularly as possible. No attempt should be made to force any small plant which has only been budded for two or three years, and it is a mistake to give any but the most natural treatment to sickly plants. Small plants crowded with bloom are very beautiful, but it injures them to cut many of the blooms from them, especially if a good piece of wood is taken with each bloom, and the best of all to cut flowers from are large established plants. Camellias planted out in beds always make much more wood than plants in pots, and those wishing to secure and cut large quantities of bloom throughout the winter should try to have a number of planted-out specimens to work with; but however they may be grown now, the object will be to obtain flowers, and it is on this point I will write.

Camellias are not like many softwooded plants. They will not be forced into flower rapidly by a brisk heat and in a humid atmosphere, and if many liberties are taken with them three parts of the buds may fall without showing the slightest sign of swelling or making any attempt to open. This habit, as habit it undoubtedly is with many plants, puzzles not a few, especially of amateur growers, and it is generally produced by some sudden change of treatment. Excessive dryness at the roots is one fertile cause of bud-dropping. A long period of dryness is not necessary to accomplish this. Once for a few days is quite enough, but no Camellias should ever become too dry that are constantly under the care of one person. It is only through carelessness that excessive dryness occurs as a rule. If the pots or borders in which Camellias are growing are well drained and the soil is in a sweet condition, it is almost impossible to injure them with water at the root, and the danger of giving them too much need never be taken as an excuse for giving them too little. Camellias have a decided dislike to a dry atmosphere, and this will make the leaves curl and the buds become brown.

In houses where there is no artificial heat there is of course no danger of this occurring, but where they are close to the hot-water pipes, and especially to old brick flues, as they still are in many old conservatories, the greatest care must be taken to keep the atmosphere humid. It need not be steaming, nor should a hot flue be damped to give off much moisture all at once, but the bushes should be syringed daily, and when the blooms are open and the branches cannot be syringed without spoiling the flowers, the bottom foliage near the ground should be damped and the surface of the soil under the trees should always be moist. We attach the utmost importance to this syringing, and we would advise all to practise it now and continue with it.—M. M.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

I HOPE it will not be thought from what I have written on page 402 that I wish to cast any reflections on anyone connected with the management of this Society, as such was far from my intention, neither did I write on behalf of my friend. I merely stated the case, thinking, as I said at the time, that it had been treated quite in accordance with the Society's rules, and as an example of the information I wanted to get for others' benefit as well as my own, as I know many gardeners could better afford to pay down a sum of ten guineas at once than to keep up an annual subscription of one guinea until they are sixty years of age if each gave equal advantages. I am very pleased to hear from Mr. Bardney that they do so, consequently the mistake was not made by my friend when he paid his subscription, as I was afraid it was. As soon as I can get the information required from my friend I will forward it to Mr. Cutler, when he will be able to see where the mistake has occurred.—W. H. DIVERS, *Burghley*.

MUSA ROSACEA.

THIS species is a native of the Mauritius, and is very ornamental in the stove, though, no doubt, it might also be grown in the open air during the summer months. *M. rosacea*, like the beautiful *M. coccinea*, does not belong to that section of this genus which is prized for its fruit-bearing qualities. Its estimable features are a noble habit, handsome flowers, and a growth from 10 to 15 feet in height. These plants are stemless, although they are generally described by the majority of people as having stout and tall stems, which in reality are composed of the very long and compact sheathing bases of the leaves. The blade of the leaf in the species here figured is dark green and oblong, with a prominent midrib. The bracts of the flowers—the special objects of attraction in this plant, are a beautiful, long-lasting, rosy pink, and, combined with the noble appearance of its leaves, produce a splendid effect in any group of plants with which it may be arranged. I would strongly urge upon every grower of stove plants

who does not already possess this *Musa*, to add it at once to his collection, if sufficient height can be allowed for its accommodation.

The cultivation of these plants is extremely simple. When young pot them in about equal parts of good rich loam, well-decomposed manure, and leaf mould, with a little sharp river or silver sand added. After they have attained to some size a little less manure should be given, for as fruit is not expected of them, the withholding of a little nutriment will only induce them to flower earlier. They enjoy copious waterings, and in the case of the fruiting varieties liquid manure is extremely beneficial, though I have never used it for this species.

In a young state *M. rosacea* forms a beautiful object for the decoration of apartments, and even when it grows too large for vases in the drawing-room, it may be used with advantage for halls or staircases, or when any

Fig. 93.—*Musa rosacea*.

special decorations for grand parties are required. This species is not used economically in any way, but several of this genus are extremely useful. One in particular, *M. textilis*, yields what is known as the Manilla Hemp, and is largely cultivated in the Philippine and other islands for its fibre. The finest portion of this is used for shawls.—W. H. G.

CHRYSANTHEMUM SHOWS.

WIMBLEDON, NOVEMBER 20TH.

WITH the small amount of funds at their disposal it is surprising what an excellent display is annually made at Wimbledon, and this season it was more than usually attractive. Mr. Lyne, gardener to A. Schlusser, Esq., Belvedere, filled the whole of the platform of the Lecture Hall with a magnificent group of miscellaneous plants, consisting of Palms, Dracænas, and other fine-foliage plants, with a number of Calanthes set in a groundwork of Ferns. This group was the admiration of everyone. Mr. Thompson, The Wimbledon Nursery, also staged a well-arranged group of ornamental-foliaged plants, which was much admired. This, as well as the Belvedere collection, was not for competition.

In the competitive classes Mr. W. Smith, gardener to J. F. Schwann, Esq., Oakfield, was awarded the first prize for an admirably flowered collection of natural-grown plants arranged in a space of 40 superficial feet. Mr. Newell, gardener to Sir E. Saunders, Fairlawn, was a very good second, and the Rev. A. Malan, Eagle House, Wimbledon, was third. But there were not many points difference between the first and second-prize collections; the former had both variety and abundance of flower, as well as a good finish in front, while the latter was more lightly arranged, but had a very badly finished front. The third-prize collection was a long way behind the other two. There were several collections of twelve cut blooms, incurved, distinct. Mr. C. Gibson, gardener to J. Wormold, Esq., Morden Park, was awarded the first place with John Salter, Barbara, Golden Empress of India, Princess Teck, Lady Carey, Hero of Stoke Newington, Chernub, Countess Granville, Golden Queen of England, Princess of Wales, and Nil Desperandum. Mr. Woodgate, gardener to Mrs. Hammersley, Coombe, was indeed a very close second, and Mr. Hepburn, Argyle Lodge, Wimbledon, a good third. For twelve Japanese blooms, distinct, Mr. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher, Mr. Woodgate, and Mr. Gibson shared the honours, all showing well. Mr. Beckett's comprised Fair Maid of Guernsey, M. Delaux, Boule d'Or, Baronne de Prailly, Triomphe de Châtalet, Meg Merrilees, Bronze Dragon, Mons. Planchenau, Peter the Great, Sultan, and Fanny Boucharet. In the class for six blooms the competition was very close, Mr. Hepburn being placed first, and Messrs. Woodgate and Beckett second and third respectively. Amateur collections were well contributed, Mr. Rolt, the energetic and courteous Secretary, was first for twelve blooms; and for six, Messrs. A. Moore, Northover, and Rolt were placed in the order of their names.

Messrs. Jackson & Sons staged a collection of new varieties, not for competition, the best being Henri Jacotot, Jeanne d'Arc, and Mdle. Lacroix, varieties which have been already described.

Table plants are usually exhibited well at Wimbledon, and on the present occasion they were very handsome. Mr. Beckett was awarded the first prize for elegant examples of *Aralia elegantissima*, *Cocos Weddelliana*, *Pandanus Veitchii*, and *Crotons angustifolius* and *picturatus*. Mr. Smith took second honours; and Mr. Bentley, gardener to Sir Thomas Gabriel, Edgcombe Lodge, third. Primulas, fruit, and vegetables were well and numerous contributed by Messrs. Bush, Bentley, Hurn, and several others, which collectively made a very attractive display.

The Exhibition was well attended, and Mr. Rolt, to whose efforts the Exhibition is mainly due, is to be congratulated on its success.

WORCESTER, NOVEMBER 20TH.

THE third annual Exhibition of Chrysanthemums and fruit in connection with the above Society was held at the Shire Hall, Worcester, excelling those of previous years in the quantity and quality of the exhibits. Groups of plants arranged for effect, and which are a notable feature of all the Worcester shows, were well represented, and were arranged in a circular form down the centre of the hall. First honours were taken by Mr. Green, gardener to Capt. Castle, Hawford House, for a very tasteful collection of healthy and well-grown materials. Mr. Cowan, gardener to H. Walker, Esq., Perdiswell Park, was second, his group being rich in foliage, but not having so much bloom to relieve it as the preceding. Mr. Helman, gardener to H. Bramwell, Esq., Crown East Court, was third, also with a good group.

Chrysanthemums in Pots.—The competition for twelve plants was limited to two exhibitors—Mr. Cowan and Mr. Helman, and the Judges placed them equal first; the former had some well-grown plants well bloomed, Meg Merrilees, To Kio, Blonde Beauty, Hilda, and Mrs. Parnell being especially fine. Mr. Helman's plants were more formally trained, but they included some good specimens, White Christine, St. Patrick, and Gluck being very good. For nine plants the same exhibitors were again equal first with similar plants; Mr. Payne, gardener to F. Parker, Esq., third. For six plants Mr. Cowan was first, Mr. Downes, gardener to T. Southall, Esq., second. His plants, with the exception of being supported by neat sticks, were untrained and had not been disbudded; they presented a marked contrast to the other plants in the Show, being profusely bloomed, but they were a little past their best. Single specimens were well shown by Mr. Cowan and Mr. Helman.

Cut Blooms.—These showed a marked improvement upon last year. For twelve incurved Mr. Barker, gardener to Sir H. Allsopp, Bart., Hindlip Hall, was well ahead, having Queen of England, Empress of India, Golden Empress, Princess of Wales, Princess Teck, John Salter, Jardin des Plantes, Hercules, Barbara, Venus, White Venus, and Cherub. Mr. Robbins, gardener to Sir E. A. H. Lechmore, Bart., Rhydd Court, was second, Alfred Salter, Queen of England, and Guernsey Nugget being his best blooms; Mr. Helman was third. Mr. Barker was also first for six incurved, Mr. Robbins second, and Mr. Cowan third. For twelve Japanese Mr. Barker again secured first honours with a splendid stand, some of the blooms being 6 and 8 inches in diameter. The varieties were Fair Maid of Guernsey, Madame C. Audiguier, Comte de Germiny (a grand bloom), Baronne de Prailly, Ile Japonaise, Thunberg, Elaine, G. Delaux, Soliel Levant, Flambeau, L'Incomparable, and Bend Or. Mr. Cowan was second and Mr. Helman third. For six varieties the same exhibitors were first and second, Mr. Robbins third. Some very nice wreaths and crosses were shown, also bouquets for a ballroom, Mr. J. S. Haywood being first in each class.

Fruits.—The display of Apples and Pears was magnificent, the majority being of large size and highly coloured. Prizes were also offered for single bunches of black and white Grapes, the first prize for white going to Mr. Barker for a compact and well-finished bunch of Muscat of Alexandria; Mr. Child, gardener to Earl Coventry, Croom Court, being second with the same variety, Mr. Cowan third with Trebbiano. For black Grapes Mr. Barker was first with a fine cluster of Alicante, Mr. Child second, Mr. Robbins third. The best six dishes of Apples came from Mr. Hughes, gardener to R. A. D. Gresley, Esq., who had splendid examples of Blenheim Pippin, Beauty of Kent, Mère de Ménage, Summer Queen, Ribston Pippin, and Cox's Orange Pippin. Mr. Child was second, his fruit being smaller, but beautifully coloured; Mr. Barker was third. Over twenty collections were staged in this class. For three varieties Mr. Hughes was again first. Single dishes were numerous and good. For six dishes of Pears Mr. Child was placed first with an excellent collection, Glou Morcean, Althorp Crassane, and Easter Beurré being very fine. Mr. Barker was second, and Mr. Robbins third, with collections little inferior to the first. The same exhibitors were first and second respectively for three dishes. Doyenné du Comice from Mr. Barker

was placed first in the single dishes. The three heaviest from the same exhibitor were Catillac, weighing 3½ lbs.

Messrs. R. T. Smith & Co., St. John's Nurseries, exhibited a large collection of Apples, all the leading varieties being represented in good condition. A collection of 150 varieties of Apples and Pears from Mr. Haywood, nurseryman, Worcester, was also highly meritorious. From Mr. Humphries, Pershore, came a very good collection of Apples. Collections were also sent by Archdeacon Lea, Droitwich, and Messrs. Rowe & Co., Barbourne Nurseries. All these collections were much admired, and being correctly named proved very useful to the numerous visitors. All the arrangements of the Show were well carried out, and great praise is due to Mr. J. Hill White, the Hon. Sec. to the Society, upon whom these duties fell.

BRISTOL, NOVEMBER 21ST AND 22ND.

THERE are few older societies than this, and few committees succeed in arranging better exhibitions. Not only are Chrysanthemums generally well shown, but nearly all kinds of fine-foliaged and flowering plants as well as fruit in season are equally well represented. The Victoria Rooms, Clifton, are particularly well adapted for the purpose of holding horticultural exhibitions, and on this occasion especially the arrangements left nothing to be desired. Everything seemed to be in its right place, and each section received the space and position they were entitled to. All large plants, including many immense Palms and Crotons, were grouped round the sides of the hall instead of the centre where they used to completely overshadow the fine show of bouquets and fruit always to be seen at these meetings. A narrower central table is now employed, the raised centre being filled with a beautiful assortment of table plants, and the lower surrounding space with the fruit and bouquets left plenty of space for the visitors, and was in every respect a welcome change. There were twenty special classes in which the prizes were presented by gentlemen and nurserymen in the neighbourhood, and all were closely contested. The Committee are all gardeners, and with their practical Hon. Secretary, Mr. W. G. Webley, deserve great credit for their successful endeavours to provide a most pleasing Exhibition.

Plants.—The silver cup offered for the best six large-flowered varieties was again won by Mr. J. Bradner with medium-sized but extremely well-flowered specimens of Hero of Stoke Newington, White Globe, Mrs. Dixon, Mrs. Forsyth, Prince of Wales, and Guernsey Nugget. Mr. E. T. Hill, gardener to T. Pease, Esq., was a very close second, his six including a fine dwarf-trained Mrs. Dixon, and a splendidly bloomed standard of Barbara. Mr. W. Smith, gardener to A. Shipley, Esq., was third with large roughly trained plants. In the class for three specimens Mr. Vowles, Brislington, succeeding in defeating the veteran grower and hitherto almost invincible Mr. Bradner, with excellent examples of the Rundle family. Mr. Bradner was a good second, and was closely followed by Mr. W. Lintern, gardener to W. Bentley, Esq. The latter exhibitor was first with six Pompon Anemone-flowered varieties, these consisting of neat and beautifully flowered examples of Marabout, Marie Stuart, Calliope, Mr. Wyness, Rosinante, and Antonius. Mr. Bradner was second with larger plants lacking freshness, and Mr. E. T. Hill third. Messrs. Lintern and Bradner were respectively first and second for four Pommans. With two standard-trained Japanese varieties Mr. E. T. Hill took the lead, his informally trained specimens of Bertie Rendatler and Fair Maid of Guernsey being exceptionally fine. The last-named was rightly adjudged the bronze Banksian medal of the Royal Horticultural Society. The other successful exhibitors in this class were Mr. Davis, Bedminster, and Mr. J. Lee, gardener to T. M. Miller, Esq. Mr. W. Vowles had the best single pyramid specimen of a large-flowered variety, the remaining prizes going to Mr. H. Smith, gardener to A. Shipley, Esq., and Mr. E. T. Hill; and in the corresponding class for flatly trained specimens the prizewinners were Messrs. E. T. Hill, T. M. Miller, and H. Smith. Trained standards of large-flowered varieties were well shown, Mr. E. T. Hill taking the lead with finely flowered specimens of Prince Alfred, Jardin des Plantes, and Mrs. Rundle. Mr. H. Smith, followed, his three including a good specimen of Mrs. Dixon, and the third prize went to Mr. Bradner. Several of the above exhibitors took other prizes for specimen Chrysanthemums, and Mr. Monkley was also successful.

With six fine-foliaged plants Mr. W. Rye, gardener to J. Derham, Esq., took the lead, his group including very large healthy specimens of Crotons, *Cycas revoluta*, and *Cocos Weddelliana*. Mr. W. J. Mould, Bath, was a good second; Mr. J. H. Stevens, gardener to S. Budgett, Esq., a close third, while to Mr. W. C. Drummond, Bath, was awarded an extra prize. In the corresponding class for four plants Mr. E. Miller, gardener to F. Tagart, Esq., was first with large specimens, the best being Croton undulatum and *Lantana borbonica*. Messrs. J. H. Stevens and W. Rye well won the remaining prizes. Messrs. F. Perry, gardener to H. C. Miles, Esq., W. C. Drummond, and H. K. Ward were the prizewinners in the class for a new or rare plant. There were two classes for six stove and greenhouse Ferns; in one case Messrs. W. J. Mould and H. Bannister, gardener to H. St. Vincent-Ames, Esq., were the prizewinners, and in the other Messrs. E. Miller, W. Rye, and H. K. Ward were successful, all staging large well-grown specimens of choice well-known kinds. Poinsettias were well shown by Messrs. E. Miller and J. H. Stevens; Primulas by Messrs. W. Bannister, C. Saggett, and B. Castle; Celosias by F. Perry and W. Bannister; berried plants by Messrs. W. Lintern, H. K. Ward, and T. West; Bouvardias by W. Rye and J. H. Stevens, and Pelargoniums by C. Saggett and J. Lysaght, who were awarded the prizes in the order named, the competition being also good in each instance. The plants suitable for dinner-table decoration were highly creditable, and notably the first-prize six staged by Mr. J. H. Stevens. Among these Croton Johannis, *Pandanus Veitchii*, and *Dracænas* of the auriantica type were particularly good. The other prizewinners were Messrs. W. K. Wait and H. K. Ward. Several excellent groups of miscellaneous plants were arranged. Mr. W. Rye was placed first with a charming mixture, in which were *Calanthes*, *Cypripediums*, *Oncidium varicosum* Rogersi, *Zygopetalums*, *Cattleyas*, and other Orchids, *Epiphyllums*, and many other choice flowering and fine-foliaged plants. Mr. F. Perry took the second prize for a better arranged group, in which Orchids also figured conspicuously.

Cut Blooms.—All the various classes for these were well filled, but though generally good, we have yet seen finer blooms at previous Bristol Shows. Mr. J. Baylis, Winterbourne, staged the best twenty-four large-flowered varieties (Japanese excluded), among these being fine blooms of Guernsey Nugget, Princess of Wales, Pink Perfection, Cherub, *Rotundifolia*, *Plutus*,

Barbara, Mrs. Heale, White Venus, Bronze Jardin des Plantes, Golden Empress of India, and Prince Alfred. Mr. T. Hobbs was second with smaller but otherwise good blooms, among which the best were Princess of Wales, Mrs. Crossfield, Barbara, and Princess of Teck. Mrs. F. Perry was third. In the corresponding class for twelve varieties Mr. E. S. Cole, gardener to W. Pethick, Esq., was a good first, his most noteworthy blooms being of Miss M. Morgan, Golden Empress of India, Cherub, John Salter, Empress of India, Mrs. Halliburton, and White Venus. Mr. J. Waite, Frampton Cottrell, was a good second, and Mr. W. Carpenter, gardener to J. G. Livingstone, Esq., third. With six blooms Messrs. Baylis, G. Milliner, gardener to Miss Richardson, and E. S. Cole were the prizewinners in a very good class. Messrs. E. S. Cole, J. Baylis, and T. Hobbs took special prizes in the order named for twelve large-flowered varieties with blooms generally good, and the same exhibitors were also successful with large Anemone-flowered. Japanese varieties were well represented. Of these the best twelve were staged by Mr. W. Carpenter, the most noteworthy being The Daimio, Bronze Dragon, Gloire de Toulouse, Parasol, Cry Kang, Fair Maid of Guernsey, and Comte de Germany. In Mr. E. S. Cole's second-prize stand were fine blooms of Meg Merrilees, Red Dragon, Sarnia, Baron de Prailly, and Grandiflorum. Mr. Carpenter was also first with twelve Japanese in not less than six varieties, the selection being similar to those above enumerated. Mr. J. Baylis was a good second, his stand including fine blooms of Golden Dragon, Bertie Rendatler, and Yellow Dragon.

There were two classes for hand bouquets, and in these there were seventeen good exhibits. As a rule the competitors appeared to have too many choice flowers available, and as a consequence made their bouquets too tight and too neat. Mr. M. Hookings was first in both classes. Messrs. E. S. Cole and J. H. Stevens each took a second prize, and thirds were won by Messrs. R. Symes and Stevens. As a central flower Mr. Cole had in his bouquet a magnificent bloom of Maréchal Niel Rose. The vases of cut flowers were also creditably shown, the prizewinners being Messrs. Hookings, E. T. Hill, and J. H. Virgo. Very beautiful were the baskets and vases filled with outdoor autumn foliage and berries. Of these the successful exhibitors were Miss Wetherel, and Messrs. Virgo, Hill, and Hookings.

Fruit.—The best collection of six dishes was staged by Mr. Nash, gardener to the Duke of Beaufort, and consisted of good Lady Downes' and Muscat of Alexandria Grapes, Blenheim Orange Melon, Medlars, Beurré Diel Pears, and Ross Nonpareil Apples. Mr. W. Bannister was second, and Mr. H. K. Ward third, both staging creditably. Mr. A. Miller, gardener to W. H. Long, Esq., Rood Ashton, took a first prize for a large and handsome well-ripened fruit of Charlotte Rothschild Pine Apple, the second prize going to Mr. A. Patison for a good-sized and rather over-ripe Queen. Messrs. Bannister, G. Bright, and J. Bradner were the successful exhibitors of Black Hamburgh Grapes, and Mr. Bannister received a first prize for fairly good bunches of Muscat of Alexandria. In the class for two bunches of any black variety of Grapes Mr. Nash had splendid examples of Black Alicante, and in addition to receiving the first prize was awarded the silver Banksian medal of the Royal Horticultural Society. Mr. W. Rye followed with two good heavy bunches of the same variety, and Mr. H. K. Ward took the third prize also with Black Alicante in good condition. Lady Downes' Grapes were well shown by Messrs. J. Marshal, gardener to M. Whitwell, Esq.; J. Loosemore, gardener to W. Cooper, Esq., and E. S. Cole. Mr. Nash was first with four bunches in two varieties, staging very fine Black Alicante and fairly good Muscat of Alexandria. Mr. Bannister was a good second, and the third prize was awarded to Mr. W. Sweeting. Pears were largely shown, and but few poor dishes were to be seen. Mr. W. Rye was first with six dishes, having very fine examples of Beurré Diel, Glou Morceau, Leon le Clerc, Doyenné du Comice, Duchesse d'Angoulême, and Beurré Bachelier. Mr. W. Bannister was a good second, and Mr. A. T. Hall third. Mr. Rye was also first with four dishes, the remaining prizes going to Mr. M. Cole, gardener to R. B. Cater, Esq., Bath, and Mr. J. Aplin, gardener to W. M. Baker, Esq. For a single dish W. Derham, Esq., was first with very fine fruit of Marie Louise. A splendid lot of Apples were shown; of these the best six dishes of dessert varieties were staged by Mr. Bannister, these consisting of Worcester Pearmain, Cornish Gilliflower, Cox's Orange Pippin, Scarlet Pearmain, Kentish Pippin, and Ribston Pippin. Mr. Aplin was a close second, and Mr. A. T. Hall took the third prize. Mr. C. Saggett was first with four varieties, these being handsome; fruit of Sturmer Pippin, Cornish Gilliflower, King of the Pippins, and Cox's Orange Pippin. Messrs. E. T. Hill and Bannister were the other prizetakers. In a large class for single dishes Mr. E. Miller won first prize with Cox's Orange Pippin; Mr. M. Cole following with Blenheim Orange, and Mr. Virgo was third with Ribston Pippin. Fewer kitchen Apples were shown, but all were good. Mr. Aplin took the lead with heavy examples of Malster, Waltham Abbey Seedling, Blenheim Orange, Lord Derby, Hanwell Souring, and Royal Russet. The remaining prizes were taken by Messrs. E. T. Hill and A. T. Hall. A very fine dish of Blenheim Orange staged by Mr. Aplin was adjudged the best in the single-dish class, Mr. E. T. Hill following with the same variety, only slightly smaller, and Mr. Bannister took the third prize for fine fruit of Emperor Alexander.

Vegetables.—Several good collections of nine varieties of these were staged. Mr. Bannister won with very good examples of Filbasket Tomatoes, Veitch's Red Globe Turnips, Danver's Yellow Turnips, Pragnell's Exhibition Beet, Lapstone Kidney Potatoes, Autumn Giant Cauliflowers, Veitch's Exhibition Sprouts, Student Parsnips, and Mushrooms. Mr. E. T. Hill was second, and Mr. O'Brien, gardener to Mrs. R. P. King, was third. The prizes for Cucumbers were won by Mr. M. Cole, Capt. Halcock, and J. H. Stevens.

BIRMINGHAM, NOVEMBER 21ST AND 22ND.

SPLendid plants have invariably been exhibited at the annual Chrysanthemum shows of the metropolis of the midlands; but cut blooms have never been seen of nearly equal merit until at the Exhibition under notice. Recognising the weak point of their shows the directorate wisely endeavoured to remedy the defect, and with this object provided a series of liberal prizes, that for forty-eight blooms being especially encouraging, for not only was the first award of substantial value, but the second, third, and fourth were of fairly graduated amounts. Viewed in this respect this was the best provided for and best balanced class of the year. It was also fairly responded to, every prize being taken, and with blooms proportionate in merit as indicated by the sums apportioned—£10, £7, £4, and £2: every exhibitor, therefore, had a just reward for his productions.

As was briefly recorded last week the prizes in the premier class referred to—twenty-four incurved and twenty-four Japanese varieties—were awarded in the order named to Mr. Tunnington, gardener to C. McIver, Esq., Calderstones, Liverpool; Mr. Jellicoe, gardener to J. H. Gossage, Esq., Liverpool; Mr. Comfort, gardener to G. A. Everitt, Esq., Knowle; and Mr. Neal, gardener to P. Southby, Esq., Bampton, Oxon. These were the only competitors, and some disappointment was expressed that no metropolitan growers had entered the lists. A disposition exists to increase the value of the prizes for cut blooms another year, in the hope that Birmingham, being so central and about equally accessible to southern and northern cultivators, will witness stronger competition and more widely representative examples of culture.

For the chief prize under notice the real contest was between the two Liverpool gardeners, and the veteran won by the superiority of his incurved flowers, his Japanese not being any advance on those of Mr. Jellicoe. Both collections, however, were highly meritorious, and for comparison we give the names of the flowers and their arrangement in each case, reading the rows from left to right as in reading these lines.

Incurved Flowers.—Mr. Tunnington's stand.—Back row: Bronze Jardin des Plantes, Princess of Wales, Alfred Salter, Mrs. Heale, Emily Dale, John Salter, Queen of England, Empress of India; a grand row, rarely equalled, and perhaps never surpassed. The second row comprised Venus, Jeanne d'Arc, a splendid bloom of a promising new variety; Golden Empress, Sir Stafford Carey, Hero of Stoke Newington, Jardin des Plantes, Prince Alfred, and Beauty, all fine. Front row: Mrs. Halliburton, Nil Desperandum, Isabella Bott, Barbara, Princess of Teck, Refulgence, Mrs. Shipman, and Eve. The finest blooms, and magnificent they were, were Alfred Salter, Mrs. Heale, Queen of England, Empress of India, Jeanne d'Arc, Barbara, and Refulgence.

Mr. Jellicoe's stand.—Back row: Mr. Howe, Mrs. Heale, Miss Mary Morgan, Princess of Wales, Empress of India, Prince Alfred, Golden Empress, and Queen of England. Second row: White Beverley, Alfred Salter, Mr. Bunn, Pink Venus, Cherub, Beauty, White Globe, and Refulgence. Front row: Lady Hardinge, White Venus, Prince of Wales, Barbara, Lady Slade, Eve, Little Pet, and Jardin des Plantes. Particularly good, indeed about perfect, were Princess of Wales, Refulgence, Barbara, and one of the finest examples of Eve ever seen staged. This was a very excellent stand, but the other was heavier, Mr. Tunnington staging in his best form—that is better than he has ever done at Kingston.

Japanese Flowers.—Mr. Tunnington's stand.—Back row: Soliel Levant, Sarnia, Ethel, Oracle, Fair Maid of Guernsey, Japonais (orange-red, effective), Madame C. Audiguier, and Elaine. Second row: Meg Merrilees, Bismarck, L'Ardoise, Hiver Fleur, Chang, Baron de Prailly, Peter the Great, and La Nympe. Front row: Rosa Bonheur, Album striatum, Patria, Criterion, Mdlle. Moulise, Flambeau, Delicata, and Striatum. The leading blooms were Soliel Levant, Meg Merrilees, Peter the Great, and Rosa Bonheur. Mr. Jellicoe's stand.—Back row: Peter the Great, M. Ardene, Criterion, Elaine, Comtesse de Beauregard, Meg Merrilees, Golden Dragon, and Sultan. Second row: La Nympe, Triomphe du Nord, Baron de Prailly, La Boule d'Or, Ducal, Bismarck, Dr. Macary, and Fair Maid of Guernsey. Front row: Mons. Lemoine, Madame B. Rendatler, Gloire de Toulouse, Sarnia, Apollo, Hiver Fleur, Flambeau, and Bronze Dragon. Very superior were Elaine, Golden Dragon, and La Nympe. These two stands were of about equal merit, but neither of them so good as the best collections at the metropolitan and Southampton shows.

Mr. Comfort was an excellent third, his stands containing many blooms of merit, including the best example of Jardin des Plantes in the Show if not of the season, also Baron de Prailly and M. Ardene in grand condition. Mr. G. Neal had smaller yet neat fresh blooms, Cherub and Triomphe de Chatelet being the gems of the stands. In the open class for twenty-four blooms five capital collections were staged, the prizes going in the same order as in the preceding class; and for the prizes offered for eighteen blooms four stands were placed in competition, Mr. Tunnington being once more to the fore, followed by Messrs. Comfort and Shingler, gardener to T. B. Salter, Esq., West Bromwich. The blooms in these collections were similar in character to those in the premier class.

The first prize for a stand of twelve reflexed varieties in six varieties was won by Mr. Jellicoe with handsome blooms of Golden Christine, King of the Crimson, Mrs. Forsyth, Chevalier Domage, Beauté du Nord, and Lilac Christine, Mr. Neale being a creditable second with neat flowers. Those exhibitors were placed in the same order with twelve Anemone varieties, the competition being extremely close. Gluck in the first-prize, Emperor in the second were very fine indeed. An admirable stand of twelve Japanese blooms was exhibited by Mr. Neale, which easily secured for him the first prize. Triomphe de Chatelet was splendidly represented in the stand. Messrs. Comfort and Shingler followed in the order named with bright and effective collections.

Specimen Plants.—These were grandly exhibited. In the chief class for nine specimens Mr. Dyer, gardener to W. Showell, Esq., Edgbaston, won the cup with splendid examples, Prince of Wales, John Salter, Bronze Jardin des Plantes, and Lady Hardinge being very striking. The plants were about 2 feet high from the pots, convex, 4½ feet in diameter, bearing from eighty to 100 grand blooms each, relieved by excellent foliage. There was only one fault in one or two of the plants—the stems had been bent too near the top, giving a laced appearance, which always detracts from their merit, still the group was a grand one. Mr. Crook, Edgbaston, was second in this class with fairly good examples. Mr. Dyer was far ahead of other competitors with six plants similar to the cup collection; Mr. W. Doughty, gardener to H. H. Hill, Esq., Edgbaston, was second, Empress of India being very striking; and Mr. Brasier, gardener to T. Martineau, Esq., Edgbaston, third with larger plants but smaller flowers. The prizes for single specimens were won by Messrs. Dyer and Brasier in the order named, both staging Mrs. G. Rundle, fine plants, but the flowers too small.

Pompons.—Mr. Dyer won the chief prize for six plants with specimens of remarkable merit, about 18 inches high from the pots, shaped like inverted saucers, 5 feet in diameter, covered with fine blooms and foliage, with not a stake to be seen. Rose Trevenna, with Mdlle. Marthe and Cedo Nulli (including the Golden variety first in the single-specimen class) have not been equalled at any show we have seen this year. They were indeed marvellous examples of culture. Mr. Brasier was an excellent second in

both these classes. Mr. Day, gardener to H. Elkington, Esq., Edgbaston, took the lead with three plants; Mr. James, gardener to W. C. B. Cave, Esq., Edgbaston, following with creditable examples.

Groups.—These were not of striking merit. The best was undoubtedly that of Mr. Hughes, gardener to F. Ostler, Esq., Edgbaston, which was awarded first honours; Mr. Shingler being second with smaller and less vigorous plants. These groups were not nearly equal to those at metropolitan shows, nor were the specimen plants of Japanese varieties, which were so weak that we did not take the names of the exhibitors of them.

Miscellaneous Plants.—In the class for nine specimen stove and greenhouse plants Mr. Jones, gardener to C. E. Matthews, Esq., Edgbaston, was first with an excellent group; *Gleichenia Mendelli*, a globe 7 feet in diameter, *Erica hyemalis* 5 feet, and *Chorozema cordata splendens* 4 feet, being the most notable examples, and fine they were. Mr. Doughty was an excellent second, *Thrinax elegans* and *Clerodendron Balfourianum* being very telling; and Mr. Shingler third. In the class for six specimens Mr. Brasier was first with very healthy and well-grown plants, *Callicarpa purpurea* attracting much notice by its long arching branches covered to the length of 2 feet with clusters of purple berries. Mr. Jones was second; and Mr. Cooper, gardener to the Right Hon. J. Chamberlain, M.P., third with fresh neat examples.

Primulas.—These plants are always well and extensively shown at Birmingham, six classes and upwards of twenty prizes being provided for them. Mr. Caldecott, a first-rate grower, appeared to be the most successful exhibitor. First prizes were also won by the Rev. E. H. Kittoe, Sutton Coldfield, for doubles, and by Messrs. Dyer and Pope for singles, with very fine examples. Mr. W. Matthews and Mr. Clarke, gardener to Lady Edwardes, Ashbourne, were also prizewinners with very creditable collections. Other classes were occupied with *Epiphyllums*, *Mignonette*, *Cyclamens*, and *Poinsettias*, but we are compelled to pass them through the great pressure on our columns. But we must not omit to mention that Messrs. Pope & Sons, Hans Niemand, and Vertegans contributed effectively to the Show; the first-named by choice and well-grown Zonal *Pelargoniums* in 4 and 5-inch pots; the second by a handsome group comprising good *Poinsettias*, *Cyclamens*, *Bouvardias*, and the charming *Adiantum Victoriae*, and the third-named exhibitor by healthy table plants, Ferns, and *Calanthes*.

Bouquets were very good indeed, Messrs. James, Harborne, and Perkins, Coventry, being the chief prizewinners; but perhaps the finest arrangements were those not in competition by Messrs. Hans Niemand and Pope & Sons. *Epergnes* were comparatively inferior.

Fruit.—Of this the display was extensive, Grapes, Apples, and Pears being very good. The collections of six dishes were the weak point. The first prize went to Mr. Coysh, gardener to E. Wood, Esq., Rugeley, one dish being Quinces, which we do not remember ever seeing before in a premier collection. Messrs. Freeman, gardener to Z. Walker, Esq., J. Bannister, gardener to H. St. Vincent Ames, Esq., Bristol, had the remaining prizes, the collection of the last-named exhibitor being probably as good as any on the table, but the Judges had evidently a difficult task in determining the awards. Messrs. Fraser, Ledbury, and Tunnington secured the prizes for Pines. For three bunches of black Grapes the prizes went as follows:—First, Mr. Fraser with Gros Colman; second, Mr. Clarke, Ashbourne, with Alicante; third, Mr. Muncaster, gardener to W. H. Wynn, Esq., Selly Oak, with Mrs. Pince, all exhibiting well. Gillman, Ingestrie, was first in both the classes for Muscats with superb examples, followed by Messrs. Comfort and Clarke. Mr. Gillman secured the chief honours also in the non-Muscate class with Trebbiano, very good indeed.

Of Apples there was a great display, Mr. Edwards, gardener to H. Higgins, Esq., Thinghall, winning premier honours with grand dishes, followed by Messrs. Ashman, Slade, and Mitchinson, all staging superior produce. Pears were splendidly staged by Messrs. Comfort, Freeman, Ashman, Bannister, Fraser, and Mitchinson, who received the prizes. Messrs. Cranston & Co., Hereford; Smith & Co., Worcester; and James Dickson & Son, Chester, were awarded certificates for admirable collections, the new variety, Taylor's Kernel, a fine new conical Apple from the first-named exhibitors attracting attention; and Mr. Mitchinson, gardener to the Hon. A. C. G. Calthorpe, Perry Hall, Birmingham, staged a good dish of *Vicomtesse Héricart de Thury* Strawberries in various stages of ripeness, showing its continuous bearing character.

Altogether the Show was an excellent one, and admirably conducted by Messrs. Latham, Stacey, with other members of the Committee, and Mr. Redfern the Secretary.

NOTTINGHAM, NOVEMBER 21ST AND 22ND.

THE first Chrysanthemum Show in connection with the Nottingham Horticultural and Botanical Society was held in the fine room of the Mechanics' Institute on the 21st and 22nd inst. The hall had a cheerful appearance, the groups arranged for effect being disposed in circles with plenty of room for visitors to pass between and around them. In the centre was an effective miscellaneous group from Mr. German, gardener to T. B. Cutts, Esq., Malvern House, comprising a very fine *Cordyline*, Ferns, &c., while at the end of the room S. Thacker, Esq., Ball Street, St. Ann's, had an attractive arrangement of very choice plants. The groups of Chrysanthemums in competition were composed of ordinarily grown plants which had not been disbudded, except the first-prize arrangement of Mr. German, which far excelled the others exhibited by Mr. Massey, gardener to Capt. Lambert, Mapperley Hall, and Mr. G. Commins, Coal Pit Lane, who had the remaining prizes in the order named. There is abundance of room for improvement in this class, and still more in the classes for specimen plants, which we never saw so inferior, the only examples worth notice being those of Mr. German.

The cut blooms were the feature of the Show, not only because of the intrinsic merit of many of them, but by the method of exhibiting. For the encouragement of small amateurs as many as thirty-six prizes were offered in three classes—namely, for six, four, and three blooms, the amounts ranging from £1 to 1s. The blooms in competition were cut with a foot of stem attached, thus showing the foliage as well as the flower, each stem being inserted in a wine bottle, the names of the varieties either being stuck on the bottles or pinned to a leaf according to the taste of the exhibitor. The dozens of bottles and blooms neatly arranged had a remarkable effect, not a few of the flowers being of considerable merit, for though not large they were particularly neat. A great favourite is Lady Slade, of which there

were many charming examples, one of which was selected as the champion of the Show. *Le Grand*, a fawn-coloured counterpart of the above, we never saw so numerous at any show, and seldom so neat and good. *Barbara* and *Cherub* were also excellently represented, as was Mr. Bunn, finer blooms of which were perhaps seldom seen. Messrs. Whitechurch, 38, Dickinson Street; Grundy & Land, Beck Street; Jackson, Welbeck Street; Church, Bloomfield Street, were amongst the foremost prizetakers, and a warm word of commendation is due to them for the excellence of their exhibits.

In the larger classes the blooms were not of equal merit, though some good examples were staged. Mr. Attewell, 273, St. Ann's Well, secured the first prize for twelve blooms shown on stems a foot long with excellent foliage—a good and effective stand, Mr. Bunn being very fine indeed. Messrs. J. & H. Hickling, Loughborough, were second with neat examples shown in boxes, and Mr. Commins third, but the flowers being almost lost in their much-too-large paper collars. In the class for twenty-four blooms the prizes went to Messrs. Hickling, Commins, and German respectively. The best twelve Pompons were staged in small handfuls by Mr. Edington, gardener to H. Ashwell, Esq., Woodthorpe Grange, who was worthily awarded the first prize, followed by Mr. Webb, Kelham Hall, with creditable examples. Mr. German was awarded the first prize for twelve Japanese blooms, neat and bright, but only about half the size of first-class examples. Mr. Wooton, gardener to Major Robinson, Widnespool Hall, had the best *Primulas*; followed by Messrs. Edington and Meadows, gardener to C. Cox, Esq., Rock House, Barford. The first-prize six were compact, the second in remarkable colours, the third large but coarse. There is room for improvement.

Fruit and Potatoes were excellent. Mr. Webb, Kelham Hall, was deservedly awarded the first prize for a collection of six dishes of fruit, consisting of a plump Pine, good Alicante and Muscat Grapes, fine Pitmaston Duchess and Fondante de Cuene Pears, and Ribston Pippin Apples. For two bunches of black Grapes the first prize went to Mr. Edington with good bunches, but rather small yet well-finished berries; Mr. Anderson, gardener to B. Clifton, Esq., Clifton Hall, being second with smaller bunches but finer berries, and Mr. Webb third. In the class for white Grapes Mr. Edington was first with neat examples of Golden Queen. A very fine collection of Grapes was staged by Mr. Goodacre of Elvaston not for competition, and was highly commended.

Large and fine collections of Apples were staged by Messrs. Ingram, Belvoir Castle; Goodacre, Elvaston; and Pearson, Chilwell, which were deservedly very highly commended by the Judges, each exhibitor having a hundred dishes. Very good dishes were also placed in competition, also splendid Pitmaston Duchess Pears by Mr. Anderson.

Potatoes were of great excellence, several being too large perhaps, but clean and symmetrical, and better examples of culture were seldom seen than those staged by Mr. Bellis, Newstead Abbey, and Messrs. Adland, Middleton, and Browne. We have made no pretence to give a full report of the Show, our object being to indicate its general character as clearly as possible in the brief space at our disposal; and, except the Chrysanthemum plants, the display was deserving of a greater crush of visitors than attended. The date was, however, possibly a little late, and a number of smaller shows had been held previously. The Committee of the Society, with Messrs. Don and Steward, the Honorary Secretaries, deserve support and the success they have so laudably endeavoured to win in seeking to establish a good general autumn Show in Nottingham.

NORTHAMPTON, NOVEMBER 21ST AND 22ND.

THIS flourishing Society held their twelfth annual Exhibition in the Corn Exchange, Northampton, on the above dates. Groups and specimen plants were arranged around the sides of the building, while long lines of tabling were disposed down the centre, on which the cut blooms, *Primulas*, table decorations, fruit, and vegetables were abundantly exhibited, and the whole of the sixty-three classes were almost without exception well filled. The Show was admirably arranged by the Hon. Sec., Mr. Draper, who was ably assisted by their Chairman, Mr. Gulliver, and others of the Executive.

Plants.—For six large-flowering incurved, distinct varieties, open, five collections were staged, and first honours were secured by Mr. Gwilliam, gardener to T. Sheppard, Esq., Billing Road, for medium-size evenly trained examples of Lord Derby, Mrs. Dixon, Guernsey Nugget, Prince of Wales, Mrs. G. Rundle, and Mr. G. Glenny. Mr. W. Rollings, gardener to the Rev. A. A. Longhurst, Abingdon Rectory, was a close second, one or two plants being fine, but others were past their best; and Mr. T. Ingram, gardener to W. Butler, Esq., Durston House, was a good third. In the class for four plants, open to all amateurs, there were six competitors. G. H. Percival, Esq., Abingdon Road, received the premier prize with medium-sized and profusely flowered examples. Mr. L. Spencer, 88, Lower Thrift Street, and Mr. Manning, 20, Lower Mount, occupied the second and third positions with very creditable collections. Japanese, upright-trained plants were well shown. Mr. W. Rollings worthily gained the first prize with Mons. Lemoine, *Espérance*, Madame Bertie Rendatler, Fair Maid of Guernsey, La Nymphy, and Elaine, very fine. Mr. J. Green, gardener to W. Shoosmith, Esq., Billing Road, was a good second, and Mr. J. W. Abrahams, gardener to Mrs. Howes, 9, Spencer Road, a close third. Upright-trained incurved plants were also represented by several collections, Mr. Green again taking the premier position with Lady Hardinge, Mrs. Dixon, Mrs. G. Rundle, and John Salter. Messrs. Rollings and Abrahams were second and third respectively. Mr. Abrahams was also placed first for four reflexed varieties, exhibiting a highly creditable collection. Specimen Pompons were of good quality, Mr. Gwilliam being placed first in the class for four plants, Mr. W. Rollings second, and Mr. J. W. Abrahams third, all exhibiting neatly trained and evenly flowered plants, the best examples being *Mlle. Marthe*; Brown, Lilac, and White Cedo Nullis, and Dick Turpin. Mr. Green and Mr. Gwilliam are first and second respectively for a single trained specimens.

Prizes were offered for standard specimens. These were poorly represented, the Judges only awarding one third prize in the two classes set apart for them. Several classes for plants followed for amateurs of Northamptonshire only. For six Japanese Messrs. Percival, Manning, and Dunkley were placed first, second, and third respectively; and in the remaining classes Messrs. Spencer, Lear, and Dunkley were the principal

prizetakers, the whole of which collections were highly creditable to them. Groups were represented by five collections, arranged in a space 6 feet by 8 feet. Mr. Green was placed first for a tastefully arranged group, the colours well blended and the blooms of fairly good quality. Mr. Abrahams followed, but his plants were crowded; and Mr. Dunkley, Hardington Lodge, third.

Cut Blooms.—These were decidedly in advance of those in past years both in numbers and quality. In the open class for twenty-four incurved, distinct, for which the prizes were—first, four guineas; second, two guineas; and third, one guinea, there were four competitors. Messrs. S. Dixon and Co., The Amhurst Nurseries, Hackney, were awarded the first position for a fresh and good collection, consisting of Empress of India, Queen of England, Golden Empress of India, John Salter, Lord Wolseley (fine), Mr. Corbay, Princess Teck, Hero of Stoke Newington, Barbara, Jardin des Plantes, Rev. J. Dix, Enamel, White Venus, Eve, Cherub, Nil Desperandum, Venus, Golden Eagle, Mrs. G. Ruddle, Mrs. Shipman, Prince Alfred, Angelina, Golden Queen of England, and Princess of Wales. Mr. Berry, Roehampton, was awarded the second honours with a neat and bright collection, his best flowers being Baron Beust, John Salter, Queen of England, Golden Empress, and Antonelli. Mr. A. Walter, gardener to A. B. Loader, Esq., third with a good lot.

In the open class for amateurs, twelve distinct, incurved, Mr. Fowkes, 30, Cyril Street, Northampton, out-distanced all other competitors with a neat stand of well-formed flowers of Empress of India, Golden Empress of India, Queen of England, Prince Alfred, Jardin des Plantes, Princess Teck, Princess of Wales, John Salter, Barbara, Prince of Wales, and Hero of Stoke Newington. Mr. Robert Hart, 20, Cyril Street, was awarded the second prize, and Mr. Dixon, Gayton, was third. For eighteen Japanese varieties, distinct, five collections were staged. Mr. Walter was a very good first with bright and clean flowers of Comte de Germiny, Rosa Bonheur, M. Delaux, Comtesse de Beaugard, Elaine, Rubrum striatum, L'Incomparable, Cossack, Ethel, Madame Lemoine, Dr. Macary, Nuit di Automne, Lady Selborne, Tendresse, Agreement de la Nature, James Salter, and Rêve de Printemps. Mr. Green and the Hon. Mrs. Eykyn were placed second and third. For six Japanese, one variety, Mr. Green was first with Elaine, Mr. Abrahams second, and Mr. J. Garfirth, gardener to P. Phipp, Esq., M.P., Collingtree, third, the first-named showing Fair Maid of Guernsey, and the latter Soleil Levant.

In the class for twelve incurved, open to the gardeners in Northamptonshire only, several good collections were staged, Mr. Green being to the fore with Queen of England, Golden Empress of India, Princess Teck, Princess of Wales, John Salter, Empress of India, Mr. Bunn, Mrs. Dixon, Hero of Stoke Newington, Barbara, Mrs. Heales, and Cherub. The Hon. Mrs. Eykyn and Mr. Abrahams were placed in the order of their names for fairly good collections. For six blooms of one variety Mr. Green staged six grand blooms of Princess Teck in the class open to gardeners, and Mr. Fowkes had splendid examples of Queen of England for first awards in the amateurs. Mr. Fowkes was also well to the fore with twelve cut blooms, distinct, with John Salter, Princess of Wales, Empress of India, Golden Empress of India, Mrs. Heales, Baron Beust, Venus, Barbara, Angelina, Princess Teck, Hero of Stoke Newington, and Lady Slade. Messrs. Ford and Hart were second and third respectively, exhibiting very creditably.

Upwards of 200 Primulas were arranged on the several tables, the whole of which were splendid examples of culture. Messrs. Rollings, Green, and Lewin were the leading prizetakers.

Fruit and vegetables, as well as collections of Potatoes, were abundantly shown and of good quality. For Messrs. Sutton & Sons' prizes for the best collection of six distinct varieties Mr. Stephens, Great Houghton, staged a most meritorious collection, consisting of Aigburth Brussels Sprouts, Veitch's Autumn Giant Cauliflower, Elcombe's Improved Parsnip, Snowdrop Potato, Dobbie's Golden Ball Turnip, and Walker's Exhibition Onion. The same exhibitor, although an amateur, also secured the first prize for six dishes of Potatoes, three kidney and three round, open to all in Northampton, in which class about twenty collections were staged.

SHROPSHIRE GARDENERS AND AMATEURS, NOVEMBER 22ND.

The above Society held their first Show of fruit and Chrysanthemums in Shrewsbury on Thursday last. The Society has scarcely been in existence twelve months, and held a successful Rose Show in July, and the fruit and Chrysanthemum Exhibition held on Thursday was another success. The plants were rather weak, but cut blooms and fruit were admirably represented. The following were the chief prizetakers:—

Plants.—For six large-flowering plants Rev. J. D. Corbett (gardener, Mr. Milner) was first with good plants of Mrs. G. Ruddle and George Glenny; second Mr. J. Watson (gardener, Mr. Pursar). Three large-flowering plants, distinct, first Mrs. Burton (gardener, Mr. Turbelle); second Mr. George Townsend. Three Pompons, first Rev. J. D. Corbett (gardener Mr. Milner). For large-flowering standards, first Rev. J. D. Corbett, and second Dr. Burd. Three ditto distinct, first Mrs. Burton; and second Mr. George Townsend, an amateur.

Cut Blooms.—These were grand and the competition close. For twenty-four cut blooms, large-flowering varieties, distinct, Mr. Lambert was first with Sarnia, Fair Maid of Guernsey, Hiver Fleur, Peter the Great, Prince Alfred, and M. Lemoine very fine, and other good varieties. Second Mr. Beatie (gardener, Mr. Bremmel); third Mr. Milner. For twenty-four Japanese, distinct, not less than eighteen varieties, Mr. Lambert was first with Soleil Levant, Ethel, Elaine, Chang, Madame C. Audiguier, Curiosity, Cry Kang, and Fair Maid of Guernsey, and others equally fine. Second Mr. J. Beatie with blooms scarcely inferior; third Rev. J. D. Corbett. For twelve cut blooms, distinct, first Col. Wingfield (gardener, Mr. Lambert); second J. Beatie, Esq.; third Rev. J. D. Corbett. For twelve blooms (amateurs), first C. M. Campbell, Esq. Twelve Primulas (open), first Rev. J. D. Corbett. Six Primulas (amateurs), first Mr. G. Townsend.

Fruit.—For three bunches of black Grapes, one variety, first Col. Wingfield. For three bunches of white Grapes, first J. Watson, Esq. (gardener, Mr. Pursar) with splendid bunches cut from Vines fifty years old; second Col. Wingfield. For four bunches of Grapes, four varieties, first Rev. J. D. Corbett with beautiful bunches of Lady Downes', Muscat of Alexandria, Pearson's Golden Queen, and Black Alicante; second Col. Wingfield. For two bunches of black Grapes (amateurs who employ no gardener). These

were little inferior to the professional classes, and were very creditable to the growers. First Mr. W. Humphreys; second Dr. Burd. Two bunches of white Grapes, first Mr. W. Humphreys. For the best collection of Apples and Pears there were three exhibitors, who staged about sixty dishes each, all showing remarkable examples. First Rev. J. D. Corbett; second Col. Wingfield. For twelve dishes of Pears, first Rev. J. D. Corbett with a fine collection, but unfortunately not named; second Col. Wingfield. For six dishes of Pears, first J. Watson, Esq., with splendid fruit of Marie Louise, Passe Colmar, Beurre Clairgeau, Winter Nelis, Doyenné Gris. Second Col. Wingfield. For three dishes of Pears (amateurs), first Mr. G. Harries; second Mr. C. M. Campbell. For one dish dessert Pears, first C. M. Campbell, Esq.; second G. Harries, Esq. Twelve dishes of Apples, distinct, first Col. Wingfield with Orange Pearmain, Waltham Abbey Seedling, Peach Apple, Hawthornden, Blenheim Pippin, Dumelow's Seedling, Claygate Pearmain, and Ribston Pippin—all grand fruits. Second Rev. J. D. Corbett. For six dishes of Apples, first J. Watson, Esq.; second Col. Wingfield. For three dishes of Apples (amateurs), first Mr. T. Wood; second Mr. George Townsend. For one dish of dessert Apples, first Mr. E. W. Pritchard; second Col. Wingfield.

Plants and fruit were sent not for competition by J. Watson, Esq.; Mrs. Burton, Longner; and Messrs. Jones & Sons, Coton Hill, exhibited a large group in the centre of the room, also a large collection of fruit and Chrysanthemum blooms, a wreath and cross, and two of their noted bouquets. Great praise is due to the Committee, and Treasurer (Mr. E. N. Pritchard), and Secretaries (Messrs. H. & S. Jones), all of whom worked hard and gratuitously. The Society intends holding a two-days Rose show next July, at the same time as the visit of the Royal Agricultural Society to the town.

READING, NOVEMBER 22ND.

FIRST attempts are always entitled to a certain amount of leniency in criticism, and as this applies equally to flower shows as to other matters, the initiatory efforts of a young Society to establish an exhibition—whether for spring, summer, or autumn—cannot always be expected to result in unqualified success. For this reason we should be inclined to regard the first Reading Chrysanthemum Show in a spirit of moderation; but as it was held in connection with the experienced local horticultural society, it is scarcely entitled to this allowance for its shortcomings. In number of exhibits there was no room for dissatisfaction, but as regards the quality we have reluctantly to record that it was one of the worst we have seen this season. With the exception of the groups there was not a first-rate plant in the whole Exhibition, and there were some that it was a disgrace to the cultivators to show. Blooms, too, were scarcely more than third-rate as compared with those at Kingston, the Royal Aquarium (Westminster), Stoke Newington, and other exhibitions, and it is rather unpleasantly evident that local growers of the Chrysanthemum have very much to learn. So great a degree of skill has now been attained with this popular plant that an exhibition must, to secure adequate support, be fairly representative of the best examples of practice, and it thus becomes instructive in a considerable degree. It is to be hoped for the credit of the district that at the Show in question the best growers did not compete, and that at the next trial a more meritorious class of exhibits will be staged. It is not easy to account for this comparative failure; for though the fixture was late, several other southern shows were equally so and yet well maintained their credit, as, for example, Tunbridge Wells. Perhaps the chief fault was in the schedule, the prizes being small, and in more than two-thirds of the classes only two prizes were offered; in fact, the schedule generally seemed to have been rather carelessly framed, and in several classes there was a want of clearness that was very confusing. For instance, a class was provided for "twelve cut blooms, Japanese, incurved, distinct kinds," and another for a "large-flowering group of twelve in pots, not exceeding 8 inches, to carry three blooms each"—neither of which is very definite. In some classes the word "kinds" is employed, in others "varieties," the former being apparently confined to the Japanese, and it would therefore appear that the Committee is deficient in those practical matters whose advice is so valuable in such cases. With more energy and more careful and liberal arrangements there is no doubt that a highly satisfactory display of Chrysanthemums may yet be seen in Reading; indeed, there is no reason why it should not rank amongst the leading shows of the kind, and thus gain a position proportionate to the fame of the town in the horticultural world.

The handsome Town Hall was devoted to the Exhibition, and it is only fair to state that the plants were well arranged, producing a good effect generally, especially the groups. In the large organ hall, which was used as a promenade, however, the plants were few, and it would have had a very bare effect without the handsome and extensive group of Palms and Chrysanthemums contributed by Mr. Phippen, which was arranged in elliptical form, the plants being mostly freely flowered and tastefully disposed.

Plants.—The best class was that for a group of Chrysanthemums, arranged for effect in a space of 12 feet by 10 feet, in which there were seven competitors. Mr. Baskett, gardener to W. J. Palmer Esq., Reading, secured the first position with a bright and tasteful group, the blooms mostly of good substance and bright in colour. Mr. Turton, gardener to J. Hargreaves, Esq., was a close second, having a larger proportion of Japanese varieties. Mr. Lees, gardener to Mrs. Marsland, The Wilderness, was third with a graceful and attractive group, an extra prize being adjudged to Mr. House, gardener to J. V. Taylor, Esq., Reading. These were placed at one end and one side of the large hall, and furnished the chief attraction of the Show. Mr. Baskett were also the premier exhibitor of four large-flowering and four Japanese, in both cases showing healthy plants. In other classes the principal prizetakers were Messrs. J. Bridge, gardener to J. F. Hall, Esq., Earley Court, Mayne; Miss Moon, Reading; Turton, Lees, and Hermon, F. Skurry, Esq., Reading. In one case the Judges had considerable difficulty in awarding the second prize, as in both collections the plants were very poor, and each included a plant that was nearly dead; and after calling in a third person the decision was, in our opinion, given in favour of the inferior plants, though both lots might have been excluded.

Cut Blooms.—Competitors were numerous in the cut bloom classes, and the majority showed small samples. Nine lots of twenty-four blooms were entered, Mr. Kendall, gardener to H. C. Holland, Esq., Templeton, Roe-

hampton, taking the first place with fairly neat blooms. Mr. Jennings, gardener to J. Freeman, Esq., Farnborough, was second, and Mr. Elliott, gardener to J. Hibbert, Esq., Braywick Lodge, third with small blooms. Mr. Kendall also had the best twelve Japanese, of moderate size, but fresh. The same competitor led in the mixed class for twelve Japanese and incurved, followed by Mr. Tranter of Upper Assenden. Mr. Elliott had a good stand of twelve reflexed blooms, which included fine samples of King of the Crimsons, Dr. Sharpe, Chevalier Domage, Christine, Mrs. Forsyth, and Ariadne.

Fruit was moderately shown, Mr. Bennett taking the chief position with a collection of six kinds, comprising Black Alicante Grapes well coloured, Maréchal du Cour Pears, and Golden Noble Apples being of good size. Mr. Hunt, gardener to Dr. Wills, Reading, was second with a collection of Apples mostly of good size.

TUNBRIDGE WELLS, NOVEMBER 22ND AND 23RD.

It is always pleasant to record success, and this we have to do in regard to the Tunbridge Wells Chrysanthemum Show, for it was undoubtedly one of the best the Society has held, and some of the plants and blooms, but the former especially, were very highly creditable to the growers. It is evident, indeed, that the Society is well managed. There is a great local interest in it, substantial support is afforded, and the result was an Exhibition of great merit and beauty. The large Skating Rink was filled with the contributions, the specimen plants and groups being remarkably fine, and arranged as they were near the walls, produced a brilliant display of colour. The effect was still further improved by having raised stages at each end of the hall upon which the plants were placed in tiers, the pyramidally trained specimens at the top and the dwarf-trained examples below. Two broad centre tables extending the whole length of the building were filled with blooms, Apples, Pears, collections of fruits, Primulas and table plants, all of which were shown in large numbers and of good quality. The general arrangements were very satisfactorily conducted by the Hon. Sec., Mr. E. Charlton, and the energetic Committee.

Plants.—One of the most interesting classes in this section of the schedule was that for eight Chrysanthemums in pots not to exceed 12 inches in diameter, for which the silver cup, value three guineas, was offered by the tradesmen of the town. Mr. A. Stringer, gardener to R. Cunliffe, Esq., Stoneleigh, Newell Park, won this honour with superbly grown and admirably trained specimens, some of which we have not seen surpassed this year. Five of the plants were dwarf-trained, about 3 to 4 feet in diameter, and were as nearly perfect in form, breadth, size and number of blooms as could be desired. Miss Mary Morgan in particular was very handsome, Prince Alfred was similar in merit, Baron Beust and Mrs. Halliburton being a trifle smaller. Three tall pyramids at the back, 5 to 6 feet high, were equally praiseworthy, the varieties being Inner Temple, Mrs. G. Rundle, and Robert James. Mr. R. Bealby, gardener to W. H. Tindall, Esq., Hollyshaw, Camden Park, was a good second, also having some well-grown plants. Three dwarf specimens in particular were excellent, the blooms being of fine substance; these were Jardin des Plantes, Baron Beust, Mrs. Halliburton. The pyramidal plants were fairly good, but thinner than those in the preceding collection. Mr. Ovenden, gardener to W. Newbold, Esq., Broadwater Down, was third. A corresponding class was provided for gardeners and amateurs residing within fourteen miles of Tunbridge Wells, eight plants being required as in the other class, and premier award was a silver cup of equal value presented by the ladies of the town. This invariably brings good competition, and such was the case at this Show, four very fine collections being entered. Mr. Killick, gardener to E. Roche, Esq., Sandfield, Nevill Park, won the cup with vigorous plants bearing large substantial and refined blooms. Hero of Stoke Newington, Lord Derby, and Baron Beust were good dwarf specimens, the pyramids also being of fair quality. Mr. Johnston, gardener to the Marchioness of Camden, Bayham Abbey, was a close second, having La Nympe in splendid condition, a mass of its delicately tinted blooms. Criterion was similarly fine. Mr. Wilkins, The Gardens, Shirley Hall, Langton, took the third place with fairly good plants, Princess Louise being especially notable for the number and substance of the blooms, while Mr. Mitting followed with smaller plants. These two classes formed the leading feature, though several other classes were well represented. At one end of the hall the Pompons were principally staged, and these included some very well grown and freely flowered specimens. Mr. Beilby was the premier exhibitor, taking first with six, four, and one. Antonius was especially good, neatly trained and profusely flowered; Fanny, Calliope, and the Cedo Nullis being equally noteworthy. Mr. Stringer followed in several classes. In the single-handed gardeners' section Mr. Ovenden had the best four Pompons, Salamon, the White and Golden Cedo Nullis, and Antonius flowering freely. Mr. Mitting followed. Messrs. Goodwin, Tilton, and Mitting also showed well in several other classes. At the opposite end of the hall large-flowered and Japanese varieties were chiefly staged, Mr. Stringer securing first honours with the best four large-flowering varieties, even and beautiful, Dr. Sharpe, Princess Teck, Mrs. G. Rundle, Antonelli, and Robert James being the most noticeable. Messrs. Wilkins and Beilby followed closely. Mr. Killick had the leading four plants, King of the Crimsons being uncommonly fine; Mr. Stringer being first in the two classes for a single dwarf-trained specimen large-flowered variety, having Mrs. G. Rundle over 4 feet in diameter and bearing fair blooms, and Pink Venus similarly good. In other classes Messrs. Ovenden, Beilby, Killick, and Tickner were the chief prizetakers, the last-named securing three firsts for dwarf plants in the eight-miles radius classes.

Cut Blooms.—In several of the leading classes blooms of excellent substance were staged, and taking them generally they were very satisfactory, fresh, clean, and neat, if not of great size. In the Mid-Kent and East-Sussex class for twenty-four incurved blooms Mr. Stringer was the premier exhibitor, having extremely refined and pretty blooms of moderate size. Mr. G. Ware, gardener to Mrs. Morgan, Hungershall Park, was second with blooms but little inferior to the first. Messrs. Cheek (gardener to T. F. Gibson, Esq., 10, Broadwater Down), and W. Cornwell (gardener to F. Burchard, Esq., Horsted Place, Uckfield), followed third and fourth respectively. Mr. Cheek had the premier stand of twelve incurved, also neat blooms; and Messrs. Allan, Paine, and Ware secured the remaining awards. Mr. Stringer won leading honours with twelve Anemone varieties, large blooms of Prince

of Anemones and Fleur de Marie being very handsome. In the corresponding class for Anemone Pompons Mr. Scammell, gardener to C. Reilly, Esq., The Priory, Nevill Park, was first, having neat examples of Madame Montels, Antonius, Perle, and Miss Nightingale. Messrs. Allan, Roberts, and Ware secured the remaining prizes. In the fourteen-miles-radius classes the competition was also good, the most important prizes being secured by Mr. Henderson, gardener to J. Deacon, Esq., Mabledon, Tonbridge; Roberts, Stringer, Johnston, Killick, and Legg.

Fruit.—Grapes were largely shown, and mostly of good quality, the black Grapes being especially well coloured, and the competition was keen, as eight collections of three bunches were staged. Mr. Scammell took the lead with Alicante, large in bunch and berry, and superbly coloured. Messrs. Allan and Bashford followed closely, also with highly coloured Alicantes. Six lots of white Grapes were entered, Mr. Legg winning first honours with richly coloured Muscat of Alexandria. Messrs. Pope and Henderson being second and third with the same variety. Apples were extensively shown, and mostly of very good quality. Mr. Goldsmith, gardener to P. C. Hardwicke, Esq., Hollenden, Tonbridge, was the most successful exhibitor in the class for six dishes of dessert Apples, staging Ribston Pippin, Blenheim Pippin, Cornish Aromatic, Fearn's Pippin, and King of the Pippins in very good condition. Mr. Hutchinson, gardener to Mr. Hussey, Scolney Castle, Lamberhurst, was a close second, having Court Pendû Plat, King of the Pippins, and Blenheim Pippin very fine, the last named being highly coloured. Mr. Bridger took the third place, there being four other exhibitors. With three dishes the competition were even more keen, nine lots being staged. Mr. Bridger, gardener to Lord de Lisle, Penshurst, was first, his Blenheim and Ribston Pippins being exceedingly fine. Mr. Goldsmith was second with the same varieties, nearly equally as good. Nine single dishes were staged, Mr. Cornwell leading with Ribston Pippin, Messrs. Goldsmith and Hutchinson following with Cox's Orange Pippin and Court Pendû Plat. Kitchen Apples were in equally strong force, the number of entries being similar in each class. For six varieties Mr. Bridger gained chief honours with fine samples of Golden Noble, Lord Derby, Tower of Glammis, Hollandbury, and Warner's King. Mr. Goldsmith was a close second, having fine Golden Noble, Lord Derby, Reinette du Canada, and Warner's King. Mr. Hutchinson was a good third with even fine fruits. Mr. Bridger was similarly first with three dishes, Warner's King, Lord Derby, and Blenheim Orange, Messrs. Goldsmith and McFeate following. For one dish Mr. F. Guest, Southborough, was first with large and handsome specimens of Warner's King, Mr. Bridger being second with the same variety, and Mr. Hutchinson third with Beauty of Kent. Pears were shown in good numbers, Messrs. Johnston, Goldsmith, McFeate, and Farrant winning principal honours with fine fruits.

Only three collections of fruit were entered, Mr. Henderson being awarded first honours for creditable specimens of Alicante and Muscat of Alexandria Grapes, well ripened, with a good Pine Apple, Pears, and Apples. Mr. Scammell took the second place, his Alicante Grapes being well coloured. Mr. Johnston was third, his collection including some fine Pears.

Miscellaneous plants, including Primulas, Poinsettias, table plants, Epiphyllums, and others were shown in numbers, and added much to the diversity and beauty of the Show. The not-for-competition exhibits comprised a collection of Cyperuses from Mr. J. Charlton, Snmmervale; a number of handsome Apples, Pears, Grapes, and Orchid flowers from Mr. F. Bridger; Grapes, Apple, Pears, Pines, and miscellaneous fruits from Mr. Rust, The Gardens, Eridge Castle; collections of Apples were also sent from J. Scott, Esq., Penshurst, and E. H. Hunter, Esq., Frant.

LIVERPOOL, NOVEMBER 27TH AND 28TH.

The above Society held their annual Exhibition in St. George's Hall. Fortunately the weather during the opening day proved all that could be desired, and the Exhibition was a very great success. It was on the whole very superior, both in the number and quality of the exhibits, to any this Society has yet held. The Grapes were good, but the Apples and Pears were very remarkable for their size and brightness of colour. The Chrysanthemums claim first attention.

Cut Blooms.—These were numerous, but scarcely equal in quality to what we have before seen them at this Exhibition, which was due no doubt to the date. In the principal class for the silver vase, value £10 10s., given by Messrs. J. Williams & Co., for eighteen Japanese and the same number of incurved, there were five competitors. Mr. T. Leadbeater, the Gardens, Bromborough Hall, Cheshire, took the lead; Mr. W. Mease, gardener to C. W. Newmann, Esq., Wincote, Allerton, gained the second place; and Mr. F. Roberts, gardener to W. D. Holt, Esq., West Derby, was third. The blooms in the first collection were—Back row: Fair Maid of Guernsey, good; Baronne de Prailly, Japonaise, Madame C. Audiguer, Meg Merrilees, and Criterion, very fine. Second row: Oracle, Hiver Fleur, Elaine, Rosa Bonheur, and Peter the Great. Third row: Flambeau, Magnum Bonum, L'Incomparable, Cry Kang, The Cossack, and La Nympe. The incurved varieties being—Back row: Princess of Wales, good; Golden Empress, Alfred Salter, Queen of England, Emily Dale, and Empress of India. Second row: Jardin des Plantes, Mrs. Heale, John Salter, Princess of Teck, Cherub, and Hero of Stoke Newington. Front row: Venus, St. Patrick, Mr. Bunn, Prince Alfred, White Venus, and Barbara. In the class for twenty-four incurved there were four competitors. Mr. G. Mease, gardener to W. Nicol, Esq., St. Michael's, secured the premier position with a capital stand of blooms of good size and quality. Mr. T. Leadbeater gained the second prize with neat but rather smaller blooms; Mr. D. Lindsay, gardener to Sir Thomas Moss, Bart., Otterspool, being third. For eighteen blooms the competition was good and keen, some six or seven exhibitors staging blooms. Mr. M. Playfair took the lead, having grand flowers of Princess of Wales, Mr. Howe, Mr. Burnlees, Golden Empress, Barbara, and Alfred Salter; Mr. R. G. Waterman, gardener to A. Tate, Esq., Woolton second; and Mr. A. R. Cox, gardener to W. H. Watts, Esq., Elm Hall, Wavertree, third. For twelve blooms there were seven exhibitors. Mr. F. Roberts secured the premier position with very fresh well-coloured blooms. Mr. G. Mease was second, and Mr. J. Fairhurst, gardener to P. Blessig, Esq., Beechley Allerton, third. In the corresponding class for twelve blooms six lots were staged, and the prizes were obtained by Mr. J. Warrington, gardener to T. Bright, Esq., Woodcote, Aigburth; Mr. Jos. Brantingham, gardener to S. Still Esq., The Grange, Cloughton; and Mr.

Thos. Foster, gardener to J. Brancker, Esq., Greenbank, Wavertree, in the order named. Of twenty four Japanese three collections only were staged. Mr. R. G. Waterman was well ahead with large well-coloured blooms, Mr. G. Mease being a good second. Mr. A. R. Cox had the remaining prize. For eighteen the same number of collections were staged; Mr. Wilson, gardener to H. Cunningham, Esq., Gateacre, being first, having remarkably fine flowers; Mr. J. Jellicoe, gardener to F. Gossage, Esq., Woolton, second; and Mr. J. Warrington third. For twelve blooms Mr. J. Wilson, gardener to J. E. Reynolds, Esq., Sandsfield Park, West Derby, and Mr. G. Burden, gardener to G. Cockburn, Esq., were the prizetakers, both showing well. For six Anemone and six reflexed Mr. A. R. Cox was well first, having good Golden Christine, Dr. Sharpe, Lilac Christine, King of Crimson, Madame Clos, Mrs. Pethers, Lady Margaret, Gluck, and Madame Godereau. Mr. J. Jellicoe was a close second, and Mr. W. Wilson third with much smaller blooms. Blooms of Pompon varieties were well shown, the principal prizewinners being Mr. A. Collins, gardener to S. Smith, Esq., M.P., Princes Park, Mr. A. R. Cox, and Mr. J. Hurst.

Specimen Plants.—These were numerous and good. In the class for six plants Mr. J. Hughes, gardener to H. McIver, Esq., Allerton, was easily first with fresh plants with large full blooms; the varieties being Lady Slade, grand; Empress of India, good; Jardin des Plantes, very fine; John Salter, good; Lady Hardinge, and Mrs. Rundle. Second Mr. S. Whitfield, gardener to J. T. Cross, Esq., Beechwood, Aigburth. Third Mr. E. Gray, gardener to C. H. Bishop, Esq., St. Helens. In the class for four plants Mr. J. Hughes was again successful with plants equally as fine as those shown by the same exhibitor in the previous class; and Mr. C. Gray third. In the class for six Pompons the same exhibitor was again first with a grand collection of plants far before anything else staged. The plants were crowded with blooms, which were of a very large size. Second Mr. S. Whitfield with very creditable plants; and third, Mr. T. Blackmore, gardener to Major Pemberton, Fairfield. For four plants Mr. J. Hughes was again first with remarkably fine plants; Mr. J. Bustard, gardener to J. Lewis, Esq., Aigburth, second, and Mr. Blackmore third, all showing well.

Stove and Greenhouse Plants.—These were shown in good condition, and in the class for six plants, three in flower and three fine-foliage, Mr. W. Mease was well to the fore with a large well-coloured Croton Disraeli, Queen Victoria 6 feet through, and an enormous Latania borbonica; Centropogon Lucianus, good; Erica hyemalis 3 feet through, fine; and Azalea Verscheffelti well bloomed, large, and good. Mr. A. R. Cox was placed second, having good Croton angustifolius and Azalea amcena. For four plants Mr. A. Brown, gardener to G. Webster, Esq., Upton, Cheshire, was first, his best plants being Calanthe Veitchii fully 3 feet through, with spikes of bloom fully 3 feet 6 inches in length. Second Mr. W. Mease, and third Mr. A. R. Cox.

Poinsettias were very fine, much better than we have before seen them in St. George's Hall. First, Mr. G. Middleton, gardener to R. Pilkington, Esq., Rainford Hall; second, Mr. E. Green, gardener to J. Woolwright, Esq., Aigburth; and third Mr. J. Wilson. Roman Hyacinths were good, and Mr. J. Phythian, gardener to D. Walker, Esq., Forest Lawn, West Derby, took the lead, followed by Mr. W. Evans and Mr. R. A. Farrington. Mignonette, Primulas, Epiphyllums, table plants, and the exhibits of a few other smaller classes were abundant and of good quality.

Ferns.—The plants staged in this class were large. For six plants Mr. Phythian was first with Adiantum farleyense, Blechnum corcovadense, Adiantum Cunninghami, Adiantum excisum, and Alsophila excelsa. Mr. J. Stephenson, gardener to Mrs. Horsfall, Cressington, Aigburth, was second, and staged fine plants of Adiantum cuneatum, A. formosum, and Davallia Mooreana. Third, Mr. Thos. Foster, having a very fine Todea superba, four or five collections being staged. For one Tree Fern Mr. A. R. Cox took the lead, followed by Mr. J. Lowndes.

Palms.—These were not numerous, but the plants staged were healthy and very fine specimens. For three plants Mr. E. Thrupp, gardener to A. Walmsley, Esq., took the lead with Cycas revoluta, Latania borbonica, and Chamærops humilis. Mr. S. Whitfield second, having good plants of Phoenix reclinata and Areca sapida. For one plant Mr. S. Whitfield was first.

Orchids.—These were not numerous, as the schedule only provided four classes for them, but those staged were very creditable to the exhibitors. For three plants Mr. W. Moss, gardener to W. Holland, Esq., Mossley Hill, took the first prize with Angræcum sesquipedale, Burlingtonia fragrans, and Odontoglossum Hallii, a good variety. Mr. J. Wilson second, showing well Dendrobium heterocarpum and Odontoglossum Alexandræ. Third, Mr. J. Edwards, gardener to S. Walker, Esq., M.D., Rodney Street, Liverpool. For two Calanthes Mr. J. Hurst was first, Mr. Moss second, and Mr. E. Green third. For one plant Mr. Moss took the lead, followed by Mr. A. Brown and Mr. J. Stephenson.

Fruit.—The classes devoted to fruit were well filled and of excellent quality. In the class for twelve dishes three collections were staged, the premier award going to Mr. Hannagan, gardener to R. C. Naylor, Esq., Hooton Hall, Cheshire, his collection comprising good dishes of Black Alicante, Lady Downe's, and Gros Colman Grapes, the latter being very fine, large in berry, bunch, and of good colour; Conqueror of Europe Melon, Queen Pine, good Marie Louise, Glou Morceau, and Beurré Clairgeau Pears; and Apples Beachamwell, Golden Reinette, and King of the Pippins. Mr. J. H. Goodacre, gardener to the Earl of Harrington, Elvaston Castle, was a close second, having good Queen and Smooth Cayenne Pines, Beurré Diel and Duchesse d'Angoulême Pears, Blenheim Pippin and Cox's Orange Pippin Apples were also good. Third Mr. J. Bennett, gardener to the Hon. C. H. Wynn. For six dishes ten collections were staged, Mr. Hannagan again taking the lead with good well-finished Alicante and Gros Colman Grapes, King of the Pippins Apples, Conqueror of Europe Melon, Beurré Diel (very large) and Glou Morceau Pears. Mr. W. Mease was a good second; Mr. J. Hurst, gardener to W. B. Bowering, Esq., Beechwood, Allerton, third. Pines were not numerous, but good. Mr. J. Bennett took the lead in the class for two with grand fruits of Smooth Cayenne; Mr. W. Speed, gardener to Lord Penrhyn, Bangor, second, having a good fruit of Lord Carrington; and Mr. G. Gibbon third with Queens. For one fruit Mr. G. Gibbons took the lead; Mr. J. Bennett, and Mr. H. Mitchell, gardener to Sir G. Elliott, third.

Grapes.—These throughout were of very fine quality, and the prizes

offered in the various classes well contested. For two bunches of blacks, Muscat flavour, Mr. J. Barker, gardener to Alderman Rayner, Rock Ferry, took the lead with well-finished Madresfield Court; Mr. A. Collins second with very good bunches of Mrs. Pince; and Mr. Goodacre third with the same variety; eight lots being staged. For two bunches of black, any other variety, fourteen bunches were staged. Mr. P. Ingham, gardener to J. Goldsmith, Esq., Windle Hall, was first with large well-finished bunches of Black Alicante; Mr. T. Elsworthy, gardener to A. R. Gladstone, Esq., Court Hey, was a close second with the same; and Mr. A. Collins third with good bunches of Gros Guillaume. For two bunches of whites, Muscat flavour, Mr. G. Middleton took the lead with well-finished examples of Muscat of Alexandria, fair-sized bunches with very large berries; Mr. J. Hurst second; and Mr. J. Lounds, gardener to Miss Crossfield, Aigburth, third; six lots being staged. For two whites, any other variety, Mr. J. Hurst was first with well-coloured Golden Queen; Mr. C. Young, gardener to Joseph Evans, Esq., Hurst House, second with the same variety; and Mr. W. Mease third with White Tokay; nine lots being staged. For four distinct varieties, one bunch of each, twelve collections were staged. Mr. C. Young was awarded the premier position for well-finished bunches of White Tokay, Gros Colman, Muscat of Alexandria, and Gros Guillaume; Mr. J. Wallis, gardener to Rev. W. Sneyd, Keele Hall, second with smaller but well-finished bunches; Mr. P. Ingham being third.

Pears.—In the class for eight dishes of dessert varieties, open, some seven or eight collections were staged. Mr. Goodacre took the lead with grand dishes of very fine fruit of Pitmaston Duchess, Glou Morceau very large, Beurré Clairgeau good, Grosse Calebasse very large, Beurré Diel large, Duchesse d'Angoulême fine, Marie Louise good, and Doyenné du Comice. Mr. J. Hannagan was placed second and staged some very fine dishes of fruit. Third, Mr. J. Kelly, gardener to R. Singlehurst, Esq., Aigburth. In the corresponding class for four dishes some twelve or thirteen collections were staged. Mr. J. Kelly took the lead, followed closely by Mr. J. Hannagan. For one dish of dessert Pears Mr. J. Kelly was first with Marie Louise, Mr. J. Loundes, gardener to S. S. Parker, Esq., second with the same variety, and Mr. M. Playfair third, sixteen dishes being staged. For one dish of stewing Pears only six dishes were staged, the first prize going to Mr. T. Wedon, gardener to J. C. Morris, Esq., for a dish of Pitmaston Duchess. They were grown inside on a tree in a 12-inch pot and had on it thirteen fruits, the heaviest of which weighed 27 ozs. Mr. J. Goodacre second, and Mr. Hannagan third.

Apples.—These were remarkably fine and shown in very large numbers. For six dishes dessert varieties, open, Mr. F. Miller, gardener to J. F. Friend, Esq., Kent, was placed first. He staged fine well-coloured fruit of Scarlet Pearmain, Worcester Pearmain, Fearn's Pippin, Adams' Pearmain, Ribston Pippin, and Cox's Orange Pippin. Mr. Hannagan was second, and staged good Golden Reinette, Blenheim Orange, and King of the Pippins; Mr. C. Rylance, nurseryman, Ormskirk, third. Twelve collections were staged. For three dishes the same number of collections were exhibited; and Mr. J. Bounds was first with Golden Winter Pearmain, King of the Pippins, and Ribston Pippin. Second Mr. J. Loundes, and third Mr. Hannagan. Some thirty dishes were staged for the three prizes offered for one dish. Mr. Playfair won first honours with Ribston Pippin; Mr. T. Foster second; and Mr. W. Evans, gardener to Mrs. Lockett, third, both staging the same variety. For eight dishes of kitchen varieties Mr. Miller, Kent, was well ahead with remarkably large examples of Waltham Abbey Seedling, Annie Elizabeth, Peasgood's Nonesuch, Lady Henniker, Hollandbury, Mère de Ménage, Golden Noble, and Emperor Alexander. Mr. T. Johnstone, Higher Bebbington, second; Mr. J. H. Goodacre third, ten collections being staged. For four dishes Mr. T. Johnstone won with very fine fruits, followed closely by Mr. J. Kelly; Mr. Wollam, gardener to Col. Blundell, Crosby, being third. For one dish the prizetakers were Messrs. T. Johnstone, W. Evans, and P. Barber, gardener to Mrs. Barnsley, Aigburth.

Miscellaneous Exhibits.—Messrs. F. and A. Dickson & Sons staged a very large collection of Apples, which was highly creditable to them. A similar collection came from Messrs. James Dickson & Sons, Messrs. R. Smith & Co., Worcester, and Mr. C. Rylance, Ormskirk. The Horticultural Company (John Cowan) had a collection of flowering and fine-foliage plants; Messrs. R. P. Ker & Sons a large collection of remarkably well-grown Cyclamens; Mr. Smith, Maiden Lane, Clubmore, Liverpool, had baskets of Mushrooms grown on the principle recommended in "Mushrooms for the Million." They were very fine, and excited much attention. Messrs. Cannell & Sons, Swanley, Kent, staged fine trusses of Zonal Pelargoniums, Primulas, and Salvias.

FRUIT-FORCING.

VINES.—*Earliest Houses.*—In houses that were closed early in the month the Vines will be showing signs of growth, and if it be found that the terminal buds are taking the lead, draw them down to a horizontal position, and syringe the less forward parts three or four times a day with tepid water. When the Vines are making top growth, the outside borders, if there be a sufficiency to continue and renew as necessary, may receive a good covering of thoroughly fermenting Oak or Beech leaves and stable litter, three parts leaves to one of stable litter answering very well, putting these on in sufficient quantity to maintain a top heat of 80° to 85°, placing lights or shutters over all with a sharp incline to the front for throwing off rain, but there must be a space between the covering and the fermenting material. If there is not such a supply of fermenting material as to allow of the bed being renewed or added to as necessary to keep up the heat until the Grapes are matured or far advanced, it will be better to dispense with

the fermenting material, and have a good covering of dry fern or litter with shutters or tarpaulin over to exclude rain, for fermenting materials allowed to become a sodden cold mass are highly injurious. Stir the fermenting materials in the house used for warmth and moisture, and if necessary add a few fresh leaves. Examine the inside border carefully, and if any part of the soil be dry steady watering must be followed up until the whole is brought into a thoroughly moist condition. Admit a little air when the weather is mild, but in no instance must it be given to lower the temperature; yet it is always advisable to admit a little air, so as to effect a change of atmosphere at least once in twenty-four hours. Raise the temperature early, when there is the prospect of a fine day, to 65° by artificial means, advancing to 75° from sun heat, ventilating a little from 70°, and close at 75°, maintaining the night temperature at 60°, allowing it to fall 5° during the night in severe weather.

Houses to Afford Grapes Early in June.—Houses that are to afford ripe Grapes early in June must now be closed. For the first fortnight a temperature of 50° to 55° artificially is ample, advancing to 60° or 65° from sun. Syringe two or three days a week in favourable weather, and make up some heaps or ridges of fermenting materials in the house on the inside borders, which will help the surface roots and give off warmth and genial moisture to the atmosphere, saving fuel and lessening the necessity for syringing. Water the inside borders with tepid water, which will be most suitable for vigorous young Vines, but old Vines requiring stimulating should have liquid manure, and at a temperature of 80° to 90°. Young canes that have not been forced early will require bending down to a horizontal position to insure an even break down to the base, but old Vines that have been some years at work will not need to be slung, as they will break evenly throughout.

Early Vines in Pots.—Attend to the fermenting materials in pits containing early Vines in pots; and if every pot is placed on a solid pedestal from the bottom of the pit frequent additions may be made as the heat declines, which should be kept steady at from 70° to 75°, the whole mass being turned over and the pots being only partially surrounded by the plunging material. The top heat should, now that the Vines are showing fruit, be maintained at 60° to 65° at night, and 70° to 75° in the daytime. Stop not less than two joints beyond the show of fruit. Feed the roots with tepid liquid manure, and damp available surfaces two or three times a day in preference to syringing overhead, which only tends to give a thin texture to the leaves.

Pruning and Cleansing Succession Vines.—As soon as the Grapes are all cut in succession houses no time should be lost in having the Vines pruned as soon after the leaves have fallen as possible, in order to give a long and complete period of rest. Vines that are in good health and ripen the wood well may be pruned to two buds with a certainty of a show of compact bunches; yet where there is room for extension the number of buds may be increased to four or six, and the bunches resulting will usually be larger but not nearly so compact as those from buds nearer the base. In dressing the Vines only remove the loose bark, and if there have been any insect pests syringe the house and Vines with a solution of petroleum, and repeat so soon as dry. This will destroy almost every kind of insect, and the wood-work and trellis may, in the case of mealy bug, be brushed over with petroleum and the walls scalded prior to limewashing. Remove the loose surface soil and supply fresh material—loam, crushed bones, and charred refuse. Collect and save thoroughly ripened wood for eyes and grafts, inserting the ends in moist soil or clay.

FIGS.—Early Trees in Pots.—The fermenting materials that have been placed loosely about the pots should be examined, and if the heat around them at the base does not exceed 80° they may be pressed down firmly and some more introduced from the reserve heap, care being taken not to raise the heat about the pots over 75°. The fermenting materials have been sufficient so far to maintain the suitable temperature—viz., 50° minimum, with an advance of 5° to 10° more by day in mild weather without much fire heat; but it is not advisable to dispense with it altogether, as a gentle warmth in the hot-water pipes admits of a little air being given, or when not it induces a circulation of air and prevents condensation. Continue former instructions in respect of damping, syringing, and watering.

Pruning and Cleansing Late Trees.—Pruning now is chiefly thinning, taking out the old shoots that have reached the extremity of the trellis, and cutting back the spurs that have been stopped. Remove every particle of scale from the wood by repeated washing with soapy water, 6 ozs. soft soap to a gallon of water, adding half a wineglassful of spirits of turpentine to two gallons. This should be applied with a soft brush and with great care, as the slightest injury to the embryo fruit would disfigure if it does not destroy the most forward. Train on the fan system, tying in loosely so as to allow for swelling, and leave plenty of room for the extension of the new growths, as the finest fruits are borne on those having well-developed leathery foliage, plenty of light being essential to fine quality.

Cucumbers.—When the plants are producing and swelling off their fruit, which takes place more or less between now and March, liberal treatment is necessary; hence copious and frequent applications of tepid liquid manure in a weak state should be given, as by this time the plants will have filled the bed with a number of roots hungering for food. A surface dressing of rich compost previously warmed will be of great benefit in keeping the roots active, especially if the bottom heat be kept steady at 80°. The day temperature should range from 70° to 75°, advancing 5° to 10° from sun heat, the night temperature being maintained at 60° to 65°, or 5° more in mild weather. In very severe weather it is advisable to cover the house with mats or other protecting materials, by which means the necessary temperature could be maintained without overheating the

hot-water pipes, and the heat thus obtained is more favourable to the plants than that radiated by a highly heated surface. Attend frequently to regulating the growths, and stop them moderately for the present, keeping free of insects.

Strawberries in Pots.—When forcing these is carried on to any extent it will be necessary to prepare and arrange batches of plants for succeeding one another in the supply of fruit, according to the demands of individual establishments. Under ordinary forcing such varieties as Black Prince started now will afford fruit at the end of February, and Vicomtesse Hericart de Thury, also La Grosse Sucrée, started at the same time, will afford a succession. A second batch of the two latter and Keen's Seedling started at the middle of next month will afford fruit about the middle of March, and early in January will give fruit early in April, President being admirable for starting at that time. The plants intended to be introduced to the various forcing houses now being set to work, should have the drainage seen to, and if necessary rectified, and any decayed leaves removed, stirring the surface of the pots, removing the loose portion, and replace with fresh horse droppings rubbed through a sieve, and water through a fine rose the first time of watering after top-dressing. Examine the plants at least once a day, and any that need water should be given a thorough supply. Avoid saturating the soil when it is already moist, and guard against the soil becoming too dry, or the roots will suffer.

HARDY FRUIT GARDEN.

Pruning.—Let the pruning of Pears, Apples, Plums, and Cherries proceed with all possible dispatch while the weather is mild as the trees become clear of leaves. The important considerations which induce this advice are that early pruning is usually deliberate and careful; the condition of the tree may be thoughtfully examined, each spur and branch taken in detail, crowded growth thinned, diseased parts removed, the work of the year passed in review, its faults set right so far as is possible, and the tree made ready for the next season's growth and fruiting. We cannot reckon upon a continuance of fine open weather in winter, and pruning left till the new year frequently has then to be deferred till spring draws nigh, and a pressure of other work leads to a hasty rush over the trees, and not unfrequently some involuntary negligence. Young half-formed trees should be carefully examined, and each tree treated solely on its merits, and not by line and rule. Stout vigorous trees should only be shortened sufficiently to induce necessary lateral growth for spurs and branches. Weakly trees require hard pruning, for slender growth cannot yield fine fruit. Trees that are termed fruiting pyramids are frequently sent from a nursery with vigorous branches on the upper half or two-thirds of the stem, but with the lower part either bare or with only weakly branches. Having regard to the future appearance of the trees, there must be no hesitation about cutting them down to about 2 feet from the base of the stem when the planting is done. Nor will this severe pruning involve any serious loss, for such vigorous young trees invariably break freely into growth in the following spring, and afford a choice of stout branches for the lower tiers and leading shoots of such strength that the top may be nipped off once and not unfrequently twice during the summer, whereby there is a clear gain of one or two years' stem and lateral growth. Young standards and unspurred bushes should have the necessary thinning of crowded branches and useless growth removed from the centre of the trees to admit light and air freely to promote health and fruitfulness.

Feeding.—Fruiting trees for which stations had to be prepared when they were planted should be carefully examined, and if necessary the soil must be removed down to the roots, and a trench excavated round the stations for a supply of rich soil. Prompt attention should be given to this matter, so as rather to anticipate the wants of the trees than to wait till unmistakable signs of debility compel attention to it. Give a surface dressing of old hotbed or farmyard manure 3 or 4 inches thick to Gooseberries, Currants, Raspberries, and Blackberries, among which there should be no digging after they are thoroughly established. Rhubarb should have its annual supply of manure now dug in so as to thoroughly enrich the bed. A warm corner should always be devoted to a few plants of Prince Albert or Johnstone's St. Martin's for an early supply to follow the forced Rhubarb.

Training.—Let the training of trees, young and old, closely follow the pruning. Look closely over old fastenings, remove any that are tight, and replace all that are rotten with new ones. Train no young trees horizontally, but let every branch point upwards either vertically or diagonally, for that is the only way to maintain an equal distribution of vigour. Make this a fundamental rule in training, and then impart whatever form to each tree expediency or fancy may suggest. The most popular and useful forms are the Fan, which has the branches spreading out right and left diagonally in the form of a fan; the Palmette Verrier, with stem from which the branches start in pairs on either side of and at right angles to it, with each end turning upwards parallel to the stem, so that eventually the tops of the branches are all at the same height; the Cordon, with a single or double stem trained either diagonally or vertically, with fruiting spurs on the entire length of stem, but with no branches; the Pyramid, which is a symmetrical cone having a stem with branches longest at the bottom tier and shortened gradually in the upper ones, so as to impart the requisite tapering outline; the Bush, having its branches trained in the form of a basin, and the laterals either pruned to spurs or left altogether unpruned. The Standard suffers so much from wind that it is only suitable for sheltered orchards. The small branches of Peaches and Nectarines may be unfastened in readiness for pruning, which should not be done for a couple of months.

PLANT HOUSES.

Forcing House.—Where a large and continual supply of cut flowers are required forcing operations must now be pushed on without delay. The house or pit to be set apart for this purpose should be thoroughly cleaned by washing the glass and woodwork and whitewashing the walls. Leaves are plentiful, and if stored when dry for the purpose will, if the beds of the house are now filled with them, and a little litter from the stable intermixed, a steady and a gentle bottom heat will be afforded for a very long time. It is important that the leaves used be dry, for upon this depends the length of time that they will keep up a gentle heat; if, on the other hand, they are wet, the heat produced will be violent, but will not last long. The moist genial heat supplied by means of a bed of leaves is far more suitable for forcing operations than the dry heat derived from hot-water pipes. Do not use too much litter from the stables amongst the leaves, or the ammonia thrown off at first will prove injurious to Azaleas and such plants if placed upon the bed at once after it is made up.

Lilacs, Azalea mollis, Gueldres Roses, Deutzias, and others may be plunged in the bed after it is found that the heat is not too strong. Azalea indica and its varieties should not be plunged, but stood upon the surface of the bed. Before introducing the latter wash them with tobacco water in which a little soft soap has been dissolved, so as to destroy any thrips that may be upon the plants, for after introduction into heat they increase very rapidly. The varieties that will force into flower the earliest are A. amoena and its varieties, A. narcissiflora, and A. indica alba. The second-named is a gem, the earliest flowering of all Azaleas, and is doubly valuable because its flowers are semi-double and pure white. How easy autumn forcing may be rendered by assisting the plants early to make their growth! To prove the advantage of this system over hard autumn forcing we may say that we have a house full of these plants, which will unfold their flowers directly the most gentle heat is applied; in fact, they are already coming into full bloom in a cold house.

Lily of the Valley should be plunged into the bed of leaves and their crowns entirely excluded from light, and they will from this date move rapidly and unfold their choice and delicate sprays of sweet flowers. A few of the earliest Hyacinths, Tulips, and Narcissus may be stood upon the bed to make a start. The same applies to Spiræas and other plants required to be forced into bloom. At first the bed of leaves will supply all the heat that is required, but if the nights prove cold maintain the night temperature at 50° by means of the hot-water pipes. The plants, after they are started, should be syringed twice daily during bright weather, and a little ventilation should be given when the weather is favourable during the morning, but close early.

If Lilacs are required white force them into flower in brisk heat in the dark, or place them in a pit where the heat is brisk, and exclude the light by means of mats secured upon the frame. The variety known as Charles X. is the best for this purpose, and home-grown plants will come into flower earlier than continental plants will; in fact, home-grown plants are decidedly the best for early forcing. A batch of Cyclamen, if required, will soon come into flower if placed on a shelf near to the glass in this house. A few Epacrises, if wanted early, may also be introduced, and will come into flower in a temperature of 50°, but they should be stood upon the curbs of the bed, or upon a board laid upon the bed of leaves. We prefer bringing them into flower without the aid of bottom heat.

Clematis.—These plants are beautiful when grown in pots for forcing; the small-flowering types, such as Lord and Lady Londesborough, Miss Bateman, and others, are the best for early work. The plants must be grown in pots and well established on trellises before they are suitable for forcing. Our plants are still outside, but the time has arrived for removing as much of the surface soil from the pots as possible, and replacing it with new rich compost. The drainage must be attended to at the same time, the plants cleaned, tied neatly upon their trellises, and placed under cover in a cool structure. Those anxious to start their cultivation for forcing should obtain strong plants established in 5-inch pots, and place them at once if well rooted into others 3 inches larger, and stand the plants in a cold frame or in the greenhouse, and train their shoots to thin cord next season under glass. Use for a compost good fibry loam, a seventh of manure, and a little coarse sand, pot firmly, and drain the pots well, for a good supply of water is needed while the plants are growing.

THE BEE-KEEPER.

ABOUT BEES.

My experience only dates from last spring. I therefore approach the subject with the greatest diffidence and every possible deference. I took to four colonies in bar hives (Neighbour's Garden Hive, which have nine bars, and a box of sectional supers) and two in straw skeps. The spring was very unfavourable, though the bees were busy on the Peach blossoms under glass, and had plenty of pollen from the Crocuses; but the frost in spring robbed the workers of much they might otherwise have made use of by the destruction of most of the Apricot and outdoor Peach blossom. There was no doubt that food fell short, and a strong colony so made war on its weaker next-door neighbour. They fought desperately, the weaker in the end

succumbing to the strong, and the remnant that remained threw in their fortune with the invaders and joined their despoilers. The slain were a great heap on the floorboard—thousands, quite equal in bulk to any swarm of the season. The strong colony, added to by the survivors from the robbed hive, was now apparently the strongest of the three remaining, and they set to work in right good earnest. Drones were plentiful early in June from this stock, and these made much essay over the empty hive adjoining, entering it and making but a short sojourn, returned to the strong colony, which I will call No. 1. The workers of this returning loaded with pollen in many instances, alighted on and entered the empty hive, and soon came out again and went to No. 1. This continued for some time, in fact until a swarm from No. 2, another strong stock, was put into the empty hive, when the stragglers lost their identity. Whether they learnt better manners and kept to No. 1 or joined the comers into their old habitation, which I will call No. 4, is matter for conjecture, certain it is that everything went well with these after the empty hive was stocked. No. 3 was a weak one, and No. 2 began paying it attention in April after the spell of severe weather, but by closing the entrance so that only a bee could pass in at a time matters turned in favour of those acting on the defensive; and No. 2 having drones very busy early in June, but not nearly equal in numbers to No. 1, a swarm issued at the middle of the month and were put in No. 4, the robbed empty hive.

I knew just nothing about hiving, but of course everybody that kept bees knew exactly how to hive them. They kept them in straw skeps, and it must be done in these first and the bees afterwards transferred to the bar hive. I could not see my way to this, so I got a galvanised bucket, took the bar hive handy, took the top off, put the frames in position, had the hair and bottom cloth ready, opening the mouth to the fullest extent, and shook the bees from the cluster into the bucket, which was not of sufficient capacity to hold the whole, carried them and upset them into the hive among the frames, put the cloth half way across the bar and from the right-hand side, covered all but the front side with a sheet, and left the bees to settle down, which they did in a short time, and was then, after the other half of the cloth was turned down and the top put on, shifted to their permanent quarters.

No. 2 threw another swarm, which was slightly less heavy than the first, and then set to work and filled a whole box of sections (twenty-one) with 2 lbs. of honey each. No. 3 cast a good swarm, and became as strong as either of those from No. 2. Two swarms issued from the skeps and were hived in bar hives, and a second came from one of the straws and were hived in a bar hive. This was very weak, made headway for a short time, then a few days' wet weather in July set its neighbour to visit them, and the colony soon became extinct. The robber hive not only took what little honey there was, but the whole of the bees from the despoiled hive, there not being any dead ones about. The bees, I presume, from the lost hive came home heavily laden, entered their late home, but soon came out again and entered that of their victors. Thus the bees did what I ought to have done—viz., joined the two weak stocks or swarms together and made a strong one.

Thus I only had four strong swarms out of five stocks, No. 1 not having swarmed, and have now seven stocks in bar hives and two in skeps—a very poor season's work, as I apprehend, on the score of increase of stock; and in the matter of honey, I took four boxes of sections, representing eighty-four sections of 2 lbs. each, or 168 lbs. of the clearest honey possible.

Out of the four swarms three took to the right-hand side of the hive, looking from the front of the hive, and one only to the left. Why? I reasoned about this, and it resolved itself into this: that in turning the bees into the hive from the bucket it was done from behind, and the bees would necessarily fall into the right side of the hive, whilst those turned-in in front would fall towards the left, and as there would be a greater number on that side the queen would probably be with them, therefore the work would commence on that side, hence I conclude there is nothing in it; but as the dividing bar is on the left, I presume the bees should always be turned in so that they drop to the right-hand side of the hive. The gleanings are small, yet not unimportant. First, the bees ought to have been fed in spring, which would have helped on breeding and conduced to earlier swarming, or, if swarming were not wanted, to a greatly increased gathering of honey from the increased number of workers. Second, the difference in the swarms from the bar hives as compared with the skeps, the strongest from the skeps not being more than two-thirds those from the bar hives, and sometimes not more than half: it is astonishing how soon even a small swarm from a skep breed up to a strong one in a bar hive. Third, the advantage of

having as much food for the bees as near home as practicable. We have a great breadth of herbaceous border, and there is always something in flower from early spring to late autumn, and a great number of flowering shrubs; and I found that on even wet days the bees were very busy on the flowers near the hives, whilst at a distance of a quarter of a mile the flowers were comparatively neglected.

Staple articles as bee food were Crocuses, blossoms of fruit trees, Almonds, Box, Honesty, Borage, Mignonette, Lime, and Ivy; abroad, white Clover and other plants—this being a purely agricultural district, no Heather, and plenty of bees about, which I think should be taken into account by anyone embarking in the pursuit. Bees, I am told, have a partiality for blue-coloured flowers. Is this a fact? I know they love Borage, Sage, and Cornflower, also the purplish Honesty; but I found them more abundant on Mignonette than any garden plant, and outside on Clover.

I have read about bees enough to make anyone believe they might be done anything with, only cast away fear. I have seen some of these try it and get their eyes "bunged up" with hiving bees in shirt sleeves rolled up, and other, to me, foolish exploits of hardihood. Our bees are not of this docile description, they have stings and use them; and as they pay me very particular attention at all times, I think discretion superior to assuming valour where none is wanted, therefore act always with a "dress," and get an insight which I fear would take as many years as I hope to accomplish in months.—G. ABBEY.

TRADE CATALOGUES RECEIVED.

Richard Dean, Ranelagh Road, Ealing, London.—*Catalogue of New and Choice Potatoes.*

Hogg & Wood, Coldstream and Dunse.—*Catalogue of Nursery Stock.*

TO CORRESPONDENTS

* All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (R. E.).—The information you require on the book, "The Culture of Vegetables and Flowers," lately reviewed in this Journal, can be obtained by writing to Messrs. Sutton & Sons, Reading. We are not able to answer your inquiry.

Primulas (F. Barron).—The lid of the box was quite crushed in, and the flowers consequently much injured. The variety appears to be a very fine form indeed of the Chiswick Red, and is well worthy of preservation.

Erecting a Greenhouse (G. B.).—As everything depends on the position of the house it is impossible that anyone can answer your question without seeing the structure as erected. In all probability the surveyor is right, as he would not venture to extort money to which he had no claim. We advise you either to pay the fee if demanded, or to consult a solicitor before refusing to do so.

Gardeners' Benefit Society (Canadian Subscriber).—We are not able to say with certainty whether gardeners who were born in the United Kingdom and served in the same capacity there, and now living in the colonies, are eligible for membership of the United Horticultural Benefit and Provident Society. We believe, however, that at least one member of the Society in question is now living in America. Perhaps Mr. McElroy will give information on this point.

Grapes Unsatisfactory (Novice).—This, we have little doubt, is one of the many cases of "gardeners' greed" that are brought to our notice every year. The Vines are overworked. Less fruit and more roots, with an ample food store, is the remedy. We should cut the Grapes at once and preserve them by inserting the ends of the laterals in bottles of water, then forthwith adopt the practice described by Mr. Iggulden on page 287, the issue of October 4th. If you succeed as well as he has done—and there is no reason you should not—you will be well satisfied with the result of your efforts.

Petroleum for Destroying Insects (Idem).—We know of no better method of preparing it than dissolving 4 ozs. of soft soap and a lump of

washing soda the size of a walnut in a gallon of boiling water; then stirring well in this 4 ozs. of petroleum; add to this four gallons of water, stirring well again, and you will have a mixture that may answer your purpose. It will destroy most kinds of insects and injure few plants, yet should be applied with caution with any of a very tender nature—that is, trying its effect on a plant or part of one before using it generally through an entire collection. The mixture will keep in bottles for any length of time.

Mushrooms (Abbots Langley).—Although we do not consider the Mushrooms you have sent of the best quality, we apprehend no danger in using them provided they are not allowed to become old and black before being cooked. Perhaps only a few of them are similar to the examples before us. If they all come like them we should send a sample to the vendor of the spawn and direct his attention to their abnormal character. He will no doubt be obliged to you for doing so, as few nurserymen make their own Mushroom spawn.

Dressing Peach Trees and Vines (E. D. O.).—We never apply any pigment to our Vines, but wash them with a solution of nicotine soap, Gishurst compound, or soft soap, whichever is most handy, dissolving 3 or 4 ozs. to a gallon of water, and applying it at a temperature of 150° with an old spoke brush. The rods are thus cleaned and the Vines free from insects. If a pigment is wanted apply sulphur in sufficient quantity to form a paint, and with this dress the Vine and Peach tree branches. This is a very good dressing for Peach trees.

Chrysanthemum Hon. Mrs. Roger Eykin (W. A. W.).—When you sent us blooms of your sport from Guernsey Nugget last year we recorded an impression that it was a variety of promise. The blooms now before us are much finer than the previous examples, much smoother than Guernsey Nugget, and distinct from all other Chrysanthemums. The colour is primrose suffused with delicate pink; the petals broad, quite incurved, and blooms large and symmetrical. They are a trifle flat, but, fully developed, the variety, we feel assured, will produce deeper flowers. Half a dozen florets taken indiscriminately from one of the blooms are each fully half an inch in diameter. If you can improve the blooms as much next year as you have done this you will have established a very effective variety.

Loam for Orange Trees (Kirby).—Provided the soil is moderately strong you cannot have any better than that skimmed off granite, and it would be improved in fertility by having the grass side charred. In that case it may be used at once if needed. If it is somewhat poor it would be well to stack it up in layers alternately with half-decomposed manure and use it a few months hence, at the proper time for repotting or planting the trees.

Maximum Thermometers (Idem).—Your thermometers are evidently made on what is known as the "Rutherford" principle. They are a little cheaper than the two forms now generally used (the "Phillip's" and the "Negretti"), but are very liable to become deranged in the way you describe. We would recommend you to get a Negretti maximum, as it is impossible without breaking it to put one of these thermometers out of order. Any good optician should be able to supply thermometers on this principle, or they may be obtained of the patentees, Messrs. Negretti and Zambra, Holborn Viaduct, E.C.

Chrysanthemums in Small Pots (Aspiro).—We agree with you that the miniature plants exhibited by Mr. Molyneux at Winchester were "quite charming." We have grown many similarly small plants of Pompons by inserting the cuttings just when the buds are forming, and striking them in a close frame, afterwards supporting the plants with liquid manure. The large-flowered varieties referred to were no doubt similarly raised, and perhaps in due time Mr. Molyneux will detail his method of producing them. In a matter of this kind, however, very much depends on the skill of a cultivator, and the gardener in question certainly ranks amongst the most competent of Chrysanthemum growers. Each cutting should be inserted in a separate small pot.

Selaginellas and Orange Trees (M. R. D.).—Whether Selaginellas can be grown on the surface of the pots containing Oranges and Camellias without injuring them depends very much on their condition and the method of culture adopted. If the Oranges and Camellias were at all unhealthy we should certainly not surface the pots with the plants in question; and, again, if the trees were healthy we should not like to allow the Selaginellas to remain year after year, as they would impoverish the soil. A safe plan is to spread 2 or 3 inches of rich rough soil on the surface of the pots, which we presume are large, and plant sprays of the Selaginella annually in spring. A fresh green covering is soon established; then at the time of planting again remove the plants and top-dressing, adding fresh, and planting sprays as before. We have adopted this plan with great satisfaction, and the Orange trees received no injury whatever. We are obliged by your letter.

Plums as Low Standards (C. H., Antwerp).—We know of thousands of trees grown as low standards. They only need to be carefully planted in well-drained fertile soil to succeed, requiring little or no pruning. You will find the method of pruning bush fruit trees concisely described in our "Garden Manual," under the heading of "Pears;" the work gives instructions in the culture of all other hardy fruits. You would probably also find Mr. Bunyard's small work on "Fruit Farming" useful. Its price is 1s. 6d. post free in England. A remittance for the work sent to Mr. Bunyard, nurseryman, Maidstone, would have attention; and the "Garden Manual" will be sent to you by post from this office by the publisher on his receiving the sum of 1s. 9d. If after reading these works you require additional information, we shall be glad to supply it as far as possible on your making your wants known to us. We are obliged by the friendly offer conveyed in your letter, and will bear it in mind.

Planting between Young Wall Trees (A. M. B.).—Red and White Currants are the only fruit it is customary to plant between the permanent occupants of walls, and these are gradually removed as the trees spread out to them. Probably your gable end of the house will afford space for a Pear cordon or two 18 inches apart trained vertically midway between the Apricots, and also one or two on each side, near the corners of the building; even if you could only have one in the middle, and one on each side the three cordons taken right up to the top of the gable would look well, and afford

you many dishes of excellent fruit. These cordons require so little space that there would be no necessity for removing them. Here are three good Pears suitable for the purpose:—Williams' Bon Chrétien, Doyenné du Comice, and Glou Morceau. If, however, you prefer flowers, then such annual or biennial climbing plants as *Tropæolum canariense*, *Cobæa scandens*, and *Ecchremocarpus scaber* might be grown while space remained for them.

Planting Vines in a Span-roofed House (J. R.).—The number of Vines you may plant in a house 24 feet by 12 feet ought not to be more than 6 or 4 feet apart. As your house is a cool one and the Grapes for market, you could not do better than confine yourself to Black Hamburgh; but as you ultimately intend to have a flow and return 4-inch hot-water pipe all round it may be worth a consideration whether you could not do this at once, and in that case we should advise your planting Lady Downe's and Gros Colman instead of Hamburghs, as late winter Grapes realise a better price than autumn Grapes, as these have then to compete with imported produce. The Vines should be "trained up one side the span and down the other," especially if the roof has a sharp pitch, but if rather flat the Vines may be trained from end to end on a trellis having the same incline as the roof, and about 18 inches from the glass. In laying down the front of the house in grass the Vine border should be kept clear, the border not being less in width than that of the house. Grass would not only keep off the sun's rays and rain, but impoverish the soil and prevent the application of surface dressings, which are essential to successful practice. The Vines may be planted on the east side of the house in preference to the west, but either will answer. In planting, the whole of the soil should be shaken from, or preferably washed off the roots, these being disentangled and laid out as straight and evenly as possible on the surface of the soil, and covered with 4 to 6 inches thickness of good mellow loam, and afterwards receiving a good watering with tepid water (100°), then mulched with short manure about 3 inches thick. The best time to plant Vines is in spring, when they have made a growth of an inch or two. If the weather be bright it is well to shade for a few days, keeping the house close and moist. Fruiting canes feel the check of dis-soiling and laying out the roots more than the smaller planting canes, and this has probably led to those planted with halls in your case doing better than when all the soil had been removed.

Planting Peach Trees (John Bradshaw).—We have never seen better Peaches than from trees grown in a border 15 inches deep resting on a gravel subsoil; but the border was composed mainly of good turfy loam of medium texture, and was mulched liberally with manure. You say you have some doubt as to whether your soil is suitable for Peach trees, yet omit to say one word as to its nature. All we can do, therefore, is to advise you to mix lime rubbish and gritty matter with it if it is heavy, and strong loam or clay dried and crushed if it is light. The trees may be planted at once, and a good covering of manure placed over the roots. You do not state the number you require. The following are good varieties for succession, and will ripen in a house without fire heat:—Alexander, Hales' Early, Rivers' Early York, Gros Mignonne, Royal George, Bellegarde, and Barrington. These will probably be as many as you require. If you desire to plant a Nectarine or two, Lord Napier (early) and Pine Apple (late) will probably give satisfaction. If you can make the border 6 inches deeper by adding fresh loam, or such soil as would grow first-class Potatoes, you will not err by doing so. You must be careful, too, not to keep the house too close in winter, or the blossom will expand too soon, and be cut off by spring frosts, notwithstanding the protection of the glass. We have seen many failures in unheated Peach houses, and we always think a well-built house incomplete where no provision is made for heating.

Genera versus Species (W. B.).—If you read the remarks of "R. I. L." upon this subject, page 458, you will be able to form some idea of the difficulty attending the matter; in fact, it is almost impossible to give a definition of a species that is not liable to many exceptions. Botanists must have some definite lines to work upon, and therefore when a competent and recognised authority describes the characters of a newly-found plant that is sufficiently distinct, and bestows upon it a name, this name is associated with the characters and accepted as a species. If another plant should be subsequently found, or raised from seed, closely resembling the other in all essential characters—namely, those relating to the fruit and flowers, but differing possibly in some minor particulars, such as the colour for example, it would be termed a variety. But there the difficulty begins. Many plants are extremely variable when raised from seed, and of two so-called species of plants, very nearly related, forms may be obtained from each that will seem to form a series of links in the chain of relationship until one is reached so exactly intermediate that it is almost impossible to state to which side it belongs. A species is really a group of individuals which closely resemble each other in certain accepted characters, and amongst these individuals may be one differing from the others in some points, and if this is perpetuated we get a fixed variety or race. A genus, again, is a group of species agreeing in some broader and less variable characters; tribes, sub-orders, and orders being simply still higher and larger groups formed in the same way for the sake of classification. The specimen shall be examined.

Names of Fruit (F. Jones).—1, Bess Pool; 2, Blenheim Pippin; 3, Hall Door; others not known. (H. C.).—1, Ten Shillings; 2, Sweeny Nonpareil; 3, Court of Wick. The others probably local varieties. (E. J. O.).—1, a grand Apple, but not Cellini. Where did you get it? 2, Kentish Fill-basket; 3, Gloria Mundi; 4, Golden Pearmain; 5, King of the Pippins. (W. W. W.).—1, Minchull Crah; 2, not Duchess of Oldenburgh: not known; 3, Blenheim Pippin; 4, Sturmer Pippin. (J. B. C.).—Pears: 1, Beurré Diel; 2, Nouveau Poiteau. Apples: 1, Dumelow's Seedling; 2 and 3, not known; 4, Kedleston Pippin. (J. F. C.).—Golden Noble. (Thomas Parker).—2, Golden Pearmain. 4, Hollandbury. Are not the others local varieties? (R. I. Lynch).—1, Dr. Harvey; 2 and 3, not known. Pears: 1, Seckle; 2, Beurré Superfin.

Names of Plants (G. Long).—As we have previously stated, it is impossible for us to undertake the naming of florists' flowers. There are so many of them so closely resembling each other that the names cannot be satisfactorily determined without comparing the flowers with others in a very large collection. The small-flowered variety is probably Eleonore;

the others are much too imperfect for identification without actual comparison with other flowers. (T. B.).—The flowers were much crushed, but Brassia resembles *B. verrucosa*, and the Brassavola is *B. venosa*. (Ardent Reader).—Such diminutive scraps of plants are totally insufficient.

COVENT GARDEN MARKET.—NOVEMBER 28ST.

MARKET quiet with fair supplies. No improvement in Kent Cobs.

ERADICATION OF COUCH, TWITCH, AND OTHER WEEDS.

THIS is an important operation, not only because it is so difficult to accomplish by ordinary tillage, but also in consequence of the expenses incurred. Economy must be the basis of all operations for freeing the land of couch or twitch grass, but also of onion grass, black bent grass, and some others which are indigenous to certain soils and climates. There are also some weeds which root under ground, and propagate from the roots, such as the coltsfoot, one inch of which if left in the land being sufficient to propagate and cover a considerable surface. There are various other weeds well known to practical men under local or provincial names; we therefore do not attach any particular importance to give the botanical names. These, however, are given fully in an excellent essay by Mr. Bravender in the "Journal of the Royal Agricultural Society of England," and may be distinguished not only by the practical man by provincial names, but also by illustrations of the growth and seed heads of the various species. This subject, now more than ever, has been prominent during the many past wet seasons, and the result of serious changes of tenancy and disastrous failures left large acres of arable land in the worst possible state, and covered with couch and weeds oftentimes over the whole extent of what used to be useful corn-producing farms; it therefore becomes a landlord's as well as tenant's question.

The couch or white-rooted grass which increases under ground as well as on the surface, is peculiar to all those soils of a sandy nature. It should be guarded against not only by fallowing at the onset and eradicating in that way, but also by arranging such a rotation of cropping as will give not only the most frequent opportunities by fallowing, but also of forking out at all intervals of cropping, or during the infancy or fall of the leaf of such crops as would not be injured by this process. These small pieces, though not likely to do any serious injury to the present crop, will if allowed to remain become parents of a large succession, and in all weather except frost can be removed, and thus prevent not only the growth of the white roots by night and by day, but also the serious and costly horse labour which can only be successfully carried out in the finest of weather at certain seasons. We are induced to speak firmly and decidedly upon this subject, having repudiated fallows as the means of clearing land and thereby preventing a quick succession of the most valuable crops, as we continued to fork out couch for a period of thirty years, and under which system no fallowing was required except an amount of tillage necessary only to promote

the successful growth of such crops as Potatoes, Mangolds, Carrots, Cabbage, and Turnips of sorts. It seems that even now, after so much has been said and written upon the subject of fallowing, that many parties do not discriminate between the hand labour compared with horse labour when a long fallow is required, and the forking-out of couch at all times and opportunities, and thus prevent the necessity and expenses of fallowing. Various farmers up to the present time are as great advocates as ever for a system of autumn tillage for the purpose of cleaning the land; now this work takes place at a time of year when all the great and important seedings for crops should be going on, such as Rye, Trifolium, Tares, Winter Beans, Winter Oats, and especially of Wheat. To show how this serious displacement of the essential seeding of these crops, we can only say never delayed our tillage operations, and that as we always forked out couch or twitch at every opportunity, we never lost a seed time of any of the many crops for sale which we grew for a very long period.

In an article by a correspondent in the "Agricultural Gazette" on the 10th of May, 1880, it is stated in speaking of "eradicating couch grass," that "Twenty years ago we used to hand-pick couch; but since then labour has become dear, scarce, and less laborious. To hand-pick couch means a terrible expense per acre. Is it, then, advisable to undertake the work? Such is a question which we have been revolving for some days or weeks past. Here is the couch lying in tiny bits over the surface. To hand-pick it is a slow and expensive job which would require more hands than we can spare. Women labour cannot be procured, childrens' labour is forbidden by the Education Act, and man's labour is not suitable. On the other hand ploughing-in such small pieces of couch means fresh seeding of the ground and new troubles with the enemy in future. What, then, is to be done? We confess ourselves to be fairly on the horns of a dilemma between cleanliness and cost."

The whole of our life endeavours have been expended in solving the problems which appear so difficult, and we have escaped the difficulties dependent on foul land requiring to be cleaned by an ordinary fallow. During that time, especially in the winter months, we quite agree with Sir J. B. Lawes when he says an uncropped surface under tillage loses a large amount of fertility, and probably of a sufficient amount to pay the expenses of a well-devised system of forking out. At any rate if we get rid of the lumps of couch in each field as the opportunity serves by forking we have neither loss of fertility nor expensive fallows to make, for let it be understood that the whole and sole reason of a long fallow being required illustrates two things most prominently—namely, that the rotation of cropping is wrong, or that the expense of forking out has been repudiated or neglected. We see the first question asked by the author of our quotation is—"Is it, then, advisable to undertake the work?" We say, No, you are on the wrong tack, you have entered upon the making of a long fallow. Nor can a short one be made of it by picking up tiny bits of grass, for either you must make a long fallow, or possibly, if unfavourable weather prevails, it cannot be made at all during that season, entirely because the hand labour of forking has been neglected.

The next question asked by our correspondent from whom we have quoted is—"What, then, is to be done? We confess to being on the horns of a dilemma between cleanliness and cost." You have no alternative but incurring the expense of cleaning the land or let it lie almost in a state of waste for the feeding of dairy cows. This involves the consideration of how best the land can be kept clean; and all the experience we have to fall back upon, and all the evidence which can be obtained from the best farmers of those soils most subject to couch, refers to the making of long fallows as being not only the most expensive but also the most uncertain of accomplishment, in consequence of the horse labour being so costly. On the other hand, if the season is unfavourable it is a failure, and the land not cleaned whatever might have been the cost. On referring to the use of the fork in eradicating couch, the cost when done with judgment and continued through the year must be successful, as we can prove on our farm, which was not fallowed for a long series of years, and was never foul during the whole period. As regards the certainty of its operation, the work being spread over the whole year makes it certain of accomplishing its object, that of clean farming. With regard to the actual cost, this will be moderate done under the proper supervision of the farmer, and when compared with the attempt to clean land by horse labour, couching, or tillage, we must remember this cannot always be done, while the forking is, or should be, continuous; and then it will be successful. Let us consider for a moment the comparative cost as between horse labour and forking by hand, and it will be found that one good man for ten months in the year in

forking will displace one horse on each hundred acres, and with greater success in various ways.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—Horses are still employed at every fine interval in ploughing, the land being seeded with Wheat as fast as the ridges are ploughed, and upon dry soils, such as limestone, gravel, sand, and thin chalk, the Wheat seed has gone in well. Upon some strong or mixed soils a considerable breadth has not yet been seeded, and will probably be held over for Lent corn, either Barley or Oats, by sowing the former on the driest and kindest land, and the latter on the coldest and strongest land. Fallow-ploughing upon those farms where all the Wheat has been sown will be going on, and various modes ought to be adopted in accordance with the nature of the soil and its condition. We may here note that any soil in good condition and clean should have been seeded with catch crops soon after harvest, especially where a flock of sheep are kept. Upon those farms where green manuring finds favour such crops as stubble Turnips and Rye will be ploughed-in in the spring instead of feeding with sheep, in order that a cereal crop for sale may be taken with great advantage. We passed over land to-day (November 22nd) which had grown a full crop of Trifolium cut up for soiling horses, and afterwards tilled and drilled with red round Turnips at 14 inches apart; there was a full plant with very gross leaves, the land having been manured with 3 cwt. per acre of bone superphosphate; but the roots were never hoed, and therefore no expenses incurred as when intended for sheep-feeding. The crop, however, was being ploughed under after the greens were mown off, and any bulbs requiring it were chopped, and a very full dressing it must be according to our experience for the Wheat which was being sown as fast as the land was ploughed. In many districts roots are so plentiful, and sheep so scarce and dear, that when offered for sale the roots cannot find a purchaser, and in consequence a large acreage will be, or ought to be, ploughed in for Wheat, and again in the spring any super abundance may or will be also ploughed under for Lent corn.

Live Stock.—Sheep are generally very healthy and in good condition, the growth of grass having been continuous upon all good grazing pastures. The ewes, either of Shropshire Downs or long-wooled breeds, are very promising, for they have for the most part taken the ram. If a moderate supply of grass can be eked out during the winter, with only hay in addition, leaving out roots altogether, so much the better, for we well recollect a friend, instead of feeding the chalk hill pasture close with sheep during the summer, made a practice of reserving the grass until the winter months for the feeding of his fine flock of Hampshire Down sheep, and never would give his in-lamb ewes any hay or roots unless frost or snow made it a necessity, and with uniform advantage at lambing time. This farmer occupied land on the chalk hills on one estate for fifty years with great success. The Dorset and Somerset horned ewes have well-nigh finished lambing, and in numerous instances half of the flocks have yeaned twins. Some of the earliest of these are now feeding with full allowances of cake and beanmeal mixed with white Carrots cut fine with Gardner's cutter, and they run before the ewes, they get a full picking of Turnip-greens. In various instances about every tenth drill is seeded with Rape, thus affording the most valuable green food which can be obtained. The choicest lambs, however, we have ever seen or made were fed in advance of the ewes without any green food at all, the roots being stacked or heaped for cutting and feeding of the ewes, with hay and cake in addition, the latter being mixed as meal with cut roots; but the lambs received all their food in troughs, such as the best Dutch Clover hay in chaff, and cut Carrots or Cabbage, at first with cake and beanmeal mixed with the roots, cut as fine as dice.

FIRING AND VENTILATING.

THESE are of no mean importance in cultural practice; indeed, very much depends upon the application of heat and air in the cultivation of plants under glass in relation to a successful or unsuccessful result, and they bear such a correlation to each other, especially in forcing operations, that the one depends greatly upon the other as to the method of applying them.

Every cultivator is cognisant of the importance of the heat being of the required degree, and yet we not infrequently find less knowledge, at least less attention, given to the matter than is considered needful in less important details. There may not be any great difficulty in large establishments where the heating apparatus is all-sufficient for its work, and the water in the apparatus kept at a temperature little short of boiling constantly, as it then resolves itself into a matter of regulating the heat by the valves, any not required being kept in stock that can be drawn upon as the necessities of the several departments demand; but the case is very different where a boiler has to do the work of but one or a few compartments, and the stoking is dependent on those but little experienced in the work. I do not propose to enlarge on the art of firing, only to point out that it is as well worth anyone's while to learn how to fire as it is to know how to attend to the requirements of plants in the matter of watering and ventilating, and the knowledge acquired on the latter point is of equal importance as that on the former in attaining proficiency in the art of gardening.

Although everybody knows that water cannot be made hotter than 212°, or boiling point, without its being converted into steam, yet it is well to bear in mind that the pipes may become too cold by an overdose of fuel; then by sharp working of the fire they are made quite hot again to atone for the mistake. Such, I need not say, is not good stoking. In fact more harm is done by this alternate roasting and starving process than any other in relation with heat. It is not corresponding to alternating blinks of sun and a cloudy sky, for the sun-heat fluctuations are accompanied with corresponding degrees of light, whilst this is not so with artificial heat, consequently the temperature needed by this means should be as little given to fluctuate as possible. The art of firing is to produce a temperature corresponding to that accorded by Nature to different descriptions of plants. It is vain to suppose that an artificial temperature can be produced superior to a natural one, yet an artificial climate may be produced in which plants will attain to greater excellence than in their native habitats; still, it is by a combination of conditions in addition to artificial heat that such are obtained, the plants not being subjected to any of the vicissitudes they incur in their native homes.

In the application of artificial heat the object should be to diffuse it at a temperature as low as is consistent with attaining the desired end. If we have a greenhouse it is pernicious to only provide so much piping that it must be kept at nearly 200° to exclude frost, as the heat radiating at so

high a temperature will dry the air in the immediate proximity of the pipes as to injuriously affect the plants. Sufficient piping to keep the temperature to the required degree without heating it more than to 100° would be far better. Then the artificial heat should always be such that the maximum temperature will be obtained in the daytime. Very frequently this is not the case, especially in cool houses. Fire heat is applied at night in case of a probable frost, and the temperature is kept at what? Well, I have often seen it over 50° at ten o'clock at night, because the expected frost has not come, and I have seen the same house the next day at 40°, with a current of air. The nights are thus turned into days, and *vice versa*. Softwooded plants soon became of a sickly green, and thin in texture of foliage, simply because the growth is made by the artificial heat in the dark. In this case the house should not have had the heat at night so as to raise it above the day temperature, and if it were needed at all the day should have exceeded that at night by at least 5°, or, if cold and dull, it may approximate as near as possible to the night temperature, or 40° to 45°.

In more highly heated houses extra heat is very often turned on in anticipation of a cold night. Those who do this know full well what it means—viz., saving themselves—providing for their own convenience, not that of the requirements of the plants. If the anticipations are not realised the fire will have raised the temperature many degrees higher than it ought to have been, and injury is done which with a few repetitions soon becomes apparent. There is no remedy for this but assiduous attention and thorough grounding in the practice of firing. A few degrees' lower temperature during sudden depressions of the external temperature are not injurious, but conducive to the health of the plants, as it is only so much more rest given them, and that they can hardly have too much, provided always that it be safe.

Then in forcing operations it sometimes is allowed to happen that a temperature is obtained which should never be tolerated. I have seen vineries at 70° at ten o'clock at night, when 60° was suitable, to allow of a fall to 55° by morning, and the pipes at the same time scarcely warm in the morning. Such is not good firing, but is a certain indication of the stoker never making a mark in his profession. But firing is dirty work. I know it, having had some twenty-four to look after when young, and half a mile to trudge knee-deep in snow to some of them when only owls kept awake. Things have altered since then, and the duties of under gardeners are very much less onerous. In the matter of heat it is only a question of turning valves in some establishments, and in most no more real work is needed than in using a poker, coal rake, and throwing fuel into the furnace. It is essential that firing be understood, and this comes of the exercise of some judgment in combination with practice.

In forcing operations sudden fluctuations of artificial temperatures are very baneful—in some instances fatal. There are a few points in connection with the application of fire heat in forcing that cannot well be overlooked. The first of these is to raise the temperature to its maximum from fire heat in the early part of the day, or within an hour or so of sunrise, and to maintain it at that until near night-fall. This will afford a long day of growth, and elaboration, and assimilation of the juices of the plants, and the growth so made will be firm and solidified, and the foliage leathery in texture, but it will be soft if made in a close atmosphere with the night temperature as high as the day. The second point is that of the night temperature being kept 5° to 10° lower than the day. This should commence to take place from dusk. The lower temperature will cause a cessation of growth, induce rest, and prevent that weak condition of the growth and thinness of the foliage only too frequently seen in forcing. A fall of 5° from dusk to nine or ten o'clock, and another fall of 5° by the time the house is entered in the morning, will approximate very nearly to a correct state of things. Then, as before stated, the heat should not be radiated at a high temperature, for where the pipes are

highly heated the growths in the immediate locality evaporate considerably, cooling their surfaces, which become soft and watery, unable to withstand sun, and forming a ready object for the attack and spread of red spider. Beds of fermenting materials are acknowledged aids in early forcing operations, both from the moisture given out and the mildness of the heat from the greater area of surface, than is the case with hot-water pipes.

As to ventilation, it seems almost needless to make any observations on this head now-a-days. If we are to credit the growing of Cucumbers without it, and if our ideas of ventilating vineries according to old notions are all wrong, I do not see this. Try keeping vineries, Peach houses, and plant houses without air. Ventilating houses through the laps of the glass sounds well in theory. Much of the heated and vitiated air passes out that way, and the balance is restored by that driven in by the wind. Waste is no doubt thus caused, but the roofs of houses are not the riddles they were. Small squares of glass were used, but large panes, reducing the laps or openings for the ingress or egress of air to a minimum, are now employed. Ventilating houses as described may answer for Cucumbers, but those grown on that system will, I apprehend, be short-lived; and for fruit and plant houses generally the plan is inapplicable.

Some, in the praiseworthy endeavour to save fuel, shut off the heat when it is likely to be a fine day, and to this there is no objection, provided it be turned on soon enough to hold up the temperature as the sun is observed by clouds, or when it declines. It is the reverse, however, of sound practice to stop the fire in the morning just because there is the prospect of a fine day. The sun heat may keep up the heat until it begins to decline in the afternoon, when, unless the fire has been set to work in good time, it drops to the maximum from fire heat long before dusk, and the fire heat only begins to tell at nights, and up the temperature goes to a dangerous point. Had the fire been kept going, the house could have been ventilated not only much earlier but more fully, commencing when the temperature rose above the day fire-heat maximum, and increasing it with the increased sun heat, so that the maximum from it would be gained at an early period of the day, and continued through it by commencing to reduce the ventilation gradually as the sun power declines, and withdrawing it altogether at the maximum for the day. Thus a good temperature will be insured during the hours of light, and from that the heat should gradually fall to the night temperature. This will be approximating to Nature without those sudden fluctuations which it is the object of the cultivator to prevent, and thus he may excel in growing plants better than they are seen in their natural state.

Air is essential to prevent a weak condition of the tissues, and to give firmness to the growths. Upon this depends very much the health of plants, their flowering satisfactorily, the fecundation of the blossoms, and the quality and flavour of their fruit. Air should never be given to lower the temperature, but to prevent it becoming too high. It should be given early, or as soon as the sun begins to act on the house; and were this more strictly attended to there would be less scorched leaves and fewer mishaps in other ways. It should be given as far as possible so as not to produce a current especially of cold air, and it is always better to allow a few degrees higher range of temperature from sun heat than admit cold air in quantity by the ventilators to reduce it to a given figure. It does not do to admit air to a house at 75°, so as to bring the temperature down, which ought to have been ventilated from 65°, for this gives a sudden and disastrous check. Even in dull sunless weather a little air is advantageous, as it keeps the foliage from becoming so soft and thin as to be unable to withstand sun. After very dull weather the foliage of many plants flags with a return of bright weather; more especially is this the case when the house has been kept close and moist, and which a little extra fire heat in the daytime so as to allow of a little ventilation would have remedied. In cases of this description, and

they are common enough in forcing operations, the ventilation of a house in bright weather following a dull period should be careful, it being better to allow the heat to rise than admit much air to keep it down, as with a comparatively close house the evaporation from the foliage will not be nearly so great as were an abundance of air admitted; then by increasing the ventilation from day to day very little effects of the transition will be felt, as the foliage will become gradually hardened through inuring it to a changed condition of circumstances.—G. ABBEY.

TRAINING RASPBERRIES.

A CORRESPONDENT ("F. J.") writes:—"What is the best kind of frame for training Raspberries to? Kindly give particulars enough as to height, &c., to enable me to make one, and say whether it is better to train the canes perpendicularly, or obliquely like cordon Pears."

As there are doubtless many persons who desire similar information, it will not be inappropriate to refer to some of the different methods of training that are practised, as each cultivator can then adopt the one that appears the best adapted to his position and circumstances.

It may perhaps be well to state at the outset that the greatest bulk of Raspberries—the hundreds of tons that are produced for sale in markets and for meeting the enormous demands of jam manufacturers—are gathered from canes that are not trained at all—that is, one neither supported by stakes, trelliswork, strands of wires, or tied to each other in the form of bows or arches. The canes are strictly self-supporting; but when grown in this natural manner there must be an absence of that dense overcrowding that is not unfrequently seen in gardens where growth struggles with growth in endeavouring to benefit by the light and air above them, the canes in consequence being long, soft, whip-like, comparatively destitute of woody tissue, immature, and essentially unfruitful. They are not of this character in the fields of Kent, but hard, sturdy, short-jointed, and in a condition generally to render stakes or any other kind of support quite superfluous. They may be also similarly grown in gardens where ample space is afforded them.

Several years ago some varieties of Raspberries were planted in a garden. Some of them were secured to stakes in the ordinary manner, others had strands of wire stretched from stake to stake, to which the canes were trained in continuous rows; but for testing the self-supporting plan a row of Carters' Prolific was planted by the side of a walk, and the canes after being duly thinned—not in the autumn after injury caused by overcrowding in summer was done, but in the spring to prevent it—were left to take care of themselves. Whether in consequence of the superiority of the variety or the plants receiving more air by being near the walk, or by a combination of both circumstances, is not perhaps exactly determinable, but certain it is this row always produced more than twice the weight of fruit afforded by any other row of the same length, whether trained to stakes or wires, the variety so grown being the true Fastolf, which is admittedly good.

It might be imagined by some readers that the untrained row in question had a slovenly appearance. The reply to that surmise is, that if such was the case no one observed it, even in winter, while in summer it was the most attractive of all, because so heavily laden with its large red fruit. This experience is recorded, not so much for the information of "F. J.," as for other persons, not a few of whom fancy they cannot grow Raspberries in their gardens because they cannot readily procure stakes, and are not prepared to incur the expense of making a wire or wooden framework for supporting the canes. With good soil and thin planting they may have the finest crops of this useful fruit without any such aids if they grow the true Carter's Prolific. Not far from Mr. Cannell's nursery at Swanley is a field of fifty acres, mostly of this variety—millions of canes without one stake, and from which ten tons of fruit are sometimes gathered during a fine morning before breakfast.

But to the training. If the canes are planted a foot apart in a continuous row, strong iron standards securely fixed at the end of each row, and two or three lines of strong wire stretched from post to post, these wires supported by lighter uprights of iron or wood at 9 feet intervals, make the best and most durable frame. Strong oak posts at each end of the row, however, answer well, but they must be well strutted, as represented in fig. 94, so that the wires can be tightly stretched. Many frames are made by driving down a row of strong stakes and attaching from stake to

stake two rows of strong roofing laths, or failing these, Kidney Bean rods; their formation is, in fact, just a question of means or expediency.

When strong posts are employed they should be inserted 2 feet deep, their height above ground to depend on circumstances. In moderately fertile ground, and with such a variety as Carter's Prolific, 4 feet will suffice; but in rich soil for such strong-growing varieties as Fastolf and Prince of Wales, the posts and stakes may be a foot higher with advantage. Mr. Bardney grows the last-named variety with canes 8 to 10 feet long. This, however, is exceptional; yet even these might by oblique training be disposed on a framework 5 feet high; and here it may be said that diagonal training should always be adopted when the canes are much higher than the fence, in preference to seriously shortening them. The tops may be taken off to the extent of a foot or so, but wherever the wood is brown and the buds prominent, it is a mistake to remove growth of that character, as such is more fruitful than the stronger portions below, where the buds are comparatively obscure. When the canes are not larger than the stakes which support the wires they may be trained vertically, and if every alternate cane is shortened at 2 feet from the ground, a better furnished row of fruit will be had than if all the canes were left their full length—that is, if they are numerous, or say 4 inches apart; if more thinly disposed—6 inches or more asunder—this alternate shortening is not needed.

For a 4-foot fence with two rows of wires or laths the lower may be 18 inches from the ground, and the upper 2 feet 3 inches

Fig. 94.—Wires for Raspberries.

above it; and as the canes may, if needed, be left nearly a foot above the top, and as the fruiting growths will be still higher, the hedge of fruit will be by no means a dwarf one. With posts 5 feet high three lengths of wire are preferable. When the frames for training are 4 feet high the rows should be 5 feet apart, and when 5 feet high they should be 6 feet asunder. This, it is hoped, will be sufficiently explicit for "F. J." and others whom it may concern. It is a simple record of experience, and on that account will not be the less acceptable.

A word on securing Raspberries to stakes will not be inappropriate. Is the time-honoured orthodox plan of driving in a stake through each stool the best? It is quite certain that by this method there is a great crowding of young growths, and these are not unfrequently broken or injured by defoliation in gathering the fruit. Is it not preferable to drive the stakes in line midway between the plants, one stake between each two stools, and to these stakes secure the fruiting canes right and left, thus allowing the young canes to extend between them, where they are not so much liable to injury and are exposed more fully to light and air? This, too, is an old system, but not by any means generally adopted. As will be seen on reference to fig. 95, six canes are grown from a stool, and these disposed as shown will produce more fruit than if bundled round a stake, the bending causing back buds to break and bear fruit that would otherwise be fruitless; while the growths for the following year have a better chance to mature than when crowded with the fruiters in the customary manner. When this method of training is pursued the stools should not be less than 6 feet apart. On paper the plan may appear fanciful, but in practice it is anything but a "fad," or it would not find favour with that stern utilitarian and first-rate cultivator, Mr. Richard Gilbert, at Burghley.

There may be other readers who have something much better to say on Raspberry training; if so, let them say it. To no one will the information be more welcome than—J. WRIGHT.

GAS STOVES IN CONSERVATORY.—May I beg the favour of any of your able contributors or readers who have used them, to give their

experience with regard to gas stoves for heating the conservatory? We have recently received one of Ritchie's patent condensing hygienic gas stoves for our conservatory, and I am rather apprehensive as to its effect upon the health of the plants. Any information derived from experience will be gratefully received by—F. W. C.

LEAF SOIL v. FUNGI.

In many gardens the preparation of leaf soil is only of secondary importance, while in others considerable care and attention are devoted to it.

The leaves collected here are from all kinds of forest trees—Oaks, Beeches, Elms, Sycamores, and others. It would be impossible to keep them separate, and even if we could the quantity produced from any one kind would be insufficient for our purpose. We take no trouble here now in the preparation of leaf soil, and have long since discontinued stacking it in heaps as practised in many gardens. Amongst a number of trees we have a square enclosure in close proximity to the pleasure grounds, and to which a horse and cart can enter when desired. The leaves are wheeled into this enclosure as they are collected, about a barrowful deep, no attempt being made to keep the place neat, for in that we should fail. The joiner's house is close by, and this leaf yard forms a grand run for his fowls, which turn over the heaps and pick out the grubs. The leaves never become heated, but are fully exposed to the action of the weather. Hitherto we have found the soil prepared under this easy process admirably adapted for the cultivation of plants.

Several years ago we were engaged in planting some evergreen shrubs during the month of May, and in the operation placed about the roots of the plants some leaves that had been collected in the previous autumn. At the time nothing wrong was observed, but in the autumn following alterations of another nature compelled the removal of some of the shrubs transplanted the previous spring, and we found the leaf soil round their roots a mass of fungus. The heap

Fig. 95.—Raspberry Training.

of leaves from which these were taken had remained undisturbed, and some time after we intended removing a good portion of them to the kitchen garden to enrich a piece of ground that had not been trenched for years. The heap inside was one mass of fungus, especially where they had become pressed firmly together, and remained in a semi-dry state. Wherever the rain had soaked through them and decomposition was well advanced, not a trace of fungus could be discovered. The conclusion then arrived at, and confirmed by later experience, leads me to the opinion that when leaves are stacked tightly together, and winter rains and air excluded from the interior, they are in the best possible condition for generating fungus. Only a short time ago, when burying leaves in some of the plantations and shrubberies, we found upon examination that those buried last year were very much decomposed and no fungus to be seen, but on the other hand, when buried near large trees, they were much drier and decomposition less advanced, fungus was to be found. Is it not the case with pieces of wood and branches of trees that have become buried and decompose in a semi-dry state, that fungi in nine cases out of ten is the result, and the very opposite when thoroughly soaked with water?

Since we left the preparation of the leaf soil to the action of the weather and fowls we have never seen any fungi in our compost. I do not believe there is any fear of it establishing itself amongst leaf soil if the leaves are not laid too thickly together. When mixed with road-scrapings, as described by "Single-handed," I should not fear the presence of fungus.—W. BARDNEY.

ORCHIDS OUT OF DOORS.

MESSRS. F. SANDER & Co. write:—"We herewith send you an article from M. Anton Joli, garden superintendent to Baron Nathaniel de Rothschild of Hohe Warte, and will thank you

to insert the same in your next issue of the *Journal of Horticulture*."

"I notice with great interest an article on 'Orchids in the Open Air' in the *Journal of Horticulture* of the 8th ult., describing the experiments of Mr. Smee, in which full particulars are also given of the results obtained. It was stated that this is the first trial of the kind made in England; but it may be of interest to Orchid growers to know the results we have obtained with similar trials in Vienna, at the gardens of Baron Nathaniel de Rothschild situated at the Hohe Warte. These trials have taken place not only during the past summer, but for four successive years, and on a rather large scale. This season the number of plants placed in the open air amounted to 2000. Besides these, 4000 seedling Orchids were placed out of doors. I believe that we have here far more difficulty than Mr. Smee has at his residence in England. The climate is milder and the air more saturated with moisture there, and Mr. Smee's garden is particularly well adapted, being shady and having several small streams. Here on the Hohe Warte the climate is rough and dry, the gardens being situated on a hill without shade. We have for the cultivation of our Orchids in the open air a space of 3500 square feet. The plants are shaded with span-roofed stages, under which water tanks are situated, each 45 feet long and 6 feet wide. Wooden lattice trellises are placed over the water, and on these the Orchids are placed. Below I have pleasure in giving a list of the results obtained during the past summer.

Date when placed in the open.	Name of Plants.	Date when placed in the houses.	Notes.
May 17th	Cypripedium insigne	Sep. 22nd	Grew strong and compact, and produced many flowers.
May 26th	Odontoglossum Insleayi leopardinum	Sep. 18th	Produced splendid pseudo-bulbs and flowers.
"	Odontoglossum pulchellum ..	"	Rested, and finished pseudo-bulbs well in houses.
June 5th	" Alexandrae	Sep. 3rd	Although late imported they made fine pseudo-bulbs.
"	" Roezli	Sep. 18th	Foliage turned very dark green, and plants are strong.
"	" vexillarium ..	"	Made many young growths.
"	" Phalaenopsis ..	"	Produced strong healthy pseudo-bulbs.
"	Cattleya Mossiae	Sep. 12th	Although lately imported they made fine pseudo-bulbs.
"	" Sanderiana	"	Had large quantities of young growths, which ripened well in houses.
June 7th	Coelogyne cristata	"	Very strong and robust.
"	" pandurata	"	Splendid results.
"	Dendrobium seedlings	Sep. 8th	Rested at first, but made later enormous pseudo-bulbs.
"	" moschatum	Sep. 12th	Produced immense pseudo-bulbs.
June 8th	Oncidium tigrinum	"	Made a number of growths.
"	Epidendrum alatum	Sep. 15th	Rested during the whole time.
"	" prismatocarpum ..	"	Rested, but began growing strongly when placed indoors.
"	" Stamfordianum ..	"	Made broad large leaves and pseudo-bulbs.
"	" cochleatum	"	Foliage very dark and with long spikes.
"	Laelia anceps Dawsoni	Sep. 18th	Rested, roots swelled splendidly, and foliage turned a very dark green. They started into fine growth when placed indoors.
"	Trichopilia suavis	"	Same result with the Aerides as with the Vandas. The foliage became greener, and they started at once into growth when under glass and flowered well.
"	" crista	"	Some made new leaves, others rested, but began growing vigorously when placed indoors.
"	Vanda caerulea	Sep. 15th	
June 30th	" suavis	Aug. 25th	
"	" tricolor ..	"	
"	" Denisoniana	"	
"	Aerides odoratum	"	
"	" crispum	"	
"	" Fiedingi	"	
"	" affine	"	
"	Saccolabium Blumei	Aug. 18th	
July 7th	Phalaenopsis Schilleriana ..	"	
"	" grandiflora	"	

—ANTON JOLI, *Garden Superintendent*."

EARLY MUNICH TURNIP.

AT page 429 of this Journal, "W. D. W." asks for information respecting this most excellent early Turnip. Its introduction into English gardens is due to the Royal Horticultural Society, I believe, who distributed it some eight or ten years ago (I speak from memory, which age does not strengthen, I can find, and so I may be wrong a year or two), amongst the novelties that they send out to their subscribers year by year. It is right that this fact should be known, as I have heard sneers about the "rubbish" and "useless trash" which the Society have sent to their members in these annual distributions.

The gardeners into whose hands Early Munich Turnip fell, however, treated it fairly, and, noting its merits, chronicled them in various gardening papers.

The gardeners who grew this Turnip first thought from its performances early in the season that they had a Turnip that was good all

through; but they found out their mistake. It is not a good garden Turnip generally and altogether; in the summer it grows coarse and strong, and tough, and high-flavoured, but as an early turning in Turnips there is none to equal it. At least that is so as far as my experience goes. It is a useable Turnip, quicker than any other that I am acquainted with, and I have matched it against all the early varieties that I could obtain. For that purpose it is a gardener's friend and will suit "W. D. W." or any other gardener who wants (and what gardener does not want?) young Turnips as soon as he can get them in the new year.—H., *Notts*.

ECONOMY IN STOKING.

THIS subject crops up every year and ought to receive serious consideration. Lately the experience of Mr. Inglis and "Dugald" has been placed before us. Mr. Inglis's remarks are certainly to the point, whilst "Dugald's" are rather complicated. Stokers may follow Mr. Inglis's teachings with advantage, but they should first learn the peculiarities of the boiler they have to attend to. There may be three saddles, or any kind of boiler, on the same place set as nearly alike as possible, but they generally require a little different attention either with the damper or ashpit door, and this can be only gained by experience. I have had to attend to the old saddle, terminal end saddle, Trentham improved terminal end, cruciform, tubular, gold medal, and other boilers as well. Some are stated to do the work well without any night stoking; but I have not had the pleasure of finding them. Certain boilers are stated to heat a certain number of feet of piping, and with this in view boilers are set to do the work. Perhaps several houses have to be kept up to a high temperature, and when frosty weather commences heat has to be turned on to several others, the result being, if the boiler is a very powerful one, that unless the stoker fires hard until late at night and starts early in the morning serious mischief might be done. I think the best system is to have two boilers, working one in favourable weather and the two together in case of frost or cold winds, and the result will be a smaller fuel bill than if only one had been employed.

Another mistake is having too little piping. There may be two houses exactly the same size and heated with the same length of piping, but if one is placed in a more exposed position than the other, to keep it the same temperature more piping would be required. In many cases the boiler power is greater than the number of feet of pipe it has to heat. In cases of this kind it is very easy to keep the houses at the proper temperature in frosty weather or during high winds if the boiler and the working of the valves are understood, which is only gained by experience. I maintain it is of no use whatever going by fixed rules, as what will agree with one boiler will not suit the other.

"Dugald" states that he would have a boiler that would not require an ashpit door in the working of the furnace. I should say that depends on the flues. If these are sharp and there is no ashpit door it would be difficult to regulate it with

damper alone; but in the case of boilers like the Improved Trentham no ashpit door is needed, the draught in this case being regulated by the damper.

I do not think "Dugald's" theory about having a furnace door at each end of the boiler would answer, as if boilers are properly set and stoked one furnace door is quite sufficient. In fact I do not think two doors would answer at all, as the cold air would rush in from the opposite side from which the fire is fed and drive the smoke out where it was being fed. Altogether it would be a complicated affair and not worth troubling about.

In all cases the flues should be well cleared out weekly, so that there may be no obstruction to the draught. I have seen cases where the flues were clogged with soot require almost full draught to keep the fire in, but when the flues had been properly cleaned very little draught has been needed to get the pipes properly heated.

"Dugald" also remarks, "Why not carry the chimney in

the shape of a flue through a stove?" If I had a boiler with sufficient piping to heat the house properly, I should not care to carry the chimney in the shape of a flue through any structure with vegetation in it. In flues there are generally some mishaps occurring. If a vinery, and an accident occur during the night, we have the pleasure of seeing in the morning the foliage burned. In my case once where a flue ran through an old orangery, one morning we found, owing to an accident to the flue, that the buds had all fallen, and in many cases the foliage of Camellias as well.—A. YOUNG.

OUR PEAS OF THE PAST SEASON.

To commence the Pea season I make a good sowing in November of Prizetaker, not forgetting to sow for the sparrows in the warm days of spring as well as for other purposes, and again in February and in March, at the same time sowing Veitch's Perfection for succession. This is a great favourite, and has been so with me since its first appearance. From the November sowing we generally gather about the first week in June. This season was an unfavourable one; they were a week later than usual, but the crop was larger. Stratagem I like very much, but when I have grown it as a summer Pea as long as I have Veitch's Perfection I may like it better. I am inclined to think it is only a selection from that fine variety. Its sturdy habit is a grand character. I shall continue to cultivate it. Sharp's Paragon is a fine Pea, but requires careful attention to keep it in the stakes in windy weather. The pods are too long in filling in our locality, and it is too tall. The seed of John Bull was mixed, so that I was at a loss to discover its true character. Some were 3 feet high some were 9, so I gave John marching orders.

Giant Marrow when true deserves all that has been said of it, but we shall have to adopt a different mode of treatment if we mean to succeed with it. It is a monster in every respect, but I am sorry to say did not satisfy my expectation. It was too long in filling; it is tall-growing, and being much exposed to winds its gigantic proportions require more than ordinary support. Too much cannot be said for Telegraph and Telephone, and I find so little difference between them that in future they will be used as one. I find the wrinkled and the smooth in each. Telegraph and Veitch's Perfection are the Peas for me during the summer and autumn. I should like Telegraph all the better were it 4 feet instead of 7 feet high. Could I have Ne plus Ultra 5 feet in height instead of 8 I would seek no further, as tall growers suffer much from winds with us. When a lad in a market garden fifty years ago we used to have a grand late Pea called Vellyfield Roughpod, but I hear nothing of it now. I might name others, but from the above we had a full supply from June to the end of October, when the wind and frost closed our Pea season.—A YORKSHIRE GARDENER.

CHRYSANTHEMUMS OUT OF DOORS.

THAT Chrysanthemums may be grown very successfully in the open air, as you note on page 463, is certain; and since reading those lines I have seen a very successful instance, in fact the best that has as yet come under my notice. This, however, is not by a professional gardener, but a very enthusiastic amateur—Mr. H. Murray, Uxbridge, who, besides the open-air collection here mentioned, has had two small houses filled with his favourite flower. Mr. Murray's outside collection is grown near a west wall; a double row of plants, which are planted out early in April, some well-decayed dung being worked into the border. During the growing summer period they are of very little trouble compared with pot plants in the way of watering—staking, tying, and disbudding being the principal consideration. Towards the end of October a coping of glass or canvas is erected in the way usually used for Peach trees, and in cold weather mats or canvas being in front. I herewith forward a few blooms cut from this open-air collection to-day (December 1st). The large Anemone varieties were in better condition than the incurved varieties, George Sands, Louis Bonamy, and Lady Margaret being very good. I have seen worse blooms in metropolitan exhibition stands this season.—C. H.

[The Anemone varieties are extremely good, and the incurved blooms are also of fair quality, and we can corroborate our correspondent's remarks that much worse blooms have been shown this year, and in winning stands.]

OUR ORCHARDS AND PARAFFIN OIL.

A CORRESPONDENT writes:—"In an article in the November number of the "Nineteenth Century" by the Rev. H. P. Dunster, entitled 'Our Orchards and Paraffin Oil,' several passages occur which are worth the attention of horticulturists, and for this reason I transcribe them. Speaking of imports, he says 'that the fruit imported under the heading of unenumerated raw reached the almost incredible amount of 4,045,691 bushels, the value of which was £1,718,907,' that is, all unless dried fruits; but we believe that a distinction has been made in favour of Apples, of which a separate return will be given. After finding fault generally with cultivators, he here says, 'We do not ourselves grow, and moreover not attempting to grow, a supply of fruits sufficient for our own consumption, but are contented to pay our money to foreigners for almost all we need;' and strongly advises 'cultivators and owners to do

something more for their own benefit,' by which he means the more extensive planting of orchards.

"There are, we learn, at present only '184,000 acres of land under orchard cultivation, and which gives a far higher average than the rent and tenants' profit of ordinary farm land.' Then follow a few questions. 'Are our orchards properly managed at present?' 'Are they not capable of improvement?' And then, 'I am in a position to prove that the health and productiveness of orchard trees may be most materially increased by a very simple and inexpensive process, and that both owners and proprietors may derive a much larger return from orchards than is now made.' And after a general review of the land occupied by orchards in different parts of England, the startling assertion appears, 'I only in a few instances' (and those were orchards planted with young trees) 'met with trees that were not covered with mosses and lichen, and in a state of canker and neglect.' 'Is it possible under such circumstances that orchards can be expected to pay, and if still under circumstances they do yield a profit—a profit far beyond what ordinary farm crops are yielding, as I have every reason to believe is the case, what would be the result of greater care bestowed upon them?'

"He then proceeds to give the experience upon which are founded the preceding assertions. 'About five years ago an old Apple tree as usual was infested with the American blight, as it is commonly called (Eriosoma). The tree appeared gradually dying, and from its situation I was very reluctant to cut it down. About a pint of paraffin oil was put in a wide-necked bottle, and with a house painter's brush a full dressing was given wherever the least blight was observed, all trace was obliterated by the process, and in a few days the moss and lichen turned black and died,' when the tree survived and flourished, made fresh shoots, and is now in a healthy bearing state. And all he affirms is that by the process above indicated 'orchard trees generally in good health and bearing for a much longer period than is found to be the case at present.' 'That trees themselves shall throw off their rusty moss-grown state and assume a healthy and vigorous appearance, also that the fruit they bear, instead of being misshapen, speckled, and stunted, shall indicate by quantity and quality their more healthy condition.'

"An instance is also given of two Victoria Plums where the stems were covered with the blight and beginning to give indications of approaching death. 'The quantity of fruit did not in the least diminish, but were undersized, spotted, and some fell before they were ripe. One of these was cut down, the other was dressed as above with the most startling results, vigorous health producing large plump well-bloomed fruits.' 'Now, with both these the gardeners' verdict would have been—They are useless, their roots are at fault, they have got down to the dead soil.' 'I have proved, and I trust satisfactorily, this is not the reason the bark and the bark only was at fault.' And after urging the growth of orchard trees in hedgerows, &c., he says 'that large growers (or nurserymen) will deliver at nearly any station standard orchard trees, in quantity, Apples 1s. each, Plums 1s. 3d. each. The landlord's cost per acre being 45s. to 50s., including three stakes to each tree. The tenant's cost for cultivating the land, pruning, &c., 3d. each tree. Dressed, on an average, 2d. or 3d. each tree, including material, &c.'"

[Injury has been done to trees by the incautious use of petroleum.]

SIX MONTHS IN A VINERY.

MARCH 17TH.—No flowers are open yet, and we are rather pleased that such is the case, for they have strengthened considerably, and cannot fail to be good when they do expand. The leaves still increase in substance, the later-made ones being particularly leathery.

On the 11th our outside minimum temperature was 18°, and 12° on the grass. It became cloudy at sunrise. There were glimpses of sunshine during the day, but it was not necessary to give air. The 12th opened brightly with a registered minimum of 22°. A little air was given at 8 o'clock, and increased at 8.30. The outer atmosphere was very dry with a brisk wind, which affected the inside of our house to such an extent that the foliage was seen to droop a little. We wish we could manage without giving air to-day, but the temperature would be likely to rise to a dangerous height, so we give as little as we think we safely can and close as early as we dare; but this is not till 1.30 P.M., the sun having great power under the glass. The thermometer at closing stood at 80° and rose a few degrees afterwards. Walls, path, and border are sprinkled profusely, and very soon we have a delightful atmosphere, in which the foliage immediately recovers in spite of the dry east wind.

On the 13th we had again a sharp frost, our minimum thermometer going down to 20°, and that on the grass to 14°. Ice was 1½ inch thick, and we put all available strength to carting and storing it. Our vinery is aired at 8 A.M., and closed at 11 on the sky becoming cloudy. The wind now changed to the west, the air became much softer, and there was every appearance of milder weather; we therefore decided to raise our minimum temperature to 60°, which, owing to our dislike to heavy firing, has hitherto been 5° lower than this figure.

The next morning (the 14th) was foggy with no frost. The sun broke through at 11 A.M., and we anticipated it by giving air a few minutes earlier than this. The litter

which had been placed on the outside border on the 10th was now removed, and we hoped that the time for severe frost had gone. On the following morning the wind was again in the east, but there was no actual frost; the sun rose brightly and we were obliged to give a little air. The afternoon was dull and cold, with an attempt once or twice to snow; but with a good damping down after closing the sun heat gained in the morning, our Vine looked, and the atmosphere felt, very comfortable. On the 16th we had sharp frost again, 13° below freezing point, and even 18° on the ground. We aired at 8.30, increased at 9, reduced at 10.30 on clouds appearing on the windy side, and closed finally at 11 A.M.

This morning (the 17th) we only had 1° of frost. The sun rose brightly and the ventilators were opened at 7.30, but they were closed again at 9.30 on the sky becoming cloudy. It appeared to be clearing again at 10.30, and before it could peep through we had a chink of air on three lights. It turned cloudy again soon after, and the house was finally closed at 11. The sun shone again at intervals during the day and kept the temperature up to 80° most of the time, and altogether we flatter ourselves that to-day at least we have made the most of the weather.—WM. TAYLOR.

CAMELLIAS.

ON several occasions notes have appeared in the *Journal of Horticulture* respecting the advantages and disadvantages of shading Camellias. Both sides of the question have been ably treated by experienced persons, and doubtless if the conditions were known under which their plants were grown the systems advocated were equally good. In my opinion, before either practice is condemned or supported, the kind of house, its aspect and position, should be taken into consideration, also whether the structure is wholly or partially shaded by trees or adjoining buildings. It is not, however, my intention to enter into the question beyond stating, for the information of the readers of the *Journal*, that Camellias can be grown successfully without any other shade than is given by the house in which they are grown.

The Camellia house at Shirecliffe Hall, Sheffield, affords an excellent example, and is well known in this neighbourhood to contain a collection of plants that are noted for their annual display of flowers. The house stands north and south, has glazed ends but no glass at the sides, and a span roof with a rather flat pitch. It is fully exposed to the sun from six o'clock in the morning until six or seven o'clock in the evening during the summer months, and is never shaded, so that the plants are exposed to the full sunshine. That this is beneficial and suitable to their requirements is testified by the health and vigour of the plants that are well set with an abundance of fine plump flowerbuds which are now expanding. The foliage is thick, of a deep glossy green colour, and the flower buds so well set that you may give the trees a good shake without dislodging one. They were produced in such large numbers that disbudding had to be freely resorted to, each shoot being laden with clusters. I send you one of the points that was not thinned out, with sixteen flower buds on it. Of course, all the shoots were not so heavily laden as this one (the average being about ten), but it will show you how freely they were produced. The plants were disbudded in the end of September, when from one plant over 1400 buds were taken, and it is now bearing upwards of 2000 fine buds and flowers, those expanded being of large size and good substance, with strong petals, testifying that it is not overloaded, and will mature its large crop of blossoms. I have seen this plant when in full bloom, and the ground around it has been thickly covered with the petals fallen from the ungathered flowers.

This plant is the good old variety *Alba plena*, a variety that will not easily be surpassed by any new one. It is now in a tub about 3 feet 6 inches square, in which it has been growing and blooming vigorously for eight years.

All the other plants in the house are equally healthy and full of well-set flower buds, and speak unmistakeably of the skill and able management of Mr. Udale, the head gardener. Amongst the plants the principal varieties, in addition to the one mentioned, are *Bealii*, *bicolor de la Reine*, *Chandlerii*, *Chandlerii elegans*, *candidissima*, *Countess of Orkney*, *Colletti*, *Donckelaarii*, *Empress Eugénie*, *fimbriata*, *imbricata*, *Comtesse Lavinia Maggi*, *Lady Hume's Blush*, *Mad. Cachet*, *Mathotiana*, *Mathotiana alba*, *Triomphe de Bossea*, and *reticulata*.—J. H.

[We have seen the Camellias referred to, and can testify to their admirable condition].

DESTROYING CRICKETS AND COCKROACHES.

I OBSERVED in the *Journal* an inquiry as to how to get rid of crickets in a vinery or hothouse. The incident I will mention may be of use to the inquirer. By some means, probably from manure purchased, crickets were introduced into my vinery and the adjoining house where my Orange and Lemon trees were. I observed the bark on these trees was nibbled, and was led to suppose this was done by the crickets. It was, however, the only mischief I ever observed. Every cricket was destroyed that could be seen, many of them young. Nothing in the way of poison had any effect. Two or three times, when one of my servants had been sent to the vinery, I was told that as the door was

opened a small tabby cat made its escape from the house. From this time I never heard the chirping of a cricket. I inquired of the gardener, and he told me he never heard them now, and mentioning the visits of the cat, I learned from him that a neighbour kept a cat, such as that described, purposely to destroy crickets and cockroaches in the house. This may be a hint to the person suffering from these pests. I doubt if all cats would be so useful, for when there were two or three in my house where cockroaches were in the kitchen, the servants did not find they were destroyed by the cats. If one cannot be found with the desired propensity, I would ask my neighbour to keep a kitten of this useful cat of hers, and would gladly let your inquirer have it.—M. D.

IN reply to the request of "J. W. R.," on page 446, for a method of destroying cockroaches, &c., I beg to say that if he will water the floors and lower parts of the walls with a solution of crude carbolic acid (1½ pint of acid to 1 gallon of boiling water) every day for a week, he will destroy them. When they are cleared out, watering once a month will prevent their reappearance. I may say that I have cleared them out of several dwelling houses where the kitchens literally swarmed with them by a liberal use of this solution. The acid I have found most easily soluble is Calvert's, for which I pay 4s. 6d. per pail. I hope this recipe will be of use to "J. W. R."—HIBERNIAN.

IF "J. W. R." were to try Chase's beetle poison, and use it according to the directions on the box, I feel sure he would soon diminish the pests which cause him such trouble. It can be purchased through the London nurserymen, but I send for it to the proprietor, who will forward it per parcel post. Without using it at intervals I can get neither Orchid roots nor flower spikes.—J. R. M.

ANEMONE JAPONICA ALBA IN POTS.

IT appears from "M. M.'s" remarks (page 464), that he is fully capable of supplying the information he credits me with omitting (page 436) or he lives in a most unfavourable locality if his outside plants do not flower before the month of October. This I infer is the case, and the reason they were planted inside with the marked success detailed. I am too much occupied to make notes when the first flower of a certain plant opens and when the last can be gathered, therefore I have no dates to give. I can only say that plants in a favourable position and which have just gone to the rubbish heap opened their first flowers in August; it might have been the middle or end of the month, but they could not have been said to have been well in flower before the early part of the following month. Plants that were one year old and transplanted in rich soil just as the foliage failed in autumn were in full flower during the same month, and continued flowering until cut off by 13° of frost a fortnight ago. Another batch of plants raised last spring, and which we intended to protect with old lights as described, were also cut off the same evening. These only commenced to open their first flowers the last week in October, when a number of the latest plants were lifted and placed in pots. These would have flowered until the end of December if the weather had not come so severe as to penetrate the slight protection I intended to afford them, but the frost caught us in this instance napping. There was abundance of small late Chrysanthemums and other plants that had to be placed in frames hurriedly, and unfortunately we had to sacrifice this batch of Anemones which had been purposely prepared for late flowering.

I have our latest of all at the present time in a cold frame, and they have had up to the time of writing only two or three flowers. The most forward I intend to remove from the frame to one of our houses in time to have upon them a good number of flowers by Christmas; but the latest of these plants will not be in flower by that date. I am expecting to bring them into flower during the following month, but when they will finish producing flowers I cannot tell. Should they go off or fail to flower satisfactorily "M. M." shall be informed through your pages.—W. B.

CHRYSANTHEMUMS.

FIXING SPORTS.

IT is quite probable that some readers of this *Journal* may have noticed during the present season distinct sports from well-known varieties of Chrysanthemums, and may be a little doubtful as to the best method of fixing them. Hence a few notes on the subject may be useful, as perhaps few have an opportunity of observing the methods adopted by successful raisers, and hints on this matter are rarely recorded. The first and simplest case is when a plant shows very little of the usual character of the variety—in other words when the sport predominates. In some instances like this the grower will take all the cuttings obtainable at the base of the stems in the ordinary way, in the hope that the altered characters may have affected the entire plant. From the stock so raised the plants that come true can be selected another season, and these increased at pleasure. Others, again, will carefully preserve only that portion of the old plant bearing the sport, and will remove the other; but this would be better practised when not more than half the plant has sported. Commonly, however, only one branch will bear a bloom differing from those of the variety in colour or some minor characters, and this is the most difficult. Cuttings of the old wood will root occasionally; but they are very uncertain, and Mr. Salter of Streatham, who secured that beautiful sport from James

Salter, Lady Selborne, a year or two since, informs me that this system was adopted, with the result that only one bud—that nearest the top of the stem—grew, and from this all the stock was subsequently raised. Mr. Orehard of Kingston, however, who has also added a beautiful sport to the varieties in cultivation—namely, Lord Wolseley, advocates another plan, and one which I believe is much preferable. It consists in simply laying a branch down in cocoa-nut fibre refuse kept regularly but moderately moist, which induces the production of roots from the stem, and it can be then cut into eyes, these being potted like ordinary cuttings. The advantage of this plan is that the sport is kept true, which cannot always be insured when it is propagated from the shoots at the base of the stem, and sometimes sports of great promise have been lost in this way. It seems that nothing is done in the way of conducting to the production of sports, though it appears that some valuable experiments might be tried by grafting light-coloured varieties on dark-coloured forms as stocks, or *vice versa*. Possibly many changes might be effected in this way with patient perseverance.

CLASSIFICATION OF VARIETIES.

The majority of the incurved varieties are well marked, the term specially applied to them conveying a clear idea of their character; but even amongst these there are some shown in the same stands that differ sufficiently to be classed alone. To these, which include such varieties as Barbara, Lady Talfourd, and Mrs. Haliburton, the term "erect" might be safely applied, as the florets, instead of incurving, as with the others, are perpendicular to the base of the bloom. There are scarcely sufficient of these, however, to form a stand, though in the opinion of many they should be excluded from the true incurved classes. The Japanese are most in need of a system of classification, and though several systems have been proposed they are all subject to objections of some kind. The following method is no doubt imperfect also, but it has the merit of simplicity, and the majority of the varieties can be readily referred to one or other of the sections—at least, so far as I have tested it. This plan is to group all the Japanese varieties in three sections—1, Those with flat florets, which include such as Elaine, Striatum, Thunberg, Peter the Great, Oracle, James Salter, M. Ardene, and Fair Maid of Guernsey. 2, Those with florets partly quilled: examples, Bronze Dragon, Soleil Levant, The Daimio, Meg Merrillees, and Erecta superba. 3, Those with fluted florets—that is, having the margins folded backwards: examples, Cry Kang, The Cossack, Garnet, Red Gauntlet, and Fulton. This may serve as a hint to some who will be able to suggest defects and possible improvements.—LEWIS CASTLE.

PLANTING SEAKALE.

I AM placed in the same position as your correspondent "B." with regard to the supply of this vegetable; but he says this is not the time to enter into the preparation of the plants, and I differ from him in that respect. I have a lot of old roots, some three, others probably of ten years' standing, and I will describe the system I am about to pursue. I have taken all the plants up, carefully preserving every root that could be found, as these are of more use than the crowns. I shall proceed with making the sets in wet weather from the roots that are anything larger than a tobacco pipe stem, but perhaps shall be induced to use larger pieces, as the supply is small. These are cut about 4 inches long, flat at the end nearest the old root, with a sloping cut at the other end to prevent the sets being planted upside down. When this is done they will be covered with ashes until next April, when they will be planted. From these I shall expect crowns equal to those which are supplied by nurserymen at 15s. or 16s. per 100.

Your correspondent finds seedlings answer well with him, I have never seen good Kale produced from seedlings. If "B." had any seedlings to dispose of he would not be able to get a very satisfactory return for them, for vendors would scarcely look at them however strong the crowns may be. I have found that crowns not strong enough for forcing are not worth keeping a second year, and I quite agree with your correspondent about forcing on the land, that it involves an unnecessary amount of labour. A light rich loam answers admirably for the production of healthy strong roots.—J. PITHERS, *Summerhill, Co. Meath*.

ROSES FROM CUTTINGS.

It is gratifying to me, and doubtless to many more of the readers of the Journal, that the above subject is being discussed. Much, no doubt, remains to be learnt, and many like myself have little spare time to try experiments, consequently are thankful to learn from others, such as "A. F. M." "Y. B. A. Z.," too, has to depend on cuttings, and considers Roses on their own roots nearly or quite equal to those worked on stocks. It is not my intention to criticise, but rather to look back on the past season's success or failure, making a few remarks thereon. I stated some time ago that my stock was not large, either as standards on the Briar or dwarfs. I usually contrive to add a few more each year to replace those that have done good service and are worn out.

To commence with standards. These have succeeded admirably—in some instances as perfect heads of bloom on the second as on the first growth. Continuing to bloom till later than usual, the blooms have been fine, considering the number on each plant. I may here state, after careful observation, that as good a Rose may be grown on the Briar as from own-root plants, and *vice versa*. With those on their own roots planted out I am perfectly satisfied, having had a long continuance of

what I consider really good blooms; yet such sorts as Charles Lawson, John Hopper, Duke of Edinburgh, Celine Forestier, notwithstanding that they have bloomed freely, have made such strong growth that I intend to lift them. Capitaine Christy on the same border made but little growth. Again, Gloire de Dijon, one on each side of the path, in the same borders, struck the same season and treated the same, have made very different growth, the one having done well, the other scarcely a foot from the ground. Both are at the present time full of good flower buds. How can we explain this? My impression is this, that unless the cutting starts from the first it had better be thrown away, as it will only dwindle and die. Do not we often see this on budded plants? Here is one instance. Last week I lifted two beds of Roses, took one plant from the kitchen garden to occupy the place of one that had died, apparently a healthy head budded last season. The situation was more open, and a gust of wind settled matters by blowing out the head with the bud entire. On examination I found that the bud had only partly taken, yet had lingered on and carried some fair blooms. It matters not whether it be a Rose from a bud or from a cutting, unless healthy from the first no attention afterwards will bring it to perfection. The Roses from cuttings in pots I am proud of, and if good stocky growth and healthy roots are any guide I shall have some excellent blooms, and if possible I will send some where non-believers can see them. Some plants from cuttings inserted twelve months ago are now stocky, in 32-size pots, capable of carrying from six to nine flowers; while those two and three years old are fine plants, and ought to give a good return of flowers. It may not be out of place to state some cultural attention is necessary, and good results cannot be looked for unless it is given from the first.

In conclusion I would like to ask, Does a Rose worked on the Manetti throw its finest bloom for exhibition purposes the second year after being worked? If so, then is its value for general purposes afterwards? Does each year see it weaker? If such be true, what shall we say of those grand specimens we see exhibited at the London shows by such well-known firms as Messrs. Paul & Son? It would appear by that, these giants must be on their own roots. To gain experience I have inserted some Manetti cuttings with a view to working them. We cannot learn too much.—A. J. SANDERS.

MUTUAL IMPROVEMENT IN GARDENING.

AMONGST the "Notes and Gleanings" on page 418 I noticed particulars of a society now formed at Manchester under very promising prospects. With Mr. B. Findlay at its head, and with an able secretary and treasurer, it is to be hoped that numbers of young gardeners especially will join the Society, and have the support of those further advanced in years and skill. It is much to be regretted that such improvement classes are not more common (they might in some cases also include lessons in drawing), as it is only by such means, or practical necessity, that some young men are led to take advantage of the valuable horticultural literature now so plentiful. No young man who takes any interest in his avocation should fail to carefully, and as often as spare time permits, read his "Cottage Gardeners' Dictionary," tracing the history and derivation of what are not unusually termed rambling nonsensical names, and by such knowledge add interest to that which otherwise would be ridiculed. I would trespass a little further and ask them to pay greater attention to other dictionaries, which are so very cheap and comprehensive.

There are many improvement societies of various forms in different gardening centres; but even where it is not convenient to form a society, would it not be possible and beneficial to young men where several are employed to set apart one night a week for mutual instruction during the winter, the head gardener to assist so far as he could? Could not each young man write out the history, soil, and climate best adapted, say, of the Apple or other hardy fruits, the Pine Apple, the Vine, vegetables, or plants, and their treatment? Even though the major part was mere copying from a book or paper it could not fail to do good and instil a desire to learn, also cause many to feel more at home with their chief. I well remember such nights being set aside for the spiritual benefit of the young men by the kind head gardener under whom it was my good fortune to receive my early lessons in gardening. Such home-improvement classes may be in practice in out-of-the-way establishments, and where they are a benefit readers will, myself included, be glad to hear how they are conducted.

It is often surprising to meet with young men who have lived with most competent head gardeners remember very little of the teachings they have had, those employed inside not taking much notice in their spare time of any operations outside or beyond their own department. Happily there are many exceptions; but let me impress upon young men the great importance of associating themselves with any improvement society which may be within reach, nor fail to closely observe all practical operations.—E. B.

STORING APPLES ON STRAW.

It is surprising how many there are who store their choice Apples on straw, and yet no greater mistake could well be made. As affording proof of the truth of these assertions I may state that a few days since it fell to my lot to taste about fifty dishes of Apples from as many growers, and of these fully two-thirds evinced by their taste that they had been stored on straw. In some cases this had quite spoiled the taste of the

fruit. Such varieties as Cox's Orange Pippin, Kerry Pippin, Blenheim Pippin, Adams' Pearmain, and Ribston Pippin apparently are especially susceptible, while many other sorts were to a certain extent also much affected by the musty taint emanating from straw. Probably those who employ straw consider it necessary for the proper preservation of the fruit, but as it happens it is both unnecessary and very unwise to use it. Clean boards are the best for the choicest fruit especially, and if it is necessary to cover these in order to prevent injury to the Apples by frosted air—and which I once found to my cost would penetrate through the joints of a flooring—then use old newspapers, kitchen or other clean paper in preference to any other material. More paper may also be placed closely over the fruit, and this will ward off a somewhat severe frost; but at the same time, if very severe weather be anticipated, it may be advisable to supplement the paper with a covering of mats, bags, frigi domo blinds, which are not often utilised during the winter months as they thus might well be, or even hay and straw. Clean boards and paper do not affect the taste of Apples and also Pears, but other musty materials may easily do so, and should not, therefore, come in contact with the fruit.—W. IGGULDEN.

SIX MONTHS OF GLADIOLI BLOOMS.

I CUT my last half-dozen spikes of Gladioli blooms to-day (the last week of November), and send you three, retaining the others, to note how long they will last as cut flowers in water to which a little salt and charcoal have been added. This has been a cloudy day and night with a warm southern breeze, average temperature 50° Fahr., so mild that I see a few single Dahlias are still blooming. I need not say with such weather these Gladioli would unfold bloom after bloom outside, and what is more, unlike other flowers, the size seems little if at all less than usual now. They will do the same inside, otherwise I should have chanced their glorious bright colours to light up the sombre huc of the flower beds some time longer. The names are not important so far as distinguishing Gladioli into early and late-flowering. They possess no such characteristic. For instance, I potted a fine corm of James McIntosh (new) in January, and put it in a cold frame, transplanting it in April outdoors. It bloomed the first week in June admirably. I had a second corm planted at the end of March, and am after cutting the last blooms off the spike to-day. I treated three corms of that fine bloomer Duchess of Edinburgh almost similarly, and enclose you the last to bloom. This was 5 feet high, and the other two were 6 feet. The colour is purplish rose with a whitish carmine stripe on the lower petals, and of all Kelway's I have seen this is the most robust. I mention those illustrations to show there is no division by Nature, as in other flowers, into early and late; the time of planting will regulate the blooming. The other varieties are La Fiancée, Brennus, Dr. Hogg, and Electra. You will notice the rich colours are in no way washed out, and that they are most brilliant and intense. Brennus, for instance, has been open a fortnight and exposed to the most violent drenching showers since; yet you have still the bright crimson-maroon body colour shading off to white in the centre, while the violet stripe on the lower divisions contrasts finely with the blue tinge throughout. Though my collection is limited to a few hundreds I can enjoy those rich brilliant blooms for six months; and while asking any of your readers who have not yet essayed their growth to give Gladioli a trial next spring, I unhesitatingly consider from the points of view stated that the Gladiolus is peerless in the flower garden.—W. J. MURPHY, *Clonmel*.

[The spikes sent are precisely what our correspondent has represented them—bright and beautiful.]

THE annual general meeting of the NATIONAL ROSE SOCIETY will be held, by the kind permission of the Horticultural Club, at their rooms, 13, Henrietta Street, Covent Garden, on Thursday, the 6th of December, at four o'clock, for the purpose of receiving the report, electing the officers and Committee for the ensuing year, confirming or otherwise the arrangements made by the General Committee for the exhibitions of 1884, and the transaction of other general business. The sixth annual dinner of the Society will take place at the same establishment after the meeting at half-past six o'clock, when the Hon. and Rev. J. T. Boscawen will preside.

— A PLANT certificated at the last meeting of the Royal Horticultural Society—namely, VIOLET COMTE BRAZZI, is destined to become a great favourite with all who prize Violets—and who does not? It is a pure white form of the double Neapolitan, large, full, and fragrant, and it is already in great demand. The size and substance of the flower,

combined with its purity, are abundant recommendations to popular favour.

— WE are requested to state that the REIGATE ROSE SHOW is fixed for Saturday, June 28th, 1884.

— IN reference to the remarks upon CHRYSANTHEMUM LORD ALCESTER (page 444), Mr. Molyneux, The Garden, Swanmore Park, Bishops Waltham, writes confirming the opinion there expressed as to the variety being a sport from Golden Empress, and not from Golden Queen as some had stated. He also adds, "It is a grand flower, and one of the best introductions of the incurved class that we have had for some years."

— M. GIRARD, Director of the Paris Municipal Laboratory, calls attention to the manufacture of "GOOSEBERRY" JELLY from seaweed, without a particle of a portion of a Gooseberry in it. The colour is given by means of fuchsine or some similar colouring matter, and the flavour is fairly well copied by means of a mixture of acetic ether and tartaric acid, with small quantities of benzoic, succinic, and cœnanthic acids, and aldehyde.

— LOBELIA PYRAMIDALIS, *Wall* (L. *Wallichiana*, *Hk. fil.*), a native of the Himalayas, and quite common from Gurwhal eastwards, promises to be a valuable acquisition to the greenhouse or conservatory at this season. The flowers, which are bright blue and white, are gathered in clusters at the extremity; they are very showy, and supply a much-needed colour to blend with Chrysanthemums, &c. It is better grown in pots, because if allowed to stand out, unless in very sheltered places, will succumb to the first severe frost. The flowering stems are bright purple and are very showy; leaves finely serrated, broad lanceolate. It is called Atia chas in the Kasi language, and is used as a stimulant by the natives of Nepal.

— "W. I." writes as follows respecting CHRYSANTHEMUMS AT CLIFTON:—"Messrs. J. Garraway & Co. have long made a speciality of Chrysanthemums, and this season they have a fine display in their Durdham Downs nursery. The plants are covered with a large tent, and are arranged in the form of a bank on each side of a central path. All the best new and old varieties are grown, thus affording an excellent opportunity to the many lovers of the Chrysanthemum to judge for themselves which sorts they may wish to add to their collections. Among the large-flowered varieties we were very favourably impressed with Le Grand, delicate rosy peach tending to fawn colour; Souvenir de F. Marouch, blood red with orange centre, reverse of petals yellow; Abbé Passaglia, brassy amber, incurved; Mrs. Naish, white, in the way of Mrs. G. Rundle; and Dupont de l'Eure, shaded brown, incurved. Strikingly good also were Cherub, Barbara, Baron Beust, Golden Empress of India, Isabella Bott, Mr. Bunn, Prince Alfred, and Rotundiflora. Of large Anemone-flowered the best were Lady Margaret, Prince of Anemones, Acquisition, Emperor, Louis Bonamy, and Empress. Pompon Madame Montels was extra good. A large number of Japanese varieties was represented, and very fine were Criterion, Comte de Germiny, Parasol, Mons. Delaux, and many others."

— IT appears that there will soon be a plentiful stock of the new EUCHARIS SANDERI in general cultivation, for numbers of flowering plants are being distributed at the auction-rooms. Some growers, however, regard the plant unfavourably, and state that the flowers will never be much valued for market, as they do not last sufficiently well. There is somewhat of prejudice in this, for other growers speak most highly of its merits. The flowers possess one quality which those of Eucharis amazonica have not—namely, they are pure white, as the corona or ring—usually greenish-coloured in the latter species—is quite absent in the former, or reduced to an almost inconspicuous ring. They are more funnel-shaped, the segments not being spread out flat as in the better-known species. The leaves are very distinct, being very strongly ribbed, like some of the Funkias, and the plant appears to be very floriferous and of easy culture.

— THE "GOOSEBERRY GROWERS' REGISTER" still continues its useful existence. That for the present year has been brought under our notice, and it fully maintains the merits and usefulness of its predecessors. We do not know exactly how long this annual has been in existence, but if we are not mistaken it is, if not quite, at least nearly coeval with this century. It is a very modest production, and is published at the low price of 1s. 3d., but it contains a great amount of interesting information to all Gooseberry growers. It contains also the melancholy

intelligence that our friend Mr. Charles Leicester of Macclesfield is no more. He was for many years Editor of the "Register," and an ardent Goosberry grower.

— AT the next meeting of the Royal Horticultural Society, December 11th, Messrs. J. Carter & Co.'s SPECIAL PRIZES FOR COLLECTIONS OF VEGETABLES will be competed for, and may be expected to form an interesting feature. Six prizes are offered—namely, £5, £3, £1 10s., £1, 10s., and 7s. 6d. for the best twelve dishes, the three new Onions, Golden Globe, Golden Queen, and Silver Ball, to be included.

— MESSRS. CANNELL & SONS, Swanley, send us flowers of their NEW DEPARTURE SINGLE CHRYSANTHEMUMS, which comprise some pretty and delicately coloured varieties. These were admired by many visitors when shown at the last meeting of the Royal Horticultural Society at Kensington, and as single flowers are just now becoming such favourites, it may be expected that they will have a large share of popularity. They are light and graceful in appearance, the colours ranging from crimson through rose, pale pink, and white, the central tubular florets being yellow. A number of varieties have received the names of certain popular actors, actresses, and others, such as Ellen Terry, Henry Irving, G. A. Sala, Mrs. Langtry, Willie Beckwith, and similar notabilities. Specimens of a double *Tropæolum* named bicolor fl.-pl. were also sent, which has full rich orange-coloured flowers striped with scarlet. It is distinct and free.

— BOROUGH OF HACKNEY CHRYSANTHEMUM SOCIETY.—The thirty-seventh annual dinner and prize distribution of this the oldest Chrysanthemum Society was held at the "Four Swans" Hotel, Bishopsgate Street, on Friday evening last, the President of the Society, E. Sanderson, Esq., in the chair. About seventy of the members and friends attended, and a most enjoyable evening was spent, and much enthusiasm was evoked, which speaks well for the future of this well-known Society under its new title of The National. Handsome silver cups were presented to E. Sanderson, Esq., Willesden; Messrs. Dixon & Co., Hackney; Messrs. Drain & Son, De Beauvoir Town; Mr. Archer, Highbury; and Mr. Hillier, The Borough, Southwark, as the selected prizes for the awards made by the Judges at the recent Exhibition at the Royal Aquarium. During the evening cash prizes were also distributed to those of the successful exhibitors who were present, and the Honorary Secretary afterwards announced that the sum of £155 18s. 6d. had now been paid as prize money for the year 1883. The Secretary further stated that the Society had greatly increased its number of members during the past year, about fifty new names having been recently added. The Baroness Rothschild and the Baron Leopold de Rothschild have consented to become patrons. A subscription list having been started for the prize fund for the ensuing year, nearly £40 was promised by members and friends present. Votes of thanks to the officers brought the business of the evening to a close.

— WITH deep regret we have to record the death of a distinguished gardener, MR. JOHN FLEMING of Cliveden, whose name is familiar to many of our readers. He has for many years held a prominent position in the gardening world, but little is known of his early history, the first tidings we have being that thirty-nine years ago he was living with a Mr. Aiton at Bardsea, near Ulverston, but in what capacity we have no knowledge. We next hear of him in the gardens at Newnham Paddocks, Lutterworth, and subsequently (in 1850) he became gardener at Harewood House, Leeds, where he left the stamp of his ability in the new Italian Gardens, which were formed under his direction. From 1853 to 1855 he served as gardener to Lord Southampton at Whittlebury Lodge, Towcester, and thence proceeded to take charge of the Cliveden Gardens, at that time the property of the Duke of Sutherland. It was there that the great work of his life was performed, the pleasure parks and flower garden being remodelled and greatly improved. A system of spring and winter bedding was commenced, which received so much attention that in compliance with the demand for information upon the subject, Mr. Fleming wrote his work entitled "Spring and Winter Gardens," which was published at this office in 1864. He also contributed several articles upon the subject to this Journal, which created a taste that resulted in many gardens being rendered attractive at seasons when they had previously been comparatively cheerless. A few years afterwards Cliveden passed into the possession of the Duke of Westminster, and in 1870 an extensive range of plant and fruit houses were designed by Mr. Fleming and erected by Mr. Gray, whose decease we recorded last

week. In recent years Mr. Fleming has led a retired life owing to the lung disease which on the 25th ult. terminated a useful and honourable career. Mr. Joseph Ellam, late of Bodorgan, Anglesea, has been appointed as Mr. Fleming's successor.

— WE are reminded of the approach of the new year by the arrival of a parcel of Messrs. LETTS & CO.'S DIARIES. We have on more than one occasion spoken in high terms of these invaluable necessities to every household, and we have no reason to unsay anything in comparing those of this year with any former one. Not the least interest in connection with these diaries is the amount of ingenuity that has been at work to devise so great a variety, for there are no less than eighty-three different forms of them, suitable to every occupation and condition in life. We would advise everyone to keep a diary, and before selecting to write to Messrs. Letts for a copy of the catalogue of their publications.

— "THE common Wild Waxwork or False Bitter-sweet, *CELASTRUS SCANDENS*, is one of the most ornamental of all hardy climbers," says the *American Cultivator*. "It is readily transplanted, and thrives under any care. At this season of the year (November) its clusters of red berries with a darker centre revealed by the splitting of the outer covering are highly ornamental. Its foliage is smooth, clean, and pleasing, and the plant is a most graceful and ready climber. It will twine tightly around an iron rod a quarter of an inch in diameter, or about a support several inches in diameter. This is the vine which one often sees twining very tightly about bushes and young saplings. When introduced upon lawns it sometimes proves quite a nuisance as a weed."

— AS an example of the comparative scarcity of APPLES IN AMERICA this year, we give the following returns, which indicate a surprising falling-off. The total exports this season are now 18,488 barrels, against 171,554 for the corresponding week in 1882. The total shipments from Boston this season have been 3322 barrels, against 52,948 a year ago; from New York they have been 12,841 barrels, against 78,059, and from Montreal 2325 barrels, against 36,717. It is, therefore, evident the crop has been as unsatisfactory in the United States as it has been full and good in England. Indeed, we believe that the tables have been to some extent turned this season, as English Apples have been exported to America.

— THE following GARDENING APPOINTMENTS have been made through Messrs. John Laing & Co. Mr. Samuel Hicks as gardener to the Rev. G. B. Moore, J.P., Tunstall Rectory, Kent. Mr. J. Rintoul, lately gardener at Dover House, Roehampton, as gardener and bailiff to C. A. Hanbury, Esq., J.P., D.L., Belmont, East Barnet, Herts.

— IN the lecture by Mr. George Murray on the POTATO DISEASE, delivered recently, a description was given of the growth and cellular construction of the Potato and Potato plant. The parts of the plants which were most susceptible to the attacks of the minute spores which produced the fungus of the Potato disease were also described. He then explained the development and rapid reproduction of these spores, and also the ease with which they were transmitted by the atmosphere. In one case a naked filament of the fungus had been known to develop and produce mature spores in four hours. He thought that in all cases the fungus attacked the leaves or stems of the Potato plant in the first instance and travelled downwards through the stems to the tuber, and it was in the highest degree improbable that they ever attacked or were able to penetrate the skin of the Potato itself. When these small fungi had completed their work among the cellular tissues of the Potato they left it open to the attacks of other fungi, thus forming the later stages of the disease. In reply to the discussion Mr. Murray said that cultivation or over-cultivation of the Potato would not affect the disease. Most probably the fungus which produced the disease came originally from the home of the Potato, and now it had become so widespread that it was almost impossible to trace the origin of any particular appearance. He thought that there was no way of checking the disease when climatic conditions, such as a wet summer, favoured its development. The only way of getting over the difficulty would be to find some substitute for the Potato, and he was much interested in experiments that had been made in this direction.

— "X." writes:—"There is no doubt, as Mr. Thomson states at page 435, that the best results are obtained with GROS COLMAN GRAPE in a temperature similar to that employed for Muscats; but those who have seen and tasted the examples of this Grape in the large conservatory at Chiswick will also be of opinion that when grown as they are, even in

a cool temperature, they leave nothing to be desired in colour or flavour. So well has this variety succeeded at Chiswick under this treatment that Mr. Barron intends grafting a number of the Vines there with it, and the merits of this handsome Grape will unquestionably soon cause its culture to be greatly extended. For market it is very useful when well coloured, as its appearance is excellent, and it is, moreover, of good weight."

— IN reference to the VANILLA GROWING WILD IN THE UNITED STATES, Mr. A. H. Curtiss, the well-known Florida botanist, in a sketch of an exploration, furnished to the *Florida Dispatch*, says:—"During another cruise I penetrated the borders of the Everglades, at a point about thirty miles east of Cape Sable. The mainland shore was there skirted with a light forest of Mahogany and other tropical trees. Following a creek which issued from it, we soon emerged into a round fresh-water lagoon, about a mile in diameter, in the centre of which was a beautiful round island. A creek emptying into it from the north I call Vanilla Creek, because on its banks grows the only Vanilla ever found in the United States. This species (*Vanilla planifolia*) is a thick, fleshy, leafless vine, which runs rampant among weeds and bushes, simulating, as it were, a slender green snake in its colour, form, and curves. This little creek is one of the small outlets of the Everglades; it has cut a channel through the underlying coral rock, and is bordered with a low growth of Saw Grass and Mangroves only a few feet in height."

THE UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

IN reply to your correspondent, "A Canadian Subscriber," there is no provision made in the rules for the election of members beyond the limits of the United Kingdom. The only reference is in rule 15, where it says that if a member leaves the United Kingdom he cannot receive sick pay until he returns, and then he must previously obtain a medical certificate showing the state of his health before he becomes eligible. The member to which reference is made, and who resides in America but continues his payments, formerly resided in England and hopes to do so again.

There is one feature in the rules of this Society which gives it a prominent claim above some of our more popular benefit societies, and that is, supposing a member from adverse or other unforeseen circumstances is unable to continue his payments, so that at the end of twelve months his account with the Society is closed, the question is then, What becomes of the balance of his deposit? It remains as he left it until he attains the age of sixty years, when he can claim the whole of the deposit standing in his name, unless in the interval he dies, when the person nominated by him receives it. The interest of his deposit after he ceases his subscription is carried forward to the benevolent fund. I think all will admit this is a boon unknown in the majority of similar societies.—J. F. McELROY, *The Gardens, Moray Lodge, Campden Hill, Kensington.*

LATE BLACK GRAPES.

THE season has again come round for taking stock and comparing the best kinds of late Grapes. Your correspondents, Mr. Thomson and "S." (see pages 435 and 437) have done good service in drawing attention to the subject. Undoubtedly Gros Colman is the grandest and most noble-looking Grape in cultivation. When grown in a Muscat house and treated to the temperature suitable for growing first-class Muscats and allowed to hang long enough, the flavour leaves little to be desired; but with us, when treated to a high temperature, it never finishes off with the same jet black colour which is produced upon those grown in a cooler house.

Mr. Thomson's list of varieties is a small one; nevertheless, with the exception of Madresfield Court, it contains all the best kinds in use from July until the end of the year, but those who must keep up a supply of Grapes through March and April cannot well dispense with Lady Downe's Seedling. So highly is this Grape esteemed by my employers, that anything short of 200 bunches would not be enough for spring requirements, and these are never touched until the Mrs. Pince's, Barbarossa (*Gros Guillaume*), and Gros Colman are done.

Like "S.," I have only a very moderate opinion of Gros Maroc. The Messrs. Rivers say they grew this Grape thirty years before sending it out, and in my opinion we should be no worse off for late Grapes had they grown it another thirty before putting it into the hands of cultivators. The same remark is applicable to Cooper's Late Black. I have grown these two in the same house for the last three years, but fail to see any difference between them either in wood, leaves, or fruit, and although they produce handsome bunches and berries covered with splendid bloom, I have never found them fit to eat where other sorts can be had. Their skin is thick and tough,

flesh dry and deficient in flavour, and with me they commence shrivelling before Martinmas (November 11th).

Alnwick Seedling is another new Grape that has precisely the same good looks and faults. These we have decided to discard, and will for the future depend upon West's St. Peter's, Mrs. Pince's Muscat, Barbarossa (*Gros Guillaume*), Gros Colman, and Lady Downe's Seedling for our winter and spring supply. With this I send samples of Gros Maroc, Cooper's Late Black, Alnwick Seedling, Gros Colman, and a bunch of the much-abused Duke of Buccleuch. These have all been ripe since August. Kindly give the readers of the Journal the benefit of your opinion upon these, and oblige—J. McINDOE, *Hutton Hall Gardens, Guisborough.*

P.S.—I may add that Gros Maroc was grown at the warm end of a house, grafted on Barbarossa (*Gros Guillaume*), and Cooper's Late Black in the middle grafted on West's St. Peter's.

[There could not be better examples of the different varieties of Grapes alluded to than those submitted to us for our opinion, and they all furnish confirmatory evidence of the grower's cultural reputation. Gros Maroc is perfectly shrivelled, and the berries almost in the state of raisins. The flavour is rich, but the skin is thick, tough, and membranous; and there can be little doubt that Cooper's Late Black is synonymous with it. Alnwick Seedling is delicious; and the "much-abused Duke of Buccleuch" would have put to confusion the most captious critic if he had only seen it. The berries are enormous; the skin thin, clear, and the flavour excellent. This is certainly a grand Grape when produced by those who, like Mr. McIndoe, know how to grow it. We never before saw it in December. Gros Colman is large and good, but deficient in colour.]

FLORISTS' FLOWERS.

FOR many years I have not known so favourable a season for florists' flowers as we are now experiencing. November, which has usually been associated with damps, fogs, and all kind of disagreeables, has been, in the south at least, exceptionally fine. The temperature has not been high, but there has been plenty of sunlight. The ground has not been soddened as of late years with excess of moisture, and those who have had to plant Roses (and who has not?) have rarely found the ground so workable. It has made the farmers rejoice, for it is many years since they had so good a "seeding" time, and a good seed bed always gives hopes of a good harvest. The previous weeks, too, have been favourable, and altogether I think gardeners are having a good time of it. My observations have, however, to do with florists' flowers in pots, and a few notes on them may not be out of my place.

Auriculas.—Last year I kept these in the same quarters as in the summer until the blooming time came on—i.e., under a hedge facing north. I have, however, this year reverted to my old plan, and about the beginning of the month placed the frames facing south. Latterly we have had some sharp hoar frosts at night, and I have therefore covered them with mats, which are taken off early in the day and plenty of air given to them. There has been singularly little green fly amongst them; but where noticed it has, of course, been at once brushed off, for with my small collection it is better to do this than to fumigate, for which, as a florist of the old school, I have not much love. Autumn-blooming, that nuisance of the Auricula grower, has not been excessive. I have from time to time examined the pots, and where I have found my old enemy the woolly aphid I have brushed it all off or squeezed it between my fingers. Opinions still differ as to the amount of injury it does, but that it cannot but be injurious to some extent I firmly believe. Every grower speaks of it now as existing in their collection, and its mysterious dispersion is one of those insect problems about which, with all the vaunted discoveries of science, we know next to nothing.

Carnations and Picotees.—I have never seen healthier or better plants than this season. It was a good season for layering, the plants rooted well, and are now well established in their winter quarters, a pair in each pot. I see no evidence of spot amongst them, and as I have seen several collections this year I imagine that my experience is that of most growers. They should have air at all times when the weather is good, green fly should be carefully watched and got rid of immediately that it appears, the pots should be kept clear of weeds, and, as with the Auricula, water should be only sparingly given. Any decaying leaves should be carefully removed, and cleanliness is the main thing to be looked after.

Gladiolus.—What unaccountable things these are! I was at my friend Mr. Banks' a few weeks ago, and of all his tens of thousands of roots he has not one left. In a small garden near here where they have grown for years the owner said to me yesterday, "I have only one corm left, and that is a seedling;" and yet I have not, ever since I grew them twenty-five years ago, had so few losses or lifted such fine and healthy corms, and this in all parts of my garden. Fresh roots, my own harvested ones, spawn, seedlings—all the same. Now, why this is I cannot tell, for I have made no alteration in my culture; but so it is. My corms have been taken up for some weeks. Each variety was placed in a pot with some of the earth attached to them, and I shall next week clean them off, remove the spawn, and put them away in the skeleton drawers in which I always store them in, place the spawn in paper bags

until the spring, and perhaps next year will be as unfavourable as this was good. By-the-by, I should like to ask "W. J. M.," who referred to me in a late article in the Journal, when, after detailing his method of storing, he adds, "I never lose a corm," does he mean that absolutely, or that he never loses one after they are taken up? If the former I cannot understand it, for he is the only grower I have ever heard of who could say so. If the latter I can understand it, for I never lose a healthy corm after it is lifted.

Pinks.—It has been a good season for planting out these, and the plants look vigorous and healthy, although I am free to confess that I have not a very great *penchant* for them. They are very pretty and very sweet, but they are unfortunately so much alike that it is very difficult, after you get through three or four varieties, to say where the difference exists, and the growers of them, at any rate in the south, are few and far between. It is not so with the beautiful Picotee, with its ranges of colour and its different edges—from the thin almost invisible wire edge to the deep heavy red, purple, or rose. It may be want of perception or want of taste, but I can but see much sameness in them.

Pansies.—Here quite a different state of things exists, especially since the wonderful improvement that has taken place in the so-called Fancy varieties; for anything more varied, more striking, and more beautiful in this way it is impossible to conceive. They are, too, much hardier in constitution than the older Show varieties. It has been a good time for them too, whether in beds or pots. In the former case care must be taken to keep them free from weeds, and if frost comes they must be watched, and if loosened in the soil they must be pressed firmly in again. Those in pots must also be kept clean, green fly speedily got rid of, and air given at all suitable times.

Ranunculus.—Nothing can be done with these now but to examine the roots occasionally to see that they are free from damp, which is fatal to them.

I do not grow Tulips; and other flowers which have of late years been called by some florists' flowers—such as Pentstemons and Delphiniums—I cannot class, with my old-fashioned notions, under this title.

When the stress of work outside is done, and when frost binds the ground, or snow covers it, or wet makes it unworkable, it will be a good time to prepare compost for the above flowers when the top-dressing and repotting begins. It is well that all this should be placed under cover, for heavy rains wash the good out of the soil and render it difficult to use when it is wanted. Auriculas will require top-dressing in January, then comes the potting into their blooming pots of Pansies, and after that the potting of Carnations and Picotees. Having made up your mind what you are going to use for these purposes, get all ready, well mixed together, and then when the time comes a great saving of trouble and annoyance will be saved. A shed where it can be exposed to the air without feeling the weather is the most suitable, but failing this any covered place will answer the purpose.

Florists' flowers do not seem to grow much in favour in these southern regions. I am fifty miles from the next Auricula grower, and collections of Carnations and Picotees are almost unknown in our county; yet what enjoyment there is in them, and in that which constitutes so great a charm in life—variety, how far beyond those things which are so much in favour now! It may be fashion will change, but in this respect it is slow in making the move.—D., Deal.

POTENTILLA FRUTICOSA.

A VERY distinct form of *Potentilla* is the one shown in fig. 96, as it departs from the low rambling or creeping usual types of the genus in its shrubby habit. Upon rockeries it succeeds admirably, forming compact little bushes 1 to 2 feet high, and covered with its neat bright yellow flowers, which are produced in great numbers throughout the summer months. It is occasionally found in mountainous districts of Great Britain, but is not common; and it is also found in various parts of Europe, especially in the Pyrenees. In well-drained borders it grows strongly, but much the best position is the rockery, upon which it is soon established, and can be readily increased by division or by seeds. I have never tried it in pots, but I should think it would be very suitable for that purpose, though the flowers are somewhat fugitive. Have any readers of the Journal tried such an experiment with it?

P. fruticosa is also found in various parts of Asia, and even in America. In the latter country, however, several shrubby forms have been noted, which by some botanists have been regarded as varieties of this one, and by others as distinct species. Examples of these are found in *P. floribunda*, a North American plant; *P. parvifolia*, from the Soongarian desert; *P. dahurica*, from Dahuria; *P. arbuscula*; *P. rigida*, *P. lignosa*, and *P. Salesovii*. This last is somewhat of the habit of *P. fruticosa*, but is easily recognised in the leaves of *P. Salesovii* not having the same silvery appearance, and the leaflets are more sharply serrated.—HERBA.

LIVERPOOL CHRYSANTHEMUM SHOW.

It may be interesting to state, as I am informed, that twenty years have passed since the first Chrysanthemum Show was held in this town.

Those who attended the first and have witnessed the last consider the latter much the finest that has yet been held. It is the fourth Exhibition held under the auspices of the Association, and it is gratifying to be able to state it has proved a success horticulturally and financially also. Its downfall was prophesied some time ago unless the Committee relinquished the system of management adopted for some other gigantic scheme, which had never been tested, and which no one appeared bold enough to explain thoroughly. The majority of the active members of the Association were against the scheme, and it will be proved by the figures I intend giving that this young Society is growing in the estimation of the public. Last year the subscribers and members numbered 868, while this year they are 1020, thus showing an increase of 152 over the previous year. The amount of cash taken at the doors in 1880, the first Exhibition, amounted for the two days to £166 0s. 6d., the following year to £171 0s. 9d. Last year there was a slight falling off, owing to the postponement of the Show and the inclemency of the weather. I would give the amount taken, but I cannot put my hand upon the report at the present time. This year £224 has been taken at the doors, £134 on the opening day and £90 the second. The entries and exhibitors have also increased wonderfully since last year, when the numbers were—60 exhibitors, entries 298; this year 77 of the former and 385 of the latter.

To give some idea of the magnitude of the past Exhibition I append

Fig. 96.—*Potentilla fruticosa*.

the following statistical particulars: The number of cut blooms, incurred, were between 490 and 500, and amongst them was a grand bloom of Lord Wolseley, which keeps well (better than Prince Alfred), and will doubtless prove a grand exhibition variety, staged by Mr. W. Mease; Japanese about 250, and amongst these was a wonderful bloom of Boule d'Or shown by Mr. R. G. Waterman; Anemones and reflexed numbered 36, and Pompones 90 bunches. There were 160 dishes of Pears entered for competition, and in nearly every instance the fruits were very large. Apples, dessert and kitchen varieties, numbered about 500 dishes, half this number being staged for competition, and the remainder by the nurserymen mentioned in the report in your last issue. The schedule only comprised about five classes for Grapes, and it will give some idea of the competition when I state 53 bunches of whites were staged and 83 of black—total, 136. This includes those shown in the collections. The Grapes on the whole were remarkably fine, but the individual bunch that attracted the greatest attention was one of Gros Colman, splendidly finished, the bunch being large and the berries of remarkable size, the largest I have yet had the pleasure of seeing. This was staged by Mr. Goodacre, Elvaston Castle, in his first-prize collection of twelve dishes of fruit. The trained plants numbered 64, besides a

few standards, but with the exception perhaps of those staged by Mr. Hughes I have seen them better. The untrained specimens showed a slight improvement over those of previous years, but there is still room for advance before they equal those shown at Manchester.

The most striking plant in the Exhibition was one of *Calanthe Veitchii*, staged by Mr. A. Brown, gardener, Upton, Chester. It was the finest variety, with straight even pseudo-bulbs, as described by Mr. D. Thomson, and the spikes were fully 3 feet 6 inches in length, the plant 3 feet in diameter and one mass of bloom. *Erica hyemalis* was shown in wonderfully fine condition; it is a grand Heath for purposes of exhibition at this season of the year. The examples referred to were staged by Messrs. A. R. Cox, W. Mease, and A. Brown. The plant shown by the former was fully 3 feet 6 inches through, with spikes of bloom fully 18 inches in length; in fact this large specimen was equally as well flowered and grown as the models of perfection we see from London annually. Mr. Mease's plant was a little more stubby, while the one shown by the last-named was splendidly grown and bloomed, but was rather smaller.

The Cyclamens staged by Messrs. R. P. Ker & Sons, and for which a cultural certificate was awarded, were the finest I have seen exhibited. Some of the plants were fully a foot through, and the whole, numbering a hundred or more, were large and fine. The strain was of the very finest, the flowers being wonderfully large. Pure white-flowered varieties, which are so useful, largely predominated.

The blooms of Zonal Pelargoniums shown by Messrs. H. Cannell and Sons were one of the most attractive features in the Exhibition. The Cyclamens referred to and these attracted more attention than any other exhibits, the cut blooms of Chrysanthemums perhaps excepted. There appears to be an idea that these Zonals cannot be flowered in this neighbourhood or grown to the same perfection as those staged on Tuesday last. They will do well if they have suitable houses and are well grown, and it would be wise to offer a few prizes for them another year, which would do more towards the extension of their cultivation in the neighbourhood than anything else.

Messrs. T. Bethel & Co., 24, Cable Street, Liverpool, were highly commended for their folding boxes for packing plants and flowers. These boxes are very similar to others already in the market, but they fold up closely, which renders them most useful, because they can be stored away in a very small space; in fact, the smaller sizes when closed take up but little more room than an envelope.—WM. BARDNEY.

A MODEL FORCING HOUSE.

WHETHER for purposes of forcing or otherwise houses are often constructed, especially in private gardens, more for appearance outside than anything else. I have seen many houses employed for forcing flowers and fruits differing greatly in size, shape, and construction, and many of them are almost useless. Who is to blame for this it is not my intention to discuss, further than say in many large as well as small establishments the gardener is not consulted in the matter. If the houses prove unsuitable, which they very frequently do, the outside gardening fraternity blame either the gardener or the builder, and both really are innocent, the former having had nothing to do with them, and the latter only working according to orders. After taking into consideration various qualifications of all the houses I have seen for forcing purposes, the best is one recently erected by Mr. John Webster, Wavertree, Liverpool, in the gardens of John Walker, Esq., Greenfield, West Derby. Light is of the greatest importance, and should be one of the first points to be studied in the construction of houses, especially where forcing operations have to be conducted during the sunless days of our winters. The house under notice is the lightest I have seen; in short, it is a model of what a forcing house should be, and reflects the greatest credit upon both the builder and its owner. In the majority of forcing houses where front lights are used the light admitted by them is almost rendered useless by the woodwork which supports the rafters of the roof, and forms in many cases the spout. But in this house it is entirely dispensed with, and the spout forms a portion of the wall plate. There is side glass, but so placed that not a ray of light can be excluded.

The house is 63 feet long, 12 feet 6 inches wide, and about 9 feet 6 inches high from the ground, and is divided into two compartments. The brickwork of the house is 4 feet high above the ground level, and the front glass about 15 inches. The rafters are about 5 feet apart, and are not so heavy as are generally seen, yet they are abundantly strong; between these are three lighter bars to support the glass. It will be seen that the squares of glass are large, being about 15 inches wide, and if I am not mistaken two form the length of the roof from the top ventilators, and these are formed with one square. The rafters of the roof are continued to the wall plate, and the stronger ones (every 5 feet) are secured with light angle irons inside. The front glass and rafters are scarcely upright, the tops sloping inward out of the square about 1½ inch. The glass which forms the front rests in the wall plate and fits close to the squares of

the roof, which projects over them about half an inch. It will be seen that this house has front glass, and the objectionable woodwork and spout that are generally used with front lights are entirely dispensed with. The bottom ventilators are formed in the brickwork, one being placed under each light on both sides, and directly opposite the hot-water pipes; these are opened from the outside. The top ventilation is on the south side of the house only, and opens with a neat lever and screw. A rod of three-quarter inch iron (round) runs the whole length of the roof on both sides, and either runs into the main rafters or through them, while all the lighter ones are secured to it to keep them in their place. The roof is further supported by two or three neat iron rods which start from the angle irons supporting the roof and front rafters, and are secured in the centre of the house by a stronger rod of iron about 18 inches in length, made fast in the ridge with a screw on the end that passes just through the centre of the rods issuing from both sides, and fastened with a nut. I need not give details of the internal arrangements; suffice it to say bottom heat is provided in one compartment and not in the other, the beds are formed on each side, and the walk is down the centre.—WM. BARDNEY.

STORED-UP SAP IN VINES.

YOUR correspondent, "A Non-Believer" (page 465) is not satisfied with my "attempt to explain and reconcile things." I will therefore try again. I am asked to explain what I mean by "implying that Vines were dependent on the stored-up sap of the previous autumn till the shoots were long and had leaves 5 inches broad." I have examined Vine roots in every stage of their existence for many years, and once at least to the extent of several thousands in one year, and only in very exceptional cases have I found root-growth to commence before some of the leaves were expanded to half their full size. A vigorous one-year-old Vine cut down early and allowed to make only a single stem will grow from 7 inches to a foot in length at the top before it makes any growth at all at the root. Just at that time (it ought to be almost to a day) the Vine will bear to have all its soil shaken off and to be transplanted or repotted without a check, because root-growth goes on immediately. The next thing to be noted is, that the bluish colouring to which I referred makes its appearance on the pale green leaves in blotches at this identical stage of the Vine's progress, never before and never later. It mingles in the course of a few days with the pale almost yellowish green, and the result of the mixture is the good healthy-looking green we all like to see in a growing plant. These are facts which anyone can prove for himself.

Now as your correspondent will not accept my unsupported explanations I must call witnesses. Dr. Hooker in "Botany," one of the series of scientific primers issued by Macmillan & Co., says at page 30:—"Nourishment is taken up by the root hairs and not by the growing point." In Johnston and Cameron's "Elements of Agricultural Chemistry," eleventh edition, at page 59 I read—"The root sends out fibres in every direction through the soil in search, as it were, of water and of liquid food, which its extremities suck in and send forward with the sap to the upper parts of the tree. The part of the roots where absorption chiefly takes place is near the extremities, but it has been shown that the tops of the roots or spongioles take no part in the process." Here, then, are two witnesses such as I presume your correspondent will treat with respect, who testify that the nourishment is taken in by the root hairs; and as these hairs do not occur on any but newly made roots, I must leave it to him to point out how they can take up nourishment when they are non-existent. I would recommend "Non-Believer," if he has no chance of finding out facts concerning common physiology by actual practice, to read some more recent authors than Dr. Lindley, for some of that learned gentleman's physiology instead of being "accepted by all" is already obsolete.

I do not know whether the following paragraph is worth treating seriously. Your correspondent says, "There is really no such thing as storing up sap in the sense Mr. Taylor states in plants like the Vine. Only bulbs and tuberous shoots store food, for reasons apparent to anyone." This was not learned from Dr. Lindley certainly, and I will quote one of that gentleman's contemporaries to refute it—"Leaves may be produced without roots, as may be observed on fresh shoots springing from trunks of felled trees, but these shoots are supported by sap contained in the trunk, and which has been elaborated by the leaves."—"Thompson's Gardener's Assistant," page 83). If this is not sufficient see what Dr. Prantl says. In his "Text Book of Botany," at page 76, second edition, I read—"Certain layers of cells, particularly the medullary rays of trees, contain in the winter a quantity of starch, which is absorbed and consumed during the spring, when new shoots are developed." And lower down on the same page he says, "The degree of development reached by plants grown in the dark depends on the supply of reserve materials, which varies in different plants." At page 82, too, are some remarks which may not be uninteresting at the present time. "The presence of plastic material is an indispensable condition of growth, but this does not necessarily imply that the nutrition of a growing plant depends upon the simultaneous absorption of nutritious matters from without; on the contrary, the young growing parts of a plant are usually supplied with plastic materials from the older parts which have ceased to grow."

These extracts will, I hope, be sufficient to prove that plants are not

the improvident things "Non-Believer" makes them out to be, but that they always, when they are rationally treated, lay up a good store for future use. If it were not so, if they only carried on a sort of "hand to mouth" existence, they would the sooner succumb to the unfortunate treatment many of them are obliged to endure, while the renovation of those which had a little life in them would take a shorter time than we find it to do in practice. If it is true that a cat has nine lives I am sure a Vine has at the least a dozen.

I must positively deny having said or implied that Vines had completed their store of sap at the fall of the leaf. On the contrary, root-action in the Vine is very busy at the fall of the leaf, and continues so for some time afterwards, say a month or six weeks. It begins later and continues later than it does with other plants. On one occasion some years ago I had my faith in this habit of the roots rather rudely shaken for a time. On examining some pot Vines which had been placed in a forcing pit in October, active roots in great numbers were found. This was after the Vines had been in the comparatively warm quarters three weeks, and before there were any signs of the buds moving. But later on when top growth commenced the active roots were looked for in vain. Those I had seen were late roots belonging to the departing season.

I ventured to hint in a former communication that water might be absorbed by the old roots before root-action proper commenced, as we know it can be absorbed by a brickbat or a log of wood. The author now before me, Dr. Prantl, at page 83 puts the matter in a much better light by referring to a Potato tuber. He says, "A Potato tuber, even if kept quite dry, will sprout under the influence of a sufficiently high temperature, and in proportion to the growth of the shoots the tuber will become flaccid and wither, beginning at the more remote parts in consequence of loss of water. This water is not only of use in that it dissolves nutrient substances, and thus renders possible their transport to the apex of the growing shoot, but it is itself of use in the process of growth; for not only are solid particles of cellulose deposited in the growing cell walls, but also a quantity of water; and moreover, the vacuole of the growing cell containing cell sap also increases in size. The water which is indispensable for these purposes is gradually absorbed from the more remote portions of the tuber. As a consequence if the tuber be kept dry it will gradually become flaccid and withered, but if it lies in damp earth it takes up water from the soil, and this water is conveyed with the nutrient materials to the growing parts. Water is similarly conveyed to the developing buds of trees, to the growing points of seedlings, and generally to all growing parts of plants, from the nearest parts in the first instance, then from the more distant, and finally from the external medium." It will be observed that the Potato absorbs the water before any roots are made to penetrate the soil, for if only one end of the tuber is inserted in the soil the effect will be much the same, and according to Dr. Prantl woody plants are capable of doing the same thing.

Here, then, I think is the key to the mystery existing in your correspondent's mind. He takes the absorption of water to mean root-action, whereas roots are not even necessary for its absorption, as we see in the case of cuttings inserted in damp soil, or even from cut flowers in a glass of water.—WM. TAYLOR.

BEING very much interested in the above discussion, I should like to know if "Non-Believer" means that Vines do not store up sap in the rods for the next year's use. I grow about 5 cwt. of Grapes yearly, and always treat mine under that impression. If they do not, how does a grafted Vine bring a different kind of Grape, or an eye when first struck grow an inch and then stop, as it were, to rest till roots are formed to carry it on? As to bleeding when started, if they are well ripened they seldom "bleed" excessively. If Vines do not store up sap what makes the difference between good and bad condition or ripe and unripe wood? If "Non-Believer" will state just what he meant, those who are looking on will understand his arguments better.—J. C.

PANSIES AND VIOLAS.

VIOLA PERFECTION AND BLUEBELL.

I AM glad to see a communication under this heading from my old correspondent, Dr. Stuart of Chirnside, who has done good service in raising and distributing some charming and useful varieties of Violas; but he is in error in stating Mr. B. S. Williams raised Viola Perfection. It was Mr. James Cutbush of Highgate who first called attention to this Viola, having seen it at Rotherfield Park, Alton, Hampshire, where it is said to have originated; but if the latter statement is correct, it had become distributed previous to Mr. Cutbush calling attention to it, as I was able to procure plants from another source. Acting on Mr. Cutbush's advice, some plants in flower were sent to one of the meetings of the Royal Horticultural Society, when it was awarded a first-class certificate of merit. Mr. B. S. Williams then bought the stock of it and sent it out; but, as I have stated above, I procured my supply from Rotherfield. It was said at the time that it resulted from a cross, but it might have been a chance seedling.

Viola Bluebell, a variety which has, I imagine, become more generally grown perhaps than Viola cornuta itself, originated in my garden at Ealing as a chance seedling. It is not a little remarkable that I had not previously grown Pansies or Violas in my garden. I discovered a dwarf tufted Viola growing, and being struck with its habit took care of it until it flowered. I named it Bluebell, and sent it out. This, then, was the origin of this popular variety, and one remarkable characteristic of it is that it is not so subject to mildew in summer as the Perfection type, and not a few others.

For some reason the Viola has declined in the south as a bedding plant—so many plants die in the height of the summer; and now there is very little demand for plants. I have given up raising seedlings for this reason; but there is no justification for believing that all the possibilities in the Viola are exhausted. Presently someone else will take it in hand, and improve upon existing varieties, carrying on the good work to a higher level of attainment than has been before reached. The floral succession, if at times a little broken, never wholly ceases, and therein lies my hope of the future.—R. DEAN, *Ealing, W.*

NOTES AT KEW.

AN IRIS GARDEN.

PREPARATION is being made for an extensive Iris garden at Kew, which will undoubtedly be a welcome and attractive addition to the numerous improvements that have been effected there in recent years. The long border near the wall of the herbaceous ground has been hitherto devoted to this beautiful family of plants, but a better position is needed for them, and the one chosen is preferable in every respect. Beds are to be formed in the turf at one end of the new rockery, between No. 2 museum and the T range, and we understand that Professor Foster will give the Kew authorities the advantage of his experience in Iris culture in determining the site, the formation of the beds, and other special details. It has already been noted that the charming Iris *lævigata* (T. Kämpferi) has been planted in clumps by the lake, a situation that is unquestionably well adapted for the species, though, of course, it will be also represented in the general collection. Judging by the plan marked out upon the turf it is not intended to have gravel walks leading to the beds, and this is rather to be regretted, for after heavy rains and in damp weather generally, many visitors (especially ladies) who wish to inspect the plants find it very inconvenient to walk over the wet grass. Indeed, this is the only disadvantage attending the beds of plants in the herbaceous grounds proper, as they are not like beds of Pelargoniums and similar occupants of the flower garden where distant effect is obtained.

BULB BORDER.

Another suitable experiment is about to be tried in the same garden—namely, the formation of a Cape and half-hardy bulb border, the result of which will be somewhat anxiously watched for. Similar attempts have been previously made with little success, but the preparations have never been so thorough and efficient as on the present occasion. The border by the wall forming the boundary of the Duchess of Cambridge's garden has been chosen, and the soil removed to the depth of about 3 feet, a good drainage of potsherds and rubble, 6 inches deep at the back and rather deeper in front, the bottom sloping slightly. Above this layers of leaves and turf are placed, and the other portion will be filled with special composts according to the requirements of the plants to occupy the different parts. This border will, unquestionably, be an extremely interesting one, and will probably be as successful as is expected, but a cool house in the style of those in the late Mr. Joad's establishment at Wimbledon would, we consider, have been preferable. Possibly, however, the additional expense had deterred anything so extensive as this being attempted at present.

HOUSE FOR HALF-HARDY PLANTS.

Such a house might at some future time be advantageously erected in the herbaceous ground, to be kept supplied with the choicest and most tender species when in flower. Under the present arrangements scores of rare, beautiful, and interesting plants flower in the frames of the private portion of the garden which the public have no chance of seeing. If a few good specimens in pots of the most attractive hardy species were added, a display of more than ordinary beauty could be maintained during a large portion of the year with little trouble or expense. One of the most attractive examples of this kind that we have seen is in Mr. Broome's garden at Didsbury, Manchester, where a small conservatory is kept furnished with hardy and half-hardy plants, and during the early spring and summer months there is a constant succession of floral beauties. The advantage this method possesses over such houses as those of Mr. Joad's is that plants can be removed when out of flower. The Cape house at Kew, it is true, provides for this to some extent, but it is confined to too small a group of plants.

ROOMS FOR THE YOUNG MEN.

Now that a spirit of improvement seems to be so general in our great public garden, it is regrettable that measures have not been adopted to provide some accommodation for the young men there. Kew ought to set an example in this respect that would be a credit to an establishment of such fame, whereas scores of private gardens are vastly superior to it in the provision for the comforts of the employés. Undoubtedly it would be an expensive undertaking to erect a suitable building, but if the advantages that would accrue to the men, and eventually to the credit of the Gardens, were pressed in the proper quarters with the same ardour as others of less importance, there is little doubt that the scheme might be accomplished. A large proportion of the young men who go to Kew have been perhaps but just released from the wholesome restraint of both life, and they do not always employ their freedom to the best advantage. Add to this that lodging and living are very expensive, and generally unsatisfactory in Kew, the men often being regarded as the legitimate prey of extortionate "landladies." Some difficulty is also experienced in obtaining rooms convenient to the Gardens, and men

employed in the Palm house, for instance, have the greater portion of the time devoted to meals occupied in walking to and from their work. Possibly the difficulties in the way of a scheme like that suggested have been already considered and the project shelved as impracticable, but the fact remains quite patent to the outside public that the employés at Kew are not adequately provided for bodily, however well their mental improvement may be studied.—VERITAS.

CYCLAMENS AND THEIR TREATMENT.

THERE is no plant so useful for decoration at this period of the year as *Cyclamen persicum*, yet it is seldom seen in first-rate condition. For this reason any hints will no doubt be valued, especially by amateurs; and as I have been very successful I venture to give the following brief directions, founded on the practice I have adopted for some time past. Sow the seed in pans at the end of July in a compost of finely sifted loam and silver sand with a small addition of leaf soil. Do not cover the seed, but simply lay it on the soil. Place the pots on a shelf in a damp place in the stove, and keep the soil moist through the winter. The seedlings will come up irregularly. Let them stay till the necessary quantity are ready, then prick them off, about twenty into 6-inch pots. This time the same soil will do, but the top must have an eighth of an inch depth of silver sand on the surface. Constantly damp them. Stand them in an early vinery at the end and close to the glass. When large enough place them in 3-inch pots. Stand them in a forcing pit on ashes. Keep the plants free from insects and well damped. When fairly rooted transfer them into 4 and 5-inch pots, and place them in a cool frame. Syringe them twice a day, and shade on hot days. Keep the flowers picked off till they are taken in the houses in October. The soil for the last potting should be loam and dried cowdung only.—A FOREMAN.

CULTURE OF LILIUM AURATUM.

THAT the golden-rayed Lily of Japan is not generally well understood as regards cultural requirements is evident from the many weakly plants to be met with; also by the enormous importations that arrive in this country every season from their native habitation, and which, did they receive the proper treatment, would make them as common as could be wished, and instead of a good stock being rarely met with, they would certainly be more frequent. I think I am right in stating that the old practice of drying-off these handsome Lilies and placing them under stages in greenhouses until spring happily is more the exception now than the rule, and so it should be, for no practice could be more adverse to the well-doing of the plants. Nothing could have done better than some bulbs we bought in about three years ago, and which were at once potted in suitable-sized pots, in a mixture of peat, loam, and well-decayed cow manure, and sufficient sharp sand to keep the whole porous, the pots being well drained. Preference is given the first season for pots rather small than too large, as they do not appear to make so much root the first season, particularly when potted late. They were then stood in a frame, watered to settle the soil, and when the surface had become a little dry they were covered with cinder ashes to the depth of 6 or 8 inches, and then covered with shutters to throw off rain. In this position they remained till started in spring, when they were removed to a light position in a cold pit, and kept as close to the glass as possible. Constant attention is needed, for when they commence producing their heads they move rapidly even in the coolest position, and would soon damage themselves against the glass. No frame unless very deep will accommodate them very long, so that some should be moved to the greenhouse if there be such at command, and others placed in any unheated orchard house or similar structure, and a third batch may be plunged out of doors in a sheltered position to succeed them. When the plants have reached about 12 or 15 inches high, roots will be found proceeding from the base of the stem. These should be carefully preserved by placing some turfy loam or peat around them, which the roots will penetrate and thus be conducted into the pot, otherwise they will perish, much to the detriment of the present season's flowers. With the natural propensity of some kinds to flower earlier than others, and the different treatment described, will give a succession for at least three months without in any way unduly drawing them.

After the flowering is over they may be placed outside, and here we come to the most important part of their culture, as it is on this point that so many have been unsuccessful in the culture of this Lily. It is by no means uncommon to see these Lilies after they have done flowering turned over on their sides, and subjected to what is termed "drying off," a practice which cannot be too severely condemned. The proper way is to stand them in a moderately warm position under a wall or hedge, where they can receive a fair amount of sunshine, for at no time of their growth are they more benefited by its influence. They must be carefully and regularly watered, never at any time being allowed to suffer for the want of it. When the stems have assumed a yellowish hue and the leaves fallen from them they should be turned out and examined, and if all has gone on right the pots

will be found to be packed with young growing healthy roots; and at this stage they should be potted carefully, giving them a moderate shift into well-drained pots, and working a similar compost around them to that recommended for their first potting. They are then set in a frame, watered, and in due course covered with ashes and the shutters placed over them, when they are free from all anxiety till the following spring. Under this treatment we have found the bulbs increase fourfold both in strength and numbers.

Some cultivators keep their plants under glass after they have done flowering, but I am of opinion that when such could be practised is more the exception than the rule, as most employers like to see something attractive in their glass structures; at least, such is the case here, and if we had plenty of room under glass we should not think of placing our stock of Lilies there to ripen. Glazed lights are so useful for many purposes, and are not always equal to the demands upon them, that it is the more pleasant to know that these beautiful Lilies can be preserved for more than half the year without their aid. I am of opinion that the shutters are advantageous, as they do not unduly excite the bulbs in the dull months of the year as does glass when closed over them.—C. WARDEN.

RETUBBING LARGE PLANTS.

HAVING some large Camellias that are too heavy to be lifted in the ordinary manner, and as these need fresh tubs, I shall be glad to know

Fig. 97.

the best manner in which to proceed. Any information you can give will be very acceptable.—W. ELLERBY.

[On this subject Mr. Van Hulle, of the Ghent Botanical Gardens, has described a plan that he has adopted satisfactorily as follows:—Take two strong posts, A and B, so securely stayed at their base that there can be no chance of their upsetting. Set them at a suitable distance from each other, and place between them the plant to be retubbed, or, what amounts to the same thing, take the uprights to the plant. The old tub or box is removed, the ball seen to, the stem carefully wrapped round to prevent injury to the bark, and the collar E put on. This can be tightened to any desired extent by the four screws shown in the engraving. Lastly, the two ends of the collar are slipped into the grooves in the uprights, which, as will be perceived, are also pierced with holes. The apparatus having been prepared for action, two men with a pole, or even one with a long lever, will raise the collar, and therefore the plant, say to the point C, and an iron pin is there pushed into the hole under the collar; the plant is then raised to D, and so on alternately. In a few minutes two, or at most four, men can thus raise up plants of the largest size. To prevent any danger of over-balancing, a strong stake has been put to the plant, and of sufficient length to slide

in the guide-ring F as the plant is lifted. When the requisite height is reached, the new tub is put under the plant, and the latter is let down peg by peg in the same way as it was raised up. The less the distance between the holes the better, and never raise up or let down more than one hole at a time. The contrivance gives perfect satisfaction. If any of our readers can recommend a more simple and better system that they have adopted we shall be glad to hear from them.]

GARDEN CHEMISTRY.

CLAY SOILS.

THE first step towards the improvement of wet clay is draining it, a subject that will claim a chapter to itself. The next thing is to find something with which to mix with the staple, and which will serve the purpose that sand serves in loam. If light sandy soil can be got that is the best corrector of clay, for the two soils mixed will give a loam at once. But light soil is just what seldom can be had in a clay district. Perhaps the next best thing, especially when it can be had cheap, is the sweepings of streets minus the broken bottles, tin cans, bricks, and other rough material that will not decay. In those districts or gardens where plenty of brushwood can be had, or even where coal is cheap, nothing will surpass the soil itself when charred. Road-scraperings, too, are often of a gritty nature, and are a valuable addition to any garden soil, especially from macadamised roads where whinstone is used. Coal ashes, too, are by no means to be despised, although in outlying districts some trouble may be experienced in getting qualities that will make matters right all at once; but if the ashes made on the place are screened to keep out cinders, and made the most of, in the course of a very few years a great difference will be apparent. Lime, too, when properly applied does much to improve heavy clay, and ordinary manure plentifully applied will in course of time make the clay much more friable.

In order to make the most of such materials as we have named some care will be necessary in their application. Digging them in will not do, though that is the usual way of incorporating such with the soil. Digging-in only masses the materials in different lots; it does not mix them.

But a word is here necessary on the digging of clay soils. It has been the custom to recommend that such be turned up early in winter, or even in autumn, in order that the frost may pulverise them. This it does not do to any great extent, and it would be better if it did not do it at all, for the looseness so induced causes the retention of rain, which settles the mass into mud. When left undug, solid, no mud is formed, the frost acts on it all the same, and when turned up in big lumps in February or March the winds dry them, causing them to shrink; when moistened by rain they swell to an extent no frost could expand them, and the pieces can then easily be knocked to powder, forming the best tilth possible in such soil either for sowing seeds on or putting out plants. This our experience in the Carse of Falkirk teaches us is the proper way to treat clay soils, and we are confirmed in it by Mr. Weir of Kerse House, Stirlingshire, Mr. Thomson of Drumlanrig, Dumfriesshire, Mr. Doig of Rossie Priory, Perthshire, Mr. Taylor, Longleat, Somersetshire, and others all in widely different parts of the country and under different climatical conditions, but all having, or having had, to deal with the heaviest clays, and all men of undoubted authority.

It is when the surface is in this condition that such materials as we have named should be applied, for only then can they be perfectly incorporated with the soil. For this purpose the fork should be used, and care should be taken that digging is not allowed. The manure, ashes, burnt clay, whatever is being mixed in, should be kept near the surface. This is the more necessary if the amount of it should be small. One of the great evils of clay soils is that when dry they are too hard to work, when wet too puddy; but if even an inch at the surface be made free much will be done in the way of improvement if every fresh-dug-up surface is every new season similarly treated.

In the case of light soil all matters must be imported. Best of these is heavy loam, and the best way to apply is to pulverise the clay in the way described above, and to fork it in. We have known clay to be dug into sandy soils, which after long years of cultivation was still turning up in lumps. As it is only when diffused through the soil that clay does any good, digging it in is next to useless—in fact is throwing money away. But hardly anything improves light land so much as road-rakings. Marl, especially when clayey, is so applied with lasting benefit. As sandy soils hold least water and are soonest dried up, perhaps a plentiful supply of water and mulching, combined with liberal supplies of manure and a continual deepening of the soil are the best improvers, for carting clay and marl, and applying them in quantities sufficient to really improve the soil is, too often, out of the question because of the expense entailed. Keeping such soils pretty compact has a beneficial effect on them. It is their openness which causes them to dry so much; hence throwing them up loosely

with the fork in spring and summer, although beneficial in so far as it breaks all lumps and diffuses the manure, so allowing the roots free access to every part, and a continual supply of food, should always be followed by consolidation in the case of loose soils, otherwise forking is a great evil.

Trenching is much advocated, but often trenching does much mischief. We have seen plots, and even whole gardens, rendered nearly sterile by injudicious trenching. No good can follow the turning-down of perhaps the few inches only of surface soil and the bringing-up of sterile clay or rusty sand; and we cannot too earnestly urge on young men to always keep the best soil not only at the surface but at the very surface. The start in life is nearly everything to all sorts of vegetation, and a good start cannot be had in any but soil friable, sweet, open, and presenting food to newly pushed roots at every stage of their progress. When soil is turned up from below, and the good soil as well as manure turned down, no matter how heavy the dressing may be or how good the soil, failure more or less will result according to the length of time the roots are in reaching them.

Still an effort ought to be made to deepen all soils that are less than 2 feet deep. Not long ago we had to deal with a soil in many places not over 4 inches thick, resting on an impenetrable pan. In a few years this pan was got rid of and the soil made $1\frac{1}{2}$ foot deep in many instances; but not by turning down the good soil. The method employed was to turn over the soil, exposing strips 2 feet wide of the subsoil. This was composed of half sandy half clayey stuff, full of stones and bound like asphalt with iron, altogether as unpromising-looking material out of which to make soil as one could look at. For a few inches in depth this subsoil was broken up with much difficulty with a pick, a good layer of manure spread over it, a spadeful of soil turned over, another layer of manure, and any loose soil over that. The upper layer of manure was just under the soil and told at once on the crops; the under was just over the broken subsoil and kept the crops going later on. It did more; it furnished a home for worms, which in summer droughts and winter frosts found their way into the hitherto impenetrable subsoil. Now worms do two things. First, they live on decaying vegetation and convert it into the finest soil. On hard soil this is thrown to the surface, but in loose soil, such as the subsoil in question, they fill the open spaces with it. Secondly, when driven deep by frost or drought they swallow the soil, out of which they extract nourishment. They do more, as Darwin has proved. They grind the particles, liberating plant food, but, above all, they dissolve the red iron oxide. The decaying layer of manure also acts in the same way. Out of it acids are formed which, washed down by rain, also dissolve the iron. In consequence of this the drainage water from soils so treated shows iron, and by-and-by the impenetrable pan which hitherto prevented roots descending or killed them if they did descend, as well as cut off the supply of moisture from beneath, thus causing crops to be burnt up in dry weather, is got rid of.

When a couple of years afterwards this broken subsoil was examined it was found very different. Poor enough still, it was now brown loam, with no trace of iron and no tendency to bind. It was now no longer inert, but soil. Again it was turned over. This time two shallow spades was to be had, and this was trenched over as before, the lowermost spading being put upmost, with a layer of manure under, and the subsoil further broken up. But the new soil at the top, mixed somewhat with the old soil, was not just the best even with a layer of manure directly under it. A dressing of thoroughly rotted dung was therefore spread over the surface and mixed in with the fork, and in this Potatoes were planted. The new soil and new manure always produced the finest early Potatoes, which, when lifted, left the soil by July in capital condition for putting out Strawberries, which, under such conditions, produced grand crops of the finest fruit the following season.

In the improving of thin clay soils some similar method should be followed, only it will perhaps be found best to *fork* in sandy stuff, ashes, street sweepings, into such subsoils for two or three seasons, so as to get them as near the condition of loam as possible before turning them up. Indeed, by always forking the under soil only, some surface soil will be always taken down, and the digging-over of the surface soil will always bring up a little of the under, when the two will become similar. But by getting the soil free enough, then throwing it to the surface in order to enrich it and pulverise it thoroughly by cultivation and exposure, a third layer may be attacked, and by-and-by a fourth.

Hungry gravels and loose sands are by no means so easily improved as clays or loams—improved, that is, in depth without outside additions. Additions of all sorts of soils will in time help such, for if depth be an advantage anywhere it is in sandy soil. Liberal admixture of everything vegetable and the repeated forking over the subsoil in the manner described will in time deepen the worst sand. But in such humus—which constitutes the main difference between soil and subsoil—disappears rapidly. They “eat up” the

manure, you will be told. For this reason every vegetable scrap should be held precious, and every opportunity taken to raise green manure, which when dug in will add to the general stock. But let the rule be with all soils to improve the subsoil where it lies before bringing it to the surface.—SINGLE-HANDED.

(To be continued.)

CYCLAMENS AND PRIMULAS AT READING.

EVERY season has its special attraction in Messrs. Sutton & Sons' trial nursery at Reading. Early in the year the Cinerarias are the leading feature; Calceolarias follow, and are usually in their best condition about the time of the May exhibitions. Gloxinias, too, are subsequently found in large numbers, with Tuberous Begonias and hosts of outdoor annuals and perennials a constant succession of floral beauty is maintained. November is proverbially the dullest month of the year; but even then the visitor to Reading can find much to admire in the houses at this nursery, for the large stock of Cyclamens and Primulas is then fast advancing to perfection. So on the occasion of the late Chrysanthemum Show many horticulturists availed themselves of the opportunity to inspect the collections of these plants, and the time thus spent was not regretted by any of them. It is an invariable rule as regards all the plants taken in hand by Messrs. Suttons' experienced growers, that nothing short of the most complete success attainable is deemed satisfactory, and no efforts are spared to insure this result. To obtain plump well-matured seeds calculated to produce plants of the best quality it is wisely considered absolutely necessary to give the parent plants the best possible treatment, and with this object in view the requirements of all the different races of plants of which specialities are made are most carefully studied. The surprising success that has been attained with Calceolarias has been frequently mentioned in this Journal. Gloxinias, too, have received their share of praise with many other notable plants, so that the Cyclamens and Primulas now in a measure demand similar attention.

CYCLAMENS.

Several large growers for market in the neighbourhood of London have been very successful with these plants in recent years, and it is now the usual practice to obtain handsome plants in one year from the time of sowing the seed, a result that was never secured by the older systems of culture. The most experienced cultivators of Cyclamens have found that they require liberal treatment, a free light soil, a moist genial atmosphere, and copious supplies of water. This system is now adopted in the establishment under consideration, and the results are most satisfactory. The seed is sown in November, the young plants so obtained being first pricked out and then transferred into 60-size pots, and finally into 48-pots, in which size they are flowered. The soil consists of equal parts good loam and carefully prepared leaf soil with no manurial aid until the plants are approaching flowering, when a small quantity of the special artificial stimulant sent out by the firm is employed. The plants are all healthy, bushy, vigorous specimens; the foliage thick, leathery, and beautifully marbled, while the corms are bristling with flower buds in all stages. It is estimated that a plant with fifty leaves as they can be obtained will bear as many as 150 blooms, often in successive batches extending over a considerable period, but with healthy plants usually in that proportion.

Varieties are of course numerous, but a few of the finest are grown in large quantities, and conspicuous among these is the noted Reading Gem, which was honoured with a certificate by the Royal Horticultural Society in 1879. This is remarkable for the great breadth of petals, which gives an appearance of extreme substance to the flowers; and another invaluable character is its great floriferousness, the white and red-tinted blooms being borne on stout peduncles well above the foliage. A similarly handsome variety is the White Butterfly, or, as it is also known, Miss Lilian Cox, but the former name is the one now adopted. This also has been certificated, and is one of the very best white Cyclamens in cultivation, the neat, substantial, pure white blooms being produced in great numbers. Phoenix is a grand crimson variety with large broad-petalled blooms and exceedingly rich in colour, bright and fresh in a more than ordinary degree, rendering it an admirable companion for White Butterfly. Several others are grown all more or less meritorious, but these can be safely and strongly recommended for general culture.

THE CYCLAMEN GRUB.

It may be observed that though the Cyclamen is subject to few diseases, and is not attacked by many insects, yet it has one great enemy that has proved very troublesome in late years. This is the grub or larva of a species of *Otiorhynchus*, one of the weevil family, which attacks the under side of the corm, destroying the roots, ultimately killing the plants. The great difficulty is that often no sign of the evil is apparent until the injury is irreparable, for a plant may be seen in perfect health and advance freely until the flowers are about to expand, and then one morning the grower finds the leaves limp and the whole plant has lost its strength. Not only at Reading had this been unpleasantly experienced, for some of the largest market growers had been similarly troubled and puzzled to find a remedy for the mischief. Many methods were recommended, some quite impracticable and others useless, but the only one found effectual is exceedingly simple, and could be readily adopted wherever similar disasters were feared. It was found that the grub was introduced with the leaf soil used in the compost, and therefore this was very finely sifted, placed in a thin layer on a cement floor, and

heavily rolled with an ordinary garden roller. This had the double effect of killing both grubs and eggs as well as any other vermin that might be present. Since this was tried no trouble whatever has been experienced, and the success attending it has induced others to test it with the same result.

PRIMULAS.

To supply the large demand for seed of these popular plants several houses are devoted to Primulas for seed-bearing, many beautiful varieties being represented. Much improvement has been effected in the forms of these plants, for numerous rich shades of crimson, purple, and rose have been obtained, besides the pure white strains and celebrated "blue" type. A compact stocky habit and large trusses of well-formed flowers are now the prevailing characters of the different strains, whether of the ordinary round-leaf or Fern-leaf groups, and in these points there is little room left for advancement. Fresh tints of colour are, however, being continually raised, while new races are being formed of the crisp-leaved and dark reddish purple-leaved types, which will impart considerable variety to collections. Prominent amongst the deep-coloured crimson forms are Ruby King with very large neatly formed flowers, intensely rich crimson, and several fine crosses between Chiswick and Swanley Reds, free and early-flowering forms having been thus secured. The Fern-leaved Prince Arthur, which was obtained by crossing the round-leaved form of that name with Swanley Red, is also a handsome dark crimson variety of very great promise. Purpureum is a fine purple form; while amongst the lighter-coloured forms Rosy Queen is especially noteworthy for the soft delicate pink hue of the flowers and their great size. A magnificent new white Fern-leaved variety is Snowdrift, which is one of the earliest to flower, and has neatly formed literally snowy white blooms in dense trusses. This will undoubtedly become a great favourite. Some handsome seedlings of the alba magnifica type have been raised, together with several curiosities, of which more will doubtless be heard another season. The Mauve Queen may be mentioned, as a distinct shade of colour is furnished by it that some people would probably admire. An attempt is also being made to form a race of Picotee-edged varieties, and some steps have already been advanced in this direction, for varieties have been raised with white flowers distinctly edged with pink, but these at present are not yet fixed, though there is plainly room for some notable achievements.

It may be added that the Cinerarias are extraordinarily vigorous this year, and we have never seen plants with larger and more finely developed leaves. They certainly are most promising, and a grand display is expected early next year.—VISITOR.

A VINERY OF THE FUTURE.

WHEN on a visit to Bath a few days ago I ventured to trespass on the good nature of my late esteemed neighbour, Mr. Taylor, at his new home in this beautiful city. Having previously heard that a vinery very similar to the one at Longleat was being erected under his supervision for that enthusiastic and successful cultivator, J. Chaffin, Esq., I was not a little curious to see it in course of erection, and through the kind permission of this gentleman I not only did so, but was enabled to discuss every detail of its construction with my old friend, into which he freely entered with his usual frankness and good nature.

The position of the garden is a somewhat elevated one on the north-east side of the city. It declines somewhat abruptly towards the west. The vinery being situated on this side of the hill, about 50 feet below the site occupied by the mansion, which is about 100 yards distant, it is consequently partially sheltered from the north and north-east, but not sufficiently so, I think, to screen it from the good influence of the sun's early rays. It is span-roofed, about 140 feet long by 30 feet wide, and is divided into three unequal compartments. The ridge runs as nearly as possible north and south, the southern end perhaps inclining a little to the south-east. It is built on substantial walls of stone and brick, which are not, I believe, arched, the intention being to form the borders inside so as to shelter the roots.

Owing to the irregularity of the ground the excavation required at the northern end is considerably more than at the opposite one, and the house, instead of being built quite level, dips considerably to the southern end. This arrangement, without being perceptible, not only admits of the rain water gutters being fixed regularly along the plates from end to end and facilitates the rapid flow of water, but it also allows the hot-water pipes which are to be heated from the southern end being laid perfectly even with the courses of brickwork on the walls, and at the same time will secure a regular and even flow in each pipe throughout the range without resorting, as far as I could see, to a single unsightly or irregular bend or elevated pipe. This to some may appear a trivial matter scarcely worth notice, and yet in a house of this magnitude it is a most essential and economical one. The pipes, which are 4 inches in diameter and ten in number, are arranged perfectly level with and parallel to each other at regular intervals over the floor; additional heat will also be obtained from the mains, which are laid under the central pathway. Provision is, of course, made by valves for heating each compartment separately. Duplicate boilers, each capable of heating 3000 feet, are to be fixed at such a level as will insure every pipe being placed well above the boiler, and thus secure a rapid flow and return of water. These boilers, which have been manufactured by Messrs. Hartley and Sugden, may be called, not inaptly, hooded tubulars. They appear to be strong, well made, and calculated to last many years.

The fixing and arrangements are entrusted to Mr. Flint of Bath, and most simply and efficiently does his work appear to be done. The wood-

work, which was only partially fixed, consists of rather deep side sashes, all of which on each side are intended to open. The rafters, which for such a wide span appear somewhat slight, are to be secured and strengthened by truss rods. They are fixed at rather a low angle, so as to secure as far as possible an equable inside atmosphere; they are placed at intervals of about 20 inches from each other. Provision for top ventilation is made by alternate opening sashes on both sides of the ridge, each being about 4 feet by 2 feet wide. It is intended to throw a somewhat flat arched trellis across the house for training the Vines at a good distance from the glass, so as not only to secure a clear space between that and the foliage for free ventilation, but also to have the Vines at a convenient distance from the floor level.

The glazing is to be executed on an improved principle of Mr. Chaffin's own invention, and which consists of long squares about 3 feet by 20 inches. These are laid between strips of prepared felt, placed longitudinally on the rafters and then secured in place by an iron cap and screws inserted at regular intervals. Judging from the appearance of a small house glazed on this system, if good stout glass be used it must insure abundance of light, great strength, security from wet, and ultimate economy, as it forms comparatively an indestructible roof.

Mr. Chaffin has chosen good local firms for the performance of his work, Messrs. Hayward & Wooster being entrusted with the woodwork, and Mr. Long the masonry, all of which appears thoroughly well executed. The subsoil, which is heavy and tenacious, is being thoroughly drained, and preparations for making the borders inside in sections are already in progress. I need scarcely add that when finished this house will be a very imposing and noble structure. To see it, although still unfinished, afforded me great pleasure, and I left fully impressed that if superlative Grapes depended on thoughtful and judicious arrangements, good soil, excellent situation and climate combined with skilful cultivation, we should ere long see something good from this magnificent vinery.—C. W.

KITCHEN GARDEN.

ALL kitchen gardens have now lost their summer aspects. Many of the quarters are empty. The fruit trees and bushes have cast their leaves, and the effects of winter are everywhere visible. But this is no reason why the kitchen garden should be untidy; on the contrary, it should now be put in order for the winter. All old vegetable and fruit-tree leaves should be collected, weedy pieces hoed and raked or dug, and all walks made clean. This has been our work during the last week. Our kitchen garden is now as clean as it can be, and so far as dressing is concerned we will have little or nothing more to do in it during the winter. Manuring, digging, and trenching will now be carried on during every favourable opportunity.

Celery.—Where the rainfall is heavy this may show signs of decaying in the centre, and much of it may be lost in consequence if something is not done to prevent it. Flat ridges are a mistake. They should be made to taper up almost perpendicularly, and they should be beaten very firmly that a hard surface may be formed to throw off the wet. When finally earthed up a quantity of sand thrown around the plants is an advantage, and finely sifted ashes answer the same purpose. One good wisp of straw put round the collar of each plant during frost does more to protect it than a great quantity of loose material put about it carelessly. As a rule we always send the inferior heads to the kitchen, and the best to the pantry.

Young Peas.—When these are just coming through the soil the Dutch hoe should be run along each side of the rows when the ground is dry, and as soon as they are a few inches high the earth should be drawn up into a good ridge on each side of them. This affords excellent protection from wind. No attempt should be made to protect them during severe weather, as they will do very well without this, and coddling only makes them more tender. Stakes should be put to them as soon as possible after they are fairly through the soil. Where those sown a while ago have failed another lot may be put in now. Indeed, Peas may be sown with success almost in every month during the winter, the main object being to have the soil in good order.

Herbs.—A quantity of Mint roots should now be taken up for forcing. They may be put into any shallow box with a little light soil over them, and they will grow readily in any house or pit where the temperature is from 60° to 70°. Tarragon may be treated in the same way. Sweet Basil may be raised from seed under the same conditions, or this may be sown in a 6-inch pot and grown there until the plants are 2 or 3 inches high, when they may be pricked into boxes, and they will give a large supply. Much of the Parsley is now turning yellow, and where it is likely to become scarce the roughest of it should be gathered and dried at once for seasoning.

Forcing Kidney Beans.—A good batch of these should now be put in for fruiting in the early spring months. Osborn's Forcing is decidedly the best of all to deal with at this season. Put a few leaves in the bottom of a number of 3-inch pots, fill them half full of light sandy soil,

then put six or eight seeds into each and fill up almost level with the soil. They should then be placed in a temperature of 65° near the light, and give no water until growth has advanced a few inches. When the soil is saturated before the seeds germinate many of them generally decay at this season. A dry atmosphere suits them at first, and they may be retained in the small pots until a few leaves have been formed, when 8-inch pots will suit them best for fruiting in. Those in bloom just now must have a very dry atmosphere, or the fruit may not form. Give liquid manure to those plants bearing heavy crops.

Rhubarb.—Where this is valued as early as it can be had, a batch of roots may be put in for forcing at once. Those roots we advised to have lifted out of the ground some time ago will force most readily. A good hotbed of leaves and littery manure is a capital position on which to place the roots, and the tops should be covered with any old box or barrel. A dark end in the Cucumber pit or Mushroom house will also produce good Rhubarb, and there are sometimes odd corners near fires, flues, or over boilers which suit well for bringing on the produce. The crowns should merely be covered with soil, and as soon as growth begins liberal quantities of liquid manure should be given.

Seakale.—This valuable winter vegetable may be forced and treated in all respects like the Rhubarb; but while good Rhubarb may be grown in the light, Seakale is best when kept entirely in the dark.

Leaf Soil.—Now that this can be formed by collecting the fallen leaves and putting them in a heap to decay, I may say that for heavy soils nothing is better than a good coating of leaf soil; and leaves collected and stored now will be in excellent order for digging in with Potatoes and other crops next spring at planting time. It is astonishing how clean Potatoes turn out of leafy soil.

FRUIT FORCING.

Peaches and Nectarines.—Earliest House.—The buds are swelling, and sufficient fire heat should be given to admit of a free circulation of air by day and a little at night if the weather be mild, as a genial condition of the atmosphere is essential to the proper development of the flowers. The temperature should not be increased beyond 50° to 55° by day from fire heat, or 40° to 45° at night, until the blossoms are well advanced; the night temperature after the flowers expand should then be raised to 45° to 50°, and by day to 55°, with 5° to 10° rise from sun heat. Old trees that have been forced a number of years will stand more heat than young ones, yet it is best to err on the safe side, particularly in the early stages, and to make up for any lost time after the fruit has passed the stoning process; and much depends upon the state and position of the roots, as if inside, as those of early Peaches should be, and near the surface in good calcareous loam, forcing may be carried on much more rapidly and with less risk than when they are outside. Discontinue syringing after the blossoms show the anthers, but damp the walls and other available surfaces in the morning and afternoon, and until syringing is discontinued it should be done early, so that the trees become dry before night. Examine fermenting leaves on inside borders, keeping them frequently turned over for the purpose of obtaining atmospheric moisture, and to prevent injury to the surface roots by becoming too hot.

Pruning Late Trees.—Continue the pruning in late houses, which should consist of cutting out the weak wood and thinning where too crowded, laying in the wood sufficiently thin to admit of the full development of the foliage, so that fruit and growth may have full exposure to light and air. Lay in the wood its full length where there is space, and make provision for a proper supply of young growths by the removal of all gross watery shoots and shortening back to well-ripened wood, or the gross shoots if they must be retained, should be cut back to near their base. The fan system of training is the best for Peaches. See that inside borders are in a proper condition as to moisture, for if allowed to become dry it is likely the buds will fall.

Cherry Houses.—The house and trees having been thoroughly cleansed as advised in a former calendar, forcing may be commenced, but in a gentle manner. The night temperature may be kept at 40°, and the day at 50°, and when the house rises to 55° by natural means air should be freely admitted, taking it off or closing the house at that temperature. Moderate syringings will occasionally be necessary to maintain a moist genial condition of the atmosphere, but the trees must not be kept constantly wet; indeed, they should be syringed early on fine days, and in dull weather syringing will not be necessary.

Cucumbers.—Perhaps more mishaps arise in the growth of winter Cucumbers from the inadequate quantity of piping, which, to keep up anything like the heat necessary for these plants, is radiated at so high a temperature as to produce a parched condition of the atmosphere highly injurious to vegetation. Damping in such cases needs to be more frequently resorted to, and the alternate roasting and stewing process is one more likely to end in disaster than anything else, hence plenty of piping is always more economical than too little. Pay particular attention to thinning the fruit so soon as they have set, and cutting them as soon as they become fit for use, which will greatly facilitate the swelling of the young fruit. Remove all staminate blossoms as they show, and bad or injured leaves as they appear, tying down all shoots as they require it. Very little stopping of the shoots will be required now, excepting on vigorous-growing plants. The object should now be to encourage free growth. Avoid, however, overcrowding, light and air being essential to properly developed foliage. See that the plants do not suffer by want of water, but care must be taken not to overwater at this season. Atmospheric moisture should be given sparingly; at the same time a genial condition of the atmosphere is essential to success.

Dust with sulphur upon the first appearance of mildew, and rub the pipes thinly with the same if red spider is troublesome, rubbing quicklime into any cankered parts.

Strawberries in Pots.—Where there are structures specially devoted to forcing Strawberries, better results are obtainable than when they are grown in Peach houses or vineries. In the former case, and a batch being introduced of some early kind as Black Prince, Vicomtesse Hericart de Thury, or La Grosse Sucrée at the middle of last month, they will now be starting, and should not be brought on too quickly, the night temperature being kept at 50°, with 5° more by day artificially, and 5° to 10° advance from sun heat. Ventilate freely at and above 55°, and in mild moist weather admit a little air constantly, as it is important that the leaves and trusses be not drawn up weakly. Syringe lightly morning and early afternoon, and see that the plants have sufficient water. Aphides very often attack the trusses as they rise from the crown, and the house should be fumigated as necessity requires, so that they may be kept perfectly clean. Especially is this necessary as they advance for bloom, for if fumigation be then resorted to it will do serious injury, if not destroy the pistils, which are very tender, and too close and moist atmosphere will destroy the anthers. Plants that have been plunged in a sheltered position outdoors will need protection in severe weather, covering with dry litter or fern, which should not be removed so long as the frost prevails, the alternate covering and uncovering daily doing more harm than good. Plants plunged in pits or frames should be kept rather dry on the approach of frost, and should they become frozen cover them until a general thaw commences.

PLANT HOUSES.

Zonal Pelargoniums.—Those plants that are now in flower require daily attention in the removal of decaying flowers and foliage, for if the former are allowed to remain in the truss they soon spoil many more that surround them. These plants are very liable to damp at this season of the year, especially in moist localities and where fogs prevail. To prevent this keep the atmosphere of the house in which they are flowering as dry as possible, and give air with a little fire heat on all favourable occasions. The temperature in which they are flowering should be maintained at 50° to 55° at night, according to external conditions, with a little air left on when the nights are such as it can be done with safety. Under this treatment they will grow slowly and continue flowering without becoming drawn. Those that were housed later and have been up to the present time in cool airy structures will, if given the night temperature named above, soon be one mass of flowers. The double and semi-double varieties appear to do better in a temperature 5° warmer. We have just divided our late batch that has been kept cool, and placed all the double forms in heat, and in a very short time they will produce an enormous quantity of useful trusses for decoration and cutting. All plants that are in 3 or 4-inch pots, whether single or double, and required for spring flowering, should have a position close to the glass where the night temperature will not fall below 45°. If they have not been stopped the points of the shoots may be removed. The object to aim at is to keep the plants in good condition and sturdy, and then when the days lengthen and the sun has more power they can be potted and will be in the best of condition for flowering, which will not be the case if a soft growth is encouraged at this season of the year.

Gardenias.—Where the flowers of these plants are required over a long period it is a good plan to insert a few cuttings at the present time. Some of the plants in the early batch will now be flowering or swelling their flower buds rapidly, and springing from below these buds and flowers will be found short growths that are most suitable for cuttings. Cuttings will root readily and quickly if inserted in sandy soil and kept in a close frame or under bell-glasses. The main stock of new plants is grown from cuttings annually, and after flowering all the worst of the old plants are thrown away. A few are retained and grown on again for autumn and winter flowering; these are not subject to much pruning. It is impossible to flower during these periods plants raised from cuttings either now or in the spring. In addition to these, what old plants we retain are pruned hard back, and strong clean growths are the result. Those now setting their buds should not have an excessive supply of liquid manure, or the roots may be injured and the flower buds in consequence deformed. Give a surface dressing of artificial manure.

Impatiens Sultani.—This is a charming plant for the stove at this season of the year, in fact through the whole of the winter and spring months. It flowers in such a very small state, which adds very much to its beauty for purposes of decoration. It is just the plant we have wanted for associating with Lycopods and Ferns in 2 and 3-inch pots for purposes of edging. In no position does it look more attractive and beautiful. Little plants can be grown in the pots above named, and it looks more beautiful in a dwarf state than when the plants are grown to a larger size. If large plants are wanted those grown from seed are decidedly the best, as they branch more freely than cuttings, but for the purpose recommended cuttings are best. They are flowering when taken off, and will flower nearly the whole of the time they are in the propagating box, and go on until they are too large for the purpose and require topping. To maintain a succession of these small plants, as soon as one batch is rooted another batch should be inserted; for this purpose we retain one fair-sized plant, and it furnishes us with nearly as many flowering shoots as we require. Any moderately light soil suits it.

Cyclamen.—If seed has not been sown it should be done without further delay, and very good flowering plants will be produced by next autumn and winter. The seed pans must be well drained and filled with

light sandy soil, upon which the seed should be scattered and then lightly covered with very fine leaf soil and sand. After sowing give a good watering, and place over the pans a square of glass and plunge in bottom heat until the seed germinates, and then gradually expose the plants to light and air, and place them close to the glass on a shelf where the night temperature can be kept about 60°. Those having young plants from seed sown during the month of July, and now growing freely in a cool structure, should place them where the temperature will not fall below 45°, keep them close to the glass, and by the end of the month they will be sturdy plants that can be placed in 2-inch pots. We have just now a number of plants that were raised for late spring flowering, and which received a check through removal from a warm to a cool structure. These are now starting fairly well, and have had as much of the old soil removed from them as possible and new supplied. The blooms will be removed and the plants grown in a temperature of 50°; the largest will be allowed if we require them to flower in spring, and the smallest will be grown on for early flowering next autumn. If any extra fine forms appear amongst the seedlings remove the flowers for some time, and allow them to come into flower in spring for the purpose of supplying seeds; by this means only can a good strain of fine varieties be obtained, and the seed from them can then be relied upon.

Primulas.—Plants that have been flowering in the conservatory since the end of October, and have tall flower stems, should be removed. They will soon come into flower again, and will be in good condition in a few weeks. We can keep these plants in much better condition by removing a few of the worst weekly, and by giving them a light position and a little more air (after they become hardened) than what we can give them in the conservatory, they soon produce strong flower trusses again, much finer than they would in the other position. A top-dressing of rich material, or a light application of artificial manure to the surface of the soil, is very beneficial.

Chrysanthemums.—Plants that have flowered, of varieties that it is necessary to retain for cuttings, should be placed in a light airy position under glass, a late Peach house being a capital place for them. Any shoots from the base that have become weakly while the plants have been flowering should also be cut off near the base, and these will break strong growths that will be all that can be desired for cuttings after a while. Strong, robust cuttings are most important, and if the stools are not taken care of after flowering it is impossible to obtain them. Some of those grown as bushes, or that have produced one or two flowers in a small pot, generally yield us our strongest and best cuttings. The cuttings are often very few and weak from those plants that up to the time their flowers were thoroughly developed had every shoot that appeared at the base removed, and have been exhausted as well by flowering.

THE FLOWER GARDEN AND PLEASURE GROUND.

Protecting and Planting Roses.—We usually find it advisable to perform much of the work of planting of the new and replanting of the old Rose bushes and standards during November. Unfortunately the weather has much interfered with the operations, as it is very unwise to touch heavy land when constantly in a wet state. Where frosts are apt to prove very destructive among Roses, the simplest method of preserving standards consists of lifting and bedding them where they can be conveniently protected with rough litter or bracken. Lay them in a sloping direction and closely, yet so that they can be removed and replanted without injuring many of the young rootlets they invariably emit in these positions. Mulch the ground about them with rough litter, and whenever severe frosts are expected shake a liberal quantity of the same material over the stems and heads. Dwarfs may also be benefited by a mulching of litter or rough manure from the stable yard. Dwarfs or standards newly received from the nurseries may either be laid in for the winter or properly planted, as the weather permits.

Occasional transplanting greatly improves Roses, and is not so much practised as it ought to be. The position may be the same, providing a quantity of decayed manure or a mixture of manure and fresh loam be well and deeply mixed in with the old exhausted soil. Roses delight in a good deeply dug soil, and if the whole of the ground is not double-dug for them it is advisable to make the holes wide and deep, the bottom spit being enriched with manure. Planting should keep pace with the digging, or otherwise the newly moved soil is liable to become saturated with moisture and unworkable for some time to come. If planted on the lawn the turf should not be returned about the roots—at any rate to within a foot of the stems. Beds may be formed with the standards 4 feet apart each way, and between the dwarfs can be worked in. Should the latter only be planted these may be about 3 feet apart each way. Most dwarfs bought in are generally worked on the Manetti stock, and by burying the junction of the scion with the stock the former soon emits strong roots, and thus become independent of the stocks. Unless deeply planted the life of the plant will be short. Those who last season neglected to plant their dwarfs sufficiently deeply should at once plant deeper, the next best plan being to heavily soil over the exposed stocks. Roses budded last year may be moved now, but it is not advisable to disturb those successfully budded this season. Before planting, the roots of all kinds of Roses should first be lightly trimmed, then be distributed evenly in good fine soil, this being made moderately firm. Extra long shoots may be shortened in order to lessen oscillation; but pruning should not yet be attempted, and standards should be staked at once. Plant Briar stocks for budding next season in rows at least 3 feet apart and 18 inches asunder in the rows.

Climbing Roses.—Now is a good time to renew the soil about these, and also to replant where vacancies occur. The soil near walls and

fences quickly becomes impoverished, and the Roses in these positions being most valuable they ought frequently to have fresh liberal additions of half-decayed manure and loam. Much of the dry old soil may well be removed. No other climbers, especially Honeysuckles, should be planted near the Roses, or the latter will inevitably suffer from the contact both above and below ground. Choice Teas may be, and in some cases must be, protected from severe frosts with either mats, heavy coverings, or bracken tied thickly over them.

Selections of Roses.—In order to secure the best plants no time should be lost in procuring the requisite number. Those ordering last get the worst plants. Of Hybrid Perpetuals a really good dozen are as follows:—A. K. Williams, Charles Lefebvre, Comtesse de Chabillant, Duke of Edinburgh, Dupuy Jamain, John Hopper, La France, Madame Lacharme, Marie Baumann, Marquise de Castellane, Mons. E. Y. Teas, and Sultan of Zanzibar. To these may well be added Alfred Colomb, Bessie Johnson, Boule de Nieve, Capitaine Christy, Charles Darwin, Cheshunt Hybrid, Comtesse d'Oxford, Duke of Wellington, Etienne Levet, Ferdinand de Lesseps, François Michelin, Général Jacqueminot, Hippolyte Jamain, Jules Margottin, Madame Eugénie Verdier, Baronne de Rothschild, Madame Victor Verdier, Mlle. Prosper Langier, Marie Rady, Royal Standard, Sénateur Vaisse, Sir Garnet Wolseley, and Star of Waltham. Good Tea-scented Roses, and which are also adapted for furnishing sheltered walls, are Adam, Alba Rosea, Belle Lyonnaise, Catherine Mermet, Comtesse de Nadaillac, Devoniensis, Etoile de Lyon, Gloire de Dijon, Homère, Madame Lambard, Marie Van Houtte, Niphotos, Perle de Lyon, Rubens, Safrano, Souvenir de Paul Neyron, and Souvenir d'un Ami.

Some of the best Hybrid Teas are Distinction, Earl of Pembroke, Lady Mary Fitzwilliam, and Viscountess Falmouth. Such Bourbon Roses as Acidalie, Baron Gonella, Queen of Bedders, and Souvenir de la Malmaison are especially good when on their own roots in the open, and are very profitable where they receive shelter from walls.

Noisettes Caroline Kuster, Celine Forestier, Cloth of Gold, Jeanne Desprez, Lamarque, Maréchal Niel, and Triomphe de Rennes are all good for walls. All the China and Hybrid China Roses are worth growing, being well adapted for the fronts of shrubberies as well as walls. They are the most free-blooming of all, and are best known as "Monthly" Roses. Of Moss Roses Lanei, Reine Blanche, Souper et Notting, and White Bath are among the best.

THE BEE-KEEPER.

THE COMING BEE—CLIPPING THE WINGS OF QUEENS.

It may, perhaps, be thought by some that enough has already been written on the subject of the coming bee, but when we consider that the question of financial success or failure in bee-culture must eventually turn on this one point, we realise that we cannot investigate the matter too closely.

What is the coming bee? It cannot be the common brown bee: the importation of the Italian and other races of queens in such vast numbers has fixed the fate of the old brown bee. What is left of the pure brown blood must soon be superseded by the various mixed breeds, and soon will only be known in history.

We are of the opinion that it will not be the pure Italian, from the fact that the "new broom" has become somewhat old and fails to "sweep clean." The fever for bright yellow stripes is fast cooling down, and honey-producing bee-keepers are beginning to learn that a cross between the different races gives better workers and more honey. Some queen-breeders are already awake on this important point, and are putting into the market queens that are bred for paying qualities rather than fancy colours; and there can be no doubt but the coming bee will be much superior to any that we now have, if we manage wisely.

It will be well, however, for us all to be mindful that after all the most careful and judicious crossings have been made, we may, by other improper management, defeat the very purpose for which we are labouring. If the bees were left to manage their own affairs in their own natural way, then the law of natural selection would dictate that none but the fittest would survive; and that "survival of the fittest" means "improvement of the stock." That improvement would be slow, yet it would be sure all the same. The most prolific queens would produce the most young swarms, and the best winged drones would meet the most queens; and also, the best workers would produce more combs and store more honey for breeding and winter supplies. But when we take control of them and dictate what shall be their conditions and surroundings, then it is better that we go a little slow and careful, lest we, in our eagerness to advance our own present interest or convenience, do a great injury to the bees; for when bees are injured, then it is that apiculture suffers at a corresponding rate.

Longevity is a most desirable quality in the coming bee, and anything that shortens the working days of the bee is all the while sapping the very foundation of bee-keeping. It is well understood that our present bees live from September until April or May following, and be it understood that it is during these cold months that bees in the northern climate are subject to disease consequent to cold and confinement; and yet while struggling against these unfavourable conditions they are found living

six or even eight months, yet in June and July, and a part of May and August they only live about six weeks. Now, why is this great difference in the longevity of bees during the different seasons of the year? It cannot be that proper exercise in the open air is what shortens their life in summer, for we know that when they are diseased in winter a good fly in the open air restores health and quietude. This fact alone is ample proof that that outdoor exercise is not what shortens the life of the bee in summer. One writer has expressed his belief that bees in summer work themselves to death. I cannot agree that this can be true from the fact that natural law dictates that all animals live by their own efforts; and we find them prosperous just in proportion as they are able to surmount obstacles and overcome difficulties that they encounter. Labour promotes health, but indolence weakens it.

Each creature is endowed with faculties or members, the functions of which are adapted to the performance of the work of procuring a livelihood, and if any one or more of these members are by accident or otherwise disabled, then the creature labours to a disadvantage, and its life is shortened just in proportion to that disability or inability to procure a livelihood. A proper exercise of any one or more of these members increases their strength and dimensions, but inactivity renders them weak and dwarfed; and long-continued disuse reduces them to mere rudimentary conditions.

While the above is true, it is equally true that over-work or excessive strain would injure any member of the bee or any other animal. I hold that incompetent wings and wing power is the chief cause of the shortness of the summer life of the bee. The first indications that such bees are failing in summer is the torn and ragged condition of their wings. It would appear reasonable to any rational man that if one bee having perfect wings, and another having its wings torn and ragged, were at the same locality and a long distance from home, each equally loaded and having to face an opposing wind, there would be a survival of the fittest, while the other would perish.

We have no proof that the general health of the worker bee, at the age of five or six weeks in summer, is more impaired than that of the bee of the same age, in inactive life, in fall or winter; or that the former would die any younger in summer, if it could have perfect wings, than would the latter in confinement. It is true that the former is exposed to birds and storms, but it is equally true that the latter suffers equally as much from confinement and its attendant results.

Let us consider for a moment what we are doing with our bees. Some are expending thousands of dollars and years of valuable time in breeding bees that show the greatest number of and most brilliant stripes. Others are striving to produce large bodies; others trying to produce tongues long enough to work on red Clover; others trying to produce a red Clover having shallow tubes to fit the tongue of the bee; others (more practical) are working for the production of bees that manifest the greatest honey-gathering qualities. All seem to be hopeful that they will attain to those desirable ends.

Now please allow me to ask, What would we think of a man that would advertise that he was trying to raise a superior stock of yellow queens and using black queens and black drones for starters? What of another that was striving for the development of long tongues, and all the while depriving the mother queens of their tongues? What of another that was working for large bodies, and all the while using the smallest queens for breeding stock? We would pronounce them all crazy, or at least most woefully inconsistent. Are not many bee-keepers (and some who claim to be teachers), virtually acting just as inconsistent? All will agree with me that a bee may have bands (or stripes), colour, long tongue, large body, and ever so much energy, and yet with feeble wings, or no wings, all these faculties or qualities would be unavailing.

I have thus led the readers along this pathway, over which I felt assured they would willingly accompany me, until we had arrived at our present standpoint. See how hard we are trying to improve our stock, and then what next do we do? Why, we just allow our young queens five, or perhaps fifteen minutes to meet the drone, and then cut off her wing or wings, and never allow her to fly again. We thus throw her flying members into disuse, and as I have shown, continued disuse renders a member or faculty rudimentary.

Again, all will agree with me that a mother can by no possible means transmit that which she does not possess; and furthermore, that the offspring cannot inherit that faculty or quality which the parent was unable to transmit. If it be asked, How, then, can the stock be improved? I would answer, An individual, after birth, may, by proper management, have its members or faculties developed to a higher and better condition, and that improvement may be transmitted to its offspring. The improvement of the race can also be made, to a certain extent, by the crossing of the different breeds. If a faculty or member of the individual becomes weak by disuse, then that condition of weakness may be transmitted from parent to the offspring. Disease may be transmitted from parent to offspring; weakness is only another name for disease.

I would ask bee-keepers a question. In view of the above truths, which queen do you think would transmit to her offspring the greatest amount of wing power? The one that is deprived of her wings, and those members all through her life being in a dormant state, or the one that is allowed to retain her wings and compelled to fly as often as circumstances would justify?

If I were offering queens for sale as superior stock I would compel the brood mothers to fly often, even if I had to toss them up to give them a start.—W. H. STEWART (in *American Bee Journal*).

TRADE CATALOGUES RECEIVED.

V. Ingegnoli, Mailan, Italy.—*List of Seeds.*
 John Fowler & Co., Leeds.—*Illustrated Catalogue of Steam Ploughs for Continental Vineyards.*
 B. W. Warhurst, 33, Highgate Road, Kentish Town, London, N.W.—*Illustrated Lists of Boilers.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Chrysanthemum Blooms (*A Subscriber*).—If well grown probably the variety, of which blooms were sent, would be admissible in a stand of Japanese varieties, but we do not recognise it. Could you not give us any information as to where it was obtained?

Scale on Arbutus (*J. W., Deal*).—The leaves sent are seriously infested with the scale insect, and we know of no better nor more ready means of destroying it than by syringing the shrub with the solution of petroleum made as described in answer to a correspondent on page 476 last week, bending down the branches so that the insecticide can be applied to the under sides of the leaves where the insect abounds. It will be well to choose a dull day for the work, as petroleum applied to plants in the sun not unfrequently results in injury to the foliage.

Growing Watercress (*Watercress*).—If the current of your stream is not strong you will have no difficulty in growing Watercress. All you have to do is to level the bottom and insert portions of plants about 6 inches apart, the same as if dibbling them in your garden, and they will grow and spread with rapidity. In properly made Watercress beds there is only a steady run of water which does not displace the young plants. If the rush of water is somewhat strong, you would find it advantageous to place large plants near the sides of the stream and fix them with stones. A few inches of soil or mud is only needed for holding the plants.

Flowers on a Wall (*Beggar*).—Unless the wall be old flowers will not answer upon it without pockets of brickwork or stone upon or near the top to contain soil. Even then you would not obtain a growth sufficiently dense or durable for a screen at the top of the wall. Far better will it be to plant Ivy *Rægneriana* now in rich soil at the foot of the wall and, with a little care in training and watering, it will soon cover a wall of 10 to 20 feet high. Yours is probably a low wall which may be covered with Ivy growth next year if extra strong plants are planted; and a trellis of wood or wire upon the top of the wall would, when covered with Ivy, form a permanent screen.

Plants for Rockery (*Idem*).—Do not confine your plants to those of a "creeping character," but mingle with them others of a dwarf compact or spreading growth, and the effect will be much more satisfactory. Among those which we find to answer are *Erica carnea*, *Azalea amoena*, *Kalmia nana*, *Erica Foxii*, *Phlox frondosa*, *P. Nelsoni*, *P. verna*, *P. setacea*, *Plumbago Larpentæ*, *Thymus lanuginosus*, *Silene maritima*, *Hypericum patulum*, *Lithospermum prostratum*, *Rhododendron ferrugineum*, *Andromeda floribunda*, *A. Catesbaei*, and *Gaultheria procumbens*.

Grafting Cherries (*Cambrian*).—If the trees are very large and vigorous, we doubt if it would be wise to head them closely down in the ordinary manner for grafting; a safer plan would be to shorten all the branches to where they are about 2 inches in diameter, thin out the young growths that would follow, and in these insert buds about August. If these should fail then you might engraft early in the spring on the same wood just when growth commences, but the scions should be taken off long before, and kept in a dormant yet fresh state by being placed in moist soil or cocoa-nut fibre refuse in a cool position. The success of budding and grafting such trees as yours depends greatly on the judgment and manipulative skill of the operator. It would be well, perhaps, for you to invite some competent person to inspect the trees and take his advice on the subject.

Vine Roots Corroded (*G. T.*).—We have examined carefully the roots you have sent, and find no traces of the presence of the phylloxera; but we have seldom seen Vine roots in a worse condition. The bark is quite decayed, and there is some ingredient in the soil that is affecting them injuriously. Is there an excess of iron in the loam that has been used? The Vines have done well for a time because the border was rich, and because there had not been time for the corroding agent to eat into the roots. We should lift the Vines at once, cut off some of the worst affected portions of the roots, remove as much of the decayed

matter as possible from the others, wash them well, and place them in fresh soil containing a large admixture of charred refuse, which with sand and other gritty matter placed round them would incite the emission of fibres, and these, having suitable soil, would speedily effect an improvement in the Vines. The border should not be too light and rich, and should be mulched in the summer to attract the roots near the surface, and by frequent top-dressings, with constant moisture, they could easily be kept there; then shorter-jointed wood with comparatively little pith would follow, also excellent Grapes. The wood you have sent is strong, but contains too much pith, this leading us to infer that your border has been fully too rich, and not sufficiently firm for producing well-constituted and long-lasting fruitful Vines.

Fixing Hot-water Pipes (*F.*).—As you appear to be aware that the pipes should rise gently from the boiler, it seems a little strange that you should have had them fixed quite level. We have had them quite level, and the circulation of the water has been good. They have been, however, distinctly above the level of the boiler, which is important. A steady rise of say an inch in 10 feet is what we prefer, and if you can elevate the pipes 2 inches at the end of the house, the greatest distance from the boiler, you will probably find the change advantageous. Are you sure there is not air in the pipes that impedes the movement of the water? The night temperature for a greenhouse should be about 45°, but 40° will suffice in severe weather, when the pipes have to be made hot, and there should be an increase of 5° in the day without sun. To your question regarding the plants you mention, our reply is in the affirmative.

Violas (*J. W.*).—If you examine the plants you will in all probability find a number of fresh green short-jointed shoots an inch or two long, several of which when drawn out will have white rootlets bristling from the base. These "rooted cuttings," inserted at once in light rich gritty soil, will make fine plants. If you want a mass of flowers as early in the year as possible you may divide the plants, inserting well-rooted tufts of the healthy portions, or you may cut off the long stems and top-dress the bed with decayed manure and fresh loam in equal parts. On this matter you must exercise your judgment, as it is not possible we can comprehend the exact condition of your plants. You can take cuttings without destroying the parent plants if you choose to do so, but inserted thus late they will not produce masses of flowers early, yet when the flowers are produced, they will, or ought to be, finer than on the old plants.

Maggots in Mushroom Bed (*Leeds*).—We fear the manure has not been well prepared and purified, and on this account we should have some doubt of the mycelium spreading freely. If the manure is really sweet, and the proper temperature is maintained, we do not apprehend that a few maggots would do much injury, but it would be better if there were none in the bed. If they are mixed with the manure, and this made up in a bed in which spawn is inserted, it is doubtful if you can destroy them without injuring the mycelium. If the manure is not made up, violent fermentation for a day or two might destroy the maggots.

Roses and Vines (*A Young Beginner*).—The Roses will be quite right in a cool light greenhouse, and if they are strong, well rooted, and have good attention, they will no doubt succeed. You have made no very great mistake about them, if a mistake at all. The best time, however, for repotting Roses is soon after they have flowered. You appear to have gone far back for information, though cultural notes equally good appeared only a few weeks ago. We fear you are either a very young or not a very attentive reader of the Journal, or you would not have planted your Vines at this season, since over and over again, and quite recently, spring planting has been recommended just when the Vines were starting growth. They may, however, do very well; and assuming they are young canes, you had better shorten them to half their length inside the house, and do it at once, dressing the ends with painters' knotting as a preventive of possible bleeding in spring; but there is very little danger to be apprehended on that score.

Raising Ash Trees from Seed (*E. R. B., Norfolk*).—Raising the trees from seeds appears to be a much slower process than you imagine, and they must be prepared in a very different manner from that indicated in your letter. Sowing on land infested with twitch would result in failure, especially as the seed is long in germinating the twitch would inevitably gain the ascendancy over the seedlings. In Brown's "Forester" the following instructions are given on this subject:—"The seeds of the Ash are enclosed in what is termed samaras or keys, which are generally ripe for gathering about the end of October. When gathered for the purpose of sowing, the seeds should be mixed with a quantity of dry sand or light dry earth, in which they should be kept for eighteen months, in order to rot off the outer coat; and in order the more effectually to insure this, the whole mass of seeds and sand should be turned every three months. This mass of sand and seed should not be much over 1 foot in depth, as, if more, it will be liable to heat, and in consequence the vitality of the seed would be injured. In the second March after they are gathered the seeds should be sown in rows rather thinly, and upon any moderately well-pulverised soil. They are sure to come up thickly and confine one another if not sown thin, and the covering of earth should not exceed three-quarters of an inch. In the following spring the plants will be ready for being transplanted into the nursery rows, which may be 15 inches one from another, and 4 inches plant from plant in the rows. When the plants have stood two years in the nursery rows they may be removed and transplanted into the forest ground; but if wanted of a larger size they may be left a year longer." Would it not be better to purchase the requisite number of trees of different kinds for planting? This is the usual custom, unless time is of little moment. In any case you will find it advantageous to have the land thoroughly cleaned, then if the ground is planted, a crop of Potatoes might be grown between the trees for a year or two, which would partially defray the cost of the work, and the working of the ground in planting and digging up the crops would be favourable to the growth of the trees and prevent the luxuriant growth of twitch. We have established plantations very much larger than that you contemplate in the manner alluded to, and the results were perfectly satisfactory.

Sparmannia africana (*Pen and Ink*).—This plant is a native of the Cape of Good Hope, and has been introduced nearly 100 years. We gave an illustration of the plant in this Journal, page 91, January 31st, 1878, when the following cultural directions were given:—"For the decoration of con-

servatories this is extremely useful, it being not only evergreen but perpetual-flowering. Fine bushes (and this we find much the best shape in which to grow it) can be had in 12-inch pots. The *Sparmannia* flowers but little in a young state unless extra sturdy growth is obtained. Cuttings taken from the ripened wood strike readily in the spring, and can soon be grown into large plants. Avoid crowding; pinch back and pot on till the end of June or early in July. A good head being obtained, discontinue pinching and potting, and turn out into an open and sunny spot. The temperature of a greenhouse is the most suitable during May and June. Old plants when no longer wanted to bloom are ripened by gradually withholding water, are cut back to within a few eyes of the old wood, and placed in a gentle heat till they break; they are then shaken out of the old soil and repotted, employing about the same sized pot or tub as they were formerly in. This is rather severe work, as the ball is one mass of roots, but when placed in heat they soon recover from the effects of their rough treatment. The soil used is composed principally of turfy loam with an addition of a little peat, leaf soil, sand, and broken crocks. When re-established they are gradually hardened off, and in June are placed in a sunny position outdoors. Early in September they are taken into their blooming quarters and commence flowering immediately. From that time an occasional dose of weak liquid manure is administered. They flower freely in a greenhouse temperature, 38° to 48°, but 48° to 53° is far the best, the blooms being finer and of a purer white; the foliage has also a better colour for the extra heat."

A Hardy Pitcher Plant (*E. L. B., Tooting*).—You have not been misinformed, *Sarracenia purpurea*, here represented in miniature, being quite hardy in favourable positions near London, and is grown by Mr. Ware at Tottenham. It is a native of the American swamps, where it forms a dwarf prostrate mass, producing large winged pitchers of a dark green colour, while the throat and lip are beautifully veined with crimson. The flowers are solitary, nodding, and of a deep purplish red colour; a fine associate for *Cypripedium spectabile*, *Parnassias*, *Pinguiculas*, and others of this character.

Fig. 98.—*Sarracenia purpurea*.

perhaps the best mixture you can apply to your fruit trees, Strawberries, and Roses. From 1 to 2 ozs. per square yard could not fail to be beneficial. For your flowers we have no doubt the article sold as *finus* would be exceedingly useful. During the growing season Rasp, Strawberries, and other fruit-bearing trees would be greatly benefited if further helped when swelling their crops by light dressings of nitrate of soda—an ounce to the square yard. Light soil which has no manure should only be very sparingly limed, if at all. Save every scrap of garden refuse for digging-in; mulch with cocoa refuse, and apply water plentifully when necessary, and there is no reason why you should not succeed in your object.

Names of Fruit (*R. P. Williams*).—Birmingham Stone Pippin. (*A. B.*)—1, Cox's Orange Pippin; 2, Margil; 3, Fearn's Pippin. (*P. A.*)—1, Beurre Diel; 3, Vicar of Winkfield; 4, Scarlet Nonpareil; 6, Yorkshire Greening 2 and 5, not known.

Names of Plants (*Pen and Ink*).—*Sparmannia africana*. See reply above. (*An Ardent Reader*).—1 and 2, insufficient; 3, *Cupressus Lawsonianus* var.; 4, *Juniperus chinensis*. (*W. B.*)—*Quercus lanata*. (*S. F. F.*)—*Pholidota imbricata*. (*A Constant Subscriber*).—The specimens were very imperfect, and as we have frequently stated, we cannot undertake to name plants from small shoots or leaves without flowers. 1, *Maxillaria picta*; 2, *Tillandsia* species; 3, *Linaria Cymbalaria*; 4, insufficient; 5, *Dieffenbachia marmorata*; 6, *Maranta Veitchi*.

Wild Bees and their Parasites (*A. M. B., Lincoln*).—The insect unearthed by you, and concerning which you have given interesting particulars, is undoubtedly one of the *Bombi*, from your description probably *B. terrestris*. A few of the females survive the winter snugly concealed under ground, and come forth during spring to found new colonies. It is well known to entomologists that these "big bees" are infested by parasites, which are scientifically called *Acari*, otherwise mites, allied to the familiar "tick" that frequently swarms in cage birds, poultry, &c. These bee parasites belong to the genus *Hypopus*. Their transformations are imperfectly known, but it is certain that in an earlier stage they do not live upon the bee. Some conjecture they fed in the nests of the bee, either upon the larvæ or upon the secretions of the bee, and so attach themselves to the insects when mature in order to be carried from place to place. It appears that when adult they have no mouth organs, therefore they cannot bite or suck the bees, and it is observable how dexterously they arrange themselves on the body of the bee, choosing positions out of its reach as far as possible.

ERADICATION OF COUCH, TWITCH, AND OTHER WEEDS.

(Continued from page 478.)

It has not been intended to recommend the use of the fork in any case where through neglect or otherwise the whole surface of the land has become a mass of couch or twitch, or both, for in such cases a long, or what is called a winter and summer fallow, is essential as a rule. Still there are other modes of cleaning the land in certain districts—for instance, paring and burning is stated to be one of the best modes of eradicating twitch, because the manure arising when the turf or foul surface of arable land has been stifle-burned is of more value than the cost of burning. This applies chiefly to the clays or strong loams, especially those situated on the limestone or chalk soils, because some particles of chalk or limestone found in the soil would be converted into lime or a valuable mineral manure of that character. It must, however, be quite understood that on sandy or almost any light soil the burning would not answer, because the act of paring would not take up the white and deep-rooted couch grass, which would afterwards require considerable tillage in fine weather to destroy it. There is yet another system on strong lands subject to couch or twitch, but more especially the latter, for it has been found that by growing and ploughing under two or three crops of white Mustard in one season, the land has been made not only clean, but also manured as well by the smothering as the poisonous and deleterious effect of the Mustard on the couch or twitch.

This brings us to the point where consideration is necessary as to the difference and habit of growth between couch and twitch; the former being white-rooted, and deeply piercing the subsoil where permitted to remain on all sandy, light, or loose soils of almost any district. The latter, however, is peculiar in growth, by running only on the surface, and at every knot or joint on the stems roots are formed, and take to the soil somewhat in the same manner as the runners of Strawberry plants, and is thus propagated. But they so differ in their habit of growth the same treatment will not eradicate both in every instance; but yet the forking-out plan, where only isolated bunches or tufts are found, each have been equally and successfully eradicated when the work has been carefully done.

After successfully accomplishing the eradication of these injurious grasses in one or two following seasons, we have yet to consider the insidious nature of their habits, for they are in some cases as it were indigenous to certain soils, for the young plants will frequently again appear on the surface, having started from seed. It must, however, be remembered also, if the home farmer has a farm thrown up by a tenant on the estate that it is usually, and especially in such times and wet seasons as we have experienced since 1874, to have been in the majority of instances left in a condition foul with couch or twitch. In such cases where bad farming has prevailed, the seed of injurious grasses have fallen and been incorporated with the soil under tillage, and these will be sure to prove serious and costly enemies. To obtain the full effect of fallowing for the purpose of eradicating either couch or twitch, the former must not be tilled or the earth moved by the common plough in the first instance unless it has gained such strong possession of the soil as to show like an ordinary pasture on the surface. It may then

be rafter or half-ploughed to lie during the winter and turned over in the spring, for it will then, as Sir J. B. Lawes says, prevent, like any other rooting crop, the loss of a large amount of fertility. It can likewise be successfully treated as regards tillage by the operation of scarifying with a strong implement like Coleman's, but only with the points in operation, for then the tillage may be considered complete by combing out the couch without breaking its roots into short pieces like the action of the same implement with shares used; now this latter point is a matter of so much importance that it should be avoided at all events.

The after tillage is of great consequence, for the object should still be carried out of not breaking the white roots of the couch, but to bring them to the surface and deal with them in an unbroken state as much as possible. After the deep scarifying with Coleman's implement we advise that, except in chain harrowing and rolling, the work should be done entirely with Howard's self-lifting drag harrow, and then if dry weather occurs and lasts long enough, the couch being loosened from the soil it may be burned. There is, however, an important consideration well worth our notice, for in the case of showery weather setting in just before the burning is done, the cultivation and future operations must not be delayed in consequence; but the couch which was ready for burning had the weather proved fine should be immediately carted away to a heap, to be either stifle-burned by a strong fire or left to decay as manure for pasture land.

The advantage of cleaning the land by carting away the couch is that the next ploughing or scarifying may proceed without hindrance, for the above observations will apply to all further tillage which may be found necessary. It is not every farm where steam cultivation can be obtained exactly when required if the power is only hired, but when it forms part of the cultivating power of the farm it will be found invaluable; for whether the deep-pointed cultivating tines are used in the autumn or spring, their action in lifting the clods and tufts of couch, however deeply buried in the soil, will be found complete, because lifted wholly and bodily to the surface for future tillage, whereas when ploughing or shallow cultivation is only applied, a large or considerable portion of the roots will be left in the soil, and they are sure to grow and make their appearance in the future, even when left below the ploughing depth.

We now come to the point of considering the operations necessary to destroy the twitch or surface grass, and as this sort of grass is usually found upon the surface of strong or heavy soils, we need scarcely speak of its destruction as requiring an ordinary naked fallow with all its attendant expenses for tillage. In the autumn period, the month of August, September, or the early part of October, if the land is deeply ploughed with an 8-inch furrow, the skim coulter being judiciously used, the grass on the surface will be turned under, so completely buried, that the land may immediately be worked down and sown with any green or catch crops like Rye and Vetches, which may be either fed off with sheep in the spring and scarified, not ploughed, worked down, and a second time seeded for either green crops or roots. After this, when the land may be ploughed for Wheat or winter Oats, the twitch roots and stems will be found dead if the work stated has been properly performed. We must now refer to those grasses or weeds which infest different soils, but are deep-rooted and very difficult to eradicate, especially upon strong land, which cracks open in dry seasons, into which the seeds of some will fall and others will propagate from the roots which may be left in the soil. It is therefore necessary that the whole of the following weeds should be forked out as the best mode of eradicating them. Broad-leaved Dock, Sheep Sorrel or Narrow-leaved Dock, Coltsfoot, Black Bent or Spear Grass, Corn Mint, tall Oat-like or Onion Grass, Hogweed, and common Nettle, with some others known only in certain localities.

WORK ON THE HOME FARM.

Horse Labour.—Wheat-sowing has now been so nearly finished in those districts where autumn sowing prevails that it will employ horse labour only at favourable intervals; but in the northern counties and Scotland much land is from necessity held over for spring seeding with Wheat in consequence of climatic influences. The horse labour, therefore in most districts in England will be now employed in ploughing the land intended for Lent corn, Potatoes, Mangold, and other root crops. The manner of lying the land during the winter months varies in different districts, and we must admit that those methods in use and approved by the experienced cultivators of the different soils and climates may be accepted generally as the best course to follow. Still it is necessary to remember that Sir J. B. Lawes in his papers relating to fertility in soils goes far to introduce alterations in the lying of land during the winter, as also the policy of cropping with early catch crops, such as stubble

Turnips and Rape, also the seeding with Rye, Trifolium, and Vetches, in order to retain not only the fertility of the land and its condition, but by the growth of the green or catch crops to obtain at all open and mild intervals of weather during the winter and early spring months the greater part of the nitrogen that enters into their composition. "We know besides," says Sir J. B. Lawes, "that these plants are only slightly influenced even when they are at all by the nitrogen of the manure that the soil may place at their disposal. This double proof is of such value that you ought to realise its full importance." Thus we see how the question of lying the land during the winter months is of far more importance than the old style of deep and naked fallows; because we are now advised not only practically but chemically that the ordinary mode of fallowing is a mistaken policy unless the land be full of couch, in which case it is our only alternative before starting on any improved system of cropping the land in the future.

Hand Labour.—Hedging, ditching, banking, and the planting of White Thorns where good and secure fences against cattle and sheep are required will now for some time be the chief work. Great attention should be paid to the water meadows, for although the trenches of both kinds needed for feeding with and draining away the flood waters, which have lately been so very beneficial owing to the deposits of soil left on the turf, yet the drowners or labourers employed in irrigating only allow the flood water to remain on the surface for a stated time, after which it is changed and diverted into other channels and divisions of the meadows with the same object. Irrigation may be continued with benefit even in the event or duration of ice or snow, because it is proved that the temperature of pasture lands as well as water meadows are highest when covered with either ice or flood water. Planting of land for woodlands with Larch Fir, Sweet Chestnut, and on the borders Scotch Fir for shelter to the woodlands, may be done during all open weather. The latest plan for either Larch or Chestnut plants is to set them close, about 2 feet apart each way when required to be thinned, and the thinnings sold for hop poles. In this way they pay well in certain districts; and even after taking large numbers for this purpose, it is often considered a good plan to leave Larch trees enough for timber, reserving the Chestnut stools for producing a future crop of underwood, which in due time will furnish a supply of valuable hop poles.

Live Stock.—Fattening cattle should now go into the stalls or boxes, the latter being by far the best accommodation for them. Stalled bullocks are never so comfortable either at feeding time or when lying down as animals which can eat and lie down without any interference with each other, and in well-littered boxes they are much more comfortable and lie warmer than tethered cattle. Where the fattening cattle have been grazing during the autumn they will as usual have left portions of grass uneaten on certain parts of their pastures. Store cattle, either steers or heifers, will do well to follow and eat down the coarsest grasses which have been left by the fattening cattle, especially if they go into littered yards and sheds at night time, eating a few roots and sweet straw. The dairy cows may be treated in the same way, except that as the nights get longer they should lie under cover, and at milking time, night and morning, should each receive in addition to Cabbage and hay some 2 lbs. of decorticated cotton cake at each feeding time. Sheep stock, especially the in-lamb ewes of any breed which are now forward and ready to lamb about Christmas, should be constantly changed from the best pastures to drier ones at night time, and we think without root-feeding, except a small bait or fold of Thousand-headed Kale with hay or sweet straw in their racks at the same time in the afternoon; but retiring for the night to the driest pastures on the farm, for the arable land makes a bad lair for ewes in lamb at this time of the year, when either heavy rains or frosty nights are expected. Dry stock, either hoggets or wethers, do not do so well nor dress the land so regularly when feeding off roots at this time of year, but should be fed with good Clover hay and cake, or bean meal mixed with cut roots in troughs.

A NEW ROSE GARDEN.

PERFECTION IN EIGHT MONTHS.

NOT perfection of the exhibition table type, but the equally laudable perfection of culture, whereby one or a hundred newly planted Roses may be grown into pyramids of beauty 2 feet in diameter at the base, and tapering upwards to a height of 4 feet, clothed with large healthy foliage, and with some two dozen clusters of flowers just expanding by the end of August. This is what I want to explain now for the assistance of those who are planting Roses simply for the embellishment of their gardens, and who are therefore likely to welcome hints of culture calculated to accelerate the fulfilment of their wish for heaps of Roses.

That the Rose is and always will be one of our most popular flowers goes without saying, nor are the reasons of its popularity far to seek, for, in addition to the beauty and fragrance of most of its flowers, it gives very little trouble when once established in good soil, and continues flowering for many years—just so long, in point of fact, as it makes healthy wood growth. With the exception of an annual pruning a Rose bush may therefore be said practically to take care of itself; and this is probably the reason why in most gardens its culture resolves itself into feeding with manure to promote strong growth, which is subsequently reduced by pruning to three or four buds with little or no regard for the formation of handsome bushes. I submit that it merits better treatment at our hands, and that we should not rest contented with an unsightly bush and a few flowers, however fine they may be, when by the exercise of care and labour we may do so much better.

Rose culture has by no means reached its possible limit of excellence with us, and this is probably owing to the rage for exhibition turning attention so generally solely to the production of flowers up to the standard of prizewinners, and which are destined to be severed from the bush before they are fully expanded, the flower being all that is cared for, the bush only being valued as the necessary means for its production. "I must have a smell," said a well-known veteran exhibitor of Roses who stood gloating over a stand containing a superb specimen of *Maréchal Niel*; but the attempt to gratify this very natural wish ended in disgust, for it led to the discovery that the much-admired flower was an artificial one of wax so admirably finished as to deceive even such experienced eyes. If the disappointment induced a greater liking for uncut flowers it certainly did no harm.

THE SOIL.—Turning now to our details of culture, first of all comes the soil, which must be well drained so as to have no stagnant water near it. It must be 2 feet deep, and thoroughly enriched with stable or farmyard manure well mixed with the whole of it. Few gardens contain good soil of this depth, and in most cases the soil will have to be laid aside, the subsoil excavated to the required depth taken away and good soil supplied. Let there be no hesitation about doing this thoroughly, for upon its success or failure very much depends. See too that the soil has sufficient stones

or gritty matter to prevent it settling down into a compact hard mass as the manure becomes exhausted; for although our immediate aim is a fine late summer display of Roses, yet it is well to have an eye to the future and do all we can for the subsequent wants of our bushes. Everybody has a certain quantity of coal ashes at hand for this purpose, and I know no better medium for the thorough mechanical division of the soil.

THE PLANTS.—Dwarf Roses on the *Manetti* stock are the best which nurserymen offer for our purpose. Select vigorous plants, prune all the shoots to three buds except one, which should have five or six buds and be fastened to a stake to form a stem, the stakes to be put in at the time of planting. Plant carefully, and at once cover the soil with a mulching of half-decayed farmyard manure: pig, cow, or horse dung answer equally well for this purpose. Do not crowd the plants, but give them ample space for full development into slightly specimens. Six feet apart may be given as the best distance, and 5 feet as the next best, only to be resorted to where space is very limited; and even then it is questionable whether a few plants thoroughly well managed will not afford more real pleasure than many, with a perceptible tendency to crowding, and a lack of vigour in the growth of branch, foliage, and blossom.

FEEDING.—Thus far we have made due provision for a good start in spring, and when branch and root are growing freely we must be ready to assist them with a thorough drenching of liquid manure twice weekly. House sewage answers for this purpose very well, but my favourite manure is two ordinary garden trowels full of three-star crown manure well stirred into an old paraffin cask full of water. Failing this, recourse may be had to a plan which I once had to resort to—a hole excavated in the soil, its sides and bottom puddled so as to hold water enriched with sheep's dung collected from an adjoining pasture.

TRAINING.—The leading shoots of the stem and branches must have the tips repeatedly nipped off at the second or third bud, as appears necessary, to induce more lateral growth; the stem being taken up the stake to the required height, and the branches tied slightly downwards and apart. Lateral growth will come freely with our liberal diet, and early in August stopping the growth may cease, for the pyramids will be fully formed and the shoots may be left to produce flowers. The stronger growers will attain the size I have indicated, others will not reach more than two-thirds of that size, but all will have such a profusion of fine flowers as will well reward us for our care and patience.—EDWARD LUCKHURST.

NOTES FROM THE NORTH.

THE INFLUENCE OF STOCKS ON GRAPES—DUKE OF BUCCLEUCH AND GROS MAROC.

THE WINTER KING.—I feel constrained to ask if those whom this Grape concerns are warranted in offering it to the public, as it is inferred they intend to do, as a new Grape that will under ordinary circumstances maintain the altered character from *Gros Colman* that it has assumed on the stock which has so strikingly affected it. Having considerable experience of this Grape under different circumstances, I quite accept the evidence that has appeared regarding the change in colour, &c., that has been wrought on it by being grafted on the stock in question. At the same time it is very much to be doubted if, when propagated and grown on its own roots, it will retain its altered characteristics; indeed, my experience leads me to say that it is almost certain it will not. Is it to be offered to the public grafted on the *Raisin de Calabre* stock? Even under these conditions, will the stock be certain to maintain the change without also having a limb of the stock in active growth? We all remember the "apparition" of *Golden Champion* at *Culford*, and what became of it when raised from eyes. Although, of course, the case is in some respects different,

it is not so much so as to place it beyond the bounds of comparison.

GROS COLMAN GRAFTED ON MUSCAT OF ALEXANDRIA.—I have this year fruited three grafts of Gros Colman on strong Vines of Muscat of Alexandria. The grafts in wood and foliage, in proportion to the Muscat stocks, were as one to twenty. The bunches they produced were a bluish black more than a month before the same Grape on its own roots in the same house were much more than half coloured; and although on its own roots it coloured as well as I have ever coloured it, the bluish plum-like tinge which the few bunches on the grafts attained to so early was never put on by the fruit on its own roots, which was very much later in every respect. Numerous callers were much struck with the great change in this respect, and, until told, wondered what Grape was attached to the Muscat stocks, and I feel warranted in stating these facts as proof of another unmistakeable example of the effect of stock upon scion. At the same time I have not the faintest hope that if the wood of the said grafts were set on their own roots the Grapes would maintain the character assumed by them on the Muscat stocks; for, in the same house, and grafted on the same Muscat Vines, I have had Gros Guillaume that exhibited to a very considerable extent the same sort of change, having more compact bunches, larger and blacker berries, than on a Vine on its own roots in the same house; but when put on their own roots the fruit harked back to its original.

GROS COLMAN ON RAISIN DE CALABRE STOCK.—Early last spring in the same Muscat house I inarched a shoot of Gros Colman on Raisin de Calabre, which shoot was established on the Muscat. The union was so complete that the shoot was cut about midsummer just below its union with the Calabrian Raisin. Above the union were two bunches of Gros Colman, and below it—and entirely dependent on the Muscat stock—there was one bunch. This one bunch was jet black, and fit to use long before the two on the Calabrian stock, which never put on the bluish-black tinge of the one on the Muscat stock. I may mention that the growth of foliage on the Calabrian Vine was more than equal to that of the Gros Colman graft. Of course this graft was but for a short time solely dependent on the Calabrian stock, and was quite different from the Grapes on the Muscat stock, though for a time nursed by it. This Calabrian Vine is grafted on a stock of Trebbiano, but there is no leaf-growth of the latter. Another year's experience of these grafts will be interesting, especially as we grow Gros Colman on its own roots side by side with them.

DUKE OF BUCCLEUCH WITH ITS ROOTS IN INSIDE AND OUTSIDE BORDERS.—We have always been under the impression that the spotting of this Grape which so many complain of was caused by a damp atmosphere until this year, when, as it happened, there were four Vines with their roots entirely confined to an inside border growing alternately with rods from Vines with their roots entirely in an outside border. To our surprise every bunch on every Vine in the inside borders was more or less and some very much spotted, while not a spot was to be seen on those produced by the Vines in the outside borders. Both borders were dressed with the same sort of manure. The inside one was cautiously watered to my own order, while the outside border had the whole rain that fell on it during a very wet summer. I called the attention of numerous gardeners to these Grapes. Not one could solve the problem, but it seems to point to some cause other than atmospheric or too much water at the root.

GROS MAROC.—This Grape was fruited here this year for the first time, and it has not been liked. Your remarks, page 488, accurately describe it. It was tolerably sweet, but it lacks flesh, its skin is like parchment, and shrivelling began early. It was fruited in the Muscat house on a stock of Trebbiano. I wish so good a grower as Mr. McIndoe and others as well would try Gros Colman on a limb of Muscat of Alexandria. My impression is that this will prove to be the

road to the highest quality in this Grape.—DAVID THOMSON, Drumlanrig.

FIXING CHRYSANTHEMUM SPORTS.

PREDISPOSING TO SPORTIVENESS.

THE information on this subject given by Mr. Castle on page 484 is valuable, as it embodies the successful practice of cultivators who have "fixed" sports of considerable merit. No doubt many sports have appeared on plants from time to time, but have been lost through lack of the requisite information for securing and establishing them, therefore the reliable methods described will be welcome to many cultivators. This matter is the more important, since so few high-class incurved varieties are now raised from seed, and as sports from the leading kinds are almost certain to be good, none should be lost if loss can be averted.

The subject is, however, mainly referred to now for the purpose of noticing a suggestion on the page quoted relative to the possibility of predisposing the plants to sporting by experiments in grafting light-coloured varieties on dark-coloured forms as stocks, and *vice versa*. At the first glance there would seem to be an appearance of probability that the practice indicated would result in the object desired; but it is extremely questionable if grafting as it is ordinarily performed with the plants—that is, uniting the soft young growths, will conduce to any appreciable extent to sportiveness, and another plan might be tried with possibly better hope of success.

Grafting several varieties of Chrysanthemums on one stock has been done in numerous instances. Hundreds of grafts have been attached of different varieties in Mr. Turner's nursery at Slough, and with great success from a decorative point of view; for few of the scions failed to "take," and the plants were curiously attractive by their heads of variously coloured flowers. The system of grafting conducted on such a large scale might be supposed to induce the plants to sport, but no evidence that such was the case has been recorded. Several private growers have also adopted the practice of grafting, handsome standards with beehive-shaped heads of flowers in concentric colours having been exhibited, notably at the Walton-on-Thames shows; but we do not hear that any distinct sports have resulted.

A few years ago I had the opportunity of having a number of plants grafted with the above object in view, most of the leading varieties being intermixed in the hope that a transfusion of essences might find expression in the flowers. But there was no such result, no change whatever in any one case. Further, after reading the experiments of an American horticulturist—Mr. Meehan, I think—on the potency of split-grafting changing the character of Apples and resulting in distinct varieties, it occurred to me that similar changes might possibly follow in the case of Chrysanthemums by raising plants from split cuttings. Split-grafting means splitting two scions, say of the Ribston Pippin and Golden Pippin Apples, joining one-half of each to the other and inserting the twin scion in a stock. Split Chrysanthemum cuttings mean just the same as regards their preparation. A deep slice, quite to the pith, is taken from two cuttings of different varieties, and these are carefully joined and secured with matting, the ends being cut off close under joints of both, and at once inserted and placed in a suitable place for striking. Most of the best varieties were intermixed and joined in this way, nearly all uniting perfectly and emitting roots from both sides of the twin cuttings. In some cases the two growths were permitted to extend, one from the apex of each split cutting; in other cases one growth was removed, the twin set of roots supporting the other. The plants grew and flowered well, but not in one instance was a change effected, the entire experiment, so far as regards its object, proving a total failure.

A full consideration of the whole matter led to the conclusion, rightly or wrongly, that there was never really any chance of the plan succeeding, and that there were no transfusion of essences, for the sufficient reason that there were none containing the elements of the colouring matter to transfuse. In ligneous plants, of which the Chrysanthemum is one, it seems reasonable to suppose that the growth must approach maturity before the particular essences that produce or influence the colours of the flowers are developed; and that the succulent growths, such as the fleshy and almost leafless suckers of Chrysanthemums which are employed as cuttings contain little but water, the sap must presumably be very different in the matured wood towards the end of summer from that of pulpy cuttings in early spring and the mere soft tips of shoots at any time. It would, therefore, seem to follow that if Chrysanthemums can be induced to sport at all by the union of varieties it must be by uniting the wood in which all the constituents of the sap are developed.

I had intended experimenting in this direction, but have not had the opportunity, and as it does not appear very likely I shall have on account of my nomadic habits in the summer and early autumn,

other persons may if they choose do what I had intended. This was to inarch growths of Chrysanthemums in summer when the wood was getting firm and the sap what I may term perfected. This would not have been done by the removal of thin slices of bark an inch long, but by rather deep cuts at least six times that length, so as to bring as much as possible of the alburnum of both varieties in contact in each case, binding with moss and keeping it moist to effect an union. This could be done, and is much more likely to result in an intermixing of sap, conducing to sporting, than by operating on soft young watery shoots for the following reasons.

The wood of which the split Apple grafts above alluded to were made was necessarily matured and the full virtues of the sap secreted. Had young growths been united and attached to others under artificial conditions, it is extremely improbable that any change whatever would have been effected. From inductive reasoning I will turn to practical experience, which has perhaps some bearing on the theory propounded. Inarching the soft young growths of Vines has been done in thousands of instances. I am unable to say how many I have seen or even done, but I have never observed the slightest change in the character of the fruit by those unions, nor seen an authenticated record of such change having been effected. But if we turn to the practice of inarching matured wood the results are very different. Changes in size, form, colour, flavour, and time of ripening of the fruit have followed in numerous instances, not a few being very marked, such as a black and white bunch on the same rod; but as showing the fugitive character of the Vine, the eyes from the lateral bearing the white Grapes produced Vines that gave nothing but black ones. There is more stability in Chrysanthemum sports; and if there are any growers who are disposed to encourage their production, and it is certain there are many, the most direct way to success as suggested by failures with these plants and experience with others would, it seems to me, be by inarching the matured growths towards the end of summer.—J. WRIGHT.

A WORD TO YOUNG GARDENERS.

In your recent announcement of the "Work of the Journal" you include "Advice to Young Gardeners." This is no new item in your programme. It is now nearly twenty years since I first appealed to you for counsel, which was responded to in a manner quite unexpected by me, and the sound advice then given in a lengthy article by your much-esteemed late correspondent, Mr. R. Fish, very much stimulated my exertions at self-improvement. I must, however, confess that too much of my time when housed in a bothy was wasted in frivolous amusement. At the festive season, Christmas, with its family parties and friendly reunions, when the wrongs of the past are forgotten, and congratulations and good wishes are freely exchanged, it may not be altogether out of place to jot down a few thoughts for young gardeners a little in sympathy with the period, as the new year, with its retrospective thoughts and fresh resolves, is approaching.

A bricklayer may soon master the few technical terms in connection with his trade, as may most of the mechanical tradesmen in a longer or shorter term of years, much depending of course on the intelligence and aptness of the pupil. The gardener's education, on the other hand, may truly be said to have no completion. The field he labours in is so vast, and the subjects so numerous, that very few indeed ever attain a perfect knowledge of all the different branches of the science and practice of gardening. One man may find himself placed in a position to study a particular branch, and having a taste for it he makes it his hobby; another man, differently situated and with different taste, strikes out on another branch, and so there may be said to exist a class of specialists. To these men horticulturists are much indebted. Their experiences are being continually held up to us in the press, and so others are aided in their efforts to follow in their steps.

A good gardener must, however, be known as something more than a specialist; he must have a good "all-round" knowledge of the business. A man may be a first-class Orchid grower, and may suit his employer in this respect very well; but if the cook begins to run short of vegetables, or the butler of salads, he will soon get into hot water, much to the annoyance of all parties. Let me urge, then, on all young men, that whatever they may take up as a special subject, never ride a hobby to the exclusion of attaining a good general knowledge of their business.

I think all young men should have a good knowledge of the kitchen and fruit garden before going permanently indoors. Digging, trenching, manuring, rotation of crops, the dates of sowing to secure a constant supply of various kitchen garden crops, planting, pruning, root-pruning, nailing, grafting, budding, and a knowledge of the numerous varieties of hardy fruits are quite as essential elements in a gardener's education as anything

to be learned in the houses. Many young men, however, when once they are placed "under glass" seem to think such things beneath their notice, and scarcely ever take note of what is going on outside. This is a great mistake. There are so many things to be learned that it is impossible to learn only one thing at a time. Whether outdoors or indoors a young man who wishes to get on must never lose an opportunity of making himself acquainted with everything that is going on about the garden, and, if need be, take a note of all operations.

The next important subject is, perhaps, the flower garden. The various plants used in summer and spring bedding—carpet-bedding plants and the mixed borders, the formation and management of walks and drives, lifting and laying turf, in making lawns and their proper keeping, planting and management of shrubberies, and other matters connected with laying out a new or renovating an old place, are all subjects of importance and cannot be too soon laid hold of.

Indoors a knowledge should be had of the various sorts of Grapes, Peaches, Nectarines, Figs, and other fruits; acquaintance must be made of the occupants of the stove, the greenhouse, conservatory, and fernery; how to propagate them, how to pot in suitable soils, watering, shading, ventilating, &c., the growing of Melons and Cucumbers, the forcing of Asparagus, Seakale, Rhubarb, and Kidney Beans, are a few of the many things that have to engage the attention of the indoor gardener. And last, but not least, good practice in the stovehole and proper management of the circulation of the water in a heating apparatus,

Some knowledge of vegetable physiology is very desirable, and chemistry, as far as it relates to soils and manures, is also useful and important. As to botany, a lecturer recently impressed upon the Manchester gardeners that "the botanist and horticulturist were inseparably connected with each other, and no horticulturist, without some knowledge of botany, would proceed clearly in his work." To young men whose education, like my own, is but limited, the study of botany with its many technical terms is uphill work indeed, and only those who have a taste for it, and perseverance enough, succeed in mastering it; but few need despair of gaining such a knowledge of it as will be useful to them as cultivators.

Geometry is also a subject that every young gardener should have some knowledge of. In laying out a geometrical flower garden, in planning and planting carpet or large beds of ordinary bedding plants, where a design or figure has to be worked out, a knowledge of drawing is absolutely necessary. It is also of no less importance that a gardener be able to understand a plan of any garden structures about to be erected, that he may be able to check any mistakes in the construction or arrangement of pipes, paths, or staging before the work is executed, and so save expense to his employer and annoyance to all parties. These are a few of the subjects it is necessary that every young man should direct his attention to. To enumerate all the things a gardener is sometimes *expected* to know would fill a volume.

And now the question arises, How is a thorough knowledge of gardening in all its branches to be best obtained? I mean, how are young men to prosecute their studies to the best advantage? There are many readers of these pages who could give us valuable information on this, and I am sure it would be prized by all who have young men under them, as well as by many who are struggling at self-improvement where there are few helps and little encouragement, where there are three or four young men together with an intelligent foreman, or a head gardener who takes an interest in the improvement of his men—they help each other on; but there are thousands who have no such advantage. If a bothy census was taken, and an average struck, it is probable it would not exceed two or three young men to a bothy. Where there is only one or two they are generally both to a certain extent inexperienced; and if the gardener does not help them, it is only those who have natural intelligence and perseverance who make any progress, till they begin to come into contact with others who exercise an influence over them.

In the first place I think it necessary that they should be methodical in all they do, from the crocking of a flower pot, the washing of a plant, to the study of physiology, chemistry, or botany. While they work with their hands let them think and always be ready to give an intelligent reason for this or that if called upon to do so. A note-book and pencil should be their constant companion. The very art of writing anything down is often the means of impressing on the memory. This is especially commendable in reading any book or periodical which when read passes into other hands, and therefore cannot be referred to again. In quoting from a standard work, or from any other source, always make note of the author, and the pages, or the date of publication in periodicals. In like manner, when visiting any neighbouring gardens never fail to take a note

of anything striking and good or ingenious, stating where it was seen. And let me say in passing that gardens of the more humble order should not be thought unworthy of a visit, for in many of them there is much to be learned, as well as in those of a more pretentious character.

I have already referred to specialists. There are few minds so evenly balanced and self-controlled that it can be made to devote an equal portion of leisure hours to various subjects, and to prosecute each with an equal amount of success and pleasure. Whatever a youth may have a special fancy for, be it botany, chemistry, or drawing, let him make it a pastime; it will always be found a welcome change from anything which in his way of thinking is dry, but do not go botany mad or drawing mad to the exclusion of everything else.

In conclusion, I would pen a few words of warning. Let young gardeners keep a respectable distance from other domestics on the establishment. Especially would I say, Avoid a too close association with stablemen. This too often leads to card-playing, drinking, and betting, which gardeners should have nothing to do with. In some gentlemen's houses some temptation is held out to those visiting the hall in the shape of the inevitable horn of beer. Many get to like it through this alone; and although it may be said that gardeners are a sober class of men, yet there are black sheep in their ranks, and doubtless many a poor man has had to regret the horns of beer first handed to him by his fellow servants. I am not a blue-ribbon man, but let me advise young men to give drink shops and drinking a wide berth. In my younger days I at one time went to a dancing class, and for the time went dancing mad, and at another to a singing class, and went singing mad. These things are all very well in their way if taken in moderation; but as it is difficult to put old heads on young shoulders, so it is difficult to moderate the excitement of either dancing, singing, or drinking when once entered into.

There is one more little matter which I think I must refer to, as it is perhaps the one thing over which I have wasted more time than on all the others put together—viz., novel reading. This is one of the most baneful things that can obstruct the path of the student, who has to read much that seems very dry and unpalatable after an exciting flight of the fancy. If given way to it, unfits the mind for anything else. This is my experience, and I have wasted many a precious hour reading them. Very few of our weekly newspapers appear without their chapters of fiction, bearing testimony to the great waste of time by the thousands who read them. But this is not the worst form of novel-reading; it is when youths take to going to a friend or to a library, and coming home with a two or three-volume novel, that the greatest evil is done, as little else is thought of till it is read through. This is, therefore, a practice that is to be avoided.

Young gardeners are not over-remunerated we all know, and it is well for them to be careful for the future as for the present. Let each try to spare 6d. a week for some friendly society, and let them do so while they are young. No reader will now have to complain of not knowing where to apply to, since the claims of the United Horticultural Benefit Society have been so prominently brought forward. I have subscribed some eight years to an Odd Fellows Club, and had I joined the above Society then I would probably had nearly as much to my credit on the books as would be paid as funeral money by the Odd Fellows if I had subscribed to them for fifty years. I have even now, at a great disadvantage, offered myself for election as a member of the U. H. B. S. I think it is by far the best and fairest scheme to individual members of any society that has come under my notice, and I hope head gardeners and under gardeners will hasten to swell the number of the "United."

I hope some young men may gather some little hints from the above letter, should its contents see the light of day from 171, Fleet Street, and that they will accept the compliments of the season from—A WORKING GARDENER.

MARIPOSA LILIES.

SUCH is the euphonious name given to a small series of bulbous plants included in the genus *Calochortus*. I refer now to the genus as including those species which Lindley was pleased to designate *Cyclobothras*, for the deviation from the typical *Calochorti* is so slight that they do not merit the separation. What gems they all are! Are you acquainted with them? Now is the time to be on the look-out for them. Like many other good things these find their way to King Street, Covent Garden, and Mr. Stevens has frequently to knock down a dozen bulbs of *C. venustus* and others for 2s. 6d. or 3s. But, coming to the point, how to grow these bulbs to insure their being lasting adjuncts to the garden, I may mention that a few

years since I visited Mr. Ware's celebrated nurseries at Tottenham, and noticed some persons preparing several small beds of good soil, the old soil being removed, if my memory serves me rightly, to a depth of 18 inches, and the spaces filled with very good soil. Upon inquiry I found these beds were being prepared for the reception of *Calochorti*, and almost every time since, when associated with these charming plants, I have wondered how they succeeded. Perhaps Mr. Ware or Mr. Perry would kindly communicate this information for the benefit of other readers besides myself. My experience is adverse to such treatment, for the bulbs seem to have a tendency to force themselves to a great depth in the soil, especially if loose, and each year get weaker and ultimately disappear. I have often been surprised when searching for the bulbs to find them much lower than I expected. I have raised a number this year and replanted them, but have placed some pieces of slate of a good size directly under the bulbs to prevent their downward course. I was induced to adopt this plan from my experience with them this year under pot treatment, having flowered a large number of kinds in pots, and when the bulbs were turned out this autumn for repotting, I found they were finer than when potted last year, and promise well for next year's flowering but they were hard down upon the crocks. They were potted three and four bulbs in 6-inch pots in the following compost—good fibrous loam, leaf soil, a little good peat and coarse sand, potted firmly, and during growth well supplied with water, even to the withering of the stems, when they were ripened off under a light, and so far the result is very satisfactory. During the flowering period they were a great source of interest to many others beside myself, the beautiful form and blendings of colours in the flowers being quite as attractive as the choicest Orchids. I may say for the benefit of those who may be desirous of growing these plants, that they are now easily procurable from both British and American dealers. Happily the postal and parcel traffic between this country and the United States largely facilitates the importation of choice plants from all parts of that vast continent so rich in plant treasures; and without any prejudice against our own dealers, I recommend the readers of the Journal, if they are unable to secure bulbs at a reasonable price in this country, to apply to some of our American cousins, and there will be no difficulty in forming a good collection at a moderate price.

I give a full list of the species and varieties now under cultivation as far as my knowledge leads. Those described in full flowered with me in pots last summer, and I carefully verified the names.

Calochortus albus, Dougl.—A very lovely species, frequently called *Cyclobothra alba*, it having been figured in the "Botanical Register," t. 1661, under that name. It grows from 9 inches to 15 inches high, glaucous throughout, with lanceolate elongated leaves and large foliaceous bracts, the stem terminated by a few-flowered raceme; perianth globular, with concave pure white divisions, bearded above the gland, and copiously ciliated with long white hairs; the gland is fringed with short yellowish glandular hairs. This is one of the handsomest and most easily grown of the genus, and is very common and rather widely distributed, occurring on the basal hills of the Sierra Nevada, and on the hills from Los Angeles Co. to Sonoma. I had one pot of this last summer with thirty flowers, and it was greatly admired, and if I remember rightly the flowers were sweetly scented.

C. Benthami, Baker.—This is the name generally adopted for this species, named in honour of a world-renowned botanist, although Mr. Bentham himself named it *Cyclobothra elegans* var. *lutea*. It is a dwarf and slender-growing little species not often more than 6 inches high, with from two to six flowers; perianth bell-shaped, nearly erect, divisions about half an inch long, deep yellow, and densely covered with yellow hairs, with a deep brown claw beneath the gland. It is a charming little gem, very easily managed in pots. Pretty frequent on the Sierra Nevada from Mariposa to Butte Counties.

C. caeruleus, Watson (*Cyclobothra elegans* var., Benth; *C. caerulea*, Kellogg).—This rather rare species grows about 4 or 6 inches high, the stem branched, and carrying an umbel of from two to five flowers more or less bell-shaped in form, and with a solitary narrow leaf much longer than the stem; the divisions of the perianth are half an inch or rather more long, the inner ones deeply pitted and arching, of a lilac or light blue colour dotted and barred with a deep shade of blue, thickly covered and ciliated with slender hairs. I had only a few small bulbs of this species, but one produced two flowers, and it was very distinct from any of the others which bloomed. Native of the Sierra Nevada.

C. elegans, Pursh.—This is one of the earliest-known of all

the species, and is well figured in the "Trans. Hort. Soc.," vii., 278, t. 9, fig. B. It grows taller than the last, and has broadish rather glaucous leaves; perianth campanulate, erect, greenish white and purplish red at the base of the divisions inside; the inner divisions are not ciliated, but there is a fringe of hairs rising from the gland upwards extremely pretty in appearance. It is a very plentiful species in its native haunts, occurring in Oregon and Idaho and on the Sierra Nevada, and it thrives as well as any species in the open border, but I think is better in pots.

C. venustus, Benth.—This is an extremely handsome species. It grows from 1½ to 2 feet high with large flowers; the outer

Fig. 99.—*Calochortus venustus*.

divisions are whitish tinged with lilac, the inner one white or pale lilac, with a large reddish spot near the top and a brown spot in the centre with a zone of yellow, while the base is brownish; the gland is large and densely clothed with hairs, and more or less heavy round about it. This forms a beautiful contrast to the luteus series, and should certainly be much more abundant in our gardens, as it thrives as well as any. I remember this used to flower well near the old herbaceous ground wall at Kew, where it first engaged my attention. The woodcut (fig. 99) gives a good idea of the form of the flower.

The following names are often met with in lists, and I have bulbs which came to me as such but have not yet flowered, but I quite expect some of them are synonyms, while others may have an equal claim to specific rank to any of those described above. These are *Greenii*, *flexuosa*, *Nuttallii*, *Leichtlinii*, and *Lyalli*.

C. luteus, Dougl.—This beautiful species is free from synonyms as far as I know, and is well figured in the "Botanical Register," t. 1567. It grows from 1 to 2 feet high, with slender stems requiring support, with very narrow leaves shorter than the stems; perianth open, broadly bell-shaped; the outer divisions narrow, lanceolate, acuminate, pale yellow shaded with purple, with a brown spot at the base; the inner divisions are much broader, deep yellow lined with brownish purple, and slightly hairy about the middle, while the broad gland is densely clothed with yellow ascending hairs with others scattered round it. There is a beautiful variety of this named *oculatus* by Watson; the perianth divisions vary in colour, but the inner ones are most frequently white, with a dark brown-purple spot at the base, usually bordered with yellow, while the gland is clothed with yellowish hairs. It is very striking, and I believe scarce under cultivation. The normal form is abundant from San Diego to Mendocino Counties, and on the basal hills of the Sierra Nevada, while the variety *oculatus* and other marked forms are occasionally met with.

C. macrocarpus, Dougl.—This is rather a strong-growing species, with stoutish stems 1½ to 2 feet high, but not often bearing more than one flower, which is open, bell-shaped, and nearly or quite 3 inches across; the outer divisions white tinged with lilac, while the inner ones are purple-lilac with a greenish medial line; the gland is large and densely hairy, the hairs ascending about one-third of the way up. It is a showy species, and a good figure of it occurs in the "Botanical Register," t. 1152. It is rather plentiful on the banks of the

Little Shasta River, extending northwards to Washington Territory.

C. Maweanus, Leichtlin.—This is the *Cyclobothra elegans* of Torrey, and is figured in the "Botanical Magazine," t. 5976, under the name of *Calochortus elegans*, Pursh having previously named the true *C. elegans*. It grows from 5 to 9 inches high, branching at the top of the stem, and carrying from three to six flowers, which are bell-shaped and about 1½ inch across; the outer divisions purplish, rather smaller than the inner, which are white tinged with purple, especially at the base, the inner surface more or less thickly clothed with erect purplish hairs and the margins ciliated. It is a charming little species, rather scarce under cultivation, although according to collectors' statements it appears to be fairly plentiful in its native habitats, occurring from San Francisco northwards to Humboldt County and in Butte County, and I believe first flowered with Herr Max Leichtlin.

C. lilacinus, Kellogg.—This is not so showy as most of the other species, but is nevertheless well worth growing. It was figured under the name of *C. uniflorus* in the "Botanical Magazine," t. 5804, most likely through a weak bulb only producing a solitary flower; it also exists under the name of *C. umbellatus*. The stems grow from 4 to 9 inches high, carrying from one to several flowers more or less bell-shaped; the divisions nearly or quite an inch long, pale lilac, purplish at the base, the inner ones free from hairs on the margins, but hairy below the middle, and the gland is margined with a narrow ring of hairs. Found on hillsides about San Francisco Bay.

C. nudus, Watson.—Mr. Bentham makes this a variety of *Cyclobothra elegans*, while Mr. Baker calls it (*L. C.*, 305) *Calochortus elegans* var. *subelavatus*; but I like Watson's name, as the plant is entirely destitute of hairs, and I think is the only species. It grows from 6 to 10 inches high, producing in a simple umbel from one to six flowers, which are from 1 to 1½ inch across; the outer divisions white or slightly tinged with lilac; the inner ones pale lilac, fan-shaped. Plentiful in the Sierra Nevada, rather widely distributed. It is not so showy as most of the others, but is well worth having.

C. pallidus.—This pretty species is now known as *C. flavus*, under which name it is described by Mr. Baker. A pretty, bulbous-rooted, half-hardy perennial. It produces a tuft of grass-like channelled leaves, and from among them a flowering stem 6 inches or 8 inches high, supporting three or four blossoms, each on a slender peduncle; these peduncles

Fig. 100.—*Calochortus pallidus*.

grow in an umbellate manner from the base of two or three small leaves, which are produced at the top of the common stem. The flowers are hexapetaloid, the three outer divisions small, ovate oblong, obtuse; the three inner much larger, obovate, rounded at the apex, and attenuated at the base; they are pale yellowish buff colour, with a broad angular blotch of dark reddish brown in the centre. From Mexico; introduced to Belgium about 1844. Flowers in the latter part of summer. It

is not much grown in gardens now. Do any of your readers know it?

C. pulchellus, Dougl.—This charming species is usually known under the name of *Cyclobothra pulchella*, so named by Bentham, and so figured in the "Botanical Register," t. 1662. It grows from 9 to 18 inches high, with slender freely branching stems carrying from two to several nodding flowers, more or less globose in form; the outer divisions are yellow, rather shorter and narrower than the inner ones, which are broadly ovate in outline, deep golden yellow, copiously ciliated, and the inner surface is more or less clothed with stiff yellow hairs, while the deep sunken gland is densely covered with hairs. The flowers are sweetly scented. It is found along the coast ranges from Monterey to Mendocino County. It is a very beautiful kind, growing as freely as any under cultivation, indeed improving, as I have seen very large corymbs of flowers produced even larger than herbarium specimens, and the flowers are very lasting.

C. splendens, Dougl.—This very pretty kind grows about 12 or 18 inches high, with one or more flowers, about 2 to 2½ inches across; the outer divisions pale lilac, rather smaller than the inner ones, which are clear lilac, with a dark claw and white scattered hairs about the middle, while the gland is densely hairy. Frequent in the San Diego district.—MARIPOSA.

NOTES ON PEAS.

MUCH has been written about the many new varieties of Peas that are placed in the market every season. The prizes offered at exhibitions for them no doubt attract attention, and I certainly do not envy the raisers or vendors any profit they may derive from their enterprise; but I would like to say a few words to both raisers and buyers of these grand Peas. The former alone know the extra attention that is paid to the plants, and the enormous supplies of manure in a solid and liquid form they receive to produce the results chronicled. The successful exhibitor has found this out too, but the majority of buyers of Peas expect the same results without bestowing any extra attention in culture, and are generally disappointed. To the latter I would say. When purchasing new Peas at a high price, however good the soil may be, always open a trench as for Celery, and apply manure quite as freely, for (should the weather be hot and dry) without this the enormous fleshy pods cannot be produced.

Where a great quantity of Peas is required many of the old varieties are not excelled, as they stand cold weather better and fill much faster than the giants, without half so much expense and attention in culture. Peas nearly always suffer from drought, not having half enough water in dry weather. Many grow higher in wet weather than dry—some the reverse.

Seedsmen as a rule often do not give the full or even the average height of Peas. I do not know why this should be so. It is very disappointing, troublesome, and leads to waste, when Peas grow much taller than the height stated. The haulm gets broken and the crop is of little value. I attach the results obtained during the last dry season.

I was told by a clever Scotch gardener that Carter's Stratagem, Pride of the Market, and Telephone would not grow so far north as here. However, being successful last year with Telegraph and Telephone, I have tried the two others. They were sown between Cabbage rows, on ground neither dug nor manured, only adding a little soot and guano.

I think it no disgrace to either Pea or seedsmen that sticks are required for good Peas; but it is very disappointing to be told they are not when they are, and then not be prepared with sticks. Carter's Stratagem and Pride of the Market, sown May 5th, were gathered July 24th, height 3 feet. Dr. Maclean and John Bull, 4 feet, were a week later. The above two former, sown May 18th, were ready August 5th, height 2 feet. Telephone, sown at the same time, were nearly ready, height 5 feet. Laxton's Superlative, 6 feet, proved a heavy crop. I have grown my own seed of this for several years, and I find by using short inferior pods and late ones I have got a very much reduced pod, and apparently mixed sample, but the flavour of all is alike good.

I gave a few packets away in exchange for others, and was told they were mixed until I explained the cause.—J. E. WAITING, *Grange-over-Sands, Lancashire*.

FIRING AND VENTILATING.

HOWEVER correct Mr. G. Abbey may be on several points of the above subject, on others his remarks are somewhat hazy and ambiguous. Especially is this the case in his reference to Cucumbers, &c. (see 480). Having long had misgivings on the soundness of the usual stock-in-trade directions given in the calendars of the gardening press upon early forcing, airing, &c., I last year decided upon trying an experiment with early Melons. The house experimented upon is a span-roofed one, 30 feet long, 10 feet wide, and 10 feet from the floor to apex, stands north and south, is glazed with 21-oz. glass in squares 2 feet by 11 inches. It is ventilated on the top by a light opening the whole length of the house, and by 2-foot-deep side lights. In order to prevent the smallest amount of external air entering we had all the ventilators tightly screwed down.

On the 27th of December we sowed seeds of Scarlet Premier and Best of All. These in due time germinated, and were planted out on January 19th into a row of eleven plants on each side of the house. The weather during February being mild and open with a fair amount of sunshine, they made rapid progress, and opened their first pistillate flowers on March 3rd. These being duly fertilised the fruit soon commenced swelling, and on April 14th those first set were observed to be changing colour, and upon entering the house the following morning a strong perfume so acceptable to gardeners proved that the period of ripening was near at hand. From December 27th up to this date no ventilation was given, although many times on bright sunshiny days the thermometer indicated a temperature of from 100° to 110°, and at bedtime stood from 85° to 90°, and this, too, without a burning heat in the pipes. The first fruit was cut on the 17th perfectly ripe and finished in every way.

The crop produced was seventy-four fruits, and to speak of their quality would on my part be mere affectation; but having more than was wanted for the requirements of my employers the surplus was sent to that source where all fruit finds its true value—viz., the Covent Garden fruit salesman. The first consignment when brought under the hammer realised 12s. 6d. each. It will be interesting to know if Mr. G. Abbey or any of your numerous correspondents can show better results from the air-giving system. I have some notes upon the early forcing of Peaches and Nectarines with a minimum of air-giving. Should you think these worthy of a place in the Journal I will gladly send them.—J. MCINDOE.

[We will readily publish the notes referred to.]

GLOXINIAS FOR FLOWERING IN WINTER.

WE have at the present time a very pretty batch of these in flower; and seeing how very easy of culture they are, the wonder is that they are not more generally grown for stove-decoration at this dull season. The plants under notice were grown from seed sown last March, but instead of their being grown in the stoves or warm pits, they were hardened as early as possible after being established in small pots, and grown all the summer on a shelf near the glass on the north side of a span-roof greenhouse. As this house was kept as cool as possible, and shaded from bright sun, the Gloxinias did remarkably well, soon filling their small pots with roots. About July they were placed in their flowering pots and again placed on the same shelf. The soil used for this last potting was of a somewhat rough character, being chiefly loam and road sand well mixed together; in this the plants made a much slower growth, but as they had a good time to fill the pots with roots, they were not hurried in any way, air being freely admitted night and day, and no fire heat being used. With this treatment the leaves were much thicker than any I have seen, and, what is more, they are perfectly free from insects of any kind. In some cases the foliage entirely hides the pots the plants are grown in. Another great point in their favour is that the flowers last much longer than could possibly be the case at any other time of year, for the reason that the sun would be too strong for the well-being of Gloxinia flowers, unless heavy shading were resorted to, and that would not suit other occupants of our stoves. Again, when arranged, as in our case, in front of a group of Calanthes, Poinsettias, and Maidenhair Ferns, they make a good finish with their "finest spotted" and charming "erect" flowers. These remarks are intended for those of your readers who may not have grown Gloxinias in the way indicated and would like to try them.—GEORGE MERRITT, *The Hoolearaens, Welwyn, Herts*.

STORED-UP SAP IN VINES.

It would serve no good purpose to follow Mr. Taylor in the irrelevant issues he raises this week. I should have thought he would have offered some kind of answer to the questions I put driving at the very heart of his argument, but he does not. I must, however, point out his misquotations and the false inferences he draws from them. Contrary to his imaginings, I have Johnston's "Elements of Agricultural Chemistry," as well as many more works bearing more directly on the subject. But the work named is quite correct on sap, and in no way controverts me. If Mr. Taylor was as familiar with it as he professes to be, and wished to be accurate and fair, he would have gone further, and at page 42, eighth edition, have found and quoted the words, clearly derived from Lindley—viz., "In spring and autumn the motion [of the sap] is more rapid. In winter it is sometimes scarcely perceptible; yet the sap, except when frozen, is supposed to be rarely quite stationary in any part of the tree." From this your correspondent will see I am as well acquainted with the works he kindly recommends me to procure and read as he is. As to my quotation from Lindley, no physiologist of standing has ever contradicted or questioned it, and I challenge Mr. Taylor to lay his hand on any authority that does. Lindley is wrong in some things, like other authors, but not in that.

Nobody disputes about the hairs of the roots being "chiefly" concerned in absorption; but they are not the only agents, and we have only Mr. Taylor's word for it that the root-hairs are "non-existent" at certain periods. Besides, we have the admission of the very authorities he quotes, that the sap is always in motion in all parts of the tree. These points, however, whatever value may attach to them, are quite overruled

by the one patent fact that, root-hairs or no root-hairs, the sap in Vines is in motion weeks and months before the rods are "in action" in Mr. Taylor's sense, for a leafless Vine will suck up a basin of water by the root, and pour it out at the top of the rod in bleeding and in a short time. Until Mr. Taylor faces that question he wastes his breath by such side issues as he raises. He quotes other authorities, but none in the sense he writes—viz., that established Vines are "dependent" on stored-up sap till the lateral shoots are 7 inches long and the leaves 5 inches in diameter. Where are his supporters on that head, which is the real point of contention? The question is *Vines*, and whether or not they absorb sap from the ground from the moment they are started. I say they do, I give him everyday, familiar, and visible proofs of it. Will he tackle these first? Why does a Vine bleed, and why does it stop bleeding when deprived of its roots?

"I most positively deny having implied that Vines had completed their store of sap at the fall of the leaf," says Mr. Taylor. Very well; let us see. He has constantly implied that stored-up sap is "elaborated" sap, and in his letter this week he quotes the "Gardeners' Assistant" to prove that "these shoots are supported by sap contained in the trunk and which has been elaborated by the leaves." Where, then, was the sap elaborated that in another part of the same letter he says was stored up in his Vines "six weeks" after the leaves fell? Again, in his first article he says "the stored-up 'food' was prepared last autumn and preserved in the stems for early use." The word "food" here and "prepared" imply elaborated sap, and, therefore, that it was stored when the leaves were on the Vine, and not as he says now. In another letter he tells us that the sap pumped up when the Vines are leafless is "pure water" only. There is, therefore, no mistake about what Mr. Taylor "implies," only his theories and his facts are now completely out of joint, and this is what comes of writers who get out of their depth I always notice. But Mr. Taylor's troubles do not end here. If his Vines went on storing sap weeks after the leaves had "fallen," which would be late in the year, they must have been storing it up to, if not beyond, the time he started them, which means they had hardly ever ceased sending up sap at any time. I might pursue him further in his dilemma, but I have said enough to show the unreliable, indeed totally untrustworthy, nature of his teachings on this subject.

In answer to "J. C.," let him lift a newly started Vine eye out of the soil and note its behaviour, or that of any rootless cutting, which alone disposes of Mr. Taylor's "hair-roots" theory.

P.S.—As I am only anxious to get at the facts in this matter, may I ask any competent authority at Kew, or elsewhere, if, in the present state of our knowledge, it is a fact that the root-hairs (of Vines, for example) which supply the food and sap to the stem, are "non-existent" till after young roots are produced? Would they kindly answer that question, and also say if a Vine does depend solely on the "sap preserved in the stems" from the following autumn till the shoots are long and the leaves 5 inches broad?—NON-BELIEVER.

In common with many other readers of the Journal I have been watching the discussion between Mr. Taylor and "Non-Believer," with much interest; and though not wishing to interrupt their consideration of the subject, I am desirous of pointing out what may be considered defects in the arguments on both sides. Possibly this may clear the ground a little for a better understanding.

In the first place with regard to "Non-Believer's" quotation from Lindley's "Theory and Practice of Horticulture." In my edition (published 1840) the passages cited do not occur on the pages named—viz., 26 and 52, but the first is on page 17, and as only a portion of it was given I will complete it. "There is no period of the year when the roots become altogether inactive, except when they are actually frozen. At all other times during the winter they are perpetually attracting food from the earth and conveying it into the interior of the plant, where it at that season is stored up till it is required by the young shoots of the succeeding year. The whole tissue of the plant will therefore become distended with fluid food by the return of spring, and the degree of distension will be in proportion to the mildness and length of the previous winter. As the new shoots of spring are vigorous or feeble in proportion to the quantity of food that may be prepared for them, it follows that the longer the period of rest from growth, the more vigorous the vegetation of a plant will become when once renewed, if that period is not excessively protracted."

The second quotation, which reads as a continuation of the former, to the effect that "the tubes are nearly empty at the fall of leaf," I have searched for without success. Will "Non-Believer" state the chapter in which it occurs? as, if there is no context qualifying or explaining this observation, I have no hesitation in saying that it is quite contrary to the facts. Undoubtedly Lindley has some errors to answer for, but I can scarcely think that he would have made so strange a one as this, especially as I can find no passage either in the work quoted or in any other of his that would lead to such a conclusion.

It would seem that the real difficulties in the matter are the following. First, that Mr. Taylor has confounded root-extension with root-action, which "Non-Believer" rightly asserts are distinct; and, second, that Mr. Taylor considers sap is stored up in summer and autumn, which is utilised by the plant in its first growth the following season, while "Non-Believer" regards the growth as due, not to a reservoir of elaborated materials, but to the constant supply of crude sap rising from the roots. These were the two matters under consideration, and as it appears to me the difficulties on both sides admit of easy removal. There can be no doubt that root-extension, meaning thereby root-growth, is

quite distinct from root-action; and though in some cases they are contemporaneous, in many others root-growth follows root-action. Further, as Lindley states in "Theory and Practice," page 37, "The flow of the sap must not be confounded with the motion of the sap, which takes place in winter as well as in the summer, and is a mere repletion of the system, caused by the attraction of the roots, unaffected by the exhalation of the leaves." When growth is started in the spring the upward current is increased, sap passes into the partly formed leaves, is exposed to light and air, altered in its chemical constitution by a process of deoxidisation, and is returned to the stem, thus producing a downward current which causes growth of the tissues of stem and root.

Turning to the second part of the subject, the storing of sap, it seems that though Mr. Taylor is right in the main, he has carried his views a little too far. That the stem of a Vine, as of most other deciduous plants or trees, contains in autumn and spring an accumulation of elaborated sap—that is, sap which has been passed through the leaves and chemically changed in its nature, there can be no doubt, as the firmness acquired by ripened Vine wood is entirely due to the hardening of the cell-walls and the matters stored within them. Similar examples are found in nearly all trees, the cells of which become gradually filled with various substances until that peculiar solidity is reached which characterises the heartwood of timber. The comparatively small amount of crude sap absorbed during winter and until leaves are formed serves in the case of the Vine as a diluent of the elaborated sap, and it is possible that chemical combinations may take place to a small extent; but before it can become of real service to the plant it must pass into the leaves, which in a measure correspond to the lungs of animals. When the buds commence expanding in the spring they unquestionably obtain their full supplies from the "stored-up sap" in contiguous cells, but immediately a green surface is exposed to the air elaboration commences, and the crude sap is then speedily utilised. It is in this respect that I cannot think Mr. Taylor quite correct in assuming that the leaves are entirely dependent on the stored-up sap until they are 5 inches broad, as the smallest green foliage surface exposed to light suffices to produce the requisite change in the fluid absorbed from the Vine. At the same time they undoubtedly derive much assistance from the previously elaborated cell-contents.—CREDO.

AT a general meeting of the ROYAL HORTICULTURAL SOCIETY held December 11th, James J. Wheble, Esq., in the chair, the following candidates were elected Fellows of the Society—viz., George Chorley, Mrs. A. Harford Pearson, W. H. Michael, Miss Michael, Edward Edwards, and William Peayters Stock.

— "NOVICE" writes respecting EXHIBITING CHRYSANTHEMUMS as follows—"Will some of your readers kindly state if Chrysanthemum Snowball is admissible in the same stand as Empress of India? also if White Queen of England is synonymous with Empress of India? In this locality the variety grown under the first name has petals more flat and more obtuse than Empress, as well as having a slightly glazed or shining surface, something like White Venus."

— WE have been favoured with a report of the YORK CHRYSANTHEMUM AND FRUIT SHOW, but it did not reach us in time for insertion. The Exhibition is described as a very good one. Mr. J. Hazel, Cockcroft Hall, Morpeth, won the cup for cut blooms, and Mr. Smith the first prize for specimen plants. Fruit and vegetables appear to have been also well represented, and miscellaneous collections of plants.

— "T. W. S." writes—"The exceedingly showy SENECIO PULCHER is still flowering with us in the open borders. We have groups of them in the herbaceous borders and on rock beds, and these have yielded without intermission a constant supply of its purple-crimson flowers for months past. The recent frosts seem to have had no injurious effect on their blooming propensity, for the flowers continue to open. This is a decided acquisition as a late-flowering plant, and deserves to be more generally grown."

— WE are informed that at the first Chrysanthemum Show of the TAUNTON AND DISTRICT GARDENS ASSOCIATION (a benefit and mutual improvement society) held recently, there was a very good display in the various classes, and altogether the show, although chiefly local, was a great success and highly creditable to the Managing Committee and Mr. R. H. Poynter as Hon. Treasurer. Among the exhibits most worthy of

mention were the stands of cut blooms of *Chrysanthemums* from Mr. E. Wills, gardener to Mrs. Pearse, Southampton; the groups of plants from John Marshall, Esq.; cut flowers, 150 trusses of *Pelargoniums*, &c., from G. Fownes Luttrell, Esq.; the Apples of Sir W. Trevelyan; Pines, Grapes, and Cucumbers from W. Speke, Esq.; the beautifully luxuriant young Palms from E. E. J. Esdailes, Esq.; the *Cyclamens*, Heaths, and hardy shrubs, and collection of Potatoes from the Taunton Nurseries (Mr. Poynter's); and the prize fruits (collection) from C. L. Collard, Esq. Also the local exhibits of cut blooms and specimen plants of *Chrysanthemums* were of more than average merit, especially those of Lionel Patton, Esq., W. Marshall, Esq., F. Woodland, Esq., Mrs. Reynolds, Captain Adderley, all foreshowing, with equal good and energetic management, the establishment of an autumn show second to none in the west of England.

— A CORRESPONDENT writes—"For covering bare patches of ground under the shade of trees near frequented walks no plant excels the small North American *MITCHELLA REPENS*. It is a plant having a dense creeping habit, with small oval-shaped dark green leaves, which lie nearly flat on the ground, entirely covering it. The flowers, which are produced in August and September, rise about 2 inches, white or pinkish, and very fragrant. It is partial to peat or decayed leaves, but will also grow in ordinary soil. It is a good companion for *Sibthorpia europæa*."

— THE CULTIVATION OF *SORGHUM SACCHARATUM* and the manufacture of sugar from its stems has of late occupied a large share of attention by the Government in America, reports on which have been issued at different times. The most recent of these is an "Investigation of the Scientific and Economic Relations of the Sorghum Sugar Industry." This is in the form of a report drawn up by the Committee of the National Academy of Sciences, in which the subject of the cultivation, production, and manufacture of the sugar is treated in considerable detail. The report is one of considerable value, especially to those interested in the progress of this industry.

— MR. G. F. WILSON writes to us as follows:—"Allow me to add to your remarks on *SARRACENIA PURPUREA* (page 499), that it was uninjured when growing on our 'Wilson raft,' though the ice was 6 inches thick on the water below it. If 'E. L. B.' plants it out I advise him placing it in the full sun. In the shade of our wood at Wesley, though the plants flowered well, the pitchers were always green. I send by post with this a couple of pitchers cut to-day at the side of our Wesley pond to show the rich colour they get in the sun. Feeling one of the pitchers heavy I found it was full of ice." [The specimens referred to are very fine, and extremely rich in colour; we have never seen more satisfactory examples.]

— THE last meeting of the Royal Irish Academy was particularly interesting, as being made the occasion for presenting the Cunningham gold medal to DR. EDWARD PERCEVAL WRIGHT, Professor of Botany, T.C.D., in recognition of his attainments and industry, not alone in his immediate department, but in almost every branch of natural science, as also for his personal research and discoveries in the Mediterranean, the Seychelle Islands, &c., all of which were alluded to in eloquent terms by the President, Sir Samuel Ferguson, and endorsed in terms equally eloquent and emphatic by the Rev. Dr. Haughton, S.F.T.C.D., in proposing Dr. Wright as Dr. M'Allister's successor to the honorary secretaryship of the Academy, to which he was unanimously elected.

— MR. JOSEPH MALLENDER sends us the following record on the WEATHER OF NOVEMBER at Hodsock Priory, Worksop:—"The sunshine during the month was 59.2 hours, or 23 per cent. of possible duration. We had eight sunless days. Total rainfall 2.54 inches. Rain fell on twenty-one days. Wind principally from S.W., average velocity 11.5 miles per hour. Mean temperature of the month 42.2°; maximum on the 28th 56.3°, minimum on the 12th 23.3°; maximum in sun on the 11th 90.9°, minimum on the grass on the 12th 20.5°. The warmest day was the 25th, maximum temperature 48.7°. Coldest day was the 12th, mean temperature 34.3°. Mean temperature of air at 9 A.M. 41.7°. Mean temperature of soil 1 foot deep 42.9°. The thermometer in the shade fell below 32° on six nights, and on the grass on nineteen nights. The highest reading of the barometer was on the 1st, 30.318; lowest reading was on the 25th, 28.876. Altogether a fine mild month, closely resembling November, 1882."

— A STAMFORD correspondent who has read Mr. Robert MacKellar's remarks on the *EUCCHARIS* on page 445 with interest, would be much obliged if Mr. MacKellar would detail his mode of culture. Our corre-

spondent also desires to know the most successful method of treating *Pancreatium caribæum*.

— THE following GARDENING APPOINTMENT has been made through Mr. D. T. Fish, Hardwick House:—Mr. Philip Chinery, late of the propagating department at Kew, to be gardener to Mrs. Tyrwhitt-Drake, Shrimpling Thorne, near Bury St. Edmunds, Suffolk.

— AN interesting course of lectures on FARM INSECTS was delivered by Miss E. A. Ormerod, Honorary Consulting Entomologist of the Royal Agricultural Society, at the South Kensington Museum, daily from December 3rd to 7th. The various families of insects were taken and fully discussed, their leading characters explained, the injury they do, and the best mode of destroying them described. The lectures were illustrated by accurate coloured drawings, representing the more destructive species, greatly enlarged, and in their several stages of growth.

— AT the meeting of the SALE BOTANICAL SOCIETY held last week "Poisonous Plants and their Uses" was the subject of a lecture before the members and their friends, Mr. F. J. Broome presiding. Dr. Armstrong, the lecturer, said he intended his remarks to be not of a botanical, but of a practical nature. A poison was defined as a substance, not heat or electricity, which either destroyed some portion of the human body or so altered the functions of its important constituents as to render life impossible. It was stated that out of sixty natural orders of plants only about one-fourth were poisonous. Of these three were permanently poisonous—namely, *Ranunculaceæ* or the Buttercup tribe; *Papaveraceæ* or Poppyworts, which consist of herbs or shrubs with milky or coloured juice, the order possessing well-marked narcotic properties; and *Solanaceæ* (*Nightshades*), also of a herby or shrubby nature, mostly natives of tropical countries, and remarkable for their strong narcotic-poisonous qualities. A number of the newest introductions of poisonous plants into medicine, including Lily of the Valley, Jessamine, and Lobelia, were alluded to. Specimens of the active poisonous principles of plants, such as morphia, aconitina, and salicylic acid (lent for the occasion by Mr. Roberts, chemist, Sale) were exhibited, advice being given as to the best steps to take in cases of poisoning where immediate medical aid cannot be had.

— AT the next meeting of the ROYAL METEOROLOGICAL SOCIETY, to be held at 25, Great George Street, Westminster, on Wednesday, the 19th instant, at 7 P.M., the following papers will be read:—"On the Explanation of Certain Weather Prognostics," by the Hon. Ralph Abercromby, F.R.Met.Soc.; "Preliminary Inquiry into the Causes of the Variations in the Reading of Black-bulb Thermometers *in vacuo*," by G. M. Whipple, B.Sc., F.R.Met.Soc., F.R.A.S.; "Report on the Phenological Observations for 1883," by the Rev. T. A. Preston, M.A., F.R.Met.Soc. The meeting will be adjourned at 8 P.M. in order that a special general meeting may be held to consider certain alterations in the bye-laws. As the draft list of officers and Council for the year 1884 will be prepared at the next Council meeting, it is requested that those Fellows who wish to suggest names for the new Council will send them in before the 19th instant.

— FROM Dr. King's annual report of the Royal Botanic Garden, Calcutta, for the year 1882-3, and Mr. J. F. Duthie's report of the Government Botanical Gardens at Saharunpur and Mussoorie for the year ending March 31, 1883, we learn something of the progress of botany at these botanical centres in India. It is satisfactory to note that at Calcutta considerable improvements have been effected during the year, not only in the general arrangements of the garden itself, but also in the scientific department. As usual at Calcutta considerable attention has been given to various economic plants, notably those which produce the valuable article indiarubber, and which have occupied so much attention of late. Dr. King says the cultivation of the Soy Bean of Japan (*Glycine soja*) has of late been pressed on the people of India, and "more in obedience to the loudness of this clamour than from a belief in its soundness" he has arranged for a supply of the Beans from Japan, which he proposes to distribute extensively for trial. Much consideration has also been given to the utilisation of the various fibrous plants. In the Lloyd Botanic Garden, Darjeeling, much damage continued to be done by the cockchafer grubs until pretty nearly every plant in the garden was killed. "The whole of the grass in the garden and all herbaceous plants rapidly succumbed to its ravages, as did many of the flowering shrubs, only the deeper-rooting shrubs and trees being spared. Even the plants in the conservatories did not altogether escape; eggs of

the insect having got in considerable numbers into the soil of the pots." In response to vigorous efforts to exterminate this plague about six millions of the grubs were collected and destroyed by the garden labourers. In Mr. Duthie's report it is satisfactory to find that economic plants, as at Calcutta, are largely cared for, and that the cultivation of medicinal plants and the preparation of drugs from them is being proceeded with. Amongst them may be mentioned Alexandrian Senna (*Cassia acutifolia*), Henbane (*Hyoscyamus niger*), and Belladonna (*Atropa belladonna*).

— THE forty-fifth ordinary meeting of the ESSEX FIELD CLUB will be held at the head-quarters, 3, St. John's Terrace, Buckhurst Hill (opposite the church), on Saturday, December 15th, 1883, at 7 o'clock P.M. The following papers will be read:—1, "Fungi and their Spores," by Arthur Lister, J.P., F.L.S. 2, "On a Specimen of a Whale, Rudolphi's Rorqual (*Balaenoptera borealis*, Lesson.) lately taken in the River Crouch, Essex," by Prof. W. H. Flower, F.R.S., F.L.S., Pres. Zool. Soc., &c. 3, "Some Additional Notes on Essex Watersheds," by Prof. Boulger, F.L.S., F.G.S., &c. 4, "Natural History Notes," by R. M. Christy. In accordance with rule 4, the Council and officers for 1884 will be nominated, preparatory to the annual meeting to be held in January. Members are requested to bring or send "Exhibits" for the meeting. The rooms will be open at six o'clock as usual. It is intended to form a Working Committee for the purpose of arranging details of field meetings, &c., during the ensuing summer. Members willing to take part in the work are requested to send in their names. The Librarian will be glad to give 1s. 6d. for clean copies of Part 4 of the "Transactions."—WILLIAM COLE, *Hon. Sec.*

— THE fortnightly meeting of the MANCHESTER HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY was held on Thursday evening in the old Town Hall, King Street. There was a very large attendance. Mr. R. Tait, who occupied the chair, said the Society, which has only been in existence about eight weeks, has already attracted much attention. Letters had been received from gentlemen in Shrewsbury and Birmingham asking for information respecting the formation and the methods of procedure, as similar societies were about being formed in their respective localities. Mr. R. MacKellar read a paper on Vines and Vine culture. He said that all that seemed necessary to make Grape-growing profitable in England out of doors was a summer of a month's longer duration. In Bedfordshire he had noticed that the Vines grew very well, showed abundance of fruit, and brought it partially to maturity; but just as the first berries began to ripen the cold weather begins, and the early frosts put a stop to all further progress. A good result, therefore, need not be expected from Grape-growing outside, but by artificial aid the matter is much simplified. Mr. MacKellar dwelt upon the form of structure necessary, whether span-roof or lean-to, inclining in the majority of cases to the latter, and he showed how indispensable it is that it should be erected in the most sunny position. Ventilation should be amply provided, and at all times used with care and caution. The formation of the borders was then treated of, showing the need of good drainage, and gradual additions as the Vines increase in size and vigour; composition of the soil; sorts to be planted, mentioning particularly the old Black Hamburg and Muscat of Alexandria as two of the best; pruning, disbudding, setting of the fruit, thinning of the berries, and perfect ripening of the fruit, particular stress being laid upon the proper thinning of the berries and keeping the Vines clear from insects. Considerable discussion took place, Mr. Neild (Wythenshawe), Mr. Upjohn (Worsley), Mr. Ellis, Mr. C. Jones, Mr. H. Driver, Mr. Butterworth, and others adding to the information. Mr. W. Swan, the Hon. Secretary, announced that at the next meeting Mr. W. Birkenhead would read a paper on the Cultivation of Ferns.

LEAF SOIL v. FUNGUS.

SEEING on pages 292 and 436 notes on the subject of fungus on Beech leaves, I send you my experience. Close by the gardens here there is a Beech wood, and it used to be the practice to collect a large quantity of the leaves and put them in a heap to decay, and use them in potting; but I found they created much fungus. I afterwards tried them mixed with manure from the stable to make hotbeds. I then did not notice any fungus, and plants and cuttings grew fairly well in a portion of the decayed matter mixed with the soil in which they were potted. I afterwards went to a place in the wood where the leaves had drifted in some places to the depth of 18 inches. I removed the top

8 inches or a foot, and the bottom 6 inches of thoroughly decayed leaves I took for potting and mixed a fair quantity with the soil for cuttings. I may add that the leaf soil was nearly dry. The result was that I lost nearly the whole of the cuttings; it was nearly one mass of fungus. I almost decided to use no more Beech leaves, but shortly afterwards when going through the wood I found a large hole full of leaf soil where the leaves had been drifted. There were two or three cartloads. I decided to give it a trial as manure for Potatoes, the ground being a rather stiff loam. The trial gave me every satisfaction, the crop was far superior in quality and quantity to that on which I had used stable manure. I then tried the same leaf soil for potting, and it excelled all other I had previously tried. I have since cut a place about 5 feet square and 2 feet deep and always keep it full of Beech leaves. It is near where we keep the manure for the garden, and it sometimes gets nearly full of liquid manure, and the enriched leaf soil I do not hesitate to use for whatever I think needs decayed vegetable matter.—J. C.

MUTUAL IMPROVEMENT IN GARDENING.

THE subject broached by "E. B.," at page 485, is one deserving of notice from all connected with gardening, but perhaps more so from those resident in large private establishments. It is true "improvement societies" are too few and far between, but there is another way by which young gardeners would be greatly benefited—namely, as "E. B." suggests, in "home-improvement classes." I am now in charge of a garden, but was formerly foreman in a garden in Kent, where such a class was carried on under the guidance of the head gardener. There were three of us in the bothy, and every Wednesday evening, from October to May, was set apart for the class to be held. We each in turn read a paper upon a certain subject selected by the head gardener, upon which afterwards would follow a discussion and explanations, our chief giving us the value of his experience upon any question we liked to ask. He also took his turn in reading a paper, dealing with the more difficult subjects, and I am sure we all derived great pleasure and benefit from listening to them.

Most young men who aim at becoming gardeners take some interest in their work, but I feel sure they would take much more were they encouraged by the holding of such classes as I have tried to give an outline. I ought perhaps to say we were not allowed to copy from books. We were expected to write upon the subject allotted us from the study of books and our own experience. Being four of us we each had a month to prepare our paper, so that there was nothing amounting to tediousness or restraint about the matter. I felt grateful to our chief then, but I feel more so now the test has come, and the value of such classes made apparent to me.—J. C., *Down Ampney.*

THE WHITE ELEPHANT POTATO.

I AM exceedingly glad to see the account of this Potato on page 465 I beg to endorse every word Mr. Muir has written. I grew one peck of it, had from the firm who advertised it as a disease-resisting sort. It had exceptional facilities—viz., was put on fresh ground, green sod, having been dug in one spit deep six months previously, no farmyard dung or manure being applied at the time of planting, which was done on the 17th of last March. I put in the drills a coating of fine sifted ashes, on the top of that nothing but Mr. With's carbon manure, as made and supplied by him, then the sets; and when the Potatoes were well up and had been once earthed with the draw hoe, I gave a thin top-dressing of the manure on a showery day. Five other sorts of early, medium, and late Potatoes were grown under exactly the same conditions. Here this was an exceptionally fine Potato season. Four of my six varieties have entirely escaped disease when growing, and since being housed. The fifth sort, Mona's Pride, badly diseased with me last season, has been a splendid crop this season, not one-fourth diseased, and the remainder still sound and superior table Potatoes. Next to them were these White Elephants. They showed disease on the leaf on the 22nd August; it went on rapidly till I cut off the stalks. When these were dead I dug the crop the first week in October. The result was what ought to have been, according to the seedsman, a splendid crop of disease-resisting Potatoes, badly diseased; all the tubers were enormous, on an average 16 to 18 ozs. in weight each, many as large as quoted by Mr. Muir, but nearly all these went very rapidly. None of them are eatable for a connoisseur in Potatoes. All that remained sound, not half taken out of ground, are being used baked, only fit for pigs if boiled. I consider all of us are bound to give our experiences of the new varieties of Potatoes as we find them, and for the good of the nation, and give all particulars as to the growing and cultivation and soil.

I beg pardon for writing at such length about an article "not worth its salt;" one has to use an extra quantity of in eating it, and which would make "a poor man" drink more after it than might be good for him.—SAXONING, *Hereford.*

GAS STOVES.—It is to be hoped that some of your correspondents who have had these in continuous use in their conservatories will reply to "F. W. C." The makers of the stove in question publish extensively a testimonial from Messrs. J. Veitch & Sons, given some time ago, but several persons who have inquired on the premises in Chelsea have found that Ritchie's stove has been replaced by an improved make known as Clark's "Syphon" stove, because of its durability and more effectual

condensation of the sulphurous vapours given off from burning gas in the ordinary way. In no case should such a stove of either make be used in a plant house without a dish to produce moisture, the heat given off by stove, though slight and local in its effect, being too dry of itself.—EXPERIENCE.

GATHERING PEARS—BISHOP'S THUMB.

THIS is one of the most fruitful Pears grown here. It never misses a crop, and it is in no way delicate, as the trees of it are large ordinary orchard bushes. In Messrs. Richard Smith & Co.'s fruit list it is described as being "large-sized, long, slightly tapering from the crown to the stalk; skin yellowish green, dotted all over with russet, dark brown on the sunny side; flesh greenish yellow, melting, juicy, and sweet; an abundant bearer." This character suits it admirably, and October is said to be the month in which it is ripe. This is correct too, but by gathering the fruit at different times we have changed its season of ripening. In October we frequently have strong gales, which blow down and spoil many Apples and Pears. Knowing about the time these may be expected, we generally gather part of our crops to have them safe. Towards the end of September we gathered about half our crop of Bishop's Thumb Pear and stored them in the fruit room. These ripened about the end of October. At that time a good quantity remained on the trees, and they were gathered and stored the first week in November. At that time they were quite hard and not fit for dessert, but they are just softening now, and will be in good condition until Christmas or thereabouts. Had they been all gathered in October we should have had none of them left good for December; and had none of them been gathered until November, none would have ripened at their stated time, so that the two gatherings have given us a very acceptable succession of ripe fruit. As a rule, when Pears are all taken in at once they ripen at once and must almost be used at once, as Pears do not keep after being ripe like Apples, and the want of a succession is often much felt. We often hear cultivators say "We had a grand lot of such and such a variety. Many of them decayed before they could be used, and we wish we had some of them now;" and I am inclined to think that gathering and storing at intervals would cause many varieties to ripen in long and useful succession, and our Bishop's Thumb proves that it may be treated with advantage in this respect.—J. MUIR, *Margam*.

NOTES ON KEW—YOUNG MEN'S LODGINGS.

As an old Kew man I gladly welcome any information respecting these magnificent public gardens, and especially interesting were the remarks made by "Veritas" in last week's issue of the Journal, page 491. All improvements are hailed with delight by a multitude of old employes widely scattered over the globe, among whom I am happy to be included; and it strikes many as most remarkable that the authorities have been so slow in many instances to appreciate what are the requirements of their own establishment. Large sums of money have been expended upon matters of far less importance than those hinted at by "Veritas" to the ultimate purposes for which the gardens exist, or for which they should exist—viz., to extend botanical knowledge in all its details and bearings; and any exhibition of feeling should be deprecated which would make it a playground, or even monopolise it for specialists. At Kew there is ample room for a spirit of broad liberality, which, I am bound to say, has not on all occasions been shown.

Alluding again to heavy expenses in matters of less importance, brings one directly to deal with the question respecting the accommodation provided for the young men, which "Veritas" has so ably advocated. Of course the young gardeners there are employes, and unhappily much disparity is generally made between them and those in authority. If employes are dutiful there is equal obligation on both sides, and I am sure this has not been sufficiently taken into consideration. If such a building as "Veritas" mentions were erected and liberally managed for the accommodation of the young gardeners, although it would involve considerable outlay, it would bring great credit to our Government, and be an immense advantage to all. Imagine a young gardener with no means but those accruing from the service of the gardens—viz., 16s. per week, with at least 3s. per week to pay for lodging, or, if he requires a room to himself, a higher sum; how is it possible for him to keep himself in good appearance superficially and bodily, as well as keep pace with the mental pursuits which the authorities require? Many a young man in his sincere endeavour to do this has greatly impaired his health, and others have become disgusted with the system and taken but little interest in their duties. Whatever arguments may be directed against this line of thought, these are facts patent to everybody that cares to investigate. It is high time something was done to increase the happiness and facilities of accumulating knowledge for the young men, either by increasing the wages or, what would be far better, by the erection of a suitable building for their accommodation, so that the small pittance they now receive for keeping what is considered the botanical landmark of the world in a state of efficiency should not be taxed by expenses incidental upon living in lodgings, without considering the inconvenience arising from the distance many of them have to walk to and from their meals.—EX-KEWITE.

ON page 491 of the Journal, under the heading of "Notes at Kew," I was pleased to see that "Veritas" had made reference to the desirability of providing better accommodation for the young gardeners there. There is ample convenient space in this establishment for the

erection of suitable dwellings, without in any way interfering with the beauty of the gardens. That the employes should be duly considered in this respect is evident from the many inconveniences they have to contend with in lodgings. In the first place, we will take into consideration the time expended in going to and from their meals. Those gardeners who are conveniently situated, and whose work lies near to the exit for the workmen, do not feel this inconvenience so much, but with others—the majority—it means something approaching running to meals. I have had practical experience of this inconvenience, as well as of others, as it was my lot to occupy lodgings a distance of nearly twenty minutes' walk from my work, and as the time allowed for breakfast was three-quarters of an hour it left about five minutes to indulge in that meal. It is obvious that, speaking generally, the lodgings are not comfortable, and in my own case I found it necessary to make several changes during my stay at Kew, and had it not been for the pleasures and knowledge afforded to me by the gardens I could not have endured it. I think if those at the head of our national garden would only seek to remedy these keenly felt inconveniences so detrimental to the well-being of the improvers there, they would deserve the thanks and support of the whole gardening fraternity. As a national outlay the cost of the erection of a suitable building would be trifling. Gardeners from all parts of the United Kingdom, from the Continent also, are to be found at Kew, and it is nothing short of a disgrace to such an establishment that better provision is not made for them.—EXPERIENCE.

KEEPING LATE GRAPES.

THE attention of those who grow late varieties of Grapes is naturally directed at this time of the year to the means of preserving them in the best possible condition during the next six months. Perhaps a few remarks upon this subject may not be out of place at the present time. Our Grape room is at one end

Fig. 101.—Grape rack.

of the fruit room, being a part of the same, divided by a wooden partition; the interior is lined with deal boards tongued together, a space being left between the board lining and the wall; the floor is also boarded and raised above the level of that of the fruit room. Racks for holding the bottles are fixed to the sides of the room, and are made in the following manner:—Uprights are fixed to the wall 5 feet apart, to which are nailed rails with scallops cut out on the inner side to hold the necks of the bottles, corresponding scallops being provided on a batten on the wall behind, a little below the rails, for the base of the bottles to rest in; 15 inches is allowed from rail to rail, and the bottles are 8 inches apart. Five rows round the room can thus be accommodated all within easy reach, for any attention that may be required to the Grapes, or for filling the bottles with water. The diagram (fig. 101) will help to illustrate this arrangement.

For filling up the bottles we have a long-spouted tin can, a sketch of which I enclose, which holds half a pint. The spout is 18 inches long, and, being small at the end, can easily be inserted in the neck of the bottle without disturbing the Grapes. Bottles with clear glass should be used, so that the operator can see to a nicety how much water is required, and stop instantly enough has been poured in to come within an inch of the mouth of the bottle. Ventilation is provided by means of a skylight, across which we can draw a shutter to darken the room.

Having thus briefly described our room I will venture to offer a few remarks upon the mode of cutting and bottling the Grapes. The bottles must be perfectly clean both inside and out. Having filled them with clean soft water place them in the racks. This is best done some days before the Grapes are cut. Muscats are the first to claim attention. We like to cut these as soon as the foliage is ripe, and before much of it has fallen off. If left until the Vines are bare many of the bunches will be brown on the sunny side through exposure, greatly marring their appearance, also being much against their keeping.

Ripe Muscats are easily damaged if shaken or roughly handled; therefore sever them gently from the Vines by means of a pair of secateurs, with as much wood as can be obtained. Trim off any knobs that will not easily go into the necks of the bottles and hand them to your assistants. When as many have been cut as can conveniently be carried proceed with them to the Grape room and place them in the bottles, returning for another lot. In this way two or three pairs of hands can soon clear a vinery. These details may appear trifling to some, but they all contribute towards success. With some of the bunches only very short pieces of wood can be obtained; these should be placed together in the Grape room, as they will require more frequent attention than the others to keep them supplied with water.

Some writers maintain that it is immaterial which end of the wood is inserted in the water, the Grapes keeping equally well either way, but such is not in accordance with our experience. We have several times proved, when the wood beyond the bunch was placed in the water, the stalks of the berries soon began to shrivel, the berries themselves following suit.

The later kinds, such as Lady Downe's, Gros Colman, Alicante, &c., we do not cut until after Christmas. About this time of the year we examine the Vines and shorten the wood beyond the bunches to three or four eyes, which greatly facilitates their removal when the time comes.

The temperature of the Grape room should not be allowed to fall below 40°, and very little above this figure is required at any time. At all times avoid an arid atmosphere, which will cause the berries to shrivel. Great care should be exercised in filling up the bottles not to spill any water on the bunches, or decay will inevitably follow. Once a week every bunch should be examined, and any decaying berries promptly removed. Those with the smallest speck of decay should not be left, for they will eventually have to be taken out, and are better removed at once as soon as detected.—A. BARKER, *Hindlip Gardens*.

CHOU DE BURGHLEY.

THE opinions respecting this vegetable are so various that the question arises as to whether the divergence is due to taste or to there being spurious varieties. I confess to having but a very indifferent opinion of "Cabbage Broccoli," which I considered identical with the "bastards" not infrequently in Broccoli, especially the autumn or early winter heading kinds such as Snow's Winter, which in stocks not uncommonly finding their way into commerce are more "rogue" than true, and form heads like a Cabbage, hearting well, and ultimately forming useless heads of Cauliflower. I thought if Chou de Burghley were no better than these it were poor indeed, hence it was through prejudice condemned before trial, and I certainly was not prepossessed in its favour by what others had to say in its commendation. To solve matters to my own satisfaction I procured a packet of seed, sowed part in March and part in April. The plants were in both cases put out when ready. The first sowing gave heads by October simultaneously with the Cabbage sown at the same time, and had much of the Sugarloaf Cabbage character similar to Shilling's Queen, only the heads were not so large—rather they were not so heavy and close-hearted. Some were cut and boiled, and as I am particular about having vegetables well boiled they were in capital condition, "tender as a chicken," and the quality excellent, being mild in flavour, not having the strong flavour of autumn Cabbage, nor Cabbage sprouts or Coleworts. I found Chou de Burghley tender and good; but I failed to detect the "smack" of Broccoli flavour, which is not any disadvantage in my estimation, as open-headed Broccoli are about the strongest flavoured vegetable I know. There is one thing in particular I like it much for, and that is not forming a close hard heart like a Cabbage, as it does not "split" like the Cabbage in wet weather as fully two-thirds of our autumn Cabbage have done this season, also Savoy, and there is not a single "rogue" in any of the plants from the two sowings, the plants being very even and all hearting well. Chou de Burghley is as "hard as nails," wet does not split its head, frost does not wither it, and it forms a first-class winter vegetable; indeed is a very delicious-flavoured Cabbage Broccoli, surpassing anything in delicacy of flavour of the Brassica tribe in the winter season. When cooked it is of a pale green colour, the hearts are of course white, and I can only say, Well done, Gilbert.—G. ABBEY.

acquainted with the subject. *Cinchona Ledgeriana* has been known in the colonies for many years, and it is by no means proved that the particular variety known as *C. Ledgeriana* comes true from seed. "*C. Ledgeriana* is a new species of *Cinchona* which promises very well. The bark is said to yield 10 to 13 per cent. of quinine. Hitherto the difficulty has been to obtain seeds, but an authority on these matters has now succeeded in getting them and raising seedlings for those interested in the plant."—X.

SINGLE CHRYSANTHEMUMS.

WE alluded to this "new departure" type last week; and as some of our readers suppose that the flowers referred to are varieties of *C. coronarium* or *C. frutescens*, we have engraved one to show that they are forms of the ordinary *Chrysanthemum indicum* or *chinense*. This is apparent by the foliage, which is identical with that of the popular

Fig. 102.—*Chrysanthemum Mrs. Langtry*.

favourites. These single Chrysanthemums, which we are informed were first brought into notice by Col. Teesdale of Winchester through Messrs. Cannell & Sons of Swanley, are not only likely to become popular for vase-decoration, for which purpose the ordinary double forms are fully too heavy, but they are naturally late in flowering, which renders them additionally acceptable, and the foliage is usually free from mildew. Mr. Cannell states, that although the foliage of the fading double forms in his nursery is now as white as millers, the leaves of the singles are as green as Leeks; and certainly all the examples that have been sent to us were free from the unsightly parasite. During the week we have received flowers of the type under notice from Mr. H. Lister, gardener to Lord Brooke, Easton Lodge, Dunmow, cut from plants that were raised from seed sown in the present year. One of the varieties is blush white, bearing a general resemblance to the Paris Daisy, and is named Mrs.

CINCHONA LEDGERIANA. — The paragraph noted below appeared in "Cassell's Magazine," which may prove misleading to anyone not

Webb; another a bright shining yellow like *C. segetum*, named Lady Brooke; and a third a purplish colour, the base of the florets white, forming a ring as in the tricolor varieties of *C. carinatum*, or a large particoloured *Cineraria*, and is named Lady Beresford. This is another "departure" and a pretty one, while Mr. Lister's flowers suggest that these single *Chrysanthemums* will not be the less freely grown, since, like the single Dahlias, they may be so readily and quickly raised from seed. The spray figured is of a charming blush variety taken from Mr. Cannell's bouquet, and is named Mrs. Langtry.

VINES IN A NARROW BORDER.

I SEND you along with this samples of the growths made by young Vines planted last year. We have two houses, each 200 feet long—one of them span-roofed, filled with Vines planted last year, and all equal in strength to the pieces sent; indeed, some of the rods are much thicker, the pieces sent being simply the tops of the rods. On one side of the span house the Vines have a border only 2½ feet wide by 1½ foot deep, all inside; on the other side the Vines have the chance of getting to an outside border through holes in the wall, and they have availed themselves of the opportunity to the utmost. These two houses were previously devoted to growing plants for market, and therefore are not the most convenient for Vine culture; but in spite of shallow borders—or it may be because of them, as some growers think—the Vines have produced splendid canes. The borders were composed of pure loam and a very liberal dressing of Thomson's Vine manure, which has proved in this case, as in previous ones, eminently suited for the production of grand results in Vine culture. These Vines made very strong growths last year, and at pruning time were cut down to within 1 foot of the ground. This spring they grew away splendidly, made growths 25 feet long, and have ripened the same to the very extremities. — JOHN THOMSON, *Clovenfords*.

[The growths sent are of wonderful excellence—solid, short-jointed, and with only a speck of pith. They measure 2½ inches in circumference, and 5 inches between the nodes, being even better than the good example figured on page 71, vol vi., January 25th, 1883.]

POTENTILLAS.

PERHAPS you will permit me to supplement the remarks of "Herba" upon *Potentilla fruticosa* last week, which were accompanied by such an admirable illustration of this pretty but rare species, by a few general remarks upon this and a few other species which I have grown for some time with much pleasure and considerable success, more especially as occupants of the rosery.

Potentillas have within recent years become, and deservedly so, very useful florists' flowers, and the care and attention given in the hybridising of these has been amply repaid by the fine-formed flowers we are in the habit of seeing at exhibitions, and also in gardens where they are made a speciality. Such forms as *P. atro-sanguinea*, bicolor, *Macnabiana*, insignis, &c., although too coarse and straggly for an ordinary rockery, are all that can be desired when grown in a rich border. They require comparatively little attention after planting, and show to more advantage when allowed to scramble at will. The following are very useful for the rockwork:—*P. fruticosa* (the Shrubby Cinquefoil) is one of the few shrubby species contained in the genus, and notwithstanding its being a native of this country is rarely seen in any of our gardens, although a plant that will bear neglect better than most herbaceous perennials. It is easily recognised from *P. Salesowii* from its alternate leaves consisting of five, sometimes seven, quite entire oblong leaflets covering the branches, while the leaflets of *P. Salesowii* are deeply serrated and never less than seven, quite glabrous and of a shining brown colour, *P. fruticosa* is always covered with stiff silky hairs, which lend a lively silvery appearance to it. The flowers are terminal, being borne on solitary stalks, and are bright golden yellow. It grows from 1 to 2 feet in height, often forming a dense bushy head, and seems to specially fit it for rockwork. It varies much in size and bushiness from different localities, and a fine procumbent form has been introduced from the Himalayas. There is a white variety called *P. glabra*, which is also very useful.

P. ambigua is a very handsome prostrate perennial, a native of the Himalayas, where it is found growing in the fissures of rocks. It has a compact habit, and the flowers, which are bright yellow, are borne well above the oval-shaped leaflets notched at the extremity. It closely resembles *P. tridentata* in general appearance. The leaves of the latter are quite entire, flowers white, useful for massing on projecting stones.

P. nitida is a very low-growing species found growing on the Alps, where in summer its beautiful wedge-shaped leaflets never fail to attract the traveller. It should be grown in a dry south position.—M., *Stirling*.

NATIONAL ROSE SOCIETY.

ANNUAL MEETING, DECEMBER 6TH, 1883.

THE open mild weather which had continued throughout November underwent a great change with the first few days of December, and the ground was covered with snow when the representatives of Queen Rosa journeyed from Hereford, Worcester, Manchester, Oxford, Norfolk, Ipswich, Hertford, Kent, Surrey, Bucks, Essex, and Middlesex to the

Horticultural Club, 13, Henrietta Street, Covent Garden, on Thursday last, to hold their annual meeting, and to make arrangements for the coming season. R. Bloxam, Esq., Eltham, Kent, was voted to the chair. There were also present the Hon. Secretaries, the Rev. H. H. D'Ombraïn and Edward Mawley, Esq., and Messrs. B. R. Cant, J. Cranston, C. E. Cuthell, Rev. A. Cheales, A. Turner, G. Prince, G. W. Piper, A. Slaughter, J. D. Pawle, G. Paul, T. Gravelly, T. B. Haywood (Treasurer), Rev. H. A. Berners, Rev. F. H. Gall, W. Brockbank, F. D. Pawle, C. E. Cant, J. W. Moorman, C. F. Hore, H. P. H. French, Rev. Page Roberts, Cecil Green, Rev. T. N. Flintoff, J. Gurney Fowler, and W. M. Westall.

The Hon. Secretary, Mr. Mawley, read the circular convening the meeting. The minutes of the last annual meeting were next read and confirmed, after which the Chairman appointed Messrs. C. E. Cuthell and G. Paul scrutineers for the election of Committee and officers. The Hon. Secretary, Rev. H. H. D'Ombraïn, read the following report:—

REPORT OF THE COMMITTEE FOR THE YEAR 1883.

The Committee, in presenting their annual report to the members of the National Rose Society, have once again the pleasure of congratulating them upon another successful year. Their exhibitions, which were well attended, proved larger than any hitherto held, and owing to the more favourable character of the seasons a higher average degree of excellence in the exhibits has been attained than in any previous year. The number of members has been fully maintained, and the influence of the Society continues to be generally recognised as authoritative on all matters connected with the Rose. Indeed this Society may now be considered as having thoroughly established itself in the good opinion of all Rose-growers and Rose-lovers both at home and abroad.

It will be felt to be a recognition of much international courtesy and co-operation that your Committee propose electing from time to time foreign rosarians as hon. members of the Society. To this position they have this year elected Mons. Camille Bernardin, Editor of the "Journal des Roses," and Herr Friedrich Schneider II., Secretary to the German Society of Rosarians, a Society recently established on the lines of the National Rose Society.

The catalogue of exhibition Roses being out of print, a sub-committee has been formed to prepare a revised edition and to add to it a similar list of garden Roses. This enlarged catalogue will, it is hoped, be issued to the members during the course of the coming spring. In order to guide the Judges at the Society's exhibitions in making their awards in the case of two stands being judged to be of equal merit and on other minor points, a short list of instructions was drawn up early in the year for their use. Again, a wish having been generally expressed that the Society should supply printed exhibition labels of some uniform pattern for the use of exhibitors, a sub-committee was instructed to decide upon a suitable form of label for the purpose. Labels of the selected pattern may now be obtained of Messrs. Blake & Mackenzie, School Lane, Liverpool, at a moderate cost. These labels, which have been much used, not only supply a want long felt, but have also added much to the general appearance of the stands.

At the meeting held in March last the General Committee adopted a resolution to the effect that in future this Committee should consist of only forty members, and that each year one half of their number should retire by seniority, such retiring members being eligible for re-election. The list of the Committee and officers submitted to the annual general meeting is therefore framed in accordance with this resolution. It was also decided that the Executive Committee should consist of eighteen members instead of twelve members, with power to add to their number.

AFFILIATED SOCIETIES.

Under this head it need only be stated that one or two additional societies have become affiliated, raising the number now connected with the Society to twenty-four.

ARRANGEMENTS FOR 1884.

The metropolitan exhibition will again be held in the gardens of the Royal Horticultural Society at South Kensington, the date fixed for this show being Tuesday the 1st of July. As regards the provincial exhibition, the Committee, having been cordially invited to visit Salisbury next year, have arranged for holding this show there on Wednesday, July the 9th; while a third, or northern show, will take place in the Botanical Gardens at Manchester later on in the same month.

MEMBERS' PRIVILEGES.

Members subscribing £1 will be entitled to two private view tickets, and also to four transferable tickets admitting at the same time as the general public. Those subscribing 10s. are entitled to one private view ticket, and also to two transferable tickets. All these tickets are available for either one of the Society's exhibitions. Pass tickets will, as usual, be given to exhibitors with their show cards, enabling them to leave and return to the place of exhibition at any time during the day.

The Committee have again the pleasing duty of returning their warmest thanks to their local Secretaries, who have endeavoured to advance the Society's interests and increase its resources by procuring new members. It is earnestly hoped that they will kindly continue their services, for the Committee feel that, considering the great number of Rose-growers scattered throughout the kingdom, the Society ought soon to number at least five hundred members.

FINANCIAL STATEMENT.

As the exhibitions under the present arrangements entail no risk to the Society, it is not thought necessary to accumulate any very large balance; nevertheless, the Committee are of opinion that the amount now remaining in the Treasurer's hands is smaller than it should for the future be allowed to become. In 1881 the balance in hand amounted to £97, in 1882 to £53, and in the present year to £6 8s. 9d. These rapid reductions are not in any way caused by any falling-off in the receipts, which have, on the contrary, been steadily increasing; but are almost entirely due to the much larger amount expended in prize money. The fact being that, in addition to the extra expense of a third show, the competition at the Society's exhibitions

will rise before your eyes. Adventurers who have been attracted to Borneo with the hopes that an unknown country might prove itself an El Dorado, finding themselves face to face with forests that appear impenetrable, to clear which would require considerable capital, are somewhat disappointed. Visitors who have only seen the coasts of Borneo, being appalled by the magnitude of its jungles and swamps of Mangrove, pronounced it a worthless wilderness of vegetation. North Borneo, as seen from the deck of a ship, is, in the main, one dense forest, covering flat or gently undulating ground. Between this mass of green and the ocean a strip of sand of dazzling whiteness forms a beach. Here and there a bluff of sandstone or a hummock-shaped hill crops up, while far in the interior, from many points, you see the rugged head of the precipitous Kiui Balu, a mountain some 13,000 feet in height. At the principal settlements in North Borneo—of which there are two, Kudat and Elopura—paths have been cut through the forests. By walking along these a visitor easily obtains an idea of Bornean vegetation, which, in the phraseology of the residents, is spoken of as "jungle." That easily penetrable forests, consisting of magnificent trees, averaging from 100 to 150 feet in height, capped with bush-like heads, which shut out the sun from Ferns and Palms which grow beneath them, should be called "jungles" is certainly calculated to create wrong impressions. These forests may be bought up at the rate of 1 dol. per acre. To fell and clear them costs about 12 dols. per acre. The hardness of the wood renders felling a difficult operation. After ground has been cleared it may be planted with Coffee, Tea, Sugar, Cocoa, Pepper, Tobacco, Plantains, and a variety of other tropical fruits. From the estimates which have been made of the cost of buying, clearing, and planting land it would seem that a settler possessing a capital of £2000 ought after his first year's residence to be in receipt of a handsome income.—(*The Times*.)

LYSIMACHIAS.

A SHORT time ago, at one of the meetings of the Lancashire Botanists' Association in Manchester, I noticed on the table of specimens for naming and discussing a spray of the old but now rare and little known *Lysimachia stricta*. It was contributed by our esteemed member, Mr. Jas. Percival, of Smithy Bridge near Rochdale, who grows it in his garden. The fact of seeing this unexpected member of the genus reminded me of others which I have grown, and a few notes of reference to the more important of them may prove of interest to some readers of our Journal. Several species are but little known in general collections, though possessing considerable value as garden plants, and for this reason they are well worth attention.

Lysimachia clethroides (Duby).—This Japanese species is one of the handsomest and latest introductions. The date of its introduction appears to be somewhat obscure. I recollect it nine years ago, at which time it was regarded as new to British gardens. Possibly some reader of the Journal can give a little information regarding its introduction. Stems smooth, simple, 2 to 3 feet high, terminating in a dense raceme of white flowers, which are scarcely half an inch across. Racemes 5 to 6 inches long, slightly curved or inclined at the apex. Leaves 4 to 5 inches long, alternately arranged, smooth, distinctly stalked, usually broadly lanceolate, but are very variable in outline. It commences to bloom about the end of July, and continues throughout August to September. This plant proved one of the most striking objects in the corridor here during the latter part of summer. I have just planted out a dozen strong self-sown seedlings, some of which I expect to flower next summer. Although it may be increased rapidly by division in autumn or cuttings in spring, it appears as yet uncommon in gardens. The first plant which came to my notice in the neighbourhood of Manchester was from the garden of a working-man botanist in Lancashire.

L. Ephemerum (Linn.).—Stems 2 to 3 feet high, simple, erect, terminating in a dense raceme of small white flowers. Leaves linear-lanceolate, sessile. Blooms from July to September. A native of southern Europe. It is the most common of the white-flowered species, and a most desirable plant.

L. vulgaris (Linn.).—The most common of the erect-growing species in gardens, and apparently at home in all soils and situations. This is abundantly evident from the fact that it is found in the majority of small town gardens in Manchester. For moist places in the wild garden this is an indispensable plant. It is an erect branching plant 2½ to 3 feet in height, and is more or less downy throughout. Leaves usually in whorls of three or four, furnished with black glandular dots, broadly lanceolate to nearly ovate, very shortly stalked; those of the branches usually in pairs. Flowers generally in much-branched leafy panicles, yellow, and more than half an inch in diameter; more cup-shaped than rotate. It is found occasionally in a wild state in Britain on shady banks and the borders of streams, and in similar places in continental Europe and northern Asia, and the fact of its reappearing in temperate Australia is a very marked example of the irregularity in the distribution of certain plants.

L. punctata (Linn.).—This is allied to *L. vulgaris*, but of dwarfer stature, 1 to 1½ foot in height. Leaves ovate-lanceolate, slightly stalked, opposite or whorled. Pedicels usually one-flowered, rarely branched, and confined to the axils of the stem-leaves. Flowers yellow, fringed with minute glandular hairs. Central and south-eastern Europe, and is said to exist in a wild state in Devon.

L. ciliata (Linn.).—Stem erect, unbranched, 1½ to 2 feet high and glabrous. Leaves 3 to 4 inches in length, ovate-lanceolate, cordate, with prominently ciliated petioles three-quarters to 1 inch in length. Flowers about the size of those of *vulgaris*, but flatter, more rotate, and of a paler yellow colour; slightly cernuous, disposed in pairs on long slender pedicels which spring from short stems or peduncles borne in the axils of the leaves, which are, I should have said, oppositely arranged. In the upper part of the plant this peduncle is wanting, and the slender pedicels spring directly from the axils of the leaves. A North American species, flowering in June and July.

L. verticillata (M. Bieb.).—This is one of the dwarfest of the erect-growing forms, but not the least in importance. It makes dense little bushes a foot or little more in height, and is admirably suited for a place towards the

front part of the herbaceous border. Stem simple, densely furnished with leaves. Leaves in whorls of four, the lower ones broadly ovate, the margins ciliate; petioles half an inch long, the upper ones ovate-lanceolate, with shorter petioles to almost sessile. The whole plant, especially the stems and petioles, densely pubescent. Flowers yellow, half an inch in diameter, on slender stalks three-quarters of an inch long, usually in whorls of eight, except the upper ones, which contain a less number and the leaves much reduced. Thus the terminal whorled raceme is seen to the best advantage. A native of eastern Europe.

L. capitata (Ph.).—Like the preceding this is a low-growing species, and is one of the earliest to bloom, expanding its blossoms about May and remaining gay till July. Stems simple and spotted. Leaves opposite, sessile, lanceolate-acuminate, spotted. Flowers yellow, in compact heads, suggestive of its specific title. North America.

L. stricta.—An erect, slender, and much-branched species, 1½ foot high, the main stem terminating in an erect raceme of small yellow flowers, the whole plant quite smooth. Leaves opposite, lanceolate, those of the main stem 2½ to 3 inches long. Branch leaves small, not more than half the size of the others. One of the most distinct species. A native of North America, and flowers in July and August.

L. longifolia (Ph.).—This is strikingly remote in its general characteristics from all the foregoing, and a very desirable species. The whole plant is glabrous. Stem erect, 1½ to 2 feet high, and much branched. Leaves linear, pointed, 3 to 4 inches in length. Flowers yellow, over half an inch across, in terminal and lateral umbels of four or five, springing from a more or less dense tuft of small linear and pointed leaves; corolla segments serrulate; pedicels slender, 1 to 1½ inch in length. A North American species, and flowers in July and August.

L. lanceolata (Walt.).—This uncommon and greatly interesting North American species is allied to *longifolia*, but the leaves are shorter, more lanceolate than linear, and less taper-pointed. Flowers yellow, and disposed similar to those of *longifolia*, but with shorter pedicels. Flowers from July to September.

L. davurica (Willd.).—A little-known well-marked species from Siberia. Stem simple or slightly branched, 1½ foot high. Leaves glabrous, opposite, sessile, narrowly lanceolate, glaucous beneath. Flowers yellow, more campanulate than flat, in terminal, simple, or more or less branched panicles. Produces its flowers from July to September. A most desirable species, and well adapted for growing in swampy ground or as a sub-aquatic.

L. thyrsiflora.—A native plant only occasionally met with under cultivation, undoubtedly on account of its being a plant requiring a swampy place or the margin of a pond or ditch where to grow. It is so desirable a plant as to fully deserve a place being prepared for it in the absence of a natural pond or swamp. A strange-looking species 1 to 2 feet in height with opposite, sessile, lanceolate leaves 2 to 3 inches long. Flowers in dense axillary racemes more or less pedunculate, but fall considerably short of equalling in length the leaves. Corolla segments very narrow and deeply cut, spotted as well as the calyx with orange. Stamens and styles much exerted, and the inflorescence has much a bottle-brush-like appearance. A native of Europe, northern Asia, and America.

L. nummularia.—This is the most familiar member of the genus, and very much grown under the local name of Creeping Jenny. This name is unknown to the artisans of Manchester, except by the few who have made British botany a study. Moneywort seems to be the most popular appellation in this part of the north. So well known is this plant by one or other name that description is needless. Like *L. vulgaris* it does well in smoky towns, but is less disposed to produce its blossoms freely; but the presence of its evergreen branches alone make it valuable for an urban garden. It is best known to the gardener through the variety *aurea*, the golden-yellow leaves of which make it a most valuable plant for a permanent edging. If it can get a position exposed to full sun the golden colour is richer; indeed, its full beauty is never seen when grown in places that have but little sunshine. It is employed in some places in carpet bedding, with this in its favour—that it can be grown out of doors all winter. It is especially useful for associating with other plants for suspended baskets and for growing in pots for the conservatory, its gracefully hanging branches producing a pleasing effect when judiciously arranged with the other inmates.—T. ENTWISTLE, *Wood Lawn, Didsbury*.

MURRAY'S VINE COMPOSITION.

A CORRESPONDENT in your issue of November 29th asks if anyone has used Murray's Vine composition. I have frequently used this composition for the destruction of scale and mealy bug, and one dressing has always proved sufficiently efficacious. In one house which I had under my control the Vines were so bad with mealy bug, that after I had been pruning them my hat and coat were so covered with the bug that I had the appearance of having had a sheet of cotton wool drawn over me. I dressed these Vines with the composition, and the result is they broke strongly, and have borne an excellent crop of fine fruit. A Maréchal Niel Rose, too, was covered with scale, and I dressed it with the composition, but applied the brush carefully so as not to rub off the scale, and in about two days the ground underneath the tree was covered with the insects. I will not trespass more on your space, but can strongly recommend this composition to any who may be troubled with these pests.—A. C.

[We have received other letters on this subject. This composition should be advertised.]

LATE PEAS—FREDERICK ROACH.—Noting remarks in the Journal about late Peas, I should like to say a few words about a late variety that I have grown, Frederick Roach. It was sent out by Messrs. Sutton & Sons of Reading last spring. It grew with me about 5 feet in height. Its growth is remarkably strong and branching, the foliage dark green, an immense cropper, producing peas of a delicious marrow flavour; in fact it was the best quality Pea that I grew last summer out of about twenty

varieties. I think when this grand Pea becomes more known it will be a general favourite.—A. STEVENS, *Holywell Park*.

CLASSIFICATION OF CHRYSANTHEMUMS.

MR. CASTLE'S remarks in last week's Journal respecting the classification of the Chrysanthemum will, no doubt, open up a little discussion, and many will be inclined to ask, Why is classification necessary, and what purpose will it serve? I cannot see that it will be of any benefit for exhibition purposes, as I much doubt that ever we shall get the types so distinct in character as to be able to offer prizes for the different sections, as is the case with the Carnation or Tulip. Still, it will serve one good purpose if we can come to some little understanding as to the terms to be used in describing the many fantastic forms and characters of the Japanese section. It will enable the trade growers to more fully explain and define to what type any new introduction may belong. Nothing varies more than the public taste, and I think the Chrysanthemum varies sufficient to suit all tastes—one of the reasons it obtains such a hold on the public favour. The incurved section I should certainly not attempt to sub-divide, and I should be sorry to see Barbara or Mrs. Haliburton left out, although Lady Talfourd is usually so quilly that her presence does not enhance the merits of a good stand of incurved blooms. As regards the Japanese, the plan adopted by Mr. Castle is certainly the only one that is likely at all to answer the purpose of defining the sections, and with a little addition may be made most useful and answer all purposes, although the Japanese Chrysanthemums vary so much under different cultivation that it will be sometimes eligible for one section and sometimes another. An early flower of M. Ardene, for instance, would be so quilly as to be entitled to be included in section 2, while the floret of a later flower would be as flat as a Fair Maid of Guernsey, and would be eligible for section 1. To the three sections named should be added a fourth—to include those with incurved petals, Japanese—viz., Comte de Germiny, Chang, Japonaise, Madame C. Audiguier, Grandiflorum, &c. They are certainly of a different type to the ordinary flat-petalled varieties.—C. ORCHARD, *Coombe Warren, Kingston-on-Thames*.

SIX MONTHS IN A VINERY.

MARCH 24TH.—The 18th opened with a sharp frost, the thermometer at 4 feet from the ground registering 24°, and that on the grass 16°. The sun rose brightly, and air was given to the vinery at 7.45. At 10.30 clouds being visible on the windward side, the air was reduced, and a little later it was taken off altogether. The temperature had risen to 75°, and we kept it up as well as we could by moving the fire a little. This was one of our red letter days, for the well-known sweet perfume told that a flower had opened. A little hunting revealed its whereabouts, and before night there were two or three more open.

The next day (19th) brought a still severer frost, the minimum thermometer registering 20°, and the one on the grass 5° lower. The morning was foggy, and no air was required till ten o'clock, when a little blue sky became visible, and soon after the sun shone brightly. We closed at one o'clock with a temperature of 85°, and the heat kept up fairly well till dark. We decided on raising the minimum temperature from 60° to 65°, and lowering the maximum sun heat from 95° to 90°. The day temperature aimed at without sun is about 70°. Written directions are given to this effect, but circumstances followed which rendered it difficult to act up to the letter of this, as will be shown further on.

The 20th brought a change. The thermometer had only descended to 31° during the night, but the ground was covered with 2 inches of snow. This was followed by rain with a south-west wind, and we fondly hoped that winter had departed.

But the 21st was worse than ever. There was no frost, the lowest point reached was 33°, but the wind had returned to the east, and there was no sunshine. With rather hard firing we could not at any time of the day get our temperature up nearer than 5° of the regulation point. It was a difficult matter, too, to keep the atmosphere of the house sufficiently moist. Water was sprinkled about five or six times during the day over the boards and the hot-water pipes and the walls were freely syringed, making almost a vapour bath for the leaves and flowers, for above all things we must prevent any drooping of the organs of which the flowers are composed. I remember being threatened with a very long holiday some years ago for spilling a little water in a house when the Vines were in flower, as that was supposed to be fatal to fertilisation, but men's knowledge and ideas have changed since then.

The 22nd was a bitterly cold day outside. The wind was in the east and it blew half a hurricane, but the sun shone for a few minutes at a time. By 2 P.M. our temperature had risen to 70°, and we managed to keep it up to that figure for two or three hours. The damping and steaming were repeated.

On the 23rd we had a return of frost, our thermometer registered 24° and 21°. The wind was still in the east and it blew hard. Our vinery was down to 55° at 6 A.M., but the sun rose brightly, and by

keeping the house closed and firing rather hard it reached 86° at noon and 88° at 2 P.M. At five o'clock it had only fallen to 80°; at 7 P.M. it was 70°; and at nine it just reached the regulation point of 65°. Altogether, considering it has been freezing hard all day in the shade, and a strong east wind has been blowing, we are very well satisfied with our day's work. The damping and steaming were again repeated.

To-day (24th) opened with the sharpest frost we have had this year; we registered 16° and 11° respectively. Happily the wind was still, and although outdoor vegetation must have suffered considerably our houses were not so badly off as they had been on many other occasions. It was a little hazy at first, but the sun quickly gained the mastery, and we gave air at 8 A.M. This was the first time since the 19th. The roof being pretty well covered with foliage now, the sun has not so much power on the house as it had a few days ago, so that less ventilation suffices. We now opened only three lights about 2 inches, and they were closed again at 2 P.M. with a temperature of 87°, and it kept as high as 80° till five o'clock.

The wind shifted to the west once to-day and seemed to promise better things, but it has not remained there. We damped down heavily in the morning and again at 2 P.M. The dose will be repeated again before 9 P.M. We do not damp down while the ventilators are open unless it is for the purpose of cooling the air; it is of no use as far as keeping the atmosphere of the house humid is concerned when there is 50° or 60° difference between internal and external temperature, for the moisture is quickly gone through the openings, and we might as well try to make humid the air of the whole country.—WM. TAYLOR.

A MODEL FORCING HOUSE.

MR. BARDNEY'S description of this structure on page 490 is interesting, but there is to me something tantalising in the want of information on one critical point—as to how the small intermediate rafters or roof-bars are supported at the eaves, where the eaves plate would ordinarily be. Otherwise the building is not extraordinary; and though it is said that it reflects "the greatest credit upon both the builder and its owner," I think the designer ought to have the first share, and the gardener who consents to such an innovation the second share, after which the fortunate owner who pays for it may take what is left. The builder, unless he be the designer, is nowhere in the matter, as he merely builds "to order," and presumably is fairly remunerated for his work. I shall take a note of this house as being an approach to what I suggested some time back—namely, a description of the best kind of house for a particular purpose by a competent authority. Though, as I have said, it is not an extraordinary building, being but a modification of the so-called curvilinear roofs with straight lines, it is an innovation by its abolishing the gardener's dearly beloved pet side lights, with their heavy framing, which for years I have vainly tried to induce the fraternity to do without. At the same time the necessity or advisability of such a height as 4 feet for brick wall, with at least 4 inches more of woodwork up to the glass line, is not at all evident, as the beds are usually only 2 feet 6 inches high.

The weak point of this house will prove to be the junction of the roof and sloping side glass. The rafters 5 feet apart are said to be "not heavy," and are secured by angle irons, but the three lighter ones between can only be joined together at the bottom in a very slight manner, and the pressure of wind and driving rain or the weight of a heavy fall of snow will try this part considerably in a year or two. If there was a slight connecting plate or rail to receive the foot of the roof and the tops of the front bars it would be an improvement, and the 2 inches of light it would intercept would not be worth consideration.

I wonder some of your able contributors have not yet discovered that the equivalent of what is gained by endeavouring to secure one object is often lost in another direction equally important. For instance, to obtain light you often lose heat by the adoption of wide panes of glass and the use of slight timbers, which the pressure of wind causes to bend, and so there is admitted double the amount of cold air at each lap that would be possible if the glass was narrower and the roof more rigid. I cannot say that such is, or will be, the case in this roof (or in the "vinery of the future," page 494), as there are said to be only two laps down the roof, but the lower one must admit more air than three ordinary laps would, though possibly not more than would be admitted all round the side lights. The obstruction of light caused by two or three light bars of wood in every 10 feet is imaginary, as the white paint on them reflects as much as the density of the wood obstructs, while a 12-inch pane will be 50 per cent. more rigid than one 15 inches wide, and will not admit anything like half the amount of cold driving wind at its laps.

The formation of a gutter in the wall plate is a mistake, as the best wood the world produces will crack there in a few summer's suns, and other disadvantages will show themselves in such a length in stormy weather.—B. W. WARHURST.

STORING GLADIOLI.—In the last issue of the Journal "D., Deal," says, on this subject, when referring in some reasonable observations to florists flowers—"I should like to ask 'W. J. M.' who recently detailed his

method of storing, and referred to me. Does he mean he absolutely never loses a corm? or, that he never loses one after they are taken up?" The former assertion would be absurd, though to the best of my judgment this year I did not lose one in twenty; while many of the corms increased twofold, and a few threefold. I have so often in your columns detailed my method of culture and storing I need not repeat it now; but you must allow me a line to express the indebtedness of all your readers and lovers of florists' flowers, to "D., Deal," for his always instructive notes in your columns.—W. J. MURPHY, *Clonmel*.

PRIMULA OBCONICA.

I sowed a packet of seed of this Primrose in April, and grew on the plants during the summer, giving the plants their blooming pots (6-inch), late in August. The plant is very similar in habit and foliage, but is less indented, altogether more rounded, than *P. cortusoides*, and is of dwarf compact habit. It commenced to flower early in October, and it is now (December) throwing up many umbels from the crowns, which it appears to form very rapidly, and by Christmas promise to be a mass of flowers. The umbels or trusses of bloom are large, the flowers individually about an inch across and quite flat, which are of a pale lilac colour, very pretty—charming indeed when associated with the bright-coloured varieties of *Primula sinensis*. It appears to be a continuous flowerer, and the flowers are very persistent. Good loam with a little leaf soil or decayed manure and a sprinkling of sand seems to suit it. Making a good pot plant and flowering in the autumn and winter when raised from seed sown in spring it will become as great a favourite as the beautiful *Primula cortusoides*, if not more so, from its earlier and continuous flowering. The treatment given to *Primula sinensis* vars. suits it—namely, an ordinary greenhouse position near to the glass after summer, with slight shade in the hot season. It is from China, and was collected and distributed by the Messrs. Veitch.—G. A.

AMONG the many plants lately introduced by the Messrs. Veitch *Primula obconica* is by no means least. It was lately figured in the "Botanical Magazine" as *P. poculiformis* from its curious cup-shaped calyx. The flowers are borne well above the leaves, and although larger, much resemble both in colour and general appearance the variety of *P. involucrata* called *Munroi*. The leaves are caudate, slightly undulated at the margins, of a dark green colour, and produced plentifully. This promises to be a very useful greenhouse plant, and no doubt when better known will take the place of those of less horticultural value. It requires to be kept moderately moist during the growing season, and with a little judicious management may be had in flower all the year round.—M. S.

ROYAL HORTICULTURAL SOCIETY.

DECEMBER 11TH.

THE last meeting of the year was fairly attended by members of the Committees, and the exhibits were sufficiently numerous to fill one table the whole length of the conservatory. A number of new plants were certificated, *Primulas* and *Cyclamens* being shown in excellent condition.

FRUIT COMMITTEE.—John Lee, Esq., in the chair. Mr. John Henderson, Haffield Gardens, Ledbury, sent a seedling Pear raised from *Beurré Diel* and *Beurré Rance*. It is a fruit with coarse and gritty flesh, thin sweet juice, and fine rosewater perfume. It was said to be rather past its best, and the Committee did not think it of great merit. Messrs. Cranston of Hereford sent specimens of *Mère de Ménage* (called *Davies' Red*), *Golden Spire*, *Parker's Pearmain*, *Ashmead's Kernel*, *Improved Plum Apple*, *Horne's Nonesuch*, *Butter Apple*, *Spring Pippin*, *Tyler's Kernel*. Rev. S. M. Laken sent a seedling Apple which had been kept too long for the Committee to form a favourable opinion of it. Rev. W. Murton, Sutton Vicarage, Wansford, sent an Apple of small size, somewhat resembling *Court of Wick*, but very inferior to that variety. Mr. Jas. E. Nelson, Stanwell, Staines, sent a seedling Apple called *Nugget*, raised from *Downton Pippin* fertilised by *Emperor Alexander*. It is a handsome, deep yellow, conical Apple, with a good, though not a rich flavour. Mr. R. Bland of Fordham, near Soham, sent a seedling which did not possess any merit. Mr. S. Facer of Northampton sent an Apple called *Perkins' A1*, raised by Messrs. J. Perkins & Son, The Drapery, Northampton. It is a handsome Apple, beautifully coloured, with tender flesh and pleasantly subacid. Mr. Perkins was asked to send it to the January meeting. Mr. John Parr, Ledbury, sent a Pear sold under the name of *Knight's Monarch*, but which was *Downton*. Mr. David Thomson of The Gardens, Drumlanrig Castle, sent four very large and handsome *Smooth Cayenne* Pines, their aggregate weight being 31 lbs. 2 ozs. They were grown from plants in 11-inch pots, the base of the fruit being about 10 to 12 inches from the rim of the pot. A silver Banksian medal was awarded. Mr. P. H. Cousens, Bower Street, Maidstone, sent specimens of *Blackberry Pippin*, an Apple popularly so called on the Hampshire coast, and which stands the sea breeze without the young shoots being killed back. A large collection of varieties of *Celery* were shown from the Society's Gardens at Chiswick. Several varieties were shown, but it was generally considered that they were very similar, the red and white being the only strongly marked sections. Mr. W. C. Leach, gardener to E. P. Monckton, Esq., Fineshade Abbey, exhibited a large collection of vegetables, comprising Onions, Turnips, Brussels Sprouts, and Beet. They were tastefully arranged with moss.

FLORAL COMMITTEE.—G. F. Wilson, Esq., in the chair. A bronze Banksian medal was awarded to Messrs. H. Cannell & Sons, Swanley, for four stands of magnificent *Zonal Pelargonium* blooms, single and double. A fine collection of *Primulas* was also staged with single *Chrysanthemum* blooms, and the pure white double *Neapolitan Violet Comte Brazzi*. Of the single *Zonals* the finest were Mr. Brunning, scarlet; Mr. Lord, crimson; Kate

Greenaway, pink; Snowball, white; Rose, salmon-scarlet; Kate Farmer, salmon; New Guinea, orange; and F. Kauffer, violet-crimson. Of the doubles the best were F. Raspail, scarlet; E. Bandonin, pink; Gen. Campenon, maroon; F. Charbonnier, orange; and La Quintinie, white. In the single *Chrysanthemums* the most noticeable were *Yellow Gem*, neat and bright yellow; *Brunette*, deep reddish brown; *Henry Irving*, pale rose; *Willie Beckwith*, rose with a white base; *Miss Cannell*, white; and *Mrs. Langtry*, blush white. Col. Clarke, Welton Place, Daventry, sent flowers and stems of a *Tropæolum* for comparison with *T. Lobbianum*, the former being stronger and deeper in colour. A cultural commendation was awarded to Mr. J. C. Tallack, Prideaux Place, Cornwall, for a number of fine flowers of *Helleborus niger altifolius*, some of which were nearly 5 inches in diameter.

Mr. B. S. Williams, Upper Holloway, sent three plants of *Adiantum cuneatum compactum*, a very dwarf form with small dark green fronds about 4 or 5 inches high. Messrs. J. Veitch & Sons, Chelsea, showed several new plants, some of which were certificated. *Begonia Autumn Rose*, a hybrid between *B. insignis* and *B. socotrana* with small but numerous rich pink flowers, was very pretty. A bronze Banksian medal was also awarded for a group of about a hundred handsome *Cyclamens*, bearing large, pure white, parti-coloured, purple, or crimson flowers. The substance of the blooms and general condition of the plants indicated the most careful culture. A bronze Banksian medal was awarded to Mr. Wiggins, gardener to W. Clay, Esq., Elm Villa, Grove Road, Kingston, for a large and handsome collection of *Primulas* and *Cyclamens* extremely well grown and profusely flowered. A cultural commendation was awarded to G. F. Wilson, Esq., Weybridge, for a plant of *Odontoglossum Alexandræ* with fifty flowers on one spike with several long branches. A spike of *Eryngium pandanifolium* was also shown 7 or 8 feet high, for which a vote of thanks was awarded. Votes of thanks were awarded to the following:—Mr. C. Turner, Slough, for a stand of the neat white *Princess Teck Chrysanthemum* and a stand of good and distinct Japanese varieties, comprising fine blooms of *Fanny Bouchardat*, *Madame C. Audiguier*, *Mons. Lemoine*, *Ethel*, *Etoile Toulousaine*, *Cry Kang*, and *Baronne de Prailly*. Mr. G. Springthorpe, gardener to G. H. Palmer, Esq., Tuddington House, Egham, sent a bloom of a sport from *Chrysanthemum Parasol*, pure bright yellow, but similar in petal and bloom to the parent variety. To Mr. A. G. Bridgeman, gardener to T. S. Cocks, Esq., Thames Bank, Marlow, for six grand clusters of *Luculia gratissima* flowers. To Mr. J. King, Rousham, for single *Zonal Pelargonium Rousham Model*, the flowers are very large, round, and symmetrical, deep scarlet; one of the finest varieties of the type. Votes of thanks were also accorded to Mr. Green, The Gardens, Pendell Court, Bletchingley, for flowering branches of the bright orange *Bignonia venusta* and *Aralia papyrifera*. A collection of well-grown *Primulas*, Ferns, *Justicia speciosa*, *Poinsettias*, and a good plant of *Cypripedium Maulei* with fourteen flowers were sent from the Society's Garden at Chiswick.

SPECIAL PRIZES.—Messrs. J. Carter & Co., High Holborn, offered six prizes for the best collection of twelve dishes of vegetables, the first prize being £5, the second £3, and third £1 10s. Only three collections were entered, and after some consideration the premier position was adjudged to Mr. Beckett, gardener to J. P. Currie, Esq., Sandown House, Esher; Mr. Phillips, gardener to Dr. Baker, The Deodars, Meopham, Kent, being placed second; and Mr. Marriott, The Gardens, Skirbeck Park, Boston, was third. Much difference of opinion existed regarding the justness of the two first-named awards, but the general verdict was that Mr. Phillips' collection was several points ahead of that awarded chief honours. In Mr. Beckett's collection the majority of the examples were too large and coarse (*Carrots*, *Parsnips*, and *Beet* especially so), while one dish of *Onions* was far from satisfactory. In all these Mr. Phillips' productions were decidedly superior, *Cauliflowers*, *Celery*, and *Sprouts* being about equal, while the *Kentish collections* had an excellent dish of *Leeks* and fairly good *Turnips*. The varieties shown in the first-prize lot were *Carentan Leeks*, *Maltese Parsnips*, *Magnum Bonum Potatoes*, *Golden Globe*, *Silver Ball*, and *Golden Queen Onions*, Veitch's *Autumn Giant Cauliflower*, *Leicester Red Celery*, *Aigburth Brussels Sprouts*, *Snowball Turnip*, *Long Red Surrey Carrots*, and *Carter's Perfection Parsnips*.

First-class certificates were awarded for the following:—

Cypripedium Schroderianum (Ballantine).—A magnificent Orchid, the flowers very large and richly coloured. The lip is full, over an inch in diameter, deep rose, white inside, spotted with rose; the petals of a similar colour, 4 inches long, about half an inch across at the base, with a few short hairs, and tapering. The sepals are broad, light in colour, with a few rosy and pale green veins. It is a cross between *C. caudatum* and *C. Sedeni*.

Cypripedium cardinale (Veitch).—A hybrid between *C. Sedeni* and *C. Schlimii album*. A charming form, with a globular lip, deep rich rose, light in the throat. Petals an inch broad, about 1½ inch long, blush white, with a few rosy hairs at the base. Sepals white, with a few faint greenish veins. Very strong in habit, with bright green leaves.

Cypripedium calurum (Veitch).—A hybrid between *C. longifolium* and *C. Sedeni*. A strong form, with three spikes of rosy purple-tinted flowers, the sepals and petals greenish, but veined with rose.

Cyathea microphylla (Veitch).—A graceful Tree Fern, with fronds 4 feet in length and 2 feet broad. The ultimate divisions of the frond fine and closely set.

Ilex laurifolia aurea marginata (A. Waterer, Woking).—A variety with neat oval leaves, having few spines, deep green edged with gold.

Pelargonium Erl King (King, Rowsham).—A double *Zonal*, with a compact neat truss of a salmon-scarlet hue. Habit of plant dwarf and sturdy.

Primula Swanley Purple (Cannell).—A free compact-growing variety, with rich crimson-purple well-formed blooms. Very handsome and useful.

Primula Queen of the Whites (Cannell).—One of the Fern-leaved type, with pure white large blooms, having a deep orange centre.

Primula sinensis Julian Lee (C. Lee & Son, Isleworth).—An interesting bright crimson variety; flowers of great size and substance, but not very even, and with a deep yellow eye. Dwarf and free.

Carnation Mrs. Keen (Veitch).—A grand variety of the tree section; blooms full, and 3 inches in diameter, of the deepest maroon tint, almost black. Very distinct and beautiful.

SCIENTIFIC COMMITTEE.—G. F. Wilson, Esq., in the chair.

Sclerotoids in Potato Leaves.—A communication from Mr. A. S. Wilson was read, in which he raised the question whether the oxalate of lime, of which Mr. Murray found them to consist, were not mixed with a protoplasmic plasmodium from the mycelium. Mr. Murray negated the idea, as, after treating them with dilute nitric acid for half an hour, no trace of any such substance remained.

Protecting Tubers by High-moulding.—A communication was read from Mr. Plowright (and which will be printed) upon experiments carried on this season, in which he again maintains the efficacy of high-moulding over low-moulding or not at all. Mr. Murray observed that there would be required fuller details of the experiments before the conclusion could be arrived at which Mr. Plowright made. He admitted that spores could impregnate the Potatoes through the eyes, but not the skin; but that the main if not sole cause of disease in the tubers was by the mycelium descending the stem.

Cephalotaxus Fortunei (?).—Dr. Masters reported on this plant, exhibited by Sir J. D. Hooker at the last meeting, and after a careful examination of the fruit and leaves he is inclined to think it an undescribed form of the female of some species.

Picea pungens.—Several young Firs were sent by Mr. Waterer and described by Dr. Masters—viz., *Picea pungens* (called by gardeners Parryana glauca), and the green and glaucous varieties of *Picea Engelmanni*.

Cunninghamia lanceolata proliferous.—Dr. Masters showed specimens with the branch protruding through the cone. He had examined it and found the so-called "carpellary scale," which carries the naked ovules in this instance, to be a cellular outgrowth from the bract, and not a separate foliar organ.

Cordiceps purpurea.—Mr. G. Murray exhibited specimens of ergot which he had cultivated, and which had borne the so-called claviceps or cordiceps, the ascigerous condition of the fungus.

Caraguata sanguinea.—A bright red and green-leaved Bromeliad, found by M. André in the Cordilleras of New Grenada, and which received the gold medal by M. Bruant.

Hypertrophied Root of Plum.—The Secretary exhibited a large tuberous root with a rugged corky bark from a Winesour Plum. It was found 10 or 12 inches below the surface. The tree had grown vigorously, but bore only a scanty crop of fruit. It came from the garden of Mr. Nelson, Hanger Hill, Ealing.

Books, &c., Presented to the Lindley Library.—"A Bushel of Corn," by A. S. Wilson. "Answapl von Ausser Tropischen Pflangen, &c.," translated by Dr. Goege (Baron V. Mueller). "Agricultural, Botanical, and Chemical Results of Experiments on Pasture Land," by Sir J. B. Lawes, &c. (from the author). "Field and Garden Crops of North-west India," part I. (from Dr. Duthie). *Books purchased*: "Flore Forestière de la Cochinchine," par L. Pierre, vol. i., 4to, 50 pl. "Nouvelles Remarques sur la Nomenclature Botanique," par A. de Candolle. "Illustrations of British Fungi," by M. C. Cooke. "Farm Insects, &c." (Curtis), new edition. "British Moss Flora," by Dr. Braithwaite. "Iconographie des Azalées," Van Gert, vol. i.

LECTURE.—The Rev. George Henslow, in drawing attention to some of the plants exhibited, first noticed a fine specimen of *Fatsia* (*Aralia*) *papyrifera* exhibited by Mr. Green. The leaves are described as being 1 foot across, but this under cultivation had become 3 feet. It is the plant the pith of which forms the well-known rice-paper of Japan and China, first discovered to be from this plant by Sir William Hooker in 1852, who described it in the "Journal of Botany" (vol. iv., page 347). Mr. Green also exhibited a fine spray of *Bignonia venusta*, figured first in the "Botanical Register," 1817, and received from Brazil. He next drew attention to a plant called *Caraguata sanguinea*, discovered by M. André in the Cordilleras of New Grenada. It is a Bromeliad with red and green foliage. It appears to be the custom to use it as a decorative plant with Tree Ferns in its native home when any spot is signalled for some remarkable event. A curious *Eryngium pandanifolium* sent by Mr. G. F. Wilson showed how one plant may, in its foliage or otherwise, imitate others. The British species common on the seashore is called Sea Holly, from its prickly leaves, and has heads of flowers resembling a Composite. As other cases of mimicry, the lecturer alluded to the genera *Euphorbia* and *Poinsettia*, the coloured involucre or leaves of which mimicked or were a substitute for coloured flowers where-with to attract insects to fertilise the small inconspicuous flowers in their centres.

He next drew attention to a fine cut specimen, brought by Mr. Green, of *Dahlia imperialis* from Mexico, a species which attains 12 to 20 feet in height or more. He remarked upon the present taste of "reverting" to single Dahlias in preference to the common double form, a reversion which Mr. Cannell had attempted in his display of fine single Chrysanthemums; but the many beautiful double forms of this genus are scarcely yet likely to be ousted by their revived progenitors.

As instances of skill of cross-fertilisers there were several of the genus *Cypripedium* and its allied form *Selenipedium*, recognisable generally by the long tails to the petals. There was a difference in the ovary in that it is one-celled and not three-celled, as in all other Orchids. Hence the first result from *C. Schlimii* (a true species?) and *longifolium* (also a true species?) was *C. Sedeni*. This crossed with *C. longifolium* gave rise to *C. calurum*, while *C. Schroderianum* was the result of crossing *C. caudatum* and *C. Sedeni*. Gardeners do not distinguish between the two original species, *Cypripedium* and *Selenipedium*, calling them both by the former name.

SOUTH SHIELDS CHRYSANTHEMUM SHOW.

DECEMBER 5TH AND 6TH.

THE above Society held their second Exhibition in the Free Library Hall, South Shields. This is the only Society in England north of York, and it promises to be a great success, as the past Exhibition had nearly twice as many entries as the previous one, and the quality of the exhibits was much improved in every class. The exhibition is under distinguished patronage. The Committee are good business gentlemen, and much of the success is due to Councillors Smith, Thornton, Thomas Binks, John Wright, Adam Hope, and R. Chapman for the energy they have shown in raising the subscriptions. This year the Society increased their prize list, which they intend to do gradually each year. Altogether the Society offer nearly £60 in prizes. In the class for a group of foliage and other flower-

ing plants, 8 feet by 6 (£2, £1 10s., and £1), there were five competitors. Mr. W. East, florist, Fowler Street, was first; Mr. H. Smail, gardener to J. C. Stevenson, Esq., M.P., Westoe, was second; Mr. W. Forsyth, gardener to G. Cairns, Esq., Monkton Hall, third. Mr. Whiting, gardener to Geo. Walker, Esq., Shot Tower, Newcastle, showed a grand *Oncidium Cavendishianum* on his stand with thirty flowers on. For six Chrysanthemums, large-flowering, Mr. G. Corbett, gardener to J. Liddle, Esq., Benwell Hall, was first with superior plants, well trained, 4 to 5 feet through; Mr. Paul Blanchard, gardener to Dr. Gibb, Sandford Park, Newcastle, was second with good plants, but taller and not so well trained; Mr. T. Richardson, gardener to Geo. May, Esq., Simonside Hall, was third. This class was much admired on all sides, and there was much improvement since last year. For three same as above Mr. Corbett and Mr. Blanchard occupied the same places. For four Pompons Mr. Corbett was again first, followed by Mr. Richardson. For two the same exhibitor was also first.

The Japanese varieties this year were also much improved. Mr. Corbett and Mr. Blanchard were again in the same positions, the former having finely trained plants. For two Anemone-flowered Mr. Fred. East, gardener to Matthew Wood, Esq., Westoe, was first, and Mr. John Allen, gardener to Henry Wilson, Esq., Westoe, second. The Society offer a prize for the best amateurs' plants in North and South Shields; both prizes were carried off by Mrs. B. W. Stainton, Westoe, with very creditable examples. There were thirteen lots of Primulas staged, Mr. Geo. Corbett again taking the first place; Mr. E. H. Turnbull, gardener to Mrs. Turnbull, High Barnes, Sunderland, second; and Mr. James Forsyth, Sunderland, third. The above were very good. Table plants, Cyclamens, and foliage plants were all well represented.

Cut Flowers.—For twelve incurved blooms Mr. S. B. Morton, Bowden Bridge, Darlington, was first with splendid blooms, similar varieties to those he had at York last week, but larger and better flowers. Mr. Fred. Bollom, gardener to Sir H. A. Clavering, Bart., Axwell Park, was second; and Mr. F. W. Jameson, Queen's Dock, Hull, third, with good flowers. There were six stands. For six incurved blooms the same exhibitors were first and second again. For twelve reflexed Mr. T. B. Morton; Mr. J. Brown, gardener to Mrs. Joicey, Whinney House; and Mr. James Anns, Gateshead, were placed respectively first, second, and third; and for six reflexed the same exhibitors were placed again in the same positions. For twelve Japanese blooms Mr. S. B. Morton, Mr. F. W. Jameson, Hull, and Mr. Anns, Gateshead, were awarded the prizes as named. Mr. Morton's flowers were here very good indeed and much admired.

For twelve bunches of Pompons the Judges disqualified Mr. Brown because he had Anemone Pompons in his stand; but the Committee annulled the decision, as they take Cannell's catalogue as their standard, therefore two firsts were awarded to Mr. Brown and Mr. Anns.

Hand Bouquets and Epergues.—Prizes were offered for the above, which produced a most spirited competition. There were eleven hand bouquets staged. Mr. T. Rutherford, Durham, was first with a graceful arrangement of Eucharis, Camellias, and other winter flowers, also tastefully draped with *Adiantum gracillimum*. Mr. E. H. Bradley second, and Mr. J. Webster, Sunderland, third. There were seven epergues. Mr. S. Adams, Swalwell, was first with a well-arranged stand containing red and white *Lapagerias*, *Gardenias*, *Camellias*, all draped with *Lygodium scandens*, and margined with *Davallia Mooreana*. Mr. Wm. Whiting was second, and Mr. T. Rutherford third.

Grapes.—Prizes were offered for black and white Grapes. There were eight lots of black. Mr. H. Smail was awarded first with Gros Colman, truly superb in berry and finish, weighing about 2 lbs. each. Mr. Wm. Jenkins, Durham, second, and Mr. Wm. Forsyth third. White Grapes were also well shown by Mr. Smail.

Not for competition was a grand stand of Coniferae which adorned the band stand by Messrs. W. F. Fell & Co., nurserymen, Hexham; and Messrs. H. Cannell & Sons, Swanley, Kent, sent a superb stand of Primulas.

The Exhibition was opened with great ceremony by the Mayor, T. J. Mabane, Esq., accompanied by the President, J. T. Ettringham, Esq., J.P., and several influential members of the Councillors' Chamber. After the proceeding the President, Council, Committee, and friends dined together. After the loyal toasts were proposed, the President proposed "The Prosperity of the Society," accompanied with the Hon. Secretary's name, Mr. Bernard Cowan.

GARDENS ABOUT BRISTOL.

COTE HOUSE, WESTBURY-ON-TRYM.

THIS pretty old-fashioned residence, of which H. St. Vincent Ames, Esq., is the much-respected proprietor, is beautifully situated in a well-wooded district, and is approached through a park furnished with many fine old trees. Mr. St. Vincent Ames takes great interest in both the park and gardens, and in the former, in addition to replanting where required, every care is taken to preserve the large trees, many of which are Elms, and unfortunately have attained an age when decay sets in, thus rendering them peculiarly liable to be blown down by heavy gales of wind. In order to obviate this danger several large trees have had their heaviest branches considerably shortened, and this it will be evident renders them less top-heavy, therefore less liable to be uprooted. This practice I commend to the favourable notice of other owners of large old Elms, who may perhaps find, when too late, that no number of young trees will compensate for the loss of a few giants.

There is no conservatory at Cote House, but the rooms which open out on to the lawns were gay with choice plants and cut flowers. The house itself is nearly covered with various climbers, and is partially surrounded by an undulating and well-kept lawn. No "fancy" flower garden disgraces the beautiful expanse of turf, but the grand old specimens of Evergreen Oaks, Tulip Tree (*Liriodendron tulipifera*), deciduous Magnolias, *Wellingtonia gigantea*, and *Cedrus deodara*, which either fringe or are dotted about the lawns, are all worthy of admiration. The few flower beds and borders I noticed were all well planted, but call for no particular comment.

The plant and fruit-growing houses are built in the kitchen garden,

this being separated from the pleasure grounds by a heavy belt of deciduous and evergreen trees and shrubs. Mr. W. Bannister, the practical gardener in charge of these gardens generally, has long been well known as a successful exhibitor of fruit, plants, and vegetables, his successes not being confined to the Bristol district. At the time of my visit, or early in September, the vineries were very attractive, notably a house of Black Hamburgh. The crop of this good old Grape was heavy, the colour and quality being especially good. Another house contained a full crop of such Grapes as Muscat of Alexandria, Lady Downe's, and Venn's Black Muscat; but as these, although good, were giving signs of deterioration, the work of renovation was to be commenced this autumn. The borders are both inside and outside, and as the latter has been made for some time and is full of roots it was intended to cut and clear a wide trench along the house, or that part of the border farthest away from the stems, and to substitute a quantity of good fresh compost. This will undoubtedly greatly benefit the Vines and improve the weight and quality of the crops next season. A good-sized lean-to structure, devoted principally to Peach and Nectarine culture, is decidedly worthy of imitation, especially where the owners of gardens happen also to do much of their own gardening. Perforated zinc in sheets is substituted for sash-bars and glass along the whole front of the house, and more zinc is worked into the front of a raised and top glazed lap which is formed along the ridge of the house. Besides being cheaper and needing no subsequent repairs, this perforated zinc does away with apparatus and the necessity for ventilating, besides keeping out the wasps. The house is completely furnished with Peach and Nectarine trees, and a failure to crop never occurs. Melons are well grown, Mr. Bannister's favourite sorts being High-cross Hybrid and William Tillery.

In the plant houses I observed very fine batches of *Pancreatium fragrans* and *P. grandiflorum*, the stock of these being imported in the first instance. A few Orchids, including a good batch of *Calanthes*, and many of the best Crotons, *Dracænas*, and other choice plants required for house and table decoration, are well grown, as are also numbers of Ferns, including several large and good seedling *Gymnogrammas*. A very fine plant of *Allamanda Hendersonii* is trained over the roof of one of the plant stoves. It is rooting in a small raised pit filled with good loamy soil, and being kept freely thinned out and otherwise well attended the result is an abundance of showy blooms from May in one year till February in the next, and very valuable the blooms prove for dinner-table decoration during the dull winter months. In the cooler houses such serviceable flowering plants as *Begonias*, single and double Zonal *Pelargoniums*, *Celosias*, and *Fuchsias* were in excellent condition.

Hardy fruits are a speciality with Mr. Bannister, and nothing could have been more satisfactory than the heavy crops of fine Apples and Pears. Particularly good were such Pears as Marie Louise, Glou Morceau, Beurré Superfin, and Easter Beurré especially were receiving the shelter of walls, and a large bush-shaped tree of Alexander Lambert was crowded with fine fruit. The rather new Worcester Pearmain Apple is found to be a good bearer, and the very handsome fruit forms an attractive dish both on the dining and exhibition tables. In spite of the poor position and heavy clayey soil of the kitchen garden, it is made to produce excellent crops of vegetables, some of which easily gained the first prize for a collection at the late Bristol Chrysanthemum Show.—W. IGGULDEN.

HARDY FRUIT GARDEN.

Renovation of Soil.—In our last calendar attention was called to the importance of adding fertile soil periodically to the stations of trees established in what is naturally a poor thin soil. This is of such vital moment to the health as well as the fruitfulness of the trees, that we revert to it in view of making provision for the future as well as doing what we still may for the present. Well would it be if such work could always be done immediately after the year's growth is over before the soil has become very wet from the heavy rain of autumn. As a means to so admirable an end, we are making provision now of a heap of soil for use next autumn, and are gradually getting a considerable quantity of ant hills carted from an old pasture. These will be chopped to pieces coarsely with spades, and thrown in a heap with about a third part added of farmyard manure, a fourth of finely sifted coal ashes, and a fourth of spent lime, for the simple reason that our poor soil contains neither lime nor coarse gritty matter. This heap will be turned and mixed two or three times in the course of the next eight months, and it will be in prime condition by the time it is required for the trees. From a rich pasture the ant hills or a top spit of turf sods would alone suffice for the trees, and would preferably be used at once; but ours is an extreme case, and we give it for the assistance of the numerous readers of the Journal who have to contend with the difficulties of a poor soil. If the trees were planted with due care there will be no occasion for any disturbance of the soil of the stations; it is the poor soil between the stations which is to be excavated to a depth of 2 feet and replaced with some such compost as we have indicated. Where the soil is too poor for fruit culture turf sods taken from an adjacent pasture are not to be depended upon, for when the vegetable matter

becomes exhausted the trees inevitably deteriorate, and it is in such cases that nitrogenous manure is beneficially mixed with the soil in the first instance, and also subsequently as often as appears necessary.

Top-dressing.—To all trees in shallow soil top-dressing with rich compost is highly beneficial. It sustains health and vigour, induces root-growth near the surface, and helps materially to prevent canker, which is frequently so baneful to trees in such soil. Care must, however, be taken not to bury the stem to a hurtful degree, especially of Cherries, or it may lead to the loss of valuable trees.

Pruning and Training.—Lose no opportunity of pushing on this work so as to make sure of finishing long before sap-movement begins again. Large arrears carried over to the new year often have to wait till spring draws nigh, and the trees suffer from hurried work, and are also enfeebled by very late pruning. Pay particular attention to spur-thinning now, so as to avoid much fruit-thinning in summer, and to afford full play to light and air upon every part of the tree. Crowded spurs form harbours of refuge for noxious insects, and are also objectionable for the unnecessary quantity of fruit produced, which is worthless if left unthinned, and leads to much wasted time in fruit-thinning at a busy season of the year.

Old Trees.—The lichen-covered branches of old trees undoubtedly harbour insects, which attract birds, whose searching after the larva leads to the destruction of blossom buds, often to a hurtful degree. Something may now be done to lessen this evil by a thorough dusting of fresh-slaked lime when the trees are damp. Such trees often suffer, too, from insufficient drainage, and from having many roots deep down in a cold inert subsoil. The remedy for these evils is obvious, and the necessary attention to it may soon be well repaid by renewed vigour and abundant fruit crops. Hasty measures with old trees are not advisable. Old spurs may be removed with advantage, but not always, and we would certainly do all that is possible to promote the health of a tree before bringing the pruning knife to work upon it.

FRUIT-FORCING.

VINES.—**Late Grapes.**—Muscats and all thin-skinned Grapes for use during this month and January must be cut early in December and bottled; but the thick-skinned varieties, such as Lady Downe's, Alicante, Gros Colman, Gros Guillaume, and the latest-keeping white varieties not attaining their full flavour and quality until they have remained on the Vines some time, which is generally not the case until the turn of the year, when their removal to a properly arranged and managed Grape room will insure their keeping fresh and plump for more than four months, or until May, without shrivelling or any depreciation of flavour. Former instructions having been attended to, the bottles will be filled and ready for the reception of the stalks of the Vine shoots, which should be cut off down to a promising bud, in order that they may go well into the bottles and admit of the bunches hanging free of the bottles. In cutting and removing the bunches the berries must not be rubbed or disturbed, nor must any of the points of the shoots or laterals above the bunch be removed, as every wound or cut acts as a channel for the escape of moisture. The room should have openings in the roof so arranged as to allow of the escape of moisture without producing a draught, and if the walls be hollow or thick there will be less occasion for dispelling atmospheric moisture, and no more fire heat should be given than to maintain the temperature about 45°, and the less it fluctuates the better. The bunches will require examining once or twice a week for decayed berries; but if the Grapes are properly ripened the loss will be small, as in the even temperature of the Grape room the Grapes will keep much better than when left on the Vines until March. This subject is referred to more fully in another column.

Pruning Late Vines.—As soon as the Grapes are cut the Vines should be pruned in order that they may have a long season of rest, with free exposure on all favourable occasions, keeping them as cool and dry as possible, a few degrees of frost doing no harm provided the atmosphere be dry. Spare the Vines if practicable the moist or damp atmosphere induced by wintering plants in the house.

Figs.—**Earliest Foreed Trees in Pots.**—Those shut up in November with fermenting materials in the pit will now be swelling the terminal buds and the fruit be gradually expanding. The roots, too, will be active, sending out young feeders, being influenced that way by the genial warmth obtained from the fermenting material. If the heat does not exceed 75° the materials may be trodden down firmly round the pedestals and bottom of the pots, and a further supply of sweetened fermenting Oak or Beech leaves introduced from the reserve heap. Care must be taken that the heat about the sides of the pots does not exceed 70° to 75°. The heat and moisture given off by the fermenting materials will greatly facilitate forcing by mitigating the aridity consequent on the employment of fire heat, of which no more than is necessary should be employed, which in severe weather need only be used to maintain a night temperature of 50° to 55°, and on very cold nights a lower minimum will do no harm; but with light an advance of 5° to 10° should be given, with a still further advance from sun heat, and lose no opportunity of admitting air without subjecting the tender growths to cold currents. Syringe the trees and all available surfaces in the morning, and again in the afternoon if the day has been fine and dry, but it should not be practised later than 2 P.M., and if only a moderately fine day the morning syringing will be sufficient, as too much moisture is apt to induce a soft growth, whereas the aim should be to secure a sturdy and well-solidified development. The glass must be kept clean, and a little extra fire heat turned on if necessary, so that a little air may be given to expel accumulated moisture.

Pruning in Succession Houses.—Lose no time in having this completed.

Cut back or entirely remove old spurs, and then cut the least promising shoots that have reached the extremity of the trellis, to make room for free sturdy growth and give a chance to the development of foliage and wood, which must have free exposure to light and air to insure a crop and colour. Spare no pains in cleansing the trees of insects. If there be scale syringe with petroleum two or three times at intervals. A wineglassful to three gallons of water kept well mixed whilst being applied is suitable and efficacious.

PLANT HOUSES.

Clerodendron Balfourianum—No plant is better adapted for forcing into flower early than this useful and beautiful stove climber. Plants that have been thoroughly ripened and at rest for some weeks past in a temperature of 55° may now be started. Place the plants in a temperature that will not fall below 60° at night, and syringe twice daily. If a little bottom heat can be given so much the better, but good results can be obtained without it. Give a little water at the roots, but not sufficient to thoroughly moisten the whole ball until signs of growth are visible. Those that have been carefully dried or are now at rest must not be placed in too low a temperature, or it will prove fatal, and the plants will not start into growth. Those that bloomed later, and have still their foliage upon them, must have—if the wood is well ripened—less water at their roots, but the supply must be gradually diminished, and the plants should occupy a drier position than the stove.

Allamandas.—Where the flowers of these are required early for filling shallow vases, in which they look remarkably well with a little Fern, a start may now be made. The plant selected for this purpose must have been well ripened and at rest for the last six or seven weeks. If the plant is large enough to cover the space required prune close back to one or two eyes. If grown in a pot it should be turned out and the whole ball reduced to half its size, retaining as many fibry roots as possible. After this the ball, if thoroughly dry, should be soaked in tepid water and then allowed to drain before it is again potted. The same size pot may be used, or a larger, according to the space the plant is required to cover. Drain the pot liberally, and place over the drainage a little decayed manure. In potting press the new soil as firmly as possible round the old ball, and use a compost of good fibry loam, a seventh of decomposed manure, and sufficient sand to render the whole porous. Place the plant after this operation in the temperature advised above for *Clerodendrons*, and syringe at least twice daily, but do not give water at the roots, for if the soil is in proper condition for moisture at potting time none will be needed until the plant commences growth. Another plant should now be at rest to succeed the one to be started, and if water has been gradually withheld it may be kept dry until the time arrives for starting it into growth. Keep it in a temperature 5° lower than advised for starting them into growth after resting. Gradually diminish the supply of water to other plants that it is necessary to bring to rest, but do not withhold it entirely until the foliage has ripened naturally. Plants from which blooms are still required must be encouraged by feeding and brisk heat. These plants produce an enormous quantity of flowers, and three plants are ample for a continuous supply of flowers for eight months out of the twelve.

Bougainvillea glabra.—This plant supplies most useful flowers for cutting, and a plant or two if grown in pots may now be started under the same conditions as advised for *Allamandas*. If the plants have not been pruned thin out liberally all weak growths, for a few strong shoots will produce more flowers than a much greater number of small ones. The old soil must be picked carefully from amongst the roots until the old ball is reduced by one-half, but this we prefer doing just as the plant is starting into growth. This, however, is not of vital importance, for good results can be obtained by potting when the plants are started, but more careful treatment is required until root-action commences. The soil should be good loam, a seventh of manure, a little broken charcoal, and a liberal dash of coarse sand.

Gloxinias.—A few of the tubers that were rested first may now be started, and the plants when in flower will be found valuable for the stove or conservatory, or the flowers for cutting. Shake all the old soil from the tubers and soak them previous to potting in tepid water. The tubers, according to their size, may be placed in the pots in which they are intended to flower in. Very fine plants can be grown 5 or 6-inch pots. If possible plunge the pots where they will receive bottom heat in cocoa-nut fibre or other plunging material. The rim of the pots may be covered, which will prevent the application of water until the tubers commence growing. If possible let the bottom heat range at from 75° to 80°, and the top heat from 60° to 65° at night. Use a compost of loam, manure, leaf soil, and sand.

THE BEE-KEEPER.

NOTES ON BEES—PRACTICAL MANAGEMENT.

Food in Hives.—We know of nothing which will conduce in a greater degree to successful bee-culture than a little extra care and attention in preparing hives for passing through the winter well. To accomplish this, the main points to be looked to are food, ventilation, dryness, and warmth. With regard to the first and main point—food—the generally accepted notion is that a stock of bees should have 25 lbs. or 30 lbs. of food to carry it safely over the winter—

that is, from November to March; but we differ from this notion entirely, and have proved in numbers of instances that a stock properly prepared will be abundantly provided if it has 15 lbs. or 16 lbs. of sealed food in November. To insure them this amount we give to a stock from which all the honey has been extracted five quarts of thick syrup, weighing about 18 lbs., and as about 2 lbs. or 3 lbs. will be lost in storage it leaves the first-named nett weight for use.

Protecting Hives.—When preparing the hive for winter nine combs are removed in the spare frame box, and in this removal we take care that only the best combs are left; all faulty ones or those which contain too much pollen being taken away. These nine combs occupy the centre of the hive body, and when the dividers are pushed close up on either side, the 6-inch hair quilts are laid on edge against them, forming a warm wall, and avoiding the litter and mess which loose chaff packing causes. The section crate with a piece of calico tacked on to its under side is filled with 3 or 4 inches of cork dust and forms the winter covering (first fixing a feeding stage 4 inches square, with high sides between the cross bars of the crate, so that the cork dust is kept clear of the feeding bottle), one thickness of carpet is laid on the wood quilt, and over this the crate prepared as above. The great advantage of this simple arrangement for wintering is that it can be so easily removed and replaced. The feeding stage, if covered with a square of glass, can have barleysugar or candy cake placed in it, thus avoiding the objectionable practice of disturbing the quilts in order to lay the barleysugar across the tops of the frames. The diagram below will explain the arrangement better than a mere verbal description.

Spring Management.—Supposing the hive to remain undisturbed until the middle of February, advantage should be taken of the first

Fig. 103.

Sectional view across the front of hive, showing winter arrangement.

A, floorboard; B B, dividers; C C, hair quilts; D D, hair quilts not in use; E E, section crate with cork dust; F, feeding stage; G G, unoccupied portion of hive.

The dotted lines indicate the form a cluster of bees assumes when wintered on shallow frames.

fine day to open the hive and note the condition of the stock. If the bees are fairly numerous remove one of the frames, uncap the whole of the food in it, and replace it in the hive near the centre, but take care not to insert it between combs containing brood, as February is too early for this. The bees will be thoroughly aroused by the unsealed food, and if the weather is favourable stimulative feeding may be continued by giving either syrup or candy food till the beginning of March, when a second examination is necessary, and if food is found on three or four combs another frame containing sealed food should have the latter uncapped and be placed between the sealed brood. As the stock becomes more populous this spreading of the brood may be repeated twice a week; when April sets in we prefer to use comb foundation instead of the reserve combs. Our reason for this preference is, that the use of foundation at this time induces the "comb-building impulse" which gives such an impetus to the working of a stock of bees in spring, while the shallow frame minimises the danger of its use, except in the most careless hands.

It must be observed that our hive is particularly adapted for continuous feeding in spring, because the body of the hive is never intended to contain much surplus food (except when put into winter quarters), and when the bees are wintered on nine small frames it will be seen that a few weeks of active breeding will see these mostly occupied with hatching bees in all stages, while the additional frames given in spreading brood contain only empty comb or comb foundation, so that if the food is given regularly and judiciously the bees

will work with all energy of a newly hived swarm, and the prosperity of the stock is insured.

Manipulating Frames.—The danger arising from careless handling of frames of comb or bees is scarcely realised by bee-keepers. Queens are oftener lost than is generally supposed by being accidentally dislodged from the comb, &c., and of course if such a mischance occurs when a successor can be raised, the loss is perhaps never noticed except in the diminished activity of the stock. For this reason we strongly object to "frame-holders" and such like contrivances.

On opening the hive uncover a few frames by rolling back the "wood quilt" and draw the divider towards the operator (who stands at one end). As each comb is examined return it to the hive, setting it close to the divider, and when the examination is complete all the combs with the dividers are pushed into their original position with one movement.

TRADE CATALOGUES RECEIVED.

John Downie, Edinburgh.—*Catalogue of Roses and Fruit Trees.*
Ant. Roozen & Son, Overveen, Haarlem, Holland.—*Catalogue of New Gladioli, Dahlias, &c.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (J. E., Hackney).—There are no "small gardening books" so cheap nor with such an extensive sale as our Manuals, those on "Flower Gardening," "Fruit Gardening," "Kitchen Gardening," "Florists' Flowers," and "Manures" being each sent post free for 4½d., while the "Greenhouse Manual" and "Window Gardening" can be had for 10d. each.

Back Numbers of the Journal (Stirling).—We have had no inquiries for the numbers you have for disposal, but for some odd volumes between the years 1865 and 1874, as you will see by an advertisement. It is only by advertising that back numbers can be disposed of and obtained, and that method is not always successful, as so few persons need the precise volumes that others desire to part with in the form of broken sets; and this circumstance, too, naturally depreciates their value.

Horseshoe Boilers (G. P., Hants).—These boilers are made in different sizes according to the extent of piping they are required to heat. If you send the size of your house, or the length of piping, to the vendors of the boilers, they will supply you with every particular you need. After our many declarations of not recommending dealers, we are a little surprised that your other question was submitted, and which, for obvious reasons, cannot be answered.

Ventilating Greenhouse (Amateur).—As you are absent from 9 A.M. to 7 P.M., your best plan will be to give instructions that the top lights be opened to the extent of 3 or 4 inches in the morning of a sunny day for an hour or two, closing them about 2 P.M. at this period of the year. On dull days the house may remain closed, as sufficient air will find admittance through the laps of the glass. One drop of ordinary gum is all that is necessary for sealing the petals of flowers, or you may purchase dextrine from a chemist's for the same purpose.

Soil for Chrysanthemums (H. B. B.).—You will not err by mixing the manure with the soil now, and turning the heap over at least once before the soil is used. The quantity of manure to add, also the kinds, depends on the nature of the soil. For very heavy soils horse manure is very suitable, otherwise that from cow stables is preferable, but should not be used in a fresh state. Partially dried cow dung is excellent for Chrysanthemums either for mixing with such soil as needs it or for using in the form of top-dressings.

Lilium Harrisii (C. U., Brixton).—This Lily requires similar culture to that afforded L. longiflorum—namely, a soil of good loam, with a moderate admixture of sand and a little well-decayed manure. It can be grown out of doors, but is much better in a greenhouse or frame, and in pots is very useful for decorative purposes. It can be purchased of any large dealer in bulbs and similar plants.

Bouvardias and Camellias (Idem).—A night temperature of 45° in

winter will be suitable for Bouvardias, increasing 5° in the day without sun. A minimum of 40° will be quite safe for Camellias. Both will succeed in the same greenhouse, assigning the Bouvardias the warmest and lightest position, the Camellias being placed at the cooler end. The fragment of Conifer you have sent is insufficient for satisfactory identification. It is perhaps the Red Cedar, *Juniperus virginiana*, but no one could name such a scrap with certainty in the absence of information relative to the habit of the plant.

Potatoes for Forcing (Cambrian).—There is no better variety for this purpose than the Early Ashleaf Kidney. Many dealers offer special selections of it, and all that we have grown are good. If you prefer a round or pebble-shaped variety they are afforded in the Early Handsworth and Early Coldstream respectively, both of which are very early and suitable for culture in frames. Kidney Potatoes usually have the boldest eye, and produce the strongest growth quite at the apex of the tuber, the eyes in other portions being smaller and producing weaker growths, hence, as a general rule, kidney Potatoes are not cut. Some large tubers are cut, and the divided sets answer very well, but not for forcing in frames.

Lilacs for Forcing (A. B. C.).—We readily answer letters, as you know by previous experience, and the replies are published as soon as possible. We have no letter of yours unanswered, so conclude the package to which you allude did not reach us. We often receive addresses that have slipped off packages in transit through the post, the packages in such cases not coming to hand. If you turn to page 475, our issue of a fortnight ago (November 29th), you will find the information you need—namely, that Charles X. is the best Lilac for forcing; and for producing white flowers the plants must be forced in a dark warm pit or frame.

Small Fruits for Market (J. L.).—It is not possible to answer your question categorically in the absence of any particular relative to the nature of the soil. We can only say that as a rule both Gooseberries and Black Currants are more profitable than Red Currants. If the soil is rather light and the subsoil dry, then Gooseberries would give the best return; if strong and the subsoil more or less wet, then Black Currants would be better adapted for it, and would be the most remunerative. Read the Rev. W. Lea's work on "Fruit-Growing on Small Farms," which can be had post free from this office for 1s. 1d. in postage stamps.

Sea Water (W. J.).—Without saying that sea water would be dangerous for the purpose you name, we should still not advise you to use it, or if you do use it to do so cautiously and experimentally. It contains manurial ingredients of benefit to salt-loving plants, its constituents being chloride of sodium, 2.50; chloride of magnesium, 0.35; sulphate of magnesia, 0.58; chloride of lime and carbonate of magnesia together, 0.2; sulphate of lime, 0.1; and water, 96.54. To plants containing the same constituents in the same relative proportions the water would be beneficial, but not otherwise, and they are not thus present in fruit trees and Vines. If any of our readers have tried the effects of sea water on plants and crops they might usefully state the results.

Mowing Lawns (Norton).—Though it is not uncommon to see lawns cut too closely very late in the season, November for instance, yet, undoubtedly, your lawn ought to have been mown after September at least once, but probably twice, as the autumn has been so mild. The precise time for cutting, however, can only be determined by the condition of the grass. Ours was cut twice in October and once early in November, but not shaved down to the roots, and now is quite smooth and green, as it will remain throughout the winter. Your lawn has been obviously neglected, and requires attention. First of all it should be rolled, but only when the grass is quite dry and the wormcasts also partially dry, so that they will not cling to the roller; then, two or three days afterwards, when the grass has risen, it should be "run over" with a very sharp scythe and cut to about half its length, the cut grass raked or swept off when quite dry and the ground then rolled again. It is important that all this be done in mild and dry weather, and as long as frost and wet prevail the grass must remain in its present unsightly state as a reproach to the contractor who undertook to keep it in good order.

The Stanwick and Stanwick Elruge Nectarines (G. P. and E. D.).—"G. P." is right and "E. D." wrong on the point submitted. They are different varieties raised by different persons, in fact the former is one of the parents of the latter. The old Stanwick was raised at Stanwick Park, one of the seats of the Duke of Northumberland, from stones given to Lord Prudhoe by Mr. Barker, Her Majesty's Vice-Consul at Aleppo, and who afterwards resided at Suædia in Syria. The seed was sown in March, 1843, and the buds were inserted the following autumn on a Bellegarde Peach, and the first fruit was produced in 1846. Lord Prudhoe, who had become Duke of Northumberland, placed the Stanwick Nectarine in the hands of Mr. Rivers of Sawbridgeworth for propagation, and on the 15th of May, 1850, the stock, consisting of twenty-four plants, was sold by auction, and realised £164 17s., which His Grace presented to the funds of the Gardeners' Benevolent Institution, such an amount never having been realised before for the same number of small Nectarine trees in pots. The Stanwick Elruge was raised from Elruge crossed with Stanwick, and is one of the seedlings of Mr. Rivers. It is a delicious Nectarine, the tree bearing small flowers, while that of the parent Stanwick has large flowers.

Planting Roses under Glass (X., Loughgall).—The house of which you send a diagram appears admirably adapted for Roses, but you have neither stated its length nor width. If it exceeds 25 long and 12 wide you may train a Maréchal Niel or other climbers like Vines at 8-foot intervals, and then there would be light enough for dwarf Roses below, and for the plants that you may train to the back wall; but if the house be very small the roof had better be kept clear, 6 inches of stones for drainage, the stones protected with turf, and a good outfall provided for the escape of water will suffice, and a depth of 2 feet of soil should be afforded. Whether or what additions your loam needs depends on its character; but you can scarcely err by adding wood ashes and gritty matter pretty liberally to insure porosity, and a seventh part of decayed manure would also probably be advantageous. See what Mr. Luckhurst says on preparing soil for Roses, and enriching it on page 501. His remarks on that subject apply in your case.

Mushrooms in the Open Air (L. L. B.).—January is a very good time for collecting manure for Mushroom beds, but for the north of England and cold districts generally the end of the month would be preferable, as then by the time the material was prepared, made into beds, and spawn inserted, milder weather might be expected, and it would be easier to maintain the requisite temperature for the growth of the crop. According to the price you quote, the manure must be considerably more decayed than that collected from the London stables, and some of it may indeed be fully too short and wet for the purpose in question. The price would appear to indicate that the manure was about in the right condition for digging into the land. Assuming, however, that it is only partially decomposed and suitable for the work, about half a ton would probably suffice for a yard of bed, this being as nearly as can be estimated what Mr. Barter uses after his material is prepared. It is quite possible with suitable manure and good management to grow Mushrooms profitably under the conditions you quote, but labour must be well applied, not wasted. In our report of the Liverpool Show, a fortnight ago, on page 473, it is stated, "Mr. Smith, Maiden Lane, Clubmore, Liverpool, had baskets of Mushrooms grown on the principle recommended in 'Mushrooms for the Million.' They were very fine and excited much attention." Perhaps Mr. Smith if applied to might grant you permission to see his beds, and if so you would obtain practical local information on the subject that might be of service.

Temperature of Mushroom Beds (Amateur).—It is rarely indeed safe to insert spawn in a Mushroom bed as soon as the bed is made. The heat of the bed often rises afterwards to a degree that is fatal to the spawn, which should never be inserted until the temperature is "decreasing." See page 44 of "Mushrooms for the Million." Still, if you can keep the temperature of the bed under the covering at 65°, by reducing or increasing the straw or hay, all will be well. This is before the soil is applied. The temperature on the soil should not exceed 60° for a month, and then when the Mushrooms are appearing 55° will be ample. Read the chapter on "Temperature" on page 49 of the work mentioned. The covering of the beds should not be packed firmly, and its thickness must be solely determined by the heat of the beds. By attention to this point it will not be necessary to add fresh manure to increase the heat. You have gone quite contrary to instructions in spawning and casing your bed with soil so soon, and if you fail the fault will rest entirely with yourself. A work on the culture of Watercress by Mr. Shirley Hibberd is published by Messrs. E. W. Allen, Ave Maria Lane, Paternoster Row, but we do not know whether it gives the particulars you require.

Digging Frozen Soil (Blacksmith).—Of all the mistakes that are made in gardening operations this certainly ranks as one of the greatest. We have seen such unsatisfactory results follow the trenching and burying of frozen soil that we would not have it done on any account, not even free of cost, if such an unlikely offer were made by generous workmen. We have seen considerable outlay incurred in trenching, and the ground when done worse than before, both by turning in frozen soil and bringing to the surface a large quantity of sour inert subsoil. Even when the soil has been in the most fertile state we have seen crops struggling for existence that ought to have been luxuriating, solely because frozen lumps of soil had been buried in the winter; and in demonstrating the cause of the failure of the crops we have dug out those lumps hard and icy as ever after mid-summer. Trenching need not be stopped by a slight frost which forms a surface crust of an inch or so deep, and which can be readily broken; but this crust must never be cast into the bottom of the trench, but taken off and thrown on the top of the land; and if a little subsoil be brought up it will be greatly improved by being mixed with the original surface soil by forking the land over when it is dry and friable in the spring. When frozen ice is buried the sun cannot raise the temperature of the soil until the ice has been melted and the excess of water evaporated; consequently, instead of the temperature of the earth a foot below the surface at mid-summer being about 58°, it might not, under the circumstances indicated, exceed 40°, and therefore nothing could grow freely. It was undoubtedly wise to stop the work when the ground was made hard by frost.

Forcing Potatoes (Alex).—A bed of fermenting materials formed principally of leaves about 3½ feet high will be sufficient for affording gentle warmth. This should be covered with 8 inches of soil made tolerably firm. The soil should be rich loam, light rather than heavy, and when it is a little warmed you may plant the Potatoes in rows 15 inches apart, and the sets a foot apart in the rows, placing them 4 inches deep. Radishes may be sown over the surface, and the seed be either raked in or covered with half an inch of soil. All the treatment required is to expose fully when the weather is mild, and protect from frost by mats and straw coverings in frosty weather, not removing them in continued severe weather until a general thaw. If you can command an abundance of protecting material commence at once, but if not we should defer planting until early in February, in the meantime having the sets in a suitable place to sprout. When they have pushed shoots from one-half to three-quarters of an inch long you may plant.

Names of Fruits (N. W.).—Formosa Pippin. (J. C.).—1, a poor specimen of Bess Pool; 2, unknown; 3, Flanders Pippin; 4, Beauty of Kent. (W. Nield).—1, Golden Noble; 2, Collini; 3, Greenup's Pippin; 4, Flanders Pippin. (J. A. W.).—Sorry we are unable to identify the Apple. (D. B.).—We have received your letter, but no Apples beyond those above attended to.

Name of Plants (G. S.).—Raphiolepis japonica integerrima, a greenhouse shrub. (Beta).—We cannot recognise the Chrysanthemum blooms, and do not undertake to name such varieties. (H. W.).—The flower sent resembles Trichopilia albida as far as we can tell from the small and withered sample received.

THE BREEDING AND TRAINING OF MULES FOR FARM WORK.

VERY few farmers have given their attention to breeding and training mules for agricultural purposes; in fact, in this country generally, except in parts of Ireland amongst the smaller class of farmers, mules or donkeys have been looked upon with contempt or ignored entirely as animals adapted for farming purposes. It may also be imagined by some of our readers that there is little to learn respecting the agricultural value of these animals. But when we consider that their use is adapted for various purposes in almost every country and climate, it is only a reasonable question to ask how it is that so little attention has been bestowed upon them in the United Kingdom, except in portions of Ireland. Still, although mule-breeding has not yet obtained the notice it really deserves, we are informed by the best authority upon the subject that it certainly is on the increase in Ireland, and particularly in the counties of Cork and Kerry, for a great number of jennets are raised annually, preference being given to the latter hybrid, because the high prices of Irish horses render mares too valuable to be used for the production of mules. Even this reason, we believe, would not exist if the same knowledge of the subject prevailed in Ireland which influences the most intelligent and practical breeders on the Continent.

The social history of the donkey is somewhat singular, for while in some countries he is the favourite steed of the higher classes and valued accordingly, yet in others he is the beast of burden and the drudge of the very lowest. Yet in order to judge of his capabilities we must first see him in his native home, and to do this we cannot do better than quote from an excellent essay by Mr. J. Chesney, the subject being "The Donkey as he is, and as he ought to be." "The wild ass (*Asinus onager*) is met with in large herds under their respective leaders in the plains of Mesopotamia, in Persia, Cutch, on the Indus, and in the Punjab, migrating from north to south, and vice versa, according as the seasons change. In Abyssinia, too, there were wild asses, probably the ancestors of the present Egyptian, and some contend of our European breeds. However this may be, these animals are extremely difficult of capture, as they are excessively shy; and Layard tells us that their fleetness is so great that only the most celebrated Arabian mares have ever been able to match them. The koulan or onagra is finer than the domesticated animal; the head is more erect, the ear shorter and more mobile, the limbs longer and more slender, and the coat and tail handsomer. It is quite possible that the European donkey may be descended from that of Abyssinia, as M. Sanson, in his 'Traité de Zootechnie,' asserts very positively, and probably on good authority, that it came to us from the adjoining country of Upper Egypt. There were donkeys in England in the time of Ethelred, but they do not seem to have become common here before the reign of Elizabeth."

These statements will give people an idea of their power of endurance and great strength according to size. Again, it is very clear that whatever were the capacities of these animals in their native countries in the wild state, it gives good grounds for our

endeavours to breed them, and mate them so as to produce not only animals of a certain type and style, but also to obtain the size we require for agricultural purposes. These objects have not only been attempted, but attained on the European Continent and in America. The power and breeding of these animals arises not only by selection as to size and various points, but by pedigree; and, like the breeders of various animals in the present day, such as cattle and horses, the Arabs and Persians know the pedigrees of their asses, of which they have several distinct races. In fact, among all the south-western districts of Asia as much attention is paid to this animal as we give to the horse; for in Arabia it is stated that the ass is used much more for riding than for carrying heavy burdens, wealthy people prize them on account of their easy pace. The animals of the finest breed, which is reared in certain eastern countries, stand about thirteen hands high, and are pure white, having a pace very nearly equal to that of an average horse. It is known that these animals are often sent to Egypt and Constantinople, and sold at from £40 to £80.

We have now to look to what can be done in England, taking for illustration the Poitou mule. Of the industry displayed by breeders in the province of Poitou an account was given from Mr. C. L. Sutherland's review of the farming in France, in the *Live Stock Journal* of July 29th, 1881. We will, however, make a few remarks relating to the effect of food and climate, not only on the well-doing and capability of the animals, but also as to its effect on growth and the ultimate size and power of the animals. The fact is, however, established that want of care in raising the young and poor food has more to do with diminution in their size than the results of climate; for in the north of India, where the donkey is used by the lowest castes, and consequently is much neglected, it does not sometimes attain a height much greater than that of a large Newfoundland dog. In Kentucky, where great attention has been paid to it for the purpose of mule-rearing, some breeders have been able to bring their animals to an average height of from fifteen to sixteen hands. These seem to be extreme views of the case, and some parties may consider them more or less exaggerated; but as this is taken from one of the best authorities upon the subject, it should act as an incentive in our endeavours to rear and train the best style and type of mules for agricultural purposes. There can be no question but that the farmers of the present as well as of the future may be able to produce animals capable of undertaking, in pairs, all the tillage required on the light and friable soils of the different parts of the kingdom. They may be made to supersede the horses now in use in part at any rate upon many small farms, and may also at the same time be made a profitable stock for breeding and rearing on certain farms both for use and for sale. We hope to make this opinion more plain to our readers when further on we take up this part of our subject, giving our plans of proceeding and compare them with those of the most successful breeders on the Continent, and more particularly of the American breeders. For of the latter we find that they have succeeded in rearing exceptionally large mules with an acceleration of speed and power for draught as well as pace in proportion to their size; and as we shall require not only strength, speed, and good shape to recommend them, but also increased height, we must do as the Americans have done, for our climate is as good for breeding this race of animals as theirs is. We must not only obtain animals having all the qualifications necessary, but also use great attention afterwards in selecting such of their descendants as we intend to breed from.

(To be continued.)

WORK ON THE HOME FARM.

Horse Labour.—During the last week of November and the first few days of December the seeding for Wheat has been continued, with the land in favourable condition, and various strong soils on which it was feared that the land could not be sown until the next spring some progress has been made by sowing the Wheat in fair condition, and certainly in better condition than large areas were put in last year. On dry friable land, however, after roots fed off by sheep, and also where the roots were ploughed under, the land has been daily ploughed and sown simultaneously, and certainly with a fair promise of obtaining a full plant should an average winter occur as regards weather. In most cases where the Wheat-sowing has been finished the horses will be employed in the delivery of corn sold, also in those cases where hay and straw have been sold the delivery of these articles has been going on. On many farms that are occupied under existing leases the tenants are not allowed to sell either hay or straw unless the value of what has been sold has been laid out in the purchase of town dung or oilcake for feeding stock, or otherwise in artificial manures. Much land has, however, been recently let giving the tenants full liberty of sale of any produce adapted to the soil, the only conditions being to keep the land clean and free from couch and other obnoxious weeds. Many of the landed proprietors have submitted to conditions enforced upon them by the tenants, or resort to the only alternative of occupying the land themselves, and to this there are many objections; but under fashionable farming so much capital is required for the purchase of stock and the difficulty of finding men (except at a high wage) to conduct the business of the home farm; and although there are numerous parties who have

failed in farming during the recent adverse seasons, such men if they undertake the system of home-farm management frequently do not succeed from causes too numerous to mention. Many, too, of the most enterprising of this class have emigrated, and thus reducing the number of eligible men to whom can be entrusted the entire management of a home farm, especially those of large acreages. One word to the landlord may, however, not be amiss, for the writer would say, Do not let the land if a good man can be found to manage an untenanted farm, for we have noticed that it is often very difficult between two evils to choose the least; but a bad and designing tenant, and we speak from some experience on the point, is certainly more injurious to a landed estate than a bad or untrustworthy farm manager, who may be changed at short notice if engaged under such conditions as give security.

Hand Labour.—Some men will be employed by filling carts with earth adapted for the flooring of cattle pens of every kind, as well as stables for horses, the earth to be removed when laid in pens where animals are tethered; but in all cases where box accommodation is afforded either for cattle or horses the earth may remain as an absorbent of urine, and prove valuable as a manure on the farm. The earth adapted for this work may be found on many roadsides or boundaries of fields, and may be stored by placing it in an elongated heap like store heaps for roots, and kept dry in the same way, being thatched with the roughest of straw or border trimmings, so that it may be dry when required for use, and it will then be absorbent enough to answer every purpose to which we have referred. Meadows should now be trenched, and no cattle allowed in them until the land is firm for feeding or laid up for a hay crop. Draining may now be done; but in the enclosed districts we advocate the grubbing-up and removing of fences and draining the ditches. This will prevent the endless labour required to keep them decent fences, and maintain clear outfalls for heavy rains.

Live Stock.—The Down flocks will now be ready to commence lambing, at least the Dorset Downs, and some Hampshires where they had been mated with the ram early and fed with liberality; and it will now be advisable to look out a sheltered spot to serve and be used for a lambing fold. In some cases, however, the shepherd lives near to a shed and foldyard, and it is a good thing when it happens to be available, because the shepherd, if he understands and attends to his business is, in the midst of the lambing season, obliged to look to his ewes day and night; and in the management of flocks of considerable size there should be an under shepherd to assist both day and night, and take his turn on the watch for those animals requiring the shepherd's assistance. It is well also that as shepherds are valuable men and require tuition for their duties, that there should be younger men in training, for the work is not only long hours and actual work required of them, but a knowledge which can only be gained by actual practice under the guidance of a superior and experienced shepherd. The home farmer, too, has also a duty to perform, not only to take care that the shepherds understand their business, but insist upon its being done under his directions during the lambing season. Now, the foldyard and lambing pens should be situated on a dry spot, if possible in a sloping position facing the south, and the floor of the yard should be covered about 9 inches thick with dry loamy earth. This will afford good lying, and require also less littering with straw; and the manure arising will be more valuable for removing after the lambing is over.

THE SMITHFIELD CLUB SHOW.—We are informed that Messrs. James Carter & Co. of High Holborn, Sutton & Sons, Reading, and Webb and Sons, Stourbridge, have splendid stands of roots and cereals at the Show. We have not the slightest doubt of their excellence. The root and seed stands exhibited by such firms as these are, we believe, unequalled in any country; but as the Secretary has again omitted to send us tickets, we are unable to give any exhibits such notice as they are entitled to. We learn that the Prince of Wales visited Messrs. Suttons' and Carters' stands for the purpose of examining the ensilage from the silo of Lord Walsingham, and the fine roots grown on Her Majesty's farms at Windsor and elsewhere.

PRUNING AND DRESSING GRAPE VINES.

THE time is at hand when innumerable growers will commence pruning and dressing their Grape Vines, and I propose to offer a few remarks upon both operations. It may be thought by some that enough has been written upon the subject, and if I were in the habit of constantly staying at home I, too, might be of the same opinion. As it is I hold that gardeners should be encouraged by their employers to visit one another in reason, as they are thus less likely to become self-conceited, and are more disposed to strive to excel in horticulture generally, and Grape culture particularly. If, however, in our rounds we discover that there are others who can excel us in certain branches, we also take a particular pleasure in noting where they apparently perpetrate mistakes. Many gardeners still need a lesson in pruning Vines and yet more amateurs, several of whom know next to nothing about it. The greatest mistake is to treat all Vines alike. Everything should depend upon circumstances. If there were no other sorts but Black Hamburgh and Sweetwaters I should still say the same. Those in the best possible condition will produce plenty of bunches, prune them how you will, but to closely prune old weakly Vines in order that no spur should be formed would result in the formation of few bunches, especially, as I have tested, if the lateral growth be badly ripened. In such a case I would not prune at all, as among other reasons I should feel certain of losing what little sap the Vines had in store. I have proved, to my own satisfaction at any rate, that it is better to disbud Vines badly ripened, and therefore badly rooted, either as the buds move in the spring, or, better still, with the point of a knife, before the leaf falls in the autumn. Here, for instance, our Vines of Muscat of Alexandria would not ripen their growths properly. Close pruning resulted in the production of but few bunches, but by disbudding we obtained more than were required. Some of the old unripened growths were still green in the autumn, and were cut and forwarded to the office of this Journal, as well as a bunch of Grapes cut from laterals produced from the back buds of these same growths. In fact, the majority of the old closely disbudded growths were quite green at the tips when cut off in the summer, and I am inclined to think that by preserving them, in addition to preventing loss from bleeding, they also served as miniature sap-reservoirs, and assisted the bunches at a time when assistance was most needed.

The spur system of pruning is that most generally popular, and even this is variously practised. Some cut to the best bud nearest to the main stem, under the impression that a good plump bud means the ultimate production of the largest bunch, when in reality it more often results in the formation of two fruitful shoots, and in this case no gain is evident. Others, in fact a much greater number, cut to the second bud from the rod, and this has been my practice for some time, as I thought that the small leaf invariably formed at the base of laterals could not possibly

perfect so valuable a fruiting bud as the first larger leaf beyond. No long unsightly spur resulted from this practice, as two shoots were generally laid in, one springing from the basal bud forming the foundation of the next season's bearing wood, while that which fruited beyond with the short piece of old wood attached was cut clean away. Many cut to the first or basal bud, and when the Vines are moderate growers and in good condition, always secure abundance of good bunches. There are others, and these, I believe, are fewer in number, who invariably cut the growth close at the junction with the main rods, and in one instance that has come under my notice good bunches have for several years been secured from buds which were certainly not produced at the axils of any leaves. This I shall term the painfully neat system, being practised by those who object to "ugly spurs." I, too, object to such cankered spurs, and for more reasons than one; but rather than run the risk of securing comparatively small bunches or perhaps only a partial crop, I would leave a long spur, and if this became an eyesore I would annually in the autumn saw a few off, so as to gradually restore the whole length of rods to a better condition. If from want of vigour they failed to break afresh, I would lay in new rods and cut the old ones out. In fact I believe there are numbers of old Vine rods that ought to be so treated and their places occupied with healthy straight rods, and we should then hear fewer complaints of indifferent crops.

Now in pruning are we to consider that a bud must be perfected by the assistance of its own particular parent leaf? It would appear not, or how is it my friends can continue for several years to obtain good fruiting shoots when they always cut every visible bud away? It must be understood I am of the opinion they would have secured much better bunches if they had left one leaf-developed bud, and this I am confident they will perceive next season. All buds are of course formed by the assistance of the leaves, but whether the shoots resulting shall carry a bunch, and whether that bunch shall be large or small, is, I firmly believe, entirely determined by the amount of stored-up food, more especially above ground, and consequently, as a rule, very little is gained by selecting and pruning to large buds. Let those who doubt this try the following experiment: At pruning time reserve a few ripened laterals their full length, shortening others to three or four buds, and others again to the first bud. Unless I am much mistaken those left at their full length will push out three or more shoots according to the vigour of the Vines, the end one bearing one or more strong bunches, the next fewer and smaller bunches, and the remaining shoots perhaps without any bunches. Similar results follow where three or four buds were left, while the single bud will produce as large a bunch as that at the end of the full-length lateral; always supposing that no old knotty spurs are selected for the experiment.

There are, however, exceptions to this rule. For instance, if the Vines are extremely vigorous growers, or such as Golden Champion, Duke of Buccleuch, and Canon H Muscat, we may err greatly by close pruning. It is in this way, if we cut a young vigorous rod hard back, the excess of sap concentrated in a single bud results in the formation of a strong bunchless shoot, whereas if we had left a considerable length, several shoots carrying as many bunches would in all probability follow. This inclines me to the opinion that the circumstances are somewhat the same with gross "shy bearing" sorts, and in pruning the above long spurs should be left, say with four or more buds, and also that close pruning is also the cause of "shy bearing" in the case of other sorts when comparatively young and vigorous. In pruning, then, I would cut Black Hamburgh, Sweetwaters, Frontignans, Madresfield Court, Muscat of Alexandria, and Muscat Hamburgh to the first discernible bud. Stronger growers, such as Black Alicante, Golden Queen, Mrs. Pearson, Gros Colman, Gros Maroc, Raisin de Calabria, White Tokay, Syrian, Mrs. Pince, and West's St. Peter's

should have two, or, if extra strong, three buds left; while Barbarossa (Gros Guillaume), Duke of Buccleuch, Golden Champion, and Canon Hall Muscat should have four or more buds left, according to the vigour of the Vines. By rubbing out all the shoots but those at the end and base of the spurs the latter may be converted into a bearing spurt next season, the other with old wood attached being cut away with the bunches. No long unsightly spurs thus result. In all cases, more especially where two shoots are laid in, the spurs should be wide apart, say not less than 18 inches on each side, and alternating, as this allows of the back shoot being properly developed.

In shortening young rods in any case where strong, say $1\frac{1}{2}$ inch in circumference, I would leave a length of 8 feet—that is, if there is so much space to furnish, while the very weak ones, say half an inch in circumference, should be cut back almost to the starting point, and others in proportion. The harder we cut strong shoots the grosser they become, and we do not want pithy rods; but as we are equally averse to weakly rods, we prune weakly shoots hard in order to induce the formation of a much stronger rod. I may be taken to task for recommending the preservation of so great a length of young rod, but I could point to a grand range of vineries where the occupants were treated in the orthodox manner—that is to say, were cut hard back after making the first strong growth, and were subsequently taken up the roof by short stages, yet in spite of everything have never satisfied the grower, and never will till the over-fatted rods are replaced by younger and more woody canes. One of our most successful Grape-growers, before he could satisfy himself and employer, had to gradually supplant similarly pithy old rods with younger ones, and with these two examples before me it is not surprising that I hold the above opinions.

Bad pruning has never to my knowledge ruined any Vines, but careless winter dressings have done so in a surprising number of cases. We are naturally anxious to clear the rods of any insect pests that may have established themselves on them, and in our anxiety we sometimes err on the wrong side. Fortunately the old barbarous practice of closely scraping the rods, and then dressing with a mixture of various obnoxious and destructive materials, is now fast becoming obsolete. At the same time I consider that those who recommend the more simple remedies should bear in mind that all are not acquainted with the dangerous properties of some of them. To be effective they must be strong, and a careless and too zealous operation may easily work irremediable harm. Poisons in the hands of those experienced in their application are of great medicinal service, but no novices are allowed to buy them without being cautioned, the bottles or packets being also labelled “poison.” Now paraffin or petroleum is the gardener’s greatest friend in the way of insecticides, but this in some people’s hands may prove a most destructive agent. Consequently, if not exactly labelled “poison,” it should have its dangerous properties well pointed out by those who advocate its employment. Mr. D. Thomson, who was the first to recommend its use, never neglected to suggest that it should be used with the greatest care, and he once strongly advised me not to use it on Vines, owing to the porous and absorbent nature of their bark. Others recommend it as a winter dressing for Vines, and not a few have suffered by partially following their advice. A rod barked and closely scraped, and when this is done even some of the newest bark is almost unavoidably cut away, may easily be damaged by paraffin and other penetrating insecticides, but where the bark has never been removed the former may, perhaps, if used at the rate of 2 ozs. to the gallon of soapy water and kept well stirred, be a safe remedy; but, all the same, I would not use it. I have never experimented with it, but have seen quite enough of other people’s experiments to warrant me in condemning paraffin for Vines.

Prior to dressing the rods with an insecticide it may be advisable to lightly trim off some of the very roughest of the

bark, but as a rule the less this is touched the better. Once we thoroughly “skin” a Vine rod it seldom if ever renews the bark in a satisfactory manner, but remains in a smooth state, and in all probability the rod will cease to swell properly; in fact, this stripping off the bark is altogether an unnatural proceeding. If the Vines this past season have been infested with red spider, and also in the case of mildew, a dressing may be formed with sulphur and soft soap. Take two large handfuls of flowers of sulphur, place in a piece of muslin, and squeeze and work it through in a gallon of warm water in which a lump of soft soap rather larger than a hen’s egg, has been previously dissolved. To this may be added two gallons of warm soft water, and to which, if there have been any thrips on the Vines, should be added at least one pint of tobacco water, the whole being kept well stirred and applied with a syringe, in this manner being more thoroughly and quickly used than with a brush. When dry a second washing may be given, and in the end this will be found a safe and effective remedy.

For mealy bug, gas or coal tar is the grand remedy. For appearance sake it is advisable to mix it with clay, the latter being worked up with the hands in a little warm water and all the gritty portion thrown out. The tar must be added in equal proportion to the dissolved clay, and if then too thick to be easily and thoroughly applied with a brush more water should be added. The tar should not be heated as in this case; it might be penetrating and dangerous. It should be kept well stirred, and the rods and spurs thoroughly coated with it, taking care not to cover the buds, or if the Vines are weak the buds may not burst through the cases formed. No injury, to my knowledge, has ever accrued to the Vines from this tar dressing, and this is the experience of several well-known gardeners who have used it much longer than I have. All other presumably infallible remedies failed with our badly infested Vines, but the tar destroyed all but a few insects, and these were easily disposed of before they had increased. By way of a preventive the following winter a second dressing was given, and now the vineries are completely free from mealy bug. Every vinery should be thoroughly washed down and the walls whitewashed, thus destroying many eggs and insects, besides preserving a clean appearance. All the ironwork and much of the woodwork of the houses infested with mealy bug should be painted with raw paraffin, this destroying all insects and eggs with which it comes in contact.—W. IGGULDEN.

DELPHINIUMS.

THESE are among the most valuable of all hardy flowers for the mixed border. Of course I refer to the hybrid varieties, albeit I entertain a high regard for all the so-called species, which are all more or less showy, but are by no means so effective as the majority of the now very numerous forms which have been raised from seed obtained by cross-breeding, a matter most easily accomplished. No flowers are more easily cross-fertilised by insects, as they hold forth the duplex attractions of nectar and colour, and in addition the stamens shed the pollen before the stigma of the same flower is matured, so it is almost, if not quite, impossible for such a flower to be self-fertilised. And this easy method of cross-breeding readily accounts for the numerous varieties which are now obtainable from florists who make hardy plants a speciality.

Most of them are robust and very free-flowering, a few are weakly, and should be planted in such positions that they may have a fair share of attention. In order to have them in the greatest luxuriance rich soil is necessary, with a good depth of it. I have never seen Delphiniums in finer condition than at Mr. Joseph Stevens’ at Byfleet, Surrey, in what he was pleased to call his variegated garden, because the majority of the plants therein grown were more or less variegated. In a long border was a magnificent row of excellent varieties growing most luxuriantly, and a very noble and effective appearance they presented. But the success was due to a deep rich soil, well worked before they were planted, and nothing more is required for some years, indeed not till the plants require dividing. Therefore where they are planted the preparation should be accomplished as for a permanent purpose, deep digging or

trenching, with a liberal supply of decayed manure well incorporated with the soil. It is needful to prepare the position assigned them after a similar fashion, in order to insure the best results, for no plants will better repay for liberal culture than these, and perhaps none will present a more miserable appearance when ill-fed and treated. Had I only one variety to plant I would prepare for that most carefully.

Their worst enemies are slugs, the small black leathery kind being the greatest depredator. Working under cover of night they eat the young buds during the winter and early spring, and you wonder why they do not shoot, but upon examination the shoots are entirely consumed. This has been a great source of vexation to me, especially when planting on fresh ground. The best remedy I have found is a mixture of lime and soot laid closely about the plants, renewing it every week or fortnight. Such a dressing assists the plants and checks the enemy. I need hardly say any more respecting the value of Delphiniums for effect either in masses or as isolated specimens; but a word as to the period of flowering. Unless it is desirable to save seed the main stem should be cut away as soon as the flowers are past, and a chance will be given for the numerous laterals to grow and thrive, for a second crop of flowers will be quickly produced, and as soon as these are past cut the whole away, and there will be ample time for a second lot of stems to be developed and flower before the end of the season, and thus a considerable display may be had by judicious management. For lines or masses in the mixed border, or intermixing with shrubs in association with tall Spiræas, Hollyhocks, &c., no plants are more highly effective. One of the prettiest pieces of garden decoration I saw last summer was some broad masses of Spiræa Aruncus with their large plumose panicles of white flowers, and intermingling therewith pyramidal groups of light blue Delphiniums, the whole backed with some Copper Beech—a picture which is not often seen and not easily forgotten. Below is a selection of good varieties both double and single, and I have not included any of the species, although, of course, some of them, such as the old *D. formosum*, *D. grandiflorum*, &c., are very attractive and vigorous.

Single Varieties.—Agamemnon, very large; Amabilis, Barlowi, versicolor, deep and bronzy; C. Glyn, Enchantress, light azure blue, similar to the charming old *D. Belladonna*, but much larger flower and more robust constitution; Madame Chute, Mammoth, Nobilissimum, the latter one of Mr. Parker's seedlings, producing an immense pyramidal spike; Pantheon, Phoenix, Roi Leopold, Voltaire, and Wheeleri, the last a dwarf and very showy variety.

Double Varieties.—Amadée Hans, Arc en Ciel, an extremely pretty form; Figaro, Globe, very double; grandiflorum plenum, one of the rarest and handsomest; Hebe, very floriferous and full; Hermann Stenger, dwarf, free, and showy; Louis Figuier, Lord Mayor, a vigorous grower and effective; Madame Henri Jacotot, Madame William Schwab, M. Rouillard, extremely pretty, pale lilac edged with sky blue; Nahamah, dwarf and showy; Palmerston, one of the noblest; Pompon Brilliant, very dwarf; President Simon, rich cobalt blue, grand spike; Suffrage, Triomphe de Poissy, bright azure blue, pink shaded, one of the best; Victor Lemoine, double, pale blue, with a distinct white centre; this is also one of the best.—T.

FIRING AND VENTILATING.

I WAS pleased to notice Mr. McIndoe's experiment in growing early Melons without ventilation, and although the results achieved were, it must be admitted, highly satisfactory, I am not by any means clear about the non-ventilating system. First, it is obvious that under ordinary circumstances very little ventilation would be needed between the 27th of December and April 14th. The first three months of 1883 were not remarkable for sun, though it was mild and open in February, with a fair amount of sunshine, yet the need of ventilating houses in which a high temperature was maintained was not appreciable; and in March and April it was, I fancy, so cold and sharp that no one would care to admit air direct to the tender foliage of plants being forced. So far, indeed, from Mr. McIndoe's experience proving that ventilation is not necessary for Melons, it only goes to show the propriety of not admitting external air when it is likely to injure the plants.

Experiments, indeed, made at a season when every cultivator is careful to keep his plants and the tender foliage of early-forced fruit trees as much as possible from the baneful influence of an external atmosphere is clearly not the point, for ventilation cannot be given without great risk, and the necessity for it is not apparent any more than the opportunities are frequent between December and April generally.

It would be more to the point if Mr. McIndoe were to give us his experience in growing Melons and Cucumbers from April to June and from July to September inclusive. Usually there is plenty of opportunity

to admit air from March to October, but what need is there to give any when the sun's power is so feeble as not to raise the temperature in a Melon house above an ordinary outdoor summer maximum? Truc, "the thermometer on bright sunny days indicated a temperature of from 100° to 110°," but these are extremes, and could only occur on rare occasions, unless the climate where Mr. McIndoe practises is different from my part of Britain between December and April; but as we are promised some notes on the early forcing of Peaches and Nectarines with a minimum of ventilation, I hope to have some of this uncertainty removed.—G. ABBEY.

SHRUB PLANTING.

THE planting season comes round with unfailing regularity. On estates with large shrubberies valuable specimens will in course of time either overgrow the space allowed them or be crowded by their neighbours. Cutting the shrubs is the easiest way to mend matters in such cases, but this does not commend itself to everybody. Removal is then the only means of saving them. Another common reason for transplanting shrubs is found in the fact that severe winters kill or render unsightly prominent specimens on lawns or in clumps. Alterations in the grounds occasionally also cause much extra labour in shrub-planting.

Though there is perhaps in the majority of cases no better time for undertaking this work than in late autumn and early winter, it nevertheless most often happens that gardeners have to take it in hand when they are able to do so, without taking into consideration whether one period is better than another. At the same time if the work is carefully managed the planter is quite independent of seasons. There is a very great allowance to be made as to the nature of the soil in which the shrubs are growing, but in no case do we find extra labour or care in transplanting misapplied; indeed it might be laid down as an axiom that the greater the care taken in the removal of shrubs the less trouble will there be afterwards as regards watering in dry weather.

First as to the planting and management of nursery-bought plants. In purchasing shrubs there are some points worth attention, and one of the most essential is to see they are of the size and quality wanted. Anyone who has not had experience in buying these could not imagine the differences to be found in nurseries. The lists of names, sizes, and prices may be very much alike, but on examination the sizes and quality of the shrubs will be found to vary considerably. Taking for examples such as Box, Yew, and Laurels, it is no uncommon occurrence to find them described as being, say, 3 feet in height, yet one-third of their length is represented by a single growing shoot, and the under portion cramped into narrow proportions by the other occupants of the beds. On the other hand, I have found shrubs catalogued in the same way represented by specimens almost as much in diameter as they measured in height, with abundance of healthy roots. Though there is a difference in the price in the two qualities, that does not amount to much, and in the one case effect is obtained at once with almost an absolute certainty that no losses will follow, while in the other at least a couple of years would be required to grow the shrubs into a proper form and size, besides the risk of loss in the transplanting at the time of purchase.

With Conifers even more caution is necessary. The size of the plants does not vary so much with these, but the roots do considerably. The trees which have been often transplanted and not crowded in rows are the best. Another point is to select shrubs which are not too large. Large plants are very much more expensive in the first instance, and no matter how well they are treated they do not make the progress that smaller plants do.

In the preparation of the ground, as much must be left to judgment as to local circumstances. Draining is a first necessity in soil that is wet, as shrubs grown on dry soil are more hardy than those in damp positions. Then if beds of shrubs are to be made in highly kept pleasure grounds, and choicer kinds employed in the furnishing, it must be considered which is the best way to prepare these beds. Trenching is generally considered of primary importance, but I have an opinion that trenching very often does more harm than good. Providing the subsoil is a kindly one, trenching as commonly practised may be beneficial, but I prefer to merely loosen the under spit with a fork or a pick, and keep the upper spit on the surface. When making alterations it is sometimes possible to remove portions of bad subsoil, filling the beds with good soil in the place of that removed. The practice of banking beds up with soil is one I do not follow and do not recommend, though it is one way of getting a good body of soil together in which to give the shrubs a start. When the turf is merely dug over on the surface the shrubs have a store of food, which is better than trying to enrich the soil with animal manures, but these are of great value placed on the surface after planting has been finished.

Much after-labour in watering is saved when the planting has

been carefully done, so that the extra expense of doing the work well at the time is really a saving in the end. Shrubs sent from nurseries by rail are sure to have much of the soil shaken from the roots in course of transit. I have seen planting so mismanaged that these roots were huddled round the ball and the soil roughly firmed round them. The best way is to dig a hole large enough to allow all the roots to be extended at full length, then place some light material over these and all round the ball as well. Leaf soil is one of the best materials for this purpose. I prefer in most cases not to mix the natural soil with any leaf soil that may be thus employed. Its main use is in causing the plants to form young roots quickly, and this is best attained by a good dressing placed next to the older roots. The soil when filled in must be firmly trodden down, always taking care not to press on the ball. A stick, or if necessary two or three sticks, should be used in supporting each shrub as planting is finished.

When the shrubs are merely for screens or divisions there is no necessity for either digging or trenching the ground. A setting of green grass is much to be preferred to bare soil. If the grass cannot be kept cut as often as is wished, it does not look so untidy at the worst as badly kept shrubbery beds. The way we proceed in planting shrubberies on grass is to first take the turf off each place in which a shrub is to be planted, then the soil is taken out to about a foot in depth, and that below is loosened; the roots are spread out in the same way, and the planting otherwise managed as noted above for planting in dry beds, only the hole in this case is made larger than the roots extend, an average of 9 inches all round being allowed. The turf is laid back into its place as planting proceeds. As giving an idea of the quantity of soil introduced, I may instance that one with a ball, say 18 inches across, and roots extending $2\frac{1}{2}$ feet in all, would require from one to two barrowloads. In watering it is much better to give more than is required early in the year, when it may be wanted to start root-action, than to wait till the condition of the shrubs shows that water is needed in order to keep them alive. Some notes on transplanting large shrubs must be left till another opportunity.—B.

RENTON'S MONARCH LEEK.

HAVING seen the above-named Leek grown at Lees this year, and admired it very much, I venture to think a short description of it might be of some interest to Leek-growers in general. I understand that this is the fourth year since it was raised by Mr. Renton, the present gardener at Lees. It is a cross between the Rouen and Carentan Leeks, both very good in their way. Its leading features are quick growth, length of white, and splendid flavour. It also stands the winter well, and is unsurpassed in this district as an exhibition variety, and has to my knowledge taken twenty-nine prizes on the borders this year. It has gained the attention of many of the best Leek-growers in the country, who are unanimous in their opinion that it is a capital exhibition as well as culinary Leek. Besides being grown on the borders, it has been tested in Fife, the Lothians, and elsewhere, with the same good results. I have this year seen it grown with Henry's Prize, Ayton Castle Giant, and Lyon Leeks, all having the same advantages, and Renton's Monarch far outgrew all the others, and was also better in flavour.—A BERWICKSHIRE LEEK-GROWER.

OUR ORCHARDS AND PARAFFIN.

DESTROYING SCALE AND AMERICAN BLIGHT.

SEEING your correspondent's article on page 483 entitled "Our Orchards and Paraffin," I wish to draw your attention to a bad case of American blight, moss, brown and mussel scale that I had to deal with. While serving as foreman in a large fruit establishment I was instructed to have all the trees that were subject to blight dressed with palm oil, which was done in March before the buds started. A few had been done the previous year to try the experiment, and it had turned out satisfactory, as in this case neither blight nor moss appeared while I was there. Turning this to account when filling a similar position where blight, moss, and scale flourished in an orchard house 300 feet long and 20 feet in width, and where it was the rule to have five or six men employed for weeks in scrubbing and painting the trees and waging war against these intruders, I mentioned what had come under my notice, and received full liberty to act as I thought best.

Procuring a half cask of colza oil from the butler, mixing with this a fourth of paraffin, adding a little soot and sulphur, and with a good staff of hands soon had them finished. With all other compositions it is necessary to move the scale from their position, and in that case hundreds of young ones are set at liberty and can be seen running about. It is not necessary in this case to remove them—paint over all. The oil will penetrate the hard scale and destroy all life, and if removed in a few days all will be seen to be dried and hard. There are two things greatly in the favour of oil. First, it will be seen quite wet for a week or two, it is neither inclined to evaporate nor to dry in the wood, and it will remain damp for months. No scale nor larvæ can exist under such circumstances. Secondly, it is not injurious to fruit or wood buds. If any of your readers would like to try the experiment I would advise them to "taste and try before they buy," and not endanger their crop

and trees rather than wait one year longer. I might say the worst cases occurred on Pear, Plum, and Cherry trees.—A FOREMAN.

NOTES FROM THE NORTH.

Cypripediums.—*C. punctatum violaceum* and *C. Maulei* are two very distinct forms of *C. insigne*, and probably the most effective and useful Ladies' Slippers known for all decorative purposes. At all events, out of about thirty sorts cultivated here I would select them if restricted to two, or perhaps *C. Spicerianum* and *C. p. violaceum*, for it is the best of the two first named, it being altogether a more robust plant. The flowers are decidedly larger than those of *C. Maulei*, the foliage broader and stiffer, the upper sepal considerably broader, more heavily and distinctly spotted, the margin of white wider, and the sepal does not reflex so much at its base as it does in *C. Maulei*. There are over twenty plants of these two varieties in bloom here just now, and for effect I do not think any other Ladies' Slippers could surpass them. *C. Haynaldianum* is in the style of *C. Lowii* and looks like a variety of it. It has more colour in its petals than *C. Lowii*, bears three to four blooms on a stem, and lasts quite as long in bloom as does *C. Lowii*. It does best in the East Indian house, and is well worthy of a place in all selections. *C. insigne Chantinii* and *C. punctatum violaceum* are synonymous. Another pretty and distinct variety is *C. alba marginata*, having a band of white all round the upper petal, but no spotting on the upper part of the white as *C. Maulei* and *C. punctatum violaceum* have.

Impatiens Sultani.—All who possess a hothouse that is kept at from 55° to 60° at this season of the year should grow a few plants of this lovely Balsam. It is one of the most easily propagated and cultivated of plants, and certainly one of the most brilliant and continuous bloomers. Seedlings seem to make the best plants, and self-sown ones can be had wherever a plant is flowered. It does not promise to be a useful plant either for room-decoration or cutting, as the blooms soon drop, and it does not thrive in a dry dusty room; but for hothouse show it is most effective, and will grow to 3 feet in diameter in an 8-inch pot.

Chrysanthemum Sœur Melanie.—This is one of the most useful Chrysanthemums for general decoration and for cut flowers. Your correspondent, Mr. Bardney, sent me some cuttings of it in spring, and I find it of very dwarf sturdy habit, can be grown into a shapely dwarf bush without any twisting and torturing, retains its foliage well, produces a great profusion of small and pure white flowers that are most useful for cutting. It cannot be too strongly recommended for all ordinary decorative purposes.

Wintering Tuberous Begonias.—I have observed that some have recommended that these be wintered in a rather dry condition. My experience in wintering them by the thousand is that they come into growth far more vigorously in spring if kept quite moist the whole winter, and the method adopted is to pack them in barrels in moist soil. Not one in a hundred goes wrong.—D. THOMSON, *Drumlanrig*.

ECONOMY IN STOKING.

EITHER Mr. Young did not read my letter carefully or he has failed to understand the plan. He says "Dugald" would have a boiler that would not require an ashpit door; but if the flues are sharp and there is no ashpit door, it is difficult to regulate the fire with the damper alone." If he had read the remainder of the sentence in my first letter he would see that the want of ashpit doors is rather more than provided for. I mean the "large outside doors over the front of the fireplace," to cover ashpit openings and all. To start the fire, or during hard firing, I would leave one of these open, at other times I would keep them closed. If Mr. Young can see how cold air could rush through closed iron doors and force out the smoke directly against the current of air drawn in to feed the fire, he can see what I cannot. "If boilers are properly set and stoked one furnace door is sufficient." Certainly there is no gainsaying that, but then there may be improvements even yet. Flint locks were "sufficient" once, and plenty of good shooting has been done with muzzle-loaders, but both are now almost superseded.

If a flue is constructed as it ought to be, and well built with brickwork, there is no danger in its use. Good plants and fruit were grown with flues before pipes were employed. A flue taken from the top of a boiler is quite different from a flue having a fire in the end of it, and the flames full length along the inside. A flue from a boiler is just one with the dangerous end left out.

A great part of a gentleman's garden is only an expensive luxury, and anything to reduce that expense must be not only for the good of our employers, but for the good of horticulture as well. The coal bill is a formidable item which could often be considerably reduced, and I think progress in that direction can only be made by first properly consuming

the coal, smoke and all, as I have tried to provide for by my new furnace; and secondly by utilising all the heat some way or other after raising it. If any good be done by discussing the subject, it is surely not by reiterating a set of truisms about clean flues, removing clinkers, &c., which probably formed part of the instructions every young gardener received the first day he commenced stoking, and which there is little chance of his forgetting.—DUGALD.

I QUITE agree with Mr. A. Young on page 482 in regard to his method of stoking. He says there might be three or more boilers in one place, and yet all require a little different attention to get them to work properly. A great mistake is often made in not having sufficient piping, as in that case the fire requires all the draught to maintain the requisite temperature; whereas, if there was more piping, the fire would not need to be driven so fast, the water would not need be near so hot as when there is a deficiency of piping, and it would not take so much fuel either to keep up the heat. I do not agree with "Dugald's" theory of having a furnace door at each end of the boiler; it would, in my opinion, require too large a stokehole. I have never found any difficulty in keeping the furnace clean with one fire-door. "Dugald" also says, "Why not have the chimney in the shape of a flue through the stove?" I should certainly object to such an arrangement, as flues are dangerous in case of accidents; the sulphur fumes from them also are also very destructive to plants.—G. T. G.

As the subject of economy in stoking is being discussed, perhaps my experience in heating boilers and flues may not be unacceptable. Where chalk can be obtained at a short distance, store it in a covered stokehole to dry, but if obtained in dry weather it may be used at once. In starting the fire put as much coal on as is required to heat the pipes or flue, then break the chalk in pieces the size of hens' eggs. Spread the coal evenly over the bars, then put on the chalk. The coal must not be disturbed from the furnace bars, but keep adding chalk as it burns. I am quite convinced there is a more regular heat from chalk than from either coal or coke. Fires can be conveniently made up at 10 P.M., but the fireman should always be up early in the morning. In bad weather 5 A.M. is a very good time. In renewing the fire I draw the chalk off the coal, put a little more coal on, and start the fire to the heat required, and then pour some water on the chalk drawn out of the furnace. When cooled, it is sifted, and the lime is very useful in the garden on heavy land. What is not sufficiently burnt will do to bank up with. There is one thing to observe—be very careful not to choke the back of the fire, which should burn to the front as much as possible. Five barrowfuls of chalk to one of coal may be used. This I call economising, and I have had a fire like a gas retort by regulating the damper and furnace doors.

Respecting flues, I should have no fear of taking them through a house. A first-rate grower of tricolor Pelargoniums and Poinsettias has a flue in his propagating house for bottom heat, and the heat is regulated by the damper of the furnace chimney. But the flue is well constructed, and has a brick rise in every 10 feet. Slates are laid on the top, resting two bricks from the flue, and covered with cocoa-nut fibre, in which the pots are plunged. Many years ago when I was with Mr. Cuthill of Camberwell, he grew many Cucumbers for market. Three ranges of pits were heated by hot water. The heat from the furnace was so great it induced him to have another pit built, and the draught from the furnace afforded sufficient to heat the extra pit through glazed pipes. It was in this pit where he grew his famed Lisianthus. I will state at some future time how this good, old, and rare plant can be grown with 500 flowers.—G. W. YOUNG.

LATE BLACK GRAPES.

I WAS particularly pleased to see Mr. D. Thomson give the Gros Colman such a high place in his estimation, more especially as regards its flavour. I send you a bunch that was grown in a medium temperature not quite so high as that for Muscats, but much higher than Alicante and Gros Maroc. The flavour of Gros Colman is very peculiar but good, piquant, and this improves by keeping. When well grown it cannot but be recognised as a Grape of the first quality. I am very strongly impressed with the need of a high temperature for this, though I cannot say it improves the colour. This is, however, a wonderful variety for colouring in the dark days, say, of November. Just lately I have marked several bunches with a few half-coloured berries, and therefore I am quite satisfied that even now they are colouring.

Gros Maroc as you see shows no signs of shrivelling, but to say this and Cooper's Late Black are the same will upset the calculations of many growers. I made the acquaintance of the latter at the last Caledonian Show at Edinburgh for the first time, but did not have the chance of tasting it. Exhibited as it was there it appeared distinct both from Alicante and Gros Maroc. One exhibitor staged both Cooper's and Alicante good, grown in the same house. Gros Maroc sometimes is longer in berry than mine, but this is, I believe, a sign of its having more heat than I gave mine. I also send a small piece of Alnwick Seedling grown with Alicante and Gros Maroc; with me it fails to set, yet shall try again. Do you think grafting Cooper's Late Black has altered its character? Gros Guillaume grown with Gros Colman does well here, though the berries are only medium Hamburg size. This, however, with me is caused perhaps by overcropping, as I have cut four bunches weighing 22 lbs., leaving still four other smaller bunches hanging.—STEPHEN CASTLE, West Lynn.

[Gros Colman is excellent in size, finish, and quality. Gros Maroc,

good berries and smooth, but not of high quality; footstalks shrivelled. Alnwick Seedling, well coloured, berries irregular; quality brisk and good. Alicante of average size and quality. The examples sent to us by Mr. McIndoe as Gros Maroc and Cooper's Late Black were undoubtedly identical. What is the origin of Cooper's Black?]

EDWARDSIA GRANDIFLORA.

AMONGST the many beautiful plants which English gardeners owe to Sir Joseph Banks must be included the above, with several other members of the same family, all shrubs of more or less elegance. Though usually grown in pots, they have also been successfully grown out of doors, and in positions against a wall where they are not too exposed they usually escape damage even during the most severe

Fig. 104.—*Edwardsia grandiflora*.

winters. When grown in pots a compost of turfy loam, peat, and sand—the former in the largest proportion—is required, and in the greenhouse and conservatory the plants will grow and flower freely.

Edwardsia grandiflora was originally known as *Sophora tetraptera*, under which name it was figured in the "Botanical Magazine" in 1791. In the remarks accompanying that a tree is mentioned which was planted against a wall in the Apothecaries' Garden, Chelsea, by Mr. Forsyth in 1774. This, it is said, grew strongly and flowered most abundantly, but the plant was protected with mats in severe winters. The leaves are very neatly pinnate, having eight or nine pairs of small pinules, which are whitish on the under surface and green above. The flowers are of a peculiar yellow hue, the calyx being darker and somewhat brownish.

Edwardsia chrysophylla from the Sandwich Islands has flowers of a similar shade of yellow and somewhat similar in form, but the leaves have a greater number of pinnæ and are of a silvery colour on the under surface.

DESTROYING CRICKETS.—I observed in the Journal an inquiry as to how crickets can be destroyed, and in reply I may state that when I took charge of the gardens here about five years ago the stove was infested with them. I obtained some common jam jars, in which was placed a mixture of treacle and beer, and the jars were sunk level with the surface

of the beds. The house was soon cleared, and we had no more until last spring, when they appeared in the Cucumber and Melon house, attacking the small Cucumbers and Melons. I used to catch a great many in the paths at night, but they at last increased to hundreds, but when the fires were discontinued in the summer they soon disappeared.—A. STEVENS, *Holynell Park.*

ALTERING THE NAMES OF CHRYSANTHEMUMS.

Now that the Chrysanthemum exhibitions are over and the cultivators of that beautiful autumn flower are looking over their catalogues for the purpose of selecting their new stock for the ensuing year, I think that a few hints may be useful to those who, like myself, are desirous of having their plants all true to name.

There are doubtless some of your readers who have purchased plants of well-known nurserymen, grown them all the year, spent time, money, and attention upon their culture, and then when the blooming season arrived have had the mortification of finding that what they bought as Peter the Great turned out to be The Sultan, and that Bismarck was really The Cossack.

Now, in my opinion, no words can sufficiently express the keen disappointment that a grower feels at being treated in that way, especially when a nurseryman of considerable reputation has served him in the same manner on more than one occasion; and he can only come to the very natural conclusion that such a proceeding is an intentional disregard of those principles of honour and integrity which every man in commerce is in duty bound to observe.

But there is another and still more serious practice going on in the trade which is less likely to be detected than that mentioned in the preceding paragraph, and which I am determined shall not be allowed to exist if any protest on my part can affect it. It is a well-known fact among Chrysanthemum growers that the majority of the new Japanese flowers sent out every year are raised by the French firm of Delaux et Fils. It is from them that the English firms obtain either directly or indirectly many of their new varieties, and they usually appear, as they should do, in the English catalogues with the names given to them by the French raisers.

But as most rules have an exception it is unfortunately so with regard to new Chrysanthemums, and one English house of business of no little importance has this year wrongly named, incorrectly spelled, mutilated, and curtailed the names of not less than thirteen varieties sent out last season by that French firm to which I have just alluded.

When I first noticed this unaccountable change nearly three weeks ago I immediately wrote pointing out the extraordinary variation, being then under the impression that it has happened for the first time, and that it was probably ignorance on the part of an employé that occasioned the errors. Since that time, however, after a careful investigation, it has come to my knowledge that precisely the same thing was done last year in at least six or seven instances.

As my letter to the firm still remains unanswered I can only assume that this respectable English house intends to let the question remain as it is, notwithstanding the distinct assertion that plants on sale there are true to name, and I fully anticipate finding when next autumn comes round the whole of the new Chrysanthemums sent out by Messrs. Delaux et Fils (and probably the other French growers) re-christened, and that they will thus be despoiled of the honour to which they are entitled for the care and unflagging zeal they have shown in the cultivation of a flower that excites the admiration of everyone who beholds it.

It is unnecessary for me to point out the terrible state of confusion that will exist if a check is not put upon this practice at once, and the useless expense which will be incurred by growers who make it a point, as some of my friends do, of purchasing all the new varieties; in addition to which they will have the vexation of finding out when too late that they have the same variety under two different names.—C. HARMAN PAYNE, *8, Kennington Park Gardens, Kennington Park.*

[No one is justified in changing the name that was attached to a plant by its raiser without his permission. Can any of our correspondents adduce examples of the practice that is very properly condemned?]

STORED-UP SAP IN VINES.

YOUR correspondent, "Credo," will find the quotation from Lindley that he failed to discover where I said he would—viz., at page 52, chap. iv., second edition, published fifteen years later than his copy. He will also find it correctly copied and applied by me, and that the first plant named by Lindley as an example is the Vine. As to the other quotation, I fail to see the object of "Credo" in reproducing it in an extended form in your pages, as it adds nothing to the point at issue. The gist of "Credo's" article is at the end where, in a few words, he utterly destroys Mr. Taylor's case and corroborates all I have said. I have not denied that Vines stored up sap, only said that they did not store it "in the sense" Mr. Taylor describes—that is like an Onion. I admitted, in my first note, that a Vine wholly deprived of its roots would burst its buds, but said it would "do barely more" unless the fresh or crude sap from the roots came to its aid. This is exactly what "Credo" says, only in other words, as follows:—"When the buds commence expanding in the spring they unquestionably obtain their full supplies from the 'stored-up sap' in contiguous cells, but immediately a green surface is exposed to the air elaboration commences, and the crude sap is then speedily utilised. It is in this respect that I cannot think Mr. Taylor quite correct in

assuming that the leaves are entirely dependent on the stored-up sap until they are 5 inches broad, as the smallest green foliage surface exposed to light suffices to produce the requisite change in the fluid absorbed from the Vine."

This is all I contend for practically. Green foliage and tissue are "exposed" the moment the buds burst through their scales, and before the roots are more than a few days old or more than half an inch or an inch long, and they avail themselves of the crude sap at once, and with which the Vines are being constantly filled from the roots. A very different story this from Mr. Taylor's. It is after this period his Vines "depend" on stored-up sap, and the Vines he spoke of were dependent on it, he said, up till the 10th of February!

What does "Credo" mean by "contiguous cells?" I admit that buds, like seeds, store sufficient nutriment within themselves to sustain their vitality and perhaps to burst their scales, but that is about all. With Mr. Taylor it is stored in some unexplained way in the stems. I do not think either of your correspondents are very clear on the subject of "elaborated" sap. I have always understood that the sap ascended by one channel, was elaborated in the leaves, and descended by another channel to the trunk and branches, where it formed new wood; but never returned to the leaves again, which are the elaborating organs, and not the final repositories of elaborated sap. But according to "Credo" and Mr. Taylor the sap or part of it elaborated in 1883 returns to the leaves again in 1884. Is this so, and is the order of the circulation of the sap reversed? Does the sap travel back and upwards by the descending channel, or how? There is something involved here. When Lindley speaks, as in the quotation I gave, and which is amplified by "Credo," it is *crude* sap which is said to be "stored up till it is required by the young shoots of the succeeding year."—NON-BELIEVER.

HAVING at last convinced "Non-Believer" of one of the great truths sought to be established in the minds of my readers—namely, that Vines do store up food during one season for use in the following season, there is a hope that the sequel to this—namely, that the Vines subsist on the food so stored up till they have reached a certain stage, may also ultimately form a part of his creed, and then he will be a "Non-Believer" no longer. Passing over his personal remarks as regards my unreliability and total untrustworthiness with the thought that he has not yet proved his capacity for judging of this matter, and that better men than myself have been abused by their pupils, I will examine the question as it now stands.

It is admitted, then, that food is stored up in Vines, and that when "Non-Believer" said "only bulbs and tuberous roots store food, for reasons apparent to anyone," he was labouring under a fundamental error. This is important, because on the existence of this truth depends all my treatment of Vines in autumn and spring. "Non-Believer" also almost accepts the statement that the root hairs are the agents by which food is taken up and carried to all parts of the plant, and he has known and acknowledged all along that root-growth commences subsequent to leaf-growth. The only question remaining at issue, then, is, Do root hairs exist before root-growth commences? I say they do not, and that they are only produced on the young growths and are only of annual duration. Your correspondent invites the authorities "at Kew or elsewhere" to settle the point for him. Now I will tell him of a very simple plan whereby he or anyone else may arrive at a conclusion without troubling the authorities at Kew, who would probably be a little more modest than your correspondent about repudiating facts noted by an observant gardener on a subject which he had made a life study, although they might fairly question his theories and deductions.

The plan I recommend is: Procure a couple of small Vines in 7-inch pots from a nursery, such as are too frequently sold for planting, and may be purchased for half-a-crown each. Cut them down immediately to a good eye near the bottom and place them in a sitting-room window where they can have ordinary attention as regards watering. When top growth commences turn them out daily and examine the coils of roots round the ball with a good microscope, and note exactly when root-growth commences and when root hairs are formed. After turning out the plants two or three times they will scarcely fit so well round the sides of the pots, and it will be necessary to place saucers under them when water is required, so as to guard against the possibility of their becoming too dry.

It may be necessary to tell some of my readers that the root hairs—the real feeders—are almost too small to be seen without a glass, and that when examined with such an instrument they are seen to be arranged around the elongating root in bottle-brush fashion a short distance from the spear-like point, which is not supposed by modern physiologists to feed at all. The way the root hairs feed shall be told by Dr. Masters in language that all can understand. "The passage of the insoluble matters in the soil into the root is effected by an acid liquid produced by the root hair or cell in consequence of its contact with the particle of soil, aided by the water in the soil. This acid fluid saturates the cell walls, corrodes, and effects the solution of the surface of the particle of the soil in contact with the fibril or root-hair. No passage of acid fluid out of the cell takes place, root-excretions having no existence, but the corrosive, and as it were digestive action above mentioned, is due solely to the absolute contact of the cell of the root with the particle of soil. The soil, therefore, is not to be looked on as containing so much liquid food ready for instant use. This may be so as regards water, but for other substances the digestive action of the roots is necessary."—(*Plant Life*, p. 20.)

It will be seen, then, by the youngest of readers that when "Non-Believer" writes of plants "absorbing sap from the ground from the

moment they are started," he is writing of something unknown to physiologists. "Non-Believer is very anxious for me to answer his question "Why does a Vine bleed, and why does it stop when deprived of its roots?" Now, although the first part of this question does not come within the range of my observation of facts, and is a purely theoretical one which has been discussed by learned physiologists for ages, I have no hesitation in giving what information I possess on the matter, but it must be accepted only as theory. The latter part of the question may be answered by another question equally profound—namely, Why does a fountain cease to play when turned off at the main? In the chapter on root-pressure in Prantl's "Text Book of Botany," second English edition, p. 85, he says "It is an old observation that Vines when pruned bleed as it is called in the spring—that is, that water escapes from the cut surfaces. Closer investigation has shown that this water exudes from the opening of the large vessels. . . . This water is absorbed from the soil and forced up into the plant by the roots, often with a force capable of supporting a column of mercury of considerable height. . . . This movement of water, effected by the root-pressure, is particularly conspicuous in the spring, and generally at the period of the most vigorous growth." The author then goes on to "show that there are three distinct modes in which water moves in the living plant. Of these two are effected by a sort of suction proceeding from the spot where the water is being used—namely, (a) the slow movement of the water in the processes of growth, and (b) the passage of water through the wood to compensate for the loss by transpiration. The third motion (c) is caused by pressure from the roots upwards independently of any consumption." The last-mentioned motion is the one with which we are just now concerned, and Prantl's theory of it agrees with what has been guessed at by several practical gardeners, and recorded within the last few years in this Journal—namely, that little or no harm happens from the bleeding of a healthy Vine, as there is little or nothing besides water exuded, and there is, or ought to be, always an ample supply at the command of the plant to replace that which is so lost.

The passage quoted by your correspondent from "Elements of Agricultural Chemistry," to the effect that "the sap, except when frozen, is supposed to be rarely quite stationary," in no way affects my argument, for there is a continual absorption of water going on by one or more of processes enumerated, and a movement of water through the plant's system means a movement of something else as well; for, as Dr. Masters says ("Plant Life," page 6), "The water from the outside has to pass through the membrane to reach the protoplasm on the other side. Speaking broadly, there are no holes in the membrane through which the water can pass. Ingress is secured by that process of diffusion [osmosis] to which reference has just been made, and by virtue of which the molecules of the membrane and the molecules of the water shift and change places; the space that was occupied by a molecule of membrane is now occupied by a molecule of water, and *vice versa*."

The word "sap" is not much used by modern authors, and has scarcely now any definite meaning. The changes continually going on in the interior of the plant are better expressed by the author last quoted at page 11—"Cell membrane, the protoplasm, the entire mass of liquid and solid constituents of which the plants consist, are, as we have seen, made up of molecules, each, as it were, with a life of its own undergoing continual changes according to different circumstances, acting and reacting one upon another so long as any active life remains. Active life, indeed, is ceaseless change, dormant life is a condition of equilibrium more often talked about than realised; in fact, it is merely relative, it implies merely a lessened degree of activity."—WM. TAYLOR.

A CONTROVERSY upon any matter connected with the Grape Vine never fails to attract much attention, and that now being spiritedly conducted by Mr. Taylor and his non-believing critic is especially interesting. These discussions elicit many instructive facts, and the principal actors may rest assured that they are neither wasting valuable space nor wearying their readers. There are but few qualified to take an active part in this discussion; but unless I am much mistaken, the majority argue out the matter among themselves whenever the opportunity presents itself. I have had several arguments on the subject, and at the risk of "getting out of my depth" shall also attempt to interpose a few remarks.

From the first I maintained that Mr. Taylor's theory with regard to the root-action and its effects upon the young shoots was not the right one, and this "Credo," in his praiseworthy endeavour to clear the ground, very plainly demonstrates. We often read that, apparently to the surprise of the writer, it is nothing better than water that comes from Vines that are bleeding most profusely, but what more can be expected? It is quite certain that such great quantities as a Vine will discharge cannot have been stored in the stems and roots of the Vines; and it is equally evident they cannot with their root hairs, or by whatever means they imbibe moisture, take up anything but nearly clear water. At any rate, I should not expect the moisture that filters through such minute openings to be either discoloured, thick, or strongly impregnated, or even perceptibly affected in its taste, by the various soluble constituents of the border. It was my argument that the young shoots, leaves, and bunches are first formed and started by the stored-up sap, (this being soon exhausted), and that the leaves begin to change colour as soon as they are able to elaborate the crude sap, thereby preparing food for themselves, the changed character of the sap in the "return pipes" being also the cause of root-action. This idea may be at variance with the teachings of our great authorities, but it is my belief "big guns" as well as "small fry" are apt to accept only such evidence as

supports their pet theories, treating other equally forcible facts tending to an opposite direction as irrelevant matter.—W. IGGULDEN.

[SAMPLES of the Vines mentioned on page 512 of last issue have been submitted to a competent microscopist, and he sends us the following letter in reference to the matter:—

"I have examined the Vine stem as desired, and find the whole of the parenchymatous tissue of the stem, excepting only the pith, to be densely packed with starch grains and other reserve food material. The swollen tumid portion at the node around the bud proper consists almost solely of somewhat thick soft-walled cells full of oval starch grains, forming altogether as evident a reservoir of food material intended for future use by the plant as the tuber of a Potato. This starch has of course been elaborated during the summer by the activity of the chlorophyll; briefly, by the process known as assimilation, the transference and re-constitution of the starch granules where we now find them having been brought about by metastasis."]

WE are informed that the VEITCH MEMORIAL PRIZES for 1884 will consist of three bronze medals and £5 in money, to be offered at Dundee, and similar medals and money prizes at one of the Royal Botanic Society's shows. Three others of the same value will be also offered at shows held by some of the florists' societies.

— AS would be seen from the advertisement in last week's Journal, the following are the dates of the meetings of the Scientific, Fruit, and Floral Committees of the ROYAL HORTICULTURAL SOCIETY for 1884. *Scientific Committee*.—January 8th; February 12th; March 11th and 25th; April 8th and 22nd; May 13th and 27th; June 10th and 24th; July 8th and 22nd; November 11th, and December 9th. *Fruit and Floral Committees*.—January 8th; February 12th; March 11th and 25th; April 8th and 22nd; May 13th and 27th; June 10th and 24th; July 8th and 22nd; August 12th and 26th; September 9th; October 14th; November 11th, and December 9th.

— THREE pretty Orchids were certificated at Kensington last week—namely, *CYPRIPEDIUM SCHRODERÆ*, *C. CARDINALE*, and *C. CALURUM*, all hybrids, in which *C. Sedeni*, itself a hybrid between *C. Schlimii* and *C. longifolium*, had been one of the parents. The most distinct of the group was *C. Schroderæ* (*C. Sedeni* and *C. caudatum*), as the characters of the latter species predominate, but in the others the globular lip and rich rosy colour derived from *C. Sedeni* indicate at once the family relationship. Both *C. cardinale* and *C. calurum* are beautiful Orchids, but the first is simply charming, the neatness of the flowers in form, together with the striking contrast of a deep rose lip and white sepals and petals, render it unique. In this case *C. Sedeni* was crossed with *C. Schlimii album*, a curious example of intercrossing; indeed, the readiness with which the forms of this section of the genus *Cypridium* hybridise is gradually giving rise to a distinct and handsome group, notable alike for floriferousness and vigour of habit.

— A PLANT was shown by Mr. King at the same meeting that well deserved notice, but which the Floral Committee passed unrecognised. This was the ZONAL PELARGONUM ROUSHAM MODEL, a variety of great merit with exceedingly symmetrical flowers, broad rounded petals of an intensely bright scarlet colour. They are borne in bold trusses, and the general habit of the plant is compact and strong, and altogether the variety is one of the finest of the type that we have seen.

— "CYMRO" writes thus respecting *CALANTHE VEITCHII*:—"Allusion has recently been made to the superiority of the straight pseudo-bulb form of the above over the compressed form. But are the straight forms always best? I am inclined to answer in the negative, for we have here at present several plants of both forms, grown under similar conditions, bearing spikes of flowers of average quality without the slightest distinction in colour. I have previously seen, as Mr. Thomson describes, the straight form much the best; but I am doubtful whether it can be relied on as a guide to purchasers, to whom the matter may be important."

— A DOUBLE SCARLET BOUVARDIA named THOMAS MEEHAN

is announced as one of the novelties of an American firm who have previously sent out the now well-known Bouvardias Alfred Neuner and President Garfield. It is said to be the result of a cross between B. A. Neuner and Ciantha; the latter, we suppose, being that known in England as leiantha. The flowers are described as very double and of a brilliant red colour. If this prove as good as the white variety it will be a great acquisition.

— "G. T. G." writes:—"I regard CHOU DE BURGHLEY as a very useful vegetable at this time of the year, as most other kinds are rather scarce. With us, as yet, it is only like an ordinary Cabbage, but much superior in flavour. Mr. Gilbert, however, says we must wait till March to see it in its true character, when I hope it will turn out what it is represented to be. If it does, it will be one of the most serviceable vegetables we have."

— THE pretty and useful ROSE, WILLIAM FRANCIS BENNETT, is attracting much attention in the United States. It may be remembered that Mr. Bennett of Shepperton sold this Rose to Mr. Evans of Philadelphia for something like £780, on the understanding that no plants or cuttings were to be sold for four years. There now seems to be some little difficulty about cutting buds with long stems, as it is feared the lower eyes may be propagated. Several methods of preventing this have been recommended; one being touching the leaf buds with acids and another cutting them out, but neither are quite satisfactory, and it is likely that the variety will soon appear in other establishments.

— As a sample of late WHITE CHRYSANTHEMUMS, Mr. Cannell has sent us beautiful blooms and a profusion of buds in various stages of development of Mrs. Charles Carey and Virginale. The former, as several of our readers are aware, is a Japanese variety, very pure, with flat incurving florets, the bloom resembling a white form of Peter the Great. The large dark foliage contrasts effectively with the flowers, and the variety would appear to be very useful, and is certainly highly effective for decorative purposes at this period of the year onwards. Virginale is a medium-sized Anemone flower, with long clear white guard florets, and a creamy white full symmetrical centre. The blooms before us are fresh and charming, and it is not a matter of surprise that this variety has already become popular in the Christmas flower market.

— A CORRESPONDENT writes respecting STRAWBERRIES AND GRAPES at LONGFORD CASTLE as follows:—"In passing through the forcing houses at the above establishment the other day we noticed a very fine batch of early Strawberry plants which looked very promising, some in flower and many with the fruit set and swelling; these will probably be ripe next month. The plants, which are growing in 6-inch pots, are from this year's runners, and are about six months old. Grapes in the new range of houses are now at their best. The crop is certainly a marvellous one, the heaviest we have ever seen on young Vines, and which are not yet three years old; this being the second season of their fruiting. In the end or west house, which is 32 feet long and 17 feet wide, are fifteen Vines bearing collectively eighty-six bunches. Many of them we estimate will weigh from 4 lbs. to 5 lbs., and two or three of the largest will probably turn the scales at 8 or 10 lbs. Although the latter are a little wanting in colour, the crop, taking it altogether, does very great credit to their grower, Mr. Ward."

— ON Monday, the 14th, at the George IV. hotel, a dinner was held in connection with the CROYDON HORTICULTURAL SOCIETY. The Committee invited some of the exhibitors at their recent shows to dine with them. Mr. Alderman Coldwells and Mr. Reed, two esteemed supporters of the Society, and Mr. Orchard, one of the Judges at the late Chrysanthemum Show, were also present. In the course of the evening Mr. Coldwells pointed out the fact that when the Society a few years ago was conducted by gentlemen and tradesmen in the neighbourhood, it was almost a failure, but when it came into the hands of practical men the results were far more satisfactory. Mr. A. C. Roffey, the indefatigable Secretary, read the balance-sheet for the last two seasons, which showed that in 1882 the total income was £336 6s. 11d.; paid in prizes, £155 1s. 3d.; balance at bank, £45. In 1883 the total income was £412; paid in prizes, £156 17s. 9d.; balance at bank, £100 17s. 10d. The health of the Mayor, J. S. Balfour, Esq., M.P., was received with much enthusiasm. This gentleman not only lent the ground for the last summer show, but also generously provided a grand display of fireworks, and allowed the Society to take the proceeds of gate money, which is

estimated at £70, from visitors to the fireworks alone. It is considered by some members that if the Society were to provide fireworks to the amount of £25 at future shows the result would be £50 at least in return for admission to see them.

— "A. O. W." writes—"For autumn and winter flowering I find HELIOTROPE WHITE LADY invaluable. Cuttings are struck in spring and grown in a cold frame during the early part of the summer, and potted as occasion requires in 32 or 24-sized pots. The shoots are well pinched to make bushy well-balanced heads. After the plants are established in the large pots they are placed out of doors until the autumn. The plants so treated are now covered with pure white and highly fragrant flowers, which are much sought after for bouquets and buttonholes. An intermediate house and a position near the glass seems to suit them well. I observe that this variety when grown out of doors in borders, also in a cold house in the autumn, has its flowers much less fragrant than those grown in a little heat."

— GARDENING APPOINTMENTS.—Mr. George Piller, late foreman at Old Warden Park, Biggleswade, succeeds Mr. Hunt as gardener to General Benson, Fairy Hill, Swansea, South Wales.

— "W. O." desires to know if WASHING PEACH TREES with Gishurst compound, prepared at the rate of six ounces to a gallon of water, would cause the buds to fall. Perhaps some of our correspondents who have tried the mixture at the strength indicated will answer the question, and state also what they consider the safest and best wash or dressing for Peach trees.

— "A CONSTANT READER" sends the following:—"Thinking that it might interest the readers of the Journal to know that the love for the cultivation of the Chrysanthemum is spreading and has now secured a firm footing in Scotland, it affords me great pleasure to inform them that the second annual Exhibition of the DUNFERMLINE CHRYSANTHEMUM SOCIETY was held in St. Margaret's Hall, St. Margaret's Street, on Saturday, the 15th inst., when there was a large display of both plants and cut blooms, the majority of which were of excellent quality; Mr. J. Graham, gardener to Messrs. McLaren, Comely Park, winning the prem prize with six well-flowered plants; Mr. E. Johnstone, gardener, Balmule, and Mr. J. Mackay, Pittencrieff Gardens, being first and second respectively for eighteen blooms; Mr. A. Buchanan, Woodhead Street securing the special prize for the best bloom in the Show with a grand specimen of Empress of India."

— NUMBER 3 MUSEUM AT KEW has been closed during a considerable time for repairs and re-arrangement, but is now re-opened. The interior has been entirely renovated, and instead of the polished woods being piled as hitherto, they are classed and placed singly against the back and front walls. Along the back two small platforms or gangways running the whole length of the building have been placed one above the other at suitable intervals from the floor, leading to which are circular iron staircases at each end for the use of specialists or those wishing to examine the woods more closely than the general public usually do. An iron fence has also been placed round the building 2 or 3 feet from the walls, for the better protection of the woods; the centre being taken up with stands of all the more recent views of foreign botanic gardens, together with portraits of the more noted botanists. Great taste has been displayed throughout in the re-arrangement, special attention having been given to make the museum as light as possible.

— Mr. A. R. Cox, Wavertree, sends the following note—"It may not be generally known that one of the most useful and interesting objects of the LIVERPOOL HORTICULTURAL ASSOCIATION is the holding of meetings during the winter months to hear essays read and lectures delivered, after which their contents are discussed by the members. The second meeting of the fifth annual session was held on the 15th inst. in the Free Library, Liverpool, when papers were read by Mr. Ranger on 'The Cultivation of the Croton,' and Mr. Powell on 'Vegetable Curiosities.' Mr. Ranger is the much-respected manager to Messrs. R. P. Ker & Sons, Aigburth, and whose success as a grower of Crotons and other choice plants is well known by those who visit the Manchester Whitsuntide shows. He treated the subject in a very able manner, and received a hearty vote of thanks from the meeting. If Mr. Ranger would consent to his paper being published in the Journal I am sure your valuable space would not be wasted. Mr. Powell's paper was also very interesting, treating chiefly on Orchids, Nepenthes, and Sarracenias. The usual vote of thanks was accorded. The meeting was well attended, and good discussions followed."

— AT a meeting of the Society of Arts last Thursday, Dr. J. Forbes Watson read a paper upon the CULTIVATION OF "RHEA," OR CHINA NETTLE, commonly called China Grass. Major-General Henry Hyde presided. Upon the platform and side tables were a number of specimens of the fibre of this plant, both in the primary form of long black twigs divested of leaves and flowers, and in various stages of manufacture, from rough white shreds to dyed yarn, reels of coloured cotton, coils of rope, sail-cloth, and the completely finished article in the form of shawls and hosiery. Dr. Watson described in detail the process of manufacture, and gave a history of the plant. The East India Company had for many years brought over a certain quantity yearly, but a demand having sprung up for it, it went up to about £85 per ton, at which price the manufacture was killed. The price now was about £50 per ton. He thought it would be possible to introduce the fibre into the market at about £35 per ton, but he was satisfied that those who thought they were going to grow the plant at a very cheap rate were mistaken, as it required great care in the cultivation. The demand for it was likely to grow, as it seemed probable that the dull-surfaced wools would give way to lustre wools, for the production of which China Grass was peculiarly adapted. It could be prepared to look very much like silk or satin, and undoubtedly it was a much superior article to mix with silk than jute.

LATE PEAS.

IN reference to Mr. Stevens' remarks in last week's Journal on the superior merits of Frederick Roach as a good late Pea, allow me to say that my experience of this variety last season fully confirms his statements as to its being a good cropper and of delicious flavour when grown in succession to Main Crop, but not as a very late Pea. Like your correspondent I grew several varieties, and I found the best variety for late purposes to be that good old Pea Ne Plus Ultra. We are able to gather abundance of Peas until the end of the second week in October. I grew Suttons' Latest of All along with this, but it failed to yield as satisfactorily as the former. My employer is a connoisseur of Peas, and his verdict as well as my own is certainly in favour of Ne Plus Ultra as the best of late Peas. It possesses so many good qualities, among which may be mentioned its capability of resisting mildew, vigorous constitution, and prolificness. What have other readers of the Journal to say on the merits or demerits of this variety?—T. W. SANDERS.

ROSES IN SCOTLAND.

THOSE who imagine from Scott's description of his own land—

"Caledonia stern and wild,
Meet nurse for a poetic child,"

that it is a cold and dreary country, where nothing but Scotch Firs and Gorse will flourish, at any rate on the northern parts of the land, would have been very much surprised had they assisted at the opening of a box which came to me the other day by parcels post from far-off Morayshire. We know indeed that in the south-west of Scotland, in Wigtonshire and Kirkcudbrightshire, frosts and snows are rarities, and that many things we fail to grow in our more southern latitudes flourish there; but Morayshire lies so far north—it faces the North Sea—and is rather more suggestive of snow berries than Roses, yet these flowers sent me by a kind correspondent, Mrs. Dunbar-Duubar of Sea Park, Forres, were all cut from the open. They had had no protection, and yet the foliage was as fresh and vigorous as in summer, the Hybrid Perpetual blooms bright and clean, and the Teas sweet-scented and delicate. A Scotch friend has gone to the Azores to see whether he can raise and grow Tea Roses there, but I could not help thinking he might perhaps have found some work nearer home. Of course climate has much to do with it, but even with this such results could not have been obtained without good cultivation, and it was a real treat when the ground in Kent was covered with 3 inches of snow to open a box from the far north so suggestive of summer.—D., Deal.

A MODEL FORCING HOUSE.

IN relation to the structure referred to by me on page 490, allow me to say the walls of the beds inside are 2 feet 6 inches high, and the outer walls are 8 inches higher, thus making the brickwork 3 feet 2 inches instead of 4 feet as previously stated. I wish to thank Mr. Warhurst for drawing my attention to this matter. I must again repeat that this house reflects the greatest credit upon the two gentlemen I mentioned. I should in this instance at least be in a better position than Mr. Warhurst to know who deserves the greatest praise. If your correspondent knew the origin of the house he would himself have placed the fortunate owner not in the last but in the foremost position. In this instance the owner is a man not only capable of designing the structure but of building it himself if he had felt so disposed.

Whether the house in question is an "extraordinary building" or not, one fact is certain, it is a change from the majority of structures that are used for forcing operations—it is a step in the direction of progress. I do not hesitate saying it is the nearest approach to what I consider a forcing house should be that I have ever seen exhibited or erected. It is a span-

roofed structure pure and simple, and I fail to discover that it is any "modification of the so-called curvilinear roofs with straight lines."

Mr. Warhurst indicates that this model structure is weak at the junction of the roof and sloping side glass, but I think differently. He appears to have overlooked the fact that a rod of three-quarter-inch iron (round), runs the whole length of the roof on both sides, passing through all the main rafters, while all the lighter are secured to it by means of thin iron hooped and a screw on each side of the rod. These iron rods are just 14 inches from the eaves of the house. This is one way of supporting the roof and keeping the lighter bars between the main rafters in their place, and will prove more durable, while it strengthens the portion near the eaves much better than a light "connecting plate or rail." All the rafters and bars connected with the front glass are let into the wall plate, and then those of the roof are fitted neatly to them and nailed.

I do not think in the house in question they have obtained light and sacrificed the strength of the roof; it is light, yet abundantly strong, and will not be twisted about by any storms that may break over it. If the glass used were light and poor I should agree with Mr. Warhurst that small squares would have been better, but that employed is 26-oz., and which will bear a storm of wind of unusual violence before the laps open to let in much cold air.—WM. BARDNEY.

CHOU DE BURGHLEY.

IT is the first time I have seen it stated that autumn Cabbage and Coleworts are strong in flavour. What can be more delicious than a dish of Ellam's Early, Little Pixie, or Coleworts at this season of the year? and they take only about twenty minutes to boil them thoroughly. These can be produced in grand condition after an early crop has been cleared from the ground, which is not the case with Mr. Abbey's pet vegetable. I am afraid your correspondent has been enjoying the former, and mistaken them for Chou de Burghley. It must have taken some boiling before it was as "tender as a chicken." Mr. Abbey failed to say how long he boiled them. Mr. Gilbert allows one hour and twenty minutes. It is true there is no accounting for tastes, and after boiling the Chou de Burghley the length of time Mr. Gilbert thinks necessary, there is no difficulty in detecting the "smack" of the flavour of Broccoli leaves. How does Mr. Abbey get that "delicate" flavour he detects, and which is evidently beyond description? I must examine Mr. Abbey's statement further. He says it is as "hard as nails." Can he write this from experience if he obtained seed only in March last? Has there been any severe weather since then to warrant such an assertion?

I consider Chou de Burghley a coarse vegetable. It is longer on the ground than Cabbage, takes up much more room, and requires four times the amount of coal to boil it; in fact, Cabbage and Coleworts can be boiled for four dinners in the same time, and with the same fuel as is required to produce Chou de Burghley in eatable condition for one day. Chou de Burghley may do for Mr. Abbey, who, I dare say, has no coal to buy and abundance of ground on which to grow vegetables. I have only a small garden, and I want the most from it that can be obtained. First I must have a crop of Potatoes, then tender Cabbages for winter that do not want too much boiling, for I know too well the cost of the twentieth part of a ton of coal before it is conveyed six or seven miles from the station.—A WORKING MAN.

WILD GARDENING.

A TASTE for natural or "wild" gardening is being much more cultivated by the general public, and it behoves every gardener to be on the outlook for the appearance of, and be in readiness to adopt anything that is likely to add a charm to the surroundings. Many really beautiful and interesting gardens may be made by utilising the narrow belts of trees and shrubberies which are so common, introducing some of our hardy shade-loving plants, Ferns, and Orchids. The latter might be introduced in quantity, and would be found to do very much better than they are generally seen in prepared beds or borders, a good carpeting of grass or some other low creeping plant being really essential to their well-being, and it is not always practicable to have tufts of grass in beds.

G. F. Wilson, Esq., of Weybridge, has within the last few years made a great advance in this direction. In the woods surrounding his residence at Heatherbank one unexpectedly finds a large clump of Lilies, some of *L. auratum* being from 5 to 6 feet high, with large well-coloured flowers, and growing, too, entirely under the shade of large trees. Old roots are used with good effect. A few thrown carelessly together are covered with the beautiful *Tropæolum speciosum*, which, by the way, does as well here as in the north, and surrounding them with the common male and female Ferns, making truly a "charming picture." At Wisley, too, this wild gardening has been practised on a much larger scale than at the former place. Large patches of *Epigæa repens* are seen quite at home trailing through the long grass, together with the pretty *Linnæa borealis*, *Sibthorpia europæa*, and a great variety of our shade-loving plants, forming a picture that contrasts strikingly with the stiff symmetrical gardening so common in the parks and gardens about London. In this way a great many of our native alpines, such as *Lycopodiums*, *Empetrum*s, *Vaccinium*s, *Pyrolas*, &c., might be grown very effectively.

At Kew a small colony of these interesting plants has been established under the shade of some Scotch Pines, and in many cases are as vigorous as I have seen them in the Highlands. Very little attention is required in their cultivation. Care, however, is necessary in the choice of a suitable position, which in no case should be over-sheltered. A bed of peat and stiff loam may be prepared, into which angular stones should be deeply

embedded, and planting as near them as possible. They will require plenty of water until they are fully established. The following is a short list of those most suitable:—*Lycopodium alpinum*, *L. clavatum*, *L. complanatum*, *L. Selago*, and *L. annotinum*; *Erica Watsoni*, *Andromeda polifolia*, *Gaultheria procumbens*, *Empetrum album*, *E. nigrum*, *Vaccinium vitis-idaea*, *V. uliginosum*, *Arctostaphylos alpina*, *Betula nana*, and *Cornus suecica*.—D. D.

MURRAY'S VINE COMPOSITION.

IN reply to "M. A.'s" inquiry (page 461), respecting Murray's Vine composition, I have much pleasure in endorsing all that he has said in its favour. Three years since I had a number of Vines very much infested with mealy bug, and being recommended to try this remedy I did so with the most satisfactory results, and now I am thankful to say they are perfectly clean. Since then I have used it extensively on my indoor Peach trees, and find it quite harmless in its application to the buds, and I have also found it invaluable for dressing hardwooded stove and greenhouse plants infested with either brown or white scale; and I feel assured that were this excellent composition better known it would prove a great boon to the gardening community at large.—BENJ. G. STONE, *Elkington Hall Gardens, Louth*.

[Why is it not made "better known" by the vendors? We have received other letters to the same effect as the above, but sufficient has been published at present on this subject.]

AURICULAS AND THE WOOLLY APHIS.

ON page 488 "D., Deal," while speaking of woolly aphides, says, "Every grower speaks of it now as existing in their collection, and its mysterious dispersion is one of those insect problems about which, with all the vaunted discoveries of science, we know next to nothing." Yet I wrote to the Journal two or three years ago to inform "D., Deal," how I had successfully stamped it out of our collection. The roots were so covered with it that they had the appearance of lines drawn with a piece of chalk when the plants were first turned out of the pots. We had it introduced into our collection by some fresh plants from a large grower in August. The following spring, when they were being top-dressed, I first discovered it. It was very bad on the new plants, but it had spread more or less on those that stood nearest to them. I made a rather strong mixture of soft soap and tobacco water (I forget the quantities that I gave them at the time). Two or three of the worst plants were shaken out of their pots, and the roots and collars well washed. Holding the foliage in my hand to prevent any of the mixture touching them, I placed them on the potting-bench for about ten minutes, and then washed them in clean water, wrapped the roots in damp moss, and left them for two or three days. They were then examined very minutely with a glass to see if there were any woolly aphides alive, and whether the roots were injured. They were perfectly clean, and I could not see that any injury had been done, so they were at once repotted. The plants, instead of being top-dressed, were shaken out, washed, laid down for about ten minutes, then washed in clean water and repotted. All the old soil was carefully collected and burnt, the frame scrubbed with hot water and soft soap, and I have never seen any woolly aphides since. But when we have had any fresh plants they have had to go through the washing process before being placed with the main stock.—J. L. B.

THE PARSLEY-LEAVED BRAMBLE.

ON page 5 of our issue of July 5th of the present volume Mr. Muir narrated, no doubt with strict accuracy, his experience of the Kittatinny Blackberry, which variety had proved with him very unsatisfactory. Our correspondent's remarks seemed also to have a wider bearing, for he suggested that probably "some persons may grow American Blackberries against a wall, and even then it would be good space badly used." We advised our correspondent at the time to try the Parsley-leaved Bramble, and perhaps he will do so despite his observation that "nothing which could be said or shown in their favour would induce him to have anything more to do with them," as this decision was founded presumably on such varieties as he had endeavoured to cultivate. Much was "said" in reply to the letter in question, and now we "show" (fig. 105), a good example of the fruit under notice as grown by Mr. W. K. Woodcock at Oakbrook, Sheffield. In October, 1882, this cultivator referred to the productiveness of this Bramble as follows:—

"A single row here 22 yards long, and trained to tall stakes after the manner of Raspberries, has been producing a constant supply of large and well-ripened fruits for six weeks now past, and looks as though it will continue to do so for another month should the weather continue mild. Up to the present time since the first gathering commenced an aggregate of more than two bushels of good fruit have been obtained, and employed by our cook in a variety of ways for pastry, also for making jam, jellies, cheese, syrup, &c., till she tells me she appears to have an inexhaustible supply. It appears to be especially adapted for training over light wire arches or trellises spanning the kitchen garden walks, where it would be both useful and ornamental. Many of the fruiting rods with us are 10 feet long, and furnished with long racemes of fruit from the base to the summit. I do not know any other fruit-bearing plant or shrub which will produce an equally large quantity and long succession of fruit for the space occupied. Its cultural requirements are very simple. The main

point being attention to training and tying out the young growths occasionally during the summer, and pruning after fruiting in the autumn, when a few of the oldest fruiting rods are cut away to make room for young growths, and those left have their laterals cut back to one or two eyes from the base, after which they are again trained to their supports and a liberal mulching of manure given to their roots."

In July of the present year Mr. Woodcock wrote:—"My notes in October last as to the quantity of fruit we had then gathered were not in any way exaggerated, and we continued to gather fine fruit for several weeks afterwards. At the present time our stock is growing very vigorously, and promises even better results than last season. The clusters of fruit produced on our canes are certainly much finer and the fruit larger than the engraving of Kittatinny shown on page 519 of last volume. I have been measuring the fruiting spurs or racemes, which are now just expanding their first blooms, and find they average 2 feet in length from their junction with the cane. There is also an average of fifty bloom buds to each spur, and forty spurs to each cane, which are about 12 feet in length. As we grow an average of four canes to each root or stool, we have a total average of 8000 bloom buds from each root, and nearly every bloom may be relied upon to produce a fruit fully as large as the largest and best Raspberries; and coming in as they do after Raspberries and all other bush fruits are over, they are highly esteemed. The roots are planted 5 feet apart in the row, and the canes are trained more or less horizontally over a row of wood stakes, which are 9 feet high and 2 feet 6 inches apart. They require an open sunny position to ripen the fruit properly, coming in as it does in the comparatively dark damp days of October. Our system of cultivating them is very simple, and consists in cutting clear away at pruning time most of the old canes which have borne fruit, to make room for the young canes made during the previous summer. If sufficient young canes have not been made to fill the space, some of the best of the old ones are left and have their fruiting laterals pruned off close to the cane. They are then again all trained to the stakes, and have a liberal dressing of decayed manure given to their roots.

"In October, 1879, Prince Leopold was staying at Oakbrook for a day or two on the occasion of his visiting Sheffield for the purpose of opening Firth College. The Bramble was then (October 22nd) in fine condition, and received very high praise from His Royal Highness both for its qualities as a choice dessert fruit upon the table and for its free-fruiting character. Messrs. Fisher, Son & Sibray tell me they afterwards had the honour of supplying his gardener with a stock of plants."

Mr. Ward of Longford Castle has grown these Brambles to his satisfaction, and he is one of the last persons to be satisfied with what is not creditable to him and meritorious. Mr. Luckhurst, whose standard of excellence in fruit culture is a high one, has stated in reference to the Parsley-leaved Bramble that "under good cultivation it has proved to be so excellent both in the size and abundance of its berries as to have a prominent position assigned it among our most useful fruits. The common Bramble grows so luxuriantly and in such abundance here that when I received some plants of the Parsley-leaved American Bramble from Brocklesby Park in Lincolnshire, where I am told it is so flourishing as to attract the notice and admiration of visitors, they were planted in ordinary soil under the erroneous supposition that no special care was necessary to induce them to grow freely and bear fine fruit. The puny growth of the first season proved that I was mistaken, and in the following autumn a trench 18 inches deep and 3 feet wide was excavated and refilled with two-thirds of spent hotbed manure mixed with a third of garden soil, and the Brambles transplanted into it. Nothing could be more satisfactory than the result, for the growth that followed was so rampant that it was obvious an ordinary trellis would be useless, and a neat one 6 feet high of diamond pattern was made of stout poles thrust into the ground and crossing each other diagonally. This was soon covered, and for some three or four years we have had an ample supply of fruit far surpassing anything ever seen on an English Bramble. No account has been kept of the actual quantity of fruit picked in a single season, but I know that from 6 to 8 gallons has been picked at one time, and this may be done repeatedly for several weeks from a row 60 feet long and 7 feet high. This season the crop promises to be even more abundant, for the row is just now one mass of blossom from bottom to top, borne in huge clusters upon stout lateral growths about 2 feet long, so that the row is in reality a thick hedge quite 4 feet through, and is probably at its best. Nor is there any fear of a cessation of vigour, for new main shoots have come freely from the bottom of the old ones, and are already from 6 to 8 feet long, and nearly an inch in diameter. The fruit is used chiefly for making jelly, which is so highly prized by connoisseurs that it must command a profitable and ready sale. Surely fruit-growers for market would do well to bestow some attention upon a fruit that is so hardy, so prolific, and so easily cultivated, and which, so far as my experience goes, is unaffected by blight or disease of any kind."

Mr. John Carter of Keighley has also written favourably of this fruit and as his letter is short we reproduce it. "I have grown these for years, and they are very beautiful so far as foliage is concerned, but what is much more satisfactory, loaded with rich luscious fruit every season. My soil is tolerably strong, and the requisite number of the previous year's shoots are pegged-in to an unsightly wall during the spring. They often make 4 or 5 yards' growth of very strong wood. In September, 1881, I sent bunches of fruit to the Journal, which were favourably noticed. Being a late fruit it is essential that the plants should be grown in a sunny aspect. I daresay every soil would not grow them satisfactorily, but with me the difficulty would be to get quit of them. Keighley station is a mile and a half from my Willow Bank nurseries, and I shall be pleased to show these beautiful plants to anyone who may think it worth while to

call and see them. I have tried Lawton and several other Blackberries, but I do not find any equal to the Parsley-leaved."

We have seen the plants referred to, which masked attractively, also profitably, the "unsightly wall." We have also tasted jelly made from the fruit by Mrs. Carter, and must pronounce it clear, very rich in colour, and excellent. We have further seen the plants grown by Mr. Woodcock, which merit all he has said of them, and have examined rows of this Bramble in the nurseries of Messrs. Fisher, Son & Sibray, that were bearing prodigiously, the variety there grown being said to have originated as a chance seedling, presumably from *Rubus laciniatus*.

From the evidence adduced it would appear that the Parsley-leaved

tions on this point as are given in the catalogues of Vilmorin and Mr. Campbell of Gourock.—A NORTHERN AMATEUR.

CHRYSANTHEMUM EXHIBITIONS.

NOVEMBER, usually noted for its fogs, has this year been almost exempt from them. With the exception of a few sharp frosts about the middle of the month the weather has been bright and open. The past month has indeed been a most busy one for all connected with the Chrysanthemum, for not only gardeners but the horticultural press have to share in the work connected with exhibitions. Something like

FIG. 105.—THE PARSLEY-LEAVED BRAMBLE.

Bramble is worthy of trial, but it does not in all places establish itself quickly, and two or three years are sometimes needed for it to develop its qualities, and Mr. Luckhurst's observations on this point may be perused with advantage by intending cultivators.

EARLY AND LATE-FLOWERING GLADIOLI.—"They possess no such characteristic" writes "W. J. M." in a recent issue of the Journal. His experience adds another fold to the mantle of mystery in which the capricious beauty enwraps herself. With me scarcely anything is certain about them but that, and I have this season additional proofs, which I mean afterwards to submit to your readers, of their very strict adherence to the same. I would caution beginners in their culture in these northern latitudes of the grievous error they will commit in ignoring such intima-

six pages in each of the issues of the Journal for three weeks have been devoted to the detailed reports of exhibitions, of which upwards of fifty have been held. Amongst the principal exhibitions devoted chiefly to Chrysanthemums I may notice the following:—Southampton, Stoke Newington, Royal Aquarium, Kingsten, Birmingham, Liverpool, Northampton, Manchester, Oxford, Bristol, Plymouth, Worcester, Shrewsbury, Lincoln, Winchester, Brighton, Bath, Gravesend, Headington, Loughborough, Devizes, Reading, Ealing, Southgate, Tunbridge Wells, Aylesbury, Brixton, Croydon, Bromley, Eastbourne, Weybridge, Ipswich, Dorchester, Twickenham, Teddington, Linfield, Staines, Lewes, Putney, Hawkhurst, Wimbledon, Chelmsford, Tooting, Dartford, and even from Durham down to Land's End. For the reason of such wide popularity we have not far to seek. With the introduction and development of the Japanese varieties we obtained such a diversity of colours that at once

supplies a want needed during the dull season. It is impossible for any one person to have seen the whole of the exhibitions above enumerated, as so many fell on the same day, but a few of the principal I have been fortunate to visit, and these I shall remark upon.

Beginning with Southampton, which was indeed a grand exhibition, a great number of classes being devoted to the flower in question, in every class the competition was most keen, as well as the quality of the flowers superb. I have never before seen classes in which collections were so nearly equal. The leading class was for eight Japanese and sixteen incurved or reflexed. A class of this description has much to recommend it, as the back row is made up of Japanese, and the other sixteen principally incurved. For my own part I would prefer to see the reflexed struck out, as they do not harmonise with incurved flowers, so that if framers of schedules were to ask for twenty-four cut blooms of Chrysanthemums, to consist of eight Japanese placed in the back row and sixteen incurved in the other two rows, they would find plenty able to compete that could not find twenty-four good incurved varieties. It is the last straw that breaks the camel's back, so it is the last one or two flowers in a collection of twenty-four incurved varieties that weakens many a stand. This is a class that will not only work well if adopted, but is most effective. The back row being Japanese brightens the stand considerably. I think the above class at Southampton, for which the first, second, third, and fourth prizes amounted to about £7, brought seven competitors, which means 168 blooms, and all good. All other classes throughout were almost without an exception as well filled, so that I have no hesitation in placing Southampton this year in the front rank of exhibitions.

Kingston was the next Exhibition I saw. Taken collectively it was not as large as last year, for we had only three competitors for the challenge cup, and here Mr. Molyneux, who has proved himself to be one of the best cut-bloom growers, was a long way ahead of the other two collections; but these three collections represented 144 blooms, and I am told there were upwards of 1600 blooms in the Exhibition. For freshness and quality of bloom, together with the numbers exhibited, Kingston may well be said to have held its own amongst the best.

The Borough of Hackney Show at the Aquarium I could not see, which I much regretted. The Society is now designated the National, but why I do not know. To be a real National Society it should hold exhibitions in the provinces. Possibly this may be the intention of the executive; if not, I fail to see how a Society always holding its exhibitions at the Aquarium can be truly termed "The National." My best wishes, however, are with them for the success they have already attained in popularising this flower.

Northampton held a splendid exhibition, enlisting two noted London growers in their cut-bloom classes; but the greatest object of interest to all growers was the class at Birmingham Exhibition, where the magnificent sums of £10, £7, £5, and £2 were offered for forty-eight cut blooms, twenty-four Japanese and twenty-four incurved—a very heavy class, in which no one can expect more than four or five exhibitors to enter. At Birmingham there were four good collections, but the number of cut blooms in the other classes must have been as disappointing to the executive as to myself, and less than 100 feet of tabling contained all the cut blooms exhibited. The plants here were a grand feature, excelling everything I have met with this season.

Passing onwards from exhibitions to Chrysanthemum sports, I confess that I am much puzzled at the change of colour as well as form of petal that sports sometimes show. It has frequently been proved beyond dispute that the change is not only in the colour, but also an improvement in petal and other characteristics—for instance, Mr. Bunn is a great improvement on Beverley, Mabel Ward appears to have a broader petal than its parent Eve; but probably the variety most given to sporting is Mrs. G. Rundle, for it is not an uncommon circumstance to see perhaps half a flower white and the other part yellow. There can be no doubt that many plants show the two characters on the same specimen, and have to be perpetuated in the manner described on page 484. There are others, however, which perpetuate themselves, or in other words the cuttings are taken from the base in the ordinary manner, and at the blooming season the lucky possessor discovers something unfolding its petals very different from the variety the cutting was taken from. Why such changes should take place I cannot answer, but it is enough for my present purpose to show that sports do originate in this manner, as well as from the transformation being noticeable at the same time on the same plant. Allusion has been made by Mr. Bardney to the keeping properties of Lord Wolseley. I thoroughly endorse them. It is a far better keeper than Prince Alfred, and a variety I hold in the highest estimation. The petal to me appears broader than Prince Alfred, and in every case that I have seen it has come true, which I think reflects great credit on Mr. Cannell, to whom the stock was transferred. It is singular that this variety originated from a root cutting. Mr. Orchard became the fortunate possessor of it, and was quick in perceiving its good and distinctive qualities, otherwise probably Lord Wolseley as an exhibition Chrysanthemum would have been unknown. I am told that White Venus originated with Mr. Shrimpton, a noted old grower at Roehampton exactly in the same way. The original plant when unfolding its white petals was labelled Venus. Will other readers throw any light on the origin of sports?—J. W. MOORMAN.

Now all the Chrysanthemum shows are over I think it would be advisable to give a few words of advice with regard to making lists of prizes for next year, and what I would suggest is that prizes should be given for cut blooms shown with foliage as grown on stems 6 inches

above the boards; say the back row of blooms Japanese, middle row incurved, and front row large Anemones, which would have a splendid effect when arranged on the exhibition table. This would give all good Chrysanthemum growers the same chance of winning; but as the prizes are given now, the one that can dress his blooms the best has much the best chance of winning, and it would look much more natural to see the flowers shown with foliage without cups or collars.—GEORGE STEVENS, F.R.H.S., *St. John's Nursery, Putney.*

MR. McINDOE'S GRAPES—DUKE OF BUCCLEUCH IN DECEMBER.

I READ with pleasure Mr. McIndoe's article on Grapes on page 488, and was especially pleased to see that that "much-abused Grape, the Duke of Buccleuch, was one of the number sent to you for inspection. That the Duke *will* keep in good condition till the end of December or beginning of January has been proved by the writer, and therefore he is glad to see that others have been able to do the same, as other writers have questioned if such could really be done. Nothing can excel the rich sugary flavour of the Duke when the Grapes hang till December; and even when hung longer and become shrivelled it has still a splendid flavour, and even richer sweetness. When plump and fresh, however, the Duke is more fitted for the table, as it has all its fine appearance to add to the fine flavour. That it can be had in such a condition at this time of year is beyond a doubt, and Mr. McIndoe is to be congratulated on being one of the few, as yet, who have so kept the Duke. Side by side with Gros Colman a bunch of Duke of Buccleuch forms a grand dish, being quite equal in size to the black giant, and easily surpassing it for quality and flavour. Though not recommended as a late Grape, the Duke can and has been kept late in good condition, and the cultivator who manages to do this is amply rewarded for his trouble.

It is to be hoped many more samples of the Duke may be met with in the future about this time of year. There is no reason why it should not be so.—N.

SALVIAS.

THESE are very useful plants, and where they succeed form a good contrast to our bedding plants. I have used the scarlet *S. splendens* for several years in a border some 300 feet long, and have planted them alternately with *Gladiolus*, and they fill up well and keep a good succession of bloom as long as the frost will allow, which this year was till the end of November. For flowering plants in pots and conservatory work I must mention four sent out by Mr. Cannell—*S. splendens* Bruanti, *S. Betheli*, *S. rutilans*, and *S. Pitcheri*. *S. Bruanti* is a large-flowered variety with splendid scarlet trusses; *S. Betheli* a strong grower, and the colour is rose with shaded white tips. *S. rutilans* is a charming plant; specimens with from sixty to eighty spikes of lovely magenta-coloured blooms are grand. A dozen plants well grown would be most valuable to anyone requiring flowering plants in autumn. But I must not forget the next, which is *S. Pitcheri*, with its compact growth and beautiful azure-blue flowers. This shade is much needed, and the plant is well worthy of being extensively grown.—S. JENKS, *Brambletye.*

POTATO DISEASE.

[A paper read before the Scientific Committee of the Royal Horticultural Society, December 18th.]

EXPERIMENTS PERFORMED AT KING'S LYNN IN CONNECTION WITH THE JENSENIAN SYSTEM OF POTATO CULTURE, 1883.—I. *Direct Infection of the Tubers by the Conidia and Zoospores of Peronospora infestans.*—It having been asserted that it was impossible thus to cause the disease in tubers because of the thickness and impenetrable structure of their epidermal tissues, the following experiments were performed, in which recently dug tubers had applied to their surface the conidia, by simply dashing them with a diseased branch; they were then placed in the earth, and examined eight days afterwards; an equal number of tubers taken from the same root at the same time were also buried as control tubers:—

Variety of Potato.	No. of tubers infected.	Date.	No. of control tubers.	Diseased on the eighth day.	
				Infected.	Control.
1. Porter's Excelsior ..	4	Aug. 1	4	4	1
2. Beauty of Hebron ..	3	Aug. 1	3	3	
3. Porter's Excelsior ..	6	Aug. 1	6	6	0

Experiments Nos. 1 and 2 were made in conjunction with Mr. John Thompson at West Lynn. Experiment No. 3 was made in my garden at King's Lynn. Porter's Excelsior is a Potato which takes the disease very readily; so that the control tuber which became diseased was doubtless affected before it was buried. Care was taken that the tubers

were free from any abrasion of the cuticle, or injury by which the disease could have entered the substance of the tubers without penetrating the skin. The control tubers were kept for several weeks, but evinced no signs of disease. These experiments would not have been mentioned had it not been recently re-asserted that the disease could not be communicated in this way.

II. *High-Moulding Experiments.*—Experiment No. 1.—Mr. John Kidd had two rows of Myatt's Prolific with thirty-eight plants in each, one of which he high-moulded on July 15th at my suggestion. On August 17th both rows were lifted; 5 per cent. of the row with the ordinary moulding were diseased, but in the high-moulded row no diseased tuber was found.

Experiment No. 2.—Four plants of Porter's Excelsior were high-moulded in Mr. J. Thompson's garden on July 14th. The next four plants in the row were left moulded in the ordinary way. On August 1st disease was general in this garden; August 18th Potatoes lifted by Mr. Thompson and myself with the following result:—

Ordinary Moulding.		High-Moulding.	
Sound.	Diseased.	Sound.	Diseased.
46	5	41	0

Experiment No. 3.—Eight plants of Elephant in the same garden, high-moulded at the same time, lifted on the same day as in the previous experiment.

Ordinary Moulding.		High-Moulding.	
Sound.	Diseased.	Sound.	Diseased.
49	10	39	0

Experiment No. 4.—Four plants of Beauty of Hebron, No disease in either high or ordinary moulding.

Experiment No. 5.—Eight plants of Ashleaf, four in one row, four in another row.

Ordinary Moulding.		High-Moulding.	
Sound.	Diseased.	Sound.	Diseased.
54	13	85	0

Experiment No. 6.—Twelve plants of American Rose, four plants in three rows, high-moulded, as compared with the four adjoining plants grown with the ordinary moulding.

Ordinary Moulding.		High-Moulding.	
Sound.	Diseased.	Sound.	Diseased.
76	13	84	1

Experiment No. 7.—In the foregoing experiments high-moulding compared very favourably with ordinary moulding, but if high-moulding be the true cause of this freedom from disease it should compare more favourably still with plants that have not been moulded at all. There is another point upon which I wished to satisfy myself, which was this—If the Potatoes had been left longer in the ground would the disease have travelled down the stem to them? Four plants of the Beauty of Hebron were high-moulded on July 14th to the extent of full 5 inches, the four plants next to them had never been moulded at all. In due course Peronospora appeared upon these Potatoes, but it was not until not only was the foliage destroyed, but long after this, when most of the stalks had vanished, that the Potatoes were lifted on (September 19th). This experiment was made in the Vineyard, West Lynn, by Mr. S. Castle and myself.

Not Moulded at all.		High-Moulded.	
Sound.	Diseased.	Sound.	Diseased.
54	65	107	0

These figures speak for themselves as to the effect of high-moulding as a preventive against the Potato disease.

Tabular Statement of the Results of High-Moulding, Showing the Number of Sound and Diseased Tubers respectively:—

—CHARLES B. PLOWRIGHT, King's Lynn, December 10th.

STRAWBERRY FORCING.

STRAWBERRY forcers will now be thinking of starting their first batch of plants into growth. At this early season the slower the start the better the finish; in fact, all through the forcing season it is best to start slowly. Different growers have different systems in the position of the pots. Some stand the pots on the bare shelves, others on turves, and some place the pots in saucers to save watering, which is time gained at the expense of the flavour of the fruit. The turves have certainly something in the system to recommend it, but I think the bare shelves are the best, where the plants are well looked after as regards watering. Strawberry plants should not on any account ever be allowed to become dry, or deformed fruit, red spider, and mildew in abundance will result.

If good fruit is desired the crowns should be well ripened. A temperature of 45° is quite sufficient at first, to be raised to 50° to 55° by the time the plants are in bloom. At the early season they should be carefully supplied with water at a temperature a few degrees warmer than the house. Keep the house well ventilated on all favourable occasions, but do not let the plants be exposed to a cold draught, or mildew will soon appear. As the flowers expand do not have the atmosphere too moist, or the result will be that the flowers will set badly. The aim of the cultivator should be to keep the pollen dry. At midday give the flowers a gentle shake, it will help to disperse the pollen. Some gardeners dust the flowers with a camel-hair brush or bunch of feathers. But a gentle shake I have found sufficient to insure a good set. Of course later batches do not require this, only abundance of air, as probably when the earliest plants are in bloom the outside temperature is not in a condition to allow ventilation, which is the reason we have to resort to artificial means to assist fertilisation.

After the blossoms have set well thin them to about eight, which are quite sufficient if good fruit is expected. Keep the plants then in a night temperature of 60° to 65°, with a corresponding rise by day. At this stage give them liquid manure about every alternate watering, until the fruit commences colouring freely, when it should be discontinued, or the flavour of the fruit will be impaired. For later batches, as the season advances, and after the fruit is set and thinned, a good syringing when the house is closed on fine days will be beneficial. Keep them well aired, and by no means ever let them become dry. Through the months of March, April, and May they will need water in abundance, using more liquid manure than for the earliest batches. The fruit should be propped up after it has set to keep it clean, and for insuring a better colour. Strawberries will not stand hurrying before the fruit is set on any account; but after it is set hasten them as fast as is needed to get them in by a certain time. If green fly should appear, as it sometimes will do just about the blooming stage, fumigate, but before the plants are in bloom.—A. YOUNG.

THE INSECT ENEMIES OF OUR GARDEN CROPS.

THE CARROT.

If we examine those bunches of Carrots which are commonly displayed in the markets and shops it is observable how frequently the roots bear traces of what is called "rust," although they must have been grown under very different circumstances, pointing to the wide prevalence of the insect known as the Carrot fly, indicating also, it might be said, that the injury done by the maggot is sometimes only of a partial character. Undoubtedly this species heads the list of the foes of the Carrot, for to that plant it is specially attached. The Latin name, however (Psila Rosæ), reminds us that it has been taken infesting the Rose, a plant of dissimilar habit and order. The peculiar reddish brown colour, which shows itself upon the places bitten, has led to the word "rust" being transferred from

the root to the offending insect, which, small as it is, yet shows itself very pertinacious in its attacks. The fly hardly measures half an inch across the wings when they are expanded; it is almost black or blackish green (hence occasionally called the Negro), with transparent wings, head and legs reddish yellow. Of this there appear to be two or three broods during the summer season, the first deposition of eggs taking place about the end of May or in June, these flies being produced from larvæ or pupæ that have lived through the winter. Like others of the group the larva or maggot is legless, having a sharp head and a blunt tail, which has just above it two raised plates that aid the movements of the insect as it forms its burrows or galleries; the surface is smooth, shiny, and pale yellow. The different forms of the insect are represented in the annexed engraving.

Young specimens of this pest are numerous during June, and from that date until the last Carrots are pulled in the autumn maggots are to be found where preventive measures have not been taken; and even after the Carrots have been removed some will still subsist upon the fibrous roots left in the soil, hence the advisableness of clearing the ground thoroughly about November, well digging and dressing with gas lime where the fly has occurred. Dressing with sand that has been moistened by the addition of spirits of tar or creosote has been strongly recommended by several gardeners (a gallon is said to saturate sufficient sand for 2½ rods); this may either be forked-in during the autumn or laid-in at the time of sowing. If somewhat expensive, its results may give it the advantage over cheaper remedies.

FIG. 106.—CARROT FLY AND LARVÆ.

1, 2, and 3, Larvæ, natural size and magnified; 4, infested Carrot; 5 and 6 pupæ; 7 and 8, Carrot Fly, natural size and magnified.

We all know that young Carrots must be thinned; this thinning operation is in this way detrimental, that it enables the first brood of flies to lay their eggs more readily, hence some have advised early thinning before the flies are out, and also after thinning a filling-up of the opened soil by a mixture of soot and wood ashes, which proves besides of value as a manure. Before thinning is requisite, if the insect has been troublesome the previous year it is of benefit to dust the young plants with these, and lime in addition. By a number of Miss Ormerod's correspondents the application of diluted paraffin, a wineglassful to a gallon of water, has been tried and found of utility; a few have tried combining paraffin with an absorbent, such as wood ashes. No doubt regular watering at the season when the flies are noticed helps to keep them off the plants, for it is in dry weather they make their attacks most readily, and the Carrots are also less able to resist the injuries caused by the maggots, their rootlets obtaining little nourishment.

Amongst the small moths we have three species, which in varying numbers derive their food whilst they are caterpillars from the leaves or bloom of the Carrot; but they are of minor importance. They all belong to the genus *Depressaria*, exhibiting the characteristics, as moths, of a flattened body, over which the narrow upper wings are crossed when the insect is not in motion. Of the three the Carrot-blossom moth, *D. Danella*, is most commonly noticed, because the caterpillars cover the umbels with a silken web, forming thereby a chamber in which they live and consume the flowers or seeds. They are about half an inch long, grey or yellowish, with brown heads; along the sides of the body are numerous black points. When alarmed they run rapidly backwards, then generally drop themselves by a thread to reach the earth. M. Bouche advises planting amongst the Carrots a few Parsnips, about one in every 8 feet; from its preference for the Parsnip the insect will single these out, and the Carrots will almost escape, while the caterpillars swarm upon the Parsnip tops, which can be collected and burnt; or the moths may be caught, at least some of them, by a hand-net in their season, usually June. Although the wings only expand three-quarters of an inch they are rather noticeable, owing to the white markings upon the reddish brown of the fore wings. The hind wings are light grey, head and body reddish black. Some have advised the application of powdered hellebore to the flower heads after rain, or when they are moistened with the morning dew.

A less frequent species has been styled the Purple Carrot-seed moth (*D. depressella*); the moth is duller in colour, with pale brown patches on a darker ground; it is also smaller than the preceding. In habit it is similar, the caterpillar spinning webs over the flower heads, sometimes changing to a chrysalis in this web, at others piercing a hole in the stalk, to dwell there sheltered until it is aroused by the warmth of spring. This caterpillar has white, not black, warts upon the body, the sides of which swell out slightly; it must be dealt with if observed similarly to the preceding species.

The third species, as simply a feeder upon the leaves of the Carrot and also of the Parsnip, occasions a smaller amount of loss than the former species, which destroy the seed effectually if unmolested. This is *D. eicutella*, its habit being to roll up the Carrot leaves into a cylinder secured by threads, sliding out at one end if alarmed. It is a pretty caterpillar, grass-green in colour, with three lines of dusky green and rings of black tiny spots, the head being brown. In appearance the moth is more glossy than the other species, the fore wings brownish freckled with a deeper brown and black; a few white dots are observable about the middle of the wing, the hind wings are of a uniform grey. The chrysalis is hidden in a folded leaf, or the caterpillar will now and then make a cocoon just below the earth. There is a brood of caterpillars on the young Carrot plants in early summer, from these come moths depositing eggs that produce an autumn brood. The moths appear again about November, and then conceal themselves for the winter, emerging to deposit eggs the next season. These little caterpillars are, it is said, specially hunted by the solitary wasps, which make chambers in sand banks or decayed wood during the summer, placing within these a supply of such larvæ that their grubs may have food close at hand.

Rows of Carrots are also sometimes noticed to decline rapidly in June or July, and the cause is a much larger caterpillar of varied tastes. The species has taken its name from one plant it greatly infests. This is the Turnip moth, *Agrotis Segetum*. The caterpillar lurking unseen will pierce the young Carrot through between the root and stem, and pass from plant to plant, working its way through the soil during the day, but usually feeding at night. Its full history belongs to the above named plant, for which we reserve it; but we may note that the free application of soot has been advised, also that of diluted paraffin or gas lime. Lastly, to the list of the enemies of the Carrot must be added the larvæ of the genus *Tipula* (crane-flies), particularly *T. oleracea*, which occurs at the roots some seasons, though seldom very destructive.—ENTOMOLOGIST.

SNOWBALL CHRYSANTHEMUM.

I NOTE at page 507 of the Journal the questions asked by "Novice" regarding Snowball and Empress of India Chrysanthemums being admissible in the same stand. I do not think they would be admissible in the same stand. I have seen fine blooms of the variety called Snowball, but consider them only well-grown examples of Empress of India. They had large broad petals, more rounded than those often seen on Empress of India. High culture will produce better petals than moderate culture will, hence the confusion of varieties. I have a variety called Snowball, which is a white reflexed flower, the florets recurving quite to the stem, the bloom being thus exactly of a snowball shape. This I consider the true Snowball. It is quite distinct from any other variety that I know or have seen. The incurved blooms are only half balls. I have never seen that White Queen of England was anything else than Empress of India.—E. MOLYNEUX.

TRAINING RASPBERRIES.

MANY will no doubt feel grateful to Mr. Wright for his able and lucid explanation of the different methods of training Raspberries. I have had an opportunity of observing the whole of the methods mentioned at various times and in various counties, and I certainly agree that the system as shown in fig. 95, and described on page 481, is by far the most preferable. It is also the least expensive of the systems of training, since no elaborate trellis or endless number of stakes are required, less than half the number of the latter being necessary. It is almost impossible to obtain thoroughly ripened canes where the fruiting canes are trained to a stake thrust through the centre of the stool, and the young growths allowed to grow up around to the manifest injury of the crop of fruit and the thorough ripening of the young canes.

We had ample experience of this system this last season. We have made fresh plantations this autumn, planting the stools of six canes each 5 and 6 feet apart each way according to the requirements of the different varieties. As was pointed out, this system is by no means a modern one. It is figured and described as long ago as 1834, in an excellent little work entitled "Hayward on Horticulture," in which also are to be found many other equally useful hints on fruit culture.—T. W. SANDERS.

MR. WRIGHT has asked for descriptions of other modes of training the Raspberry. I forward a plan of my own which I consider as one of the best, if not the best, for this fruit. I think that for small and moderate-

size gardens it is best to support the canes in some way, as, owing to the growth being more drawn than where growing in fields, the canes sway about more, and the fruit gets bruised, &c. My fences consist of two end standards of wrought iron 4 feet out of the ground, and double lines of wire 15 inches apart, the Raspberry canes being planted in a line right down the centre. I use three lines of wire, one 12 inches from the ground, and the other 18 and 36 inches higher. The fruiting canes are tied to each side about 1 foot apart all along the row. The new growth rising straight up does not shade the fruit. When pruning time comes round the old canes are cut out and the young growths tied in their place. It is a very cheap trainer, gives double fruiting space, yet allows for the young growths without crowding, and it is durable.—T. WILKINSON, *Newton-le-Willows*.

VINES FAILING—STORED-UP SAP.

HAVING read with considerable interest the discussion on stored-up sap in the Vine, I shall make no apology for troubling you with the history and description of the Vines in reference to the subject, as I believe it will do something to elucidate matters. In the first place I must take exception to the term, "stored-up sap," which cannot of and by itself produce a shoot either of a Vine or any other plant, therefore I should consider "latent energy" as the more appropriate term.

When I took charge of the gardens here (June 2nd, 1881), there were two small vineries of ten Vines each, which had been planted by my predecessor in the winter of 1880 and 1881, with Vines furnished by Messrs. F. & A. Dickson of Chester, and were, as far as I was able to judge of them when I entered on the place, well-ripened canes of good medium strength, in fact such as are usually sold as first-class one-year-old fruiting Vines. The vineries are of a peculiar construction, and not well adapted for the purpose to which they are applied. First, they are built in two spans with a glazed partition running down the centre, to divide the block into two houses. The roofs are glazed with Hartley's rolled plate, which is very heavy. There is one ventilator in each gable and sliding sashes at the bottom, but no ventilation in the roof, so the two houses run side by side. There are two rows of Vines in each house, and only an inside border without any partition, so that the roots in the early and late house are all in the same border.

Now for the state in which I took them in hand on the 2nd of June, 1881. They had been planted in the winter or early spring. The canes had been left about 6 feet long, and were tied down to sticks in a horizontal position about 1 foot above the surface of the border, and had thrown out some four or five small yellowish leaves, from some six or seven eyes in each Vine, all much alike in this respect, and the appearance of the shoots was that of half-ripened, half-starved growing wood, with a leading bud in some of them very soft, sealy, and white in appearance. I could not at first give the Vines the examination which I had intended to do at the earliest opportunity, so I decided to keep the houses at a good and steady temperature, with plenty of atmospheric moisture, and relieved the Vines from the horizontal position in which they had been kept apparently ever since they had been planted, giving them an upright position. This treatment was continued for ten days, during which time a few showed signs of improvement. In the meantime my employer informed me that he had only recently purchased the place, that during winter and spring he had spent much money in the garden, and amongst the items was £25 for soil for the new Vine borders. This soil had a very good appearance. Nearly the whole of it was formed of loamy sods about 4 inches thick, very tough, full of fibre—in short, was the top spit of an old meadow from the neighbourhood of Liverpool, and of a dark brown colour. The only addition which was made to it was one cartload of cow's dung to ten of the turf. As to drainage, we are on the blown sand, and it is quite unnecessary to think of it except to bring water to the place. There was a quantity of brick and mortar rubbish put at the bottom of the border, but the action of these are rather as retainers than carriers of water, therefore nothing could be wrong in this direction.

This was therefore a curious dilemma. It was approaching the middle of June and not one of the Vines had a shoot over 9 inches long. I at last resolved to face the difficulty in another direction, so with a trowel I carefully removed the soil from the roots of the poorest Vine in the earliest house. The result was that I found a ball of earth nearly, if not quite, entire, and on disentangling the roots observed some spots and patches of white mould, which was clinging to the dead strong roots at the places where fibres had been growing in the previous summer. There was not a live root in the ball. Following up my search through the first house, there were six Vines in this condition, and four showed signs of life in some of the strong roots with a good circle of collar roots. These four I replanted, well burying the collars in the good soil of the new border with the addition of a little leaf soil and old mortar broken up to encourage root-extension as quick as possible. I subsequently learned that the Vines while in their pots had been frozen very hard.

This being the history of the condition of the early house it is useless to say anything on the late house, except that we had six Vines showing a little life and only four quite dead. Two of the dead Vines after being divested of all roots, and, having broken only two eyes near the top of the canes, I tried a little experiment with. I dug a small trench about 4 feet long and about 8 or 10 inches deep, in which I laid the canes, turned their ends up and secured them to a stake, one at each end of the early vinery. Some fresh Vines were obtained to fill the places of those which had been pronounced dead. But this brings us into July, a

curious time for planting, and how these progressed shall form the subject of another paper.—R. LIVSEY.

POTENTILLA FRUTICOSA.

In the *Journal of Horticulture* of December 6th a description is given of this plant, with an engraving, which conveys a good general idea of its habit. I have for some years grown it here on my rock border, and quite agree with "Herba" as to its being a very desirable addition there. Although its flowers are fugacious, they are very bright and well shaped. It may be interesting to some of the readers of the *Journal* to know that it grows in abundance on the banks of the Tees, above High Force, in Teesdale, Yorkshire, associated with *Primula farinosa*, and not far from the home of by far the loveliest of British alpines, *Gentiana verna*. In Scotland we sometimes see *Potentilla fruticosa* grown as a bush among shrubs, where it is entirely out of character, a grey rusty-looking object. On the rock garden it retains its natural dwarf habit, and when in flower is very distinct and attractive.—CHARLES STUART, M.D., *Hillside, Chirnside, N.B.*

HEATING SMALL GREENHOUSES.—May I state for the information of your inquiring correspondents that I have just had fitted up for heating a greenhouse 17½ feet long by 8 feet wide, a small boiler heated by gas outside the house, with a 3-inch iron pipe running along the wall under the front stage, and as I have tried it, so far it answers to keep out the frost and to dry the house? I do not like to take up your space by writing more, but shall be happy to give any information.—GAMMA.

KITCHEN GARDEN.

Hotbeds.—These are useful in every forcing garden in the spring months, and provision should always be made for them. As a rule they are not made up until after the new year, but the material for their formation should be collected some time before that. In October and November we use all the manure we get from the stables for mixing with vegetable refuse for digging into the soil in spring; but now hotbed-making is in view, and everything in the way of stable manure, old leaves, and spent or half-decayed vegetables are put into a heap ready for use early in January. In making beds thus early they ought to retain the heat until April at least, and to do this there must be a large body of material.

Forcing Potatoes.—A fortnight or so before these are planted the seed tubers should be prepared. Only the earliest varieties should be dealt with now, and the tubers should be of a fairly good size. Those to be planted first should be selected at once, and they should be put in single layers in shallow boxes with a little Mushroom manure or leaf soil underneath and above them. The boxes must then be placed near to the glass in a cool frame or pit where they can have a temperature of 55°, and there they will soon begin to produce short robust growths and a few roots, and it is when this has been accomplished that they should be transferred to the frames. In growing them in frames a good hotbed is made, frames are placed on the top of this, and soil is added to about the depth of 1 foot; in this the Potatoes are planted 3 inches below the surface, 18 inches between the rows, and 9 inches apart. Where there are permanent frames for forcing they are generally from 4 feet to 6 feet deep, and hotbed manure is put in firmly until it is 2 feet from the top, when 1 foot of soil is placed on and the tubers planted as in the other case. A few dishes of early Potatoes may also be had from pots or boxes, 10-inch or 12-inch pots are the most suitable. They should be well drained, half filled with good soil, three seed Potatoes placed in each, and then more soil, until the surface is 2 inches from the rim of the pot. Boxes of various sizes may be filled in the same way, and they may all be placed in an early vinery, Peach house, or pit to grow. When first they begin growing Potatoes should have very little water, as they are not benefited by much until they have luxuriant stems and are forming tubers. No good produce will ever be forthcoming unless they are grown near the glass and in abundance of light.

Forcing Carrots.—A manure bed and frame are the best of all means for forcing Carrots. The bed is made as if for Potatoes, but the soil for the Carrots should consist of at least one part sand, and it should be quite free from lumps. A little soot or lime mixed with it is also an advantage, as the roots are worth nothing unless they are free from wormholes. French Horn is the best variety for frame culture, and the young roots are amongst the most delicious of spring vegetables. The seed should be sown very thinly broadcast, and only covered to the depth of 1 inch. We generally make the surface of our Carrot beds all sand, as it is not so liable to become green and too firm on the surface as soil does.

Stored Roots.—These should all be examined and decaying roots removed. In warm sheds Carrots and Beet generally commence top growth at this time, but in turning the heaps all this should be rubbed off and be re-stored in as clean and firm a state as when first taken in.

The main secret in keeping stored roots sound and sweet until young ones come again is never to allow damp or decay to progress to any extent. Badly matured Onion bulbs may also be showing signs of growing, but those bulbs which are most likely to do this should be used first. The smallest and firmest should be placed aside for late use.

Kidney Beans.—It is now a critical time for those being forced, and unless where the very best means exist their progress will be very slow now. Nothing less than 65° will do for them, and 5° or 10° more than this will suit them better. Careful watering at the roots is very necessary now, and a dry atmosphere is the only one in which the flowers will develop and the fruit form properly.

Rhubarb, Seakale, and Asparagus.—These force more readily now than they did six weeks ago, and where a constant supply is desired successional batches must be brought into the forcing quarters every three weeks. A steady temperature of 65° is better for all of them than an excessive heat. Spent roots should be removed as soon as all the produce has been taken from them, as profitable forcing can only be carried on where the most rigid attention is given to make the most of everything.

Kitchen Garden Work.—This is not very pushing at present, but manuring and digging should always be kept well forward.

Seed lists for 1884 are coming to hand, and a selection will soon have to be made from them; and although space forbids this here at present, we can only remark that extreme cheapness and high quality are never combined.

FRUIT-FORCING.

PEACHES AND NECTARINES.—Earliest House.—The blossoms are expanding, and appear strong and promising. Syringing the trees must, when this stage is reached, cease, but a good amount of moisture must be maintained by damping available surfaces—*i.e.*, the floors, borders, &c., in the morning, and again in the afternoon. This, with a proper temperature—*viz.*, 50° at night and 55° by day from fire heat, will produce a genial condition of the atmosphere so essential to a healthy and vigorous blossom; yet a close confined atmosphere is fatal, and must be guarded against by admitting a little air constantly—having the top ventilator open about an inch. This will cause a circulation of air under the most adverse circumstances, and prevent a close vitiated atmosphere. In the daytime no opportunity should be lost of admitting air, commencing from 55°, increasing it with the sun heat, so that the ventilation is full by the time the sun raises the temperature to 60° or 65°, at which it may be kept from sun heat, reducing the ventilation as the sun heat declines, withdrawing the ventilation for the day at 55°. In severe weather the temperature may with advantage be kept 5° less both day and night. If there be an abundance of blossoms some of those on the under side of the shoots may be removed by drawing the hand the reverse way of the growth. When the flowers have ripe pollen it should be carefully applied to the stigmas with a camel-hair brush. If there be any deficiency of moisture in the borders a good watering should be given not less in temperature than that of the house.

Second House.—The trees in this house having been pruned and dressed the house should now be closed, but no fire heat need be given, or only to exclude frost, and above 50° ventilate fully. A thorough soaking should be given the inside borders, repeating the watering if necessary, so as to thoroughly moisten the soil in every part, and in the case of weakly trees liquid manure may be given, but it must be weak and tepid. Syringe the trees in the morning and again in the afternoon, but not the latter on a dull day, as it is important that the trees become dry before night. On New Year's day forcing may commence in earnest, the temperature being kept at 40° to 45° at night, 50° by day, above which ventilate freely, and close for the day at the latter temperature.

Succession Houses.—The trees in these should be pruned, dressed, and the houses cleansed, and should be kept as cool as possible by admitting air in all but frosty weather, and even then a few degrees of frost will not do any harm providing the air be dry; and should the lights have been removed they need not be replaced, as frost is not injurious on any but unripened wood and whilst dormant, but after the buds begin to swell, and the sap becomes active, safety from frost is necessary. Yet to retard the flowering, especially in late houses, they might be kept as cool as possible, ventilating fully whenever external conditions admit.

Cherry House.—Everything being in order, a start may be made at once by closing the house, but there must not be any attempt at keeping it close and warm, as this would cause a weak development of the blossoms—hence the nature of the treatment should be such as will not excite growth prematurely, but such as will insure a slow progressive development, a temperature of 40° to 45° at night being sufficient, and 50° in the day by artificial means, at and above which ventilate freely, allowing an advance to 60° or 65° from sun heat, and close at 55°. Maintain a genial condition of the atmosphere by syringing in the morning and afternoon of fine days, but in dull weather damping in the early part of the day will be sufficient; yet it is essential that a growing temperature be secured. Keep a sharp look-out for aphides, and if any appear fumigate on calm evenings.

Cucumbers.—Let every effort be made to retain the sun heat by closing the house early in the afternoon, damping at the same time with tepid water. Pathways and other available surfaces should be damped every morning, and again in the afternoon if the day has been bright. Afford liquid manure in a weak and tepid state to plants that are making growth freely, but those that are stationary should not have this until they again show signs of free growth. A little fresh lumpy loam placed over the roots is a great incentive of root-formation, and when these are plentiful

feeding will soon enable the plants to commence healthy free growth. A little air on mild days will be advantageous in giving the foliage an improved texture, but cold and drying currents must be avoided as much as possible. Remove all superfluous fruit from the plants as they show, and let all shoots be tied to the trellis as they require it, removing bad leaves and superfluous growths, it being essential that the foliage have free access to light and air, and the glass should be kept clean, so as to admit all the light possible. Little stopping will be needed now, although vigorous growths may need their points pinched out, the object being to encourage free growth. If mildew appear dust the affected parts with flowers of sulphur, and for red spider coat the pipes thinly with a wash of sulphur and skim milk; for aphides fumigate moderately on two or three consecutive calm evenings. A few seeds of Cardiff Castle or Telegraph may be sown now to produce plants for early spring fruiting. A bottom and top heat of 70° is as little as they can be brought forward in, and plenty of light is required to make the plants robust.

Preparing Material for Hotbeds.—Where Cucumbers and Melons are grown in pits or frames heated by fermenting materials, these should now be prepared for raising the plants and growing them. Oak or Beech leaves with about a third of stable litter are far preferable to all stable litter, as they afford a milder and more lasting heat. Material of this description should now be thrown into a heap, mixing them as evenly together as practicable, and, if dry, they should be damped as they are thrown together. In the course of a week or so the materials will be warmed through, and should then be turned over, throwing on more water if there be not sufficient moisture in the material to insure fermentation, and that without causing it to be so violent as to heat itself dry, and which should be obviated by turning frequently and throwing on water according to the state of the material. As much of the after-success depends on the preparation of the material, this should be commenced in good time, so as to have thoroughly sweetened material by the time it is deemed advisable to make up the beds.

PLANT HOUSES.

Calanthes.—Few Orchids are more beautiful or useful than *Calanthes* at this season of the year. Those that have their spikes fairly well advanced will need no more water at their roots, but those that have not yet commenced to open their flowers may need occasional applications until the spikes are further advanced. Do not keep them while in flower too warm or where the atmosphere is rather moist. They look handsome arranged amongst *Adiantum cuneatum* grown for cutting, and now in a temperature of 50° to 55° at night according to the weather. *Calanthe vestita nivalis* is later coming into flower than either *C. v. lutea* or *C. v. rubra oculata*, but *C. v. Turneri* is much the latest and flowers when all the others are over. It produces large pure white flowers with a rose-coloured eye, and its spikes are longer than those named above, but its greatest value is its late-flowering habit.

Centropogon Lucianus.—This is a grand winter plant, and the earliest are just now in full beauty. They are at home in the stove or in an intermediate temperature, but in the latter they last very much longer than they do in the former. Our plants are all grown in 5 and 6-inch pots, and are in early autumn supplied with stakes about 1 foot in length and the growth made afterwards allowed to arch naturally, and in which condition they are the most effective when arranged amongst other plants. A number of plants associated with an early batch of *Euphorbia jacquiniæflora*, and rising above *Zonal Pelargoniums*, *Primulas*, *Cyclamen*, *Hyacinths*, *Tulips*, *Chrysanthemums*, and other dwarf flowering plants in the conservatory, have a very charming effect. This plant when well grown is beautiful, and we cannot dispense with it from the stove, and in consequence it is grown in large numbers. Our latest plants are in a temperature of 50°, and are not yet showing the colour of their terminal truss of flowers. We rooted a number of cuttings late, and the growth made does not exceed 4 to 8 inches. They are flowering profusely, and we find them most useful where small plants for decoration are appreciated.

Poinsettias and Plumbagos.—These should now be in grand condition, and the former will last nearly double the length of time after their bracts are fully expanded if not kept in strong moist heat. The former will stand for a long time in a night temperature of 45° to 50° if gradually hardened previously and cold draughts excluded from them. If removed from stove heat to the temperature given without previous preparation their foliage will turn yellow and fall, and half the beauty of the plants is lost. The *Plumbago* will not open its flowers freely if kept in too low a temperature, and should not be subject to one lower at night than 55°. *P. coccinea superba* is very much brighter in colour than the old *P. rosea*, but is taller in growth and not quite so freely branching; both should have a place in every garden. These plants look light and effective when arranged with the yellow *Linum trigynum*; in fact, they are more striking with this than any other plant. The last-mentioned plant, although useless for cutting, is beautiful for decoration, and not grown half so much as it deserves to be.

Begonia semperflorens grandiflora.—This is one of the best and most useful winter varieties. The last batch of plants if treated as directed some time ago will now be flowering profusely in 3-inch pots. We have just taken out the central shoot of half our batch and placed them in 5-inch pots. These will make beautiful plants in a very short time. To grow this *Begonia* well during the winter it should be kept in rather a dry atmosphere, close to the glass, and where the temperature will not fall below 60° at night.

THE BEE-KEEPER.

THE COMING BEE.

THIS is once more announced on page 497. I wish it would come, we shall be glad to see it if it arrives in our day. It has been long talked about, and so far as we can learn it is as far off as ever. Predictions made about the coming and the departing bees have not been realised. The prophecies touching them have not been true. Doubtless more assertions and predictions will be made from time to time about coming bees and improving the race of bees, and hence I venture to take leave to ask the readers of the *Journal of Horticulture* to think for themselves on these and all matters, and take nothing for granted and little on trust.

On the page quoted we had a well-written article by Mr. W. H. Stewart, an American bee-keeper. After asserting that the question of financial success or failure in bee culture must eventually turn on this one point—viz., “the coming bee,” and that the subject cannot be too closely investigated, he asks “What is the coming bee? It cannot,” he says, “be the common brown bee: the importation of the Italian and other races of queens has fixed the fate of the old brown bee. What is left of the pure brown blood must soon be superseded by the various mixed breeds, and soon will only be known in history. We are of the opinion that the coming bee will not be the pure Italian, from the fact that the ‘new broom’ has become somewhat old and fails to ‘sweep clean.’ The fever for bright yellow stripes is fast cooling down, and honey-producing bee-keepers are beginning to learn that a cross between the different races gives better workers and more honey. Some queen-breeders are already awake on this important point, and are putting into the market queens that are bred for paying qualities rather than fancy colours; and there can be no doubt but the coming bee will be much superior to any that we now have, if we manage wisely.”

This writer has fixed the fate of the old brown bee and the Italian. If this gentleman be correct there is nothing for us of much consequence but the coming bee; and he tells us where it must come from and how produced. I should like to quote his letter and mark for the reader's notice the unsound positions he has taken in almost every paragraph, and the self-contradictions. His theory is to have breeding queens with strong wings. “Let us consider,” he says, “for a moment what we are doing with our bees. Some are expending thousands of dollars and years of valuable time in breeding bees that have the greatest number of and most brilliant stripes. Others are striving to produce large-bodied bees, others are striving to get bees with tongues long enough to work on red Clover; others, more practical, are working for the production of bees with honey-gathering qualities. All seem to be hopeful that they will attain these desirable ends. All will agree with me that bees may have bands (or stripes), long tongues, large bodies, and ever so much energy, and yet with feeble wings all these faculties or qualities would be unavailing.” These are Mr. Stewart's opinions. Nothing will do for him but strong wings. He has got some crude notions which he is trying to shape into a theory, by which bee-keepers may raise queens and bees with strong wings. It appears that in America some bee-keepers let their young queens out amongst a class of favourite drones for a few minutes, and then cut their wings off lest they should fly any more and come in contact with drones of another kind. Mr. Stewart strongly objects to this, because he thinks the cut wings will decay for want of exercise. Here follows his theory. “If a faculty or member of an individual becomes weak by disuse then that condition of weakness may be transmitted from parent to the offspring. Disease may be transmitted from parent to offspring; weakness is only another name for disease. I would ask bee-keepers a question: Whether a queen with wings or one without would transmit to her offspring the greatest amount of wing power?” I have tried to condense his theory and make it clear, but his words touching the two queens are these—“The one that is deprived of her wings, and those members all through her life being in a dormant state, or the one that is allowed to retain her wings and compelled to fly as often as circumstances would justify? If I were offering queens for sale as superior stock I would compel the brood mothers to fly often, even if I had to toss them up in the air to give them a start.”

Mr. Stewart should know that queens do not naturally leave their hives for wing-exercise; that they leave their hives when very young once or twice, or thrice it may be, if drones are not plentiful. After fertilisation they never leave their hives but on

swarming occasions. The queens that retain their wings do not exercise them, and their progeny are never weak. If he throws queens up to make them fly or take wing-exercise he will not succeed, for queens thus treated would fly to the first hives they see and very likely be killed at the door. This theory is quite outside practice, and therefore the coming bee will not come from the garden of Mr. Stewart. If it ever does come it will not be found better than those now so common in England, and the profits of it will go into the pockets of those that sell and out of the pockets of those who buy. Unfortunately some people are fond of novelties, and dealers ever bent on commercial success know best how to take advantage of these weaknesses.

The Italian bee came amongst us many years ago amid extravagant and exaggerated praises. It is a very good and beautiful bee, but does not possess one point of superiority over the common bee, and if a cross between the two sorts be an improvement we have it already all over England, and have had it for years. First, second, and third crosses are common everywhere; for years my stock has been mixed with Ligurians. I care nothing for them beyond the common sort, finding that its breeding and working powers are unsurpassed for excellence. I have not been able to discover a fault or failing in the common English bee.—A. PETTIGREW.

TRADE CATALOGUES RECEIVED.

Thomas Laxton, Bedford.—*List of New Vegetables for 1884.*
James Carter & Co., 237 and 238, High Holborn.—*Vade Mecum for 1884 (Illustrated).*

TO CORRESPONDENTS

* * All correspondence should be directed either to “THE EDITOR” or to “THE PUBLISHER.” Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

Books (A. J. B.).—As an elementary work you should first procure Sir Joseph Hooker's little work on “Botany,” one of the Science Primer series, published by Macmillan & Co. You might also obtain Professor Oliver's “Elementary Botany,” published by the same firm.

Murray's Vine Composition (R. D. North).—We regret we are not able to answer your inquiry, as we have not seen this insecticide advertised.

Rose Shows (E. R. H.).—The National Rose Society has fixed the following as the dates of their Shows for 1884:—Metropolitan Show, South Kensington, July 1st; Salisbury, July 9th; and Manchester later in July. We have no knowledge of an “International Rose Show” to be held in England.

Chrysanthemum Sport (I. J. R.).—Although the flowers in their present form are not of striking merit, the variety may improve with good culture, and is worth preserving for further trial. We do not remember one exactly like it, but have seen an old variety similar in colour, orange tinged with brown.

Rhubarb (Yorkshire).—We are sorry you have failed to obtain the early variety, Buck's Scarlet, by advertising. A sample was sent to us from Lincolnshire some time ago, but perhaps the grower of it has no roots for sale. More prolific than the variety mentioned, larger, yet of medium size, and of good colour and quality, is Johnston's St. Martin's. Linnæus is also of similar character, and is much grown by market gardeners near London. If you obtain those varieties true we think they will give you satisfaction.

Cocoa-nut Fibre Refuse (A Tyro).—To detail the various uses to which cocoa-nut fibre refuse is applied would occupy more space than can be afforded in this column. You will find all the particulars you require on page 365, October 21st, 1880, and page 458, November 18th, of the same year. If you do not possess these numbers they can be had in return for 7d. in postage stamps sent to the publisher, with a request that he post you Nos. 17 and 21, third series of this Journal.

Peas and Slugs (A. D., Isle of Man).—We do not raise our Peas in shallow trenches at this period of the year, as in some soils they are kept too wet. We have often sprinkled sawdust amongst them as you propose for affording them protection, and we should prefer it to manure and leaf soil where slugs abound; but for the purpose in question we find cocoa-nut fibre refuse the best material, and this is so cheap and useful that a supply should be had

in all gardens. A thick layer of ashes on each side of the Pea rows, sprinkled occasionally with petrolcum, is a good barrier against slugs. Answers to your other questions will be published next week.

Pruning Young Vines (R. G. M.).—It is not unlikely that your young Vines that produced "a splendid crop of Grapes on 6 or 7 feet of wood" have been much overcropped. When such is the case bold eyes cannot be expected, as the strength of the Vines is exhausted in maturing the crop; still there may be buds at the base of the laterals that you cannot clearly distinguish. You had better prune the laterals at the lowest eye that is clearly visible; then in the spring, if another should break below it about as strong, and showing an equally good bunch, rub off the shoot the furthest from the rod, as one lateral from a joint will be quite sufficient. We fear, however, you will not have such a splendid crop of Grapes next year as you have had this. It is a great mistake to seriously overcrop young Vines, being, in fact, akin to killing the goose that lays the golden eggs, and nowhere has the practice been more frequently condemned than in this Journal.

Bottling Grapes (A Lady Gardener).—As you are a total stranger to this practice you will better understand the sound instructions on page 510 last week by a glance at the annexed figure (fig. 107). We have only to say that the wood bearing the bunch should be inserted quite in the water, and the bottles may be placed in any cool room having an equable temperature of about 40°, and a not very dry atmosphere. The bottles are simply fixed in

Fig. 107.

a slanting position in order that the Grapes may hang clear. Any ordinary wine bottles will do, and you will easily devise a simple method of fixing them. Some gardeners place a little charcoal in the water to keep it pure, and stop the necks of the bottles with cotton wool. Your Grapes have presumably been kept too warm and dry. If you cut them at once, if you have not already done so, treat as directed by Mr. Barker on the page quoted above. We will in an early issue show a ready method of fixing the bottles to the edge of shelves in a fruit-room.

Small Brussels Sprouts (J. C.).—The Brussels Sprouts that your employer had in Brussels, and which he describes as being "very small, firm, and of delicious flavour, far superior to those grown in this country," are not so produced by climatal influences, but the qualities pertain to the variety that is grown. It is the typical form of this vegetable, and was plentiful in this country many years ago, but has almost been "improved" out of existence—that is to say, seed of the true stock is not easy to procure. Not a few persons esteem this as the best of all Brussels Sprouts, as being more delicate in flavour and having a more agreeable appearance at table than the large, lighter green, newer varieties. The old form alluded to has smaller, much bullated, and rounder leaves than most of the strains now cultivated, hence the plants can be grown closer together. We have seen fine breadths where the plants were only 18 inches apart, the stems upwards of 3 feet high being densely studded with small glaucous green knobs. We saw this variety, or one closely resembling it, last year at Mentmore, and perhaps if you were to send a return post card to Mr. Smith he would inform you where he obtained the seed.

Plants for a Hall (M. C. B.).—All the plants you name—*Latania borbonica*, *Rhaphis flabelliformis*, *Phormium tenax*, and *Aralia Sieboldi*—are well adapted for hall and room decoration, and if they have been gradually inured to a dry temperature before being taken from a plant house will remain fresh for a considerable time. They will, however, decline in health and vigour more or less, according to the positions they occupy, gas being injurious to them, and cold draughty corridors. The soil in the pots must always be kept moist, not saturated, but as soon as the soil slightly crumbles when rubbed with the finger tepid water should be applied, and always in sufficient quantity to moisten the entire bulk. A damp sponge drawn carefully over the foliage twice a week will also conduce to the health of the plants. They will not need potting until spring, but if the present pots are crowded with roots they will need liberal supplies of water.

Unhealthy Vines (H. S.).—It is very difficult to advise you in this matter, since you neither state the age, size, nor character of the Vines; yet as you say they have been planted four times with no improvement following, but rather the reverse, it would appear to us very undesirable to risk further loss and waste further time in attempting to renovate them, as in all probability they are practically beyond recovery. The roots sent, by being packed in cotton wool, arrived in a dry and shrivelled state, yet we

have no hesitation in saying they were very unsatisfactory when severed from the Vines. In our opinion it would be far better to make a new border and plant young Vines than to lift and replant the old ones. Well ripened and rooted, young Vines would, under good management, be certain to flourish; but it is extremely unlikely that the others would ever be made healthy and fruitful. A border 4 feet wide and 2 feet deep would be quite large enough the first year, and could be added to yearly as the roots extend.

Fragrant Roses (W. S., Quebec).—The following rank amongst the most fragrant of the Hybrid Perpetual Roses:—*La France*, Charles Lefebvre, Louis Van Houtte, Alfred Colomb, Marie Baumann, Bessie Johnson, Abel Grand, Senateur Vaisse, Camille Bernardin, Madame Knorr, Pierre Notting, Richard Wallace, Madame Victor Verdier, Mdle. Marie Rady, Jules Margottin, Madame Furtado, Ferdinand de Lesseps, Comtesse Cécile de Chabillant, François Michelin, Général Jacqueminot, Duchess of Edinburgh, Xavier Olibo, Rev. J. B. M. Camm, Duke of Edinburgh, Madame Fillion, Madame C. Joigneaux, Dr. Andry, John Hopper, Antoine Ducher, Baronne Louise Uxkul, Duke of Wellington, Annie Wood, Beauty of Waltham, Centifolia Rosea, Mons. E. Y. Teas, Harrison Weir, Madame Gabriel Luizet, Marchioness of Exeter, Sir Garnet Wolseley, Miss Hassard. If any of our readers can add to the list of highly scented H.P.'s we shall be obliged if they will send us the names of the varieties.

Order not Executed—Sample Post (Idem).—Strictly speaking the florist to whom you refer is right. In the first regulation under the sample post, published in the "Post-office Guide," it is stated that packets containing goods for sale, or in execution of an order, however small the quantity, are not actually samples or patterns, and are treated as letters; and in the sixth regulation we find "samples of saleable value must not be sent to any foreign country or to any of the British possessions that are comprised in the postal union." Nevertheless, we have no doubt it is quite true that you "have received hundreds of plants through the sample post." The date of the letter in which the money was returned is October 8th, and we did not send you post card to the florist in question until a month after that. Everything appears to have been satisfactorily settled now.

Painting a Conservatory (Fifteen-years Subscriber).—Although we believe that the interior of the large temperate house at Kew was painted with anti-corrosion paint, and the occupants of the house, many of which are permanent, received no injury, yet we have found the same kind of paint affect the plants injuriously in a small greenhouse. We have also found this paint so rough after being dried that it cannot be washed clean the same as paints can that produce a smooth surface. We are not able to recommend any paint that can be used with safety in a conservatory in which such plants as *Pelargoniums*, *Camellias*, *Callas*, *Chrysanthemums*, and bulbs are flowering, as at this period of the year the ventilators cannot be left open to any considerable extent night and day as in summer. If any of our readers have found any paint quite safe to use in a house of flowering plants in winter we will readily publish their experience.

Heating a Stove (Rosa).—Owing to the raised banks at the sides of the house it would not answer to have the pipes there, as they would not only be unsightly, but dry the atmosphere to an extent injurious to the plants, besides not making the walls available for the growth of plants, which we presume it is your intention to cover. The pipes would be best placed in the pathway, having an open flue, and covered with an iron grating so as to form part of the floor. You will need six rows of 4-inch pipes up each walk—viz., three flows and returns, and the one over the other, taking two branch pipes from the main flow after it enters the house, one of necessity being taken along the boiler end of the stove. The pipes along the walk of the stove on the side next the greenhouse should be taken to the full extent of the walk, also along the other side as far as can be done for the curve; or you may have the pipes to go all round in the pathway, but it will be necessary to have pipes cast so as to correspond with the curve of the walk, which last arrangement would be the most complete and satisfactory, but a little more expensive. The "banks" at the sides would be much too steep to "hold up themselves," and would be best formed into rockwork, which would look much better than having the sides bricked up, and the rockery would form a good position for Ferns and Mosses. Orchids would not do well in the pockets in the wall, but you could have brackets to stand the pots on, or a shelf at a suitable distance from the glass, whilst those in baskets could be accommodated over the pathway sides, suspended, of course, from the roof. A tank in the centre of the centre bed would be available for the growth of a few choice aquatics, and the pillars covered with climbers would enhance the appearance of the structure.

Propagating Chrysanthemums (A. Tyro).—*Chrysanthemum* cuttings may be inserted at any time when they can be obtained and when conveniences for striking them are afforded. The best are those that spring from the roots and severed within the soil, and if a few white rootlets bristle from near the base of each of the suckers will be the more readily established. These if taken when about 3 inches long, inserted in light gritty soil, kept moist and close in a gently heated frame or propagating case, will soon become small healthy plants. For cuttings or suckers of this kind a temperature of about 55° is ample, and immediately they are established they require air and a graduating reduction of temperature to 45°, with abundance of light. When the tops of young growths are cut off and made into cuttings in spring they require a little more heat to strike freely, but they seldom make such sturdy plants nor produce such fine blooms as the others. The suckers referred to may be successfully established at any convenient time between now and next March, but for the production of large specimen plants the sooner they are established the better.

Mushroom Bed in an Orchard House (E. A.).—Provided the manure is well prepared and sweetened before you take it into the house, and the top and front ventilators are thrown wide open day and night for some time after the bed is made, we do not apprehend that any steam rising from it would do any injury whatever to the trees when they are leafless. After the bed is spawned and cased with soil there will be no appreciable amount of moisture from it, and any little there may be can be dispersed by extra ventilation. Unpurified manure should not be taken into the house. We cannot tell you the smallest length a bed may be, as this depends very

much on the condition of the material that is used and the after-management that is accorded. With the best material and subsequent attention Mushrooms are producible on a bed 6 feet long, but you would have a better chance of success if it were longer. We intended to have published this reply last week, but it was crowded out. It will, however, be soon enough for you to act safely, as it is advisable that the trees be quite at rest before you introduce fermenting materials into the house, and then, as above intimated, you must give abundant ventilation.

Love-in-a-Mist (*Reader of the Journal*).—This name is popularly applied to *Nigella damascena*, a plant included in the *Ranunculus* family, found in several parts of Europe, and has been cultivated in Great Britain for over 300 years. Its flowers are bluish, and it owes its popular name, as well as several other local titles, to the number of finely divided bracts. The generic name *Nigella* is from *niger*, black, in reference to the colour of the seeds, those of some species (especially *N. sativa*) being formerly employed in medicine as a stimulant and carminative, and in some parts of Europe they are yet used as spice and in adulterating pepper. *N. arvensis* is a nearly related species, its seeds having been employed in a similar manner. *N. hispanica* and several others are also grown in gardens. They are hardy annuals which thrive in any ordinary garden soil, the seeds being sown early in spring. The leaves are finely divided, and to this character is due the English name applied to all the species—namely, Fennel Flower.

Apples for Shallow Soil (*J. E. B.*).—Six kitchen Apples: Duchess of Oldenburgh, Keswick Codlin, Stirling Castle, Warner's King, Wormsley Pippin, Dumelow's Seedling. Six dessert: Red Joanetting, Worcester Pearmain, Margil, King of Pippins, Adam's Pearmain, Sturmer Pippin. All these answer well in such a soil as yours, but they will not continue healthy or live long if the soil is not deepened and enriched with manure. Artificial drainage is not required in your subsoil of sand and gravel. Make stations for the trees a little raised above the common level, 2 feet deep and 6 feet square. Procure strong healthy trees of the varieties named, plant carefully, fasten securely so that they cannot become loose in the newly moved soil. Attend closely to the directions in our hardy fruit calendar, where all cultural details are fully given from time to time, and you will obtain fruit in due course and have no further difficulty. You might also endeavour to improve the trees you already possess by replanting the best of them on prepared stations, the mounds to be quite 9 inches above the ground level of the soil.

Vine Roots Cankered (*A. E.*).—We have examined minutely the roots you have sent and find them seriously cankered, the injury, we conclude, being done by some corroding agency in the soil. There are no insects on the roots nor signs of any, and no fungus except that which is usually found on decaying matter, and what little there is, is a result of the canker, and certainly not the cause. What the nature of the fungus may be to which you allude appearing on the blotches on the leaves we have no means of knowing, but it seems evident that it did not cause the injury to the Vines. The state of the roots is quite sufficient to account for the blotching and shrivelling of the foliage and the shanking of the fruit. We should at once lift the Vines, wash the roots, removing all cankered and decayed portions, replanting in a narrow border of fresh loam with an admixture of bones, lime, and wood ashes; and should prepare a compost of the latter with good leaf soil, a little loam, and a liberal admixture of gritty matter for placing in immediate contact with the roots, with the object of accelerating the emission of young fibres. If it be necessary to prune the roots severely, as is probable, then the rods must also be pruned closely, perhaps shortened, and the Vines should not be forced into growth in the spring. If nothing was added to the soil in the border that would cause decay of the roots it would be wise to procure loam from another source for making a new border. It need not be much wider than the extension of the roots after pruning, but the surface should be kept moist during the summer by an ample mulching of manure.

Senecio pulcher (*M. E. H.*).—This is a vigorous-growing perennial, with large fleshy or almost leathery leaves of a deep green colour and shining; the radical or root leaves are variously dentated and lobed, while those on the stem are ragged and irregularly cut. The flower stems are from 2 to 3 feet high, very stout, freely branching at the top, and supporting numerous flowers with the rays of a brilliant purplish crimson colour, and the disk or centre golden yellow, measuring 3 inches or more in diameter, and lasting a considerable time in beauty. It flowers during the late autumn months, when it is of special interest and very welcome; and when well cultivated it is a most attractive plant. It may readily be cultivated in ordinary borders, but especially does it thrive in rich loamy soil in a damp situation, as it enjoys plenty of moisture during the summer months. As regards the pot culture of this plant, there is no difficulty in securing good flowering plants by that treatment in, say, 5 or 6-inch pots, using as soil good yellow loam, leaf soil, and well-decayed cow manure with some wood ashes and sand, or in lieu of the ashes fine nodules of charcoal: the latter is of decided advantage in growing the plant. Perfect drainage is also essential, and an abundance of moisture during the growing season; and it would be advisable to plunge the pots in some material such as spent hops or ashes, which would greatly assist to keep the roots cool and moist. Other particulars in reference to the culture of the plant are given in this Journal on page 131, August 10th, 1882, and an illustration was published on page 312, October 6th, 1881.

Names of Plants (*W. H.*).—The specimen sent was very imperfect, but it bears some resemblance to *Agrostis alba*, which is a Grass with creeping roots frequenting moist situations. Several varieties are known and cultivated in such positions. It could be removed by forking out the roots.

Drones still Living (*J. H.*).—Both Italian and common bees kill their drones at certain periods of their history, generally twice a year—once after swarming and at the close of the season if the hives are healthy and have fertilised queens. A few years ago many of our hives did not kill off their drones till October and November, but this is very unusual. Your Italian swarm that has drones alive now has probably lost its fertilised queen, and has now one unfertilised and worthless, hatched at the end of the season

But on this point no one can speak with certainty. Stimulate the bees to breed early, and the brood will reveal to you the state of your hive.

COVENT GARDEN MARKET.—DECEMBER 19TH.

OUR market is considerably depressed, only first-class samples of Apples meeting with any demand. Foreign importations short. Grapes firmer. Kent Cobs quiet.

THE BREEDING AND TRAINING OF MULES FOR FARM WORK.

(Continued from page 522.)

A VERY important point to be considered is the longevity of the mule, as when employed in the tillage of the farm and other work, including the pastures and parkland, some comparison must be made as between it and the cart horse. Horses are sometimes useful at a great age, say over twenty years, but the general capability of the horse for farm labour on the average we only estimate at about nine years—that is to say, that if horses are capable of farm labour at four years old, they do not last more than about nine years, or, in other words, fail to pay for food after the age of thirteen years, except sometimes for breeding purposes. Still, looking at the matter in this way, accidental injury and disease have to be included in deduction for inefficiency. The mule is much more hardy than the horse, and less prone to disease. They will labour for a longer day than horses, and especially if well eared for and fed at the same cost and expense as horses; the amount of active and heavy work they are capable of is quite unknown to farmers in general. The type and size of mule required in this country is that which is used in America for agricultural purposes, the next best is that of Poitou. The best Poitevin sires are reared in the district of Melle in the Deux Sèvres. The most esteemed are black or brown-bay, but the tip of the nose must be of a greyish white (commonly called mealy white) like those of the finest Jersey cattle; a black-nosed mule being condemned as not thoroughbred. We are told by Mr. J. Chesney in his essay previously referred to, that the sale of sires is so profitable that the greater number of farmers in the district of Poitevin keep females, and nothing can exceed the extreme care of which the future mother is the object during the last month of her gestation. She is watched day and night, and very rarely will the Poitevin householder delegate even to his son the performance of this important duty. If a young male arrives in due season great is the joy of the whole family, while one of the opposite sex is received with expressions just the reverse. The young male once born receives the greatest possible attention, although through ignorance and prejudice the care and attention in various points is extremely injudicious, for the French farmers, few of whom can be persuaded to let the young animal have its mother's first milk, a deprivation which naturally causes the death of not a few of these little creatures.

Besides this, the mother is rarely in a condition for making a good nurse, these people being deluded with the idea that the more the

female is emaciated both before and after gestation the less liable will she be to abortion. Now these prejudices which exist amongst the peasant farmers have a deteriorating effect upon the size and value of the mules bred by them. The young animals, both mules and donkeys, are weaned at nine months old. Those which are reared on the farms and intended for sale are fed at first upon mashes of bran and barleymeal, and afterwards on grain; at about eighteen months old they are bought by the stud-masters; at the age of four years they rank as full grown stallions. The best stallions cost from 3000 to 4000 francs, and these prices will give some idea of the importance of the industry. It has indeed been asserted, whether the stud-masters gain or lose, it is very certain that the Poitevin farmers profit largely by rearing both mules and donkeys, and at the autumn fairs the young animals fetch from £20 to £30, and even more for large up-standing mules showing power and size.

In any attempt to breed mules for farm work in this country we must not think merely of external matters, but also of docility and intelligence as well as size and strength, and these can be obtained and increased just as easily as can the others, for if we breed from obstinate and ill-tempered brutes what reason have we to expect that the progeny will be of a different disposition? There is in fact a strong unlikeness in mules, some being vicious and stubborn, others are docile and easily managed. This, like the neglect of the Poitou breed we have alluded to, arises from the want of proper care first of all in breeding from none but docile parents, and those which have been selected for all the points which we require in the mule for farm work. We cannot fix a limit in size except that mules of fifteen or sixteen hands high, if stout in proportion, would, when kept in good condition, be equally powerful and useful if well trained to perform in pairs all the work on the land usually done by a pair of ordinary farm horses. For odd or light work on the farm, including horse-hoeing of roots, corn, &c., we have found these superior, and have known constantly at work in our district mules of about thirteen hands high capable of drawing singly 24 cwt. of corn to the railway station in light spring four-wheeled vehicles. We have already had donkey shows in various places. Let the committees of agricultural shows give prizes for the most powerful mules, and we shall like our American cousins produce all that can be desired to render them capable of farm labour and other useful purposes to the exclusion to some extent of horses, especially for drawing tradesmen's vans in both town and country.

The most essential points in breeding and rearing as well as training animals must now be considered, also with sufficient care and condition to bring them out for show purposes. All these matters must be made by a well-devised system, for animals cannot be allowed to run in the pastures and lead a life like the forest ponies, but must receive protection from bad weather, ill-usage in various ways, and also protection from blemishes and injuries through accidental causes, and also in that case whilst young we may find out their tempers, so that they may be disposed of if not likely to yield to careful training. To obtain all these necessaries our system which we adopt for the careful rearing of farm horses is exactly suitable in our humble opinion and long experience, which is as follows: It is by a plan of shed and yard accommodation. The sheds and yards are made to face the north or north-east, as we find the animals become more hardy, and also suffer less from flies in summer time when kept in yards of that aspect. The sheds are 12 feet wide and 9 feet high up to the eaves, the shed is partitioned off where numbers are required to be kept at 12 feet, thus giving accommodation under cover 12 feet by 12 feet. These are enclosed with open boards and door 5 feet wide. The yards in front are of the same width, 12 feet, surrounded by four rails 18 or 20 inches apart, but extend as may be convenient either 15 or 20 feet, thus giving plenty of room for the young animals to take moderate exercise. The floors both of sheds and yards are covered with earth 9 or 10 inches in depth for absorption and removal, and the manure allowed to accumulate, straw being applied as cleanliness requires; the droppings are spread daily before applying fresh litter, and either fine earth, damp ashes, or yellow sand is strewed over twice a week. This consolidates the dung during accumulation and prevents heating, which it is more liable to do than manure made under bullocks, as horses or mules do not void so much urine.

The mares are allowed to work as usual until about a week or ten days before foaling, they are then put into the sheds and yards and shut up at night, and these are very safe places for them to foal in. A short time after foaling, say a fortnight, the mares go out to work, the foals being kept in the pens until the mares return from work; here the foals learn to eat, and are weaned at the end of four or five months. Here they remain until they are fit for sale or work at two or three years old, in pairs up to a year old, then singly. These sheds have low racks and mangers for hay and fodder. The food, commencing with Trifolium and Clover, with bruised Beans or Maize, and bran, Oats, and chaff, is gone on with until the roots are ready, when a moderate quantity with hay and corn is the food given until

green fodder comes in again. Under this system, with careful attention the colts become not only exceedingly docile, but are positively free from accidents or blemishes, and are easily broken in for work with little risk or trouble. It should not, however, be forgotten that the manure made in this system is an important and valuable item. Having carried out this system for rearing horses with great success, we can recommend it for rearing mules.

WORK ON THE HOME FARM.

Horse Labour.—There is still some Wheat to be sown in certain districts of the kingdom, and in fact more than usual, in consequence of the lateness of the harvest, and the change from fine weather to storms and heavy rains which occurred in the latter part of October and first fortnight in November, and on cold flat-lying land not so much Wheat has been sown as was intended; in fact, even within the past week Wheat-sowing has been continued in certain districts with the land in drier condition than a few weeks previously. It should be remembered that, except in certain districts of the northern counties and Scotland, it may be advantageous to continue sowing Wheat at every opportunity in December and January, where in certain cases and by hindrance not to be avoided, for every day is an object gained if open weather occurs, so that the land will work fairly well, because it always grows more like Wheat sown in autumn, and in consequence will generally yield better than spring-sown crops. There are no doubt some instances in which the land may best be held over until spring, but the intelligence of the home farmer and the soil and climate of the district will generally go far to decide this point. Fallow ploughing will now be going on in the absence of frost or heavy rains, but we advocate rather ploughing or stretching the land to lie the winter; it should, however, be crossed with water-furrows if flat cold land, that water may not lie in puddles in certain parts. We have another idea also relating to the land lying fallow and uncropped during the winter months; for although Sir J. B. Lawes is no doubt correct in saying that certain soils lose fertility through not being cropped in winter, yet we consider that this observation only applies to porous soils, and that strong soils may lose fertility likewise, but they gain more in amelioration and working condition than they lose by fertility being diminished; in fact, it is for the most part and frequently the only opportunity that strong and flat soils can be ameliorated, especially when we get only wet and unfavourable summers. The carting of earth to heap, and when dry enough earthy composts with manure into the grass land and park pastures, should now be done, and whenever this application is given, 3 cwt. of dissolved bones or bone phosphates should be applied also in the months of February and March. When frosty weather occurs after Christmas it is a good time to do the threshing of corn in stack, either of Wheat or Barley, in order that when sold the delivery may employ the horses at the least busy time of the year.

DONCASTER AGRICULTURAL SOCIETY.—We are requested to state that the next Exhibition of this Society has been fixed to take place at Doncaster on Wednesday and Thursday, June 25th and 26th, 1884.

OUR LETTER BOX.

Analysis of Soils (Anxious).—This is not only very costly, but very unsatisfactory as far as the fields are concerned, because the soil varies so much, not only on the surface but also the subsoil. We therefore cannot recommend analysis of land as a prelude to manuring it. We advise you to try the effect of farmyard dung, nitrate of soda, bone superphosphate, Peruvian or British guano, in patches side by side for various crops both of corn and roots. The result and teaching will prove lessons which cannot be learned in any other way with so little cost and trouble, taking care, however, to secure the purchased manures of genuine quality and at fair prices.

REMARKS.

9th.—Overcast and misty throughout; sprinkle of rain 8.30 p.m.
 10th.—Dull and damp, but milder; fine sunrise; rain in evening.
 11th.—Fine and bright, gorgeous sunset; strong gale at night.
 12th.—Fine and windy.
 13th.—Fine and mild.
 14th.—Showery and windy morning; fine afternoon and evening.
 15th.—Fine bright morning; overcast afternoon; rain and wind in evening.
 Rather warmer than the previous week, but chiefly noticeable for strong wind on 11th.
 —G. J. SYMONS.

TUBEROUS BEGONIAS.

OH, how lovely! I never knew that there were such exquisite varieties of Begonias," said many of my fair visitors who saw my house full of these charming plants last season. And indeed anyone who had only seen the small narrow-petalled single kinds generally grown might well be astonished. There might be seen singles, like great butterflies, 4, 5, and 6 inches across, some pure white, others yellow, pink, flesh, orange, scarlet, and every conceivable shade of red; some wide open and erect, with their four wings spreading at right angles, others gracefully drooping and hanging in clusters from their slender arching stems like cascades of pearls and rubies. And then the doubles. What a charming combination of colours! What diversity of shape and habit! Some like a Cactus Dahlia, some like a very double Hollyhock, others like beautifully imbricated Roses or Camellias, and others, again, forming the very prettiest of rosettes. Then see how beautifully the flowers contrast with the shining stems and quaint tropical-looking foliage—foliage which differs almost as much as the flowers—dark green, light green, veined, marbled, narrow and tapering to a point, broad and heart-shaped, with one of the lobes always smaller than the other, giving it that appearance peculiar to the Begonia tribe.

Truly the tuberous-rooted Begonia is a flower with a future! When it is considered that we have only just begun with it, and that a few years since it was almost unknown, what may we not expect now that enthusiastic hybridisers are diligently at work on this comparatively virgin soil which has already produced such great results? We have almost ceased to hope for anything really new in the way of Pelargoniums or Roses. The poor old Zonal has been nearly done to death, and even the queenly Rose has been repeated again and again almost *ad nauseam*. But the Begonia—well, we shall see. One thing I feel convinced of—that everybody with a greenhouse must grow Begonias if they wish to enjoy a really new sensation in floriculture, and, indeed, everyone who has a garden without a greenhouse; for, startling as it may appear to some, this glorious flower has proved itself to be almost hardy. The very choicest kinds will stand one or two degrees of frost without injury to the foliage, and even should the foliage be cut by a harder frost the tuber will survive, and, with a little protection, will winter in the open ground and throw up again vigorously in the spring. But if the cultivator is not inclined to run this risk, he can take them up and store them like Dahlia tubers in earth or sand in any place safe from frost, and be happy and forget them until spring comes again. Think of that, ye who worry over tall scraggy Pelargoniums all the winter, and after all have the mortification of seeing them damp off.

But it will perhaps be said, "How am I to get these fine varieties of Begonias? I cannot afford to give 2s. 6d., 5s., or 10s. 6d. a piece for them, and I see that nearly all the

best are about this price." True, but I do not advise you, unless "money is no object," to buy these expensive varieties to start with. Try some unnamed seedlings of a good strain. You can buy them as dry tubers in winter and spring at a very trifling cost, and many of them you will find to be almost equal to the named sorts; or, better still, if you have any means of raising the seed, a couple of half crowns will secure you enough plants to fully stock your garden or greenhouse, and among them, from really good seed, you ought to get some as good as any with the very finest of names. For this let me state what is required and how to set to work.

In the first place there must be either a house or frame heated to about 65°. If this cannot be managed, let the seed alone. But I will suppose that my readers are happy enough to have either the one or the other. Buy the seed in January or February, the earlier the better. Buy the best that can be had, it is the cheapest in the end. Do not be disappointed at finding the packet to consist of what appears to be the tiniest pinch of snuff. The seed is very fine indeed; take all the more care of it. Prepare a 6 or 7-inch pot thus: 1½ inch of broken crocks at the bottom, then a thin layer of moss, then nearly fill it with finely sifted leaf soil, with which about a fourth part of silver sand is mixed. Press the soil level, water it thoroughly through a fine rose, allow it to drain for a few minutes, then sprinkle the seed evenly over the surface. The seed need not be covered with soil; a sprinkling of sand may be placed over it, but it is not really necessary. Cover the top of the pot with a square of glass, and then with a piece of brown paper to exclude light. Place it on your hotbed, and watch carefully for the germination of the seed. The moment it appears remove the paper, and when the seedlings are fairly up the glass also. No watering ought to have been required up to this time, but now if getting dry place the pot in tepid water to within an inch of the rim until it has sucked up sufficient moisture. On no account drench overhead, or many of the tiny seedlings will be destroyed. Never allow the soil to become dry, and as the plants gain strength water through a rose in the usual manner. Do not be in too much of a hurry to prick them out, but when they can be handled well place them in the same kind of soil as before, and continue careful treatment, transferring them to single pots as they become large enough. If these directions are successfully attended to by June the grower will be the happy possessor of a fine stock of healthy young plants, many of them by that time showing flowers, and all through the season there will be the intense pleasure of watching the development of the flowers, speculating as to what they will be when fully open—hoping, fearing, triumphing by turns as some new beauty gradually expands.

Seedlings always grow well and are easily managed. But if the named expensive varieties are purchased, many of them require care. They have the unhappy knack at times of decaying just at the collar, and it ought to be seen to that the earth in the pot is slightly raised towards the centre, throwing the surplus water to the sides of the pot; this prevents damping. In watering do not wet the stems, and avoid a close stagnant atmosphere.

Begonias are by no means difficult to propagate from cuttings. Inserted either singly in very light soil, or planted out over a slight bottom heat in cocoa-nut fibre or some such material, they soon root and form small tubers. Their great enemy is damp, and while rooting the foliage and stem must not be suffered to remain wet, or they will decay. No plant is more easily hybridised. Here in Devonshire, where the climate seems to suit them, they seed very freely, and nearly every pod even of the doubles ripens well. I am looking forward to the coming season with the greatest expectations, and, judging from past success, hope to see some new wonders. In the open ground here they do remarkably well. Some of my acquaintances had beds of them which were really beautiful, and I quite expect that ere long they will be as

common in every garden as the old scarlet Pelargonium.—
R. W. BEACHEY.

THE "JOURNAL OF HORTICULTURE."

THAT admirably written and sensibly expressed communication by "A Working Gardener" in last week's Journal set me thinking. It took back my thoughts to the days of twenty and thirty years ago—to the days when Robert Errington, Robert Fish, Donald Beaton, Thomas Appleby, and John Robson were writing in the then *Cottage Gardener* as no other writers (now, don't stop me, Mr. Editor, please) have ever done either before or since in any paper. There, now! Crack that nut all ye modern scribes! I read my Journal now as I have read it all these thirty years and more. I read it dutifully and respectfully as I ought. I am fully alive to the ability and earnestness of the writers in their several departments. I appreciate their labours in the cause of good gardening, and in all that concerns the gardener at its highest estimate; yet the Journal of to-day has not the same flavour to me as it had in "the brave days of old."

Of course some Philistine will suggest that I am getting into the "sere and yellow leaf" of life, and therefore cannot be expected to appraise at its proper value the work of the present time, nor the manner of doing it or speaking of it. I grant all that; but now, my Philistine friend, just let me ask you one question. I will take you to be a head gardener, and I ask you fearlessly and honestly, Do the young men under you read any gardening paper with the same eagerness, the same greediness, almost the same relish, as you and I read at their age and in their circumstances? Well, you'll hum and ha, and say, "No, I don't think they do; but, then, you see there's so much now-a-days to attract young men, even in country villages, that did not exist in our day." Perhaps there is; but, then, is that right or good for them? I know quite well that the old plodding spirit is fast dying out of our young men, and that there is a large section, far too large, of our young gardeners who prefer to walk about with gloves and cane rather than sit down and read; and there is as large a class, if not larger, who only read superficially, skimmingly, slightly, who want all their thinking done for them by other people, and the results administered to them in a concentrated form and in sugar-coated homœopathic doses by publicly read essays or lectures. The class of young men like you and I, dear Philistine, and our good brother, "A Working Gardener," is, I am afraid, very small. There are a few members in it we know, but not many.

Said a brother head gardener to me not many days ago when speaking on this very subject, "I don't know what's come over the young men in the bothy. Our lady takes in for them all the horticultural journals, the "Quiver," "Cassell's Magazine," and other serials for their use, and I can go into their room any week and find the gardening papers with not even the leaves cut, to say nothing of being read. I know it was not so in my time. I had to find my own gardening paper, and pay for it myself out of very small wages, and then I read every word of it from end to end. I begin to think that there's too much done for them." Is this so, and that our young men do not prize the papers because they come too easily? The old saying that "proffered service always stinks" has some truth in it we know. How many gardeners twenty years hence will be able to write such a letter of sound sense and such a testimony to his early reading as that of "A Working Gardener" in the Journal of the 13th of December? It's a grand letter; his words to young gardeners are most excellent, and deserve the attention of every young man in a garden. If he and I could have changed bodies we should have the same things to say. I, too, owe a deep debt of gratitude to the *Journal of Horticulture*. In 1856 the then editor, Mr. G. W. Johnson (God for ever bless him) did me an altogether inestimable service. Through him I was introduced to those who helped me up to my present position; and to the writings of the staff of the Journal of that time, specially mentioning Mr. R. Fish, I am largely indebted for the ability and skill to maintain that position. Herein again is one characteristic feature of our Journal—its warm personal connection with its readers; its home-like, family-like union of directors, writers, readers. There is no stiff, formal, unfamiliar flavour about it, as if both editors, writers, and readers were abstractions rather than substantialities or living personalities. That is what I feel about the matter, though I may not be able to put my thoughts in the clearest words. May our Journal go on doing the good work it has done in the past, and may such readers as "A Working Gardener" be multiplied a thousandfold. A happy new year to everybody.—H., *Notts*.

TRAINING RASPBERRIES.

I CANNOT name any better methods of doing this than those described by Mr. J. Wright (page 480), and I am not writing to go beyond his instructions but merely to confirm them. The fence way of training is very

familiar to us, as seven years ago we put down six of them 30 yards in length each, and they are as good and useful now as the first season. The end posts and some of the uprights are of iron. The stools are those planted seven years since, and I think it speaks well for the system that we have annually secured first-rate crops of fruit from these rows. I could never wish for a better way of training them, as it is most convenient in every respect, and agrees with cultural details admirably. The top wire is 5 feet from the ground, and the tops of the canes are about 1 foot above this. In July they often grow much higher than this, but when we thin out the old canes in September the young ones are cut back to the height indicated, and then they never fail to ripen and swell their buds to the fullest extent.

No digging or forking is ever done amongst Raspberry roots here. Late in autumn or some time during the winter a quantity of good manure is spread over the surface of the soil, and this is all the attention the roots ever receive. The rows are 5 feet apart, and the centre of this space is forked over now and again, and in the early spring before the leaves produce any shade worth speaking about we grow a row of Spinach, Radishes, or Lettuces between the rows of Raspberries.

There is one profitable way of growing Raspberries which I have not often seen practised. This is not cultivating them in gardens, but planting them in odd corners under trees and about the rubbish heaps which are to be found in the back grounds of all gardens. It is astonishing how well Raspberries do in such positions, and the enormous quantity of small fruit they produce. In positions of this kind they are treated quite naturally, or in fact they are not treated in any way, but simply left to themselves, and they form both a pretty undergrowth and a good cover for game, which is a consideration in many places. Raspberries will grow and fruit better under the shade of trees than any other fruit we could name, and if those with surplus canes would plant them in such places as I have mentioned I am sure they would be pleased with the result.—J. MUIR.

SELECT TABLE PLANTS.

THE following is a selection of useful decorative table plants, well-grown examples of which cannot fail to give satisfaction. For this purpose well-furnished plants in 4-inch pots are more desirable than those grown in larger sizes, as many of those plants which have variegated foliage develop their rich colours best when somewhat restricted at the roots.

Pandanus Veitchii.—This is one of the best and most popular table plants in cultivation, and being of slow growth it remains a long time useful. To have well-coloured plants select offsets from the old plants which have most colour, insert them singly in small pots in a mixture of cocoa-nut fibre and sharp silver sand, and plunge them in a brisk hotbed. They will soon form roots, but they may remain in these pots till they are well filled with roots, when they may be shifted on into 4-inch pots, in which they will attain to a most serviceable size. I find they colour best in a rather poor compost, equal parts loam and peat, with about a third each of charcoal, broken bricks, and sharp river sand. The months of March and April are the best to insert cuttings, but it may be done well at any time.

Croton Weismannii superba.—This is a great improvement on that old and truly useful sort *C. Weismannii*. It is of a more densely compact habit, and assumes a beautiful golden variegation more freely. It ought to have a place in the most select collections.

Croton Warrenii.—Undoubtedly this is the most majestic and graceful *Croton* grown. The leaves on well-grown examples attain a length of more than 2 feet, and are of a beautiful spiral form, boldly arching and very regular. The colour is of a deep olive green, irregularly blotched and spotted with yellow and carmine. This I believe to be one of the richest-coloured table plants.

Croton angustifolius.—Well-coloured plants of this old favourite are very highly esteemed for table work, and deservedly so, possessing as they do a most graceful habit. They give a light and cheerful appearance to the surrounding objects on the table.

Crotons are easily propagated from cuttings inserted in the spring in a rather brisk hotbed, using as a compost that recommended for the *Pandanus*. When rooted pot them into small 60's, and again plunge in the hotbed, and as they require it transfer them into 4-inch pots, using as a compost equal parts of loam and peat, about a third each of sand and charcoal, with a handful or two of ground bones. To bring out their beautiful variegation to the greatest perfection they will require more exposure to the sun than is generally accorded the inmates of the stove. If possible they ought to be placed together in a position where they can enjoy the full light of the sun during the early morning and afternoon, shading being necessary during the middle of the day to prevent scorching. To maintain a supply of useful plants the propagating bed should never be kept empty, as they are very fast-growing, consequently they soon become too tall. A good and safe plan is to strike the tops by mossing them—that is, by cutting the stems of those that are too large nearly through, firmly tying wet moss with a dash of silver sand round the wound, and allowing it to remain until roots are emitted, when they should

be cut off and treated as rooted cuttings until established, when they are at once fit for use. The following, in addition to the above, are very good—*C. Johannis elegans*, *C. Chelsonii*, *C. Archibaldi*, *C. interruptus aureus*, *C. Lord Chelmsford*, and *C. undulatus*.

Dracæna Cooperii.—One of the oldest and best of the variegated section of this popular genus, possessing colours which I have not as yet seen surpassed in any of those of a more recent date. Its culture is simple, and propagation is effected by cutting up the stems of the old plants into eyes, and inserting them in cocoa-nut fibre in a hotbed. But as these young plants do not colour well they ought to be grown on until they begin to show their lovely markings, when the tops may either be severed from the plants placed in bottles filled with water and plunged in the hotbed, a piece of charcoal being placed in the water to keep it sweet, or they may be mossed in the same way as recommended for the *Croton*, care being taken that they are well rooted into the moss before they are severed from the parent stem, as they are very apt to lose a few leaves if they are cut away prematurely. The compost recommended for the *Pandanus* suits them admirably, giving slight feedings with weak guano water when the pots are well filled with roots. Thrips are particularly fond of these plants, and a fearful havoc they make if left undisturbed. To prevent their depredations the plants ought to be sponged at least once a fortnight. The following are also very good:—*D. Bausei*, *D. superba*, *D. splendens*, *D. Moorcana*, *D. Baptistii*, and *D. gracilis*.

Cocos Weddelliana and *Geonoma gracilis*.—Nearly all the Palms are of more or less value as table plants when in a young state, but I do not think any other two are more popular for this purpose than those mentioned above. Happily they are of slow growth, and therefore they remain a long time useful. They are increased from seed, which method, however, is rarely attempted by private growers, although those possessing a propagating house need have no difficulty in raising any number of them. The seed should be sown in pans of cocoa-nut fibre and sand, and plunged in the hotbed. In about six or eight months they will germinate; prick them out into small thumb pots, and plunge again. The compost should consist of peat, loam, sand, and charcoal until the last shift, when pure clayey loam and sand will be needed.

Some others which I have found very useful, but will not describe at this time, are *Aralia Veitchii*, *A. Veitchii gracillima*, *Asparagus plumosus nana*, *Dracæna Goldicana*, *Reidia glauceseens*, and *Cureuligo recurvata*.—WM. MARSHALL.

LADY DOWNE'S GRAPE.

So much has been written about this Grape in common with others that it may be questioned if there is anything new left to chronicle regarding it. However, it may not be known to all your readers that Lady Downe's, though possessed of a good constitution and having every appearance of being a very free-fruiting and strong-growing variety, has one or two peculiarities that make it less easily grown to perfection than otherwise it could be. First of all, then, Lady Downe's requires a high temperature when setting, and is very much benefited by having the flowers brushed with a feather when in bloom. After the period of setting has passed, and supposing a good set has been obtained, another difficulty has to be encountered at stoning time, when scalding appears, and unless carefully guarded against makes sad inroads on the bunches. During this trying period the temperature must be kept low—not above 65° by day if such can be managed. This is the great secret in combating the evil of scalding, and though generally known to most gardeners, there are sometimes found cases where a want of knowledge of this has been displayed with disastrous results.

Scalding is caused both by the direct rays of the sun and by a high temperature in the house during stoning time; and in addition to keeping the house cool by the admission of plenty of air, a slight shading thrown over the house, when such is practicable, is of much use in preventing the sun scalding those bunches that may not be shaded by foliage.

All stopping of laterals and sub-laterals should be discontinued a fortnight before stoning time, and not commenced again till the first berries have begun to colour.

The temperature should then be increased, and a good Muscat house heat maintained, not a "cool" Muscat temperature, but a genuine hot one. When the leaves begin changing colour at the end of autumn there is often much damping to be met with in Lady Downe's. The sooner the leaves are carefully removed after the end of November the better, and a careful watch should be kept for all signs of decaying berries, which if allowed to remain soon spread and multiply the evil greatly.

When kept till February or March Lady Downe's has a good flavour, and is possessed of a very refreshing crispness, which makes it much appreciated by some. Not possessing the grand appearance of *Gros Colman*, it must, in my opinion, be placed before that

noble-looking Grape in regard to table qualities; and though in some cases, notably in the case of Mr. D. Thomson's noble employer, *Gros Colman* is preferred for table use, still a census of opinions would show a decided majority in favour of Lady Downe's. Grown in a house where all things favourable can be bestowed and things prejudicial guarded against, this Grape is unequalled for quality by any other in use as a late variety, except Muscat of Alexandria, which is *facile princeps*, and will, when thoroughly ripened, keep as long as Lady Downe's.

Then, to all intending cultivators of the Vine who have not practical experience of the Lady Downe's Grape as a variety ranking A1 as a late source of supply I would say, that when a few extra precautions are taken in the culture it will reward its cultivators by hanging well, looking well, and, above all, eating well.

Muscats may be put alongside of Lady Downe's in regard to the scalding, as they not unfrequently suffer therefrom. So our favourite black Grape is not alone in this drawback, and therefore cannot be made to bear all the odium. As there is nothing perfect under the sun, it cannot be expected that Grapes would prove exceptions to the infallible rule; the great matter is to weigh carefully and well the various shortcomings of different kinds, and thereby endeavour to arrive at just conclusions.—S.

TRANSPLANTING SHRUBS.

THE most important point in connection with the transplanting of shrubs which have for several years grown in the same spot is securing a good ball of soil with the roots. In some soils there is no difficulty in thus lifting shrubs. Last winter, for instance, I had some removed from one part of the estate to another, and from one portion of ground the men had nothing more to do than to cut around the ball with their spade, then two or three of them worked well in on one side, while the others pulled the shrub, and thus very easily raised specimens 6 feet high and as much in diameter. Some others growing in pure sand had to be lifted with all the rootlets possible, and it is wonderful how well those have done. One of them is a Portugal Laurel 9 feet high and bushy. The roots were all carefully spread out, and a compost of half soil, half leaf mould, placed round them, with the result that another season's growth will make it better than ever it was.

The greater part of the soil here, however, is very friable, and there is no use in attempting to move even such an easily transplanted shrub as the Box without making sure that the ball will not fall to pieces at any moment. We almost invariably take the extra trouble of excavating deep enough to allow for getting broad planks underneath the ball, on which the shrub rests securely, and by which it is carried. One broad short plank is sufficient for a small shrub of, say, 4 feet in height; for larger shrubs two planks may be sufficient, and for those of 15 cwt. or a ton weight it is necessary to employ, in addition to the two planks next the ball, other two cross planks on which the others rest, and these cross planks again rest on cross bearers of oak or larch. Birch planks, it may be stated, are particularly well fitted for this work. We have a low-wheeled truck for carrying shrubs with balls up to 2 tons weight. In the case of those averaging a ton, after the planks and cross-bearers are in position, one of the bearers is grasped with a chain, and the other end of the chain lifted with a lever until it is raised about a foot. It is there kept in position by wooden blocks, when the other bearer is raised in the same way and also blocked. The shrub is thus raised by degrees until the trunk can be run underneath it, when it is let down till it rests on the body of the trunk, and then removed to its destination. If the shrubs have to be taken a distance of half a mile to two miles thin deal boards are placed round the sides and surface of the ball and kept lightly in position by means of chains and screws. The shrub is also firmly fastened to the truck.

Balls of roots weighing a couple of tons we do not attempt to raise. It is just as expeditious to throw out the light gravelly soil deep enough to allow the truck to be run underneath them as it stands. In this case, besides allowing sufficient space at what we will call the back of the shrub to excavate under the ball, it is also necessary to make a sloping road for the truck to be drawn out after the specimen is fixed on it. The way we manage these is to work down to the required depth at the back and front, then cut underneath the ball both at the back and front, so as to allow two broad planks to be fitted close up to the bottom of the ball; these are kept in position with wooden blocks. A narrow gallery is then driven through underneath the centre of the ball, and a strong batten pushed through. The two cross planks rest on their centres on this batten each end of which is kept tight up with blocks. The soil underneath one side of the ball is then taken out and a long plank fitted into its place, so that one end of each of the cross planks rests on it. These are also blocked up, and the other side done in the same way. The central batten is taken away, and all loose soil cleared out so

as to give plenty of room for the truck. The blocks on which the two lengthwise planks rest are, however, in the way, so we have to employ two strong caken battens to put along the back and front, on which these lengthwise planks in turn rest. These battens are long enough to allow for blocking up securely at each of their ends, and yet allow space for the wheels of the truck to run in. We find it of great advantage to lay planks underneath the wheels, this keeping them from sinking into the soil when the weight of the ball is put upon them. It is also of advantage to lift the front of the ball by raising the front cross batten a few inches with a screw-jack, so as to allow the truck to be run in without so much excavating in front. The sides of the ball are cut out after the trunk has been put underneath the plant. A few inches clear at the sides is all that is required, and allows for getting thin deals down the sides of the balls. Such a ball as the one we are now considering requires to be boarded all round and firmly bound round with chains. The trunk is also bound to the ball with chains and tight ropes to secure the top of the shrub to each corner of the truck. For shrubs of 12 or 15 feet in height or upwards this is very necessary. When ready to be removed we employ block and tackle for the purpose, and after it is on firm ground draw with horses.

Two men are quite enough to excavate under the plant and prepare it for removal. The hole for the plant requires to be made sufficiently deep to allow the ball when the truck is under it to stand about 6 inches above the general level of the lawn where the shrub is placed. Before the work is finished the level of the top of the ball will have sunk that much.

The work of planting is just the reverse of the lifting process. After the shrub is let into its place, and chains and ropes removed, the four ends of the bearers are again blocked up and a wedge driven under each so as to raise them off the truck, which is then withdrawn. Soil is then thrown in under the ball and made firm with wooden rammers. When the centre of ball is sufficiently rammed with soil, the two first cross-bearing planks are blocked up and the other planks and beams removed. The soil is now rammed underneath the ball from the clear sides. Then the blocks are knocked out from under one of the remaining cross planks, which is also withdrawn, and the soil rammed in on that side. The last plank is removed in the same way, and the planting finished.

We remove all kinds of evergreens, Yews, Box, Laurels, Hollies, Conifers, and, with the care we take to secure large balls, have no after trouble with them. One good watering is generally sufficient in early summer to keep them going, and quite as good growths are made the first year of shifting as they made previously. When a gentleman says he would not for many pounds like a shrub damaged or lost in transplanting, his gardener cannot for his own sake be too careful in doing the work. It is a commendable plan to cut round two opposite sides of a ball the season previous to removal.

In connection with transplanting shrubs it may be noted that valuable trees blown down by gales, provided the trunk is not broken, are easily set up, and in a few years grow as well as ever. After clearing enough soil out to allow the tree to be on the same level as before, a strong rope should be so tied round well up the tree as to allow the two ends of the rope to be grasped and pulled by two sets of men at the same time, the one set being a little to the left of the hole and the other to the right. After the tree is up and the soil filled in, wire stays will be required for a couple of years until the roots are again established. For large trees of 60 feet altitude, say, it requires a good amount of soil to be taken out in order to let the trees down to their former level. The tree must then be raised with screw jacks working on the bole until a grip can be got with a rope working with block and tackle, when the work goes on very rapidly. It is very essential to water these large trees very freely for the first two or three years.—B.

EXHIBITING AND KEEPING GRAPES.

It is much to be regretted that promoters of fruit shows do not name the size and shape of boards or boxes upon which Grapes are exhibited. Nothing that we can place on exhibition tables creates so much interest as Grapes, yet how often do we see them indifferently staged? Boxes and boards of all shapes and sizes, and of many angles, presenting when placed in a row a grotesque appearance when compared with uniform rows of Dahlia and other boxes which have been reduced to some sort of a standard.

Some time ago I was much interested in watching the unpacking and staging of Grapes at a local show where they were well represented. The Grapes were a very good lot, and the majority of them were well staged, but owing to the different angles of the boards, some of which could not well be altered, they did not look so well as they might have done.

I think the best and simplest form of box is that represented at fig. 108. The angle is 45°, and anyone can make one by the

following directions. Get a piece of three-quarter-inch deal 10 inches wide by 12 inches long, cut it perfectly square at both ends, draw a pencil mark to correspond with the dotted lines in fig. 109, each 1 inch from the ends and parallel with them. This leaves the spaces, A B C D, a square 10 inches each way, and if cut through with the saw from B to D, and each set on its square, they will be of the desired angle. Upon these fix the board (three-eighths of an inch thick) for the Grapes to rest upon, which for this size will have to be about 14 inches wide. Another piece of deal (half inch thick) 6 inches wide is fixed at the back

Fig. 108.

of the stand, and rising 2½ or 3 inches above it, pierced with two holes opposite where each bunch is to be placed, by which means they are secured to the board with twine or tape. A very thin lath about 2 inches wide is fixed along the front, its upper edge rounded off and standing a little above the board, and similar pieces at each end forming a narrow beading all round, makes the stand look neat. As to length, each bunch should have 8 or 9 inches of board; thus a box for three bunches should be 27 inches.

Fig. 110, next page, shows the stand in a box ready for travelling¹

Fig. 109.

It should be just large enough to hold the stand, should be light and have a handle fixed in the centre of the top to carry it by.

Fig. 111 is a simple form of board, supported behind by two legs, connected by a lath and generally held in position by a piece of twine, but instead of that it would be preferable to have short spikes as at A A, so that when on the table it can be placed at any desired angle, the spikes keeping it from slipping about. This can be placed in a box the same as at fig. 110, the legs of the stand being laid parallel with the board.

Some exhibitors place their Grapes on the bare boards. A better plan, I think, is to place a covering of cotton wool all over the board, leaving about an inch clear all round the outside. With a small brush apply some gum or paste just inside the beading, and have a sheet of white tissue paper ready to cover the whole of the cotton wool, and adhere to the stand round the edges. Examine each bunch before laying it on the board and place it on its flattest side, and secure it by means of string or tape, as shown at fig. 108; or if the bunches are large the tape may be placed round the junction of the shoulders of the bunch, placing the bunch higher on the stand than is here shown, at the same time twisting the stems of the bunches along the face of the upright board, so that they do not come in the way when placed in a box. When large bunches have to travel some

distance it is desirable to have them secured to the board about the middle of the bunch. Two small holes should be made in the board under each bunch, and by means of a small packing needle carefully pass a piece of narrow tape up from below through the bunch and down again on the opposite side of the main stem of the bunch, using a pencil to guide the needle amongst the berries, which must not be touched with the hands. This should be tied just tight enough to steady the bunch. The figures added to fig. 110 are the measurements of stand fig. 108 in section. If some such standard were given in our fruit schedules it would be better than leaving everyone to make their own standards.

KEEPING LATE GRAPES.—Mr. Barker has given sound and seasonable advice as to the setting in order and management of

Fig. 110.

the Grape-room. Several gardeners will be found who have a few bunches of Grapes hanging but have no Grape-room to take them to. It is our practice to cut all that remains after Christmas, and place them at the driest end of the fruit-room, where they keep fairly well for six or seven weeks. Instead of a proper Grape rack as described by Mr. Barker, we suspend the bottles from the front of the fruit shelves as shown in the annexed sketch (fig. 112). The bottles are placed about

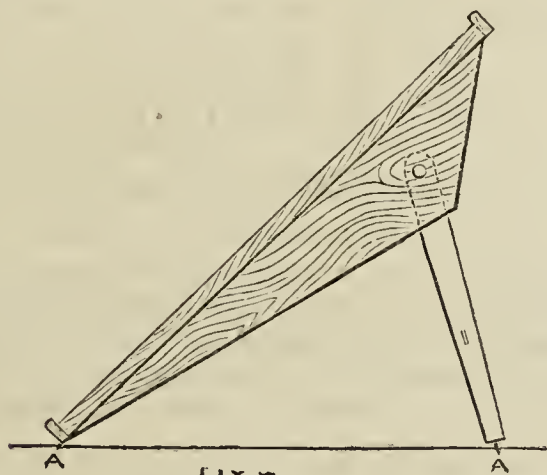

Fig. 111.

7 inches apart. Two ordinary carpet tacks are driven into the front of the shelf (1 inch apart) for each bottle. A piece of ordinary binding wire is fixed to one tack, a bottle is placed in the desired position, and the wire pulled tight round the neck and round the other tack; it is then passed along without cutting it to the next bottle, twisting it round the necks in the same way. The tacks are then driven home, so that the wire does not slip. In a similar manner another wire is fixed so as to form a sort of "sling" to pass over the bottom end of each bottle and support it at the desired angle. These should be fixed on the top and passed down between the openings of the fruit shelves. The wires are not the least in the way when the bottles are removed.—R. INGLIS.

WORDS TO YOUNG GARDENERS.—I read with much pleasure the article "A Word to Young Gardeners" in your issue of the Journal for December 13th, and I think it but just that "A Working Gardener"

should receive the thanks of all young gardeners for his kind advice, which I am sure will, if followed, be of great benefit to them, myself for one. I shall be much obliged by full particulars respecting the U. H. B. S., as I have not heard of it before, and am desirous of joining the Society that offers the greatest advantages to gardeners.—J. P., *Under Gardener*.

[Send 3½d. in stamps to the publisher and ask him to send you No. 174 of the Journal, the issue of October 25th of the present volume.]

AURICULAS.

TRULY, as Mr. Douglas has said, "there is always something to admire and interest in these very charming flowers," and another equally important fact, there is always something to be done for them, as constant attention is the only road to success. I have not half so much time to bestow upon those under my care as I could wish, but every time I look at them something wants doing—dead leaves require removing, green fly is showing itself, and owing to the very mild autumn this pest is active late this season. I do not notice that the cultivator above named often refers to the mealy pest which attacks the root; perhaps it is because he is not troubled with it. A most enthusiastic grower recently informed me that every grower had their share of it except Mr. Douglas, and long may he be spared the vexation it causes to those whose plants it attacks. I am not sure that it does much harm to the plants unless it gets at the neck and punish all the young roots as fast as they show. As soon as the insects get a foothold there the plants sicken; they are easily removed from that position, and the sooner the better. Take a brush and remove them, and well saturate the parts with a strong solution of soft soap. The difficulty is to remove them from the roots, for they are firmly embedded even to the very centre; but very frequently we find them quite outside the ball, feeding upon the extremities of the

Fig. 112.

rootlets, from which positions they are easily dislodged; and although we may fancy they are not very injurious to the plant, yet it is far from pleasurable to see even one of them, and I am glad to say by persistent effort they are becoming much less numerous. When the plants are potted a good opportunity is afforded of checking them materially. The plants should be well shaken out and dipped in soap solution, and the parts brushed if needful, for it is surprising how rapidly even the weakest of them regain strength and position, and their mealy covering greatly protects them from superficial treatment.

From this time onward till the beginning of February the plants should be kept moderately dry, so as not to induce growth. Especially is it desirable to attend to this if we experience a mild winter, for after the slightest excitement they start into growth, and the flower spikes appear before they are required, especially if they are required for an exhibition. Look well after any drips from the lights, for it is most prejudicial for any moisture to rest in the hearts of the plants, speedy decay following. Ventilate on all suitable occasions, and if the plants are in a cold pit do not cover more than is absolutely necessary, for they will endure much cold without injury, especially if kept dry. With these items of attention and removing all decaying leaves as soon as they are functionless the plants will pass the winter happily until it is time to top-dress them, when a few more notes may be serviceable. In the compost I use for top-dressing, cow manure is an important item; mine is already collected, kept under cover in an open airy place, spread out thinly, often turned over so as to become thoroughly frosted and sweetened, and moderately dry before it is required.—AURICULA.

BOTHY LIFE—ROOMS AT KEW.

OF late some letters have appeared in the Journal relative to the want of bothy accommodation at Kew, as if this were an almost unendurable hardship. But when the subject is considered in all its

bearings is there anything really to complain about? If rooms are not provided for the young men there they have no doubt compensating advantages; and it is very questionable if quiet private lodgings are not more favourable for reading and study than a noisy barrack-room, for that is what bothy life would amount to in such a large establishment.

It has become almost fashionable with a certain class of pessimist writers now-a-days to represent young gardeners as more thoughtless, careless, and reckless than they were a generation ago. I can only say if they are, which I do not believe, they are better separated; while if they are more studious, as I hope they are—and I know not a few who conduct themselves creditably—they will prefer quietude for self-improvement.

I have had a fair share of bothy life, and in what I may call the olden time it was composed to a very large extent of domino and card-playing, fiddle-scraping, accordion-grinding, dancing, boxing, and such-like intellectual accomplishments; and if a young man should engage himself in writing an essay it would be probably to the accompaniment of a recitation not altogether bearing on his subject; or if engaged in an exercise in geometry he would be lucky if an accident did not occur, such as an old hat or cap coming in contact with the candle, or a casual pish against his elbow.

That was bothy life when I was young, in the halcyon days when under gardeners were so gentle, studious, kind, and good; and if they are less gentle now, then I can only say the fewer there are together the better, and that lodgings in respectable families are altogether better for them morally and intellectually. But I do not believe, judging from those I have had under me, that, as Tennyson says in his "Northern Farmer," the men "in the loom is bad." I am distinctly of opinion that they compare favourably with those of any past time, and for the maintenance of their general respectability and their self-improvement I venture to think they are better out of barracks. What do others say?

A Boss.

ORDERING SEEDS.

As the seed catalogues will soon arrive, it will be well to be in readiness to order the seed for next year's supply. It is often a difficult matter to know which to order of the numerous varieties in the seed catalogues even to those who have had years of practice, but to young beginners it is simply bewildering. I will add a list of well-tried sorts, and I shall be glad if others will give lists of varieties they have found best. In doing so new varieties should not stand before old sorts, unless they have been well tried together, or in similar positions, as new varieties generally get the best positions, and the ground especially prepared for them, and well cared for afterwards. When this is the case it is hardly fair to compare the results with older sorts that have simply been sown on any piece of ground, with only the ordinary preparation.

I think everyone that can do so should try some new varieties, but they should do so in addition to their list of well-tried sorts, so that they will not have to depend upon the new ones for a supply. I cannot recommend the Chou de Burghley from the first season's trial. With me it is inferior to a good Cabbage; just now Rosette Colewort is far before it.

Beet.—Egyptian and Nutting's Dwarf.

Beans, Broad.—Johnson's Wonderful and Improved Windsor. *Kidney*.—Canadian Wonder, Negro, Sion House, and Osborn's Forcing. *Runners*.—Scarlet Champion and Suttons' Giant White.

Borecole, Scotch.—Cottagers and Buda.

Broccoli.—Walcheren, Veitch's Self-protecting, Snow's White, Osborn's White, Cooling's Matchless, Cattell's Eclipse, Late Queen, Model, and Purple Sprouting.

Brussels Sprout.—The Aigburth.

Cabbage.—Improved Nonpareil, Rosette Colewort, Red Cabbage, and Couve Tronchuda.

*Savoy*s.—Dwarf Green Curled and Drumhead.

Cauliflowers.—Suttons' King of Cauliflowers and Veitch's Autumn Giant.

Celery.—Major Clarke's Red and Sandringham White.

Cucumber.—Telegraph.

Carrot.—Early French Horn, Scarlet Short Horn, and Long Red Surrey.

Endive.—Picpus Green Curled, and Improved Round-leaved Batavian.

Leek.—Musselburgh.

Lettuces.—Early Paris Market, All Heart, Paris White, and Paris Green.

Melons.—Eastnor Castle and Blenheim Orange.

Onions.—Improved Reading, Brown Globe, Deptford, The Queer, and Red Italian.

Parsnip.—The Student.

Peas.—Suttons' Ringleader, William I., Nelson's Vanguard, Dr. MacLean, Telegraph, Veitch's Perfection, and Ne Plus Ultra.

Tomatoes.—Hathaway's Excelsior and Orangefield Dwarf.

Turnips.—Early White Stone, Early Munich, and Veitch's Red Globe.

Vegetable Marrows.—Custard and Moore's Vegetable Cream.

Early Munich Turnip is a very quick-growing Turnip, with a very small top. I thought so highly of it last year that I have grown it largely this season; but, although it is a gardener's Turnip, the cook does not like it in the kitchen. It is better even in its young state, and as soon as it gets to a fair size is very woolly.

If Melons are only grown in frames, Blankney Hero might be sub-

stituted for Eastnor Castle. The latter is a good old Melon in a house, but it is not so satisfactory in a frame as the other two varieties.—J. L. B.

THE CATERPILLARS OF THE BROWN-TAIL MOTH.

It is now some six years since I gave in this Journal some account of a colony of this species, which I had had under observation for several seasons. The species appears now to be by no means generally distributed in England, but I have proofs of its occurrence in various places in Kent. The particular colony I noticed was upon a strip of hedgerow at Denton, near Gravesend; a few stragglers were to be seen as far off as Northfleet and East Chalk, but the main body of the insects did not seem inclined to extend itself. In one season the broods were so numerous that the task would not have been difficult to have collected ten thousand of the caterpillars, and the floating hairs thrown off by them in their moults were numerous enough to irritate the skin of by-passers. At that time the Whitethorn in the hedge was defoliated by them, and they also devoured the leaves of Elm, Elder, and Blackthorn growing there.

As much fruit is produced in districts of North Kent not very remote from the spot mentioned, and the caterpillars have been reputed to be the cause sometimes of much damage to fruit trees, I drew the attention of gardeners and others to the circumstance. I advised the destruction of this colony of the brown-tail moth in the winter by the removal of their nests, which could easily have been done, and prevented any possibility of either moths or caterpillars migrating to do mischief. This was not attempted, however, but fortunately Nature effected a cure by means of the winters of 1881-82 and 1882-83. Both of these were mild and moist; as a consequence of the former I noticed very few caterpillars in the summer of 1882, and last summer I could not find one. The rains of the winter and spring doubtless loaded their winter nests with moisture, which proved destructive to the insects within.

It is remarkable that although this species (*Liparis chrysothorax*) occurs in fruit trees, its near relative, the gold-tail (*Liparis auriflua*), appears restricted to the Whitethorn. The late Mr. Edward Newman, when I mentioned the subject of the ravages said to be committed sometimes by the brown-tail caterpillars in orchards, admitted that he thought there was a degree of exaggeration, or else an error as to the species. I am anxious to learn if any of our friends who are growers of fruit have ever observed it on Apple, Pear, or Plum. The description of the caterpillar is briefly as follows:—It is stout, about an inch long when full grown, black, with four rows of warts running from head to tail; these warts have short tufts of hairs, some of which are white and some black. Its most marked characteristic consists in a couple of cup-like scarlet spots in the centre of the back, at a short distance from the tail. I should add that August and September are the months when it would be observable.—ENTOMOLOGIST.

WE learn that the VEITCH MEMORIAL PRIZES offered by the Royal Botanic Society will be awarded at the Shows held at Regent's Park on May 21st and June 18th, 1884. They will consist in each case of a medal and £5 on the first-named date for the best specimen Orchid and the best stove or greenhouse plant in flower, and at the latter date for the best dish of three bunches of Grapes, one variety.

— WE are informed that an extensive programme of HORTICULTURAL SHOWS AT THE CRYSTAL PALACE is now under consideration, and it has been proposed that something like £1500 should be given in prizes during the year. Now that the Alexandra Palace appears to have passed from the sphere of usefulness in this direction, a good opportunity is afforded to the southern Palace for extra efforts.

— IN accordance with requests that we have from time to time received from correspondents, we shall early in the year publish the results of an ELECTION OF CARNATIONS AND PICOTEES, to which the leading florists have kindly contributed, and Mr. George Rudd obligingly arranged. In this election we shall have brought to the front the leading varieties of this sweet and beautiful hardy flower that are, as they eminently deserve, becoming increasingly popular. As border flowers they are unequalled in their season, and for cultivation in pots they are admirably adapted for amateurs, well rewarding the cultivator for the skill and care evoted to their production in their highest form of excellence.

— RELATIVE to the question of LARGE V. SMALL BRUSSELS SPROUTS

which was alluded to last week in our correspondence columns, Messrs. James Veitch & Sons have sent us three plants, which admirably represent the small, medium, and large forms of this esteemed vegetable. The smallest is named Paragon, and in the character of the knobs very closely resembles the original type, these being round, firm, small, an inch in diameter, and closely set on the stems, but the terminal head is larger and plant dwarfer. It is very neat and the produce of high quality. Veitch's Exhibition is the tallest of the trio, with medium-sized firm knobs $1\frac{1}{2}$ inch in diameter, less closely arranged on the stems—good and productive. The Aigburth is dwarfer than the last named, but a little taller than Paragon, with knobs nearly 2 inches in diameter, but not all of them solid; still the robust plant is undoubtedly productive.

— A LARGE importation of the new *CYPRIPEDIUM RÖBELINII* was sold at Mr. Stevens's Rooms, Covent Garden, on Thursday last, but though the plants were very healthy and vigorous they did not realise high prices. It may be known to some that a large importation was received last year, but the plants arrived in such bad condition that they could not be disposed of. This time, however, the plants were most satisfactory, the fresh, green, substantial foliage giving every hope that they will be speedily established. It is said to be a near ally of the well-known and beautiful *C. lævigatum*, of which possibly it may prove to be a variety.

— A SAMPLE of SPRATT'S PATENT BONEMEAL has been sent to us, which is now used as a fertiliser. It is prepared from bones that are thoroughly cleaned before being ground. We never examined a cleaner sample, and as a top-dressing for plants in pots, also for flowers and vegetables in the open air, as well as for Roses, Vines, and fruit trees, it is undoubtedly a safe and excellent stimulant, not the less acceptable by being inodorous.

— "A GROWER" writes that "EUCHARIS SANDERI does not by any means deserve the doubtful character some have given it, and I feel confident those who condemn it have not fully tested its merits. It is free in growth and flowering, its flowers last for a long time in good condition, they are devoid of the sickly green tinge so much disliked in *Eucharis grandiflora*, and are altogether much more suitable for bouquets. I anticipate that it will supersede the older form for this purpose, though it is scarcely so well adapted for wreaths."

— MR. S. CASTLE, The Vineyard, King's Lynn, sends us samples of VINE LEAVES very beautifully coloured, and proving how admirably adapted such are for table decoration and garnishing dishes of dessert. The colours are varied and much richer than are ordinarily seen, especially in the case of Alnwick Seedling, which is superb in this respect. The veins are a rich rosy crimson, with irregular dark crimson or almost black patches between them: this in the sunlight has a fine effect. Alicante has a leaf of a uniform rosy red tint, bright and chaste, the veins being yellow. Gros Colman has broad sharply defined yellow veins on a ground of dark crimson-maroon; this is very distinct. Gros Guillaume has a leaf somewhat similar, but the yellow colour is more diffused and the ground colour not quite so dark. Lady Downe's has an orange yellow leaf with numerous but irregular rosy spots, which are chiefly concentrated near the margin. In the case of Gros Guillaume and Gros Colman the leaves remain attached to the Vine for a considerable time, and have a very beautiful appearance.

— "X." writes:—"It appears probable that the PELARGONIUM SOCIETY may soon terminate its career. Its supporters have fallen off greatly in the past season, and there is much uncertainty as to whether the Society will hold another show. Perhaps the thought has occurred to many that the reason why the labours of the Society were not duly appreciated was because they were not really needed. The majority of the more important horticultural societies provide fairly liberally for Pelargoniums in their schedules, and the Royal Horticultural Society itself is amongst the number. Further, the Floral Committee of the latter body is quite sufficient to adjudicate upon the merits of new varieties that may be raised, while the comparatively small number of exhibitors rendered the prizetaking almost a monopoly. Some daring spirits even bring a similar charge against the National Carnation and Picotee, and Auricula Societies, and it is evident that if the numbers of exhibitors are to be increased there must be some regulation that will not permit one or two growers to sweep off all the leading prizes."

— AS an example of the way in which the VALUE OF ORCHIDS vary at sale-rooms, the following is worthy of notice. Early in the

year a fine variety of *Odontoglossum Alexandræ* was put up to auction with a reserve price of ten guineas, but as the bidding only reached six guineas it was not sold. Recently the same plant in even better condition was again put up and sold for 30s. The frequenters of the sale-rooms are well acquainted with this variability, and by that means are occasionally able to make an excellent bargain; often, however, to the disadvantage of the vendor. There is a certain amount of chance in sales of this character, as so much depends upon those present. Some ardent Orchids lovers will give almost any price to procure a particular variety or species to add to their collection, and plants are often thus credited with a fictitious value that is never maintained.

— THE customary plenitude of garden produce in COVENT GARDEN MARKET AT CHRISTMAS TIME has been maintained this season. Abundant stores of vegetables, fruits, flowers, plants, and those important adjuncts to Christmas rejoicing, Holly and Mistletoe, during the greater portion of last week occupied all available space. Of the last-named the supply appeared to be unusually large, but the Holly generally is rather deficient in the number of berries. The cut flowers include Roses, Camellias, Eucharises, Bouvardias, Lilies of the Valley, Orchids, late Chrysanthemums, Violets, and many other choice kinds; while of plants Poinsettias, *Ericas* *hyemalis* and *gracilis*, Primulas, Cyclamens, and Richardias constituted the leading features. Amongst the fruit Apples are especially abundant, Grapes being also in strong force, both foreign and home-grown. Of the latter some magnificent bunches of Gros Colman in the Grand Row have been attracting the admiration of visitors.

— THE annual meeting of the members of the ROYAL CALEDONIAN HORTICULTURAL SOCIETY was recently held in the Music Hall, Edinburgh, Professor Dickson presiding. An abstract of accounts for the year ending 30th November, 1883, was submitted, and showed receipts amounting to £1568 14s. 3d., and expenditure amounting to £1409 17s. 6d.—leaving a balance of £158 16s. 9d. The receipts at the three shows held during the year amounted to £1029 12s. 9d., and the expenditure to £582 1s. 9d. The total amount of the funds in the hands of the Treasurer at present amounted to £1205 16s. 2½d. The Earl of Hopetoun was elected Vice-president in room of the Earl of Stair, who retired by rotation; and Mr. James Buchanan and Mr. David Thomson were elected members of Council in room of Mr. John Clapperton, who retires by rotation, and Mr. Mackintosh, nurseryman, whose death was recently announced. Messrs. Stewart, Neill Fraser, and Turnbull Smith were respectively re-elected Secretary, Treasurer, and Auditor. In replying to a vote of thanks, Mr. Fraser said that the financial condition of the Society was very satisfactory, as the members' subscriptions and the receipts at the shows had amounted to a larger sum than they had ever done previously on ordinary occasions. He also stated that upwards of 40,000 persons had visited the shows during the five days they were held, or about 8000 per day, showing the appreciation of them by the public in and around Edinburgh. The Secretary was instructed to communicate with the Market Committee of the Edinburgh Town Council, asking if steps could not be taken to provide better means of entrance and exit at the principal door of the Waverley Market, which, it was stated, was too narrow. The shows to be held in 1884 are announced for April 2nd and 3rd, July 9th and 10th, and September 17th and 18th.

— AT the last monthly meeting of the ROYAL METEOROLOGICAL SOCIETY, Mr. J. K. Laughton, M.A., F.R.A.S., President, in the chair, the following were elected Fellows—viz., R. Bentley, W. Bonallo, Miss E. Brooke, Rev. A. Conder, T. H. Cowl, J. A. W. Oliver, C. M. Powell, W. B. Tripp, and Fung Yee. The papers read were:—1, "On the Explanation of Certain Weather Prognostics," by the Hon. Ralph Abercromby, F.R.Met.Soc. The author explains about forty-four well-known prognostics belonging to the following groups—1, Diurnal; 2, sun, moon, and stars; 3, sky; 4, rain, snow, and hail; and 5, wells, springs, and coal mines, by referring them to the isobaric conditions in which they are observed. By this means he is able to indicate the circumstances under which any prognostic fails, as well as those under which it succeeds. 2, "Preliminary Inquiry into the Causes of the Variations in the Reading of Black-bulb Thermometers *in vacuo*," by G. M. Whipple, B.Sc., F.R.Met.Soc. It has long been known that there is a want of accordance between the different instruments used for measuring the intensity of solar radiation; and with a view of ascertaining the cause of the variations in the readings of the black-

bulb thermometers *in vacuo*, the author has made a comparison with a number of these thermometers, the results of which are given in the paper. It is shown distinctly that the effect of an increased coating of lamp-black on the bulb is to raise the temperature, and also that the size of the thermometer bulb is a most important factor in the case of this instrument. 3, "Report on the Phenological Observations for 1883," by the Rev. T. A. Preston, M.A., F.R.Met.Soc. Mr. J. S. Dyason, F.R.Met.Soc., exhibited a series of coloured sketches illustrating the recent atmospheric phenomena during November and December.

ORCHIDS OUT OF DOORS.

ATTENTION has been very properly called to recent experiments in growing Orchids out of doors, and the subject is an important one in several respects. It is not likely that the ordinary exotic Orchids will ever be of any decorative value in such positions, but the outdoor treatment is likely to prove beneficial in another way, especially with regard to some of stronger and more robust species. If the growth can be better ripened by this practice—and there is every probability that in suitable situations and with ordinary care that will prove to be the case—an advantage will undoubtedly be gained in the resulting finer, more lasting, and more highly coloured flowers. Experiments similar to those described at Mr. Smec's garden have been tried in various gardens for many years, and Mr. Burbidge has recorded (in "Cool Orchids," page 4) some extensive trials instituted as long ago as 1852 by M. François Josst, gardener to Count Thun Hohenstein, at Tetschen, in Bohemia. These are so interesting that they are well worth being reproduced at the present time.

"In 1852 I observed that some of the species did not flower well; and it then occurred to me to place them in the open air in the early part of July. The plants which I put out were *Brassavola glauca*, *Cymbidium marginatum*, *Cypripedium insigne*, *Dendrobium Pringianum*, *D. speciosum*, and *Lycaste Skinneri*. They grew perfectly, although in the morning the temperature was sometimes as low as 5° Reaumur (43° Fahr.). In the daytime the heat in the shade was often as high as 30° Reaumur (99½° Fahr.). Tetschen is subject to frequent changes of temperature; it is surrounded by mountains, and is in a valley along which the Elbe flows after receiving all the waters of Bohemia. I took the plants in at the end of August. After a short time flower buds made their appearance, and a little while afterwards flowers followed in perfection. This good result led me to try the same experiment again on a larger scale; and I have since repeated it every year, until I am now in the habit of putting seventy-five species or varieties out into the air for three months in the year—viz., June, July, and August. What I do is this: I select a half-shady place, where I put some trunks of trees (Oaks), on which I place my baskets of Orchids. Between the trunks I plant Ferns, some *Philodendron pertusum*, *Tradescantia zebrina* and *viridis*, and *Cissus marmorea*, so as to produce a pretty effect. In order to protect the plants against the scorching rays of the sun and very heavy rains I cover the spot with canvas, but I endeavour to avoid too much shade, for I find that plants which are shaded too much never flower so well as others. I water in the ordinary way employed in hothouses. This year the temperature has several times fallen as low as 4° Reaumur (41° Fahr.), but the plants have not suffered in the least; they are even more vigorous, several of them actually flowered. These facts prove that many gardeners keep their Orchids and other exotics too hot. All plants require some period of rest in order to vegetate well.

"The following is a list of the Orchids which I treated in the way above described:—*Barkeria spectabilis*, *Brassavola glauca*, *Calanthe striata*, *Cattleya citrina*, *Cœlia macrostachya*, *Cypripedium insigne*, *C. insigne* var. *parviflorum*, *Dendrobium calamiforme*, *D. Jenkinsii*, *D. Pringianum*, *D. speciosum*, *Epidendrum Candollei*, *E. cochleatum*, *E. diffusum*, *E. falcatum*, *E. radiatum*, *E. selligerum*, *E. Skinneri*, *E. Stamfordianum*, *E. varicosum*, *E. virgatum*, *E. vitellinum*, *Gongora galeata*, *G. Batemani*, *G. luteola*, *Lælia acuminata*, *L. albidula*, *L. anceps*, *L. anceps* var. *Barkeriana*, *L. anceps* var. *superba*, *L. autumnalis*, *L. candida*, *L. furfuracea*, *L. Galeottiana*, *Lycaste majalis*, *L. rubescens*, *L. superbiens*, *L. violacea*, *L. aromatica*, *L. Colleyi*, *L. consobrina*, *L. cruenta*, *L. Skinneri*, *L. Skinneri* var. *alba*, *L. Skinneri* var. *latimaculata*, *L. Skinneri* var. *leucochila*, *L. Skinneri* var. *picta*, *Maxillaria cucullata*, *M. tenuifolia*, *Odontoglossum bictoniense*, *O. citrosimum*, *O. Cervantesii*, *O. grande*, *O. Insleayii*, *O. læve*, *O. nebulosum*, *O. pulchellum*, *O. pulchellum* var. *grandiflorum*, *Oncidium bicallosum*, *O. filipes*, *O. leucochilum*, *O. microchilum*, *O. sphacelatum*, *O. suave*, *Sobralia decora*, *S. dichotoma*, *S. Liliastrum*, *S. macrantha*, *S. violacea*, *Stanhopea connata*, *Trichopilia tortilis*, *T. tortilis* var. *pallida*."

Orchid growers would do well to follow up these experiments, as it has already been proved that many species will succeed in a much lower temperature than was originally supposed to be necessary. When Orchids first began to attract attention it was a general idea that they must be placed in a highly heated house, which was frequently kept too dry, and in consequence scores of plants were killed, and it was only by degrees that growers became aware of the fact that Orchids could be more successfully cultivated in a moderate temperature with more liberal supplies of water. Still further experience has proved that numbers grow and flower most freely in a cool house, which has now become one of the most important departments in large collections of Orchids, and is continually attracting more attention, as in it we obtain diversity of

richly and delicately coloured flowers, without the disadvantage of being nearly roasted in inspecting their beauties. It was but one step from this to the cold frame, and now it is probable that we shall soon hear of Orchids being out of doors in many large establishments. But let me give a word of warning to those who may be desirous of testing these matters for themselves. Do not be too hasty in exposing any valuable or delicate plants to the uncertainty of an English climate even in summer. If the garden is not fairly sheltered and in a moist situation do not attempt anything on a large scale, but submit a few of the comparatively worthless varieties to the test at first, and be guided by their condition as to future trials. There are, however, many gardens, especially in the south and west of England, where almost any Orchids could be safely placed out of doors for at least three months in the year—namely, from June till August.—ORCHIDIST.

TURNIPS.

THE above indispensable vegetable having been lately under discussion in your columns, and thinking the time not inappropriate for a few remarks, I give my experience. Turnips to be grown well, like most other vegetables of kindred nature, require liberal treatment. In the first place the ground on which they are to be grown should be dug deeply and well, and if it is poor a good dressing of manure ought to be given. Previous to sowing the seed the ground should be well broken up with the fork. Choose a fine day for this operation and for sowing, as nothing is more detrimental and more disappointing than to sow seed when the ground is wet. It is simply courting failure. Far better defer the operation for a few days, or if needs be longer still, than to sow on a particular day or week whether the weather is suitable or not. Sow the seed thinly and not too deep in lines about 15 inches apart. Cover them lightly, and make the ground level with a large iron or wooden rake. When the young plants are sufficiently advanced in growth for thinning they should have immediate attention; carelessness in this respect often leads to failure. They should be thinned to about 9 inches to 1 foot apart. Their after treatment consists in keeping down all weeds that may appear, which is readily done by running the hoe occasionally between the lines. This not only keeps down all weeds, but is very beneficial to the growth of the Turnips.

As to varieties, I much prefer the three undermentioned—namely, Early Snowball, Orange Jelly, and Chirk Castle Black Stone. These I have grown each successive season for the last eight years, and have always found them do well, and, what is more, to give satisfaction in the kitchen department. They are sown in the order named. I generally make a sowing of Snowball the first week in April, and in case they "bolt," which those from the first sowing are apt to do, another sowing is made ten days later. Orange Jelly is sown in the latter part of May, or at the latest the first week in June. Chirk Castle, than which, in my opinion, there is no better winter Turnip, is sown in the first week of July, and with the above treatment they make good serviceable Turnips, and stand the winter remarkably well.—J. RICHARDSON.

SIX MONTHS IN A VINERY.

MARCH 31ST.—On the morning of the 25th the minimum thermometer outside registered 22°, and that on the grass 16°. It being bright the ventilators of the vinery were opened a little at 7:30 and closed at 1:30. On the 26th we had a change from frost to snow, the ground being covered in the morning at six o'clock, and snow was still falling. The lowest temperature during the night was 30°. The sky showed signs of clearing at 9 A.M., when two lights were slightly opened, but which we closed again at 12:30 on the approach of another snowstorm. On the 27th the frost had returned again, the thermometer registering 24° and 17° respectively. We gave a little air at 8:0, reduced it at 9:30 on some clouds appearing, and closed finally at 11 A.M.

On the 28th we had both frost and snow. The lowest temperature registered was 25°. The snow was an inch deep at 5:45 A.M., and was still falling heavily. By eight o'clock the sky cleared, and three lights were opened 2 inches each. Ventilation was reduced at one o'clock and taken off at two with a temperature of 88°. This is the tenth day since the first flower opened and thinning is commenced. Some berries on the most forward bunch already measure three-sixteenths of an inch in diameter.

On the morning of the 29th the lowest temperature was 28°. We had very little sun, and the wind changed during the day to the south; no air was given. It became colder again at night, and before the morning of the 30th the minimum thermometer outside had registered 35°, but at 6 A.M. it had risen to 44°, and rain was falling heavily, which continued uninterruptedly till noon. There was some sun during the afternoon, and the air was warm and soft. It was not necessary to open our vinery, which, however, rose to the maximum temperature, and the inmates seemed to be enjoying it. The 31st, however, brought us another slight frost, thermometer down 28°, but it rose to 51° at mid-day with a soft and balmy air. Two lights were opened an inch each at 8 A.M., and the temperature keeping up well they were not closed till 3 P.M., when the mercury stood at 88°.

A few of the most forward bunches are thinned each day. Some berries on two or three of the most forward bunches measure a quarter inch through, and this is only the thirteenth day since the first flower opened. Think of this, you who allow a fortnight or three weeks to pass before commencing thinning, and judge how much you lose in size of berry. One point lost now means many lost by the time the fruit is fully grown.

We commenced watering again to-day, not that the border which was last watered on the 7th and 8th is considered to be dry, but several other houses will need watering during the coming week, and at this time it is better to water too early than too late. Clear water is used at a temperature of about 60°, and without any stimulant this time; the same quantity is given as before. A few sublaterals have to be stopped, otherwise there is very little to do now besides thinning in the way of manipulating the Vines.

April 4th.—The berries now measure three eighths of an inch, and the branchlets of the forwardest bunches, which have hitherto stood out at right angles to the main stem of the bunch, show signs of drooping. This is caused, I presume, by the weight of the fruit, as those which are not so forward are still in their original position. I hope to see the upper branchlets not only come out to where they were before, but to curve inwards towards the upper part of the stem and nearly hide it. This will happen when the berries are swollen sufficiently large to force the upper ones out of their present position. The power to do this is lost when the bunch is thinned too much, and it will, under such circumstances, always remain in a loose condition.

The 6th, although the minimum thermometer only indicated 42°, brought with it a very cold wind. The sun shone brightly, but the wind was sufficient to keep the temperature of the vinery from going too high. It reached 93° at 2 P.M. Abundance of water was sprinkled about, and the house felt very comfortable. The occupants did not find out there was a cold wind at all. It is a great advantage to be able to keep the house closed on such a day as this. The berries continue to swell at the rate of one-thirty-second part of an inch in twenty-four hours, and now measure seven-sixteenths in diameter.

On the 7th the minimum thermometer indicated 27°, while that on the grass had been down as low as 18°; the wind was even colder than the preceding day. No air was given, and our Vine rejoiced in a temperature of 92° at 2 P.M., and kept as high as 80° till after 5 o'clock. Altogether these cold bright days are perfect for forcing purposes. There is just sufficient air gets through the laps to prevent the interior reaching too high a temperature, and yet the apertures are not sufficiently large to allow of the moisture escaping very freely.

Note, December 17th.—I have received some complaints from friends as to the manner and contents of this diary, and as it is sometimes useful to know how "others see us," though we cannot possess the power of vision the poet sighed for, and use other people's optics for that purpose, I feel grateful for such friendly hints as I have received.

No. 1 says my remarks will be of little use to him, as he does not want to start a vinery on New Year's day. Why did I not give the particulars of one started in March, as that is the month nine out of ten vineries are started?

No. 2 thinks I have a great deal too much to say about the weather and outdoor temperatures; and No. 3 thinks, and not over-delicately hints, that I am somewhat monotonous and dry. To the last indictment I must plead guilty, but I think there are extenuating circumstances.

The notes given were made on the dates placed against them, and they are transcribed verbatim except when something is omitted. The vinery in question I attended to personally, nothing was done in it without my direction from day to day, and every operation of any importance was chronicled and is here reproduced. When notes are made daily of the same sort of work there must of necessity be some repetition. I could now make my notes much more readable, but I do not think they would then so well convey the actual ideas and aims I had at the dates mentioned. The outside weather is always my guide, and my aim is now to show that if that is watched and the houses are worked according to it, what a very simple matter it is to grow good Grapes. By going on wrong principles many amateurs give themselves ten times as much trouble to grow third-rate fruit as a proficient cultivator does to produce the most splendid results. It may be taken for granted that any of the routine usually carried on in vineries and not mentioned by me has not been practised and is not considered necessary. Much of it, indeed, is positively mischievous.

Calendars of operations can never be strictly followed, because the calendar writers not being Zadkiels cannot gua-

rantee the sort of weather they are writing for, consequently to be successful the cultivator must in a great measure depend on himself, and I should like to teach every cultivator to be to some extent self-reliant. Let him get all the advice he can from current literature and friendly practitioners, but after all he will always find his own a peculiar case for which there has been no rules laid down that will exactly suit.

With reference to starting Vines at different seasons, artificial temperatures for starting in spring need not be quite so high as for starting in winter, because the natural mean temperature is so much higher. I have given ample statements of temperatures in my treatise which appeared in these pages last year.

It will be borne in mind that this series of articles is not intended for professionals, but is only an endeavour to make amateurs acquainted with my practice, and to teach them to be more self-reliant.

The measurements of the berries till the stones hardened were taken by cutting through the centre and placing a thin steel rule across. When the stones hardened the measurements were taken with callipers.—WM. TAYLOR.

VIOLETS MARIE LOUISE AND NEW YORK.

I HAVE many sympathisers in the liking for this lowly sweet flower. Owing to a change last spring I had to collect material for a fresh start, and had plants from many quarters both north and south, altogether securing nearly thirty varieties, or so-called varieties, which, however, I do not now propose to criticise; but I received Marie Louise from at least three sources, and all turned out to be New York, and I consequently have come to the conclusion that there is a confusion of names. This is a misfortune, as there really is considerable difference between the two varieties, and as some of your many correspondents from time to time praise Marie Louise it is well the matter should be made clear, for should any from what is stated order Marie Louise and receive the true kind they will be disappointed.

Marie Louise is similar in foliage to the old Neapolitan; the leaves are slightly larger, longer, and more pointed, and of the same lively green. The plant is of free growth, and usually commences to flower in August, and reaches its best from late September to November, and is good again in February or later, according to the weather. The flowers are palish blue, deeper in colour than the lavender of the type, but only a shade, have long stalks—5 inches or more according as they are drawn by the frames being kept close or open, and about 1½ inch across in good examples, the flower having a somewhat large white space at the base of the petals, which gives it a rather conspicuous white eye.

New York is freer in growth than Marie Louise. The plant forms a more compact tuft, does not form runners to any great extent, and has the defect of forming abortive crowns, which, however, is reduced to a minimum by putting in fresh suckers each spring or small rooted runners. The foliage is darker—a deep green with a bronzy tint in the centre, and is more leathery and persistent than any of the Neapolitans. The flowers are borne on stalks 5 to 6 inches long, stout, but not so stout as to support the flower, which from its weight becomes prostrate, hence I presume the name of pendula. They are large, in good examples over 1½ inch across, dark slate in colour with a purple tinge, and the centre petals tinged and splashed with red, the base of the petals having a little white, but not nearly so much as in Marie Louise. It commences flowering early in September, and blooms through the winter in favourable weather, being at its best from late September to December, and in February onwards. I am pleased to be able to confirm the opinion of the grower, Mr. Beachey, who first brought this variety to the notice of the gardening public through your Journal—namely, that it is the best and most floriferous as well as the hardiest form of Neapolitan Violet in existence. It is, however, not so much liked by some as the bluer forms, whilst others like it better. Taste differs even in Violets.

What difference is there between Venice, Marguerite de Savoie, and Princess Louise? In what do they differ from New York?—G. ABBEY.

OUR ORCHARDS AND PARAFFIN OIL.

THE brief summary of the Rev. P. Dunster's paper given on page 483 of the *Journal of Horticulture*, which comprehended the principal points of the writer's argument, ought not to go unchallenged, as I do not believe many gardeners will be numbered among the reverend gentleman's converts. That he has done good service in calling the attention of capitalists and agriculturists to the discreditable state of the Apple industry will be conceded by all who take any interest in the matter, but that paraffin is to work such wonders among apparently worn-out trees not many will believe. A fruit tree well dressed with crude paraffin would soon be rid of all parasitical diseases, insect or otherwise, and in addition would have many buds destroyed unless I am greatly mistaken as to the dangerous properties of the oil. The tree might yet survive the process, make numerous fresh shoots, and present a generally improved appearance; but the question is, How long will this satisfactory state of affairs last? Not long, I am afraid, unless other remedies are simultaneously applied.

Moss and lichens I believe are much less injurious than the above writer considers them. If they were capable of sending roots into the

inner bark of a tree the case would be different; as it is they are apparently merely attached to the old or outer bark, and derive their sustenance principally from the air. They may, fungus-like, be contagious, and be also to a certain extent injurious, though as a rule I should say they as well as canker, unless caused by American blight, are the consequence and accompaniment rather than the cause of the tree's decadence. Restore the surroundings as well as the tree to a better state, and the diseases will disappear not to return again for some time to come.

If I advised a practical fruit farmer to dress all his large orchard trees with paraffin, also to scrape and clear off all the moss and lichens, in order to restore them to their former healthy and fruitful condition, I should very likely get laughed at for my pains. What I would strongly advise the holders of many debilitated orchards is to examine well into the drainage, as in all probability many of the drains are either dislocated or choked by the roots of the trees, while many low-lying orchards found undrained ought at once to be thoroughly drained. It is only in damp congenial positions where mosses and lichens abound; and by changing the conditions, as we do when we drain land, thereby making it warmer and drier, the atmosphere also being changed for the better, they soon disappear. Shallow drains in most places would be injurious, as being liable to drain land too quickly and thus impoverish it. It is deep drains, say from 3 to 4 feet according to circumstances, that are required, these doing their work slowly but surely. They should not be under the trees. No distances can be given to suit all cases, but generally speaking one running midway between the rows of trees if these are 25 feet apart, or if much closer together through every other space, would afford ample drainage. Then in many cases fully one-third of the tree's growth ought to be thinned out, and the branches where they meet be freely shortened to admit more light and air to the trees. If badly infested with American blight as well as moss and lichens the bulk of the two latter may well be scraped off, and the trunk and principal branches dressed with either coal tar and water in equal proportions or soapsuds and brine. A dressing of quicklime and water will also destroy various parasites, and is easily applied with a syringe or more thoroughly with a brush. If the land is poor it ought to be heavily surfaced with good farmyard manure, and much liquid manure is often wasted in farmyards that might with advantage be given to the fruit trees. An orchard thus treated, even if we omit, as I suppose many will do, the scrubbing and dressing, will undoubtedly soon give evidence of renewed vigour, and this will be of a more permanent character than can possibly be brought about by a bark-improving process alone.—W. IGGULDEN.

INFLUENCE OF STOCKS ON GRAPES.

IN the Muscat house here I grafted Gros Colman three years ago, and this is the second year it has fruited. But unlike your correspondent, Mr. Thomson (page 502) I have not the means of testing so closely the grafted Vine with Gros Colman on its own roots in the same house; but we grow it in the late vinery, where the colour is all that can be desired, yet the flavour very indifferent when compared with the same variety grown on the Muscat stock. The stock has not influenced the scion here to ripen its fruit earlier than on its own roots, neither is the colour so good, but the berries are larger and considerably improved in flavour, and the leaves do not show to the same extent that curled unhealthy appearance characteristic with the variety on its own roots.

A little over twelve months ago in the pages of the Journal, in an article on late Grapes, I there referred to the improvement the Muscat stock had effected in Gros Colman, and I am glad to hear such an excellent fruit-grower as Mr. Thomson has met with even greater success than myself on the improvement of so noble a Grape.

Alnwick Seedling grafted on West's St. Peter's is larger in the berries than when grown on its own roots, but not otherwise improved. This Grape is considered much better in flavour than Black Alicante; but if kept long after being ripe the skin becomes tough and leathery, which is no improvement to this otherwise good Grape.

I consider Barbarossa (Gros Guillaume) the most unsuitable stock anyone can graft other varieties on. I have grafted several different sorts on this, but never found any improved or even so good as when grown on their own roots.—CHS. ROBERTS, *Highfield Hall*.

PROPAGATION OF ERICAS, EPACRISSES, AZALEAS, AND CAMELLIAS.

ERICAS, Epacrisse, and Azaleas should be propagated in the spring, and Camellias in the autumn months. The numbers of plants that are killed in large establishments make it necessary to keep up a good supply of younger plants to take their places. I do not mean they are killed through any want of attention, but through rough usage—viz., hard cutting for flowers, furnishing, and conservatory decoration.

To succeed in striking a good per-centage of those inserted, it is necessary to carry out something like the following instructions. In February or March make a compost of two parts peat, one leaf soil, half sand, and half of charcoal. Fill to within an inch as many 32-size pots as required; fill the remaining space with dust-dry sand. Take all the cuttings that can be obtained, which are about 1½ inch long, from the old wood with a hecl. If sufficient cannot be so procured, take the remainder from the most sturdy growths. Do not remove any of the leaves, using a sharp knife to insure a clean cut. Insert them without the aid of a dibber; the dry sand will then fill up all the cavities. Give them a thorough watering, not permitting them to get dry afterwards. Place under a bellglass, and stand them in a propagating or

forcing house. Wipe the glass once or twice a week, and shade if exposed to sun.

When the cuttings have formed roots and grown 2 or 3 inches pot them into 60's, return them to their warm quarters for a short time, after which they can be placed in a cool house previous to standing them outside under a north wall. They will require another shift, this time into 48-pots, and I would advise a rougher compost for this potting. I have struck hundreds of cuttings of the above plants, much to the surprise of friends and visitors, who were ever eager to know my mode of treating them. After the first year, to make doubly sure, I always dipped the end in ether previous to inserting them, and in many instances never lost a cutting. When potting them into larger pots my friend, Mr. Carmichael, Nowton Court, is strongly in favour of broken flints being mixed with the compost, and I can testify to their value. They keep them cool through the summer, and absorb no moisture in winter, and in a year or two it is impossible to see the flints for the roots that have netted them.

Camellias are more easily propagated than Ericas, and many succeed with them where they have never succeeded with the former. Still a few hints may not be out of place. When well grown there is nothing to surpass them for conservatory decoration. What finer sight could we wish to see than a lot of Camellias in 48-pots, varying from 2 to 3 feet high, with from six to a dozen blooms? The advantage of keeping them in small pots is that you can have some in almost all times of the year. Even when not in bloom they could occupy many a worse plant's position.

October is the month for propagating them, as then is the best time for getting well-matured wood or growths. Take them about 3 inches long, and with large wood buds. Remove all but the two or three topmost leaves. Place fifteen or twenty into a 9-inch pan, the soil to be one part peat, one loam, one leaf soil, one charcoal and sand. Put them under a handglass and stand in a north greenhouse or some cool and shady place. After being well callused remove them to a warmer quarter, where they will soon root, and can then be potted into 48's, using two parts loam, one peat, one leaf soil and sand. They can remain in these for four or five years, and always standing in an early Peach house except when they are in bloom, and the house being cleared, as the temperatures for the Peaches at different periods suit them. When full of roots feed them with liquid manure and water them over the foliage every time the house is damped.—A FOREMAN.

BOUVARDIAS.

Too much cannot be said in favour of Bouvardia Hogarth. At this time of the year its charming vermilion flowers are very acceptable either cut or on the plants for decoration in the house or conservatory. Another very good variety is Bridal Wreath; white slightly tinged with pink. We also have several more first-rate sorts coming into bloom at present, and will continue so for a long period yet.

The cuttings were inserted early in March, and when they were well rooted each one was placed in a large 60-size pot. They were grown in a cool stove until the early part of June, then they were turned out of their pots, planted in a cold frame, and kept close for a few days. After that a little air was given, and subsequently the lights were drawn off on very fine days. The plants were syringed twice daily, in the morning and afternoon about 2 P.M., when the frames were closed for the day. The tops were pinched off until the middle of August, when they were allowed to grow. In September they were taken up and placed in 7-inch pots, and then transferred to a heated house to give them a start. This I consider the best way of treating Bouvardias, and they are now blooming profusely in a temperature of 55° to 60°.—G. T. G.

A WONDERFUL VEGETABLE MARROW.

IN September of the present year we were invited by a gentleman, Mr. Sechiari, to inspect in his garden what he described as a "wonderful Vegetable Marrow plant—a perfect novelty, quite a phenomenon; yet it can hardly be called a phenomenon or freak of Nature, because more than one such plant was raised from the same packet of seed, which was sent to me by my relatives from France."

As we were unable at the time to accept that invitation, Mr. Sechiari very kindly forwarded samples of the Marrow to our office. They were truly wonderful—a large vegetable hamper full of fasciated stems thickly studded with young Marrows from 1 to 4 inches long, struggling with each other for supremacy, many succumbing, but numbers of others attaining the proper size for cooking. A more striking example of the familiar doctrine of the "Survival of the fittest" it would be difficult to imagine. Still there is a survival, for Mr. Sechiari sent us a developed specimen 17 inches long and 7 inches in diameter, yellowish green in colour, mottled between the ribs with brown. Some of the flattened stems were a foot in diameter, and about twice that length. One of these we divested of leaves, which were about as numerous as the fruits, and requested our artist to represent as accurately as possible. The result is seen in the annexed figure. The specimens are reduced one-

fourth, but there is not the slightest exaggeration, the figure being engraved from a photograph, hence is a strictly truthful representation of the original.

The important question arises, Can this remarkable form of fasciation be retained and transmitted by seeds? Observing Mr. Sechiari's remark that he had "more than *one* such plant," we made specific inquiry on the point, and were informed that he raised ten plants, five of which were like the examples forwarded, and the others more or less fasciated. This would appear to indicate that there is at least some degree of probability that this extraordinary form can be reproduced in the ordinary manner of raising plants; yet further experience is requisite and this we shall await with interest. That fasciation can be perpetuated through the agency of seed we have conclusive evidence in the

do better than ask your attention and your correspondents' to it, confining myself to a few observations of my own experience. Most of my home-grown bulbs were potted long since, and the pots are full of roots; and I may here say I invariably shake them out when the stems have decayed. Those of the speciosum (*lancifolium*) type are fit for this purpose generally towards the end of September, and *L. tigrinum* outdoors even earlier, except the Martagon Lilies. Though I try to find a sheltered corner for those last named, the Tiger and Turk's Cap Lilies outside, I must say, except under exceptional circumstances, I dislike seeing *L. auratum*, *L. speciosum*, and its fine varieties, *L. longiflorum*, &c., dashed down by a fierce wind or splashed and blurred by a drenching rain. I am aware there are several gardens near here where Nature or the gardener's art has afforded protection, and where the Lilies luxuriate and increase from year to year in hardy Azalea and Rhododendron beds.

Wherever, then, accommodation can be had I consider those beautiful

Fig. 113.—MR. SECHIARI'S VEGETABLE MARROW.

ockscomb, and we are not without hope that Mr. Sechiari will be able to show us further examples of this wonderful Marrow next year. It is something more than a curiosity, being, as the cultivator informs us, and which the examples in question substantiate, much more productive than the ordinary varieties of this vegetable; while as evidence of its being earlier we have only to add that the matured specimen was cut in June in a garden in Middlesex.

IMPORTED v. HOME-GROWN LILIUMS.

A LADY from Dublin writes, "I have seen some notes of yours in reference to potting Lilies in a recent issue of the *Journal of Horticulture*. . . . I have some home-grown, and I am about to receive a number direct from Japan through Messrs. Carter, London. As my stock is increasing I shall plant some outside and pot the remainder, but would first thank you to say if you would treat the former (home-grown) and the latter differently?"

As I have reason to know there are others beside my fair correspondent who would like some additional information on the point, I cannot

Lilies deserving of space indoors. Had the lady above referred to shaken out her Lilies when the stems had decayed she would have found a large or small system of roots resembling a miniature mop, one from the base of the bulb and the other from the stem. The former, if vigorous growth and careful treatment (not merely before flowering, but afterwards) had been pursued, would be quite healthy and ready to commence root-action again. The stem roots are generally cut off along with the withered stem at repotting, and of course decay with it, having performed their function of assisting the feeding roots below. If my correspondent has left her Lilies outside until now the pots are perhaps waterlogged, and roots and bulbs are probably decayed. If left to become dust-dry inside they will equally be valueless; and lastly, if not regularly watered, fed, and matured after flowering there will be no satisfactory flowering next year. These hypotheses will likely answer partially if not wholly the often-repeated questions, Why must we buy imported Lilies every year? Why are imported Lilies better and more certain flowering? In order to extend the time of blooming I pot from time to time up to March next, as I want them for decorating our church, for which purpose nothing can compare with them. The imported Lilies generally arrive from Japan minus the sheaf of roots above referred to, and considerable

care must be used to prevent rotting or mildew until roots are emitted. For *L. auratum*, if possible, a large portion of the potting material must be good open peat (not retentive peat), and no water until the stem appears. I lost some of the finest bulbs I had last year by premature moisture. Sand at the base helps root-formation. I never force Lilies, except what heat comes from tan.—W. J. MURPHY, *Clonmel*.

STORED-UP SAP IN VINES.

NINE years ago I had to shift my vinery to new premises. The Vines, seven in number, were lifted a day or two after the new year. The weather was mild and dull, and as each Vine was lifted the roots were carefully covered. They were then carried into a wash-house near their new home. The vinery was then taken down, everything carted off, even to the border, as it was only six years old. The masons went to work at once, but were stopped by frost and snow after getting the back wall to a height of 5 or 6 feet. It was then the 22nd of January, and to all appearance we were going to have a spell of frost. I had taken precautions for such in this way. I spread 6 inches of dry sawdust on the floor of the wash-house, laying out the roots of the Vines on the top of this, and covered the whole with 2 feet of the same material. My object was to keep air from the roots; and although I had never tried sawdust before, I would strongly recommend it to anyone who should get into the same difficulty as I was at that time. As the frost became stronger I got a quantity of sacks and an old carpet and packed these carefully over the dust. The taps in the wash-house were by this time frozen, and outside the thermometer was registering from 12° to 25° of frost. The second week in February brought a change, but in a day or two it was as hard as ever. Near the end of the month a thaw took place, and March was ushered in with "dirty" weather.

I examined the roots of my Vines as soon as all danger was past, and found them quite comfortable. The masons made a start once more, but owing to rain, snow, and frosty nights it was the second week in April before I saw the furnace ready for a fire. The joiners had the house ready for the Vines on the 24th; and on the 25th, after being sixteen weeks in a wash-house, the Vines were planted. They were carried out of the house one at a time, planted, and tied to the trellis. I hope "Non-Believer" will ponder well the next sentence. Every eye on every Vine was started, some an inch, some even more. I would ask your correspondent to account for these Vines starting into growth. They had made no fresh roots, nor could they in dry sawdust, yet here was as fine a "break" as any Vine-grower could desire.

It caused me no surprise to see these Vines starting, but after reading "Non-Believer's" theories I am certain this "true tale" of mine should surprise him.—S. HALLIDAY.

My reason for giving the whole of the quotation from Lindley's work was simply to complete the sense, and to show it expressly referred to *fluid food*—namely, that which had not passed through the process of assimilation. My thanks are due to "Non-Believer" for pointing out where the other passage occurs, and I have now obtained the later edition. The remarks are, however, as I conjectured they would be, of a general and not of a special character, serving merely to illustrate the ordinary processes of absorption. This will be best perceived when the passage is seen in its entirety, and I therefore reproduce it:—

"The sap then ascends in consequence of an attracting force exercised from above downwards by the foliage of plants. But it is evident that this is only a partial explanation of the phenomenon; for it does not account for the ascent of sap in winter when leaves are absent. In order to explain that fact we must have recourse to the action of endosmose, a force the effect of which is to produce propulsion. A tree may be assumed to be a combination of hollow tubes freely communicating with each other, and enclosed in a skin through which fluids are capable of being absorbed on the one hand and expelled on the other. If we conceive a body of this kind, in which the tubes are nearly empty, to have its lower extremity plunged in water, the absorbing power of the skin at that part will begin to introduce the water into the interior, and this continuing to go on for a sufficient time, the tubes must necessarily become at last filled with water rising upwards from below."

After some further remarks explanatory of this system Lindley continues:—

"A tree is just such an apparatus. Its tubes are nearly empty at the fall of the leaf. During winter the roots absorb water from the soil and fill the tubes again. By the arrival of spring they are filled almost to bursting, and then if the stem is cut it bleeds, or if the roots are cut they bleed. Bleeding ceases as the leaves unfold. The Vine, the Walnut, the Birch, are all as incapable of bleeding as other trees when their leaves are formed, because the leaves gradually empty the tubes, put an end to their distension, and prevent its recurrence so long as they remain in an active state."

The whole of this is intended to render clear the principles which regulate absorption in plants, and throughout the fluid or crude sap only is referred to. That the cells of the Vine stem are not empty after the leaves fall is conclusively proved by the statement of a microscopist last week, page 529, and the matter is such a simple one that it admits of easy proof by anyone possessing a microscope of moderate power. The starch granules have been derived from the sap altered in the foliage during the summer, and that they are stored there for the future support of the plant cannot be doubted by any reasonable person. Before this starch can, however, be utilised in the growth it must undergo some

change, and this change is effected by an increase in temperature and sufficiency of fluid present in the cells. Other compounds are formed which can be at once converted into the growing tissue of the plant, and so the process advances.

It is obvious that the contiguous cells—namely, those composing and immediately adjoining the bud, must be the first to yield the requisite supply, and the cellular tissue of plants is permeable by fluid or semi-fluid contents, the direction of the flow being determined towards that portion of the plant where the demand is greatest. Thus until the absorbing and assimilating forces of the Vine are balanced—that is, when the roots are active and the green foliar surface sufficiently extensive to elaborate the sap so rapidly transmitted to the leaves, there is a demand upon the reserve force constituted by the starch and other matters congregated in the cells. Afterwards the processes of absorption and assimilation would be conducted in the usual way. The precise period when the change takes place is difficult to determine. It probably varies according to the condition, strength, and other characters of different Vines. In some cases nearly the whole of the starch would be exhausted, and in others comparatively little would suffice. These are matters that are well worthy of investigation, and much valuable information might be obtained by a course of judiciously conducted experiments.

On page 465 "Non-Believer" remarks, "There is really no such thing as storing up sap in the sense Mr. Taylor states, in plants like the Vine. Only bulbs and tuberous roots store food for reasons apparent to anyone." After the evidence of the competent microscopist on the page quoted, "Non-Believer" has no other course than to withdraw this unsupported assertion, and then there will be little difference of opinion between us.—CREDO.

THIS discussion is not only one of great interest, but it is also of great importance to everyone connected with horticulture, because in his operations the gardener must to some extent be actuated by those theories which are impressed upon his mind in respect to it. Judging from the discussion, it is, as well as the precise manner and time in which roots commence growth and absorb food, a physiological subject somewhat shrouded in mystery; at least the teachings of the authorities past and present, unless they have been misunderstood or misquoted, do not appear to coincide thereon. Books are invaluable aids to the gardener, but when the principles they set forth do not perfectly agree with the practical lessons he has received, it behoves him to accept them with extreme caution, till by actual experience he has thoroughly proved whether they are correct or not.

Without attempting to say more on this subject, or even to hazard a reason for saying this much, save that the minds of physiologists, like all others, do and will differ, I should like to record a few practical observations made at different times and places, which to me appear to bear either directly or indirectly on the question at issue.

In the winter of 1849, in the gardens where I then was, a large Apple tree was uprooted by the wind. On one side the roots were found to be quite decayed, and the only live ones it possessed were snapped off close to the butt of the tree, and it became rootless, with the exception of about 12 inches of tap root only. It remained in this position for several months, and produced blossoms, foliage, and even set fruit, and then succumbed. My note-book contains the query, How were these leaves and blossoms supported during this period?

In 1861 I took charge of a Peach house, which contained three very large and very old trees, one of which had upon its stem an enormous boss 18 inches in diameter, at about 4 feet from the ground, and just at the junction of the stock and scion. Immediately below this boss the stem was quite decayed, and had entirely disappeared with the exception of the dead heartwood and a strip of bark and young wood scarcely an inch wide, which formed the only living connecting link between the boss and the roots. How long it had been in this state I could not ascertain for certain, but it continued for ten years afterwards to make a fair amount of annual growth, as well as to produce regularly fair crops of good fruit. Is it possible this thin shred of bark conveyed all the sustenance the tree obtained?

When the practice of preserving ripe Grapes by placing the shoots in bottles of water was first mooted, I gave it an early trial. The mouths of the bottles after inserting the shoots were made perfectly tight by fitting in corks and cotton wool. Notwithstanding this, the water disappeared and had to be replenished from time to time so as to cover the bases of the shoots. Where did the water go, and by what means did it go? The Grapes were cut as required for use, and compared with similar ones left hanging on the Vines, and their comparatively inferior and watery flavour solved the first question, but not the second. The shoots were allowed to remain in the bottles till late in the spring; the terminal buds expanded, leaves and shoots were developed, but no roots were visible, as could be plainly seen through the clear glass bottles, till ten days afterwards.

In the spring of 1877 I had occasion to take up some eight-year-old Vines which were completely denuded of fibrous roots, and for the sake of experiment two of them were replanted in a new border. The stems were completely covered with moss, which was kept frequently moistened. They broke fairly well, and made considerable growth before even roots were formed, and these started at the surface of the border inside the house. As these advanced the stems were severed just below them, and on lifting the old roots no new ones were found upon them.

For several years we have used shoots of Privet for tying up the flower stems of Hyacinths and other bulbs in the flower garden. They

invariably make, when allowed, 5 or 6 inches of young growth before roots appear.

Three years ago I purchased a poor plant (not recently imported) of *Lælia purpurata*. It had been badly treated and had lost every particle of root, being composed simply of three pseudo-bulbs with leaves and an embryo bud. It neither made roots nor growth till this spring, when the bud began to extend, and it reached 9 inches in length before any roots appeared at its base, nor have any yet been formed at the base of the other bulbs. By what means, I would ask, was sufficient vital force retained or restored (for the partially shrivelled pseudo-bulbs began to swell even before the bud started) after such a lengthy suspension between life and death, to enable this plant to grow without a particle of root, and what different laws of Nature were put into force in either of the instances enumerated. If stored-up sap in the pseudo-bulbs of the *Lælia* preserved its life, surely the prolonged life of the other subjects was due to the same cause.

In respect to root hairs on Vines, I have no hesitation in saying if they do exist on one year's and on older roots, they are infinitely less than on those recently formed. In my leisure hours during the last two months I have done little else than examine Vine roots through a very powerful microscope, and although not for this specific purpose, still I have not detected any of these hairs except on the youngest roots. Whether these hairs, however, are the only means that Vine roots possess for taking in their food is, I think, doubtful, and requires further demonstration before being finally accepted.—C. W.

THIS discussion originated, I believe, in a statement made by Mr. Taylor in one of his articles, "Six Months in a Vinery," page 372, to the following effect:—"The shoots are now from 3 to 7 inches long, with two to four fully expanded leaves, the largest of which measure $4\frac{1}{2}$ or 5 inches across. Here and there in a few of the older ones are patches of dark colour, a sort of bluish green, only visible at present to the practised eye which is watching for its appearance. Yesterday it was only discernible on two or three leaves, now it shows slightly on a score or more, and indicates that the roots have commenced action, and that the leaves are no longer dependent on the stored-up food which was prepared last autumn and preserved in the stems for early use." Does Mr. Taylor adhere to this idea still, or is he prepared to admit that as soon as the growth commences, and a green surface is exposed to light, changes are also commenced in the crude sap. It appears to me that he has avoided repeating the statement as to the exact size the shoots and leaves attain before the stored-up sap is exhausted. In his principal argument he is undoubtedly right, but in this I consider he errs, and I would advise a graceful retreat from an untenable position. Is he also prepared to adhere to his statement that "root-action and root-extension are synonymous terms? If so, what does he mean by this?—BETA.

I WILL not prolong this controversy with Mr. Taylor, as it seems hopeless to expect him to answer any questions involved in his arguments, and so make himself clear. I am driven, however, to point out his inconsistencies and contradictions, for they indicate unsettled convictions and loose teaching which may mislead. He has all along spoken of his stored-up sap as "prepared" and "elaborated" sap, but finally admitted the sap was stored up a month to six weeks after the elaborating organs were dead (I notice he makes no answer to that this week). Next he said one reason why Vines depended on stored-up sap was that in spring when growth began the only roots which could absorb the sap from the soil were "non-existent;" but now this week he says that when Vines bleed, as it is called, in spring the water is absorbed from the soil and forced up into the plant by the roots—*i.e.*, when the latter are "non-existent!" At page 490 he says "he would leave it to me to find out how roots could take up nourishment when they were non-existent," the only means of absorption being by the root-hairs, he said. This week he says, "There is a continual absorption of water going on by one or more of the processes enumerated," which, to explain, he launches into a description of "osmosis," protoplasm, and the like—all matters no more affecting his original assertions than the man in the moon. I ask any reader what reliance is to be placed upon a writer who confuses his points and contradicts himself in this way?—NON-BELIEVER.

P.S.—I have no difficulty in accepting your "Competent Microscopist's" statements so far. We know starch granules are hardly found anywhere else than in the cellular tissue of plants, but they have to undergo certain processes before becoming available by seeds or buds. When "Microscopist" brings his facts to bear in support of Mr. Taylor's original assertions on the subject of Vines depending on the stored-up sap alone from December till the 10th of February, when the shoots were 7 inches long, and each bore a number of leaves from $4\frac{1}{2}$ to 5 inches broad, I may have more to say.

In the second paragraph from the top, right-hand column, page 528, for "roots" read "shoots" in the third line.

[The portions of Vine shoots were certainly not sent for microscopical examination with the object of supporting the arguments of any individual, but for the purpose of obtaining information that should be equally acceptable to all. Mr. Taylor has not yet proved the strict accuracy of all his statements, and we doubt very much whether the revelations of the microscope in question will assist him in doing so.]

BATEMANIAS.

THOUGH some seven or eight Orchids are described by certain authors under the title *Batemanias*, three only are really worthy of cultivation, except

where the object is to form as complete a collection as possible. Some of the species have been referred to the genera *Galeottia* and *Huntleya*, but those now included in *Batemanias* are the following:—*B. Colleyi*, *B. fimbriata*, *B. grandiflora*, *B. melcagris*, *B. Beaumontii*, *B. armillata*, *B. lepida*, and *B. Wallisi*. Respecting these, however, Mr. G. Bentham has stated that "*Batemanias*, reduced to the original Guiana species, appears to be very different both in habit and character from *Huntleya melcagris* and the allied species referred by Reichenbach to *Batemanias*, but which we should include in *Zygopetalum*." Of the latter genus it may be noted Mr. Bentham makes six sections:—1, *Zygopetalum* proper; 2, *Zygopetalum* of Reichenbach; 3, *Huntleya*, including *Galeottias*; 4, *Bollea*; 5, *Warszewiczella*, including *Psecatorea*; and 6, *Promienæa*, including *Kefeirsteinia*. A large group of closely allied species thus formed, the majority of which can be traced through various steps into others. The great similarity between the *Bolleas* and *Psecatoreas* is well known, and the generic distinctions between some of the others are so slight that it often puzzles experienced observers to determine to which a particular species may belong. As, however, Reichenbach's system is generally adopted, the few species may be noted under this head.

Batemanias Burtii.—The most beautiful of them all is this fine Orchid, which, though having the reputation of being difficult to grow satisfactorily, has proved in competent hands that the opinion is an erroneous

Fig. 114.—*Batemanias Burtii*.

one. There is some uncertainty about what growers commonly term the "Bollea breed" of Orchids. They will appear to progress well up to a particular stage, and then almost without warning the leaves turn yellow and the whole plant fails in an unaccountable manner. Such is the general idea, and there is some ground for it, though the causes no doubt vary under different circumstances. One of the chief reasons for failures of this character which has come under my observation is placing the plants in too strong heat, where they seem to make good progress at first, but ultimately become enfeebled and collapse. Cool treatment suits most *Batemanias*, and especially *B. Burtii*, whether it be grown in a pot or on a block, and the finest plants that I have seen have been subjected to a much lower temperature than usual. Peat and moss form the best compost, but when grown on blocks of course the first-named can be dispensed with. Liberal supplies of water are required under either system, especially in the growing season.

B. Burtii is a native of Costa Rica, whence it was introduced in 1872. It has small pseudo-bulbs and leaves about a foot long and 2 inches broad, of compact and sturdy habit. The flowers (fig. 114) are 4 inches in diameter, the petals $1\frac{3}{4}$ inch long and 1 broad at the base, ovate, tapering, of a peculiar shining reddish chocolate colour, very distinct and beautiful, and the surface is studded with little bladder or wart-like dots; the base is yellow with a few crimson streaks radiating from the column. The sepals are 2 inches long and seventh-eighths of an inch broad, the same colour as the petals; yellowish fading to white at the base. The lip is ovate, 1 inch broad and $1\frac{1}{8}$ inch long, the upper half reddish, the

lower white, the surface not shining as in the other portion of the flower, and without the warts. It is hinged at the base to a projection from the column, which is furnished with a fringe of stiff filaments about a quarter of an inch long, six or seven in the centre being erect and facing the column, and a number on each side incurved laterally. The column is white with a few rosy streaks, and the sides at the upper part are prolonged into a kind of hood. The hinged lip and fringe seem to have some object in relation to the fertilisation, but what that special purpose may be it is difficult to say, for in many members of this wonderful family we frequently see contrivances, obviously for some object, concerning which often the most we can do is to conjecture its use.

B. meleagris.—This also is a very distinct Orchid, and is very generally known under the name of *Huntleya meleagris*. It is a native of South America, having been found in the "gloomy damp woods on the banks of Rio Perapitinga in the district of Bananal." Plants were first introduced in 1836, and some of the first plants to flower were in Messrs. Rollisson's nursery at Tooting. The flowers are 3 to 4 inches in diameter, of a pale yellow, nearly white tint, tessellated with purple or brown, especially towards the upper part of the sepals and petals. This plant requires rather warmer treatment than the preceding, and it is generally grown at the cool end of the tropical house. Mr. B. S. Williams recommends the *Cattleya* house as the most suitable, and his opinion is worthy of weight, but like B. Burti and others this, I believe, is more often injured by excessive heat than by too cool treatment, although some growers entertain a different opinion.

B. grandiflora is a New Grenadan species with greenish flowers striped with brown, not particularly beautiful; and *B. Beaumontii* also has greenish flowers, both being more curious than handsome.—LEWIS CASTLE.

MIXED SHRUB AND FLOWER BORDERS.

SHELTER for Lilies was the primary cause of an opening some 20 feet wide being cut through a thicket of Holly and Rhododendron, a narrow path being afterwards made along the centre with a border on each side of very rich soil quite 2 feet deep—really a compost of garden refuse, peat, coal ashes, stable dung, and lime, thoroughly mixed by repeated turning, admirably adapted for the Lilies as well as for many other plants; but it was the Lilies for which the borders were prepared, and to them we will first turn our attention.

About a year ago I purchased fifty of the finest imported bulbs of *L. auratum*. On the following day they were potted singly in 6-inch pots in similar soil to that of the borders, and then plunged in a bed of coal ashes in a cold frame, the tops of the pots being covered two inches deep with ashes, precisely in the old-fashioned way of treating Hyacinths in preparation for forcing. In March the growth of many bulbs had pushed through the ashes, and all the pots were well filled with roots. They were then taken to the borders, turned out of the pots and carefully planted, so that the tops of the bulbs were 6 inches beneath the surface. To finish my account of the Lilies I may add the pleasing fact that all of them grew freely and well, the first flowers opening in July, and some of the last flowers were still lingering upon the stems at the end of October. This delightful succession of opening flowers for nearly four months was partly owing to portions of the borders being much shaded by trees. The flowers were fine ones and very fragrant, but none of the bulbs had more than seven flowers—some of them not so many. The bulbs are left undisturbed in the soil, and I hope to be able to give a satisfactory account of them next year, but that is a matter so beset with uncertainty that more bulbs will be procured now and treated in the same way. Even if the first batch of bulbs do no farther good with us, yet it is felt that they have already well repaid the cost of purchase and subsequent care.

Lilies alone are somewhat tame in effect, except when they are in bloom, and even then they gain much in appearance from association with many other plants. I had already got them well established among Rhododendrons, and therefore resolved to mingle other shrubs and flowers with them in the new borders, so as to impart an air of novelty and distinction to that part of the garden. All the shrubs known as American shrubs answer so well here in the ordinary soil that they have been planted extensively, the only exception being in the Lily borders, partly because of the lime, and also for the sake of variety. The shrubs planted in the new borders stand singly with plenty of space to develop into fine specimens. All of them have thriven, so too have the plants, the luxuriant growth affording pleasing evidence of the fertility of the soil. *Ligustrum japonicum* has not answered well here in the ordinary soil, but in the rich compost of the new borders the one or two plants of it have changed from a sickly greenish yellow hue to the deep rich green of rude health, and have made growth of extraordinary vigour; so, too, has the handsome *Ligustrum ovalifolium robustum*. *Arbutus procera* and *A. rubra* evidently enjoy both advantages of rich soil and thorough wind-shelter. *Cornus mascula elegantissima aurea* made a pretty picture in partial shade. *Abelia rupestris* has grown and flowered freely; and of others introduced as very suitable for this position there are *Rhus laciniata*, *Mespilus canadensis*, *Hydrangea paniculata grandiflora*,

which had very large trusses of its lovely white flowers; *Olearia Haastii*, *Prunus sinensis flore-pleno*, *Potentilla fruticosa*, a couple of neat specimens of variegated *Weigela*, *Hypericum patulum*, *Rubus phoenicolasius*, the Chinese Bramble, with remarkably handsome foliage, deep green above and silvery white beneath; *Cordyline indivisa*, a couple of the handsome *Phormium tenax Veitchii*, *Phormium tenax Colensoi*, some fine specimens of *Acacia lophantha*, which have been laden with snow, and have also borne 8° of frost with apparent impunity. I may mention here that *Cordyline indivisa* left out fully exposed last winter only suffered somewhat in appearance from having its leaves broken by snow, and it has grown so freely this year that the stem has now a tree-like appearance, and the handsome new crown of foliage is some 10 feet high. This fine specimen is one of a batch of seedlings from a packet of seed sown on February 19th, 1874. It would probably have been a much finer plant now had it been turned out sooner, but it was kept in a pot long after the roots had absorbed most of the soil, air and water being sufficient to keep its foliage green although the growth was stunted.

Mention must not be left out of some fine young specimens of *Erica codonoides* now full of flower buds, with the growth tapering upwards into soft green feathery columns. Some *Iris germanica* gave an attractive and peculiarly pleasing aspect to the borders while they were in bloom, and they were all the more appreciated from the sickly flowerless aspect of other plants in our common soil where Rhododendrons grow with singular luxuriance. Brighter and even more attractive were the *Tigridias* when they in turn for many weeks were brilliant with flowers that are worthy rivals of our best Orchids. Why are they not more common? Once established in good soil they grow yearly in size and beauty, and although the lovely flowers soon perish, yet others follow quickly for a considerable time. Some strong clumps of *Schizostylis coccinea* have now plenty of flower spikes, and the bright pretty flowers continue to expand whenever the weather is favourable. A few strong clumps of *Tritoma* told well till late in autumn with bright flower spikes.

I might go on and enumerate many other treasures rich and rare which are worthy of a place with the Lilies, for the rich soil is absolutely a temptation to plant more and more thickly. Crowding must, however, be avoided, or all will be spoilt; but the plan will commend itself to everyone caring for something more than a mere flower bed or shrubbery border, for sure I am that such a mixture of our choicest varieties of perennial flowers and shrubs if well placed will prove attractive at all seasons of the year.—EDWARD LUCKHURST.

A HORTICULTURAL RAMBLE.—No. 2.

CHRYSANTHEMUM shows, year books, and one thing or another have so interfered that I have not been able to finish the account of a pleasant ramble now two months ago, and as a consequence of this delay I find the wind almost taken out of my sails, as far as one place that I visited is concerned, by "W. M.," who in his account of Penllergare has forestalled me. However, I cannot let my visit to it pass without notice.

SUFFOLK SQUARE, CHELTENHAM.

My visit to Cheltenham was in one respect a sad one. I was only there for clerical work, but I could not deny myself the pleasure of going to see my friend Dr. Abercrombie, whose garden at Suffolk Square has been for years so well known. It is, as many know, the square round which the houses in Suffolk Square are built; and here for many years, formerly under my friend Captain Lambert, and now for many years under Dr. Abercrombie, has retained its character as a true gardening home. His long ribbon border has been the delight of the habitués of Cheltenham for years, while his zeal and skill in the cultivation of Carnations and Picotees has been shown by some of the seedlings he has sent out through Mr. Turner from here, notably such flowers as *Royal Visit* and *Lady Louisa*. Well, I am sorry to say that one of those changes which come to us all sooner or later has happened to him, and, his own home being broken up, he was then on the point of leaving Cheltenham to get nearer to his sons in London. Possibly we may see him oftener, for I do not think that he will be content to keep away from his favourites; but none the less must we mourn that for the present at least his gardening days are in abeyance. Nor must one omit to notice the loss that horticulture has experienced in the death of Mr. Pilgrim, whose plants some years ago used to make such a conspicuous show at Manchester and other places in the west and north. For some years the state of his health had prevented him from exhibiting, and very lately he entered into his rest. A quiet, gentle, and unobtrusive man, ever ready to help where help was needed, many will miss him at Cheltenham.

PENLLERGARE.

From Cheltenham through the Vale of Neath, in many parts very lovely, to Swansea is a few hours' run by rail, and thither I went to pay a long-promised visit to one well known to the readers of the Journal—Mr. J. T. D. Llewelyn. Happily I was favoured with very fine weather, and in scenery such as this it is no small matter. Indeed when afterwards I went to that most lovely spot Tintern Abbey the weather was if possible too fine. The wind was from the east, and there was the thin gauzy veil which an east wind so often brings with it, which, while in

one way giving a charm to the scenery, does also take away some of the distinctness with which distant objects are seen. Need I say how I was received, and how everything was done to make my short stay as pleasant as possible? After the description which has been so lately given of Penllergare it would not be fitting to dwell upon it; but this I must say, that in no place that I have ever been to is there such a treat provided for those who, like myself, have somewhat omnivorous tastes in gardening. Here for the florist were grand collections of Auriculas, Pansies, Carnations, and Picotees, and all those other flowers in which a florist delights, and that not as some of us are obliged to indulge our taste in small collections, but in large ones containing full collections of the very choicest kinds. Here, too, were Primulas of all kinds, not in one or two cherished plants, but in profusion. Such kinds as rosea, latifolia, cashmeriana, obconica, cortusoides, luteola, &c., being grown in quantities. Then for the lovers of trees and shrubs there were sights to gladden them, such sights as one rarely sees—Conifers, Sikkim Rhododendrons, Azaleas in grand profusion; while to the lover of stove and greenhouse plants there were houses devoted to their culture and filled with healthy and well-grown plants; and then the place itself, standing in the midst of grand woods in which Ferns luxuriate and Rhododendrons abound, is in itself a thing of beauty ever to be remembered. Of course it has, as everything has, something to counterbalance. The climate is very moist, and many things which in our drier climate in Kent flourish cannot be grown there, but take it altogether it is a very paradise of horticulture.

SINGLETON.

Perhaps one of the most interesting places that I have ever seen was Singleton, to which Mr. Llewelyn most kindly took me. Here, under the care of the late Mr. Vivian and now under that of Mrs. Vivian, an amiable and dignified lady of eighty and more, with a real love for her garden, are sights which one seldom sees. I had lately been to Dropmore, where its grand Conifers had so impressed me that I thought I shall never see anything in them again to much interest me; but Singleton made me alter my opinion. It is true that the Conifers have not attained the grand development that they have at Dropmore, nor are they planted—as in some places—as single specimens on a lawn, but interspersed among other trees, which have afforded them shelter while growing, and have been thinned out when they had fulfilled their purpose. Singleton is situated in a sheltered corner of the Bay of Swansea, and a good view of the well-known headland of the Mumbles is obtained from various parts of the ground. This coast of South Wales, boisterous though it is and much given to rain, is yet sufficiently under the influence of the Gulf Stream to give it a mild winter temperature, so that many things can be grown here which in many parts of the south and south-east of England could not be attempted, and many even of the more tender kinds of Conifers flourish here. Thus *Abies Albertiana* is 75 feet high and 4 feet 4 inches in girth, *A. Menziesii* 68 feet high and 4 feet in girth, *A. Morinda* 57 feet high, *A. Douglasii* 75 feet high, *Picea grandis* 68 feet high, *Sequoia sempervirens* 65 feet high. The whole place is singularly interesting. One is quite unprepared, when seeing the grimy cloud that hangs over Swansea and Landore, to find that vegetation can be so good and healthy. The gardens are under the care of Mr. Harris, and while the glass is old and would, perhaps, be condemned by many gardeners, he has managed to grow most things in them to perfection. His culture of Pines is well known. There are none who can well excel him in the culture of Cayennes, in which he has so often distanced all competitors. Ferns and greenhouse plants were well grown, and in all points utility was considered. Mrs. Vivian's own taste leads her to the old-fashioned flowers of our gardens and to all sweet-smelling plants, hence there is none of the gaudiness of bedding-out, but in all directions the eye is feasted with varied forms and colours.

But the glory of Singleton—that which so especially marks it above all other places that I have seen, although, of course, there may be some such—is the grand collection of Himalayan Rhododendrons which are scattered throughout its grounds. Forty years ago, when the meeting of the British Association was held at Swansea, Sir William Hooker and others who had gathered or received seeds of these magnificent flowers from India presented some to Mr. Vivian. They were carefully watched over, were planted out in various parts of the grounds, and favoured by the mild climate and sheltered position that they occupy, they have now attained a great size, and when they are in bloom in the spring it must be a grand sight. I have seen these same Rhododendrons at Lord Stair's, Inch Castle, in Scotland, where the conditions of climate are somewhat similar, and there they were evidently trying to make themselves at home; but they were pigmies in comparison with these giants. One can but faintly imagine what a sight these grounds must be when all these magnificent shrubs are in bloom; when, for instance, twenty large plants of *Rhododendron barbatum* 20 feet in height, with an average diameter of 20 feet, are displaying their beauties; when the snow-white *R. niveum* 15 feet high, the glorious *R. fulgens* 10 feet high and 12 feet through, the lovely *R. arboreum* and its pink variety, *Falconeri* 18 feet high and 17 feet through, *eximeum* 19 feet high and 15 feet through, *Thomsoni* 15 feet high and 10 feet through, are all expanding their flowers. Why, it must be a sight well worth the whole journey, and ever so much more to see them. The whole place is very delightful, but the Rhododendrons are its special feature, and amongst the most pleasant and instructive days of the last summer I must ever remember the day I spent at Singleton.

BATH.

On my homeward journey I spent a day at Bath, and this visit, too, must—like that to Cheltenham—be associated with sadness. It was the

second and the last visit I paid to that well-known florist, Henry Hooper. One could then see that the hand of death was already upon him, and I am sure he felt it to be so himself. Everyone who has been at all interested in florists' flowers must have known him and how diligently he has carried out their culture. In Pansies, Pinks, and Picotees especially did he delight, and although his garden was, like himself, somewhat rough in its exterior, yet no one had ever complained of the plants sent out by him, which were always vigorous and healthy. One is pleased to think that, as I have already noticed in the Journal, he has left behind him an intelligent son who will carry on the business. This ended my ramble, and, combining as it did duty and pleasure, it was a very pleasant ten days, and I should be glad enough if next year I could enjoy as pleasant a time.—D., Deal.

MEALY BUG AND SCALE ON VINES.

MEALY bug has been a great trouble to me ever since I became responsible for the production of Grapes, and anyone who has had any experience with this pest may imagine that things reach the climax when it takes to the bunches. For twelve years I have been carrying on a conflict with it on my Vines, which, I must confess, has been more injurious to the Vines than to the insects; for although I at times flattered myself I had them (the bugs) almost abolished, with the summer they again appeared in surprising numbers. Year after year nothing that appeared in the Journal about mealy bug escaped my eager eye, but till last year I had come to the conclusion that there was no exterminator like good manipulation both in winter and summer, and by close picking I was enabled to keep them from doing much injury to the Grapes. I tried Mr. Wm. Taylor's remedy against all such pests—namely, petroleum, but that did not prove so efficacious in a beneficial form as it did in an injurious one. But in all justice to your highly intelligent correspondent, I did not apply it as he had given instructions, for I obtained a wooden trough into which I put a certain number of gallons of water and then as many glasses of petroleum, and in this trough I immersed my Vines; but I found a few Vines at the first felt the full strength of the oil, and the remainder very little—so much the better for me, as those first dipped were nearly killed, but towards the last it had little effect on either Vines or bugs. This having been done after pruning, the oil entered the open pores of the cuts, and hence the damaging effect on the Vines.

At last I believe I have, through the pages of the good old Journal, found a remedy, and can exclaim, "There is nothing like tar!" Many thanks to Messrs. Pettigrew and Murray for their recipe of coal tar and clay for mealy bug on Vines. Last season I at once prepared some according to recipe (see Journal for December 14th, 1882) and applied it to Vines very much infested with bug, without much previous scraping, and I now can tell your correspondent "M. A. S." in the Journal of 29th ult., that it has proved to my joy a complete success. I have had no trouble ever since with my Vines, and they are now comparatively clean of this horrible pest. The other day I prepared some for this winter's dressing, of equal parts of clay and coal tar mixed with water to the density of good cream, which I find it retains till all is used. I apply it with a painter's brush, filling all holes, young wood and all. The Vines rather seem to like this paint, as mine never grew so strongly as this summer. Again permit me to thank the above-mentioned gentlemen for making known what to me and many others must be a great boon.—J. KENNEDY, *Comber, Co. Down.*

ORCHIDS AND ORCHID HOUSES.

To cultivate Orchids successfully, well-appointed houses appear to be regarded as necessary, but this is a mistaken notion, and is proving a great barrier to the extended cultivation of these plants. Many species and varieties can be grown as well in houses that accommodate mixed collections of plants as when separate houses are devoted to them. This is fully demonstrated by the many examples of successful cultivation that can be seen in gardens now. I can go even further, and say that some prefer the atmosphere of the stove, and grow and thrive much better than they often do in Orchid houses constructed and set apart for their cultivation. I am inclined to believe that novices in the cultivation of these plants often fail, or partially so, by following out some principle laid down on hard-and-fast lines. For instance, when these plants are grown, say, in a small house by themselves, the atmosphere is either maintained too dry, or, on the other hand, it almost approaches saturation. The latter is a great evil, and it is scarcely to be expected that these plants will thrive long and remain healthy when fresh air is almost totally excluded from them, and the atmosphere in consequence becomes stagnant. Spot and other diseases make their appearance, and to obviate this state of things the atmosphere is kept drier and the plants are subject for a time to the opposite extreme. How long will Orchids or any other plants remain healthy under such treatment? The admission of air daily when the weather is in any way favourable would, to a large extent, prevent these irro-

gularities, and give the plants the atmosphere they require, if only the air is admitted with care and intelligence.

Many may be ready to exclaim that it is impossible for the air in the house to become so confined as to prove injurious to the health of the plants generally. In order to prove this, we are told abundance of air will be admitted through the laps of the glass. I am afraid many are led astray by this. We have two extremes, especially during winter, coming in contact, and the moisture of the house is condensed by the external atmosphere, and thus the laps are filled with water. How much air, if any, can pass in through this medium if filled by the means referred to?

Phalanopses will do as well in the stove as in the Orchid house proper; in fact, the temperature and conditions of the former appear to suit them exactly. I have generally found them in better condition when under the same treatment as regards heat, air, and moisture, as stove plants, than has been the case when they have occupied positions in houses entirely devoted to Orchids. The same may be said of all Dendrobiums that need heat, differing only in requiring a lighter position after the growth is fairly completed, and a cooler and drier atmosphere when at rest; but even under these conditions they should not be subjected to cold currents of air. The greenhouse, or rather a greenhouse temperature, will suit them, but not where air is admitted injudiciously and allowed to strike directly upon the plants. I have seen injurious results follow, especially if the flower buds along the pseudo-bulb were in an advanced condition, they often turn yellow. The old *D. nobile*, one of the easiest to manage and best growers of all Dendrobes, will, in the majority of instances, do better in the stove than in the Orchid house. This is proved by the many splendid examples to be seen that are grown with stove plants, and the poor examples often to be seen in Orchid houses.

We had a small house (span-roofed) constructed for plant-growing, and some time afterwards our Orchids were arranged in it, thinking that by so doing they could be given the treatment they required better than in the stove. I allude to those that require heat, for the cool varieties were never subjected to stove treatment. Amongst the Orchids transferred from the stove to the small new house was a number of plants of *D. nobile*, some of them being of a large size and all very healthy, which flowered profusely under stove treatment while making their growth. Strange to say, the whole of the plants of this variety failed to grow and do well in their new quarters, and gradually decreased in the size and strength of their pseudo-bulbs. No treatment in their new quarters would induce them to grow as well as they had previously done. At last the two best plants were taken back to their old quarters, in which they began to grow again with vigour, and in another year will have regained their former strength. The remainder are still decreasing in size and strength, and all will be placed in the stove to make their growth next season. "What was the reason of this strange freak?" many may ask. In fact, I asked myself this question many times. After carefully studying the conditions of the two houses I found it to be impossible to maintain in the small house the same uniformity of heat and moisture; it presented greater irregularities in this respect than the larger house in which the mixed collection of stove plants is grown, and if this is not the cause of the evil I have failed to find it out. In the little house where *D. nobile* failed to grow, *D. thyrsoforum*, *D. chrysotoxum*, *D. densiflorum*, *D. heterocarpum*, *D. crassinode*, *D. Parishii*, *D. primulinum*, and others thrive satisfactorily, including the puny but beautiful little *D. pulchellum*. The pseudo-bulbs of the first mentioned I have never seen surpassed, and those capable of judging have pronounced them wonderful growths.

Another old inhabitant of our houses that will do better under the treatment of the stove than what it will in the Orchid house is *Phajus grandifolius*. Formerly I grew them in the stove, and when in flower placed them in the conservatory. These were placed in the new house, and when in flower were taken into the stove and arranged with *Eucharis* in full bloom. They were removed from the small house while in flower, because there was not room for their flower spikes, and the reason they did not go to the conservatory as usual was because we had abundance of flowering material without them. Ever since they have failed to do well. The reason in this case we ought to have discovered long before we did. By their removal to the stove while in flower instead of the conservatory, where the temperature was much lower, the plants were deprived of their season of rest. A season of rest is all that is necessary to recruit these plants, but they will not grow with the same robustness and vigour in their new as in their old quarters.—WM. BARDNEY.

NOTES FROM A SCOTTISH GARDEN.

PEACH TREE BORDERS.—It may safely be presumed that turf for border-making is not to be had for the asking on every estate. I, at least, have found it so. Therefore, when planting a Peach tree in a new house two years ago I had to use common soil, but as I had the privilege of some turf for other purposes I was not so badly off. The way this border was made was simply to employ the ordinary soil up to the level where the roots of the Peaches were spread out, and above the roots a thick layer of turf was placed. This year the trees have filled the trellises, and some plants that would not be permanently required had to be lifted. I make a note of this because of the good effects shown by merely employing a layer of turves on the surface of the roots, and because it may be useful just now to others whose turf supply is limited and who have borders to make. Well, the trees lifted without exception—and one of them was of large size—had the main leading roots on an exact level with the top of the ordinary soil, very few roots of any kind having penetrated downwards. The surface turves on the other hand were netted with the smaller roots, which had branched upwards. I have little doubt that the under-layer of soil will also in time be penetrated by the roots, but the result up to the present is as above stated.

On the remaining permanent trees another layer of fresh turves have been placed, the surface of the others having been pared off in the first place. The crop of fruit in the past season was good, and the fruit of extra size, some *Victoria Nectarines* being more like Peaches in size than ordinary *Nectarines*. Large as these were not one of them cracked. Growths like osiers, 6 to 8 feet in length are covered from base to tip with healthy flower buds. The stronger-growing trees, however, were partially lifted in early autumn in order to induce the formation of buds in these strong shoots. While writing of Peaches it may be noted that they are extremely liable to be injured through insufficient supplies of water. It would, perhaps, be speaking too widely to say that no commonly cultivated fruit tree requires more of that very necessary element; but this it is safe to state, that trees in healthy growth and in a border with good drainage are more liable to be under-supplied than the other way.

CHRYSANTHEMUM LADY SELBORNE.—I purchased a stock of this variety in spring, expecting it to come a little earlier than Mrs. Rundle. The result is, however, that both have opened at the same time, and a little later than James Salter. I am also disappointed in the shade—if such an expression is correct—of the white, it being inferior to Mrs. Rundle in that quality, and much inferior to Elaine from a decorative point of view. I do not know whether others have noticed this fact with regard to Chrysanthemums. It is this. So long as the weather continues open and fine the buds come on more rapidly with the plants standing out of doors than when housed. Our plants were abnormally late in budding this year, but as the weather was exceptionally fine the plants were left out a fortnight later, and the result is that early varieties have opened quicker than usual. At a certain stage of the bud, when placed in a house and freely ventilated, they almost stand still; and I find that it is only by applying heat to the plants, both early and late sorts, that the side growths will develop into useful flowers; while later still in the season a mild stove temperature induces the stems to break, and a supply of blooms is secured in spring. As a matter of course, healthy plants must be kept in health in order to insure these results.

TEA ROSES AND MILDEW.—Our stock of Tea Roses for blooming from January onwards has been placed into a temperature to induce them to break. Mildew, when it attacks the foliage, is most difficult to deal with. I have found that if the plants, from the time they are started into growth until they are no longer wanted in early spring are kept growing in a pit without any ventilation, they keep quite free from mildew. Immediately it is necessary to give air in spring mildew appears on the young foliage. Where I imagine many people fail with plants in pots during the winter months is, first, by keeping them too cool, and allowing their soil to become too dry. We never find any difficulty in keeping such things as *Pelargoniums*, *Callas*, *Bouvardias*, and *Begonias* in continuous and uninterrupted bloom, nor in getting *Primulas*, *Pelargoniums*, and bedding plants such as *Lobelias* and *Verbenas* to make healthy growth provided these two points are attended to. Too much heat, however, is perhaps more harmful than if a too cool temperature were kept up. The safe medium is that which gives a slow firm growth with a root-action requiring a good supply of water.—X.

PRUNING AND DRESSING GRAPE VINES.

MR. IGGULDEN has communicated a most excellent article on this subject at a time when it will be particularly acceptable to many who may be in doubt as to the best method to adopt in the important work in question. No greater mistake can be made than in pruning all Vines alike regardless of their condition. There is not a doubt that many very strong Vines are too closely pruned so far as regards the ensuing crop, and, on the other hand, many young canes that are weak are not sufficiently shortened. In a word, the very strong canes should be left longer and the weak cut shorter if the best crops in one case and most satisfactory rods in the other are desired and expected.

How many gardeners are there who have not been disappointed with the produce of vigorous young Vines? They have been grown well and pruned in the orthodox manner. Grand canes, perhaps 20 feet long, have been shortened to within a foot or two of the base of the rafters, and a bunch or two allowed on the resulting laterals, the leader again

making a magnificent cane, the pride and glory of the cultivator. At the next pruning this is shortened again to within about 3 feet from whence it started, the side spurs being cut as close as possible to the main rods, and huge bunches of exhibition Grapes are expected. But they are not produced, and the disappointed grower "cannot understand it." "Look at this growth," said a good gardener to me the year before last, "did you ever see better? Look at the foliage, did you ever see finer? But," and this in a despairing tone, "look at the fruit, did you ever see worse? I can't make it out; they will come all right, I daresay. I think they must, but I wanted some fine fruit this year and have none. I wanted a few, only a few, handsome bunches and large berries, and here they are ugly clusters and small berries. I can't make it out." He had simply cut off all the best fruit-producing growth. At the next pruning he left some of the strong canes, they were nearly 3 inches in circumference, 8 feet, shortening the others as usual, and in every case the former produced by far the best fruit this summer, and are in every respect in as good condition for future use as those that were cut needlessly close. Had the canes been weak, not more than an inch in diameter, then the pruning adopted would have been right.

Then as regards the laterals of older Vines, I know nothing about those not pruned acting as "miniature sap reservoirs," but I know that the best buds on weak laterals will give the best bunches and stronger growths; and do not these stronger growths excite correspondingly stronger root-action? Here I should be at issue with your correspondent when he says "very little is gained by selecting and pruning to large buds," did he not in the next sentence, in adducing evidence to prove his point, somewhat curiously succeed in demolishing it. "At pruning time," I read on page 523, "reserve a few ripened laterals their full length, shortening others to three or four buds, and others again to the first bud. Unless I am much mistaken those left the longest will produce strong bunches, the next smaller bunches, and the remaining shoots will, perhaps, be without any bunches." Exactly. This proves the case against himself, for in all the Vines I have seen which produced laterals that were stopped in the usual manner, the leaves and axillary buds the farthest from the rod that bore the best bunches were the strongest, those close to it being the weakest, and hence "perhaps without bunches." With this I agree, having seen the best results follow when the practice has been applied to weak Vines; with the strong short-jointed and free-bearing sorts it is not required. The next sentence immediately following the one quoted is quite above me. There is no doubt profound wisdom lurking somewhere in the four lines, but I cannot dig it out.

The remarks bearing on pruning vigorous-growing and shy-bearing varieties are very sound, and ought to be remembered by those who fail in producing satisfactory crops by the stereotyped close pruning. Even the usually free-bearing Grapes that, from whatever cause, make very long-jointed wood will afford far better crops if regarded as "shy" bearers and pruned accordingly, for the basal buds of such Vines are usually fruitless.

Your correspondent gives a well-merited rebuke to the irrational practice of scraping all the bark off Vine rods. Polished rods seldom break freely and regularly. The bark is an absorbent of moisture and a non-conductor of heat. Moisture that is conducive to free sap-movement is thus provided, while the fluidity of the sap is kept uniform, as it cannot be under sudden fluctuations of temperature as often occur during bright sunny days and clear frosty nights.

Just one other point I would notice. Equally with Mr. Iggulden I am glad to see that the practice of dressing the rods with "obnoxious materials is becoming obsolete," therefore it is, I presume, that he daubs the stems with a very pleasant, sweet, agreeable, and clean compound of clay and tar. I find no fault with him for using this, to him, delightful mixture, if he cannot extirpate the insects in any other way. I have never found it necessary, and have had more than one successful battle with the gardener's enemy the mealy bug. I consider tar "obnoxious;" but tastes differ.—IPSWICH.

HARDY FRUIT GARDEN.

Failures.—At the end of the year we may usefully give attention to faults of practice and causes of failure, with a view both to prevention and cure, so far as it is possible in the new year. Soil difficulties are among the more prominent evils commonly met with. Poor and shallow, or heavy, cold soils and very retentive of moisture, are the faults so frequently complained of by correspondents. That is why we define so clearly and repeatedly the preparation of stations; and as a safe test for general guidance we repeat here that soil which will produce good vegetables answers admirably for fruit. Only remember that the actual station of each tree must be 2 feet deep of the fertile soil. Very few gardens have good soil so deep, however rich it may be at the surface. Make stations 6 feet square of it resting upon a substratum of 6 inches of broken stones rammed hard, or better still of concrete, connect each station with the garden drains by a 2-inch drain, and then you will

have done all that is necessary to insure success so far as soil affects it. If the trees are planted in a kitchen garden the subsequent culture of the soil surrounding the stations for the vegetables insures a further provision of food for the roots as they spread into it from the stations; but in an orchard due care must be taken to enrich the soil between the stations in the third or fourth year after planting, or the trees will inevitably sustain a check, debility will then soon follow, canker will appear and spread with more or less rapidity, and will kill outright many delicate sorts of Apples and Pears. To prevent this by timely attention is far more commendable than any subsequent remedy however good it may be.

Pruning.—Faulty pruning is another source of mischief. To prune, or not to prune, may well be a moot point for those who cannot give the correct reason for every stroke of the knife. Excessive wood growth from inattention to root-pruning; crowded growth from a too frequent use of the knife and insufficient thinning; abortive growth from pruning too late in autumn, are some of the evils resultant from ignorance or carelessness in this important matter. To the amateur who keeps no skilful gardener, and is himself ignorant of pruning, we say, Plant dwarf bushes or standards if you have thorough shelter, and only prune sufficiently to admit air and light freely among the branches.

Pear Failures.—Of a list of twenty-five sorts of Pears recently sent us eight had proved very good, seven good, and ten worthless. This is a common result of Pear trials, but it must not be forgotten that the fruit of so-called worthless sorts makes a delicious "sweet" when stewed, and it should always be turned to account for that popular and wholesome dish stewed Pears, which with plain boiled rice we may especially commend to the attention of any of our readers suffering from dyspepsia. Trees of worthless sorts may also be headed back, and grafted with any of the good ones, for which purpose let grafts be saved now and thrust into the ground to keep fresh. Do not, however, hastily condemn a Pear because its fruit keeps obstinately hard and will not ripen, but first remove some of the fruit to a warm room, a few degrees of heat often very soon setting matters right and making us regard so-called worthless sorts as treasures rich and rare.

Arrears of Work.—Turn all favourable weather to account for pushing on all seasonable work of pruning, planting, training, and feeding. Look closely over all established trees, remove faulty labels and supply new ones, renew supports, and see that no wire stays are overgrown or are clasping the trees too closely. Much evil arises from inattention to this matter, the growth of a vigorous young tree often swelling over and burying its wire fastenings in the bark. Do not forget to leave all Filberts and Cob nuts unpruned till the pink brush-like female blossom is impregnated with pollen, which is likely to be plentiful, for the catkins or male flowers are very abundant. Young Nut trees not yet bearing fruit may be pruned at once. Retain only six to nine main branches upon each tree, and tie these entwined to pegs driven into the ground, so as to gradually impart the form of a shallow basin to them. Our fully grown trees so trained are now upwards of 30 feet in circumference, yet none of the branches are more than 4 feet high, and the trees planted by us some thirteen years ago, have long been without training or supports of any kind.

FRUIT-FORCING.

VINES.—*Early Vines in Pots.*—Those that were started early in November are well advanced for flowering, and will need a night temperature of 60° to 65°, and 70° to 75° by day, with an advance from sun heat to 80° or 85°, admitting a little air above 70°, but being careful to avoid cold currents, and close early in the afternoon. If the external air be cold and sharp it will be advisable to have some wool netting tacked over the ventilators to break the force of the otherwise cold air that would pass into the house. The shoots will ere this have been stopped two or three joints beyond the bunches, and the laterals allowed to make headway; or, if the space prevents their extension, they should be stopped at the first leaf, and so on as produced, but where there is space extension should be allowed. If the pots are plunged in a bed of leaves these should be added to as necessary, so as to keep the heat about the pots steady at from 70° to 75°. Some turves may be placed on the surface of the pots, and hanging over the sides on the fermenting material, and being kept in moist condition with waterings of tepid liquid manure the roots will find their way over the rims of the pots into the fermenting material, and with those issuing from the holes in the pots will be a means of support far in advance of those which have the roots restricted to the pots. In the latter case top-dressing will need to be given frequently. Employ short manure for the purpose, and every time water is required it should be given abundantly with weak tepid liquid manure. Damp the house morning and afternoon in bright weather, otherwise little beyond that afforded by the fermenting materials will be needed; but where these are not employed damping must be more frequent; and, if there are evaporation troughs keep them filled with weak liquid manure, with which the floors may be damped in the afternoon.

Earliest Forced Vines.—The planted-out Vines that were started in November are growing freely, and, the show of fruit being good, dis-budding must be proceeded with, leaving the most promising and removing those not required by degrees, but no more growths should be allowed to remain than can have full exposure to light and air. Allow the shoots to make two or three joints or more beyond the bunches if there be space, and stop the laterals below fruit to one joint; above they may be allowed to extend according to the space, being careful to make provision for the due exposure of the principal foliage. The night temperature should now range from 60° to 65°, with a rise of 5° to 10° by day, and a little higher with sun heat. Lose no opportunity of admitting air in mild weather, as

obtaining thick leathery foliage is of great consequence. In cold weather proceed cautiously, giving no more fire heat than is absolutely essential to steady progress. Continue to turn and add to the fermenting materials within the house, and if there be any need of water a good soaking should be given the inside border, affording it in a tepid state. If fermenting materials are employed on the outside borders turn and add fresh as may be found necessary.

Vines to Afford Ripe Grapes in June.—Houses of Hamburgs that are to afford ripe Grapes with certainty at the beginning of June, or of Muscats at the close of that month, should have anything yet remaining to be done in the way of cleansing the house, repairs, or dressing the Vines, completed at once, and the surface soil removed down to the roots, and good loam to which has been added some crushed bones and charred refuse supplied. Forcing should commence the 1st of January, the house being closed, and a good watering given to the inside border. The outside border should be protected with a good thickness of leaves with litter or shutters over all to keep them from blowing about, and, if available, shutters, tarpaulin, or spare lights will be advisable to throw off cold rains or snow. A bed of sweetened leaves and litter made up in the house on the floor or border will give a moist ammonia-charged atmosphere, and do much to lessen the necessity for fire heat. If the Vines are young they should be depressed to, or even below, the horizontal line, especially canes of last year's growth. Syringe the Vines and house two or three times a day, but do not keep them in a constantly dripping state, allowing them to become dry at least once in twenty-four hours. Keep the day temperature at 55° and the night at 50°, advancing with sun heat to 65°.

Strawberries in Pots.—The condition of the weather has not been favourable of late to forcing operations. Although it has not been severe it has been cold, and high winds have prevailed; hence forcing must be conducted rather slowly, especially in the absence of sun and light. A night temperature of 50° with a rise of 5° by day from fire heat, or 10° to 15° with sun heat, will be a safe maximum for the present. Now the trusses are showing from the crowns of the earliest batch see that there is not any trace of aphides, or, if there be, fumigate on two or three consecutive evenings, and keep a sharp look-out afterwards, as it is important there be no need to fumigate after the plants come into flower, which is highly injurious to the anthers and pistils. Examine the plants daily, and when any plant needs water give a liberal supply. On fine days a light syringing may be given in the morning and early afternoon.

Another batch should be started—shelves in a vinery or Peach house about to be started being suitable where proper structures do not exist. See that the drainage is in good order, remove the loose surface soil, and top-dress with a rich material, or a pinch of some fertiliser sprinkled on the surface and pointed in or added to the top-dressing will be of great benefit. Remove any dead leaves, and have any green or dirt on the pots washed off.

Plants out of doors plunged in ashes on a hard bottom will not need any further protection than a covering of mats or straw hurdles in severe weather, which, as long as the frost prevails through the day, should remain on until a general thaw commences. When the frosts are but slight no protection is needed, the coddling system of exposing daily and covering at night being needless and injurious. Plants in pits or frames cannot have too much exposure in mild weather, and in severe weather should be covered with mats.

PLANT HOUSES.

Anthurium Andreanum.—This will never supersede in popular estimation the old and useful *A. Schertzerianum*, although it is curious and striking when well grown, and should have a position in every stove. It is of great value, because its spathes of scarlet flowers are freely produced in succession through the autumn and winter months. Few plants are of easier culture, provided the requisite heat and moisture can be supplied to it. The smallest specimen with one or two leaves may in a solitary season be grown into strong robust plants that will flower freely. In a young state it requires plenty of root room, and should always be transferred from small into larger pots as soon as its roots have reached the sides of the pot. It should not in its early stages be allowed to crowd its roots into a mass in small pots, or else the progress of the plant will be much impeded. The compost that appears to suit it best consists of equal parts fibry peat and living sphagnum moss, with lumps of charcoal freely intermixed. The pot in which it is grown should be filled one-third of its depth with drainage. This is important, for abundance of water is required at the root during the whole season. In potting the plant should be well elevated above the rim of the pot, and the old compost removed from amongst its roots annually and fresh supplied. When potting a good-sized specimen we fill the pot only level to the rim, and after the plant has commenced growth and is forming roots from the stem a good top-dressing is added of the material advised above, and then covered with a layer of living sphagnum, which is encouraged to grow. Potting may be done now with safety, or at any time during the year when deemed necessary.

Achimenes.—Remove the tubers of these from amongst the old compost, and place them in pans or boxes, according to the quantity required, amongst any light soil, and stand them in a temperature of 60° to 65° until they commence growing. Water may be required occasionally before the tubers commence growth if the boxes and pans containing them are only stood in the temperature indicated; but if plunged or covered with cocoa-nut fibre refuse no water will be needed until they commence growth, providing the soil was moderately moist. Few plants are more accommodating than these, either for the stove, conservatory, or intermediate

structures, and will do well in either pots, pans, or in baskets suspended, and for the latter purpose no plants surpass them.

Amaryllises.—These are most useful plants for decoration when in flower, and their large blooms have a noble and conspicuous appearance in the conservatory when elevated above plants of a dwarf nature. Those that made their growth early have received a good period of rest, and a few may now be introduced into moderate heat to bring them forward into flower. By judicious treatment and the introduction of a few into heat at intervals of a few weeks a succession can be produced over a long space of time. The treatment we find most satisfactory is to replot them annually as they are selected for placing in heat. The whole of the old soil is shaken away, good loam and sand with a seventh of manure being employed in its place. Very large bulbs can be grown in 5, 6, and 7-inch pots, and in these sizes they are the most useful. If the soil at potting time is in a satisfactory state for moisture no water will be needed until their roots commence action and their flower spikes are visible; a light dew over with the syringe daily will be ample. Those still at rest should be kept dry and cool.

Spiræa japonica.—This is one of the most useful plants we have for forcing, and can be home-grown for that purpose equally as well as those that are annually imported. Lift the whole stock if not already done, and select from amongst them those plants that possess the largest and most prominent crowns for potting. The remainder may be cut into two or three, according to their size, to be replanted for another year. Do not leave the pieces to be planted too large, or after a season's growth they cannot be placed in 5 and 6-inch pots. The larger the pieces the smaller the crowns generally, because they are more crowded, and have not room for proper development. We generally cut out some of the smallest with a knife before planting. In planting select an open position, but do not crowd the plants. Give them ample room for development—say 1 foot apart from root to root, and if planted in rows side by side 18 inches is a good distance. Give the plants plenty of decayed manure, and bury their crowns about 1 inch below the surface. By this simple process forced clumps that will flower well can be produced annually.

THE FLOWER GARDEN AND PLEASURE GROUND.

Leaves and Leaf Soil.—Every opportunity should be taken to collect the fallen leaves, as until this is done it is almost impossible to maintain the requisite neat appearance of the grounds. If the leaves are required for hotheds they should be collected as dry as possible and carried where they can be thrown into a large heap, and covered with litter to prevent their being blown about. If leaf soil is wanted the leaves may be stored in small heaps in any spot about the shrubberies where they will not prove unsightly and yet be accessible. Large heaps will encourage heating, and this, unless they are frequently turned, invariably engenders fungus, which quite spoils the soil. The heaps ought to lay nearly or quite two years before being used for potting purposes. All the exposed margins of fully furnished shrubberies should be lightly dug as well as the open spaces of those thinly planted, a considerable number of leaves being turned in during the process. Any leaves which cannot thus be dug in, and are not worth preserving ought to be raked together and buried, or otherwise they will be constantly blown about by the winds or be scratched over the edges by birds.

Treatment of Bedding Plants.—A considerable number of stock plants are invariably lost through the winter months, and that, too, under various circumstances. Damp is the greatest enemy of those who are obliged to rely principally upon frames, and perhaps a much-crowded house or two, while a free use of fire heat ruins many semi-hardy plants, such as Verbenas, Lobelias, and Calceolarias. The choicest varieties of Pelargoniums are most liable to damp off, and in frames especially should still be kept perfectly dry at the roots, have all decaying leaves removed, and the atmosphere of the frames kept as dry as circumstances permit. Give air at the back of the frames containing these, Verbenas, Lobelias, Ageratums, Gazanias, Alyssum, Polemonium, Heliotropes, Tropæolums, freely both night and day whenever the weather is mild, and on clear sunny days throw the lights off them for a few hours. It is not advisable to keep any but the Pelargoniums dry at the roots, but no water should touch the foliage and be spilt among the pots more than can be helped. Keep all closely picked over, as one decaying leaf quickly affects others, and then the points go. In anticipation of frosts, it is advisable to bank up the whole of the woodwork of frames, and even the brickwork of pits, with either leaves or rough litter, the former being enclosed with hurdles strongly supported with stakes. Do not give much air during frosty weather, and, if very severe frosts are imminent, in addition to the mats, old pieces of carpet, hop bags, or other available protecting material, a considerable quantity of rough dry litter should also be thrown over. Nothing will thus be seen of the pits or frames, nor should they be uncovered while these severe frosts continue. They will suffer more from want of light than air; therefore uncover when practicable, but be not in a hurry to give air. If frost is found to have penetrated, damp the frosted plants overhead with cold water at once, and keep them quite dark and close till they have gradually recovered. Rapid thaws are most injurious.

Where the plants are wintered in vineries and other houses the greatest difficulty will be experienced in keeping them clean and from becoming "hard and wiry." The driest shelves may be given up to the Pelargoniums, and these require but little water. Verbenas, Ageratums, and Lobelias should be the farthest away from the hot-water pipes, as unless they are kept succulent and growing very steadily the cuttings of the two former and divisions of the latter may prove of no use. Heliotropes are less difficult to manage in this respect, but are very tender,

and a low temperature is maintained, they should not receive much water at the roots. All succulents used for bedding-out purposes need not, unless stood on a very dry shelf, receive any water at the roots, neither do they like much fire heat, though they are easily damaged by frosts. Iresines, Coleuses, and Alternantheras are best kept steadily growing in a moderately warm house. The two latter require very careful watering.

THE BEE-KEEPER.

BEES v. GARDENERS.

Two instances have lately come to our knowledge in which all the bees belonging to two lady friends have died. In one case, two years ago the owner had in her possession five hives, in the other case when last we saw her bees our friend had three strong colonies. The bees were in skeps, placed in what is commonly called a bee house, but which we should designate as a cupboard, in one instance; but the box hives belonging to the other lady were placed in a well-built roomy shed, the roof of which was thatched, and the walls built of timber and plaster; the hives standing on a shelf with separate entrances through the wall, against which was fixed an alighting board. These ladies both liked bees, and perhaps they liked honey still more, but it was very seldom indeed that they tasted any. In both cases the gardeners had charge of the bees, and neither of them evidently knew much about them. And this brings us to consider what we may call our text, "Bees v. Gardeners," and we feel that at this dead season of the year it is a fitting time to read gardeners a short sermon on bee-keeping.

We know very well that in nine cases out of ten the gardener, or, generally speaking, the factotum of the small establishment, has quite as much work, often more, than he can honestly do well; and what with his fruit, vegetables, flowers, lawns, hedges, paths, greenhouse, and frame, besides the pony and carriage, he sometimes hardly knows where to begin first, and in the busy season his work accumulates and is often in arrear. Then his mistress, a widow lady or spinster, returns from a flower show where she has seen honey exhibited in its most inviting form, where she saw the bees handled like so many bluebottle flies, and heard how easily they could be kept for profit and amusement, and the next day it is, "John, we must keep bees. I want you to buy a swarm from old Mrs. Jones and try and get honey like those beautiful little boxes so neatly filled I saw at the flower show." Or perhaps she has returned from a visit to a friend who knows how to keep bees successfully. She has gained but one idea as to bee-keeping, and that is that they *can* be made to give beautiful honey, and so she makes John the same speech as above. John, ever willing to try and oblige his employer, who has been his kind friend since he left the village school, and who is ever ready to help him and his family in their difficulties, acquiesces. He says he doesn't like bees, that he is rather afraid of them, but that he will get the swarm. He does get the bees, places them on their stand, and lets them alone. Presently a swarm comes off, then a cast, and the first swarm doubles itself, and he sees his one hive increased to four. Both he and his mistress look upon this as a great piece of success; but when autumn comes, after a showery summer, all the hives are very light. Autumn is allowed to drift nearly into winter before John or his employer learn that they must feed their bees or they will die. The feeding is carried out clumsily, and perhaps the hives are thrown into a state of the greatest commotion at the time they should be perfectly quiet. Robbing may have been brought about, and before winter actually has set in the weakest hives have already succumbed to the strongest, and are destitute of inmates. This is unknown to the owners, for is not the food rapidly taken down still? The bees are passing from hive to hive, and the food is all being stored in the two strongest ones. Then comes the winter in earnest, snow and frost, and a long confinement for the bees. A warm sunny day in February brings them out, but hundreds fall about in every direction never to return. Dysentery in its worst form has attacked them, and if they live on until honey appears again in the flowers it is a marvel. The chances are that by May all the hives are tenantless. This is a picture not overdrawn, but the kind of thing that occurs constantly, and in every neighbourhood. And why should it be so?

If ladies and gentlemen want to keep bees should they attend to them themselves? There are very many who do so. It has become almost "the fashion" now, thanks to the widely spread influence and teaching of experts and amateurs, which through the exertions of the British Bee-Keepers' Association

and its affiliated county societies, have permeated every part of the United Kingdom. But there are also, as in the cases we mention, many who expect their gardeners to attend to the bees, and we would therefore point out that it is the duty of young men who are hoping to obtain situations as gardeners or factotums to endeavour to obtain a general knowledge of the practical management of a small apiary. There are very many ways in which this can be obtained. Nearly every county has now its Bee-Keepers' Association and one or more experts employed by the Association to attend shows, to give lectures in various parts of the county, and to visit and re-arrange apiaries belonging to members. Instruction obtained from such men would be invaluable to young gardeners, and an hour or two spent in the practical overhauling of hives and other manipulations in connection with bees would teach more and give more confidence to a man than as many days spent in reading bee literature. Young men with still more "go" in them would not be satisfied to rest at this point. What a recommendation it would be to any man who is applying for the situation of gardener, whether single-handed or with many men under him, if he could show the certificate granted by the British Bee-Keepers' Association to those who can pass an examination in the practical and theoretical science of bee-keeping. These examinations are held in connection with the annual show of the central Association in London, and certificates of three classes are granted to successful candidates. But those who cannot obtain the assistance of paid experts, and who could not incur the expense of attendance afterwards to win the certificates, might in nearly every neighbourhood obtain valuable information from some amateur bee-keeper who manages his bees successfully on the modern humane system. Many clergymen and other gentlemen, and ladies as well, now take up bee-keeping as a delightful recreation, and they would generally be willing to give assistance to men who are anxious to initiate themselves into the best manner of managing bees. Much, very much, may be learnt from books and from such teachings as have lately been published by our friend Mr. Carr in this Journal, but some of those lessons put into practice under the eyes of those wishing to learn, as we said above, teach and give confidence to tyros in the art such as no amount of reading can do.

There is, moreover, another aspect in which the subject under consideration is to be viewed. The unalienable connection between bees and flowers should weigh much in causing gardeners for their own sakes to understand bees, their habits and management. The man who keeps bees is bound in scarce seasons to get more fruit than his neighbour who has not such busy friends to assist in the fertilisation of blossoms. We have a long time since shown in this Journal the effects produced by bees on the crops of bush fruit, notably Gooseberries and Raspberries, and we feel that we can never over-estimate the value of these useful insects to the gardener. With bees close to his Gooseberry plantations, the blossoms are fertilised in the short half hours of intermittent sunshine which some cold springs only give us, and the bushes are burdened with fruit, while a neighbour a few hundred yards away has hardly a berry to boast of. Then, again, where seed is grown, how much the bees help in swelling the harvest! Thus we hope that we have shown how much it is to the gardener's advantage in many ways to make himself conversant with the proper method of bee-culture.

We wish that gardeners who desire information on particular points in the science would put their questions through the medium of the Journal, and we would always do our best to reply to them for the benefit of the querist and the readers of the Journal in general.—P. H. P.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—*Special List of Novelties for 1884.*
Waite, Nash, Huggins & Co., 79, Southwark Street, London, S.E.—*Wholesale Price List of Seeds.*

* * All correspondence should be directed either to "THE EDITOR" or to "THE PUBLISHER." Letters addressed to Dr. Hogg or members of the staff often remain unopened unavoidably. We

request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post, and we do not undertake to return rejected communications.

To Correspondents.—We desire to thank our correspondents for supplying us with such an abundance of material as to allow of our pages being prepared several days earlier than usual, and thus to enable our staff to enjoy a well-earned holiday during the festive season. The publication of several valuable communications must of necessity be postponed, also answers to correspondents that arrived at this office after Saturday morning.

Mistletoe Propagation (R. H. W.).—Your letter shall have attention, and the information you require be published in an early issue, in time to be of service.

"Mushrooms for the Million" (A. T., Liverpool).—The articles under the above heading, which you "think" you saw in the Journal some time ago, were long since published in pamphlet form. The first edition was fully reviewed in these pages, and the second edition has been more than once referred to. The pamphlet, which has had the largest sale of any gardening work of the year, is published at this office, price 1s., post free 1s. 2d.

Selections of Vegetables (E. Adams).—You will find a selection in another column by an excellent gardener; but we shall shortly publish estimates of the leading kinds by a cultivator who devotes much attention to vegetable culture, and who has opportunities for testing a large number of varieties.

Phalænopses (S. E. Merton).—These beautiful Orchids require stove treatment, but certainly not what you term a "roasting" temperature. Mr. Bardney grows them admirably in a mixed collection of ordinary stove plants, and we have an article detailing his method of culture awaiting publication.

Vine Unhealthy (No. 2).—We never saw more unsatisfactory wood. It is weak and immature, and the Vine is evidently in an enfeebled state. We suspect its roots are not nearly so abundant and healthy as you anticipate, and it is a question if it becomes vigorous. We should remove it and either plant another or train up an additional rod from a strong Vine, as one good set of roots in suitable soil will support two rods as well as one. The Grass appears to be *Panicum plicatum*.

Evening Exercise for Young Gardeners (W. R. G.).—We have received your "poetry," and we note your remark that this is the "first time you have tried anything of the kind." We strongly urge upon you the extreme desirability of letting it be the last. Waste no more time in this form of exercise, but follow the advice of "E. B." on page 485, and endeavour in plain prose and good English to write the history and culture of plants and crops that will be of substantial value to you in after life, and also to others.

Moss Litter for Mushroom Beds (J. H. Bell).—Great success has been attained with this material as a medium for growing Mushrooms, but its use has been limited, so far as we are aware, to the ordinary flat beds formed under the cover of a roof. It would not be easy, we think, to form ridges of it out of doors that would throw off the rain sufficiently, nor do we think the material you describe is in the best condition for the purpose in question, though the little lime that has been sprinkled in the stables we do not apprehend would be injurious. First try a bed in a cellar or shed, and if you do not succeed with it, it would not be encouraging to use it in the open air as you suggest.

Quick Mushroom Production (D., Manchester).—We have known Mushrooms produced in five weeks from inserting the spawn, but this is unusual, and such precocious beds are not usually lastingly productive. The spawn does not as a rule penetrate quite through the mass, but spreads near the surface, owing no doubt to the temperature and moisture, these being specially favourable. When the spawn is seen to be "running" freely, as it may be often in three days after inserted, and soil is added, keeping the surface of the bed warm and moist, Mushrooms form quickly. We have more than once forced a bed into bearing in the manner indicated to insure an unbrokeu supply, but it has nearly always been at the sacrifice of the general productions of the bed.

Wintering Chrysanthemums (A. D., Isle of Man).—When the plants are removed from the greenhouse cut down the stems and place the pots in a cold frame, admitting air on every favourable occasion, and drawing off the lights on fine days to keep the growths sturdy. They must, however, be protected from severe frost by packing litter or ashes round the sides of the frame and covering the glass as needed. A few degrees of frost will not injure them, but the growths that have been produced in a greenhouse are always more or less tender. When stout rooted suckers can be had they may be placed singly in small pots, kept close for a time, then have all the light and air they will endure without sustaining any check in their growth.

Starting Amaryllises (Idem).—Keep the soil in the pots dry, and store them in your greenhouse either on a shelf or under a stage where they do not receive drip from plants above them. In the spring, when signs of growth are apparent, which will probably be about March, it will be advantageous if the pots can be plunged in a gentle hotbed, or they may be placed on a shelf in the warmest part of your greenhouse, water being given cautiously at first, then more copiously as the growth increases. They will start in a temperature of 60°, with a corresponding increase by sun, and must have a light position throughout the spring, summer, and autumn.

Cutting Down Trees (Idem).—Whether your proposed plan of leaving 8 or 10 feet of the trunks as supports for Clematises would answer depends entirely on the circumstances of the case. If the shrubs are sufficiently thin that the Clematises would receive the requisite light and air for their healthy growth, then you might expect satisfactory results, but not otherwise; and in all probability they would need fresh soil, as that of the border is probably not exactly suitable for the plants in question. Whether boring a hole through the stem of a tree with an auger and filling with salt would kill the tree or not we are not able to say; but if the hole were large and near the ground it probably would do so. We have heard that it will, but have not tried the experiment. If the young growths that issue from the stem of a cut-down tree are constantly rubbed off before leaves are developed the trunk is soon divested of its vitality. If any of our readers have tried the salt method of killing trees they might let us know the results.

Metastasis (J. W. B.).—This term is a physiological one, which is employed to designate the change which takes place in the cell contents of plants after assimilation. The materials absorbed by the roots of plants are chiefly compounds in which oxygen forms an important part, whereas it is found that in the substances stored in the plant as a reserve supply for various purposes contain but little of that element. The crude sap when passed into the leaves undergoes a process of deoxidation under the influence of sunlight, assisted by the green substance of the leaves (the chlorophyll), a considerable proportion of the oxygen is released and fresh compounds are formed, this is termed assimilation. Many of these compounds are found to undergo other changes in the course of their transference to different portions of the plant; and as these alterations occur indifferently in cells containing chlorophyll and in those having none, both in the light and in the dark, and are, moreover, usually attended by the absorption of a small quantity of oxygen, the term metastasis has been applied to distinguish them from the primary changes produced by assimilation.

Covering a Fruit Tree Border (C. T. H., Weymouth).—For protecting fruit against a west wall and on the border from the ravages of birds we advise the use of 2 by 3-inch material for rafters. Posts 4 inches square should be placed at intervals of every 6 feet as far as required. These may be rendered firm by means of strips 1 inch thickness secured from post to post along the top with nails or screws. The rafters should be placed so that the one end fits exactly on each of the upright posts, and the other firmly bedded in the wall. Consequently the rafters occur with the posts every 6 feet. As regards the size of wire netting necessary to exclude small birds, three-quarter-inch mesh will be sufficient. Thus far your questions are simply answered. If, however, the wall and border you propose to cover is not an extensive one you would find the following plan likely to answer your requirements more fully than the one you have proposed, and will cost but little more. Instead of having the height of the front 4 feet you would find it much better to have it 6 feet, thereby allowing greater freedom to move about inside. The upright posts for the front should not be less than 7 feet 6 inches long. These must be sunk in the ground to the depth of 18 inches (the ends being previously dipped in creosote) at intervals of 6 feet apart, as previously advised, as also the rafters and strips; then light moveable square frames of deal, made out of strips of half-inch thickness and 2 inches wide, with a similar piece across the centre to fit in the spaces in front to the uprights, to which they can be attached by means of a hook in each corner, thus rendering them easy of removal at any time it is desired. The ends should be similarly treated, with the exception of adopting a portion to the size and purposes of a door. The roof should then be covered with three-quarter-inch mesh wire netting, and also the framework in front, ends, and doors. Care must be taken to procure the netting 3 feet wide, two breadths of which will just cover the frames in front. This plan will be found to be a more efficient and durable one than yours. A protector thus made will stand for years, whereas with string netting endless trouble would arise from so many causes incidental to its use. See notes on this subject on page 329, our issue of October 18th of the present volume.

Cucumbers for Seed (Idem).—To grow Cucumbers for seed a plant should be set apart for that purpose, and it must be healthy and vigorous. Seed should be sown in March, and as soon as the seedlings are ready planted out, either in a Cucumber house or on a hotbed. Encourage it to grow freely until several embryo fruit are shown, then carefully fertilise these with the pollen from the male blossoms. As soon as the fruit commences swelling select two or three of the finest, according to the strength of the plant, for bearing seed, and remove all the others. Attend carefully to the supply of water and air, as for the ordinary routine of Cucumber-growing. As soon as the fruit becomes deep yellow or golden in colour cut it, and let it be exposed to the sun for a few days, afterwards cutting it open, removing and washing the seeds, and drying them in the sun or on a dry shelf under glass. We would, however, remind you that unless you have the necessary space and means at disposal you will find it much cheaper to purchase the few seeds necessary for a small garden than growing them. Occasionally a Cucumber plant that has borne freely will produce a few club-shaped fruit. These generally contain seed, but it does not usually ripen well late in the season. After raising one or two plants early in the season any number can be provided for succession by striking cuttings.

Names of Fruits (T. Hobbs).—1, Dr. Harvey; 2, Margil; 3, Court of Wick. (T. W. Sanders).—Apple, Ribston Pippin. Pears.—1, Charles Van Mons; 2, Bergamotte Esperen; 3, Martin Sec; 6, Vicar of Winkfield. Zephirin Louis is correct. It has a rather coarse-grained flesh, but is of good quality otherwise. (J. Hartland).—1, Beurré Diel; 2, St. Germain; 3, Easter Beurré; 4, Red Doyenné; 5, Ne Plus Meuris. The Apple is Golden Reinette. (J. E. L.).—1, Soldat Esperen; 2, Josephine de Malines; both very fine specimens. (Col. Gleig).—Gravenstein.

COVENT GARDEN MARKET.—DECEMBER 26TH.

A BRISKER demand for high-class produce of all kinds has been experienced, with a tendency to firmness in the prices of superior goods.

NEW AND IMPROVED AGRICULTURAL MACHINERY.

UNDER this heading we intend noticing some of the various changes which have taken place since our last remarks on agricultural machinery in December, 1881; more attention will, however, be given to those implements and machinery exhibited at the Islington Hall meeting of the Smithfield Club, held in the second week of the present month. After full consideration of this matter we can only use words of caution to the purchasers of labour-saving implements. In addition to the large outlay required to furnish a farm with the best implements and machinery, another matter has to be considered—that is, the annual repairs to valuable machines, for these require skilled labour to effect them, a large covered area is also essential to their preservation, and the skilled labour required for conducting farming operations by machinery is an important item in the labour bill which these implements were designed to save on the farming accounts. To avoid a wrong position as to the purchase and usage of some costly machinery, it becomes an important question as to the adaptation of implements to the acreage and soils of the farm; and when its need is considered it is quite impossible to leave out of calculation the size of the farm, for as a general rule it is only the requirements of the largest arable farms which can justify the use to the full extent of the best machinery. We have no better illustration of the soundness of this idea than the practice of the Americans on the large prairie farms, where the use of the best and most costly machinery is a great necessity. These observations apply more particularly to costly machinery, such as reaping and binding machines, threshing machines, ploughing and cultivating by steam power, which the home farmer can nearly everywhere hire for use upon moderate occupations. It is, however, true that the farming upon small acreages may be carried on with more advantage by the purchase and use of various implements as adapted for the tillage operations. For instance, farms of 300 acres, and often less, of arable land, the ploughing, harrowing, rolling, scarifying, and horse-hoeing will require implements of the best and newest designs. The same observations apply with equal force to the carts and waggons available at haying and harvest time. In these and numerous other requirements machinery becomes a necessity upon small farms, more especially in those instances where a full complement of sheep are kept, and also where dairy farming and bullock-feeding are included, because under the latest style of management these animals require great attention and much hand labour, which can be greatly economised by using the best implements.

In commencing our notice of the exhibits at the late meeting

in Islington Hall, we derive great assistance from the well-arranged illustrations and remarks in connection, as given in the *Bell's Weekly Messenger*, by Mr. John Algernon Clarke, one of the most experienced agricultural writers to be found connected with the agricultural literature of the period. One of the important novelties exhibited by Messrs. John Fowler & Co., of the Steam Plough Works, Leeds, is their compound traction engine fitted on springs. These engines work with 30 per cent. less fuel and water than those of the ordinary type, they are more easily handled than any single or double-cylinder engine, and are noiseless. The introduction of the spring enables the engine to travel faster, and reduces the wear and tear considerably, with other valuable improvements. An interesting exhibit was their working model of the new patent combined roller, cultivator, and harrow. This implement is intended to be employed for pulverising land after ploughing, and by the successive action of the roller, the cultivator tines, and the teeth of the drag harrow, the clods turned up by the plough are effectively pulverised.

We must also noticed a new sectional system of ploughing, the working model being exhibited. By this new method, recently patented, can be attached to the ploughing rope as many implements as the engine can pull. Each implement ploughs its particular length of ground, joining the work done by the one fastened next on the rope. One-third of the wear and tear on the rope is saved, and on rough uneven land, by using two narrow implements instead of one broad one, more regular and better work is done, and there is less danger of the implement choking. A slower speed can also be used if necessary without reducing the quantity of work done. Several of these sets have been at work during the last season on the prairie lands in America, and with a pair of ten-horse power engines an average of 35 acres of ploughing per day has been done. Great improvements are also made by the mode of laying down the engine railway lines, taking up, removal, and relaying very expeditiously without the exercise of skilled labour. The home farmer should know how to estimate the advantages just enumerated, besides many more, of which details will be found in the catalogues of the implement makers. As the occupation of large farms increases through so many small farms not being let, improvements in machinery will be more imperative than ever, especially in the event of overwhelming supplies of foreign corn continuing.

The new and improved implements offered by Messrs. James and Frederick Howard of Bedford have next to be noticed, taking first the new portable straw-trusser, which in use is intended to be attached to the rear end of an ordinary threshing machine. The increasing value of straw as a marketable commodity, especially in the various pasture districts of the kingdom, and the relaxation of many landowners of the restrictive lease clauses as to its sale, have lately given great prominence to the inquiry for a practicable machine for binding straw in trusses as it is leaving the threshing machine. This machine was awarded the medal of the Royal Agricultural Society of England at their last meeting held at York in July last, where it was exhibited for the first time. This machine was worked throughout the Show, and elicited the general opinion that its exhibition marked the introduction of an important labour-saving machine. The straw-trusser is easily understood and readily managed. The whole, very portable and compact, weighs but 12 cwt., and is mounted on an axle with a pair of travelling wheels, and when the machine is set to work it is simply hooked on to the threshing machine. It is driven by a chain from the shaker spindle. The threshed straw on leaving the shakers passes between canvas conductors to the cultivators, which receive and compress it against weighted levers, and when the required quantity of straw is collected to balance and move the weighted levers, the binding mechanism is thereby started, the pair of binding arms from below the collected straw rise up, enclose, and bind it with two bands whilst the truss is under compression. The sizes of the trusses may be regulated to suit different requirements, but it has been found that a truss of about 18 lbs. weight is the most useful size for general purposes. The average cost of twine to bind a ton of straw is 1s., which is not more than the cost of labour for making straw bands to bind the same weight of straw, whilst the whole of the labour for trussing is saved. This new patent trusser is made to attach to the threshing machines of nearly all makers, and to suit different widths of drums.

One of the most ingenious mechanical notions lately applied to field implements was seen in the new ring and self-lifting steel beam cultivators which Messrs. Howard brought out at the York Show. This is the first riding and self-lifting cultivator

yet introduced for working with horses, and is likely to prove a very valuable implement, with which more work can be done in a day than with any other cultivator yet produced. This new patent cultivator is provided with a seat for the driver, who, instead of having the fatigue of walking over rough clods, rides comfortably on the implement. The tines and beams are steel, and it is strongly constructed throughout. We hope to return to this subject again at an early date.

WORK ON THE HOME FARM.

Horse Labour.—The work is now various and must continue so for a time, this being the dullest and least important period for beneficial horse labour. Rafter-ploughing is now being done on the fallows which were steam-cultivated on the stubbles and since worked down fine, the couch removed and drawn to heap to decay. This, if mixed with manure, will afford valuable compost for the pastures, especially low-lying or peaty meadows, upon which this dressing effects a wonderful improvement when laid on in January in frosty weather, or in July immediately after the hay crop is removed. It has in various instances doubled the produce of meadow land both in quantity and quality when we have applied couchy earth at any period of the year when the pastures are under feeding. Chalking should now be provided for, and all the finest chalk should be put away under cover in an old barn, where it may be passed through an iron ash screen. What passes through may be stored for drilling with root seeds and artificial manures, instead of ashes, upon land deficient in lime and chalk; the residue not passing the screen may be laid out on the land most requiring it, and take the frost and changes of the weather which will make it valuable as soon as ploughed in.

Any threshing of corn for sale should now be deferred until the end of January; in fact, it is nothing but the low prices for both Barley and Wheat which can justify any delay in this work, for, strictly speaking, threshing corn for sale, especially where good granaries are found, should be done during the winter, in order that no more important work may be displaced at the spring or summer seed time for the Lent corn or Potatoes and roots. The question of ricking the straw is an important matter also, especially when grown near large towns in which the demand and price for this article are both good. Messrs. Howard's new straw-trussing machine is an excellent move in the right direction, for the straw may now be not only threshed but trussed also at one and the same time, and as fast as trussed it may be ricked by little labour, seeing that it can be so easily handled by the fork. The sale and delivery of hay and straw is now a matter for consideration, as this is the period of leisure for horses, if there ever is or ought to be leisure of costly working animals. The old idea which formerly prevailed that the farmer's rickyard ought to be the nation's granary is quite out of date, nor can it ever hold good again, excepting under serious and disastrous circumstances; and we must therefore look well to the changes going on around us in order to make them advantageous to ourselves as individual farmers, for it is very seldom indeed that farmers are situated exactly alike, and therefore commercially the wisest course is to follow in that direction which points to profit only.

Hand Labour.—The growth of fruit in connection with ordinary farming is attracting more attention than previously. The low price of corn induces the farmer to look to the commercial part of the subject, for we once heard a commercial gentleman say, in going over a farm with us, when he was told that although such and such crops were grown and properly manured, yet there was no profit on the farming, "Well, as you derive no profit you might in fact as well have grown only so many acres of Thistles." This is certainly very discouraging to farmers, but it is not far from the truth, commercially speaking. In various districts the planting of the best sorts of Apple trees, Plums, and Damsons would answer a good purpose, especially upon farms in hand or home farms, particularly if the trees were planted at certain distances and the intervals filled with bush fruit trees, such as Black Currants and Gooseberries of the best sorts. Forking out couch and root weeds at all intervals of open weather may now be done; in fact, upon all soils cropped with roots before the sheep are allowed to be folded on them. The land should previously be hand-forked immediately after the fall of the leaves. Planting Firs for permanent woodlands may now be done, hedging, ditching, and banking, and the planting of Whitethorns for hedges should also be attended to in all the enclosed districts where fences and small fields render it necessary; but on all dry friable soils it is better, agriculturally speaking, to grub the hedges, pipe-drain the ditches and fill them in level, so that the plough may pass over without hindrance. In this way much land is gained for producing crops, and much labour saved both in horse and hand tillage.

Live Stock.—The horned Somerset and Dorset ewes and their early lambs are now improving fast, some of the earliest being sold for the Christmas shambles. The main portion of both ewes and lambs should receive a liberal allowance of the best field hay, a moderate quantity of roots passed through Gardner's cutter, with cake and bean meal mixed with the roots in the trough. In this way there is little or no waste, and the food certainly entering the stomach together is not only more forcing, but more healthy for the animals; in fact, it is the only way in which every animal gets its fair share of cake when mixed with the cut roots. We reckon this much better than the plan pursued by some farmers formerly, who mixed the broken cake or cracked corn with hay-chaff, for sheep are sure to rout out the hay-chaff in searching for the superior food. The best of the fattening bullocks will now go to the market at Christmas time, but various farmers hold on a portion of their cattle in the boxes for succeeding markets, more particularly when the roots have

proved not only abundant crops, but also those stored have been secured better in condition than usual. Dairy cattle have fared better than usual in the pastures in the December month, which, together with an abundant supply of roots and hay, and a clean bed of straw to lie upon, leave nothing to be desired, except an allowance of cake when in milk.

AN AMERICAN FARM.

The correspondent of a daily paper in recounting a journey to Yellow stone Park thus describes a farm on the route:—"Our next stopping place was Dalrymple Farm. The land takes the name from Mr. Oliver D. Dalrymple, who was born in the oil district of Pennsylvania. At the age of twenty-one he came to Minnesota and established himself at St. Paul, and, being a lawyer, tried the first case in a court of law in that State. Seeing the possibilities of the country for great Wheat farms, he gathered round him one or two men from his own neighbourhood, with a Boston man named Chennery. They determined to move to Dakota and take advantage of the exceedingly low rates at which land was offered by Government and the Northern Pacific Railway Company, and accordingly purchased thousands of acres of rich soil at from 45 to 60 cents—2s. to 2s. 6d.—per acre. Ultimately they secured 55,000 acres, of which 30,000 are under cultivation, but within two years of buying they sold 13,000 acres at prices ranging from eight to twelve dollars per acre. There are four partners—Messrs. Dalrymple, Alton, Glastin, and Chennery. Their system of farming is the result of Mr. Dalrymple's personal experience on a small scale in Minnesota. He saw the necessity of using machinery of the best kind with which to accomplish work in the shortest possible time and at the cheapest cost. Having secured the land they broke up about 2000 acres, and each succeeding year the work has proceeded and their investments have proved more and more valuable. The particular farm we inspected was twelve miles square. It was one vast field of Wheat; no division of any kind appearing except roads for waggons and horses. On the morning we visited it the harvesters were to commence reaping, and one hundred machines waited our arrival as the signal to begin. What a sight! two Scotch farmers who were with us were simply amazed. While the harvest lasts there are transported over the Northern Pacific line to Buffalo, as the objective point by way of Duluth, from 25,000 to 30,000 bushels daily, employing some thirty-five to fifty railway cars. It was estimated that this year the yield would be about 20 bushels per acre, but if a careful system of farming were pursued—anything like thorough English cultivation—the outcome would be 30 bushels. The top soil was 18 inches to 2 feet of the finest loam—absolutely free from grit or stones of any kind. The subsoil is peat, retaining moisture all the year round. In winter the cold is intense—sometimes 52° below zero, and averaging 20° below freezing point. Yet the workmen who lived on the farm all the year round did not complain. Mr. Dalrymple and his family only reside here about six or eight weeks during summer."

OUR LETTER BOX.

Cleaning Land (Lundy's Lane).—All the chief implement makers in the kingdom, like Messrs Howards of Bedford, make and sell strong horse hoes calculated not only for cultivating between Vines, Hops, &c., but they are also fitted with shares or knives for surface-hoeing and the destruction of weeds under all systems of field culture. The working by hand labour is quite out of the question in destroying weeds when compared with a good strong horse hoe.

Alderney Cows (A Lover of Cattle).—The Alderney cow has evidently been injured to cause lameness, or otherwise is suffering from rheumatism brought about by exposure in wintery weather, especially as it is stated that the animal does not suffer from lameness in the summer time. Channel Island dairy of cows cannot be allowed to remain out in cold wintery weather without loss of flesh and diminution of milk. When a dairyman will not listen to reason and common sense try a more suitable, good-tempered, and intelligent servant for the management of dairy cows.
