chona (such as Condaminia, pubescens, pitayensis) has been thoroughly established by the success of the society's own operations, and a coffee plantation is now being formed under the management of a skilled planter from Ceylon. But above all is this great fact, which places this country beyond all other districts in South India, that these lands are entirely free from malaria—unless, of course, lands are selected at the bottom of one of the valleys running into the plains. But on the plateau there are some thousands of acres of forest and grass as entirely free from fever influences as Coonoor and Ootacamund, or the Pulneys themselves. Rain falls in every month of the year, except February, and sometimes January. English vegetables grow excellently. English stores and liquor are easily procurable from the neighbouring town of Madura, where there is a good club. Carpenters come up from Cochin, their pay being one rupee a day; but lime must be brought up from the low country, which is one of the drawbacks of the place.

The scope and profits of cinchona growing are now being recognized. It is an enterprise particularly suited to a man who has a small income to enable him to keep going till his trees are big enough to produce the chemists' bark, who likes leisure for shooting, and is not to be worried by the ceaseless and minute superintendence that a coffee or tea garden requires.

There is no place in South India where a married man of small means, with a little capital, would do better than by taking a house at Kodekânal, on the Pulneys, and by purchasing a hundred acres of forest land and a hundred acres of grass land on the Kannan Devans, wherewith to form a farmstead and a cinchona plantation.

At the present moment the prices of cinchona bark are so high that it has been calculated by good authorities that an acre of land with a thousand trees on it, ten years old, can be worked to give a return of £100 per annum. These authorities also say that the value of the best barks, which are brought to market for the manufacture of the alkaloids, will never materially decrease.

It is not necessary to wait ten years for a return, because from four to seven years old trees (according to growth), yield a bark that is known as druggists' bark, used for decoctions. The prices of the best kind of cinchona bark that is diverted to this purpose is now very high, and the thinning out of the plantation in its early years would quite certainly repay all outlay, and leave a large margin of profit. But there is a consensus of opinion that the production of this druggists' bark may be overdone, and the planter must be prepared for this contingency. The cost of purchasing such a block of forest and grass would, we understand, be now in the early days of the society, about £3 per acre for forest, and £1 an acre for grass land.

The cost of opening 50 acres of the forest land will be approximately as follows for the first year:—

	£	s.	d.
Felling at £1 5s. the acre	62	10	0
Pitting, lining, planting, &c., at £2 per 1,000 pits 3,000 pits to the acre ..	300	0	0
Price of plants, at £1 per 1,000 ..	150	0	0
Temporary buildings, paths, drains, tools, &c., say	150	0	0
Native superintendent, at £5 per mouth	60	0	0
	722	10	0
Add price of 100 acres forest land, £300; 100 acres of grass land, £100 ...	400	0	0
Total .	£1,112	10	0

The upkeep and gradual extension of the cultivation would be effected for £200 a year, so that the estate would cost about £2,000 before a return could be expected. It is difficult to say what amount of dry bark would be harvested from the first thinning out in, say, five years; but it is not unreasonable to estimate that 5,000 lb. of dry bark, presenting a net profit of 2s. a pound, would be the result of the first cropping. But if the planter does not want to open himself, he can buy a young plantation from the society, this being part of their business. A year or a year-and-a-half old cinchona plantation, with a portion opened, would be possibly sold for cost of opening and value of land, plus a good interest on the money sunk.

We are not well informed on this matter, but we should think that such a plantation could be purchased for £20 an acre the opened block, and £5 an acre unopened forest. Thus, a block of 100 acres forest and 100 acres grass, with 40 acres opened in cinchona a year old, would be priced at about £1,200 to £1,500. A planter with an available capital of £2,000 would thus find a property suited to his pocket, and subsequent extension of opening would be deferred till crop time.

The objections to Kodekânal as a place of residence are, that the society is limited in extent, that the cart road from the plains is not yet finished, and consequently everything has to be carried up by coolies; that there are no schools; and that bungalows are few, and hard to get for a term. But the climate is exquisite, and, with an occupation as is suggested in this letter, there would be no tedium, or difficulty in finding ample employment on one's own property or in looking after estates for others. Further, there is the shooting, which is very indifferent on the Pulneys, but improves every mile towards the west until the Kannan Devans are reached, whence extensive and unexplored wilds, teeming with elephants, bison, ibex, and deer, stretch away south forty miles to Peermaad, and north into the British Anaimallais.

STAPLEGROVE.

We would strongly advise intending planters to visit the Pulneys and spend a year on the spot (learning to plant) before investing their capital either in forest-land or a cultivated property.

SORGHUM CULTIVATION IN INDIA.

A paper published by the Madras Government contains a letter from the officiating Under-Secretary to the Government of India, Home, Revenue and Agricultural Department (Agriculture and Horticulture), to the Secretary to the Government of Madras, Revenue Department, forwarding for experimental cultivation in the Madras Presidency a small quantity of the seed of the "Minnesota Early Amber Cane," a variety of the *Sorghum Saccharatum*, and requesting that careful experiments may be made to test the value of this variety of *Sorghum* as a sugar-producer; and also that the seed produced may be preserved for further experiments. In this letter were enclosed copies of two memoranda on the subject by Surgeon-General Balfour, dated 28th September 1880, and 8th February 1881. In the first of these Dr. Balfour refers to the introduction by him in 1859 into India of imphee from the Cape of Good Hope, and of sorgho from the United States of America, and the subsequent results. That the juice of the sorgho has not hitherto been crystalized into sugar is due not to any inferiority of the cane but to a method not having been discovered to overcome the difficulties in the way of crystalization. These have now been removed. Dr. Balfour therefore points out the desirability of once more trying the cultivation. He says—"Its treatment should be precisely that of the Sorghum *vulgare*, the juari, cholum or jonna of the Hindustan,

Tamil and Tiling countries, and the seeds might be carefully collected for future experiments. The Agricultural Department of the United States has 32 varieties of sugar-producing sorghums and millets, but the Minnesota Early Amber Cane is considered the best; after it come the Chinese Sorgho Cane, the White Liberian Cane, and the Honduras Cane. I introduced the Chinese Sorgho into Madras in 1859 (Proceedings, Revenue Board, 18th January 1863), but it was seemingly neglected. I will obtain and forward samples of all the varieties." In the second memorandum Dr. Balfour gives further information on the subject, quoting the opinions of Dr. Roxburgh, Mr. Wigley, and a writer in the *Madras Mail*, who says :—"To sum up the advantages of Sorgho, it produces a good grain about equal in value to ordinary cholum (*Sorghum vulgare*); it should produce sugar worth at least two or three times the value of the grain; the crushed canes are still useful as fodder or as manure, if not used in boiling the juice; the produce of 'cerosie; should more than pay all the expenses of cultivation' and a valuable dye (note paragraph 12) can be extracted from the seeds. And if the cultivator does not choose to manufacture sugar, he can sell the stalk as a pleasant succulent, or he may sell the syrup as molasses or manufacture vinegar or brandy. Paper can also be made from the stalk, and it is possible that if the cane refuse were collected and made out here into 'half-stock,' a large demand might arise from it in Europe." Dr. Balfour adds:—"In conclusion the efforts made in India to introduce the 'sorgho,' great as they may seem, are slight compared with those of the United States Agricultural Department when they have a new plant to establish; and as the farmers of the States have found it a profitable crop, it is reasonable to suppose that the ryots of British India should also be able to cultivate with even larger profits."

NEW PRODUCTS IN CEYLON: LOW-COUNTRY REPORT.

DROUGHT—CRICKETS AND LEAF DISEASE—USE OF BASKETS IN PLANTING OUT—THE GIGANTIC VARIETY OF LIBERIAN COFFEE THE LEAST SATISFACTORY OF ALL—DISTRIBUTION OF RAINFALL.

WESTERN PROVINCE, 31st July 1881.

In my last report, I professed to have had sufficient rain for my purposes up to that date. But since then there has been none, and for the last ten days the usual cloudy July weather has given place to bright sunshine, and intense heat, alternated with passing clouds, carried forward on the wings of a chilling breeze that feels as if it went to the very marrow of the bones. In consequence of those sudden changes of temperature, there has been a good deal of semi-sickness among the coolies. Nothing very serious, but enough to make all but the old well-seasoned hands shirk the afternoon sun, and the chilling blasts. The wind blows stiffly for eight hours daily, and is of an extremely dry, searching quality that finds its way into the most sheltered nooks, and wheels round the most intrusive corners.

Hitherto, the coffee plants put out in the early part of the month have suffered nothing, but they will have to be looked to in the way of additional shade, if this weather continues for a few days more. The older coffee plants seem to grow even better for the dry weather, bowing their heads at the bidding of the wind but assuming their natural position when it ceases. At this stage of growth, they are very much given to throw out numerous suckers near the ground, which require a good deal of trimming, but this habit ceases when they begin to branch, which is generally at from fifteen inches to two feet. The plants cut by the last hatching of crickets are coming on (that is to say those cut above the buds), but they are a long way behind those that escaped, and will only rank with the supplies put or to be put down from eight to twelve months later, and they will be again liable to attack, when the enemy again appears. On the last occasion, many plants that had stems too hard to cut had their leaves pruned off for six inches or so, and a large proportion of those so trimmed have been attacked by leaf disease in a very virulent form, while hardly one of those that have thrown out shoots from the cut stem are so affected. I am stumping all that have caught the disease, so as to give them another chance, for, as I have formerly stated, the pest seems never to leave the plant it has once fastened on.

The dry weather has been more troublesome in the nursery than elsewhere. I am obliged to use baskets for two reasons :—1st.—If I transplanted the seedlings from the sheds into the open ground, a month after the cricket season opened I would not have a plant left, but they do not touch them in the baskets, placed on their bottoms on the surface. 2nd.—Plants in baskets may be put out at any time after the third pair of leaves are out, when there have been a few showers, and a fair prospect of more within fifteen days. Our climate is too uncertain to prudently put out plants with naked roots at any time of the year, and in baskets they are safe at almost any time, if subsequent shading be properly attended to. Plants in baskets, however, have the disadvantage of requiring an amount of care and labour in shading and watering altogether unnecessary in the case of plants in the ground. A few hours of hot sun and dry wind parches the earth contained in the baskets, and in dry weather watering must go on continually, and shading must be done in the last resort, though not to be prescribed except when the well goes dry—an event which has taken place here, towards every evening, for the last week.

After the Liberian coffee plant has two pair of leaves, it enjoys all the sun it can catch, so long as it can draw on the soil its roots occupy for the necessary supply of moisture; the moment the moisture fails it begins to droop and if not quickly attended to will die. The blossom on the older trees due a month ago struggled out on several occasions, but the greater part of the promise remains unfulfilled, and will continue to be till rain comes. In the case of almost every one of the remaining two year trees, during the last few months, the stem has run up, two, three, and even six pair of leaves without a branch. This is the true habit of the tree variety, but even the best behaved hitherto have run up from nine inches to two feet of stem without a branch, and this has happened at all the various heights attained, from three to six feet. Since the rapid growth has in some measure ceased, they are again getting into regular habits.

One of the correspondents of the *Observer* complained lately that he had been deceived in the seed supplied to his order, because the whole did not turn out of the gigantic variety. So far as my present experience carries me, I am inclined to think the gigantic variety the least satisfactory of all. It runs rapidly up to four or five feet and produces one pair of branches up the stem; runs another foot and produces a single one; and so it goes on, till at seven feet it has not seven branches. It was not the size of the Liberian coffee that first called my attention to it, but the fact that it would flourish and be productive in a temperature ten degrees higher than suited the Arabian kind. I do not care for the size of the tree. A giant or a dwarf variety are all the same to me, if only they can be profitably cultivated, where the known and tested variety fails. I have devoted the fag end of the longest consecutive planting career in Ceylon to the developement of this plant, in a small section of country, with a peculiar climate, and so far, through

many disappointments, I am satisfied with the results. To naturalize an exotic, in soil and climate closely resembling those of its habitat, should be a comparatively easy task; but when we carry it into a region where it would be impossible for it to maintain a permanent footing without human aid, we require to watch its habits, and study its wants, with unwinking vigilance, and every one for himself: for, in this land of Ceylon, the experience acquired in one quarter may be of little use in another not very remote. The distribution of rainfall, which varies from 31 inches at Mannar to 250 at Padupola, shows too remote extremes for any one species of plant to flourish in both places. Indeed, it is questionable whether any profitable cultivation can be conducted in the neighbourhood of either. My own experience in the cultivation of Arabian coffee, within a mile of the Ceylon waterpot, was not by any means satisfactory, but it is said tea is succeeding in that vicinity. There is sufficient choice of locality between the two extremes, and in the Pasdun Korale, with its 150 inches of rainfall, Liberian coffee seems to have found a congenial home, but the chief question now to be settled is how far the cultivation can be pushed into the drier districts, with a fair chance of success. At what measure of rainfall will we be forced to draw the line? Nor is this the sole question to be settled. There are tracts of good land, in districts where the annual rainfall would be ample, if well distributed over the year. It then is an important fact still to be tested: how long can the Liberian coffee plant endure, without permanent injury, deprivation of rain? I cannot from my own experience throw much light on this point, as I have not been tried with more than thirty days, since I had to deal with well grounded plants, but in the land I have to work a plant of six months can stand a month not only without injury but with advantage. At the same time, I must admit that I have seen a well branched plant, five feet high, with a heavy crop, droop in a bright afternoon, with only fourteen dry days behind it.

August 3rd.

On the 31st we had a few light showers, and the like on the 1st, but it was at 4 a. m. on the 2nd we began to get real rain. We have a right to expect more or less rain late in July or early in August, and on this occasion we are not disappointed.

The first cricket work of the season appeared on the morning of the 1st in the cutting of two coffee seedlings in the nursery. It is a month earlier than I expected them, but it is to be hoped that an early entry will precede an early exit. I do not much like their first appearance among the plants in baskets, where the plants have been comparatively safe on former occasions. Curious that the breed should have such a hold on this place, and nowhere else within my bounds of *ken*.

9th August.

More or less rain daily; rained all day on Sunday; planting out with fear and trembling.

COFFEE ADULTERATION AND THE PLANTERS' ASSOCIATION.

A Ceylon estate proprietor now at home writes:—"London, 15th July 1881.—I must send you a few lines to express the disgust I feel at the reception accorded to the proposed memorial against coffee adulteration at the meeting of the Planters' Association last month.

"Luke-warmness or faint-heartedness in such a cause, it is, perhaps, possible to understand. But, opposition from the planters to their best interests, and with out the slightest show of rhyme or reason!? No wonder that Mr. Wall lost heart and would fain have thrown up the thing in despair.

72

"The subject of adulteration has been much before the public at home during the past few months; partly, no doubt, owing to the boldness with which the promoters of the Date Coffee Company have advertized their scheme; and as you are doubtless aware, more than one journal has been threatened with proceedings for boldly expressing opinions affecting the character of the above iniquitous concern.

"I say, therefore, that a more fitting time than just now for the presentation of such a memorial, it would have been impossible to select.

"The Chairman of the P. A. has done his duty: the *Observer* has done *its* duty. To them both, as a unit of the planting community and a member of that Association to which I used to consider it an honour to belong, I desire to tender my thanks, and to the former my sympathy that his labour should be so little appreciated. I fear that the opposition to the memorial has been prompted by the same petty jealous spirit which caused the P. A. to reject the medical aid scheme drafted by the Chamber of Commerce last year.

"The enclosed cutting from a London paper of to-day's date will show you that the Date Coffee Company at any rate is looking after *its* interests with some energy however base those interests may be:—

THE DATE COFFEE COMPANY REPORT.

The Second Ordinary General Meeting of the Date Coffee Company was held yesterday in the Great Hall of the Cannon-street Hotel, Henry Haymen, Esq., in the Chair.

The CHAIRMAN,—Gentlemen, the Secretary will read the notice convening the meeting.

Mr. T. Fortescue Haymen (Secretary) read the notice.

The CHAIRMAN.—Will you take the Report as read, or have it read?

The Report was taken as read.

The CHAIRMAN:—Gentlemen, I will commence the proceedings to-day (and I will detain you but a very few moments) with the formation of the Company. We have so many new shareholders come into the Company within the past few months who are constantly asking questions; and I think therefore we shall take this opportunity of endeavouring to place before you a short résumé of the Company's affairs from the first day it started until now. Those who remember the first prospectus of the Company, and the figures which were then put before the public, will recollect that we stated to you upon a make of 40 tons per week, we could return a profit of 100 per cent. Works have since that date been established at Kurrachee, in India. We have been enabled to show you by the actual making of the Coffee the price at which it can be manufactured, and we know also the price at which it can be sold. During the last few months you will have noticed that we have been enabled to considerably increase the quantity, and by the last letter from the manager in Kurrachee we are informed that the first of the sets of ovens, dispatched to increase the quantity, will be erected within the week, and I think I am justified in saying that by the end of August we shall be in a position to put out close upon 40 tons per week, (cheers). So much for the question of manufacture. The accounts before you show most clearly that we can manufacture at the price we originally anticipated, and there can be no question of doubt about it selling at the price we thought, and if so we shall realise the profit also we anticipated. We will now take you a step further with respect to what has taken place since we had the pleasure of meeting in January of this year. All sorts of rumours and statements have been made, most of which I have met with statements from the chair at the various meetings of the Company which have been called during that time. You have also been informed an attempt was

made to get an injunction against this Company, and thereby stop its proceedings. Those who have watched the papers will have noticed that the case was set down for hearing to-day. The case came on before the Vice-Chancellor to-day, and with the following, which I think will be a most gratifying, result to the shareholders. It bears out on the face of it, I may say, all you have been led to suppose, and it puts an end once and for all to all questions of litigation, and places the Company in the position it was in—in fact in a better position than it was in before these proceedings commenced (hear, hear). I will read you what took place:—"The Plaintiffs having since the commencement of the action made inquiries and had an opportunity of investigating the Defendants' patent and their mode of manufacture, and, being satisfied that it is not an infringement, desire to withdraw from the proceedings, each party paying their own costs. To put an end to the possibility of further litigation and competition, the Plaintiffs have agreed to dispose of their Patent to the Defendant Compauy for a small sum which scarcely covers the amouut paid by the Plaintiffs, in the belief that Montoison's Patent was the sole one capable of being upheld for this manufacture, and both parties now ask the Court to direct an Order in the terms of this arrangement, which is embodied in an agreement dated the 6th day of June, 1881." That, gentlemen, has passed by an Order of the Court; we are now once more perfectly free from litigation, and we start on the commencement of what we term a new financial year, free from all disturbances of a legal nature (cheers). I thiuk, as many of you are interested, and as the Parent Company is interested in the French Company, I should state to you that we are proceeding now rapidly to the completion of the French works. We had an interview with our commercial manager in Paris yesterday. I do not think it would be wise to go into figures with you at this meeting, but I may tell you that there is not the slightest shadow of a doubt that the prices which have been arranged at which the coffee can be sold in Paris, and the price at which it can be manufactured, will lead to such profits to the Freuch Date Coffee Company that the prospectus, as originally issued to the shareholders will be more than fully carried out (cheers). With respect to the German Date Coffee Company, the position of affairs is simply this: By the commencement of August we shall be in a position to sell our Coffee. We have entered into a provisional arrangement with a very large merchant in Germany to undertake the sole sale of the manufactured Coffee there at a price considerably in excess of the price which we thought satisfactory in this country, and at a price which will leave very large profits to that Company. Now, gentlemen, as we are more free, we shall be able in a very short time to bring before you our American and Spanish and our other Patents (hear, hear). From Spain we have most satisfactory intelligence, after tasting the Coffee, that there will be a very, very large trade indeed. The documents are all being translated into Spanish. A certain amount of time must take place before we can bring these matters before you in the shape of a prospectus, but at a very early date we shall do so. The United States Company is also progressing very satisfactorily. Arrangements, or, rather, communications, have taken place with very eminent firms abroad, and I have no doubt that we shall be speedily enabled to place that before you (cheers). With regard to Belgium and other places we are in a similar position. And now, as I said before, we are once more free, and all litigation is at an end; and I feel certain every day more and more, that everything which has been said to you from the Chair from the time we started up to the present time will be more than fully realised, and the Parent Company will take that position which in the month of January it was pointed out that it would take, and which I feel certain will be as satisfactory to you as it will be to the Board of Directors (cheers). Before I sit down I should like to say that if, in defending the Company against these peculiar attacks which have been made upon it, I have personally in any way given offence to any one in connection with it, it was simply done as a matter of duty in defending your interest. Courtesy is the style which I should always like to deal in, and if in any way I have trodden upon any one in connection with it, I trust, as litigation has ceased, all ill-feeling has ceased, and that we shall go on carrying out the programme which we have laid down, and that we shall see by the balance sheets of this and the other Companies, that the Date Coffee Company and the subsidiary Companies will all pay very large dividends, and be of that commercial value which, from the first, I have predicted (cheers). With these few remarks I formally move the adoption of the report and accounts; my friend Lord Poulett will second that, and I will sit down to give any shareholder an opportunity to put any question which he may be inclined to ask.

The Right Honourable Earl Poulett.—I beg to second Mr. Haymen's statement.

The Chairman (after a pause), said.—As no shareholder has any question to put, I will put the question—that the report and accounts be received and adopted. Those in favour of that will signify the same in the usual manner.

The resolution was carried unanimously.

The Chairman.—The next question is the re-election of Auditors, which I will propose, and which I will ask some shareholder to second; it is as much a Shareholder's question as a Director's, in fact, more so. I therefore beg to propose that Messrs. Fred. Maynard & Co. be re-elected Auditors, and perhaps some shareholder will kindly second that.

Mr. Barton.—I will second that.

The resolution was carried.

The Chairman.—That, gentlemen, concludes the business of the meeting; but perhaps you will allow me to state once again my entire confidence in the success of the Company, and I am confident that before the close of this year we shall be calling you together for that happy sort of meeting in order that we shall propose a dividend to you (cheers).

A Shareholder.—If I am in order, I should like to ask one question.

The Chairman.—I will answer any question.

The Shareholder.—I do not know why the Government charge us 2d. a lb., and why coffee and chicory are admitted at 1½d. per lb. I have made a calculation on the basis of 40 tons per week, and I find it makes a difference in the year of 10,000*l.* in the profits of the Company.

The Chairman.—It is impossible to ask the Government why they charge it. They charge it to us on ground coffee and the berry. If ground coffee is brought to this country it is charged 2d per lb.

Mr. Frost.—What is the nature of the opposition to the German Patent?

The Chairman.—I think it would be unwise to say. We are not a German meeting.

The Shareholder.—The result is, that we have not had any bonus from the German Patent.

The Chairman.—I do not think it would be wise to make the statement.

The Auditor.—I am much obliged to you, gentlemen, for re-electing me auditor, and I congratulate you on being shareholders in so prosperous a Company.

The Chairman.—That concludes the business of the meeting.

Mr. Maitland.—I think, gentlemen, before we separate we should propose a vote of thanks to the Chairman.

Mr. Pittman.—I beg to second that.

The motion was carried.

The Chairman.—Well, gentlemen, on behalf of my colleagues and myself, and my worthy friend the solicitor—I must include him; he gets the blame if there is any blame, and he should have some of the praise—we are very much obliged to you. We have tried to deserve your confidence. I think we have shown we have managed your affairs at all events with zeal, and if there have been errors, they are errors which any one might have committed. If you are firm in holding to your property as we will hold the reins of management, I feel more and more convinced, as I told you before, there is not a single shareholder in this Association who will not have reason as years go by, whether I am in the chair or anywhere else, to feel that he has got an investment which he can count upon as a safe investment from time to time to those who may follow him. I hope and trust we shall be spared many, many years, in order to meet you from time to time, and to prove by the distribution of dividends that the faith you have had in the Directors of this Company has not been misplaced (cheers). I thank you cordially for the vote of thanks and for your confidence to day.

The meeting then broke up.'

FROM THE LONDON "TIMES" OF JULY 13.

HIGH COURT OF JUSTICE: CHANCERY DIVISION.

(BEFORE VICE CHANCELLOR HALL.)

CARDEW V. THE DATE COFFEE COMPANY (LIMITED.)

In this action, which was for a supposed infringement of Montoison's Patent for Date Coffee, counsel this morning stated on behalf of the plaintiffs that, having since the commencement of the action had an opportunity of investigating the defendants' Patent and their mode of manufacture, the plaintiffs had satisfied themselves that there had been no infringement, and accordingly an arrangement had been entered into that the plaintiffs should sell their Patent to the defendants for a sum which would cover the amount they had paid for it, in the belief that it was the sole one which could be upheld, and that all proceedings in the action should be stayed, each party paying their own costs.

Mr. Northmore Lawrence appeared for the plaintiffs; Mr. Pollard and Mr. Buckley for the defendants.

Our correspondent adds:—

"We are having a tremendously hot summer. The heat, I think, is greater than I ever remember to have experienced it in England. Now-a-days it is not considered *infra dig.* or effeminate for a man to use an umbrella as a protection from the sun. The example is no doubt set by Anglo-Indians, who have long conquered any squeamishness on the subject, and others are often only too glad to follow suit."

"CHICK COFFEE" AND PLANTING PROSPECTS IN COORG.

SOUTH COORG, 1st August.—In the June number of the *Tropical Agriculturist* at page 15, you recommend the trial of new seed coffee and mention that of Coorg as "Chick Coffee," which, if not a "goak" at our expense, I shall be glad if you will correct. The Coorg tree is very different from the Chick, which is an imported one from Mysore and very like what Ceylon planters call the "male tree." To it we owe much of the loss by borer and I may safely say leaf and other diseases inherent to coffee. It only gives a crop once in three years and then ripens at all sorts of times, so that much is lost on the ground and to this fact I attribute the large numbers of these trees to be found on every old estate, which were invariably planted from seedling plants from under the trees instead of from plants raised from carefully picked seed of the Coorg tree, which came from West Coorg and is known amongst old planters to this day as the Nalkenaad tree. If you recommend this to your readers, they will benefit by the change.

The monsoon is still very light here. I have only had 8·13 inches of rain for July against 10·84, the average for past five years, and 21·14 against 34·902 for the seven months.

Plants are drooping in old coffee and clearings, and enquiries are being made on every side for plants.

Labor supply, which three years ago was short, has yearly been increasing and now the cry is "What am I to do with my coolies?" This (where funds are available) is easily settled as South Coorg is interseeted with swamps which are mines of manurial wealth in themselves (when properly treated) and lime and bones are readily procurable at reasonable rates to mix with this; and I doubt not that your Ceylon men can testify to the benefits derivable from bulky manures when the bulk is on the spot, and merely wants to be carried a few yards to the trees.

The great want in this district is field surveys and a regular system of recorded manuring. At present, I could point to dozens of estates where the same fields are manured year after year, with resultant loss to the proprietors. Nearly all of them spend large sums for manures, yet very few can be induced to spend the sum of one rupee an acre for a detailed map of their estates, which, on an average, would not amount to more than R150 each, and which would, in one year, save more than the cost of the map, by enabling V. A.'s to check the various works in progress and save many a Chick Dhorie from a "stinker" as well. Thus we swallow whales and strain at gnats in "the Bamboo."

EFFECTS OF MANURES UPON FOLIAGE.—A very interesting example of the diverse results obtained in density of colour in the foliage of the Potato plant through the use of diverse manures may now be seen at the Bedfont seed ground, where Mr. Dean is carrying out some simple trials. Phosphatic manures, designed specially to assist in the promotion of tubers, not only do so, but also excite or stimulate earlier and more robust growth, whilst the normal tint of the foliage remains. Nitrogenous manures prepared for cereal and bulbous root crops, on the other hand, produce stems of a stouter kind, and foliage so dark in hue that but for assured certainty on the part of the planter it would scarcely be credited that the rows of Potatos were of one and the same kind. Even more interest will perhaps attach to the appearance of those rows, the ground being poor, to which no manure was applied. Compared with these, the manured rows, even now, indicate that more than double the produce will result.—*Gardeners' Chronicle.*

THE SARRACENIAS or side-saddle flowers, better known as pitcher plants, and that have long been grown in hot houses for the sake of their pitchers, are now found to be well worth cultivating on account of the size and beauty of their flowers, Messrs. Bull, Williams, Veitch, and others have furnished the *Gardeners' Chronicle* with specimens of flowers, some of which have been figured and described in that journal. They are said to be magnificent flowers, and the use of this superlative is, no doubt, fully justified so far as size and singularity of form are concerned. The colours, however, appear to be dull.—*Australasian.*

THE "T. A."—We have received a copy of the *Tropical Agriculturist*, a monthly record of information for planters of coffee, tea, cocoa, sugar, palms and other products suited for cultivation in the tropics. The contents of the number before us, which is issued from the *Ceylon Observer Press*, show that great pains have been bestowed upon the compilation of the publication, and we have no doubt that it will secure a large constituency not only in Ceylon but in the large planting districts of Coorg, Mysore, &c. Much of the information published in the *Tropical Agriculturist* appears in the daily issue of the *Ceylon Observer.*—*Madras Standard.*

THE "T. A."—A new monthly publication has been started in Ceylon, called *The Tropical Agriculturist.* It is published at the office of the *Ceylon Observer* and consists chiefly of extracts judiciously selected from that paper and from the Indian, Home, and Colonial, journals. The present preliminary issue, the conductors say, cannot be taken as a fair specimen of what will follow, and it will be their endeavour to find a place in the pages of *The Tropical Agriculturist* for everything bearing on the practical work of a tropical planter. We hope the present attempt to supply a want which has long been felt in Ceylon will meet with success.—*Madras Athenæum.*

RAPID CURE FOR FOOT-AND-MOUTH DISEASE IN CATTLE.—A very rapid cure of the foot-and-mouth disease in cattle is said to have been discovered by the Duke of Brunswick. He uses a solution of salicylic acid, prepared by pouring some hot water on about three tablespoonfuls of the acid in an earthen vessel, adding lukeworm water to make up a gallon. The mouth and feet of the diseased animal should be carefully washed three times a day with this liquid, and the tops of the hoofs well powdered with the dry acid after each washing. To the drinking-water should be added two tablespoonfuls of the acid dissolved in hot water.—*Family Herald.*

HEDGE PLANTS.—One prominent name is that of R. Hornsby & Sou (Limited) whose hedgecutting machine I saw at Kyneton trimming a furze fence beautifully. One horse pulled the machine on one side of the hedge, and by merely adjusting the guillotine-like shears both sides and the top were trimmed. The use of this machine removes the one objection to what in Scotland we call "whins." The plant, if left to itself, blossoms so as to compete with the most brilliant of the Australian acacias,—indeed it is difficult at a short distance to distingnish the introduced gorse from the native "wattles." The sced is in proportion to the blossom. It is far more lastiug as a hedge than the Kangaroo acacia, and its only rivals are the English "May" thorn, or hawthorn, and the Cape box thorn. The latter, with its formidable spikes is getting into favour. If only the furze can be kept well-rimmed, it makes a perfect hedge and a good breakwind, a fact which I recommend to the attention of planters in the neighbourhood of Nuwara Eliya, where "whins" and "the lang yellow broom" flourish side by side with rich flowered fuschias and brilliant scarlet rhododendrons. The trimmings of a furze hedge thoroughly qruized, could be utilized as fodder for horses or cattle.

NILGIRIS.—Up to date it may be considered that the monsoon rains have disastrously failed throughout the plateau; the July rainfall has been exceedingly scanty compared with the fall of the same month in previous ordinary years. The scarcity of rain gives the country a parched appearance, and estate operations are retarded. Native cultivation in parts is considered even at present to be a failure past recovery, while in other parts rain within the next week may save some of the standing crops, and produce a scanty yield. Many of the coffee and tea estates have suffered from the seasou, and crops, which looked favorable a fortnight ago, are jcopardized, by the rain holding off. On tea estates the flush is not coming out with the desired rapidity. Appearances are in favor of a change for the better, and the knowing ones predict copious showers within a week. The South-West wind has almost cleared within the past week or ten days, and this augurs a fresh burst.—*South of India Observer.*

MERCARA, 23rd July.—For rice cultivation in Coorg this year has been very favourable, and the ryots have availed themselves of it to the utmost by ploughing up disused rice fields, and using them for the coming crop. With the immense natural reservoirs of water, always on hand, more land could be utilised for rice than is the case, for the fields in most cases are continuations of steps at the bottom of declivities, with ever flowing streams from above, which could be turned on the land at will: there is rice growing here at an elevation of 4,100 feet. There is also a good prospect of a rich crop of cardamoms, there having been a very fair flowering, and a genial season afterwards; the cardamom pods now half-grown and well forward. The prices still continue high, fetching five shillings and sixpence for some parcels shipped to England in March. A parcel of cinchona bark (succirubra) sent home a month previously, and stripped from trees thirteen years old, grown at 3,700 feet elevation, only sold at the average price of one shilling and five pence halfpenny: the highest fetching 2s. 2d.—the lowest rate 9d. a pound.—*Madras Standard.*

THE "TROPICAL AGRICULTURIST."—The above is the title of a new monthly issued from the *Observer* office. It is edited by the enterprising Messrs. Ferguson, of the *Ceylon Observer* and the object of the publication is to furnish planters, for easy reference with information of coffee, tea, cocoa, cinchona, sugar, palms and other products suited for cultivation in the tropics. The contents consist of editorial correspondence extracts and miscellaneous notes. The articles are written in a clear business like style and contain very useful information. Replete as they are with figures, we have learnt many new things from them. The correspondence is very properly confined to matters of planting importance such as coffee leaf disease, tobacco cultivation, &c. The extracts comprise very useful selections from home, Indian and Ceylon papers, bearing ample evidence to the facts that the Editors know what planters of the tropics want. Every page affords pleasing proofs of the ability, and the extensive knowledge brought to bear upon the new venture. We have read it with great interest and have no hesitation in saying that every planter who monthly invests a rupee in it will ultimately find the money not mis-applied and that the publication itself is a mine of useful information evidently worth more than its present price. Satisfactory as is the *Agriculturist*, there is still a want, which we feel sure requires only to be pointed out to be remedied. Native agriculture does not seem to receive sufficient attention in its pages. That natives are more largely interested in planting than a quarter century ago is undeniable. The products cultivated by them are tobacco, coconut vanilla, pine-apple, grapes, mango, paddy cereals, &c. —*Jaffna Patriot.*

Correspondence.

To the Editor of the Ceylon Observer.

CINCHONA STUMPS *vs.* PLANTS IN DRY WEATHER.

August 4th, 1881.

DEAR SIR,—It has been a matter of surprise to me, especially after this unusual spell of fine weather, with newly planted cinchonas dying right and left, that notice has not been made by any one in your columns hitherto, as to the very great superiority of cinchona stumps to plants, especially the small fry so named! I speak from experience. When plants were dying all round, the stumps put out throve without exception, growing more vigorously than the plants that survived, giving to the clearing, I believe, in growth, the full benefit of their additional age. They are less liable to the attacks of grub and other insects, and insure an even clearing, and save much loss in plants and supplying. Let any of your readers who have not done so try, and they will not be disappointed in the results, but some extra care in removal and planting is necessary to prevent the bigger roots from being broken and damaged.—Yours truly, STUMPS.

CASUARINAS AT A HIGH ELEVATION NO GOOD; C. URITUSINGA (OR CONDAMINEA) IN DIMBULA.

Langdale, 6th Aug. 1881.

DEAR SIR,—Casuarinas are no good at this elevation, 4,600 feet. I grew one certainly for 10 years, and probably longer, and it measured, when cut down, about 13 inches diameter at ground and only 9" at 3' 3" high. You would not get much timber if this is a fair growth, for this includes bark, which is thick, and you would have to wait longer than most men could afford, to get even this.

Then as to Mr. Deane-Drake's cinchonas: is the measurement given correct? To me it seems there is some error, for I have a tree, I think, of the same kind, but 2 years older, and it only measures 1'7½ in circumference at ground, but it is 1'5½ at 5 feet high, while the height is about the same as Mr. Drake's tree, 22 feet.—Yours faithfully, E. H.

"HIBISCUS CANNABINUS."

DEAR SIR,—I send by this post a box, containing the flower, seed-vessel, and stem of a plant, from which the coolies say twine and sacks are manufactured on the coast. It is commonly grown in the line gardens, as the leaves are used for curries. Can you tell me if it is jute?—Yours faithfully, W. B. H.

[Our correspondent W. F. reports as follows:—"By a singular coincidence your packet of specimens, and a notice of contributions to the Colombo Museum in your issue of the 9th August, have reached me at the same time. The specimens from your correspondent 'W. B. H.' and the donation of cord from the fibre *pulac i keri* (? *pulchay kvery*, Tamil) from Mr. P. N. Brain have reached me at the same time, and I have no doubt they refer to the fibre of the same plant, viz., that of the *Hibiscus cannabinus*, or Hemp-leaved Hibiscus. The stems of this plant furnish abundant fibre in various parts of India, and its leaves are in general use as an excellent vegetable (Tamil, *keeri*), and taste something like sorrel. The plant is very commonly planted in the gardens near coolY lines in Ceylon, and it is not an uncommon roadside plant in the island, but it is not a native of Ceylon, though the *Flora of British India*, I. p. 339, refers to Thwaites' Enum. 26 erroneously where it does not occur. In reply to your correspondent's question as to whether this is jute, I may reply that though a very common Indian fibre it is not jute, which is the produce of *Corchorus capsularis* and *C. olitorius*."—ED.]

RATTANS FOR MATTING.

Ratnapura, August 6th, 1881.

DEAR SIR,—Can you inform me whether the same description of rattan cane as is used by the Malays in the manufacture of matting, chairs etc., is to be found in Ceylon, and if so where plants can be procured? Rattan cane of a very inferior kind is found in the jungles of this district; so that cane of the better description ought to be easily grown. —Yours, NEW PRODUCTS.

[W. F. reports:—"There are seven species of rattans indigenous to Ceylon: some very stout and long, and others very like the common rattans used for matting, chairs, couches &c., some of which were extensively sent from the Southern Province some years ago, and are no doubt still used by Sumps for the various uses to which rattans are put. These plants, Calamus, are not uncommon in various parts of Ceylon, and are no doubt collected for local use, but your correspondent's trite remark that "rattan cane of a very inferior kind is found in the jungles of this district, so that cane of the better descriptions ought to be easily grown," reminds me of Pat's remark, "No wonder that this place is called Stoney Batter, for for I was never so bitten with fleas in my life."]

THE EDUCATION OF THE COFFEE TREE —PRUNING.

Coppa Kadur District, Mysore Provinces,

20th July 1881.

DEAR SIR,—In the interest of a large and influential community busily engaged in "coffee planting," I solicit space, in your most invaluable journal for "coffee planters," to place one subject above all others most prominently for the best consideration of one and all.

It is not within my province to say anything—beyond this—of the present industry and how it has been executed. It is enough for me to know and say that from "Laborie" to "Hints and Wrinkles," every information, as far as their researches and experiences warranted, have been duly placed before us, and they are all entitled to a universal acknowledgment, and at least the warmest and most hearty thanks.

There can be no doubt that "coffee planting" has had all the advantages of superior intellects and intelligences, and deep study also from the most different points of view by men of known talent and ability: add to which the exercises of the many with the two most valuable and necessary ingredients "capital" and "self-interest." These two, one can easily conceive possible, would only go in for "results." But, notwithstanding all this, I believe—and I am sure others will be found to agree with me in this belief—that the education of the coffee plant is not perfection, and it will be found that there are many matters requiring very, very serious consideration. Surely, your kindest of journals is open to have every one's view most openly placed, fairly to be examined, duly criticised, and ultimately "admitted" or "rejected" of course, by a competent body, capable of undertaking the responsibilities of a close examination of the different subjects and scientifically deciding thereon.

I write scientifically, because I believe in science and my knowledge is that she rejects anything that cannot be proved. However, ignorant a man therefore may be, it is quite possible that he may have

practically stumbled on perhaps the most intricate theoretical subject and by placing his views for a scientific understanding thereof he may even assist those gigantic minded bodies, the "hem" of whose mantle he may not deem himself worthy to touch, but, who in the interest of the world and the only too humble opinion of themselves come forward most manfully to assist mankind and *solve the problems.* I have but one fear: that at the very first glance at the simple heading of my subject weary-tired and worried, heads and hearts will only be too ready to rush to an exclamation at once:

"Oh, we have had enough of all this! We know all about it! This no use, it won't phix! But in your land of 'bide-a-wee'!" I only ask to be heard out and it will be that you yourselves will be able hereafter to prove the results of your "short crops" and "leaf disease." My beading is "pruning." I only ask you to follow me in what you do and I propose to show you only this much: that the "one" important matter has not received that due consideration to which it is most assuredly entitled for the best results.

Let me get a fair position for my subject. So I shall start with the entering of the seed into the soil, till by half evolution of "crosses," the coffee plant with its primaries answer to that height (say 3 feet) at which you intend it to staud. Here man proposes to dispose of God's works contrary to his ruling and he does a process called "topping." What are man's hopes? That the wind will not blow the plant down—and that the cutting of the "sap" will force into other channels, and so strengthen his plant. Oh! erring mortal! What are your results? Projectious the most unnatural; suckers, upward shoots and downward shoots, backward shoots, gormandizers, and other confusions. You have bleeded the head of your stream of sap too close to your roots; and you have lost sight of a most important point that while you have reduced the natural height of your plant, you have done nothing to the root itself, the energetic worker and the supplier of the necessities of the plant above the soil, according to their nature. How have you proposed to remedy your evil of "topping"? By removing all these unnatural now trying projections. And what do you effect? Sicken your roots for they sent up these different saps for different executions. Branches, pith, leaves, etc., to bring back to them light, heat and carbonic acid gas. But alas! there has been no return, for man in his superior knowledge has been most ruthlessly removing all that nature was issuing forth from the roots to the very leaves for a return of strength; but is now exhausted as all love's labour has been lost, and mother earth unable to stand this sort of strain begins to call for strong stimulants known as "manures" and unless this is fully supplied "crop fails" and "leaf disease" results.

Just read at this point "Lab ries's" deep researches. He tells you distinctly "Nature makes no blunders;" that the plant in its growing, grows up with a stem putting out primaries. These extending themselves *horizontally* throw out "secondaries." These in their turn "Tertiaries." He says and let us have it in his own words:—"they are placed by pairs on both sides, all spread out *horizontally* and with a direction in some measure towards the circumference. *If any should grow upward or downward*, they would become intricate and the tree embarrassed." But nature "can neither be perplexed nor intricate," because "the boughs from the ground will extend wider as they are nearer the source of vegetation so that the shape of the tree is pyramidal. All those branches of *three orders or more garnish it richly, but as all are horizontal from below upwards*, all *diverging from the centre more or less*, all placed either at the four faces of the trunk or both sides of the matted branches (primaries) *the profusion of nature,*

"Can neither be perplexed nor intricate."

"If such happen to be the unintentional effects of Art, art must redress them." Surely, our doings of removals of upwards, downwards, backwards, and suckers is not redressing the introduction of our evil. —It is making it more grievous to the plant and hence to all those who are trying to grow it.

Let each of us examine this matter for ourselves. Do we not want all the fruit we can get? Can we get it by removal of all the very growing material that is sent up from the roots to produce it? This excess energy of man and plant is wasted for an "ideal" in my humble opinion of a good looking plant. Not that I do not think that good looks are also desirable, and can be worked out.

My suggestion, therefore, is that since you do top the plant at three, four, or five feet height; so you should in like manner nip the primaries, secondaries, &c., when overflow by suckers appear. I cannot do better than give you a figure by which to convey my view of this subject. Supposing I had a stream at head so great that it must overflow its banks. The only way I could reduce its strength and still have the whole of the water would be by guiding and directing it below into different channels and thus force it a great deal, so as not to lose a drop of the water, and so we ought to treat the coffee plant when it is overflowing with its sap. Let it get to its extremities, and if it offers to overflow, you have then to divert it; that is give at its extremities space to flow onward.

In concluding this a little hastily, I have to add that I shall send you a set of rules, giving my views of pruning, which will clear up my writing, if there be any misunderstanding about it.—Yours,

G. H. K.

CINCHONA STUMPS.

Dikoya, 11th Aug. 1881.

DEAR SIR,—Your correspondent "Stumps" is quite right in recommending planters to plant cinchona *stumps* in preference to *plants*. I have been in favor of the former for the last two seasons, and out of the thousands I have put out, scarcely one has failed or been dried up with the drought. The difficulty is *where* to *get them*! Plants even are not to be had, except at a high price.—Yours truly,

A PLANTER.

CINCHONA STUMPS.

SIR,—Will some one kindly enlighten me on the following points? :—

1. Is the method of planting equally successful with succirubra and officinalis?

2. Should the plants be stumped in the nursery some time previous to putting out. If so how long? and at what height above the ground?

3. Is there any objection to this mode of planting? Its advantages are obvious in a monsoon like the present, especially when plants are not A 1.—Yours, etc.,

IGNORAMUS.

"ILANG-ILANG.—The Manila manufacturers of essence of Ilang-ilang are going about excitedly, and are actively at work producing this essence for exportation to Paris, with every prospect of a profitable result. It is said the essence of Ilang-ilang of good quality is quoted there at 400 to 425 francs per kilogramme. Trade is benefitted, but it should not be forgotten that when the perfumers of Paris have once bought each a couple of bottles of Ilang-ilang they buy no more for a long time, and the price of the article may fall.—*Straits Times*, 9th July.

INDIA-RUBBER.

A local advertisement announces that "Mozambique pink rubber seedlings" are locally available, and it is added that the rubber is in high favour with English manufacturers. In respect of the *Landolphiae* species generally, the following information may be of interest, taken from Collins' and Brandis' Report on the Caoutchouc of Commerce":—

Landolphia Owariensis, Pal. de Beauv. Fl. Owar et Benin, I., p. 54. t. 34, D.C. Prod. viii., p. 320.

Synonym.—*Pæderia Owariensis*, Spreng., Say. i., p. 669.

Vernacular Name.—*Licongue* or *Licongue* (sing.). *Macongue* (plural form) (Plate 4).

Geographic Distribution.—Dr. Welwitsch remarks (in MS to Collins) that this species "first discovered by Palisot de Beauvais in Owar and Benin, and afterwards by Don in Sierra Leone, I have encountered rather frequently in several of the highland districts of Angola, and consequently the habitat of this plant may be stated as extending from 10° lat. N. to 10° lat. S. on the tropical coasts of West Africa."

Remarks.—Dr. Welwitsch (l. c.) describes it as a "large climbing plant, four to six inches in diameter, at a height of two or three feet from the ground. From this point it is divided into several long thin branches which are again and again divided, climbing along the stems and larger branches of neighbouring trees, to which they fix themselves by means of most tenacious spirally-twisted tendrils formed out of the indurated flower-stalks after the ripe fruit has fallen off. The fruit is about the shape or a middle-sized orange, containing under a hard, nearly woody, reddish brown shell, a sweet, rather acidulous pulp, which is eaten by the natives."

L. Heudelotii. D.C. Prod. 1. c.

Geographic Distribution.—Senegal.

L. florida, Benth. in Fl. Nigritiana, p. 444.

Vernacular Name.—"*aboh*" or "*abo*" (Fruits).

Geographic Distribution.—Dr. Welwitsch remarks (l. c.) this species is found "rather frequent in most of the primeval forests of inner Angola, where, at an elevation of 1,500 to 2,500 feet, I often met with this beautiful climber, and gratified myself with its sweet, acidulous fruit, though not less so with the beauty and marvellous abundance of its large snow-white and jasmin-scented flowers."

Landolphia species incerta. In the Kew Herbarium and Museum are the following:—

L. species.

Geographic Distribution.—Tropical Africa, lat. 1° N.

Remarks.—"The leaf of the African Rubber plant."

Coll. G. Mann.

L. species, Prov Zanzibar Coll. Dr. Kirk.

L. florida? Fruits and Caoutchouc from the district on the Congo River. Coll. Dr. Hilliard.

Carissa species. Wood and rubber collected by Dr. Kirk (Livingstone expedition).

L.? "Shinpanga, India Rubber shrub." Coll. Dr. J. Kirk.

L. near *Owariensis*, Shinpanga, India Rubber liana, wood, fruit, &c. Dar Salam, 1868. Coll. Dr. Kirk.

General Remarks. Of these unascertained species of *Landolphia* which yield Caoutchouc, the Caoutchouc sent by Dr. Hilliard is identical with our West coast "bali" Caoutchouc. The last two specimens sent by Dr. Kirk are identical, and a portion of the stem of the "India Rubber plant of Zanzibar and East tropical Africa," as he calls it, also sent by him, is, at least as far as comparison of woods will admit, identical with the first specimen sent under the name of *Carissa* and both agree with a piece sent by Dr. Africanus Horton in Cape Coast Castle. Dr Kirk, in a letter addressed to Dr. Hooker, C.B. (and which the latter has kindly allowed me to copy), says:—

"This plant (referring to the last sent) is a woody climber, common along the maritime region, and abundant at the mouth of the Zambesi, being found largely at Shupanga on that river at 100 miles from the coast. The produce of this has been shipped from Quillimane for America. The fault has been that the rough bark has often been imbedded in the gummy mass through careless collection. It is not an article of trade at Zanzibar, but I have been endeavouring to induce the natives to collect it. John Kirk. December 25th, 1868."

To Dr. Welwitsch however (whose valuable additions to our knowledge of the Flora of tropical Africa are so well known) belongs the credit of first identifying the plants yielding African Caoutchouc. He says (l. c.) it was principally from the *L. Owariensis*, Beau., that he saw the Caoutchouc collected by the natives of Golungo-Alto and of Cazengo. Du Chaillu speaks of the Caoutchouc vine, doubtless a *Landolphia*, known by the name of Dambo, as being common about the River Benito Also more plentifully in the valleys, bottomlands, and high grounds about the Rivers Moondah and Ikoi, the produce of those growing on high grounds being considered the best,

Collection and Preparation.

The collection and preparation of African Caoutchouc is conducted in a very slovenly and wretched manner. The natives cut off a piece of bark and the milky juice is allowed to run into holes made in the ground or on leaves. In Angola Dr. Welwitsch describes the method there resorted to as even if possible worse. A native having cut a tree places the palm of his hand against the stem and allows the milk to trickle down his arm. He goes from tree to tree, and when his arm is covered, beginning at his elbow he rolls the Caoutchouc back towards his hand, till it comes off in the form of a ring. It is also by some collected and allowed to coalesce in wooden vessels. The wood of the plant contains a gum, so that if the cut penetrates it this becomes mixed with it and spoils the Caoutchouc. African Caoutchouc has however improved in some districts recently, and the price has been higher for the improved kinds. Mr. Lee Norris, late Manager of the North British Rubber Company, wrote me that he believed the better kinds were prepared with the aid of strong liquor ammonie added in the proportion of 3 per cent. The chief districts from which African Caoutchouc is exported are the Gaboon, Congo, Angola, Benguela, and Zaubesi.

African Caoutchouc is received in the form of flakes, round balls, and tongues, has a disagreeable odour, possibly the result of decomposition, is viscous, and generally least elastic of all the varieties.

JUTE CULTURE IN EGYPT.

La Cultivateur, of Cairo, of June 1st, says:—We have on several occasions mentioned to our readers the jute culture which Mr. Grant has been trying to introduce into Egypt. Since our last advices several bales of this textile have been sent to England. These have been much appreciated, recognised as of excellent quality, and sold at a very remunerative price. This culture, it seems, then, should give good results. Daira Sanieh and the Administration of the Domains have resolved to appropriate a certain extent of territory. There have been 200 acres sowed. Daira Sanieh has ordered from India a quantity of seed, and it is announced in the journals that they are willing to sell some of it to the public at cost price. We strongly recommend our readers to profit by this circumstance, and make a trial with a small piece of ground. The price of grain comes to P. T. 27 per feddan. The sowing should be accomplished 15 days at latest from this date. *La Cultivateur* also gives "Instructions on the Cultivation of Jute in the First Period"

Under the head of Soil it says:—The Jute grows provided that it gets the necessary moisture, and in all kinds of earth except sandy and gravelly. But the culture has much better results in rich alluvial soil, such as that on which cotton is cultivated in Egypt. It grows very well also in light sandy soil, and, as in Bengal, in soils impregnated with salt, or those which can be inundated by salt water at high tides.

Preparation of the Soil.—The preparatory work ought to be done more or less often according to the nature of the soil; thus a hard and compact soil requires to be more worked than a light and powdery soil. The principal thing is that the earth be exposed to the sun at intervals, and that it be well pulverised.

Grain and Sowing.—The day chosen for the sowing ought to be bright, with good sunlight, and after a shower or after irrigation has rendered the earth damp. The grain is sown with the hands, and then with the harrow or wooden plank. The seed should be covered with a light layer of soil.

Quantity of Seed to the Feddan.—The quantity of grain per feddan is nearly 12 pounds (English). After that, during germination, the plants may be found at a distance of 6 inches the one from the other. This distance permits the rays of the sun to penetrate to the roots, and the damp atmosphere to circulate freely on the earth and in the interior of the plant itself.

Time of Sowing.—The period during which the sowing of the seed takes places depends, as in Bengal, on the soil, the situation, and the season. It commences in March and finishes about the middle of June.

Germination.—Supposing the earth has been irrigated the evening preceding the sowing, the plants should appear on the surface of the earth at the end of three or seven days.

Irrigation.—The climate of Bengal, where the rains are alternated by sunshine, is best for the culture of jute. In Egypt the irrigation should be regulated by the progress and the vigour acquired by the plants. The critical period for the growth is during the shooting. When the plants have attained the height of two or three feet the ground ought to be irrigated at least once every month, or more if required. After this period of growth, or until the plants have attained from 6 to 10 feet, the irrigation is not of much consequence, for they have acquired enough force to support themselves. However, jute certainly prospers better from the beginning to the end of its growth in a humid climate, well exposed both to sun and moisture. In Egypt this is a question the solution of which can only be obtained by practical experience.

The pulling up of Bad Plant and Weeding.—When the plants attain the height of 2 or 3 inches the bad plants ought to be pulled up, and when the plants have attained at least one foot in height the thinning of the plants should be proceeded with, as crowding hinders their development and in thinning it is necessary in the first place to pull up those plants that are most behind, or those hindering the growth of others? As has been already indicated, the most favourable distance for the growth and prosperity of plants is 6 inches the one from the other.

Period in which the Plant has Attained a Certain Degree of Development.—When the plants have attained about 3 feet there is no need to do anything except to irrigate from time to time, and to pull up the bad plants which remain, especially in places where they are crowded together.

Height of Plants.—The jute grows to the height of 6 or 10 feet, according to the nature of the soil, the heat and the regularity of the irrigation; under favourable conditions it has been seen to grow to 15 feet.

Best Time for Harvest.—Harvest should be made when the plant is in full flower, which is three or four months after the sowing. When the harvest takes place at this time the plant gives the most supple fibre, and that of the most brilliant colour, which is most appreciated by manufacturers and most easily prepared. When the plant is left to ripen more in order to procure seed that gives a greater quantity of fibre, but this fibre is hard and thick, and very little liked by manufacturers.

OLEANDER POISON.—We had lately occasion to mention the danger to stock arising from placing oleanders in positions to which animals might obtain access. The *New York Tribune* narrates a fatality that recently occurred:—"A fine healthy mare ate a single tuft of leaves from a branch of an oleander temporarily set by the door, then went on a journey of six miles, appearing playful and well, but on returning refused her feed. Next morning she still refused to eat, looked dull and haggard, and had partially lost control of her hind limbs. The mare died before assistance could be obtained, and on opening the body the dark red congested stomach showed the action of an acrid poison, and inquiry brought out the account of the cropping of the oleander, of the injurious qualities of which the owner was entirely ignorant. As this ignorance is very widespread, it may be well to say that all parts of this plant are deadly. A very small quantity of the leaves are fatal to the horse, as we have just seen. The flowers have produced death in those who carelessly picked and ate them. The branches, divested of their bark and used as skewers, have poisoned the meat roasted on them, and killed seven of twelve people who partook of it.—*Australasian.*

TEA.—Mr. Inglis, Indian Commissioner to the late Exhibition, gave an interesting lecture in the Presbyterian Church, at Elsternwick, on Thursday evening, to a large audience, who evidently appreciated the lecturer's efforts to interest and instruct them. The subject chosen was entitled "A Cup of Tea," and consisted of a series of graphic word paintings, descriptive of planter life on an Indian tea garden. Mr Inglis took his audience with him from the plains and forests of Assam to the valleys of Northern India and the hills of Darjeeling. He explained the method of culture, the growth of the plant, the mode of picking the young leaves or "flushes," the fermentation stage, the drying, sorting and packing, and the differences between the various sorts of tea. While fully admitting the excellence of much of the Chinese product, he conclusively showed the superiority of Indian over Chinese teas, on the grounds of their absolute purity, and because they are made under the supervision of men of our own race, with the best of machinery, backed by capital, intelligent organisation and with a minimum of handling. The value of the interchange of products between Australia and India, and the probability of its unlimited application, was also powerfully dwelt upon. The more stirring phases of planter life, the superstitions, amusements, manners and curious customs of the natives were fully illustrated, and the anecdotes and stories of hunting, forest scenes, and wild jungle life fully sustained the interest of the audience to the close of the lecture. Mr. Inglis, we believe, leaves for Sydney to-day, and we can safely say that both he and his colleague, Mr. Buck, have fully realised their functions as representatives of a foreign country at the Exhibition. They have used their utmost endeavors to place the resources of the great country, India, which they represented, ever before the people of Victoria; and we are justified in predicting that the fruit of their wise and spirited efforts will be yet seen in an extended interchange of commodities between the two countries.—*Melbourne Age.*

CEYLON FISHERIES.

From the report of Mr. Steele on the Hambantota district for 1868, we make some further quotations in connection with the fisheries off the Southern coast of Ceylon :—

73. The sea which bounds the district to the south abounds in fish. More advantage might be taken than is at present the case, in turning this valuable store-house of food to account, especially in the curing of fish which, as salt of the best quality is obtainable here, might be prepared and sent inland in very large quantities. A great demand for cured sea-fish always exists inland, as it is a prime requisite in the making of curry, the universal dish of the country. River fish is, as a general rule, reckoned unwholesome in Ceylon. Canoes, each holding four men, come all the way from Dodanduwa, Dewundara and Gandara, to fish off Hambantota and Tangalla, and the intermediate coast. During the North-East monsoon, many boats also go to Patnangala,* a rocky headland, a few miles to the west of Yala (not far from where the Menikganga, the *Jewel River*, empties itself into the sea.) There they build huts to shelter themselves, and continue fishing for many weeks together, salting what they catch, or drying it in the sun, until a goodly supply has been secured. They then set sail for Hambantota and elsewhere, to sell their stock. The buyers here hand over their purchases, after making a very liberal profit, to the tavalam-men, who carry the fish to Uva district. Welipatanwila, a village in Giruwa Pattu, about two miles west of the mouth of the Walawe river, is inhabited exclusively by fishers, a robust and healthy race of men, and is noted for the abundance and excellence of the fish captured in its waters.

[Para. 74 has been already quoted in our article.—ED.]

75. In connection with Hambantota, there are at present six boats used with dragnets, and about twelve with the small nets. Of the small nets, besides the four sorts enumerated above the Patabendi Arachchi of this place, the chief Fisher Headman here, informs me four other descriptions are in use, namely *lagu del*, *ihi*, *kara*, and *wara* del. The last named is made of the fibre of the hemp bush, which grows plentifully on the sea shore. The thread is extremely tough, and makes admirable pack-thread. During the month of March, 1869, it is worthy of note, no fewer than seventeen sword-fish—one, eleven and a half feet long and five and a half in girth, have been caught and brought into Hambantota B.y; and of sharks of all sizes about two hundred. The hammer-headed shark is also caught, and so is the spotted species, but neither is very common. Close in shore sharks have never been known, so the fishermen here assert, to do any harm to human beings. When fresh fish are brought ashore here, the Patabendi Arachchi conducts the sale immediately held on behalf of the shareholders, the four canoemen, and receives one twentieth of the proceeds for selling and collecting the money. Long ago, before the abolition of the tax, it appears, the share apportioned to the Fisher Headmen was one-twentieth. The four canoemen share and share alike. In the case of the drag-nets, the owner of the net (which is a costly affair, worth, with the boat, £15 to £20) takes the whole, giving the canoemen, and the people who drag, such share as he pleases. The people who drag the net are of all ages and sizes; and it is amusing to see little boys, without a rag of clothing, rushing home well pleased with two or three small fish, the reward of their valuable assistance! A great deal of shouting always goes on as the net is dragged ashore; and towards this part of the entertainment the throats of the young people no doubt contribute largely.

76. Amadawa (which means *Turtle Island*, though the first half of the word is Tamil, and the latter Sinhalese—perhaps a token of the intermixture of races here in ancient times) is about two miles from Palatupana, and about twenty-seven from Hambantota, and is noted for the abundance of turtle frequenting the place. It is no longer an island, sand having drifted up and connected it with the shore. Much of the tortoise-shell, wrought up so largely in Ceylon into various articles, was formerly, I understand, obtained from this place. Turtles come at regular seasons and in great numbers to the sea shore near Hambantota to deposit their eggs in the sand. It is considered highly irreligious to kill them by the Sinhalese.

* This bold and conspicuous rock, called Little Elephant Rock in the Admiralty Charts, is believed to owe its Sinhalese name, Patnangala, or (by *perali* or transposition), Nampatgala, "*The Rock of the Bestowal of Titles*," to the ceremony of the investiture of native chieftains by the ancient kings, having taken place at or near the spot. All round, the scattered piles of rock, now, by the way, the chosen haunt of bears, are very romantic looking. Two remarkable *kemas*, or caverns for holding fresh water, are to be found on one of them. Not far away is Akasechaitya, "*The Temple in the Sky*" a very striking object in the landscape. The magnificent park-like plain of Butawa stretches between the two. *Agil*, a beautiful tree much resembling myrtle, which, when burnt, yields a sweet perfume, is plentiful hereabouts. In April, the jungles abound with star jasmine, with profusion of snow-white blossoms of the delicatest perfume.

CASUARINA CULTIVATION.

We learn that some of the members of the Eurasian Association and their friends have taken steps to start a casuarina plantation Company, and that it is to be worked on the joint stock principle. The Company is not a large one and it is intended to work the land which the Eurasian Association has lately bought at Kollady, the value of the land being paid in full or taken on rent. The cultivation of casuarina in parts of Madras and Chingleput district has turned out pretty well, but in all cases where these undertakings were managed by joint stock Companies they went to the wall. We may allude to one or two undertakings to show that casuarina plantations, though managed with some economy by Hindu projectors, did not pay. Two Companies were some years ago started in Madras for the purpose of growing casuarina. They were started with fair success, but in a few years when the trees were coming on and they needed a little care, funds were not available and the labor of two or three years went for nought. This is one of the rocks that the proposed Company must avoid. The undertaking, if carefully managed, will give good returns. The hundreds of acres of land in Madras, Pulicat, Coromandel, Cuttewak, Sadras, and along the railway lines planted with casuarina are ample proofs that its cultivation ought to be encouraged and that a well managed business will pay fairly well. There is no doubt that the failures we have alluded to were the result of defective working. The Company which is to be started may have many difficulties to contend with: there may be failures at the outset, but with perseverance, success will come. Certain persons who profess to know a good deal of casuarina planting have supplied the projectors of the undertaking with information which shows that a plantation well managed will produce results that ought to satisfy the most speculative ambition. But the projectors of this Company are not likely to be deluded into the belief that a casuarina plantation, though a good speculation, will be a source of unfailing wealth.—*Madras Standard.*

LIFE AND WORK IN JAMAICA.

(From the *Field*, 25th June 1881.)

SIR,—I shall be glad if you can afford me room to say a few words in reply to "Inquirer" (*Field*, Feb. 26) and "Captain" (*Field*, Feb. 12) as to the advantages offered by Jamaica to men of small capital. In previous letters (No. 1,416 and 1,427 of *The Field*) I have given details regarding the cultivation of fruit, chocolate, and coffee; and I should now like to say something about cinchona.

In 1868 the Jamaica Government established an experimental cinchona plantation in the Blue Mountains, about twenty-five miles from Kingston, and last year the bark sold from this plantation fetched higher prices in the London markets than either India or Ceylon bark of the same class. I have recently visited the plantation, and can say in support of Mr. Morris, the director of the botanical department, formerly assistant botanist in Ceylon, that Jamaica presents a splendid field to capitalists willing to embark in cinchona.

There are numerous advantages which Jamaica possesses over other places for European settlers, and I may mention a few. In regard to mail communication and steam lines between England and the United States, the island is singularly fortunate. In the harbour of Kingston a day does not pass without a steamer arriving or sailing. We have also a weekly coastal steamer of the Atlas Company under contract with the local Government for conveying passengers and goods round the island, calling at all the chief outposts.

In the mountains of Jamaica—from two thousand feet to nearly eight thousand feet—there is the finest climate in the world, and abundance of fine land to be had cheap. With the aid of coolies (East Indians) to augment the fitful labour of the natives, the cultivation of coffee, cinchona, jalap, ginger, &c., affords certain profit and pleasant occupation. For the cultivation of sugar, Liberian coffee, Indiarubber, cotton, cocoa (chocolate), bananas, and other fruit, the lower lands are best adapted. On the north coast the climate is cooler and more healthy than on the south side; but the island of Jamaica has ever been most wickedly maligned when described as unhealthy. Our death rate is very low as compared with many places supposed to be more healthy. The temperature is much cooler than most people suppose, in the hills especially. Last year there was not a death from yellow fever in the Naval Hospital at Port Royal among the military or in the general population; and yet there are persons who suppose—even say—that yellow fever is a Jamaica disease. Since the establishment of quarantine, the deaths from this disease are so few as not to be worth mentioning. There are no diseases peculiar to Jamaica, the most fatal being that of spirit drinking, to which new comers are liable if they accept the inevitable invitation, "Have something to drink?" which unfortunately is as common in Jamaica as in many other places. If a man will make up his mind to drink nothing, except at meals, and to be only moderately careful during the first few months of his residence in the matter of not over-heating himself—needless exposure to the sun in the middle of the day, changing his clothes if he gets wet in the rain, wearing flannels and avoiding linen clothes—I am sure his chance of long life is as good in Jamaica as any where on earth.

The island being so large and the population so sparse, there is not much society; but with frequent letters and newspapers from England, books, and one's occupation, time goes all too quickly without any necessity to yearn for society. There are nice people in Jamaica, as there are in most places; and everywhere there is real hearty hospitality, and a desire to welcome new blood, energy, and capital.

Instead of burying themselves at the Antipodes, the Cape, India, and other distant lands, persons with small capital and income could go far before they would find a more healthy and pleasant residence than Jamaica. I know no place that offers such inducement to the small capitalist who is willing to occupy himself in superintending personally the investment of his capital.

All kinds of English flowers, vegetables, and fruit are cultivated and do well in the hills; and our beef and mutton, poultry, turkeys, ducks, fish, and fruits are excellent, and moderate in price. Beef, 6d per lb., all cuts; mutton, 9d. to 1s.; pork 6d. to 7½d.; turkeys, 9d. to 1s., live weight; ducks, 5s. to 6s. per pair; fowls, 6d. per lb.; fish, 6d. per lb., all kinds; turtle, 3d. to 6d. per lb.; eggs, 9d. to 1s. per dozen.

Servants are cheap, but not good. Men cooks and butlers, from 10s. to 14s. per week; house girls, from 4s. to 6s. per week; washing, 2s. to 3s. per dozen pieces; grooms and coachmen, from 8s. to 12s. per week; water boys and grass cutters, from 4s. to 6s. per week. All servants in Jamaica feed themselves out of these rates of wages.

Horses are good and not costly. A good cob for mountain riding from £14 to £20; a buggy horse, from £25 to £40; a good milch cow and calf, from £10 to £12. Taxes are light—on nonses, 1s. 6d. in the pound rental; land, cultivated, 4d. per acre; not cultivated, from 1½d. to 3d. per acre; horses, 11s. a year; wheels, 15s. for road purposes. The import duty is heavy, being 2s. 6d. in the pound on clothing and most articles of necessity from abroad. Houses are to be had on short or long leases, sometimes furnished, but generally unfurnished, at not costly rentals. There are many properties to be purchased now for less than the value of the buildings in many cases, from men who have not capital to develope their resources. Money fetches from 7 to 8 per cent on first mortgages and perfectly good security.

I shall be pleased to afford my individual reader of *The Field* further information regarding Jamaica if he will apply to me.

W. B. BANCROFT ESPEUT.

Jamaica, April 26.

P.S.—I would strongly advise all who contemplate seeking a home abroad to visit Jamaica before deciding upon anything. It only takes two months to go and return, and need not cost more than £60 or £70, all told.

AN AGRICULTURIST'S TOUR IN BELLARY.

THE Government have published a valuable report by Mr. C. Benson, late Acting Superintendent of Government Farms, on a tour that he made on the Bellary District last autumn. He says:—"The tour was a short one, but afforded me an opportunity of extending my experience of South Indian farming to a set of conditions of which I had previously but little knowledge. This is, however, only the third in the Presidency which I have as yet been allowed to visit, although I have been in the service of Government for nearly seven years, My first opportunity of personally gaining an insight into native farming was not afforded me until I had been nearly five years in India, and thus my knowledge of the country was until recently very small. This tour is further only the fourth that any officer of the department has up to the present time been allowed to make in the plains, and yet blame is often cast on them for not appreciating the good points of native farming, although their opportunities of becoming acquainted with these points have been few. Hearing and reading chiefly of the defects of the native system, and working out the conclusions to which official statistics point agriculturally, my opinion of South Indian husbandry was not a flattering one, as I

showed in a paper I laid before the Famine Commission. Further experience does not lead me to modify in any important particulars my previously expressed opinions, although I can now better appreciate the difficulties with which the ryot has to contend, and also the good points of his practices as far as I have become acquainted with them. With every extension of my experience, the conviction also grows upon me of the great difficulties of bringing home to the ryot information regarding the manner in which his practices can and should be altered. The two most important points on which reform is urgently required—the use of a better plough and the manufacture and use of manure,—are of such a nature as to render demonstration of the necessity for change of the greatest difficulty. Everything, as far as I can see, points to the advisability of energetic action on the lines mentioned in my Cuddapah tour report; but even with the greatest possible effort progress can only be slow. Unless Government are prepared to act energetically and on a far reaching system in the matter the hope of doing any good to the country at large must be very small, and it is scarcely worth while to carry on our work in a 'half-hearted and experimental' manner."

The Board of Revenue observe that "Mr. Benson's tour was confined to the month of August, when crops were on the ground, and it is therefore difficult to understand how he arrived at the conclusion that the agricultural operations of the district are carried on in a 'lazy and perfunctory manner,' or on what ground he basis his assertion that the system in Bellary 'is the most inefficient cultivation he has ever come across.' Subsequently, however, when describing the mode of cultivation more particularly, he practically retracts this charge, and shows that the operations are conducted in an intelligent and skilful manner. Mr. Benson appears to be puzzled to account for cholum and korra being the staple crops and says: 'I am unable to suggest any reason why they should so exclusively occupy this position.'" The Board says that the "reason why these cereals are more largely cultivated than other grains is that, being the staple food of the people, there is a large demand for them, and its pays the ryot to grow them just as in England it pays the farmer to grow wheat and barley. In regard to deep ploughing and the alleged prejudices of the ryots against this and other approved modes of farming, it is observed by the Board that the only way to overcome prejudice is to demonstrate practically that scientific farming pays; and a few model (not experimental) farms conducted on commerical principles established in the midst of the ryots' holdings would produce a greater effect than a long series of lectures at the school of Agriculture. The Board consider that this practical test is what must be insisted upon as the first and most important step towards the improvement of agriculture in India." The Government says that they have perused the report with interest, and that it is a valuable contribution to the literature on the subject. They concur with the Board in desiring that tours be undertaken as frequently as possible, and would be glad of any suggestions the Board may offer to that end.—*Madras Mail.*

LOCAL INDUSTRY.—In pursuance of their policy that it is expedient to encourage Indian industries, the Government of India have directed that the following shall in future be procured of Indian manufacture wherever possible, and when they can be supplied at rates no higher than those for which imported articles of the same quality can be obtained: namely "*Sundials*, the Government Workshop at Roorkee makes sundials, and no doubt they can be made at other establishments of a similar kind; *Sulphuric acid*, made in Calcutta by Dr. Waldie, and probably elsewhere; and *Alcohol*, made at all large distilleries and sugar factories."—*Madras Mail.*

COORG.—WE learn from Mercara that there is some probability of the planters securing a fair average crop of coffee this season in Coorg. It is hoped that the planters will not be disappointed as they were on a previous occasion. Coffee is not likely to turn out well in some of the producing tracts of the presidency owing to unseasonable rains.—*Madras Standard.*

FOOCHOW TEA.—Bad news from home has produced quietness here, (Foochow) and the week's settlements of Congou are less than half the total of the previous seven days. Teamen so far remain firm holders. It is understood that two fine "chops" of American Oolong have been sold, but the purchase has not yet been declared. Scented Orange Pekoes have sold on easier terms.—*N. C. Herald.*

COFFEE IN BURMAH.—The Government of British Burmah is making a laudable effort to put new life into the southern districts of the Province by offering liberal terms to intending coffee planters. The coffee industry would be certain to pay in these parts, if private efforts were wisely fostered by the administration, the chief necessity being a supply of labour, for lack of which many a fair enterprise in India has gone astray; as, for instance, the tobacco industry in the northern Aracan Hill Tracts. Labour is exported, with the sanction and by the favour of Government, in large quantities to Trinidad and Guiana; while all the time wide fields are lying vacant within the boundaries of British India.—*Pioneer.*

A RESOLUTION of the Bengal Government deals with the subject of the manufacture of paper from the fibre of the wild plantain stem. The Deputy Conservator of Forests, Sunderbunds Division, drew attention to the subject, which was referred to Dr. King for report. Dr. King, though he thought that the estimate of profit was too sanguine, expressed the opinion that the proposed industry had a good deal of promise about it, and recommended Government to send a trial shipment to London, to make the fibre known to English manufacturers. The Lieuteuant-Governor, however, considers the suitability of the wild plantain for paper manufacture so well established that it is not necessary for Government to initiate experimeuts. Private enterprise will, however, be liberally encouraged; and Government will, at the outset, and for a reasonable time, supply plantain stems free of cost to any mercantile firm or individual wishing to try such experiments in the Chittagong Hill Tracts or elsewhere in Bengal."—*Madras Mail.*

OOTY, 8th Augt.—Although we are having rain every day, the climate is milder than usual at this time of the year, which may be the reason that the *Acacia Dealbata* is coming into flower before its usual time. What a fortune might be made out of the trees if they could be transported to London; all the wants and necessities of Ooty could be paid for without stint or limit, for one little spray of this yellow blossom sells for one shilling in the great metropolis, or did do so a few years ago. The trees or shrubs, for I believe they are no more than shrubs, grow at Mentone and the South of France, and the blossom is carefully packed and sent to the London markets, where the feathery yellow blossoms and perfumes are thought much of as a green house plant in England. It does not exceed the size of a Fuschia or Geranium; it would be impossible to count the number of shilling sprays Ooty could send to market, but it seems that all things become possible in course of time; who would have thought some years ago that meat could be sent from America and Australia to London without being tinned, and yet we have lived to hear that frozen meat answers so well that the importation of it to London is likely to become general; perhaps we shall be able to sterify the acacia blossom some day, and send it to London without being withered in the transport.—*Madras Times.*

The United States wheat crop this year is estimated at 400,000,000 bushels, against 480,000,000 bushels last year. The stock on hand is now 41,000,000 bushels above this time last year, so the export surplus will not fall off to the full extent of the decline in the crop aggregate.—*Ibid.*

DEARTH OF POTATOES IN COLOMBO.—Potatoes have been at fourpence and sixpence a pound for the last fortnight. When will a fresh shipment arrive? Their proper price here is from five to eight cents per lb. according to the supply. What are up-country cultivators about?

GAMMIE'S SULPHATE OF QUININE.—The Calcutta "Englishmau" having inspected samples of the sulphate of quinine prepared in India by a new process by Mr. Gammie, and the crystalline febrifuge which the same gentleman has succeeded in producing, says :—"The sulphate of quinine appears in every respect equal to the best sulphate of quinine of commerce. A professional analysis shows it to contain, in every hundred parts, quiuine 76·88 ; sulphuric acid 11·62 ; water 11·50. The crystalline febrifuge is a sulphate of the whole of the alkaloids of the red bark, except the uncrystallisable amorphous alkaloid, which is believed to be the sole cause of the nausea produced in some coustitutions by the uncrystallised febrifuge hitherto manufactured by the Government. It is more granular in texture, and only slightly less white in colour, than sulphate of quinine, and, if it can be sold at a proportiouate price, will probably supersede the cinchona febrifuge. Arrangements are now being made to manufacture the sulphate of quinine ou a large scale, and it is hoped that it will be possible in a few years, to meet all the demands of the Goverument for this drug." —*Madras Mail.*

PLANTATIONS OF CASUARINAS have been largely cultivated in the neighbourhood of Madras for supplies of firewood to the railway, as well as to the city. An old Ceylon planter, Mr. MacIntyre, one of the triumvirate (Stewart, Brown and MacIntyre), who opened Glenapine and other Uva estates in the early days, was interested in this casuarina cultivation in the Madras district. The finest casuarina trees in Ceylon are probably those in front of the Galle Face Boarding-house, which newcomers from the "North Countree" have very frequently taken for Scotch firs. The timber of well-grown trees ought to be useful for other purposes than firewood, but the latter ensures a speedy return from quick-growing trees. To ensure success, however, it is needful that the plantation should be within easy reach of the railway or city. Mr P. O'B. Horsford, who is Superintendent of the Railway Firewood Supplies in the Western Province, is very confident that planters cultivating a regular plantation of quick-growing trees for firewood purposes at any spot not far from the line between Peradeniya and Nawalapitiya ought to find it a very remunerative speculation, the demand for firewood being greatly increased when trains begin to run up to Nanuoya. We are not sure, though, that the casuarina would be the best tree for up-country cultivation : it is certainly not likely to succeed in a paddy field, and apparently prefers dry sandy soil. Our Maturata correspondent will find that casuarina seed is procurable from the Director of Botanic Gardens at R 5 per ounce.

GLYCERINE.—We learn from the *Pharmaceutical Journal* that the price of refined glycerine has duriug the last two years advanced from about £30 to £103 per ton. This euormous advance is due partly to increased consumption, diminished production, and the influence of speculation working on a market devoid of stocks. In view of the present position of the article and the prospect of a continuance of high prices for a considerable time to come, the attention of soapmakers is now being turned to the utilization of their waste "leys," and various new processes for recovering the glycerine contained in these liquors have lately been tried with more or less successful results Apart from minor impurities, waste soap 'leys,' are generally found to contain glycerine, carbonate of soda or caustic soda, chloride of sodium, gelatin, and albumen. One of the processes for recovering the glycerine which promise to be the most economical and the most successful begins with concentrating the liquor until the salts contained therein begin to crystalize. The liquid is then cooled and filtered to rid it of gelatin and albumen. It is afterwards made to absorb carbonic acid, which precipitates bicarbonate of soda. and first is separated from the liquor in the usual way. After undergoing this process the liquor is then made to absorb gaseous hydrochloric acid until what remains of carbonate of soda has been converted into chloride, and further, until all, or almost all the chlorid of sodium has been precipitated and separated from the liquor in the usual manner. Arrived at this stage, the liquor contains water, glycerine, and hydrochloric acid. The acid is then evaporated entirely and absorbed in water for using afresh. The dilute glycerine remaining can be purified by filtering it through animal charcoal or by concentrating and distilling it in the usual way. Messrs. Price & Co., the well-known candle manufacturers, were, we believe, the first to utilize this formerly wasted product, the value of which has increased so enormously.

CINCHONA.—The following appears in the July number of the *Chemist and Druggist* :—"Cinchona is accumulating to a very large extent, the stock in the port of London amounting to over 37,000 packages. The point seems to have been reached when the supply can more than meet the demand, unless under very exceptional circumstances, and it is likely that a period of low price for quinine will now set in. At present, as will be seen, the prices for English and French manufacture are abnormally high in comparison with those for German make, in consequence of special contracts. It is quite certain that, for some time to come, the arrivals of the bark will continue to increase, and it is probable that the proportion of the imports rich enough in alkaloid to be worth working will also become larger. That a further reduction will result in the price of quinine, if no exceptional demand occur, is almost certain, and it may be considerable. Holders of South American barks, who have tried to maintain prices for some time and have refused to let their stocks go, have shown more inclination to meet the market, and the consequence has been more extensive transactions at declining prices. It must be noted that buyers at the last sales seemed more willing to do business, and the demand is evidently strong. As there is often a large market for quinine in the summer, a temporary improvement would not be suprising. One of the chief influences affecting the cinchona market has been the introduction of the so-called cuprea barks, which seem to be well suited for manufacturing purposes. These barks come from the State of Santander, in Columbia, and it is yet unknown, we believe, to what extent a supply from that source may be expected. The bark is named "cuprea" from its copper-looking appearance. Present prices for this bark vary from 1s. 10d. to 2s. 6d." Under the head "Cinchona in Africa" we are informed that a very interesting experiment is to be tried in West Central Africa by the members of the Livingstone (Congo) Inland Mission and that seeds of the different species of cinchona, which have been obtained from the Government plantations in India, are to be sent out to them with a view to ascertaining whether it could be successfully cultivated in the mountain valleys of the Congo."

PLANTAIN TREE.

(From the *Journal of the Society of Arts*, July 15, 1881.)

Mr. L. Liotard has prepared an elaborate memorandum on the plantain tree (dated Calcutta, January 22, 1881), of which the following is an abstract:—

Dr. Balfour,* in a note dated the 15th October, 1880, has noticed the Agricultural Department departmental memorandum on fibrous materials in India suitable for the manufacture of paper, and he specially directs attention to the chapter on the plantain tree. Many species of this tree, or rather plant, have been grown in India from the most remote times; but as a producer of marketable fibre, the only species which has yet come to note is the *Musa textilis* of the Philippine Islands: this yields the fibre known in commerce as Manila hemp.

The introduction of the *Musa textilis*, in 1858, direct from the Philippine Islands into the Madras Presidency, is described in the printed memorandum, where it is shown that attempts made to extract the fibre in this country for commercial purposes proved fruitless, although thousands of tons of it were being extracted every year in the Philippines.

There is no doubt that the Manila hemp plant (*Musa textilis*) grows as well in British India as other species of the plantain genus; and Dr. Balfour justly says, that British India could in a couple of years supply the London market with all that it could take of Manila hemp fibre. He therefore observes that the prospect of benefiting British India by creating an export trade from it of the extent and value above indicated might well incite to considerable efforts to attain success; and he suggests that the attention of the Boards and Commissioners of Revenue and of the Agri-Horticultural Societies might be re-directed to this plant.

It is known that the *Musa textilis* was reared with success in Calcutta as an experiment in 1822, 1836, and 1840; that fibre was extracted from the plants and made into a neat cord no way inferior to English whip-cord; and that a project was then put forward for the establishment of the manufacture of paper from the fibre; but we do not know how or why the project was not carried out. The projector, we learned, went to one of the British colonies in South America.

We know also that in the Madras Presidency the efforts to introduce the *Musa textilis* were of a more extended nature, beginning from 1858; that the trial planting proved very successful; that numbers of the plant were introduced and reared; that the fibres extracted therefrom were cleaned and experimented upon, and were found to possess considerable strength and gloss; to be very clean; and fit for taking dyes; also that success in the rearing of the plant was especially attained in the Wynaad, where it grew remarkably well and was multiplied in large numbers in several of the coffee estates both easily and cheaply; and that there was no doubt as to the value of the fibre, but that the efficient and cheap preparation of the fibre remained an unsurmountable difficulty.

In the Andaman Island also the plant was successfully reared and propagated, and fibre was extracted; but the process of extraction, which consisted in steeping the stem until decomposition set in, was probably a very bad one, and consequently the fibre, which was reported to be creditable in other respects, was found harsh and wanting in strength.

The experience gathered thus seems to point to the discovery of some satisfactory process for extracting the fibre cheaply and efficiently as the essential preliminary to any extensive Indian trade in the product. The mode of treatment followed in the Philippines may first be noted; the British Consul at Manila explained it as follows:

"When the trees have matured, or are ready for cutting, they are cut down about a foot from the ground, and the labourer then proceeds to strip off the layers from the trunk, which are cut into strips of about 3 inches wide, or say, three strips to each layer. These strips are then each drawn through between a blunt knife and a board to remove the pulpy vegetable matter from the fibre, which is then spread in the sun to dry. As soon as it has been thoroughly dried, it is ready for the market. The appearance of the fibre depends entirely on the care bestowed in drying it, as, should it be exposed to rain, or not thoroughly dried, it becomes discoloured, or assumes a brownish tinge, and loses the strength to some extent.

* * * * *

"As regards machinery, several attempts have been made, but have proved unsuccessful, to invent a suitable machinery for cleaning to supersede the primitive method still in use, which consists of a few cross and upright bars of bamboos, to which are fastened the board and cleaning knife, the fibre, or rather the layer of strips being introduced between the board and the knife, which latter is then held down by a string attached to a cross bamboo, on which the foot of the workman is placed, and the slip is pulled through, thus removing all the vegetable matter."

The annual quantity of Manila hemp which is extracted by this means in the Philippines is reported to be about 40,000 tons, of which the United Kingdom takes about half.

Whether any improved method of extracting the fibre be or be not discoverable, there does not appear to be any reason why the method of extraction followed in the Philippine Islands should not be adopted in British India, with any modifications which experience may suggest.

I have myself tried an experimental process, in devising which, I was guided by the considerations below explained.

The first of these was the structure of the plant. It is composed of layers of fibre united together longitudinally by cellular tissues which contain a very large percentage of mucilaginous and pulpy matter in which a strong colouring matter is present. There are in the layers of the trunk three distinct qualities of fibre—it is coarse and strong in the outer layers, fine and silky in the interior, and of a middling quality in the intermediate layers, while the central foot-stalk contains no fibre at all. The mid-rib of the leaves also contain strong fibre.

Secondly, the proper time for extracting the fibre. This is of importance if the fibre is ultimately to be used for cordage or textile manufactures, but of less consequence, perhaps, if the fibre be destined for paper-making. The proper time is when the purple fruit-stalk is about to rise, but has not quite appeared yet; it is then that the fibres are in their best condition: before that, the fibres will be immature, after that, they will have lost their strength.

Thirdly, the appearance of the fibre. All fibre is valued according to the degree of its cleanness, its tenacity, and its uniform structure; and if, in addition to these three qualities, the fibre is of fine texture, it will command a high price. It is thus necessary to classify the fibres. The easiest way to do this is, after the plant is cut down, to strip layer after layer from the trunk, each strip being about two inches wide, and to group the layers according to the fibres they contain, which will be found to present the features above noticed. The stripping is very easily effected by the hand with the help of a knife, and has the advantages of both securing uniformity in the fibres by classification and of facilitating their extraction, as will presently be explained. The mid-rib of the leaves should be slit into four parts to facili-

* See p. 16 of the *Tropical Agriculturist*.—ED.

ment at R1-8-0 per acre to such of the planters as may at once offer for it. As it is understood that the above terms generally meet the wants and wishes of the planters, His Highness the Maha Raja directs that the Survey Superintendent, in communication with the Deputy Commissioners of the respective districts, will at once take steps to carry into effect a settlement of the coffee lands on the above terms in the current year. The Survey Superintendent should, in communication with the Planters' Association and the Deputy Commissioners of Hassan and Kadur, submit a draft form of the title-deed to be issued to the planters.

2. It will be seen that the Government right to a royalty on metals and precious stones, to sandal, and to an excise duty on arecanuts is reserved, and that the lands will continue to pay the established local cesses.

3. The halat duty on coffee as well as on cardamoms will, on the introduction of this settlement, be abolished. In regard to cardamoms on Government forest lands which are not held on cultivation pattas, arrangements should be made for their being given out on rent annually or for longer terms.

4. Where the lower rates of assessment provided for temporarily by Rules 3 and 7 are fixed, planters will be allowed a permanent assessment at R1-8-0 per acre to take effect after the expiration of the temporary assesement, but their applications for the same should, as in other cases, be submitted at once.

5. If Rule 9 requiring that estates not exceeding fifty acres in extent should be relinquished wholly and not in part is found to operate with hardship in the case of the smaller coffee estates held by Native ryots, the Survey Superintendent should submit for consideration any modification of the Rule which may be required in the above cases.

USEFUL WRINKLES AND RECIPES FOR PLANTERS.

(From the *Indian Tea Gazette*, 16th July 1881.)

Fertilizer, A cheap.—This consists of sulphate of ammonia, 60 lb.; nitrate of soda, 40 lb.; ground bone, 250 lb; plaster, 250 lb.; salt, ½ bushel; wood ashes, 3 bushels; stable manure, 20 bushels. Apply the above amount to six acres. It is said to give as good results as most of the commercial fertilizers sold.

Bones, Value of, as a fertilizer.—100 lb. of dry bone-dust add to the soil as much organic animal matter as 300 lb. of blood or flesh, and also at the same time ⅔ their weight of inorganic matter—lime, magnesia, common salt, soda and phosphoric acid. Superphosphate of lime, commonly used by farmers, is simply bones treated with ½ their weight sulphuric acid and an equal quantity of water.

Sub-Soil Drain, A simple.—An excellent sub soil drain may be made by digging a trench, and filling in the bottom with sticks of wood compressing them together with the feet and then covering them with the mould. The effectiveness of such a drain will endure for several years, and the final decay of the wood will serve to enrich the soil.

Caterpillars, Remedy for,—A solution (1 part in 500) of sulphide of potassium, sprinkled on the tree by means of a hand-syringe, is extensively used in France.

Insects on Plants, To discover.—If the leaves of the plant seem reddish, or yellow, or if they curl up, a close inspection will generally disclose that the plants are infested by a very small green insect, or else with red spider, either of which must be destroyed. For this purpose, scald some common tobacco with water until the latter is colored yellow, and when cold, sprinkle the leaves of the plants with it. It is a good plan to pass the stems and leaves of the plants between the fingers, and to then shake the plant and well water the bed immediately afterwards; the latter operation destroys a large proportion of the insects shaken from the plant.

Stumps, Clearing off.—In the autumn, bore a hole 1 to 2 inches in diameter, according to the girth of the stump, vertically in the centre of the latter and about 18 inches deep. Put into it from 1 to 3 oz. saltpetre; fill the hole with water, and plug up close. In the ensuing spring take out the plug, pour in about ½ gill kerosine oil and ignite it. The stump will smoulder away, without blazing, to the very extremity of the roots, leaving nothing but ashes.

Trees, Felling.—To find the height at which a tree must be cut, so that its top will strike a given point on the ground: Square the height of tree and the given distance from tree to point. Divide the difference of these squares by twice the height of tree, and the quotient will be the height from the ground where the tree has to be cut. Example: Height of tree=60 feet, distance of point to the tree 20 feet, then $60^2=3600$, $20^2=400$, difference=3200. $3200 \div (2 \times 60) = 26.6$ feet.

Saws, Hints concerning.—A saw just large enough to cut through a board will require less power than a saw larger, the number of teeth, speed, and thickness being equal in each. The more teeth, the more power, provided the thickness, speed, and feed are equal. There is, however, a limit or a point where a few teeth will not answer the place of a large number. The thinner the saw, the more teeth will be required to carry an equal amount of feed to each revolution of the saw, but always at the expense of power. When bench-saws are used, and the sawing is done by a gauge, the lumber is often inclined to clatter and raise up the back of the saws when pushed hard.

The reason is that the back half of the saw, having an upward motion, has a tendency to lift and raise the piece being sawn, especially when it springs and pinches on the saw, or crowds between the saw and the gauge while the cut at the front of the saw has the opposite tendency of holding that part of the piece down. The hook or pitch of a saw tooth should be on a line from one-quarter to one-fifth the diameter of the saw: one-quarter pitch is mostly used for hard, and a one-fifth for a softer timber. For very fine toothed saws designed for heavy work, such as sawing shingles, &c., even from soft wood, one-quarter pitch is best.

ANENT TEA PLUCKING.—I have been trying to make very fine teas separately by the following means, viz., by plucking the tip and *one* leaf, and then as many leaves as were tender; I mean plucking the tip and one leaf separately, but putting all the leaf in one basket and then sifting it when half rolled. By doing this, when once the coolies get in the way of it, they can pluck nearly as much as by the ordinary system, and what little less they bring in is made up for by the advantage of being able to roll and ferment the fine tea by itself.—J. P. B.—*Indian Tea Gazette.*

EIGHT DAYS' LEAF.—Tea shoots are seldom plucked at less than 30, 35 and 40 days old at soonest, and occasionally 50; a shoot of 8 days' old is generally about ⅜th of an inch long, and the sort of crop we should get by this we can guess,—very "tippy" indeed, I should say. He has evidently heard the expression 8 and 10 days' leaf, *i. e.* time since last *plucking*, and imagines this the *age of the shoots* taken, but which then were part grown, but not mature enough to take. A shoot from the axil of a leaf just plucked, is about ¼ to ⅜ of an inch long 8 days after, at 20 days is about an inch long, at 30 days 3 inches, and 40 days 6 inches thereabouts; the sketch enclosed of a *vigorous* shoot 11 inches long and 5 leaves is 50 days from time it started till drawn.—S. E. P.—*Indian Tea Gazette.*

APHIS BLIGHT ON PEACH TREES.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—Could you kindly give a remedy for peach blight? My trees are covered with aphis, which, I believe, prevented them from bearing last year.—N. M. Corryong, June 27.

[Syringe the trees with an infusion of quassia chips. A pound of chips, which may be got for a trifle of the chemist, will serve for a long time. They may be infused again and again. Let the infusion be just unpleasantly bitter. In the event of quassia not being obtainable, employ soapsuds.—ED. "AUSTRALASIAN."]

COST OF MANUFACTURING TEA IN A HILL DISTRICT.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

SIR,—In reply to your request for figures showing the actual cost of manufacturing tea, I am able to supply you with the following as a sample of a Hill District.

The figures include only the cost of (1) Fuel and bamboo work; (2) Plucking; (3) Rolling; (4) Firing; (5) Assorting and packing.

They apply to a garden where labor is cheap, but this advantage would be balanced by the better and thicker flushes and smaller cost of plucking in a Regulation District. The plucking average here was about 3 seers per cooly per diem last year, and 5 seers per cooly per diem this year to 30th June.

It only remains to add that 1880 was an unusually good one.

1880—	As.	P.
Fuel and Bamboo work	0	2·30
Plucking	1	3·10
Rolling	0	3·80
Firing	0	1·20
Assorting and packing	0	3·20
Cost of manufacture per lb. 1881— ...	2	1·60
Fuel and Bamboo work ...	0	1·50
Plucking	0	10
Rolling	0	3
Firing	0	0·75
Assorting and packing ...	0	1·50
Cost of manufacture per lb. ...	1	4·75

Yours faithfully,
TWICE TWO.

DUAL SAP.

TO THE EDITOR OF THE "INDIAN AGRICULTURIST."

The treatment of coffee is what I will first take up. While accompanying a friend in charge of a coffee estate on the Neilgherries, I observed him plucking up the young shoots on which there were no flowers; and was told by him that by so doing the sap which went to their nourishment would tend to increase the size of the berries. This first led me to draw the distinction between the fruit and leaf-sap. It appears to me that as with the human being and animals so with plants; Nature changes its condition at the time for propagating its specie. The same nourishment tends to support blood and milk; yet no one would, I suppose, be so bold as to say they were synonymous. Good milch cattle will never be found to carry much flesh, hence the inference that the greater portion of nourishment taken is converted into milk instead of blood. Now I hold that with the change of seasons plants always take their turn, and that this period to them is like the seasons for propagation to human life, the same sustenance undergoes a different process by which fruit sap is created, and so long as it exists, it performs its functions towards supporting the fruit; but so soon as no longer required, ceases to flow as in the case of milk, and changes its nature into leaf-sap as milk does to blood. There could not be a better illustration than the mango tree, of a year when the pollen is destroyed. On examination, the leaves will be found covered with a coating of sugar-sap ejected from the flower. If Nature could utilise this sap in the support of leaf, is it likely that it would exhaust itself in the manner it does? You remarked that if this theory were correct, what would be the advantage to tea planters, in their removing the flower of the tea plant? This can easily be shown, the flower being removed which to the plant is like the young to the animal, the necessity for its nourishment ceases, thus the space occupied by the fruit-sap is taken up by that of the leaf, and a considerable portion of the time which would be spent in the fruit is devoted to producing leaf.

I have a theory of my own with regard to the cultivation of vine, which I should like much to have discussed.

E. A. C.

Hardoi, 26th June 1881.

TEA: HINTS CONCERNING THE INTERESTS OF PROPRIETORS AND PLANTERS.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

DEAR SIR,—I will try to shew proprietors of tea gardens, and those men who have not had any really *practical* experience in tea manufacture, what fools they make of themselves in the eyes of planters, by giving the said planters strict orders as to how they should manufacture their leaf (hoping that I may be of service to the said proprietors, and so open their eyes to see what a hole they are likely to fall into by doing so). I will also give them a few hints about management.

First, I ask any reasonable being—How can a man, who has never made tea, know what produces the various stages, such as *colour of infusion, darkness, of liquor, thin liquor, flat, soft, pungent, good or bad flavour, sourness, &c., &c.*, except from hearsay, and hearsay is what other people with the same inexperience as himself say. Now planters will not be astonished, but unpractical men will be probably, when I say that *each* of the above stages I have mentioned may *each* be produced from as many causes nearly. Unpractical men will say *dark infusion* is over-fermentation, practical men will say—"yes, it may be."

Unpractical men will say darkness of liquor is again over-fermentation, and the same answer will come from the experienced planter; and so on with *thin liquor, flatness, soft, pungent, flavory &c., &c.*

I now beg to say that *dark colour of infusion* may be produced, as far as I know, from six distinctly different causes, and without attending to and counteracting, &c., every one of them, a perfect outturn can never be obtained.

Darkness of liquor may be produced from 4 distinctly different causes.

Thin liquor ,, ,, ,, ,, 5 ,,
Flat and soft ,, ,, ,, ,, 3 ,,
Pungency ,, ,, ,, ,, 5 ,,
and many lesser and trivial causes.
Flavor ,, ,, ,, ,, 2 great causes and many trivial ones.

Then again we have appearance of tea to keep in mind, and the following terms are applied. *Much tip, black, irregular, curly, well twisted, open, shaggy, handsome, hairy, chaffy, brown, common, &c., &c.* All these can again be divided into as many other particulars.

Much tip the unpractical man will say is fine plucking. But planters know that this may be one

ment at R1-8-0 per acre to such of the planters as may at once offer for it. As it is understood that the above terms generally meet the wants and wishes of the planters, His Highness the Maha Raja directs that the Survey Superintendent, in communication with the Deputy Commissioners of the respective districts, will at once take steps to carry into effect a settlement of the coffee lands on the above terms in the current year. The Survey Superintendent should, in communication with the Planters' Association and the Deputy Commissioners of Hassan and Kadur, submit a draft form of the title-deed to be issued to the planters.

2. It will be seen that the Government right to a royalty on metals and precious stones, to sandal, and to an excise duty on arecanuts is reserved, and that the lands will continue to pay the established local cesses.

3. The halat duty on coffee as well as on cardamoms will, on the introduction of this settlement, be abolished. In regard to cardamoms on Government forest lands which are not held on cultivation pattas, arrangements should be made for their being given out on rent annually or for longer terms.

4. Where the lower rates of assessment provided for temporarily by Rules 3 and 7 are fixed, planters will be allowed a permanent assessment at R1-8-0 per acre to take effect after the expiration of the temporary assesement, but their applications for the same should, as in other cases, be submitted at once.

5. If Rule 9 requiring that estates not exceeding fifty acres in extent should be relinquished wholly and not in part is found to operate with hardship in the case of the smaller coffee estates held by Native ryots, the Survey Superintendent should submit for consideration any modification of the Rule which may be required in the above cases.

USEFUL WRINKLES AND RECIPES FOR PLANTERS.

(From the *Indian Tea Gazette*, 16th July 1881.)

Fertilizer, A cheap.—This consists of sulphate of ammonia, 60 lb.; nitrate of soda, 40 lb.; ground bone, 250 lb; plaster, 250 lb.; salt, ½ bushel; wood ashes, 3 bushels; stable manure, 20 bushels. Apply the above amount to six acres. It is said to give as good results as most of the commercial fertilizers sold.

Bones, Value of, as a fertilizer.—100 lb. of dry bone-dust add to the soil as much organic auimal matter as 300 lb. of blood or flesh, and also at the same time ⅔ their weight of inorganic matter—lime, magnesia, common salt, soda and phosphoric acid. Superphosphate of lime, commonly used by farmers, is simply bones treated with ⅓ their weight sulphuric acid and an equal quantity of water.

Sub-Soil Drain, A simple.—An excellent sub soil drain may be made by digging a trench, and filling in the bottom with sticks of wood compressing them together with the feet and then covering them with the mould. The effectiveness of such a drain will endure for several years, and the final decay of the wood will serve to enrich the soil.

Caterpillars, Remedy for.—A solution (1 part in 500) of sulphide of potassium, sprinkled on the tree by means of a hand-syringe, is extensively used in France.

Insects on Plants, To discover.—If the leaves of the plant seem reddish, or yellow, or if they curl up, a close inspection will generally disclose that the plants are infested by a very small green insect, or else with red spider, either of which must be destroyed. For this purpose, scald some common tobacco with water until the latter is colored yellow, and when cold, sprinkle the leaves of the plants with it. It is a good plan to pass the stems and leaves of the plants between the fingers, and to then shake the plant and well water the bed immediately afterwards; the latter operation destroys a large proportion of the insects shaken from the plant.

Stumps, Clearing off.—In the autumn, bore a hole 1 to 2 inches in diameter, according to the girth of the stump, vertically in the centre of the latter and about 18 inches deep. Put into it from 1 to 3 oz. saltpetre; fill the hole with water, and plug up close. In the ensuing spring take out the plug, pour in about ½ gill kerosine oil and ignite it. The stump will smoulder away, without blazing, to the very extremity of the roots, leaving nothing but ashes.

Trees, Felling.—To find the height at which a tree must be cut, so that its top will strike a given point on the ground: Square the height of tree and the given distance from tree to point. Divide the difference of these squares by twice the height of tree, and the quotient will be the height from the ground where the tree has to be cut. Example: Height of tree=60 feet, distance of point to the tree 20 feet, then $60^2=3600$, $20^2=400$, difference=3200. $3200 \div (2 \times 60) = 26.6$ feet.

Saws, Hints concerning.—A saw just large enough to cut through a board will require less power than a saw larger, the number of teeth, speed, and thickness being equal in each. The more teeth, the more power, provided the thickness, speed, and feed are equal. There is, however, a limit or a point where a few teeth will not answer the place of a large number. The thinner the saw, the more teeth will be required to carry an equal amount of feed to each revolution of the saw, but always at the expense of power. When bench-saws are used, and the sawing is done by a gauge, the lumber is often inclined to clatter and raise up the back of the saws when pushed hard.

The reason is that the back half of the saw, having an upward motion, has a tendency to lift and raise the piece being sawn, especially when it springs and pinches on the saw, or crowds between the saw and the gauge while the cut at the front of the saw has the opposite tendency of holding that part of the piece down. The hook or pitch of a saw tooth should be on a line from one-quarter to one-fifth the diameter of the saw: one-quarter pitch is mostly used for hard, and a one-fifth for a softer timber. For very fine toothed saws designed for heavy work, such as sawing shingles, &c., even from soft wood, one-quarter pitch is best.

ANENT TEA PLUCKING.—I have been trying to make very fine teas separately by the following means, viz., by plucking the tip and *one* leaf, and then as many leaves as were tender; I mean plucking the tip and one leaf separately, but putting all the leaf in one basket and then sifting it when half rolled. By doing this, when once the coolies get in the way of it, they can pluck nearly as much as by the ordinary system, and what little less they bring in is made up for by the advantage of being able to roll and ferment the fine tea by itself.—J. P. B.—*Indian Tea Gazette*.

EIGHT DAYS' LEAF.—Tea shoots are seldom plucked at less than 30, 35 and 40 days old at soonest, and occasionally 50; a shoot of 8 days' old is generally about ⅜th of an inch long, and the sort of crop we should get by this we can guess,—very "tippy" indeed, I should say. He has evidently heard the expression 8 and 10 days' leaf, *i. e.* time since last *plucking*, and imagines this the *age of the shoots* taken, but which then were part grown, but not mature enough to take. A shoot from the axil of a leaf just plucked, is about ¼ to ⅜ of an inch long 8 days after, at 20 days is about an inch long, at 30 days 3 inches, and 40 days 6 inches thereabouts; the sketch enclosed of a *vigorous* shoot 11 inches long and 5 leaves is 50 days from time it started till drawn.—S. E. P.—*Indian Tea Gazette*.

APHIS BLIGHT ON PEACH TREES.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—Could you kindly give a remedy for peach blight? My trees are covered with aphis, which, I believe, prevented them from bearing last year.—N. M.

Corryong, June 27.

[Syringe the trees with an infusion of quassia chips. A pound of chips, which may be got for a trifle of the chemist, will serve for a long time. They may be infused again and again. Let the infusion be just unpleasantly bitter. In the event of quassia not being obtainable, employ soapsuds.—ED. "AUSTRALASIAN."]

COST OF MANUFACTURING TEA IN A HILL DISTRICT.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

SIR,—In reply to your request for figures showing the actual cost of manufacturing tea, I am able to supply you with the following as a sample of a Hill District.

The figures include only the cost of (1) Fuel and bamboo work; (2) Plucking; (3) Rolling; (4) Firing; (5) Assorting and packing.

They apply to a garden where labor is cheap, but this advantage would be balanced by the better and thicker flushes and smaller cost of plucking in a Regulation District. The plucking average here was about 3 seers per cooly per diem last year, and 5 seers per cooly per diem this year to 30th June.

It only remains to add that 1880 was an unusually good one.

1880—	As.	P.
Fuel and Bamboo work ...	0	2·30
Plucking	1	3·10
Rolling	0	3·80
Firing	0	1·20
Assorting and packing ...	0	3·20
Cost of manufacture per lb. 1881— ...	2	1·60
Fuel and Bamboo work ...	0	1·50
Plucking	0	10
Rolling	0	3
Firing	0	0·75
Assorting and packing ...	0	1·50
Cost of manufacture per lb.	1	4·75

Yours faithfully,
TWICE TWO.

DUAL SAP.

TO THE EDITOR OF THE "INDIAN AGRICULTURIST."

The treatment of coffee is what I will first take up. While accompanying a friend in charge of a coffee estate on the Neilgherries, I observed him plucking up the young shoots on which there were no flowers; and was told by him that, by so doing the sap which went to their nourishment would tend to increase the size of the berries. This first led me to draw the distinction between the fruit and leaf-sap. It appears to me that as with the human being and animals so with plants; Nature changes its condition at the time for propagating its specie. The same nourishment tends to support blood and milk; yet no one would, I suppose, be so bold as to say they were synonymous. Good milch cattle will never be found to carry much flesh, hence the inference that the greater portion of nourishment taken is converted into milk instead of blood. Now I hold that with the change of seasons plants always take their turn, and that this period to them is like the seasons for propagation to human life, the same sustenance undergoes a different process by which fruit-sap is created, and so long as it exists, it performs its functions towards supporting the fruit; but so soon as no longer required, ceases to flow as in the case of milk, and changes its nature into leaf-sap as milk does to blood. There could not be a better illustration than the mango tree, of a year when the pollen is destroyed. On examination, the leaves will be found covered with a coating of sugar-sap ejected from the flower. If Nature could utilise this sap in the support of leaf, is it likely that it would exhaust itself in the manner it does? You remarked that if this theory were correct, what would be the advantage to tea planters, in their removing the flower of the tea plant? This can easily be shown, the flower being removed which to the plant is like the young to the animal, the necessity for its nourishment ceases, thus the space occupied by the fruit-sap is taken up by that of the leaf, and a considerable portion of the time which would be spent in the fruit is devoted to producing leaf.

I have a theory of my own with regard to the cultivation of vine, which I should like much to have discussed.

E. A. C.

Hardoi, 26th June 1881.

TEA: HINTS CONCERNING THE INTERESTS OF PROPRIETORS AND PLANTERS.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

DEAR SIR,—I will try to shew proprietors of tea gardens, and those men who have not had any really *practical* experience in tea manufacture, what fools they make of themselves in the eyes of planters, by giving the said planters strict orders as to how they should manufacture their leaf (hoping that I may be of service to the said proprietors, and so open their eyes to see what a hole they are likely to fall into by doing so). I will also give them a few hints about management.

First, I ask any reasonable being—How can a man, who has never made tea, know what produces the various stages, such as *colour of infusion, darkness, of liquor, thin liquor, flat, soft, pungent, good or bad flavour, sourness, &c., &c.*, except from hearsay, and hearsay is what other people with the same inexperience as himself say. Now planters will not be astonished, but unpractical men will be probably, when I say that *each* of the above stages I have mentioned may *each* be produced from as many causes nearly. Unpractical men will say *dark infusion* is over-fermentation, practical men will say—"yes, it may be."

Unpractical men will say darkness of liquor is again over-fermentation, and the same answer will come from the experienced planter; and so on with *thin liquor, flatness, soft, pungent, flavory &c., &c.*

I now beg to say that *dark colour of infusion* may be produced, as far as I know, from six distinctly different causes, and without attending to and counteracting, &c., every one of them, a perfect outturn can never be obtained.

Darkness of liquor may be produced from 4 distinctly different causes.

Thin liquor	,,	,,	,,	5	,,
Flat and soft	,,	,,	,,	3	,,
Pungency	,,	,,	,,	5	,,

and many lesser and trivial causes.

Flavor ,, ,, ,, ,, 2 great causes and many trival ones.

Then again we have appearance of tea to keep in mind, and the following terms are applied: *Much tip, black, irregular, curly, well twisted, open, showy, handsome, leafy, chaffy, brown, common, &c., &c.* All these can again be divided into as many other particulars.

Much tip the unpractical man will say is fine plucking. But planters know that this may be one

of the causes of which, as far as I know, there are 4 distinctly different causes.

Black.	There are I think	3	distinct and other trival causes.		
Irregular	,, ,, ,,	4	,,	,,	,,
Curly	,, ,, ,,	2	,,	,,	,,
Well-twisted or open	,,	4	,,	,,	,,
Showy, handsome, &c.		4	,,	,,	,,
Leafy, chaffy	,, ,,	3 or	4	,,	,,
Brown	,, ,, ,,	2	,,	,,	,,
Common	,, ,, ,,	4 or	5.	,,	,,

As it is impossible in some gardens which have not got the proper appliances and are deficient in labour force to carry out their manufacture exactly as they should like, many of the above causes have to be neglected to procure good tea. I will just mention a few, viz. *supervision, cultivation* and *plucking at too long intervals*; these are some of the main reasons. A man may not be able to give sufficient time for supervision, and thus many of the above causes have to be neglected in order to procure good tea; his insufficient labour force deters him from making tea of a good quality (it he is an honest man), otherwise he might make it off only a certain portion of the garden, and make it good by keeping a large staff in the tea-house, whilst in the mean time he is losing thousands of young seedlings in nurseries, or new planted out seedlings, for want of keeping them clean and not catching crickets, the ground they occupy not being a yielding area. Also he may have some low flats requiring draining, when a stitch in time would save nine, but as this area is also not yielding, it is also neglected, and only sufficient pluckers, cultivators, and people to supervise the best yielding portions of the garden are given, and all improvements sacrificed to the manufacture of good tea, which he has got the *hookum* to make, and which if he does not he will get the sack. Now I say this is false policy, and only done through ignorance on the proprietor's part. If owners will not leave their affairs in the hands of their trusted and tried planters, and abstain from giving strict orders, they must come to grief.

Now we come to look at another side of the question, viz., the interests of the planters themselves, how that affects the interests of the proprietors. I think it will be the exception (not the rule) where experienced planters are under terms of agreement, and in fact during the last two years comparatively few agreements have been given to any planters; on the contrary, a large number left the tea districts for want of employment. The remainder were, as a rule (I think I may say), willing to sign agreements, as their situations in tea were made very precarious. Now why did not proprietors give agreements? Simply because they themselves are desirous of making the planter's situation a precarious one. They take not the slightest interest in him, they think oh! we can easily get another man any time. But now if tea goes up, I am not so sure of that. When a planter is placed in such a precarious position by his employers, and does not know at what moment he may get kicked out, he will not endeavour to make himself comfortable or improve his garden. For the future he'll simply do what I have stated above, viz. sacrifice future pounds for the present pence; he loses confidence in his employers, and they distrust him, and the inevitable consequence is, that after a year or so, an entirely new man is substituted, because, as the proprietors will say. "latterly the garden has not done very well." Hoping these few hints may do good, and prove that many are unconscious of being penny wise and pound foolish, and also prove that nothing is lost by taking proper care of employer's interests,

I am yours,

Sylhet, June 1881. "FAIR PLAY."

ON THE BARK OF BROUSSONETIA PAPYRIFERA AS A MATERIAL FOR PAPER-MAKING.

Memorandum by D. BRANDIS, *Inspector-General of Forests, on the bark of Broussonetia papyrifera as a material for paper-making—dated the 29th November* 1880.

In a memorandum on the subject of the cultivation of bamboo for paper stock, dated 8th July 1875, I made the following remarks regarding the Paper Mulberry:—

In conclusion, it may not be out of place to draw attention to a tree which is grown largely in Japan as coppice wood on a short rotation similar to osier-beds, and which furnishes a large proportion of the paper stuff used in the country. This is the Paper Mulberry (*Broussonetia papyrifera*: 'Forest Flora of North-West India,' page 410). This tree appears to accommodate itself readily to different conditions of climate; it thrives in Western Europe, on the South Sea Islands, and in Siam, and there seems every reason to believe that its cultivation may succeed in North-West India. I know of few trees more promising (in a suitable climate) for the supply of paper stuff on account of its free and rapid growth and the abundance of its fibre.

In the report on the progress and condition of the Royal Gardens at Kew during the year 1879, just received, the following passage regarding this subject occurs:—

Broussonetia papyrifera.—'The bark of the well-known Paper Mulberry supplies the material from which the tappa cloth of Polynesia and the bulk of the paper of Japan and China is manufactured. The Japanese cultivate the plant very much in the same way that we grow osiers, and they use only the young shoots for the manufacture of paper. A sample of the bark, which came into the hands of Mr. Routledge, is stated by him to be 'nearly if not quite, the best fibre I have seen.' * * * 'I must admit it is even superior to bamboo.' * * * 'It requires very little chemicals, and gives an excellent yield—62·5 per cent in the grey, *i.e.* merely boiled, and 58 per cent bleached.' The tree is indigenous in the Upper Salween forests of British Burmah, and as soon as reserves have been demaracated in that district, and officers placed in charge, efforts should be made to establish regular plantations. In March last I visited, on the banks of the Maytharouk River, a settlement of paper makers from Siam, engaged in making the well known snow-white paper, which is sold in the bazaars in Burmah. The procedure is of the simplest character, and the great advantage of this fibre is that it is white naturally, and that it is readily cleaned. It should also be cultivated as an experiment by forest officers at other places in Burmah, in forest gardens, or regular plantations. And I would recommend that it be tried at the Sitapahar and Ramanpokri Plantations in Bengal, at Shillong, and at the Kulsi Plantation in Assam. It is not impossible that it will be found to succeed elsewhere in India, for the trees thrives in Western Europe where it stands frost and snow, in China and Japan, and on the South Sea Islands.—*Indian Forester.*

USEFUL GARDEN RECEIPTS.

(*From Hogg's Gardeners' Year-book.*)

PETROLEUM *vs.* AMERICAN BLIGHT.—I have been able to almost entirely get rid of that pest to my apple trees, American blight. Last year the trees were completely covered, but after the fall of the leaf I had them carefully dressed with petroleum, which was applied to the affected parts with a paint brush. Contact with the petroleum seemed to destroy the insects, and I was in hopes they had entirely dis-

appeared. This summer, however, there have been signs of them again, but whenever the blight makes its appearance, an application of the brush dipped in petroleum at once extinguishes it. The contact of the oil with the leaves and fruit buds apparently does no injury, and I see that with a little patience and perseverance, my trees, which were in a fair way for being ruined, can be preserved.—E. B.

To CLEANSE FRUIT TREES OF MOSS.—Not only the mosses and lichens which so generally affect fruit trees, but the eggs of insects may be effectually destroyed by dressing the trees in winter with a wash composed of a saturated solution of soft soap and common salt or brine. The trunks and large branches ought to be first scraped with a scraper made of old hoop or any other implement that may be improvised for the purpose, and when all the scales of bark are removed, apply the mixture with a painter's brush, working it well into the crevices. This is much preferable to, and not so unsightly as, washing with lime.

To DESTROY GRASS AND MOSS IN PAVEMENTS AND WALKS.—Dissolve 1 lb. of powdered arsenic in 3 gallons of cold water, boil and keep stirring; then add 7 gallons of cold water and 2 lb. of crushed soda, stir the whole well whilst boiling, and with a rose watering pot apply to the walks in dry weather, from March to May inclusive, being the best time. The above quantity will be enough for 25 square yards. An inclining board should be placed at the sides of the walks or grass to keep off the hot liquid. Salt will destroy weeds for a time. If you have box edgings, the salt or the soda and arsenical solution above-named must be kept from them, otherwise they will be killed.

To REMOVE WORMS FROM LAWNS AND POTS.—Half an ounce of corrosive sublimate (bichloride of mercury) dissolved in 15 gallons of water will cause worms to come to the surface; but care must be taken that fowl do not eat them, otherwise they will be poisoned. A peck of freshly made quicklime mixed with 40 gallons of water, and allowed to stand till it clears, it applied through the rose of a watering-pot will have the same effect. These mixtures may also be used to remove worms from flower pots.

ORCHIDS FOR AMATEURS.

(From the *Country Gentleman's Magazine.*)

DENDROBIUMS rank among the very finest of all orchids. Most of the species which we named in the March number of the *Villa Gardener*, will grow well in the warm end of a Cattleya or intermediate house. They may all be grown either in pots or baskets, but those most fitted for basket culture are Chrysotoxum, Densiflorum, Devonianum, Parishii, Pierardii, Thyrsiflorum, and Wardianum. The others do fully as well in pots. Strong-growing kinds should have a good depth of material to root in such as nobile; weak rooters, such as Parishii, should have but little material.

The two great secrets in the successful cultivation of the Dendrobium are a decided season of growth and a decided season of rest. This is best secured by affording a pretty brisk heat from the time the growth commences, until it is fairly finished, and then the plants should be kept comparatively cool. During the growing season a plentiful supply of water is necessary, and during the resting period only just as much as will prevent shrivelling. It is only by such treatment that *D. nobile* can be made to yield a profusion of flowers. By keeping the plants warm and moist they go on growing, but flower only sparely; but by the opposite treatment abundant floriferousness may be had. The evergreen kinds should not be kept quite so dry as the deciduous kinds. During winter the baskets in which these are growing should be damped weekly with the syringe.

DISA GRANDIFLORA.—This is a very fine cool-house orchid, and when there is only such a house as we have recommended, it should be put in the coolest position possible, and near to a ventilator, for it must be borne in mind that too great a heat is against the plant's well-doing. The ordinary orchid mixture will suit it well. Some growers add a little very fibry loam, but we cannot say that it does better in it than in the ordinary mixture.

LÆLIAS.—Anceps and Autumnalis should be in the smallest collection. Anceps does best in pots, but Autumnalis requires a basket or a block. Both thrive well in moss and charcoal, and a fair supply of water, while growing, especially if they are on blocks. Both are winter-flowering plants, and require a good season of rest after they have flowered. Re-potting, basketing, or blocking should take place just before new roots are pushed in spring.

LYCASTE SKINNERI is a real gem for an amateur. There are many varieties, but all are good. Its main requirements are:—The cool end of an intermediate house or warm end of a cool one; moss and charcoal, with a little fibry peat, plenty of water while growing, and moderate dryness while at rest. Scale is apt to trouble it, but the use of the sponge will keep it under.

MESOSPINIDUM VULCANUM and sanguineum are two neat, free-growing plants which freely produce elegant spikes of sanguineous flower. Both are easily cultivated.

MILTONIAS are good, free growing, free-flowering orchids. The cool end of the house, and a couple of inches of material to root in; steady moisture and shade from sun will secure success in their cultivation.

TOMATOS FOR THE MILLION.—Mr. John Hepper, formerly gardener at The Elms, Acton, and who has long enjoyed a good reputation as a successful cultivator of the Tomato, is now illustrating in a remarkable degree at Mr. Hawkins' Floral Nursery, Haven Green, Ealing, the capacity of well-grown plants to produce large quantities of fine fruit. In a span-roofed house of 216 feet in length there are growing 400 plants, 200 on each side, planted in a bed of soil resting on somewhat narrow wooden and slate shelves. The house is warmed solely by solar heat; the plants, which represent a good type of the large red Tomato, were raised from seed in March, and planted out at the latter part of April. Layers of turf were first of all laid on the shelves, and on this was placed a compost formed of good fibry loam and dung, and in this the Tomatos were planted. In it they have made a very robust growth, the plants average 3½ feet in length, but with stems of remarkable stoutness. They are trained straight up to the roof, and the laterals are kept thinned out. Already the plants are producing ripe fruit; as soon as they begin to show signs of colouring they are picked off and ripened on shelves. One remarkable feature of the plants is their short-jointed growth, and Mr. Hepper calculates there are eight joints to the yard, and that the plants, after thinning, averaged eighteen fruit to the foot run. And such fruit too—large, symmetrical, and highly coloured. Let it be remembered that the shelves are narrow, and that the depth of the bed of soil scarcely exceeds 6 inches. As the roots find their way to the surface a little fresh soil is added, and copious waterings are given. The bunches are thinned out to about nine fruits by removing all the malformed ones. Mr. Hepper confidently predicts a great weight of fruit from this house, and its appearance justifies his expectation. With constant attention and careful cropping, Mr. Hepper hopes to gather fruit up to Christmas. There are also four smaller span-roofed houses planted in beds for a latter crop, but the plants are similarly trained. These houses give another 500 plants, and it is believed each plant will produce on an average fifty fruits. With such productiveness, good Tomatos should be within easy reach of the million. —*Gardeners' Chronicle.*

MASKELIYA, 17th Aug.—I send you two coffee roots. Can you tell me what the white fungus or insect feeding on the rootlets is ? [The little white patches on the coffee roots are mealy or white bugs. A description of the bug *(Pseudococcus adonidum)* will be found in Nietner's "Coffee Tree and its Enemies," page 5, second edition. —ED.]

AGRICULTURAL EDUCATION IN SCOTLAND.—As noticed in these columns two weeks ago, the Highland and Agricultural Society of Scotland resolved on the 15th of June to memorialise the Lords of the Committee of the Council on Education, expressing the desire that existed in Scotland to have the teaching of agricultural sciences included in the subjects taught in the board schools throughout the rural parishes. The secretary of the Highland Society accordingly, having communicated the resolution to the Education Department, Whitehall, Londou, has received the following favourable reply :—"Scotch Education Department, Juue 27, 1881. Sir,—I have the honour to acknowledge the receipt of your letter of the 23rd inst., which I have submitted to their lordships. I am directed to request that you will inform your society that my lords are fully alive to the importance of the subject which has been brought under their notice by your letter. They have had under special considerationu arrangements by which encouragement will, it is believed, be given to the study of the principles of agriculture in the schools under inspection, and they trust that these arrangements, when finally settled, will be found to go far to meet the wishes of the society.—F. R. SANDFORD."—*Field.*

THE GUAVA AND THE BEETLES.—I noticed another curious fact, in the same strain, in that same island of Luçon. The common Guava, undoubtedly imported from America by the Spaniards, has run wild there like the Lantana Camara in Ceylon, and is very fast invading the grassy savannas of the interior, probably through the agency of the pigs scattering broadly the undigested seeds. Well, if there is a true Malayan type of beetles it is the Pachyrhynchi, a tribe of Curculionidæ, whose gorgeous metallic colouring cannot fail to attract the eye of the least attentive observer. I was at the time doing a little bit of beetle collectiug just for the sake of the sport and for pleasing friends, and from several hundred specimeus of Pachyrhynchi, in about fifteen species I caught, all but half-a-dozen were found on the Guava bushes, where they looked settled and at home; the few others were stray individuals, distributed by some cause and trying to regain their favourite haunts. What did they feed upon before the introductiou of the Guava ? By-the-bye these weevils mimic wonderfully some spiders. so much so that it struck even my Tagal servant who, after a while, took readily to beetle hunting, and used to call them "spider-beetles," but then you must see them alive and not pinned down in a drawer.—*Gardeners' Chronicle.*

OSTRICH FARMING IN CAPE COLONY.—From time to time there appear in your widely read paper communications, as well as reviews on books, relative to ostrich farming. Advertisements are often inserted with a view to obtain the investment of the young Englishman's moneys in birds, and as an inducement a calculated return of 50 per cent is held out to him. That 50 per cent, and even more, has beeu obtained annually as interest accruing from money invested in ostriches, there can be no gaiusaying; however, that such a handsome return is uot withiu the reach of "prentice hands" would probably soon become apparent to the investor, and he would find that he had been building his hopes on "fancies as twinkling and vague as the stars." In any case, such a high percentage is the exception rather than the rule. Ostrich farming, properly conducted, is certainly lucrative; but my advice to young men coming from England to this colony is—first, to gain experience and a knowledge of the relative value of birds before investing their money in them. It is only natural that the ostrich farmer will fancy his own stock, and fix a high price when offering it for sale. As there are public auctions and sales of birds very frequently, there would be no difficulty in ascertaining the market value of ostriches, and opportunities would offer of judging of the merits of their feathers. Experience in colonial ways, and amongst birds, are necessary preliminaries before investing. If this plan is adhered to, the investor will have no cause to regret having gone in for birds; but, on the other hand, a hasty investment will certainly not meet with such happy results. In fact, the former procedure will in all probability conduce to give an impetus to ostrich farming, and be beneficial to the whole ostrich-farming community; whilst in the latter case a few interested individuals will be the only gainers; ostrich farming will get into bad odour in the old country, and thence the enterprise will suffer.—GYPOGERANUS SERPENTARIUS (Cape Colony, May 24).—*Field.*

NOTES ON CASSAVA GROWING IN SUMATRA.—The following extract from a letter from a planter in Sumatra affords a little novel information. In reply to your question of the probability of Cassava paying in Ceylon, and its cultivation out here, I can only give a very outline reply, as to go fully into the subject of Cassava cultivation would require a lecture of considerable length, and which I fear I have not the time at my disposal now to undertake. I will however speak of one thing that will give you an idea of the capital required to work Cassava profitably. The first outlay is in machinery and buildings, as they are the chief expense, on one place here they cost $ 185,000, so that you see for such an outlay in mills, a very considerable acreage is required to make it pay. Then again Cassava wants any quantity of manure, as it cannot be profitably cultivated without. The plant literally grows on a muck heap, dead dogs and horses cut in pieces are often added with advantage besides lime, cattle manure and bones, heaped in ridges or mounds, before the slips are planted. These are put in 2 feet by 3 feet apart, the ground being previously manotied up. Roots are not dug up before 18 months, but plants must be so planted that sufficient may be uprooted each day throughout the year to feed the mills in proportion to the capacity of driving power of the steam engine, and the number of cooking pans. hands, and tanks. Tapioca requires a large tract of land, as the soil so soon gets exhausted. A 1,000 acres is a fair estate and some have that nearly under cultivation. The market is London, but greatly influenced by Tapioca coming from Rio and the Brazil, so I think it could not be profitably cultivated especially as laud costs so much more in Ceylon than here. I fiud that Johore, where I was going first, is rather a snare and a delusion than otherwise. The place is very sickly, and unless one can breathe in a miasma, and has a very good situation arranged for him, I should not advise his going there. If your friend is still thinking of going, advise him not. The Maha Raja does not carry out his promises, and at present every one there holding coffee land is looking on at the few adventurers. By and bye when more land is opened up, the place may be a prosperous country for capital, especially to those who now hold land at $ 1 per acre for 99 years. Advertisements, as you are aware, I have found out in other parts of the world, are only flaunted to catch the odd thousands of adventurers and speculators, but are not to be believed in by hard working poor planters. People here get commissions on produce in addition to salary, so they live on their screws and lay by the commission, as something to fall back upon.—*Ceylon Times.*

PITA OR AGAVE, COMMONLY CALLED ALOE.

HINDEE, *Cantala*; TAMIL, *Petha-kala burtha*.

This species of agave, commonly called aloe plants, are natives of America, which have become so naturalized in many parts as to appear to be indigenous in Africa, India, and the coasts of the Mediterranean.

So much is the latter the case, that some authors take this American plant to be the aloe wood mentioned in Scripture. But there is not the slightest foundation for this opinion, nor indeed for the true aloe plants of which the agaves so frequently assume the name. The aloes wood of Scripture is the ahila wood of the east, so famed for its fragranee, yielded by *Aquilaria agallochum*.

The agave plants, to which the name of American aloes is so frequently applied, resemble the true aloes in their sword-shaped leaves with parallel veins, which, however, grow to a gigantic size, that is, from eight to ten feet in length, in a cluster from the root, with their margins usually armed with short thorns, and their points with a hard and sharp thorn. This makes these plants so useful in the construction of hedges, a use to which they are generally applied. These plants come to perfection in about three years, they do not flower for eight, and in some situations perhaps not for twenty years, when they throw up a tall candelabra-like flower stalk. This has no doubt given origin to the fable of their flowering only once in a hundred years. It is the leaves of these plants which abound in fibres of great length and of considerable strength. Being also tough and durable, they are separated for the purpose of making string and rope, not only in their native countries but also in those into which they have been introduced. The roots as well as leaves contain ligneous fibre, "pita thread," useful for various purposes. These are separated by bruising and steeping in water, and afterwards beating, practices which the natives of India have adopted either from instructions or original observation.

The Mexicans also made their paper of the fibres of agave leaves laid in layers.

The expressed juice of the leaves evaporated is stated by Long, in his "History of Jamaica," to be useful as a substitute for soap. The fibres of the agave leaves is in Mexico converted into twine, cord, and rope, the last used in mines and the rigging of ships.

"Humboldt describes a bridge over the river Chambo, in Quita, 131 feet in span, of which the main ropes, four inches in diameter, were made of the fibres of the agave, and upon these ropes the roadway was placed."

In the West Indies the negroes make ropes, fishing nets, and hammocks, of agave fibre.

The fibre is thus prepared: the longest and most useful leaves being cut off are laid upon a board and scraped with a square iron bar, which is held in both hands, until all the juice and pulp are pressed out, the fibres only remaining. In Portugal, Spain, and Sicily, the fibre is applied to various purposes. Pita fibre is extensively used in South America for even large-sized rope.

The name pita seems to be also applied to similar fibres obtained from species of bromelia, yucca, as well as agave. The weight of pita fibre being one-sixth less than that of hemp, the difference would be very considerable for the entire rigging of a ship and produce a sensible reduction in the top weight, and thus increase the stability of the hull.

The agave grows well on the north coast of Africa, and its fibre has been paid much attention to by the French since their occupation of Algeria.

When fodder is scarce, cattle will eat the younger leaves when cut into transverse slices.

A cloak and paper made of this fibre were sent to the Exhibition of 1861, and ropes have been made of the fibres, showing considerable strength.

The agave or pita fibre being so extensively employed in different parts of the world, there is no doubt that it will become a valuable culture in India. It was probably introduced into India by the Portuguese. The species *A. vivipara* seems to be the same as the *A. americana* of Roxburgh, and *A. cantala* had also become naturalized.

In our cooly districts of Southern India it is very abundant, and the method they use in preparing the fibre is very simple. The leaves are pressed between two horns and the pulp washed away. The agave will grow in dry climates and poor soil, and is most suitable to plant in waste and abandoned coffee land. A report published by the Agricultural Society of India some years ago on the aloe fibre manufactured at one of the jails shews the following results:—

Aloe fibre rope 1 fathom long and 3 in. in circumferenee broke in a weight of ... ... lb. Troy 2,519½
Coir do. do. do. do. ... ,, 2,175
Country hemp do. do. do. do. ... ,, 2,269
Jute do. do. do. do. ... ,, 2,456

In a trial made at Paris between ropes made of hemp and of the aloe from Algiers, the following results were obtained, both being immersed in the sea for six months and exposed to the atmosphere for the same time:—

Pita.	Weight supported.	Hemp.	Weight supported.	In favour of Pita.
	lb.		lb.	
Plunged in sea...	3,810	Plunged in sea...	2,538	1,272
Exposed to air...	3,724	Exposed to air ..	3,622	702

These experiments prove that the pita fibre is possessed of very useful properties. "Another product," I trust soon to see it quoted in our commercial list.

J. A.

TEA AND SILK FARMING IN NEW ZEALAND.

TO THE EDITOR OF "THE COLONIES AND INDIA."

SIR,—Your interesting paper having been brought under my notice a few days ago as a valuable medium for the discussion of Colonial affairs, I hasten to acquaint you with a suggestion referring to New Zealand, which is at present being critically examined here, in England, in India, and at the Antipodes. The proposal is to commence tea and silk farming as a combined industry in Auckland, and I am encouraged to submit the scheme to your readers partly on account of the favourable reception it has already met with, and in the hope of eliciting every shade of opinion, so that the undertaking, if generally approved, may be speedily brought to a practical issue.

I shall not occupy your space with the reasons which have led to the selection of New Zealand as the scene of the experiment—these having already appeared in the pages of the *Glasgow Herald*, *New Zealand Public Opinion*, and *Chambers' Journal*—but shall simply epitomise the chief points of the projected design.

A comparison of the aptitude of different Colonies for tea and silk culture with the advantages known to exist in the countries to which these important products are indigenous has resulted in the belief that the province of Auckland offers most, if not all, of the required facilities. Accordingly, the formation of a public company, to commence and prosecute the combined industries, has been for some little time and is now being advocated. The special objects to be accomplished are:—

1. The acquisition of a tract of perhaps 30,000 acres in New Zealand, for the purposes partly of a Land Settlement Association, and partly for the inauguration and prosecution of tea production and sericiculture.

2. The affording of pleasant and remunerative employment to women and girls.

3. The attraction of the aborigines to systematised habits of usefulness.

It has been suggested that the proposed tea and silk farming operations should be conducted somewhat as follows:—An expanse of say 3,000 of acres suitable land having been selected, the area to be gradually planted with tea and mulberry shrubs at the rate of 100 or more acres of each per annum, according to the capital subscribed. Meanwhile other lucrative articles of commerce, such as grapes, oranges, lemons, small fruit, honey, sugar, &c., might have portions of the estate assigned to their special production, most of them yielding a more encouraging return generally than that from ordinary farming. During the time the tea and mulberry bushes were maturing, the former in four years and the latter in two years if transplanted when two years old—no income from their produce would accrue; but these periods would be partly employed in erecting the necessary buildings, digging, and arranging waterservices, fixing water-wheels, erecting the machinery required, and extending the cultivation and development of the whole estate. In the course of the second year, the first of the mulberry leaf crop would be ready for plucking, when, all being in a state of preparation and wages moderate, a return in cocoons, raw silk, and grain, of probably £80 per acre might be anticipated. It may not be out of place at this point to mention that, considerable as this estimate may appear, it is dwarfed by the average returns from agriculture in America—which are sometimes £93 per acre for honey alone—and from oranges in New South Wales, where certain groves possess individual trees which for twenty years have yielded three hundred dozens of oranges each, showing a gross return of £500 per acre per annum. Indeed, the experience of mulberry-growing in other patts of the world teaches that well-situated and thoroughly-cultivated areas of twenty-five-year-old bushes double their yield after five years *in situ*, when, of course, the harvest of cocoons may be double also.

Until the fourth year, as already stated, there would be no appreciable return from the acreage under tea, but during that season leaf-gathering would commence, which, according to Chinese and Indian observation, would annually improve up to about the twelfth year, when renewals of the plants might be required. Tea-growing at the Antipodes not having yet been attempted on a commercial scale, it would be premature to hazard an opinion as to the probable return per acre from this source. But having regard to the very suitable climate offered in Auckland, especially for teas of the China and Japanese type; recollecting that the demand on the spot is at present about one and a half million lb. per annum, with a constantly increasing tendency; and keeping in view the circumstance that New Zealand-grown tea would not be saddled with the expensive items of inland conveyance and freight to a distant country, which handicap the products of China, India, and Ceylon, experts who have studied the matter are of opinion that, after allowing liberally for higher-priced labour, the cost of producing tea in this Colony will probably compare most favourably with the outlay elsewhere.

One of the early effects of the prosperous initiation of tea and silk farming would be the immediate influx of the numerous kindred professions, arts, and trades which in older communities are invariably found clustering around the chief centres of important industries. To accomodate these, the surrounding land would become available, and the farmers, labourers, and others would provide food for the Colony, and furnish a supply of reliable outdoor labour for emergencies.

I have no hesitation in appealing to the philanthropists of both sexes throughout the British Empire in favour of the proposal to employ women and girls of education in some of the more delicate manipulations connected with the production of both tea and silk. Every year numbers of delicately-nurtured and well-educated females are, through death, misfortune, or other causes, left destitute. Many of these ladies, although unable perhaps to support themselves becomingly at home after a crisis, would prove valuable assistants in the operation of tea and silk culture in one or other of the Colonies, and in such service find a comfortable and independent refuge. "They know nothing about the management of either product," it may be urged. True, perhaps, yet they might learn. It so happens that the opportunity of gaining instruction in the mysteries of at least the silk industry from ladies like themselves may very soon be brought within reach. Along the Levant, silk in its various forms is largely produced under purely domestic circumstances by many respectable European ladies, who, I am told by an eminent authority at present in London, "piece out a subsistence by this occupation." Among these ladies it is believed there are some English widows with daughters, left with small means, who would doubtless be only too glad to go to New Zealand among their countrywomen, and give practical lessons in their interesting avocation.

There are many points connected with the proposal as a whole, which would require more space than I could expect any journal to afford for their elucidation. Enough has perhaps been said for the present, however, to extend the feeling of interest in the enterprise which has already been created, and I shall be happy to reply to any *bona fide* enquiry concerning it which may be addressed as below.—I remain, &c.,

July 21. WILLIAM COCHRAN.

THE CULTIVATION OF BAMBOO.

(From the *Indian Tea Gazette*, 6th August 1881.)

Happening to take up the *Indian Agriculturalist* for 2nd June 1879, containing the report of a meeting at the Society of Arts on March 7th, 1879, I could hardly believe my eyes as I read therein the opinions of some of the speakers. The exhibition of so much ignorance, by earnest men met to discuss and forward an economic question of moment, was humiliating, and Mr. Routledge himself seemed as much in the dark as any of them.

At page 200 he says: "The young bamboo sprang from the seed of the old plant, and it took about 15 years before it became silicious. No matter what species it might be, it went on maturing for a series of years, and being an eutogenous plant, it grew until the inside got filled up and it could grow no longer. It could then no longer transmit the sap, its pores or vessels became ossified, like the veins of an old man, and it died having first seeded." Now there are some 14 or 15 kinds out here in Eastern Bengal that I know pretty well, have planted Baries and cropped them for some 12 years, yet I must say there is not one single statement in the quotation that is accurate, even approximately.

The Bamboos here vary greatly in kind, in size, modes of propagation, in value, &c., but taking the most common and most useful one, the "Jati" (or one with best jât) let us compare notes. 1st.—It does not seed, and is propagated, like most others, by a young root and piece of stem 8 or 10 feet long transplanted. 2nd.—These stocks are of young and not "old plant." 3rd.—The Bamboo generally becomes

silicious (?) at 2 and 3 and not 15 years old. 4th.—All species do not take a series of years to mature; some mature in 2, others in 6 to 12 years. 5th.—The Bamboo attains generally its full height, girth and thickness of walls in 1 year, and the latter do not grow thicker and thicker yearly, and eventually cause death.

One gentleman—Mr. Cobb—stated that the Chinese "let some grow so large that they make buckets of them," as we might say of a knowing fellow who let his pony alone so as to grow into a horse! This applied to the "Ming" Bamboo of the Nagas, a peculiar species, and if anything larger when young than when old. These I give as samples of the facts guiding (?) the meeting. It seems to me the best thing Mr. Routledge could have done would be to pick out some 2 or 3 of the most likely kinds, clumped or gregarious, cultivated or wild, and have learnt all about them. Instead of this, stray facts, relating to perhaps a hundred species, have been collected, mixed, and poured out, resulting, as we might guess, in a nice *mess*. Undoubtedly there are enormous areas all through the hill tracts of Eastern Bengal where the Bamboo grows rampant, and could supply the demand until it was systematically *cultivated* for fibre, and this, I take it, is the object in view. Now the leading fact in this case is one that Mr. R. seems not to have grasped, and may account for the divergence between him and Dr. King, *i. e.*, that the most likely cultivated kinds do not propagate by *seed* or from *old* stems, but shoot up from the very kind he wants to cut] away, *i. e.*, the *young* stems; cropping the young stems (from which alone pulp should be made) cripples the propagation. What he needs to leave is what he also wants to take away: a case of eating his cake and yet having it. Even if he takes but a few here and there, it is still the same in the end: what he gains in crop for fibre, he loses in propagation, and this in the cultivated kind is no small difficulty. This is Mr. Routledge's particular nut, and not an easy one to crack, you would say, if you knew the facts thoroughly. As it bears on this matter—but also because it may be of use to so many of your readers—I will describe shortly the way to plant a Bamboo Bari. Firstly, the site should be above swamp level, and secondly, near enough to the station to be watched, so as to keep out pigs, cows, elephants, and *thieves*. If grass land, it may be cleared and burnt, though this is not absolutely necessary; if forest, it should be cleared, and then the lines laid out about 20 or 24 feet apart, and holes of 2 feet × 2 dug about every 12 or 16 feet in these rows, each hole to take 2 or 3 root stocks. If Jati Bamboo is to be planted, the root-stems of young ones should be selected, say of one or at most 2 years old, and which can be known by the white band round the stem just above each joint. The root should be carefully bared and the stem cut above it at 10 or 12 feet, foliage left on. When dug out the stem and root will look like the letter J., and care should be taken not to injure the eyes on the lower bent part, as it is from these (3 or 4 on each side) that the future Bamboos shoot. February or March is a good time, and the early rains in April will prevent these stems drying up. It is a good way to plant these root stems slightly inclining outwards, and have them well tamped in, with some rubbish thrown over as shade for the ground. In the Kachari country and from Borpettah past Nol Bari, Komalpur, and Darang, where there is no building timber, fine Bamboo Baries are seen, and in many cases a large square of an acre or so has the outer rows all round of the Bahuka Bamboo,—a stronger kind both as protection from storms and as posts for buildings, bridges, &c.

During the 1st year very little more may shew than an addition to the foliage sprouting from the 6 or 8 joints above the ground; here or there a small whip-like shoot may rise to 16 or 20 feet. In the 2nd year, about the end of June, larger shoots will rise, growing 4 or 5 inches per day and up to 20 or 30 feet, with girth of 4 or 5 inches. In the 3rd year still larger ones will grow, and all the time creepers should be now and then cut away. In the 4th year full-sized growth may be expected, *i. e.*, shoots 50 feet high with stems of 8 and 9 inches round, and the number of such should about equal and double the number of stems first planted. Each year thence should add 50 per cent to the numbers, if in fair soil, and in the 8th or 9th year there should be some 3,000 full sized stems, mature enough to cut, per acre per annum.

For building purposes or making use in the ground, no bamboo should be cut of less than 4 years' old, and should be steeped a month in water. "Jatis" increase in value with age up to 12 or 14 years, after which they gradually "dry up," turn yellow and die. If grown in the open they are often short, small and solid; those in shade, are tall, large and thinner walled. If required for tying or rude ropes, only the young ones of 1 or 2 years old are used. From having more water and less wood, they are more easily twisted, and a whole stem can be at once used in this way, though it is more usual to split and then twist them. When split up very small it is called "Tougal."

It seems extremely probable that young stems would furnish more and better pulp than old ones. In cutting bamboos out, old ones should be cut at or near the ground, and young ones 5 or 6 feet above, as the old ones do not readily throw out shoots or new sprouts, while the young ones do if some foliage is left on, and this leads at once to the solution of the difficulty that lay between Mr. Routledge and Dr. King, *i. e.*, that cropping of the young bamboos (near the ground) cripples the propagation, whereas if ⅓rds are cut at say 6 or 8 feet high, enough is left to keep up the supply of new shoots, provided of course the *foliage* is encouraged on the part left. The remaining ⅓rd is left altogether, and only cut when old, *i. e.*, useless for propagation and useful for building. I have cut 300 bamboos for one rupee out of a Bari, and as they are often 16 for the Rupee in the villages for Tea Factory building, a Bari is a source of great saving, and in a few years pays its cost many scores of times over.—S. E. P.

SERICULTURE.

The following are a few interesting figures which may prove useful to silk growers:—

Weight of Cocoons.—This varies with the breed and feeding. Pasteur calculates that 1 kilogramme contains 785 to 921 cocoons of the Japanese sort, 505 to 726 cocoons of the Italian yellow sort. Comalia found that 360 cocoons of the Meldola sort weigh 1 kilogramme.

Loss of Weight in Cocoons.—This is caused by time of keeping. Dandola found that at a temperature of 17 deg. R. 1,000 kilos. of cocoons was reduced to—

Kilos	·991	·982	·975	·970	·966	·960	·952
Number of days	1	2	3	4	5	6	7
	·943	·934	·925				
	8	9	10				

Weight of the various parts of the Cocoons.—By taking at 1,000 the weight of the whole cocoon—

The chrysalis alive weighs from			850 to 850
The refuse of chrysalis	,,	,,	4 to 9
The clean cocoon	,,	,,	140 to 166

After the moth has left the cocoon in 1,000 parts of them—

Refuse of moth	5 to 6
Remains of chrysalis	7 to 9
Clean pure Cocoon.	140 to 165

Number of Eggs.—Malpighi has found that the number of eggs deposited at one laying is generally 404 or 516, and sometimes only 446. As an exception he met once with only 393, without taking into account any which may have remained in the ovaries.

According to Barti-Pichet, 100 females deposit at one laying 40,000 to 45,000 eggs, 108 females of the Trivoltine sort are required for one ounce of eggs, 100 females of the common sort, 95 of the large, and 105 to 110 of the Japanese.

Number of Eggs in an Ounce.—1 ounce of 30 grammes of eggs was found to contain—

27,000 eggs of the Trivoltine breed.
39,000 ,, common ,,
37,000 ,, large ,,

1 ounce of 25 grammes of eggs was found to contain—

33,550 to 37,000 of the yellow breed.
48,000 to 51,900 ,, Japanese breed.

Eggs which are deposited from the first are little larger than those from the second, average number in one ounce 48,000 eggs.

Weight of each Lay of Eggs.—To find out this without removing the eggs from the cloths or cards, the basis of the calculation is to take the weight of each separate laying. It is known that to obtain the weight of two grammes it requires

5 lays of the large French breed.
6 ,, common ,,
7 ,, Japanese ,,

From this we can conclude that to make up 25 grammes there is required—

63 lays of the first sort
70 ,, second ,,
75 ,, third ,,

To make up one ounce of grammes 70, 84, 90, respectively, to make up one ounce of 30 grammes, 75, 95, 105, respectively.—*Journal of Applied Science.*

RUST-PROOF WHEAT.

(From the *Queenslander.*)

It is to be be hoped some of our farmers have this year experimented with the Champlain and Defiance wheats, which were last year introduced into South Australia by Dr. Schomburgk, and into New South Wales by Mr. Dunnicliff, of Burrawong. As most of our readers are aware, they were supposed to be rust-proof, but this characteristic was not entirely borne out by last year's experience. Mr. Dunnicliff's plots told almost conclusively in favour of their resisting rust. Dr. Schomburgk distributed 100 parcels of the seed, and received thirty-nine replies from farmers as to the results after harvest. Of these, ten reported that the rust had attacked both kinds more or less, but in no instance to the injury of the grain, which was plump and well developed. The other twenty-nine reports were to the effect that the wheat had most effectually resisted the rust, although the entire crop of wheat of other varietics—especially the purple-straw—had in some instances been destroyed by the disease. Whether Mr. E. Way's experience at the Toowoomba gardens—that rust-proof varieties retain that characteristic only for the first year of their culture in Australia—will be borne out by this present year's experiments in South Australia, is a point of great interest to all our wheat-growers. The Champlain is said to be rather flinty, and it is thought that it will not produce the fine flour the farmers have been used to getting from their wheats; but we suspect that a certain amount of flintiness—that is, an excess of silica—is a characteristic inseparable from a wheat whose constitution is such as to make it capable of resisting rust.

BARREN APRICOTS, &c.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—I planted a lot of apricots about 16 years ago, they are splendid trees, touching one another at 24ft. apart, they bloom splendidly, and every flower looks perfect, yet some of them never bear a single fruit, some three or four, and some about a dozen. I have tried all plans that I could think of except pulling them up or grafting. The last advice I saw in *The Australasian* was let them grow; what would you advise me do with them now? Please tell me the best stock to graft apricots on. I also planted at the same time a lot of damsons, they bloom every year, flower all perfect, and yet they only commenced to bear fruit about three years ago little bigger than marbles and that falls off after a time. What would you advise me to do with this lot? I put in a lot of Muscat of Alexandria vines; for about five years they looked all right, about the sixth year I detected black spots on them. I tried all plans that I could think or hear of, such as lime, sulphur, soot, and ashes. I have kept them extra clean, as they were the favourite grape in the kitchen. The whole of the ground where the above are planted is hand trenched from 18in. to 2ft. with drains through.

Rutherglen. J. C.

[In the absence of information regarding the character of the soil and sub-soil, it is almost impossible to offer advice on the management of your apricots, which we note bloom finely, but do not bear. We should, however, be inclined to try root-pruning in this case. It might be tried at once on a few of the more vigorous. As a further experiment we would take a few inches off each of the shoots of other trees. From the results an indication may be gleaned of the proper course to pursue with the whole. The damsons also may be similarly treated, *i. e.*, a portion be root-pruned, another portion be slightly branch-pruned. The proper stocks for apricots are seedling apricots; the cherry plum is also a good stock, and would be likely to answer with you. There is some reason to suspect that the drains, at so shallow a depth as 2ft., dry the soil early and thus conduce to the dropping of the fruit. In your climate drains, where employed, should be fully four feet deep. For what reasons were drains regarded as necessary? You do not state what is now amiss with your lines.—ED. AUSTRALASIAN.]

QUANTITY WITH QUALITY.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

SIR,—As some planters may at times make teas to send home direct, let me offer a few suggestions to the *new* ones (old Planters are warned off) as coming from one who has had some little experience of sending teas to England direct for retail sale (*not* for sale on the wholesale market, as in the latter case of course the same teas as those made for Calcutta are required).

1*st*. Make your tea intended for home separately from your Calcutta or wholesale teas.

2*nd*. Make it in the middle of the season, not at the beginning or end.

3*rd*. Ferment to a copper colour, and aim for dark, smooth, full liquor.

4*th*. Fire rather highly and briskly, but don't burn.

5*th*. Don't sort in any way whatever, but pass all the rough tea through a single sieve. If for Ireland or North of England, the smaller it is the better, and no matter how dusty. In sieving send the Pekoe and small tea through first by shaking; break the rest through. Some firms of large retail business at home have now taken to breaking up all their teas to about the size of broken Pekoe, only very dusty. This was possibly owing in the first instance to a

prejudice for teas of the appearance of B. P. The advantage of this to the dealers in being able to buy our dust so cheap, as they have been able to of late, is obvious. Above all things don't send home to friends a white elephant in the shape of Assam Orange Pekoe : even Pekoe is too strong. You wouldn't drink it yourselves with your taste already accustomed to Indian teas; how do you expect your friends to? As regards diffiently in separating fine leaf from coarse without injury before manufacture, has he ever tried a cylindrical sieve of large mesh (different for China and Assam leaf) say 9 feet long by 3', 6" in diameter, and working round on an axle placed at an angle of about 8° to 10°, through which to sieve his *withered* leaf? mesh nearly 1 inch. This sometimes requires the "Pekoe Souchong" leaf to be plucked like the "Souchong," separately from the Pekoe stem. This allows the old leaf to be rolled, fermented, and fired separately from the fine tea,—a great advantage to the latter, quite compensated for by the little extra trouble in plucking. This leads me to join issue with your correspondent "J. A. H. J." when he says that by making *less*, the fine tea would fetch more than it did when quantity was made. The tea, *i. e.*, withered leaf, being sieved as above, and the tea-house accommodation being in proper proportion to the outturn, I do not see why the fine teas should have had any better chance had they been plucked without the coarse, as they never came in contact with the latter after being sieved *before* rolling.

I will accept for the sake of argument your correspondent "Twice Two's" figures as given in your last issue. He mentions two experiences, viz., 2 annas 1·60 pie per lb. and 1 anna 4·75 pie per lb. as the cost of plucking and manufacture. Let us take nearly the mean of these two, say 1 anna 9 pie as a fair guide Then the 405½ maunds "trash" would have cost

R. 3,548 say for *plucking and manufacture.*
,, 2,000 boxes and charcoal (pluckings)
,, 811 freight
,, 200 Calcutta charges.

Say totalR6,559
and these teas fetched R10,732. !

This profit of over 60 per cent between leaving the tea on the bushes and taking it off, plus the fact that the next flush in a healthy *Assam* Garden would be *benefitted*, and the further fact that the general average cost price per lb. of the factory's outturn would be reduced, all taken together might be used as arguments in favor of quantity with quality, but I think my case is strong enough on other grounds not to require support from these, though I mention them in passing, for what they are worth.

"THE CHIEL AMANG YE."

[We agree that if none but fine qualities were sent home we should be ruined; but making fine, good, and good medium, is very different from flooding the market in too great quantity with weak liquory kinds which cannot compete, to pay, with China Congous. On this subject we cannot do better than conclude with the following extract from Messrs. Gow and Wilson's Circular :—"Fine" plucking means a considerable percentage off the crop, and we trust those who have adopted this system have thoroughly satisfied themselves that better returns will be shown from higher prices for diminished production. The question arises whether the simultaneously adopted policy of production of Fine Teas will not adversely affect the prices of high-class descriptions. Owners will really be consulting their interests by striving to understand the requirements of the trade, and every endeavour should be made to get the largest possible yield out of a garden: the "sorting," to show a proportion

Fine, a proportion Good Medium, and the remainder good useful Pekoe Souchong, and Souchong, and a small percentage broken Tea. Last year's results all tend to prove that the British public have decidedly shown taste for Indian Teas, and it now remains for the grower to meet the trade demands.—ED. INDIAN TEA GAZETTE.]

CAMPHOR.—THE *Journal of Applied Science*, in a note on the Camphor Forests of Sumatra, states that the trees yielding Borneo or Sumatra camphor (*Dryobalanops aromatica*) in large quantity are now becoming rare. Owing to the great demand for the sulphur by the Chinese, who use it to embalm their dead, the Battaks cut down the trees recklessly and without planting young ones. The camphor is said to fetch 10,000 guilders per picul (135 lb.) in the Singapore market. The gutta-percha trees in the Sumatra forests are being treated in the same way. It is remarkable, however, that the Battaks take great care that fresh benzoin trees replace those they cut down, by scattering the seed on the ground. The camphor and gutta-percha trees require more care and trouble in planting, hence this is neglected.

SEEDS.—IN a note in *Nature* (May 26, p. 80), communicated by Mr. W. Carter, an account is given of the effect of pressure on the germination of seeds. He found that under a pressure of two and-a-half atmospheres mustard seed germinated twenty-five hours earlier than when under the ordinary pressure of the atmosphere, but that the early development became permanently arrested during the eight days of the experiment, and the cotyledons of one that had escaped entirely from the seed coat remained as etiolated as if grown in absolute darkness, while those under ordinary pressure grew rapidly and their cotyledons became of a deep green colour. The etiolated plants, when removed from the pressure, rapidly grew into vigorous young plants. An increased pressure would therefore seem to stimulate germination and prevent the formation of chlorophyll. The pressure was obtained by the use of a column of mercury. The seeds were sown on moist cotton wool, placed in a small bottle, which was then secured to the curved extremity of a glass tube, into the long arm of which mercury was poured until it reached a height of forty-five inches above the level of the metal in the shorter arm.

PEACH PRUNING.—In the majority of cases this work is left till the winter or spring, but I see that Mr. Wallis, of Orwell Park, like a few others of the best cultivators, thins his trees in the houses directly the fruit is off; thus fully exposing the whole of the young wood well to the light, and giving it every chance of ripening off early, which shoots cannot do when buried up under their foliage. Not only does the thinning greatly aid the ripening process, but it assists the trees materially in plumping up and protecting their buds, without which the flowers must of necessity be small, and their setting uncertain. With good fat buds that result in big bold blooms, the organs are sure to be right, and when that is the case a crop of fruit and its safe stoning is almost certain to follow, for the success of next year, as regards Peaches and Nectarines, depends in a very great measure on the doings of this. Even more important perhaps than the thinning of the wood, is the keeping of the foliage clean and free from red-spider, which can only be done during such hot weather as we have recently had by the aid of a good garden engine or syringe, and a thorough soaking of water at the roots, as dryness, either in the air or border, brings on languor, insects, and weakness sooner than anything else.—F. S.—*Gardeners' Chronicle.*

Correspondence.

To the Editor of the Ceylon Observer.

"SELF-FERTILIZED COFFEE FLOWERS" AGAIN.

Maskeliya, 9th August 1881.

DEAR SIR,—I would wish to add a few remarks to a letter of mine, which you published in your valuable journal a short time ago, concerning "self-fertilized coffee flowers and the result"; and any subject connected with our principal product, if well ventilated and discussed, cannot but be beneficial to our knowledge of its successful cultivation. I drew attention to the fact, that Darwin (who is our greatest authority on this subject) had said, that "if self-fertilization was continued through several generations, the plant at length becomes altogether sterile"; and also that "nature abhors perpetual self-fertilization."

As an instance of the latter, if we look into Youatt's book on Cattle, their breeds and management, we read:—"The breeding from close affinities —the breeding *in and in*—has many advantages to a certain extent. It may be pursued until the excellent form and quality of the breed is developed and established. It was the source whence sprung the cattle and the sheep of Bakewell, and the superior cattle of Colling; and to it must also be traced the speedy degeneracy—the absolute disappearance of the new Leicester cattle, and in the hands of many an agriculturist, the impairment of constitution, and decreased value of the new Leicester sheep and the short-horned beasts." The Rev. H. Berry in his Prize Essay remarks that "close breeding, from affinities, impairs the constitution, and affects the procreative powers, and therefore a strong cross is occasionally necessary. In the breeding of horses and greyhounds for racing and sporting purposes, it is a well known fact that it is arranged that (in stud parlance), the breeding should be twice in and once out; so that a cross every now and then may stop any bad effects from close affinities. Further, in the human race, it has been proved that intermarriage continuously between close relations has led to most pernicious results.

If we take these facts which relate to mammalia, as being equally applicable to other systems of life, such as the vegetable kingdom, we must allow that laws that act on the one will act in a similar manner on the other, and therefore what will produce degeneracy in the one will have an equally deleterious effect on the other. Now in plant life, we have a very large proportion of flowers that are so constructed as to preclude all possibility of self fertilisation: some by having male and female flowers, and others that have been so formed as to prevent fertilization, except by extraneous aid, generally performed by the help of various kinds of insects. Coffee is like neither of these, it is a self-fertilizer, and has, unfortunately for the present generation, obeyed the common law of nature, and degenerated. estates opened during the last ten years or so have a similar soil to those of thirty years past. Old planters of long standing have said for the last two or three years, that the seasons have returned to the old standard: we cannot now blame inferior soil or extraordinary weather for the want of crops. How is it that old estates of thirty and more years working compare favourably in their bearing capacities with the younger districts? For the last forty years, clearings have been planted from seed taken from trees grown in previous clearings, and which we have no reason to doubt sprang originally from one parent stock; consequently our present young trees are from seed which has been self-fertilized for several generations. In the case of cattle, we learn that continual in-breeding impairs the constitution, and affects the procreative powers. No one will deny that coffee has not the strength and vigour that it used to have, and this is generally laid down to the effects of leaf disease: it is more than probable that leaf disease is one of the effects, and not the cause, of want of vigour in the tree. If the constitution, so to speak, of the tree had not previously been impaired, disease would not have shown itself, or at any rate the tree would have been able to have shaken it off in a short time. Disease can be kept under, as it were, by a liberal application of stimulants, but it can only be kept so for a certain period, for the shattered constitution must eventually give way; and it follows that, if the constitution be gone, the procreative powers become exhausted. It may be said that, if leaf disease is a result, indirectly, of an impaired constitution in plants grown from a young generation of self-fertilized seed, how is it that old coffee is attacked? The old trees have their age, and consequent weakness, against them, and living as they do, in an atmosphere contaminated by an epidemic of such a virulent type, must naturally be expected to receive some of the seeds of the disease. That coffee can be easily cross-fertilized, I have no doubt, as I have succeeded in doing so, by removing the stamens from flowers, whilst in spike, and afterwards, when fully opened, depositing on the stigmas pollen from another tree: these set well, and will, I hope, be shortly ripe enough to sow. At the same time, to test the possibility of their having set in spike, stamens from other flowers were also removed, and nothing further done to the flowers: none of these set. Not being a proprietor, and so liable to be moved at any time, I am not in a position to try this to any extent; but any one who could afford the time and had the inclination to experiment upon it, and prove its practicability on a large scale, would confer a boon upon future planters, by being able eventually to supply plants which might be designated disease-proof. Another interesting and at the same time valuable experiment would be the fertilizing of the ovules of Arabian coffee, by pollen obtained from the Liberian variety, and *vice versa*.—Faithfully yours, SWADDY.

ALOE FIBRE.

Auchintoul estate, Belihuloya, 13th Aug. 1881.

DEAR SIR,—Some time ago I noticed a letter in your paper *re* aloe fibre, which induced me to try the experiment, and I have now the pleasure of enclosing you samples shewing the result.

I may mention that I have about 60 tons now under treatment (of course this will only turn out six tons of fibre).—I am, dear sir, yours faithfully,

W. McDONALD YOUNG.

[The samples are very satisfactory: we sent them round the Fort, so there ought to be a demand for our correspondent's 6 tons!—ED.]

CINCHONA STUMPS.

15th Aug. 1881.

DEAR SIR,—Your correspondent "Ignoramus" asks for information regarding cinchona stumps, and I take the liberty of replying to him:

1. *Officinalis* is preferable to succirubra, owing probably to the roots being smaller.

2. The plants should be stumped after being pulled out of the nursery and before planting. Stumping them while in the nursery and allowing them to remain induces them to sprout, and the suckers will be damaged in being planted out.

3. I heard of no objection and everything in their favor. The roots should be trimmed with a sharp knife, as in the case of coffee stumps, and the plant

stumped about 8 inches above the roots. Stumps will grow almost in any weather, if the soil is free and damp. The tree afterwards has a firmer hold than if it had been a plant, and in some cases does away with the necessity of staking. In some very wet and cold districts they may not succeed so well, but in Dimbula and Dikoya they succeed perfectly. On Erlsmere estate in Dikoya, some officinalis trees were pointed out to me as having been grown from stumps. They were only two years old and magnificent trees for the age. The percentage of deaths is trifling, compared to that of plants, and I strongly advise planters to plant *stumps*, if they can get them.—Yours truly,

CINCHONA.

WOOD ASHES.

Gas Testing Rooms, Colombo, 19th August 1881.

SIR,—I send you analysis of a remarkable sample of wood ashes received from Mr. Elphinstone, passed through a sieve having 900 meshes to the square inch, 1·71 per cent of quartz was seperated; the remainder had the following composition :—

	per cent.
Moisture	·38
Insoluble silica	2·35
Soluble silica	·26
Oxide of iron and alumina	·75
*Lime	56·00
Magnesia	·37
Potash	·54
Phosphoric acid	Trace
Carbonic acid and other constituents	39·35
	100 00

* equal to carbonate of lime 100·00

The remarkable feature of the sample is that it contains more lime than coral or the purest limestone; indeed after separating the small proportion of quartz foreign to it, it contains as much lime as chemically pure and dry carbonate of lime, A portion of the lime is in the caustic state. M. COCHRAN.

CINCHONA CULTIVATION.

Maskeliya, 20th August.

DEAR SIR,—Your correspondent "Cinchona" advises stumping off plants at eight inches. My experience is that four inches from the collar is quite sufficient. The object to be gained is to secure a greater girth of stem and a corresponding increase in the solidity and stamina of the tree.

The Erlsmere trees referred to are certainly very wonderful examples of what stumped plants may become, but it must be remembered that there is probably not in the island a finer soil or more congenial climate for the growth of cinchona, than is to be found on that estate. The plants therefore having been stumped does not entirely account for their rapid and vigorous growth.—Yours truly,

STUMPSO.

COREA.—Dr. Frank Cowan, an American, who has just returned to Japan from a trip in Corea, says:—"With respect to gold, I am of opinion that the next of the countries on the golden rim of the Pacific, after Peru, California, and Australia, to disturb the monetary equilibrium of the world, will be Corea. From Fusan to Genzanshin, or the Gold Mountain, a distance of 310 miles, the geologic structure is not incompatible with the theory that the whole region is productive of the precious metal.'—*Madras Mail.*

CEYLON AT THE MELBOURNE EXHIBITION.

CEYLON AND INDIAN TEAS IN AUSTRALIA.

Melbourne, 1st Aug. 1881.

On returning I find Mr. Moody of Messrs. Jas. Henty & Co. as active and earnest as ever in the cause of Indian and Ceylon teas. There is to be an extensive sale of the former on the 4th of this month, and at the end of the catalogue there is a note to this effect:—

"The Importers challenge comparison against the Indian teas for leaf, for strength, flavour and analysis against all or any of the China teas imported this season."

Comparative analyses are appended which I hope will be copied into the *Observer*, as Mr. Moody tells me he has sent copies of the catalogue of the little pamphlet which I enclose. Of this pamphlet 10,000 copies have been distributed and 5,000 more are being printed.

Mr. Moody tells me that some of the Rookwood teas and those from Messrs. Whittall & Co. which have reached him recently are of high quality, but others (big leaf, on the one hand, and dust on the other) are not so suitable for this market. About this Mr. Moody, says he has written. While I am writing Mr. Moody brings me a specimen of stuff, coarse and mouldy which Mr. Rowbotham has attempted in vain to sell by auction as Ceylon tea. Mr. Moody says it is damaged, and he can scarcely believe it is Ceylon tea. The attempt to sell such trash as our produce is exceedingly injurious to the interests of pure Ceylon tea. A. M. FERGUSON.

INDIAN TEA.

SEASON 1881-1882.

MELBOURNE, 20th July 1881.

The Calcutta Tea Syndicate, in conjunction with the Government of India, have determined to carry on their operations during Season 1881-1882, with the hope of establishing on a firm basis the tea trade between Australia and India.

During the last twelve months the export of tea from India to Australasia amounts to about 1,000,000 lb. weight, of which quantity 671,000 lb. weight was actually sold in Melbourne.

With the experience derived from the past season's operations, the Syndicate will be able to improve their selection of teas for the Australian markets, and every attention will be paid to having the bulk of uniform quality; and the various requirements of Tea Merchants, Blenders, and Consumers will have careful consideration, and shall be complied with.

India, with her tea gardens at altitudes of from 400 to 7,000 feet above the sea level, her climate and rich soil, possesses advantages unequalled in the world. Her teas are prepared under the immediate supervision of Europeans, and with the help of the best machinery procurable, and many of the Indian tea growths are as much in repute as some of the far-famed vintages in France.

N. B.—Mr. James Inglis, Commissioner for India to the Melbourne International Exhibition, in a letter to the *Argus* dated 25th June, 1881, says—

"There has never yet been placed on record an instance of adulterated tea having been sent from an Indian warehouse. I challenge the world to show one instance. The tea is made by our fellow-subjects, under the direct supervision of our fellow-countrymen, who drink our wine, wear our wool, ride our horses, burn our candles, long for our beef, cry out for our timbers, want our flour, our fruits, our hops, our dairy produce, and who have never yet in one solitary instance turned out anything but pure, aromatic, fragrant, and genuine tea."

Mr. A. M. Ferguson, Commissioner for Ceylon to the Melbourne International Exhibition, in a letter to the *Age*, dated 15th June, 1881, says—

"Teas grown, prepared, and shipped by men of the British race are certain to be genuine. * * * What I should like to impress upon tea consumers here is that, although the teas of India and Ceylon may occasionally be defective in make (a fault that is sure to be remedied as experience is obtained), the genuineness of such teas, their purity, freedom from adulteration with foreign or deleterious substances, and perfect wholesomeness can always be relied upon. If tea drinkers will only persevere in the use of even the harshest Assam tea, they will soon find themselves not only reconciled to the infusion, but most unwilling to return to the weaker China stimulant. Where cream or rich milk is so plentiful as in this favoured land, the experience of the north of Ireland may be repeated. There people of limited means long ago discovered that pure, strong Assam tea at 4s. per lb. was cheaper, as well as better, than weak and perhaps adulterated China leaf at 2s. Making a strong infusion, they half-fill the cup, and then fill up with rich milk. To those —and they are the vast majority—who like milk or cream in their tea, this is the very perfection of the cup which cheers, but not inebriates."

Messrs. Cosmo Newbery and Frederic Dunn, of the Industrial and Technological Museum Laboratory, say:—

"Genuine tea contains between 4 and 6 per cent. of mineral matter, 3 per cent. of which consists of soluble salts, and yields, in its ordinary air-dried condition extract ranging from 32 per cent to over 50 per cent. As a rule, the younger and better the the tea, the higher the percentage of extract."

The following tables, compiled at the Industrial and Technological Museum by Messrs. Cosmo Newbery and F. Dunn, give the average results of a series of analyses of Teas carefully drawn from the bulk:—

Season.		Percentage of Mineral Ash.	Percentage of Extract.	Percentage of Soluble Salts.	
1880-81	Auction sale Indian tea, 15 sample, 770 hf.-chts., avgs. ...	5·34	39·42	3·16	
1880-81	Auction sale Indian tea, 46 samples, = 3,131 hf.-chts., avgs. ...	5·46	42·40	4·06	
1881-82	Auction sale Indian tea, 36 samples, = 1,312 hf.-chts., avgs. ...	5·54	43·91	3·27	
1880-81	Auction sale Foo-Chow Congous, 15 samples, = 1,904 hf.-chts. avgs. ...	5·20	29·26	2·88	
1880-81	Auction sale Foo-Chow Congous, 50 samples = 2,880 hf.-chts. avgs.	5·40	31·30	3·60	
1881-82	Auction sale Foo-Chow Congus, 20 samples common, = 6,230 hf.-chts., avgs. ...	5·32	33·60	3·26	Firstcrop Teas.
1881-82	Auction sale Foo-Chow Congous, 20 samples medium, = 4,152 hf.-chts., avgs. ..	5·40	35·20	3·48	Firstcrop Teas.
1881-82	Auction sale Foo-Chow Congous, 10 samples good, = 1,757 hf.-chts. avgs. ...	5·44	35·04	3·54	Firstcrop Teas.
1881-82	Auction sale Foo-Chow Congous, 10 samples, fine, = 957 hf.-chts., avgs. ...	5·50	34·32	3·52	Firstcrop Teas.
	Genuine tea of lowest class continues ...	4 to 6	32	3	

N.B.—The result in favour of Indian teas is too marked to need further comment. Many of the China teas will not pass the standard of a genuine tea.

Mr. J. O. Moody, Tea Expert, in a letter to the *Argus*, dated 5th July, says—

"Perhaps the extract of tea, or that part drunk in the infusion or cup of tea, is the most important and no tea should fall below 30 (the standard at home). Some of the Indian and Ceylon teas go to 52. This extract contains the essential oil or flavour which pleases the palate, and the active principle, theine (tasteless) which mostly invigorates the drinker."

Again to another paper, under date 3rd June, the same writer says:—

"Hops deteriorate by keeping, owing to oxidation of the essential oil, a chemical process well known to scientists, and which gives the old hops their 'faintish' or 'cheesy' flavour, most strikingly brought into prominence when new pickings come to hand; the contrast between the two is then so great that it usually causes a fall in price of pence per lb. on old hops. Exactly the same thing goes on in the China teas, and has been most noticeable for many seasons past, and well do holders know the risk and loss of retaining this class of tea till the arrival of a new season's growth. The bulk of Indian teas, on the contrary, seem to ripen with age, and are famed for their good keeping qualities. Samples of these teas, after five or six year's time, have been found to have well preserved their flavour and good qualities. * * * It is estimated that 10 pounds of tea from the districts of Assam, Cachar, &c., equals 15 to 20 pounds of the ordinary China tea (the bulk of consumption) sold on the Australian market. The Darjeelings, &c., grown at the higher elevation, are generally milder, and possess, as a rule, fine delicate bouquet and flavour."

CEYLON PLANTERS IN SARAWAK.

Mr. Loyalty Peake, late of Maturata, writes from Sarawak, under date 29th July, as follows:—

"This is certainly a great country for vegetation. I am receiving every assistance from the Rajah in opening up. The products most likely to prove suitable are cinchona, tea and cardamoms, none of which have been tried. The chief products now are sago, gambier, and pepper, also coal and cinnabar, the Borneo Company having the monopoly of the latter. A good deal of gutta percha is exported and fetches very remunerative prices. I am getting 30,000 seeds to send to Ceylon where they should thrive. When I have been over more ground, I shall send you a long account of the country. I have been here now over two months and have seen hardly any rain, though Sarawak is supposed to be very wet."

TEA ON THE NILGIRIS.—A planter of Coonoor expects in the present season to manufacture 15,000 lbs. of tea off forty acres of land. Average quality Pekoe Souchong. This is almost at the rate of 400 pounds of made tea per acre, and must be reckoned an excellent yield, especially when the class of tea turned out is considered. The estate of course is highly worked and carefully supervised in all its departments.—*Indian paper.*

SALT DEPOSITS.—A Mannar correspondent writes:—"A short time since you referred, in your paper, to a report by Mr. Allen Hume recently published by the Indian Government, on agriculture in India. Can you kindly procure a copy of it for me? It contained some observations on a peculiar salt deposit in irrigated lands, you stated. I should much like to see what he says regarding it: there is nothing of the kind in this district, nor has it even been known here, although all the soil is more or less strongly impregnated with salt., In fact, so much so, that the water of all wells is slightly brackish. It seems unlikely that the soil in the north of India contains more salt than this."

THE ACTUAL COST OF MANUFACTURING TEA.

(From the *Indian Tea Gazette.*)

Assuming that the garden to be reckoned for is in these hills and of average moderate size—say 200 acres—yielding say 500 mds., and that the salary of the Manager and his Assistant amonnt to R300 a month, *i. e.*, R1·8 per acre, I reckon the charges to be as follows for each lb. of tea :—

	R.	A.	P.
Salary of Manager R250, 2 Native Assts. R50	..0	1	6
Fuel { Wood—reckoned @ 4 as. per md. / Chareoal ,, @ R1 per md. } (Govt. rates.)	0	0	6
150 coolies a month, for *cultivation* R9,000 a year	...0	3	6
10 Tea makers R84 / 4 extra hands for sifting, cleaning, &c., R20 } 104—monthly, 1,248—a year	0	0	6
Implements, &c., R300 per annum (½ pice per pound)	...0	0	1½
Boxes, Lead, &c.	...0	0	6
Sundries—Including Interest, Repairs, Medicine, Pony allowance, } R1,250 per annum	...0	0	6
Transit charges	...0	0	6
	...0	7	7½
To the above should be added what is, I fear, very often overlooked in such cultivation, viz., the value of the fuel used by the *coolies* for cooking purposes. For 150 coolies I would reckon not less than 15 mds. per diem, and at the Government price this would mean R3·12 per *diem*, which would add another two piece per lb to the cost of Tea ...	...0	0	6
	0	8	1½

There may be other items omitted in my calculations, but if the above are very nearly correct, it will be evident that Darjeeling tea cannot be landed in Calcutta for less than 8 as. per lb from a small garden. It would be interesting to find out whether these charges could be very much more moderate on large gardens.—Yours faithfully, PUNDEEM.

Darjeeling, 28th July 1881.

[We should say the rate is over estimated, but shall be glad to hear the opinions of other Darjeeling planters on the subject. Our correspondent does not seem to have taken into account the economy which machinery should effect in manufacture.—ED., *I. T. Gazette.*]

SILK PRODUCTION.

It is curious that for all that is constantly being said about "new products" in the local press, there is hardly ever any mention of silk except in our paper. Yet there is no product for which this country is better adapted, none that requires a less outlay of capital, and none that gives a more speedy return. The silkworm eggs obtained from Japan by Father Palla did not turn out so well as was expected. The silkworms from them were as healthy as could be wished, but many of the eggs did not hatch, and only about seven ounces of Ceylon eggs were produced from each ounce of Japan once. This is perhaps nothing to grumble about, but it is hoped that a much better result will be obtained in the second generation. The Japan eggs reached this country in the beginning of last December, and they began to hatch immediately after their arrival. The first Ceylon eggs were laid about the middle of January, and these began to hatch in the middle of July, exactly six months after they had been laid. A few eggs of the second generation have already been obtained, and it is confidently expected that there will be some for exportation in time for the next European silk season. In countries where silk is an established industry, it is not necessary that every silk producer should be a mulberry planter. The "education," as it is called, of the silkworm and the cultivation of the mulberry tree can be—as in France they often are—separate employments conducted by different persons; but in this country it is, for the present, necessary to have a plantation of mulberry trees before the rearing of silkworms in sufficient quantity for commercial purposes can be successfully attempted. Three species of mulberry have already been naturalized in Ceylon, namely, the common sort (*Morus Indica*), the large-leafed Philippine Island variety (*M. multicaulis*), and the white mulberry (*M. Alba*). Books on the culture of silk say that if the leaves of the black, red, and white mulberry trees be given to silkworms all at once, they will eat the white first, then the red, and lastly the black, but here they seem to like the leaves of the *M. Indica*, *Alba*, and *Multicaulis* all equally well. If there is any difference in the quality of the leaves of these three species, those of the white mulberry are the best, but this tree requires better soil than either of the other two, and other things being equal, it will not bear so large a crop of leaves as the *multicaulis*. The common sort is the best kind for fruit, but its habit of bearing fruit abundantly is not a desirable quality in a tree grown for the sake of the leaves. The best way to obtain large leaves of good quality is to prune the trees into short pollards, as the leaves borne on suckers are larger and better than those borne on the old branches of high trees. This is the Japanese method, as the Japanese do not approve of having the trees of a greater height than sufficies to keep the leaves from being splashed with mud by the rain. They do not often make plantations of mulberry alone, but usually have the trees planted in hedges across their corn fields, the mulberry being a tree that, unlike most others, does not injure plants growing near it, either by abstracting nourishment or by the shade or dropping of rain from its leaves. The mulberry itself does not, however, grow luxuriantly in the shade of other trees, and leaves that have been grown in the shade are not so much liked by silkworms as those that have been grown in sunshine—probably owing to a deficiency of saccharino matter in the former. In Europe, the mulberry is commonly grown as a large tree, a method which besides producing leaves of inferior quality, renders the gathering of them more troublesome than when the trees are pruned in the Japanese way. One advantage of high trees, however, is that they do not require to be fenced, as the leaves are beyond the reach of cattle; but the Japanese do not keep many cattle, and consequently do not care for that advantage.

Though there is less noise made about silk than about several of the other "new products," yet we believe the time will come when it will be a more important product than any of them, as it is adaptable to a greater diversity of soil and climate than any of the others, and is an article for which the demand is practically unlimited. Silk production is also a business that can be done by persons who can neither do hard work themselves nor afford to pay much in wages to others.—*Ceylon C. Messenger.*

VANILLA.

(From the *Monthly Magazine.*)

The genus vanilla, says Mr. G. W. Septimus Piesse, is indigenous to Peru, Brazil, and Mexico, and some of the species have been successfully cultivated in

the West India Islands, Ceylon, Mauritius. From the last-named, wonderful specimens were sent to our intercolonial exhibition of 1862, for which the jurors awarded a gold medal.

The vanilla will produce saleable pods the third or fourth year after propagation, and they may then be gathered annually in September in increasing quantities for thirty or even forty years. Two good specimens of the plant may be seen in the Orchid House at Kew.

When the pods are gathered, which should be done before they are quite ripe, it is most important that they be properly cured, otherwise they rapidly become mouldy and lose their scent. Parcels in this condition may often be found in the Mincing Lane drug auctions. The curing of the pods is best effected by drying them in a moderate heat, pressing them with the thumb and finger from end to end, and then brushing them over with an oil that does not itself become rancid, such as that of cocoa or cashew nut. It is at the apex of the pod that the mouldy parasite first appears, the pods then quickly become soft and flabby, or dry and chippy. On the other hand, when vanilla pods are in good condition, they become covered with an efflorescence of needle-like crystals of vanillic acid; the interior of the bean is then soft, unctuous, and balsamic. These crystals may be sublimed by heat of a sand bath. Few objects are more beautiful than this when viewed by a microscope with the aid of polarised light.

I. F. H. Johnston states that the fruit of this plant when ripe is said to yield from two to six drops of a liquid which has an exquisite odour, and bears the name of "balsam of vanilla." This balsam is, however, never seen in Europe, consequently it has never appeared commercially in the market. The pods are dried in the sun and afterwards slightly fermeuted for the purpose of developing their odour; when fresh, they are said to have no perfume. Physiologically, the fragrance of the vanilla acts upon the system as an aromatic stimulant, exhilarating the mental functions, and increasing geuerally the energy of the animal system. About two centuries ago vanilla may be said to have been unknown in this country; it is however stated, that Morgau, apothecary to Queen Elizabeth, showed Her Majesty a sample, but he knew nothing more about it than that "it was brought from abroad by some Spanish merchants."

A few years back the average importation of this article was about five or six hundredweight, which arrived, from some unknown cause, very irregularly, and as a consequence caused great fluctuations in the price. At the present time the total annual average crop of all the varieties of vanilla from the several countries which produce it may be estimated at 80,000 lb., representing a value of not less thau £150,000.

In order to obtain the perfume or essence, half a pound of the pods are slit from end to end, so as to lay open the interior; then cut them up in lengths of about a quarter of an inch, and put into one gallon of pure alcohol of 600 over proof, and macerated with occasional agitation for about a month, at which time all that is worth extracting will be found in the spirit, which may theu be strained off quite clear and bright. It is then suitable as a flavoring agent, or when blended with other scents it makes compound odours or boquets. Those sold under the titles of clematis, heliotrope, wall-flower, &c., mostly contain about one-half of vanilla extract.

The following gives a good

ESSENCE OF WALLFLOWER.

Extract fleur d'orange	1	pint
,, ,, vanilla	½	,,
Esprit de rose	1	,,
Extract of orris	¼	,,
,, cassic	¼	,,
Essential oil of almonds	5	drops

This should be prepared for two or three weeks prior to putting up for sale.

The odour of heliotrope resembles a mixture of vanilla and almonds, and is well imitated thus:—

EXTRACT OF HELIOTROPE.

Spirituous extract of vanilla	½	pint
,, ,, French rose pomatum...	¼	,,
Spirituous extract of orange flower...	2	ounces
,, ,, ambergris ...	1	ounce
Essential oil of almonds	5	drops

USEFUL WRINKLES AND RECIPES FOR PLANTERS.

(From the *Indian Tea Gazette*, 6th August 1881.)

(*Continued from page* 300.)

Stables, To remove rank smell of.—Sawdust, wetted with sulphuric acid, diluted with 40 parts of water, and distributed about horse stables, will remove the disagreeable ammoniacal smell.

Horses, to keep flies from.—Make an infusion of 3 haudfuls of walnut leaves in 3 qts of cold water. Let this stand over night and boil for a quarter of an hour in the morning. When cold rub it over the ears, neck and other irritable parts of the animal, with a moist sponge.

Eggs, To preserve.—Mix together in a tub or vessel 1 bushel of quicklime, 32 ozs. of salt, 8 ozs. cream of tartar, with as much water as will reduce composition to a sufficient consistence to float an egg. It is said that this treatment will preserve the eggs perfectly sound for two years at least.

Insect Bites.—A good remedy is borax, 1 oz. dissolved in 1 pint water previously boiled and allowed to cool.

Mustard Poultice, To make a.—In making a mustard plaster use no water, but mix the mustard with white of eggs, and the result will be a plaster which will draw perfectly, but will not produce a blister, no matter how long it is allowed to remain.

Sleeplessness, Cure for.—Mr. Frank Buckland says: "If I am much pressed with work, and feel I shall not sleep, I eat two or three small onions and the effect is magical. Onions are also excellent things to eat when much exposed to intense cold. In salmon fishing, common raw onions enable men to bear the ice and cold of the semi-frozen water much better than spirits, beer, etc. If a person cannot sleep, it is because the blood is in his brain, not in his stomach; the remedy, therefore, is obvious: call the blood down from the brain to the stomach. This is to be done by eating a biscuit, a hard-boiled egg, a bit of bread and cheese, or something. Follow this up with a glass of wine or milk, or even water, and you will fall asleep."

Styptic paper, For stopping the bleeding of small wounds.—Mix gum benzoin (best quality), 1 lb.; rock alum, 1 lb.; water, 4½ gals. Boil in a tin vessel for 4 hours, replacing the water lost by evaporation. Saturate paper with the solution, dry carefully and brush over with a concentrated solution of perchloride of iron. Keep in a water-proof and air-tight case.

Toothache.—Saturate a bit of cotton wool in a strong solution of ammonia, and apply it immediately to the affected tooth.

Mucilage, Pocket.—Boil 1 lb. best white glue and strain very clear; boil also 4 ozs. isinglass, and mix the two together; place them in a water-bath (glue kettle) with ½ lb. white sugar and evaporate till the liquid is quite thick, when it is to be poured into moulds, dried, and cut into pieces of convenient size. This immediately dissolves in water, and fastens paper very firmly.

Boots, Wet.—When the boots are taken off, fill them quite full with dry oats. This grain has a

great fondness for damp, and will rapidly absorb the least vestige of it from the wet leather. As it quickly and completely takes up the moisture, it swells and fills the boot with a rightly fitting last, keeping its form good, and drying the leather without hardening it. In the morning, shake out the oats and hang them in a bag near the fire to dry, ready for the next wet night; draw on the boots, and go happily and comfortably about the day's work.

Mildew, To remove.—Make a very weak solution of chloride of lime in water (about a teaspoonful to a quart of water), strain it carefully and dip the spot on the garment into it; and if the mildew does not disappear immediately, lay it in the sun for a few minutes, or dip it again into the lime water. The work is effectually and speedily done, and the chloride of lime neither rots the cloth nor removes delicate colors, when sufficiently diluted and the articles rinsed afterwards in clear water.

Boots, Waterproofing.—Use a piece of paraffine candle about the size of a nut, dissolved in lard oil at 140° Fahr. Apply once a month.

Rats, To catch.—Cover a common barrel with stiff paper, tying the edge around the barrel, Place a board so that the rats can have easy access to the top. Sprinkle cheese or other bait on the paper, and allow the rats to eat there unmolested for several days. Then place in the bottom of the barrel a stone 6 or 7 inches high, and pour in water until all the stone is covered, except for a space about big enough for one rat to crawl upon. Now replace the paper, first cutting a cross in the middle. The first rat that climbs on the barrel-top goes through into the water, and climbs on the stone. The paper comes back to its original position and the second rat follows the first. Then begins a fight for the possession of the dry place on the stone, the noise of which attracts the others, who share the same fate.

Leather, to water proof.—Saturate with castor oil. This is excellent for winter boots.

Mice, To kill,—Sprinkle some grain near the holes, and throw near by a few bits of cotton saturated in chloroform. This has been tested, and mice have been found dead, two or three at a time, lying with their noses near the cotton.

GRAFTING DECIDUOUS FRUIT TREES.

(From the *Australasian*.)

Although we published as lately as last year directions for performing the operation of grafting, we are again under the necessity of repeating, in effect, the information then given, in order to comply with the request of several of our readers. The term grafting, as interpreted by British gardeners, has a more restricted application than is accorded to it by the French. In England the term grafting is applied only to the practice of affixing to a tree, called the stock, a portion of a branch of another tree, which portion is called the scion. English gardeners divide the operation of grafting into three species, viz, grafting, budding, and inarching. On the continent of Europe no such distinction is observed; in France all of these operations are represented by the general term *greffe*, hence, *greffe par gemmes*—grafting by buds, which we call budding.

We are about to speak of grafting in its limited English application. The *scion*, then, is a cutting of a tree or plant on which the scion is to be engrafted. *Grafting*, therefore, is the operation of placing and affixing together two cut portions of plants or trees in such position as to permit of their becoming permanently united. It is important to understand that the union does not extend over the whole cut surface of the scion, much less over that of the stock, which is larger, and of which, therefore, only a portion is even covered by the scion. Wood already formed is incapable of further growth, and, therefore, cannot unite. The true union is effected at the point at which sap exudes from the stock, namely, between the wood and the inner bark. The new layer of cellular matter would be there formed were the tree left to grow as usual, and by the formation of the new layer the union of the stock and scion is effected. From the foregoing it will be clearly understood that the success of the operation of grafting depends upon the accuracy of the joining. If the inner barks of scion and stock do not meet and fit closely, the circulation of the sap between the stock and the new head will not be maintained, in which event the scion will die. This principle applies to every description of grafting—and there are many—the differences being such as are due chiefly to differences in the sizes and ages of the stocks; scions of last season's growth being used alike for all. The kind of grafting most commonly used for small stocks is whip, splice, or tongue grafting. Figure 2 is an illustration of a very common method of tongue-grafting, but we shall first refer to figure 1, as affording an illustration of a very perfect method of applying the principle. If in the young stem (figure 1) the edge of a sharp knife be entered at *a*, and with one straight, sloping cut brought out at *b*, and if the parts be again joined exactly, ties at *c* and *d* will hold them together, so that they would not be readily displaced. As the inner barks would exactly meet, the circulation of the sap would proceed as usual, and a union would be effected in due course. This, then, would afford a most perfect example of grafting—like parts being everywhere joined to like. But as it is rarely possible to employ scions of the same sizes as the stocks, except in the case of yearling stocks, the process of grafting has to be varied—still, however, keeping the principle in view of placing in close contact a sufficient portion of the inner barks of both stock and scion to maintain the circulation of the sap. Where the stock and scion do not differ very greatly in size, as in the case of figure 2—which illustrates whip-grafting, the whole of the inner barks can be brought into contact—A is the scion, B is the stock. Mr. Robert Thompson, whose illustrations we have produced, thus describes this example:—

"In each a cut surface is exhibited, showing the wood *a a*. The points at the extremities of the dotted line, *a* and *a*, touch the inner barks of both stock and scion, whilst the points at *b* touch the outer barks. It will be readily observed that the bark of the stock, because older, is thicker than that of the scion; consequently if, as ought to be the case, equal surfaces of wood are exposed, the cut surface of the scion would not completely cover that of the stock, nor would this ever be the case except when the barks of both stock and scion are of equal thickness. In proceeding to operate cut the top of the stock in a sloping direction from *c* towards *d*, terminating, if possible, above a bud, developed or latent, as at *d*. Then take the scion and cut it sloping from above *c*, and thin towards the end at *f*; next enter the knife at *h*, and cut a thin tongue upwards to *c*. The scion is now prepared. Then, proceeding to the stock, enter the knife at *g*, and cut a slice upwards to *c*, so that the surface of the wood shall be, as nearly as possible, a counterpart of the exposed surface of the wood of the scion. If this should happen to be the case by a single cut, so much the better, but if not, it should rather be too narrow than too wide, for in that case a shaving can be taken off till the cut face *a* of the stock equals that of the scion. Enter the knife very little below *c*, and cut a notch to receive the tongue of the scion; this notch should be kept open with the point of the knife whilst the tongue of the scion is being inserted, the inner bark

indicated by the points at the ends of the dotted lines *a a* of the scion and stock, should be placed in contact, the parts secured by tying with matting or other material, and surrounded with clay, grafting wax, or other substances, to exclude the air and wet.

"Saddle-grafting.—This is represented by figure 3. It cannot be well performed except when the stock and scion are of nearly equal thickness. The stock A is cut sloping on both sides like a wedge terminating at *c*. The scion B is split up the centre, and each half is thinned to make it fit astride the wedge-like end of the stock. A thin, narrow-bladed knife should be employed for this purpose. The inner bark of the scion and stock having been made to coincide as nearly as possible, the parts should be secured by a ligature and covered with some grafting composition.

"This mode of grafting is liable to some objections. Unless the scion is cut out without splitting, there must be a rent, as from *c* to *d*, which will never unite, and is even liable to open and form a blemish. The operation requires more time to perform than whip-grafting, and, as already observed, it cannot be well employed unless the stock is nearly of the same size as the scion, for, supposing the stock to be $\frac{3}{4}$ in. in diameter, and the scion only $\frac{1}{4}$ in., the inner bark might be joined at the lower part, but could not possibly be so at the thinned edge at the top of the stock; on the contrary, $\frac{1}{2}$ in. of the wood must be there uncovered by the scion."

In our next the practice of cleft, notch, and crown grafting will be described.

CINCHONA IN WEST AFRICA.—Under the auspices of the Livingstone Expedition, the cultivation of the various species of cinchona is to be tried in the mountain valleys of the Congo.

TEA FERMENTATION.—A simple and practical way to make *all* your leaf ferment evenly, is to sift it with a half inch (mers) sieve immediately after the final rolling, and it will be found that about 4 per cent. of ordinarily rolled leaf will have fallen through; put this into your fermenting trays, but in a separate line to the coarser leaf, which has not gone through the sieve, and when ready for opening out (which will vary from a quarter to three-quarters of an hour before the other) keep and dry it separate, as it will also take less time to dry than the harder; one man can easily sift 12 mds. per hour, *i. e.*, by having the sieve suspended from some support to enable him to use it somewhat after the motion or action of Jackson's sifting machine, which is by the way something like his dryer.—*I. T. Gazette.*

TEA PRUNING, ITS CONNECTION WITH RED SPIDER.—I have noted that the bushes pruned in December and January, became dry in the outer bark from long exposure to the sun, and were soon affected with spider; those pruned in February and March, before the bushes began to put out new shoots, escaped spider; while those pruned after the new shoots sprung, were covered with spider. On blocks of tea at different ends of the garden, the early pruned parts were brown, the later pruned parts green, and only half the bushes in a few of the intervening rows were touched with spider. Red spider wastes about an eighth of the crop, and reduces the quality of the tea for the season. Trusting these remarks may elicit some further practical information on the subject.—*I. T. Gazette.*

PAPER MATERIALS.—From time to time appear in the periodicals notices of some new material like Banana fibre, Bamboo shoots, Blue-grass, and the like, which have all in common the same grave defect—the necessity of special cultivation, and therefore I have never seen anything to come out of them except hobbies for benevolent and sanguine persons to trot out. But from the trade returns of India it appears that Flax must be grown extensively in the north-west, and that the Linseed alone is saved. What becomes of the stalks? By steaming and treating them with alkaline washes, or by some other of the many patented processes for disengaging the fibre from the gum and the bark, will it not be possible to convert that mass of refuse material into paper pulp, if not into fibre fit to be spun?—has it ever been proposed or tried? I could say the same of the twigs of the silk Mulberry, the bark of which is one of the various materials used in making the tough paper of Japan, though less generally than that of the paper Mulberry (Broussonetia) or the Edgeworthia papyrifera. Any quantity of Mulberry twigs could be had in the south of France and Lombardy, where those cuttings are used only as household fuel. Suitable spots with an abundance of good water could be found in those countries for establishing the works. —F. VAN VOLXEM.—*Gardeners' Chronicle.*

TOBACCOS.—Should the report that the Spanish Government is about to discontinue the tobacco monopoly in the Philippine Islands prove true, one of the closest and most strictly enforced monopolies that ever existed will be put an end to. The production of the Manilla cheroot was fenced about with protective regulations even from before the moment that the tobacco seed was put into the ground almost until that at which it was placed between the lips of the smoker. Some land in the Island of Luçon being better suited to the cultivation of the plant than others, all owners and occupiers of property in certain districts had to see that a proportion of their land under cultivation—the amount being regulated by the Government—was devoted to growing tobacco. The kind of seed sown and the mode of rearing the plants were closely supervised by the authorities. The product of the harvest could be purchased only by the Government; and no one else could manufacture it into cigars or cheroots. No unmanufactured tobacco could be sold even for exportation, unless it were to be carried beyond the Cape of Good Hope—a regulation made to prevent the starting of a rival manufactnre at Macao or Hong Kong. The factories of Manilla and Cavite are immense establishments. Every visitor to the former city must have been struck by the crowds of "hands"—chiefly Tagal women and girls—which stream out of their gates at the close of the working hours. Their interest in the proposed change must be considerable. The system pursued in Cuba has long been altogether different. The *vegas* or tobacco farms of the celebrated Vuelta Abajo—the region in which the finest tobaccos are grown—are usually small holdings cultivated chiefly, if not entirely, by white men. Slave labour in Cuba has had little to do with the production of at least the raw material of the celebrated Havana cigars, but was principally employed on the great sugar estates. The cultivation of the plant, free as it is, is not more so than the manufacture of the cigars and cigarettes. Though the huge factories of Manilla are not to be found at Havana, a remarkable change in the system of cigar making has taken place within the last five-and-twenty years. At the beginning of that period the small factories were many in number; some streets—notably the Calle del Sol and the Calle Obispo—were lined with little shops, in which might be seen some half-a dozen white creoles vigorously smoking and rolling cigars. Some years later these had nearly all disappeared, and the manufacture had apparently passed into the hands of large firms, with manufacturing establishments of considerable size. The great cigarette works of La Honradez were one of the sights of the city. Though perhaps not even those whose Eastern experiences tend to preserve pleasant recollections of the Manilla plant will dispute the superiority of an Havana, it is worth remembering that the former was, and indeed is, by a long way the cheaper.—*Pall Mall Budget.*

THE LABOUR DIFFICULTY IN FIJI.

(From the *Fiji Times*, July 6th.)

In again reverting to the reply of his Excellency to the deputation that recently waited upon him with reference to the insufficiency of the labor supply for 1881, we propose to draw attention to its general bearing upon the native question. The proposition of the hon. Edward Langton was to the effect that in view of the serious losses certain to be entailed on planters through a want of hands, and considering the extent to which the progress of the colony would be thereby retarded, his Excellency should intimate to the chiefs that the Government opposition to their young men engaging as agricultural laborers was temporarily withdrawn. The reply was as decisive as the reasons advanced in support of it were weak and untenable. "His Excellency was opposed to the indenture of Fijians for a long period, at a distance from their homes, and while he was willing to devote his time and energy to assist the planters in other ways, he could hold out no hope whatever in this direction." It will be noticed that the use of the words "long period" is almost Gordonian in its diplomatic finesse. To the Fijian public it of course conveys no other meaning than that of twelve months, the longest period permissible under Ordinance, but to readers at a distance it is charmingly indefinite, and may mean any interval supervening between boyhood and old age. In arriving at the above conclusion, Mr. Des Vœux was dealing with a matter seriously affecting two distinct but not diverse interests. If these interests are inimical; if an assent to the suggestion made on behalf of the planters could in its operation exercise an injurious effect upon either the moral, social, or general well-being of the Fijian, then, the decision is most undoubtedly the correct one, even though the progress of the colony should suffer in consequence. If, however, instead of being inimical, these interests are identical; if the benefit conferred upon the planter by a consent to this proposition would be equally shared in by the Fijian, while at the same time the progress of the colony would be thereby materially advanced, the official veto can but be regarded as a most lamentable error in judgment. His Excellency affirms a belief in the first position,. and therefore claims to be right in his refusal; we as confidently assert the correctness of the second, and consequently impeach both the justice and good policy of the course adopted. The hon. E. Langton represented no less than £100,000 of imported capital invested in the colony by the Mango Island Plantation Company on the strength of this implied promise, and, failing the supply of Polynesians, he simply asked that those Fijians who were willing, might be permitted to work for wages, thereby benefiting themselves, the planters, and the colony at large. Had the request been made of Sir Arthur Gordon, he would have given an overpoweringly gracious consent to it, if only to add a specious color to his own previous assertions, and the same evening would have despatched a message to the chiefs, directly prohibiting any laborer leaving his province. Mr. Des Vœux has preferred to deal honestly with the planters; he has utterly discarded the transparent tie ion of free agency hitherto so persistently employed and has the courage to state the naked but unpalatable truth; that the Fijian British subject is not a free man; that his labor is not his own to dispose of; and that he shall not earn his living in his own way by working for the planters, however much his inclination or interest may prompt him to that course.

The system by which the entire labor of the Fijian is monopolised by the Government for revenue raising purposes is inherently vicious in principle and most disastrously ruinous in practice, both to the morale and physique of the native, besides which it has not even the contemptible merit of financial success to recommend it. It is slavery, with the disgraceful adjunct that it perseveres in the miserable affectation of an attempt to disguise its real character under the hypocritical garb of philanthropy. Can the Fijian subject of the British Crown, existing under its operation, say, "I am a Free Man." His Excellency has answered "No." Then the perpetuation of the system is a disgrace to the Government that has inaugurated it and a scandal to the flag under the shadow of which it is maintained

INDIAN GOLD MINING.

A "Practical Miner" writes to the *Mining Journal*:—

I have read in your valuable Journal of July 9th, a communicated article on the Indian gold mines, written, I suppose, by some mining engineer who has had the necessary training and education to understand gold mining at a glance.

First, he says the character of the quartz in the mines of Wynaad and Mysore has a waxey or milky appearance, and it is entirely free from any ferruginous matrix—pyrites of iron. Now, Sir, I have worked in the most productive mines of both California and Nevada. My experience teaches me, if you wish to find good profitable gold mines you must find your lodes and reefs well charged with iron pyrites. In fact, all profitable gold mines on the Pacific Coast are found on large north and south ferruginous veins in slate, gneiss, greenstone, quartzite, etc. I never saw a profitable gold mine on the Pacific Coast or elsewhere in the pure compact quartz 60 feet from surface. I have seen gold mines in California—the Sutler Creek Mine which was profitably worked near 200 fathoms from surface, but the gold was associated with iron pyrites and a small percentage of galena. The celebrated gold mines of Nevada County, California—the Rocky bar Eureka, Allison's Ranch; French Lead, and Idaho Mines—which have been the best paying mines of California—were found in ferruginous lodes, some of them worked to a depth of 170 fathoms. I have seen in the pure compact quartz veins good deposits of gold near the surface, but never a mine that was worked profitably 50 feet from surface. At Sonora in Tuolumne County, I have known the clean quartz veins productive, 20 and even 30 feet from surface My practical experience in gold mining tells me you may as well expect to find a profitable copper mine without sulphur as a profitable auriferous mine without iron pyrites. Australian gold mines have precisely the same characteristics, also the gold mines of Nova-Scotia, Brazils. The late Capt. Thos. Treloar, of the Don Pedro Mines, says the rich portions of the lodes are found more auriferous in the ferruginous matrix than elsewhere.

Secondly, your correspondent says in the Kolar district the ground is not broken up or disturbed by, I suppose, cross-courses or intersection of any other strata, but simply the reefs are confined between two well-defined walls of exceedingly hard gneiss, almost like a fine grained granite. Now, any practical gold miner would consider this an unfavourable omen for the production of gold. I have always found the veins most productive for gold near these interruptions, cross courses, heaves and dislocations; they are the great irrigators of all metallif rous veins and rocks; without these disturbances the veins are seldom productive for any distance. All intelligent gold miners know from experience that the quality of the veins in California is dependent on the mysterious effects of the junction of rocks of different composition.—*M. Mail.*

CASTOR OIL GAS-WORKS AT JEYPORE

A hint for Ceylon where the castor oil plants grow freely can surely be taken from the following:—

A report by Major S. S. Jacob, on the Jeypore Oil

Gas-works, an establishment founded by the late Maharajah of Jeypore, is quoted in the *Journal of Gas Lighting*. From the memorandum on the working of the establishment prepared by the present manager (Mr. S. J. Tellery), whose administration is highly commenced by Major Jacob, it appears that the gas is principally produced from castor oil, with the addition, when the castor seed is not available, of poppy, til, or rape seed. According to Mr. Tellery's own records, he produces from one maund of castor oil (82 lb) about 750 cubic feet of 26½-candle gas; or 1,000 cubic feet of 18½-candle gas; or 1,250 cubic feet of 9-candle gas. With other oils the same quantity of material worked to make gas of equal quantities will produce 610 cubic feet, 762 cubic feet, and 914 cubic feet of the respective grades of illuminating power. According to these results, taking the current prices of oils delivered into the works—castor oil being R11 12a (22s 4d), and the other oils R10 (19s 10d) per maund—the castor oil gas is R0 10a 4p (1s 3d) per 1,000 cubic feet cheaper than other oil gas. The works was double in all respects, duplicate sets of retorts, purifiers, &c., and gasholders being erected, for which arrangement no reason is given. At present two horizontal retorts are used, which are kept at work during about 218 hours per month, and produce something like 98,720 feet of gas in this time. Worked in this way, the cost of manufacture (exclusive of the cost of oil) is as follows :—

	R.	a.	p.
Wear and tear	1	3	2¼
Fuel	2	11	7
Labour	0	5	3¼
Purification	0	0	4½
	R.	a.	p.
Total cost per 1,000 cubic feet =	R4	4	4½, or 8s 6d.

This high charge for manufacturing expenses is said to be due to the fact of so little gas being required; if the consumption should increase to about 260,000 cubic feet per month, which could be supplied without increased cost for establishment charges, the working expenses per 1,000 cubic feet would be reduced to R2 9a 5¾p (5s 1d). Another peculiarity of the Jeypore undertaking is the necessity that exists for the manager to unite the attributes of a farmer to his other acquirements, for the purpose of securing a constant and cheap supply of raw material for gas-making. Last year Mr. Tellery personally superintended the sowing of 300 acres with the castor plant (*Ricinus vulgaris*), and the establishment includes a hydraulic oil-pressing apparatus. The process of extracting the oil for carbonising is as follows :—First, the castor seed is passed through the crusher, when the shells only are broken off. The shells are then picked out by hand, and the seed is again introduced into the crusher, where it is ground to a paste. It is then passed into the heating pan, and, after being well heated it is packed into horsehair bags and filled up hot into the press immediately. After about 20 minutes pressing, the exuding oil being meanwhile collected, the cake is removed and ground over again. It is subsequently heated and pressed a second time, until about 33 or 40 per cent of oil is obtained from the seed. The labour of preparing and pressing the castor seed costs R1 1a 8p (2s) per maund of oil. The cost of extracting other seed oil is about the same, with the exception of the cost of removing the shells. For generating gas, the oil is used as it comes from the press.

ANALYSES OF NEILGHERRY CINCHONA BARK.

Mr. J. E. Howard, F. R. S., has reported for the information of the Secretary of State and of the Government of Madras, on 30 samples of cinchona bark sent home from the Government Nilgiri plantations by Mr. Robert Cross, who collected them in November and December last. He congratulates the local Government on the value thus shown of the plantations, the average yield of the best alkaloids being second only to that of the most useful sort of cinchona (the Ledgeriana) in the island of Java. It is, therefore, he says, of great importance that the trees, whose superior quality is thus ascertained, should be reserved for seed. "The first object mentioned by Mr. Cross in obtaining these specimens is to test 'the relative excellence of each species in the production of quinine.' It is, therefore, unfortunate that he includes more than two-thirds of his samples under the head of 'Crown Condaminea.' I conclude that he saw no difference of species amongst these, and if so, I must conclude from previous knowledge that the whole must belong to the true '*Cinchona officinalis*,' as defined by Sir Joseph D. Hooker in the *Uritusinga* form. This latter was the name conferred by the first Spanish Botanists employed in the study of its characteristic and retained by Mr. McIvor and myself. I have reason to plead for the retention of the original name, as a large portion of the trees of the above plantation are the descendants of one raised from seed sent me 'from the mountain of Uritusinga' in the year 1859, which I gave to the Indian Government. Mr. McIvor wrote me in 1875 as follows:—'The extent planted with *C. Uritusinga*, the plant you sent out by Mr. Lyall, is over 70 acres and originally 65,000 plants were planted, but of course the failures thereof should be deducted, and this will leave in round numbers, 60,000 plants, the progeny of the one you gave to the Indian Government, Mr. McIvor sent me samples from the *branches* of these trees, from which I obtained an extraordinary result in quinine. This is now confirmed by these samples of trunk bark obtained by Mr. Cross, and the examination proves that the Uritusinga is as much superior to the more commonly cultivated varieties of *C. officinalis* as the Ledgeriana is to the common *C. Calisaya*. It is to be regretted that more attention has not been paid to the selection of the best seed. I have frequently pointed out the superior quality of the importations from the Doddabetta Plantation especially, from which a quantity that seems disproportionate and exhaustive has been sent home in recent years. I am glad to speak in almost equally favorable terms of the Pitayo bark, No. 15. I have before urged special attention to the cultivation of this species, because it is the quinidine-producing sort, thus yielding, in addition to a fair quantity of quinine another valuable medicine, which sells easily at more than half the price of quinine, and can, no doubt, be passed off *as such* by those who regard more the cheapness than the exact chemical composition of their medicines; but, if sold *as quinidine*, it is of service to the community, and involves no breach of commercial morality. The value of this specimen of bark would be at this moment 9s per lb."

Mr. Howard forwards the following analyses of the samples referred to, which were made by his nephew, Mr. David Howard, F. C. S. :—

CROWN CONDAMINEA.

Original Bark taken from stump of a cut down tree planted in 1863, which was found over-grown with grass in an old fence of the Government Garden Ooty.

Quinine.	Cinchonidine.	Cinchonine.	Quinidine.	Amorphous Alkaloid.

From Government Plantations, Nadnvatam. Original Bark from a shrub-like tree. Date of planting uncertain.

4·98	0·58	0·83	0·16	0·50

Mr. David Howard says with reference to these analyses:—"The samples have the appearance of being taken from the lower part of the stem of the tree; if this is the ease, our experience would show that the average bark of the whole tree would give a lower test; the small and young bark from branches of crown bark in the last sale of Dodabetta bark yielded less than 1 per cent. of quinine. The same cause may explain in measure the high percentage of quinidine in many of the samples; this alkaloid appears to increase in a marked degree in the bark near the root. Sample No. 15 is the very finest quality of Pitayo bark. This sort of bark sells freely at prices exceeding those given for good South American calisaya. Sample No. 21, though marked 'Red Bark,' both in appearance and test resembles fine crown bark. Sample No. 25 appears from the analysis to be true Ledgeriana, the small percentage of cinchonidine which it gives is generally found in that variety both from Java and from South America. To compare the above analyses with those in which quinine is returned as sulphate one-third must be added to the percentage: thus 6 per cent of quinine is equal to 8 per cent. of sulphate of quinine."—*Madras Mail.*

CEYLON-LIBERIAN COFFEE SEED IN FIJI: AND A FINE SAMPLE OF FIJI COFFEA ARABICA.

Messrs. Leechman & Co., Colombo, have received the following letter from Mr. A. R. Wilson of Forest Creek estate, Taviuni, Fiji, dated 2nd July:—

"I duly received your favour of the 15th of March, as also the therein mentioned registered packet containing 10 cherries and 150 seeds of Liberian coffee. I delayed an answer until I should see how the seeds turned out. According to your suggestion, I cut the ends off one or two of the seeds. The embryo in the seeds had begun to germinate and throw out radicles through the moisture and air in the box in which they were enclosed. I planted the beans on several different spots on the estate, and at various altitudes, on the principle that

'The mouse that trusts to one poor hole
Can never be a mouse of any soul.'

"In each spot some of the seeds have thrown out their radicles and stems and appear thriving. The Liberian coffee in cherry arrived in like good condition, the saccharine matter having remained moist and sweet. I think the average size of the Liberian coffee beans in parchment is no larger than the average size of the parchment beans of the coffea Arabica, grown on this estate. I notice in a little pamphlet by John Walker & Co., entitled a 'Hand-

book' under the heading 'Sieves,' the following specification : 'The bottom is of perforated metal with round holes from $\frac{3}{8}$ths to $\frac{1}{2}$.' 'As a rule, the holes should be so small as to hinder the smallest cherry from passing through, but wide enough to admit the largest parchment bean.' A 'sieve' with holes of such dimensions would hardly admit any bean grown on this estate. I enclose half-a-dozen parchment beans chosen indiscriminately, from an inspection of which you will notice that their average dimensions are about from $\frac{1}{2}$ an inch to $\frac{5}{8}$ths of an inch in length, and from $\frac{3}{8}$ths of an inch to $\frac{1}{2}$ an inch in breadth. The Ordinance prohibiting the importation into the Colony of seeds and plants has been repealed. I should take it kindly if you would submit this letter to the editor of the *Ceylon Observer*, in case he should like to publish it."

The sample of Fiji parchment sent is certainly a very good one, equal to our very largest Ceylon beans of Coffea Arabica.

SOUTH AFRICA.

IN PARAGUAY the preparing of Indigo from the *Eupotorium tinctorium* is a large industry. The plant would grow in Natal.—*P. E. Advertiser.*

THERE IS AN ORANGERY in this division which is expected to yield 250,000 oranges this season ; 50,000 have already been sold with a pecuniary result which beats sheep and ostrich farming hollow.—*East London Despatch.*

OSTRICH FARMING.—The *Cape Argus* gives a wail for the decrease of the ostrich industry in the Colony. It says : That ostrich farming in this colony has seen the best of its days is pretty generally understood, South America will soon be competing with us, and in Australia the industry is already established. We learn from the *Colonies and India* that on an ostrich farm on the River Murray (New South Wales) there are fifty-six birds, which, with two or three exceptions, are in excellent health, and in a thriving condition.—*Natal Mercury.*

THE DATE COFFEE COMPANY.

A correspondent writes :—"I cannot think why you have not given the benefit of the analysis in *Truth* of the affairs of the *Date Coffee Company*. You will find it in the paper for 14th July. If true, the superlatively happy state of affairs made out by the chairman at the yearly meeting is a delusion and a snare, to enable the wire-pullers to carry on their little game a little longer."

We thank our correspondent for the hint. The extract is as follows :—

"This remarkable Company has issued its report. According to its balance-sheet the assets consist of debts to the amount of £20,201, machinery and plant which has cost £3,789, and about £4,500 in cash. Who the debtors are that owe it £20,201 is not stated. It has 'sold' date coffee for £2,111, and its current expenses have been £5,433. Some of the items are curious. Thus, advertising figures for £1,665, printing and stationery for £215, law charges for £497, and directors' remuneration for £500—that is to say, these four items alone considerably exceed the gross returns on sales. The directors, however, 'are sanguine that when the make amounts to forty tons per week: the original estimate of their engineer will be realized, and the Company earn 100 per cent on its capital.' When this does occur I will engage to drink date coffee for my breakfast. I do not think that I can in more precise terms express my utter disbelief in the probability of the Company ever earning 100 per cent. by inducing the public to adopt a beverage composed of an infusion of ground date stones, and to play at believing that it is coffee. So far as I can make out the balance-sheet, almost all the capital has already gone into the pockets of the promoters. The share capital seems to be £34,000, and the debenture capital to be £6,340. Against this, the patent rights are set down for £2,400, royalty compounded £30,000, and preliminary expenses £2,926, thus leaving a balance of £5,014 for the Company. The payment of £32,400 for the right to grind date stones, the sale of this right to a German Company for £50,000, and the fact that the £5 shares of the Date Company were actually quoted at 45, are the most singular instances of the success of unblushing impudence that have occurred during the present rage for Company-mongering."

CHEAP GUM FOR LABELS.—Extract from the *Scientific American* :—Postage Stamp Mucilage. Gum dextrine 2 parts ; water, 5 parts ; acetic acid, 1 part; dissolve by aid of heat, and add 1 part of spirits of wine.—*I. T. Gazette.*

AGRICULTURE FOR EDUCATED CEYLONESE.—Enjoying the pleasures of a country life just now, and taking an active interest in the working of this place, I wish more of my countrymen would take to agriculture. There *are* obstacles arising from want of capital, but unfortunately those who have the means seem to prefer a town life and Government employment to independence, and an active healthful life. Your *Tropical Agriculturist* is a most useful publication, and is simply invaluable to those who would keep abreast of the times in matters agricultural at a minimum of cost.—*Cor.*

CATTLE-BREEDING AT THE SAIDAPET FARM.—The experiments now being carried on at the Saidapet Farm, Madras, with cattle-breeding with stock imported from Aden, seem to be succeeding. The satisfactory results that have attended the importation of Aden cattle into Madras have induced the Board of Revenue to sanction a further outlay of Rl,200 for the purchase of fresh stock for the Saidapet Farm. The bulls that are now to be ordered "should," the Superintendent of Government Farms says, "not be over five years of age, should be docile, and of a good shape ; the cows should be young and by preference, rearing their *first* calves ; and that they should undoubtedly be good milkers and docile ; the whole of the stock to be in perfect health."—*Pioneer.*

LIBERIAN COFFEE.—Friend Edward S. Morris, merchant, Philadelphia, whose advertisment appears in our columns with satisfactory English references, is very anxious to become the agent for Ceylon Liberian Coffee in America. We believe he has exceptionally good opportunities for disposing of such produce. He writes to us as follows :—

Established 1855. Appointed Commissioner for Liberia to the U. S. Centennial Exposition, 1876. J. J. Roberts, President.

Philadelphia, July 7th, 1881. Edward S. Morris, No. 6, South Merrick St, opposite New City Hall.

Mr. J. Ferguson, Colombo, Ceylon.

DEAR SIR,—Many thanks, my kind friend, for the copy of "*Liberian coffee, its hist ry and its cultivation.*" I value of very much, as it so substantially confirms all my claims for this coffee as made by me in 1862-3, to the people of Liberia. It is a pleasure always, to feel we have not made a mistake in our calling. As I cannot get enough Liberia coffee properly cultivated and cleaned to supply my nice and very particular Centennial customers, I am more than willing to introduce Liberia Ceylon ; and I know it will take with them. Indeed, I shall leave nothing undone to identify myself with Liberia Ceylon, as I have with Liberia, the only coffee I ever sold, I have customers throughout the U. S., and I know how to reach them.

—Yours truly, EDWARD S. MORRIS.

We would recommend consignments to be made to Mr. Morris.

LIME AS A MANURE.

"3 TO 10 TONS OR SO APPLIED PER ACRE"?

An estate proprietor (who signs himself "A Great Ignoramus") writes:—"Mr. R. C. Haldane says (*vide* your editorial in a recent issue:— 'Some of my readers may think that such a quantity of lime would burn up the coffee.' Then he goes on to quote from Stephen's 'Book of the Farm':—'I have used 150 bushels [3 tons?] of lime per acre with benefit. I have seen as much as 510 bushels (10 tons?) applied to the acre of wheat with manifest advantage and (says Mr. Haldane) what the tender wheat roots can stand' I believe the strong coffee roots can stand also. Does Mr. Haldane here refer to immediate applications of freshly burnt and UNSLAKED LIME, or immediate application of *slaked* lime; or lime slaked on a heap, then covered up with earth, and used only after a certain interval of time? and if the latter what interval of time ought to take place before it is applied? If you quoted freely in your *Tropical Agriculturist* regarding the right and wrong uses of lime, as regards coffee cultivation, I am of opinion *great benefit* would arise; for I am under the impression that a vast amount of injury has been done to coffee of late years by lime being *improperly applied*. Definite and reliable information is required as to the form in which lime should be used simply by itself and forked into the ground, and also when applied mixed with other manures such as bones, castor cake or cattle dung, or when applied as a mixture to compost heap, or again when applied to newly dug up but unplanted land of poor quality in order to prepare and improve it for planting a few months (?) later on In a case of this kind (light and poor soil) the application in quantity of *unslaked* lime would probably fig it up for one year but utterly ruin it for ever afterwards: the question is would it? What effect would unburnt powdered limestone have, if applied to coffee fields?" Another estate proprietor writes:—"Why do you not place on record some easy method for planters to test limestone. A lot of worthless stuff must often be used."

The following extract from the "Elements of Agricultural Chemistry and Geology," by Johnston and Cameron, will give planters some useful ideas on the subject if carefully perused. As a general rule these eminent authorities are in favour of both burning and slaking lime before applying it to the soil; but whether this would apply in all cases to our Ceylon soils and to coffee cultivation is a question we are not prepared to answer. Once again, let our correspondent get his superintendent to experiment and let him treat a few acres in different ways on the same field and report the result.

"LIME: ITS USES IN AGRICULTURE.

"The use of lime is of the greatest importance in practical agriculture It has been employed in the forms of marl, shells, shell-sand, coral, chalk, limestone, limestone gravel, quicklime, &c., in almost every country, and from the most remote period.

"COMPOSITION OF LIMESTONES AND CHALKS.—When diluted muriatic acid, or strong vinegar, is poured upon pieces of limestone, chalk, common soda, or common pearl-ash, effervescence takes place, and carbonic acid gas is given off (p. 35). If a current of this gas be made to pass through lime-water (see fig. 21), the liquid becomes milky, and a white powder falls, which is pure *calcic carbonate*. It consists of—

	Per cent.
Carbonic acid (CO_2)	44
Lime (CaO)	56
	100

Limestone, marble, and chalk consist, for the most part, of calcic carbonate. In soft chalk, the particles are held more loosely together; in the hard chalks and in limestones, the minute grains have been pressed or otherwise brought more closely together, so as to a more solid and compact mass, sev-

In regard to limestones and chalks, there are the eral circumstances which it is of importance for form practical man to know. For example—

a. That they are not composed entirely of mineral or inorganic particles, such as are formed by the passage of a current of carbonic acid through the lime-water. They consist in great part, sometimes almost entirely, of minute microscopic shells, of the fragments of shells of larger size, or of solidified masses of corals, which formed coral-reefs in ancient seas which once covered the surface where the limestones are now met with. The blue mountain-limestones contain many of these coral-reefs, while in our chalks rocks vast quantities of microscopic shells and fragments of shells appear.

b. Being thus formed at the bottom of masses of moving water, the chalks and limestones are seldom free from a sensible admixture of sand and earthy matter, Hence, when they are treated with diluted acid, though the greater part dissolves and disappears, yet a variable proportion of earthy matter always remains behind in an insoluble state. This earthy matter is sometimes less than half a per cent of the whole weight, though sometimes it amounts to as much as 30 or 40 per cent.

c. All animals hitherto examined contain in certain parts of their bodies traces more or less distinct of phosphoric acid, generally in combination with lime, forming *phosphate of calcium*, This calcic phosphate, their remains, when dead, retain in whole or in part. It thus happens that limestones very frequently contain phosphoric acid, and that the proportion of it usually increases with that of the visible remains of animals, shells, corals, &c., which occur in it. In the magnesian limestones of the county of Durham, the proportion of phosphate of calcium is found to be as small as 0.07 to 0.15 per cent; while in a limestone from Lanarkshire (Carluke), it amounted to 1¼ per cent; or 100 lb, of the burned lime contained as much as 2½ lb. of phosphate of calcium—(Johnstone.)

d. The parts of animals also contain sulphur, and this has given rise to the presence of sulphuric acid in chalks and limestones. This acid exists in them in combination with lime—in the state of gypsum. The proportion of this gypsum hitherto found in native chalks and limestones is small, varying from one-third to four-fifths of a per cent.

e. Magnesic carbonate, the common magnesia of the shops, is also present, almost invariably, in all our limestone and chalk rocks. In the purest it forms 1 or 2 per cent, in the most impure from 40 to 50 per cent, of the whole weight. The rocks called *dolomites*, or magnesian limestones (p. 107) are characterised by the presence of a large proportion of carbonate of magnesium. In the Old Red Sandstone formation also, beds of limestone occur which are rich in magnesia. Such limestones are usually considered less valuable for agricultural purposes. They can be applied less freely and abundantly to the land, and possess what practical men call a burning or scorching quality. They are, however, preferred to purer limes in some districts, as in the highlands of Galloway, for application to hill-pastures,

ANALYSES OF LIMESTONES FOR PENRITH FARMERS' CLUB, BY PROFESSOR ANDERSON, GLASGOW.
(1 out of 10 specimens).

Quarry.	Calcic carbonate.	Magnesic carbonate.	Iron oxide and alumina.	Insoluble matter.

Alston Moor	97·31	1·43	0·18	1·08
Ravenstonedale	95·20	1·67	0·56	2·57
Brampton ...	94·80	2·36	0·81	2·03

No phosphate or sulphate of calcium could be found.

COMPOSITION OF CORALS, SHELL-SANDS, AND MARLS.—1. *Corals*, as they are gathered fresh from the sea on the Irish (Bantry Bay) and other coasts, contain, besides calcic carbonate, a small percentage of calcic phosphate, and sometimes not less than 14 per cent of animal matter. This animal matter adds considerably to the fertilising value of coral-sand, when laid upon the land in a recent state, or when made into compost.

2. *Shell-sand* consists of the fragments of broken shells of various sizes, mixed with a variable proportion of sea-sand. It contains less animal matter than the recent corals, and its value is diminished by the admixture of sand, which varies from 20 to 70 per cent of the whole weight. On the shores of many of the Western Islands, shell-sand is found in large quantities, and is extensively and beneficially applied, especially to the hillside pastures and to peaty soils.

3. *Marls* consist of calcic carbonate—generally the fragments of shells—mixed with sand, clay, or peat, in various proportions. They contain from 5 to as much as 80 or 90 per cent of calcic carbonate, and are considered more or less rich and valuable for agricultural purposes as the proportion of lime increases. They are formed, for the most part, from accumulations of shells at the bottom of fresh-water lakes which have gradually been filled up by clay or sand, or by the growth of peat.

THE BURNING AND SLAKING OF LIME.—1. *Burning.*—Limestones, when of a pure variety, consist almost entirely of calcic carbonate, which, as we have seen, contains 56 per cent of lime, or 11¼ cwt. to the ton.

When this limestone is put into a kiln, with as much coal as, when set on fire, will raise it to a sufficiently high temperature, the carbonic acid is driven off in the form of gas, leaving the pure lime behind,

In this state it is known as burnt lime, limeshells, caustic lime, and quicklime, and possesses properties very different from those of the unburnt limestone. It has a hot, alkaline flavour, absorbs water with great rapidity, falls to powder, or slakes, and finally dissolves in 732 times its weight of cold water. This solution is known by the name of lime-water.

2. *Slaking.*—Its teudency to combine chemically with water is shown in the process of slaking. Almost every one is familiar with the fact that, when water is poured upon quicklime, it heats, emits steam, swells, cracks, and at last falls to a fine, nsually white, powder, which is two or three times as bulky as the lime in its unslaked state. When thus fully slaked and cool, the fine powder consists of—

Lime	...	...	76 per cent (nearly).
Water	...	...	24 ,,
			100

Or 20 cwt. of pure burnt lime absorb and retain in the solid state 6⅜ cwt. of water, forming 26⅜ cwt. of slaked lime, called *hydrate* of calcium by chemists.

When quicklime is left exposed to the air, even in dry weather, it gradually absorbs moisture from the atmosphere, and falls to powder without the artificial addition of water. In this case, however, it does not become sensibly hot as it does when it is slaked rapidly by immersion, or by pouring water upon it. Some chemists state that this powder contains both hydrate and carbonate of calcium.

EFFECTS OF EXPOSING LIME TO THE AIR.—When lime from the kiln is slaked by means of water, it still retains its quick or caustic quality. But if, after it has fallen to powder, it be left uncovered in the open air, it gradually absorbs carbonic acid from the atmosphere gives off its water, and becomes reconverted into dry calcic carbonate.

When lime is allowed to slake spontaneously in the air, it first absorbs water, and slakes, and falls to powder, and then absorbs carbonic acid and is changed into carbonate.

But as soon as a portion of the lime slakes, it begins to absorb carbonic acid, probably long before the whole is slaked Thus the two processes go on together; so that, in lime left to slake spontaneously, as it often is on our fields and headlands, the powder into which it falls consists in part of caustic hydrate, and in part of mild carbonate of calcium. Its composition is nearly as follows:—

		Per cent.
Calcic carbonate	... ...	57.4
Calcic hydrate	{ lime, 32.4 } ...	42.6
	{ water, 10.2 }	
		100

When it reaches this stage or composition, the remainder of the hydrate absorbs carbonic acid much more slowly, so that, when spread upon or mixed with the soil, it takes a much longer time to convert it into carbonate. At last, however, after a longer or shorter period of time, the whole of the lime becomes saturated with carbonic acid, and is brought back to the same state of mild *un*-caustic carbonate in which it existed in the native chalk or limestone before it was put into the kiln.

ADVANTAGES OF BURNING LIME.—If the lime return to the same chemical state of carbonate in which it existed in the state of chalk or limestone,—what is the benefit of burning it?

The benefits are partly mechanical and partly chemical.

a. We have seen that, on slaking, the burnt lime falls to an exceedingly fine bulky powder. When it afterwards becomes converted into carbonate, it still retains this exceedingly minute state of division; and thus, whether as caustic hydrate or as a mild carbonate, can be spread over a large surface, and be intimately mixed with the soil. No available mechanical means could be economically employed to reduce our limestones, or even our softer chalks, to a powder of equal fineness.

b. By burning, the lime is brought into a caustic state, which it retains, as we have seen, for a longer or shorter period, till it again absorbs carbonic acid from the air or from the soil. In this caustic state, its action upon the soil and upon organic matter is more energetic than in the state of mild lime; and thus it is fitted to produce effects which mere powdered limestone or chalk could not bring about at all, or to produce them more effectually and in a shorter period of time.

c. Limestones often contain sulphur in combination with iron (iron pyrites). The coal or peat, with which it is burnt, also contains sulphur. During the burning a portion of this sulphur (oxidised) unites with the lime to form gypsum, by this means adding to the proportion of this substance, which naturally exists in the limestone.

d. Earthy and silicious matters are sometimes present in considerable quantity in our limestone rocks. When burnt in the kilu, the silica of this earthy matter unites with lime to form *calcic silicate*. This silicate being diffused through the burnt and slaked lime, and afterwards spread, in a minute state of division, over the soil, is in a condition in which it may yield silica to the growing plant, supposing silica to be essential.

Thus the benefits of burning are, as we have seen, partly mechanical and partly chemical. They are mechanical inasmuch as, by slaking, the burnt lime can be reduced to a much finer and more bulky powder than the limestone could be by any mechanical means; and they are chemical, inasmuch as, by burning, the lime is brought into a more active and caustic state, and is, at the same time, mixed with variable proportions of sulphate and of silicate of lime—which may render it more useful to the growing crops."

INDIAN TEA.

TO THE EDITOR OF "THE LONDON TIMES."

Sir,—*Apropos* of the remarks on the subject of Indian tea in your leader of to-day, it may interest your readers to learn that since 1860, when the imports of Indian tea first reached 1,000,000 lb., the growth of the trade has been rapid and continuous. At the end of the first decade, in 1870, the quantity imported was 13,000,000 lb., while last year, at the close of the second decade, the imports were 45,000,000 lb., of the estimated value of £3,000 000. The area of land now under plant is over 200,000 acres, representing an investment of British capital to the extent of £15,000,000, and giving employment to a population of over a quarter of a million souls. The crop of tea this year is not likely to be less than 50,000,000 lb.

India, as you remarked, can grow "far better tea" than China can, and as the public learn this fact, thay will not be content with inferior sorts, even when blended with Indian, but will insist on having pure Indian tea.

The tea plant, as you are aware, is acknowledged to be of Indian origin, and is indigenous to Upper Assam, from whence in byegone ages it must have been introduced into China.—I am, Sir, your obdt. servant,

ERNEST TYE, Secretary.

Indian Tea Districts Association, St. Mary's-chambers, St. Mary-axe, July 27.

SUGAR-PLANTING IN QUEENSLAND AND FIJI.

Owing to causes which are easily explained, the development of the sugar industry, both in Northern Queensland and in Fiji, received a check last year. As regards the former, the exceptional severity of the frosts of last winter destroyed many acres of cane, and also seriously affected the results of the crushing, which showed a falling-off in the quantity of sugar produced of 3,150 tons as compared with the yield of the preceding season, and this notwithstanding that there was an increase of 3,326 acres under crop as compared with 1879-80 This somewhat discouraging result does not appear to have affected the enterprise of the planters, for there is reason to believe that during the present year a still larger area will be placed under cultivation, particularly along the banks of the John-tone River in the Far North, and in the Bundaberg district. The acting chief inspector of distilleries in Queensland also reports that many of the old established plantations are extending their cultivation fields, which is itself a satisfactory indication of the payable nature of the industry. Mackay still remains the chief producing district, nearly one-half of the total acreage under crop being situated there. The quantity of sugar exported was upwards of 4,200 tons less than that of the preceding year, but with that exception, it was still considerably higher than that of any other year during the decade. When it is borne in mind that 10 years ago the export only amounted to 1½ tons, it is something to be proud of to be able to point to an export trade of even 7,721 tons. The export of rum shows a corresponding decrease, having fallen last season to 68,792 gallons. In the rival sugar-producing colony of Fiji, the export of sugar was also considerably less than in 1879, although its value exceeded that of 1878 by £5,279. This is attributed to the want of sufficient manufacturing power, but this difficulty is now being met by the erection of new mills in several centres of the industry. We are also glad to notice that, in both Queensland and Fiji, other articles of tropical agriculture are being successfully introduced. Much attention is being paid to the cultivation of the coffee berry, especially in Fiji, where the industry seems destined to become a source of national prosperity.—*Australasian.*

INDIA-RUBBER IN HONDURAS.

(From the *American Exporter,*)

Mr. Floyd B. Wilson, a member of the New York bar, left here in the last steamer for Philadelphia, carrying with him some very valuable concessions from this government upon which he proposes to organize a company in New York. His principal object is to gather and prepare for market the silk grass (*pita*), which grows wild and covers immense tracts of land in this country. His attention, as well as that of others, has also been attracted to the *tuno* tree which produces a gum about "half and half" india-rubber and gutta-percha.

The forests of Honduras are full of it, and there is no doubt about its soon becoming an important article of commerce. The tree is almost exactly liko the caoutchouc, for which it is often mistaken.

The milk coagulates by heat and changes into a mass resembling curd, which becomes hard by washing it in cold water. When immersed for a few minutes in water above 150° it becomes plastic and can be moulded into any shape, which it retains on cooling. I believe this beautiful gum is worthy of being investigated by American manufacturers, and for their benefit I will copy from a letter which I have received from a gentleman in Nicaragua on the subject:—

"Cape Gracios a Dios, June 12, 1881.— * * * I am buying tuno, a gum intermediary between rubber and gutta-percha. The English trade receives it in large quantities under the name of "Balata" gum, from the west coast of Africa. That identical gum is common to all the Central American Republics, as also to a large part of South America. The trees producing it are confined within a certain distance of the Atlantic coast, climate and altitude above the sea level influencing its production. The best markets thus far are England and Germany, where it is used in certain proportions in the manufacture of submarine cables and for other insulating purposes. I shipped one lot of 4,000 pounds last fall to the United States, but as yet I have received no returns. I understand that the manufacturers do not know what it is, and are unwilling to give it a trial. Generally the consignees of a new article are not disposed to take the necessary trouble to introduce it to the trade. As they only receive a small commission, they are not willing to spend money for advertising in scientific and commercial newspapers. In your official capacity you can benefit the manufacturers of the United States, if you can induce some of the papers having a large circulation to publish articles on the subject. I am about going to New York with another lot of balata gum, and shall make an effort to induce some manufacturers to try it. On my return here in September next I may be better posted."

The writer of the above letter is a stranger to me, but I believe that he is quite correct in his estimate of the value of the tuno or balata gum, and I do not hesitate to indorso his ideas and suggestions. I shall be pleased to send specimens for analysis and experiments to any chemist or manufacturer who may wish to give it a trial. Either the milk or hard gum can be sent. The supply of rubber and gutta percha is constantly decreasing, as the natives kill the trees to obtain the milk; if in the balata gum a substituto should be found for either or both of the others, its value to the arts would be immense. I hope that somebody will soon give this matter the attention which its importance merits.

WRINKLES FOR TEA PLANTERS.

(From the *Indian Tea Gazette*, 20th August 1881.)

Dear Sir,—*Coloring Pans.*—"Shiny" should try putting on his pans a coating of dissolved sal ammoniac (nausadar in the bazar). An application of this will

give them a heavy coat of rust: renewing it for 2 or 3 days will allow it to eat into the surface of his pans, thereby arriving at the rough surface he wishes to get. Of course the pan must be thoroughly cleansed before using again.

Artificial Manures.—"F." says, "by applying 6 oz. of superphosphate of lime, 60 lb. of tea might be got." If he means that this amount may be got annually per acre in excess of former outturn, I should say it would pay. He does not allow for the bushes being permanently improved, also the quality of the tea being improved; as no doubt the more vigorous the growth, the better the tea.

If manure can produce an extra maund per acre the first year, (which I have no doubt it can), and if "F." can sell it at Rl a lb. in Calcutta, artificial manure will pay for itself the first year: any future benefit is all *labh*.

I give the relative proportions of the constituents of the ash of young tea leaves as given by Mr. Schrottky in the "Tea Cyclopædia," page 121, and the artificial manure supplied by Odam & Co. Also the analysis of some tea soil in Assam, that has been 12 years in cultivation without any incentive.

Mr. Schrottky's analysis of the ash of young tea leaves of Hybrid plant—

I should like to know the cost of the "fertilizer" recommended.

The "wrinkles and receipts" column ought to be invaluable to planters generally. I hope planters will contribute their knowledge.

31st July 1881. KENT.

CATTLE FOOT AND MOUTH DISEASE?

(From the *Indian Medical Gazette*, 1st August 1881.)

The following sensible directions for the treatment of foot and mouth disease in horned cattle have been drawn up by Mr. Warren Stirling, Tea Planter, and circulated by the Government of Bengal. The plan was tried at Durbungah with success:—

For the mouth—

Honey	1 lb.
Muriatic acid	1½ oz.

Mix well in an earthenware or glass vessel with a wooden or glass rod. Apply with a wooden spatula about a dessert-spoonful to the tongue, leaving the animal to distribute it over the inside of the mouth by the champing motion that is sure to follow its application.

In ordinary cases this should be administered twice a day, but in very severe cases, or should the beast have been affected some days before notice had been taken, three or four times daily will be requisite.

For the feet—

Socotrine aloes	1½ oz.
Rectified spirits of wine ...	4 ,,
Alum	½ ,,
Water	8 ,,
or	
Calvert's carbolic acid... ...	4 ,,
Sweet oil	20 ,,

Dissolve the aloes in the spirit, and the alum (after powdering) in the water, and mix. Apply twice a day between the claws for mild cases, and three or four times for severe or neglected ones.

Suggestions as to the Treatment, Food, &c., &c.

Immediately upon a beast's becoming affected (which may be easily known by daily inspection when grazing or when fed in the stockyard, the affected beast appearing listless and disinclined to feed, head generally drooping, and a slightly frothy saliva flowing from the mouth), it should be isolated from the herd and treated at once.

The disease being very infectious, a close watch should be kept upon the remaining cattle for some days after the infected beasts have been detected.

A separate attendant should be deputed to attend upon the sick cattle, and must on no account be permitted to go near the remainder of the herd. As it would be impossible for him to administer the medicine without some of the beast's saliva (the virus of infection) falling about his clothes, he should be made to change them whenever he may have occasion to leave the hospital, and he should always wash his hands in some disinfecting fluid (a weak solution of Calvert's carbolic acid is the best). Care should also be taken to keep dogs away from the hospital, as they moving amongst the litter, &c., would be likely to carry the infection to the stockyard.

From the soreness of its mouth, the beast, however much inclined, will be unable to eat anything but the smoothest gruel or something of that nature. The best thing to give in India until the mouth becomes somewhat healed, is rice boiled down to a thick congee, with a little goor mixed with it. No salt should be given on any account.

Water should be supplied freely, as the beasts appear to suffer much from thirst.

Whenever medicine is given, the nozzle and legs should be washed with a weak solution of carbolic acid—one part of acid to twenty of water.

Should aloes and spirits of wine not be easily procurable, the sore on the feet should be treated with a mixture of one part of carbolic acid to five parts of sweet oil.

My experience leads me to believe that the sore between the claws is only sympathetic. Many cases occur, and some very severe ones, without any sores

upon the feet, but in no instance does the sore appear on the feet unless accompanied with affection of the mouth. Moreover, the sores on the feet invariably disappear as the mouth heals.

After the disease has disappeared, all utensils, ropes, litter, &c., should be burnt on the site of the hospital, together with the materials of the shed or hut under which the cattle have been tethered, thus preventing infection, and also disinfecting the ground upon which the sick beasts have been stalled.

As everything used should be destroyed, only cheap vessels, such as common earthen pans, wooden buckets, &c., need be procured for hospital use.

TEA :—EXPERIMENTAL PRUNING.

(From the *Indian Tea Gazette*, 20th August 1881.)

CHANDPORE ESTATE, CHITTAGONG.

Season 1875.

The piece of ground selected was perfectly flat and from 80 to 100 feet above level of dhan-khets, and the soil a good and fairly richloam, the sandy particles slightly in excess in the composition.

The bushes were planted out in July 1868 from seed sown in December 1867 : consequently were $7\frac{1}{2}$ years old. 100 bushes were worked off in patch *A.*, and a like number on plot *B.*, contiguous.

The jât an ordinary hybrid.

The height of the bushes on 21st January 1875 on both sections was 30 inches, and the pruning for season 1875 commenced in this area on the 22nd.

The prunings and all weeds being buried when green, as usual, between the rows of plants which were $4' \times 4'$, or 2,722 per acre, and the land received six combined hoeings and weedings in the year.

The plucking commenced on 17th March and terminated on 17th December, making in all 17 flushes : $2\frac{3}{4}$ leaves being gathered each time.

Section *A.* was merely topped down to 24 inches, and long surface roots clipped and rounded off with shears, as was the custom in vogue 15 years ago and upwards, barring the height which was generally 3 feet and more, and no knife used in the operation, which at that time went by the name of pruning.

Section *B.* was treated with the knife and cut down to 20″, or 4″ lower than the former. The branches were thinned out low down, so that none touched each other (the cut open to north), and old wood, if any, removed; also all whippy twigs growing crossways, and laterals on the *interior* perpendicular branches, were likewise cut off to within one eye, leaving on only those that grew towards the circumference, or the exterior of latter. All small branches near the ground were also cut away to allow proper circulation of air.

The above description of pruning fairly represents, I think, the extremes in either case, although as to height I have frequently cut down to 18″ with good effect old bushes, and those also in full bearing that grew upon poor soil, or which subsequently became so through wash and other causes. The results of this trial unmistakably proves the great superiority of the present style of pruning, and its modifications over the old method, which it was the object of this experiment to ascertain.

EXPERIMENT WITH MONEY AND PONDER'S MANURE MIXTURE.

CHANDPORE TEA ESTATE, CHITTAGONG.

Season 1877.

The plot of ground selected was perfectly flat at an elevation of from 80 to 100 feet above the dhan-khets, and soil open and friable, and what may be termed a sandy loam, and well suited for the profitable growth of tea. The age of the bushes was in 5th year from transplanting, or 6th year from date of germination of seeds in nursery.

The bushes are planted $4 \times 4 = 2{,}722$ per acre. Half an acre was fenced off for the manure, and another half acre contiguous without any.

The mixture was applied at ½ lb. per bush in the former, equal to 12 cwt. per acre on 5th and 6th July 1877. It could not be done earlier in consequence of the lateness of its arrival on the garden, and by this time 8 flushes had been removed from the experimental pieces, which represents nearly 30 per cent of the season's outturn.

This table shows there was an increase in the manured piece of 99 lb. 7 oz. of green leaf, which is equivalent to 14% in the 10 flushes which comprised about 70 per cent of the actual outturn. Had the manure been applied in February so as to have embraced the whole season, doubtless the results would have been more

satisfactory. To show this in another way. Excess of leaf 99 lb. 7 oz. say $\frac{100}{4}$ = 25 lb. tea per the $\frac{1}{2}$ acre, or 50 lbs. per acre, the increase due to the mixture, which was certainly most horrible stuff for the olfactory nerves, so much so, that I had to pay the coolies extra, and supply them with a bandage for their nasal organs before I could prevail upon them to apply it.

Assuming that 30 % of outturn is made by 8th July, which was actually the case in this season, (the yield per acre from manured piece would be nearly 7 maunds tea per acre, and from unmanured plots 6¼ maunds tea per acre. To make the comparison more equable, however, so far as can be done by calculations on the quantity of tea made in the 8 flushes prior to the applicatiou of the manure, and which, as I have stated, is about 30 % of year's outturn, and which would be 152 lb. tea per acre on the unmanured plot, and allowing an increase of 14 per cent, equal to 21 lb. tea on this due to manufacturing, the real yield of tea per acre should be 7¼ maunds nearly, that is between ¼ to 1 maund of tea in excess per acre of the outturn on the piece of ground not so treated. Say, however, the increase is *one maund* per acre. The manure was made at Koosteah, the railway terminus in that direction, and originally cost there R105 per ton, some said R110, but I take the former, and I found that to bring it to the garden and apply it to the bushes cost exactly R87-6 per acre. Now as the increased crop is but 80 lb. tea per acre, it is evident no object is gained by its application but a loss, unless the tea sold at R1-3-3 per lb., which would precisely square the account, allowing R9 per maund as cost of manufacture. There is this to be said however, that its beneficial effects, if any, extend over about 3 seasons, and although I have never weighed the leaf on the plots of ground and experimented beyond the year of application, I have observed that the weeds grew more quickly and flushes came out earlier, and also more abundantly on the manured piece than ou those next to it. I also manured another flat hill of very poor soil the same year with this mixture, and the increase of yield was very marked; but I never kept an account of how much. On this area likewise the effects were apparent for about 3 years in all. I doubt, though with the prices the teas have been until lately selling at, whether it would pay to use this manure, spreading the cost over three seasons, unless the produce averaged about 8 annas per lb. at least.

I have tried animal guano from Australia iu 1873, but the results were not satisfactory, and I have lost my notes regarding it. I recollect, however, ½ lb. was applied to each bush, and I made the unpardonable mistake of not mixing the powder *well with earth* before putting it in the ground round the bushes. This was done though thoroughly with Money's and Ponder's mixture, and before removal to the field, which is most essential always when using artificial manures.

My experience has led me to believe that plant food of this description, although it increases the yield for a time, is much too stimulating for tea; and granting that its effects of 2 cwt. per acre extend over 3 seasons, I have noticed that after that period the bushes begin to fall back again, and actually yield worse than prior to its application, which is proof I think that when once artificial manures are used, the supply must be maintained at stated intervals ever afterwards. Why the bushes fall off subsequently is due mainly to the soil being impoverished in consequence of the excessive and abnormal demand made upon it by the bushes in extra yield. They themselves also suffer from the latter cause.

F. McL. CARTER.

A WALNUT WOOD FAMINE.—Canadian and American papers are full of complaints of the scarcity of walnut wood, and fears are expressed that the stock of this valuable tree is being rapidly exhausted. At one time the Province of Ontario, then known as "Canada West," produced an abundance of walnut of fine quality, but it now yields little or none. In the United States, Indiana has been looked upon as the "Walnut State," but the supply is not now equal to the demand, and "lumberers" are at their wits' end to meet the requirements of the furniture manufacturers in the States. Considerable quantities of walnut exist further south, but there are swamps and various other physical difficulties in the way of the full development of the trade there. The threatened walnut famine is only another proof of the recklessness with which timber is destroyed not only in America but in all new countries. The needs of the present moment are gratified, but no care is taken for the requirements of the future. The planting of young trees as old trees are cut down is seldom systematically carried out, and the consequence is that the supply is gradually exhausted. Nor does the evil end here. As we have frequently pointed out, the whole climate of a country may be altered by the clearing of its forests, and its very fertility seriously affected if the due proportion of forest-land to open country is not maintained. There is not a Colony, however large, and however abundant its natural supplies of timber, which can afford to go on felling and burning without planting. The recent experience of Mauritius, and the example which that Colony is setting, should be taken to heart by every other Colony.—*Colonies and India.*

TOMATOS.—A clever writer has declared that in the eating of tomatos lies the hope of the human race for deliverance from liver complaiuts. This should be good news alike to unfortunate sufferers from the ills to which the liver is heir and also to growers of the tomato. We may be pardoned for thinking that this assurauce is a little exaggerated, and that, further, it is not probable that because of the discovery medical men will have to shut up shop. If but one tithe of the virtues found or said to be found in various fruits or compounds were genuine, death should long since have become unknown to us, and the human race should be enjoying the felicity of living in perfect health and beauty for ever. But whilst we may throw just a shade of doubt over the light of the tomato discovery, we can hardly desire to offer any check to the general, and, if the public like, unlimited consumption of that fruit. That they will ever become acceptable as ordinary uncooked fruit seems improbable. A boy who would devour sour apples with gusto, and think himself the envy of the human race if he had a bushel of such acid and indigestible products, would turn with disgust from the mawkishly sweet tomato. We must train for a long while to get an appreciative palate for them, and when we have obtained that, too probably the appreciation for better fruits will be gone. Therefore we must fall back upon the tomato in its cooked form, if we are to be saved from the horrors of bile and disorganised livers, and there it is our troubles begin, because it is not every one who can cook a tomato. We may go further and say that, what with the difficulties with which bad seasons now and then beset the plants, it is not every one who can grow them. All the world eats potatos, and to these we have already ascribed certain antiscorbutic properties: who will so far become the benefactor of mankind, particularly that portion troubled with deranged livers, as to tack on to the potato the medicinal properties of its brother solanum, the tomato? That would be indeed a glorious result, worthy the approbation of grateful humanity.—*Gardeners' Chronicle.*

GENERAL PLANTING REPORT: DIMBULA.

Of the 150 estates in Dimbula not more than a dozen or fifteen are giving really good crops; the rest vary from indifferent to bad. Some will pay expenses, and others, if cultivated properly, will be worked at a loss. Cinchona, though everywhere to be seen, is not sufficiently advanced to come to the rescue and it is feared that many will have difficulty in pulling through. The ravages of grub are extending, and leaf disease is perhaps, on the whole, more severe than it ever has been before. Notwithstanding this, most estates are fairly well supplied with wood for next year, and those who have had the means of cultivating their estates liberally are the ones who may be expected to get the best crops. Manure is quite as necessary in Dimbula as in Dikoya, and the trees will not mature the blossoms without it. In the Railway Gorge a great improvement has taken place in the appearance of the grubbed estates. Portions of the Walaha valley and the Agras are now affected, and the pest appears to be moving from east to west. Mr. Schrottky's experiments on Gleneagles have not thus far been attended with success. The fall of leaf seems just as great, and the disease so far from having been checked is as bad, if not worse, than on a neighbouring estate which has had nothing done to it. Three applications of carbolic powder and finely sifted coral lime have been given, and only one more is, I believe required to complete the test. Mr. Ward is more in favor of sulphur and lime than carbolic acid, but neither from the one nor the other can we expect permanent relief, unless the leaves on the ground are destroyed, which, being impracticable, leaves us very much where we were three years ago.

TRAVANCORE PLATERS' ASSOCIATION.

Experimental Stations.

The Chairman, in introducing the subject of experimental stations, said that this matter had been thoroughly talked over by members of the Association, and he was glad to think that the members present were unanimous in their opinion as regards the advantages to be derived from such experiments. The only question remaining to be settled was the question of cost. This, however, he trusted would be got over.

After some further conversation on the subject, it was proposed by Mr. D. G. Cameron, seconded by Mr. J. S. Valentine and carried:—

1st.—That two experimental stations be established on the basis of Mr. Cameron's letter to the Secretary; the working of the stations to be carried out in direct communication with Mr. Cameron by the Superintendents of the estates experimented on.

2nd.—To enable the Association to carry out these experiments it is necessary that a sum of money be guaranteed and unless this be done the experiments will not be gone on with.

3rd.—That Mynall and Scalield estates be selected as experimental stations.

4th.—That the Secretary address absent members of the Association with copies of this resolutions, and ask for their support and for an expression of their willingness to contribute towards the expense of such experiments; said contribution not to exceed 2 annas an acre on the area brought under cultivation.

GENERAL PLANTING REPORT: DIKOYA.

Shaving and Manuring Cinchona.

This district has also gone back a good deal in appearance the last month or so. Leaf disease has been much more severe than usual and wind also. As regards crop, estates at the Castlerea end are bearing well, and properties in the middle of the district are holding their own. In Bogawantalawa and the back valley of Dikoya the yield is disappointing, and it is a good estate that will average 3 cwt. an acre. The wood for next year is better as regards quantity than quality, and however doubtful may be the results of manuring operations, proprietors are beginning to see that they cannot do without them. The fact, of a larger percentage of March blossom having set on manured land and naturally strong coffee than on fields less liberally dealt with, is strong evidence in favour of good cultivation, and there is hardly a planter in Dikoya who does not believe in the efficacy of manures, if properly applied early in the season. As a cinchona district, Dikoya enjoys a well-deserved reputation, and in a few years' time coffee will be of secondary importance on many estates. Some superintendents are planting up good as well as bad coffee with the different varieties of cinchona: which is a mistake and will be duly regretted. The shaving process is being largely adopted on an estate not far from the Dikoya caddies, and the condition of the trees operated upon (succirubra) is not improved thereby. Planters in the district are watching with some anxiety the result of this experiment, and will be guided by it a great deal in harvesting the bark from their own trees as they approach maturity. The value of the renewed bark secured from a spoke-shaved succirubra has not yet been established. In one case the report of a London authority was decidedly unfavourable, but in others the results are described as satisfactory. That the shaving process will be found to answer better than removing the bark in chips and mossing is probable; but there are those who still incline to "coppicing," believing that this method will prove the most remunerative in the long run. On an estate in Dimbula the different ways are being fairly tested, and we may therefore expect ere long to have reliable data to guide us in future operations.

Manuring cinchona has not yet been generally adopted. In fact, very few planters have even gone so far as experimenting on individual trees. This is hardly creditable to those who look to cinchona to pull them through their difficulties.

The respective merits of the various methods of harvesting bark, and the possibility, or otherwise, of increasing the alkaloids by the use of manures, are surely the questions to which the attention of intelligent superintendents should be specially directed. The tendency to canker is more marked in the lower and upper portions of the district than in the middle, which seems to indicate that the rainfall is somewhat too scanty in Bogawantalawa and too heavy in lower Dikoya.

COFFEE IN BRAZIL.

Messrs. Kern, Hayn & Co's Market Report for the past season and dealing with old and new crops, is as follows:—

Santos July 1st, 1881.

Coffee.—Another shipping year having closed it may be of interest to pass once more through the various stages of the Santos coffee-market during the last campaign. As the most prominent feature in 1880/81 we have to point out that this market has to a certain extent emancipated itself from the Rio-market, on which it was before much dependent, and with the growing commercial importance of our port it is not at all unlikely that its emancipation from Rio will make further progress. Banking transactions, for which formerly the interference of Rio was required, are now to a large amount done direct in this city, and the number of institutions engaged in this line of business has increased to four, it being rumored that a fifth one would soon follow. As will be seen below, the quantity of coffee exported from this port during 1880/81 remained little behind that of the shipping-year of

1878-79, the largest which was ever witnessed. In spite of this fact, however, the crop-year just closed has proved less satisfactory to the trade in general and to the planters in particular, than the preceding one, during which but little over a million of bags of coffee were exported, for not only was the movement of prices, with few exceptions, a steadily retrograding one, but also the prices paid here for coffee during 1880-81 were far behind those which the planters realized during 1879-80. Whereas during the latter crop-year the highest price paid for goodfirst and superior was ... ...6$700 to 6$800 per 10 kilos and the lowest for same descriptions ... ...5$400 „ 5$500 „ „ „ the highest point ever reached during 1880-81 for goodfirst and superior was only ...5$500 „ 5$600 „ „ „ and the lowest point during the same period .. ...4$200 „ 4$400 „ „ „ or with other words: the highest point reached in 1880-81 hardly equalled the lowest in 1879-80 and during a period of 24 months prices for Santos coffee declined by about 35 per cent. The month of July 1880 opened dull and with a pretty large stock, so that dealers, in order to effect sales, lowered their pretensions gradually from 5$400—5$500 rs. to 5$100—5$200 rs. for goodfirst and superior. In spite of this decline in prices transactions remained but regular, as on the other hand the rising exchange enhanced the sterling cost of the article. Better news from the United-States, however, called forward a former tone towards the end of the month. In August a steady demand was reigning, but transactions remained limited on account of the reduced stock and the poor assortment. The movement of prices was upward at first and downward during the latter half of the month. The principal buyers were the United-States, where a consortion had been formed to drive up prices, which attempts led afterwards to the well-known lamentable disasters. September witnessed increasing receipts and a fall of 8 per cent to 9 per cent in currency prices. New coffees, having then become more abundant, began to attract buyers, so that in spite of the flat news from consuming markets regular transactions took place. The closing rates were 4$900—5$100 rs. for goodfirst and superior. Dull news from consuming countries kept business in suspense during the first half of October and made prices descend to 4$700—4$800 rs. for goodfirst and superior, whereas during the second half of the month considerable transactions took place and prices advanced again to 5$000—5$100 rs. The month of November commenced dull, but the declining exchange facilitated business afterwards. On the whole the market experienced slight fluctuations, but closed after all at the same rates at which it opened. During the greater part of December the market was very quiet, but transactions still reached a high figure towards the end of the month, when dealers submitted to concessions. Receipts increased at the same time materially, leaving a stock of about 130,000 bags for the new year to begin with. The month of January 1881 presented no features of particular interest, whereas during the first half of February a declining exchange and reduced steamer-freights to Europe unexpectedly called forward a large business, so that dealers obtained 5$000—5$100 rs. for goodfirst and superior. Since middle of February, however, the movement of prices was downward up to middle of May, when sales were effected on a basis of 4$200—4$300 rs. for goodfirst and superior. The impulse to this steady depreciation was given by the increasing stocks on all sea-pots and the continued dull news from abroad. In February still considerable sales took place, whereas during March, April and the beginning of May transactions were regular. During the latter part of May, however, when prices had reached the basis of 4$200—4$300 rs. with all prospects of a further decline and a healthy business, speculation in Europe caught hold of the article; 60,000 bags were taken out of the market within a few days at rising prices, and the stock became reduced to 50,000 bags of a very poor assortment. Subsequent animating news from European markets and decreasing receipts here caused dealers to raise their pretensions to 4$600—4$700 rs. for goodfirst and superior during the beginning of June and to insist upon their demands after the favorable result of the Dutch auction of 15th June became known, this is still to-day the case notwithstanding that reports from abroad again assumed a quieter tenor.

The Stock, after a small reduction has been made, consists to-day of about 38,000 bags.

The receipts averaged about 1,230 bags a-day since 1st ultimo.

During the shipping-year just closed 1,204,244 bags of coffee were exported from Santos, of which 952,837 bags have been shipped to Europe, 235,137 bags to the United-States and the balance of 16,270 bags to South-American ports, which figures are quite in conformity with what we said in our report of 1st July 1880, viz: that 1,100,000—1,250,000 bags might be put down as the probable export during 1880/81.

According to reliable reports, as far as such can be gathered, the coming (1881/82) coffee-crop will far exceed all former ones. The estimations vary considerably, as it is usually the case, but none goes below 1,400,000 bags, while others speak of 1,800,000 bags. In our opinion the yield will be nearer to 1,600,000—1,700,000 bags than to the lower figure named.

We estimate the stock of old coffee left in the interior at about ... ... 100,000— 150,000 bags.
the to-day's stock in Santos 40,000— 40,000 „
and the probable yield of the new crop ... ... 1,600,000—1,700,000 „

making together an available quantity of ... ... 1,740,000—1,890,000 bags.

and we believe that at the end of the new shipping-year a larger stock than usually will be left in the interior, so that about 1,400,000—1,500,000 bags of coffee may come forward for shipment during 1881/82.

As regards the quality of the new crop nothing can be said as yet, only a very few samples of new coffee having appeared so far; we will, however, not omit to state that reports from the interior speak of a small sized bean and an abundance of lower grades, the ripening of the fruit having been some what unequal.

Shipments of Coffee during the last six years.

The Louisiana crop of oranges is a failure, in consequence of a so-called "ice-wave" having passed over the orange groves. The misfortune of the people of Louisiana will be the gain of many Dominicans, for the exports of oranges to the United States will doubtless be greatly increased this year.—*Colonies and India.*

Correspondence.

To the Editor of the Ceylon Observer.

CAOUTCHOUC OR INDIA-RUBBER-YIELDING TREES.

Dear Mr. Editor.—Can you, or some of the numerous readers of your valuable paper, give one thirsting for information a few hints on the question of the Ceara rubber tree. Dr. Trimen might, should this meet his eye, throw some light on the subject. We have now a number of fine handsome trees of Ceara growing here with large quantities of seeds, their outward appearances being of a fresh, green-looking colour. How is one to know a ripe from an unripe seed? The seeds are most wonderfully covered by nature, and are somewhat difficult to get at. There are three seeds in a pod, black, I presume, when ripe; but the difficulty is, to find out if the seed is ripe before opening the outer green skin and the inner parchment incasement. The trees here are over 23 feet high by 20 inches circumference at the thick part of the stem. Is it not time for us to commence tapping some of the larger trees? If so, what is the approved method of tapping? What should be the yield of milk per tree, and to what proportions should it manufacture? The age of the trees in question varies form 9 months to a year and 3 months. Ceara rubber trees will grow! Will they pay?—Yours faithfully,

RUBBER.

[So far from "Rubber" asking other people to help him to an answer to most of these questions, we consider it is he who ought to be the first to decide points which all Ceylon India-rubber planters have to settle for themselves. Let him experiment with seed and tapping, and report results.—Ed.]

"NAKANAAD COFFEE"; AND CROP PROSPECTS.

Dear Sir,—I have noticed in the issues of your paper lately some remarks about the introduction of the Nakanaad coffee into Ceylon. I remember travelling with an old Ceylon planter who had settled in Travancore, when he visited the island after an absence of 20 years We were on our way to Matale, the scene of his first labors, and, in looking at the Pass estates, he said that if he had any interest in that direction he would certainly try there what he was doing at Travancore: that is, as his Coffea Arabica showed signs of unproductiveness, here placed it with what he termed "the indigenous coffee of Coorg," viz., the Nakanaad coffee which he had found very hardy, and though *Hemileia vastatrix* attacked it, the trees appeared to suffer less from it than the C. A. He said these Nakanaad trees had yielded 8 cwt. an acre, on an average, notwithstanding *H. v.*

I have since then seen quantities of this Coorg seed advertized, and lately I saw some fine nursery plants raised from it in the neighbourhood of Matale. It cannot be amiss to try these plants among the C. A. in the hope that the two may hybridize and give us a steady plant able to resist attacks of *H. v.* It is worth a trial.

AN OBSERVER.

CURE FOR COFFEE LEAF DISEASE.

Rewa river, Fiji, July 11th, 1881.

Sir, Ever since the importation of the Ceylon coffee leaf disease (*Hemileia vastatrix*), I have made its life history a study, not microscopically, but from the gardener's point of view, and have arrived at certain results, which I am now ready to bring before the planters of Ceylon and other coffee-growing countries suffering from the pest There being very little hope of the Fijian Government entertaining the question of a cure at public expense after the disappointment they have met with, I shall have to look abroad for support, and hereby announce to the planters of Ceylon that I have applied for patents in this country, Ceylon, and elsewhere for my process. It was my aim to entirely stamp out the disease here, which is yet possible, as every plantation, nursery, native patch, and even solitary tree, is known. The whole could be done in six months, if the Government would assist me with regard to their nurseries and the native plantations, without which the planters of this group will have to adopt the permanent system of treatment, just as much as such a treatment is necessary in Ceylon, where there are so many sources of reinfection beyond the operator's control.

I have made two cures by different treatments, the one direct, the other atmospherical. The first, although a very useful experiment, and which there may be many occasions to employ, I have rejected for general use, the system being open to failure through vicissitude of weather and careless work of labourers.

The treatment I have finally adopted is, as stated above, purely atmospherical, will cost no more (or even less) than the one alluded to in a former letter to you, and can, once established, be carried on for years at a mere nominal cost. Nothing will interfere with it, and women and children can do the work. The system means the establishment of a permanent enemy to the fungus: all-pervading, ever present, as subtile as the disease itself. It enables me to keep an estate free from disease, even though it were surrounded by plantations reeking with the fungus.

With the assurance that I am still at work with success to back me, I sign myself, until I can make it convenient to pay you a visit, yours very faithfully,

JACOB P. STORCK.

ALOE FIBRE AND A FIBRE MACHINE.

Lagalla, Rattota, 24th August 1881.

Sir,—I see a correspondent, in writing to you on the subject of aloe fibre, says he has 60 tons in the course of preparation. I have paid some attention to the preparation of this fibre, and, unless he can get a very *quick* process for cleaning it, I fear he will find it comparatively valueless, except, perhaps, for paper making, as aloes deteriorate more rapidly by soaking than any fibre I know of.

Some months ago, Messrs. John Gordon & Co., of 9 New Broad Street, London, sent me out a fibre machine, exhibited working at the last Paris Exhibition and said to be capable of cleaning fibre of aloe, plantain, &c., &c., at the rate of 10 cwt. per diem. It has been attached to the machinery on this estate, but the S. W. monsoon having utterly failed, as regards rain, in this part of the country, we have not yet had a fair opportunity of testing it, and probably shall not, until the N. E. sets in. A half cwt. sample of its work is now on the way home for report and valuation.

This machine is said to be working in Mauritius. It costs £90 f. o. b. in London. I enclose a drawing for inspection.—Yours truly, W. C. DUNCAN.

COFFEE CULTIVATION IN CEYLON:—THE SYSTEM OF BREEDING-IN; HEAVY PRUNING AND WEEDING A MISTAKE.

Kotmale, 26th Aug. 1881.

Sir,—As in the human system all diseases, save perhaps old age, may be traced to some deviation from the paths laid down by intuitive reason, some cramping of the limbs, overcharge (or the reverse) of the internal machinery, in short to some unnatural or artificial treatment—mal-treatment would be the

more correct term—so with coffee: the reason of the malady from which it has suffered for some 10 years is not far to seek. In the first place, the trees which now cover so many thousands of acres in Ceylon are the direct descendants of plants, grown from seed imported by the Dutch some 150 years ago. This leads us to an apparent paradox. The breeding-in-and-in of all animals tends to degeneration, and doubtless this law applies to the vegetable kingdom as well. The laws of nature cannot be wrong, where her surroundings are nature's self. For instance, the little honeybird instinctively carries the seeds of parasites from tree to tree; these obtain a bold and eventually flourish on the remains of the tree whose death has been their life. Man comes and clears his land. He plants his vineyards and his orange groves, but he cannot leave all to nature. If his object be to gather into his garner grapes and oranges, he must keep down all parasitic growth, while encouraging his trees to grow as naturally as possible. Why does nature permit of parasites at all? Perhaps it may be for this very reason: as a preventitive of in-breeding; for it is seldom, if ever, that a parasite-vegetable—of course, we know about big fleas and their attachments—adheres to another parasite; and we know that it is only plants of the same germs that fertilize one another. But if we are to grow our trees naturally, and at the same time suppress any extraneous efforts of nature (which we may almost term, having regard to the unnatural isolation of distinct genera of trees, extra-natural or extraordinary), we must be cautious in no way to hinder the natural flow of sap, which should be as carefully attended to as the opening of sluices of an unsafe dam when the burst of the monsoon is imminent, especially if a town may be inundated by the bursting of such embankment. The gist of all which is that Coffea Arabica should never have been topped or pruned. Shutting the stable door when the "kuthirei" has bolted! Mistake-finding is the simplest of simple matters!! Allowing that the mistake has been committed, is there no remedy? Here is the chance of a remedy, Try it! Allow your trees to throw up one healthy stem sucker from as near the top as possible. In course of time nature will assert herself, and draw all the sap from your poor old hacked and worn out wood to this new tree. *Let that tree grow.* If you *must* prune, do so; only let that work consist simply of the removal of dead wood. Naturally your tree will not throw out cross wood. It is your topping, and pruning, carried on *so carefully* for years, that cause your coffee to throw out three cross or centripetal branches for every handsome centrifugal one.

Then there 's your weeding. Carbonic acid is essential to the growth of all plants. The simplest way of obtaining a plentiful supply of this gas for your coffee is to hack down your weeds and let them rot.

There are many young places where it is not too late to give this rational and most economic system a trial. If from contagion estates cannot be kept free of Hemeleia, its effects will most certainly be mitigated by the above treatment.—Faithfully yours,

POST TENEBRAS LUX.

[Has the treatment not had a trial and without success? Are we not told by men who have tried both systems that heavy pruning and liberal manuring is the only way to fight leaf-disease?—Ed.]

Cure for Tape Worm.—If M. H. H. G. will take of Kousso (Brayera anthelmintica) half a drachm, made into a ball with fat, and give it to the dog fasting, it will remove the worm. The dose should be followed by a purgative in two hours. The worm should be examined for the head, which is the smallest part, and if not found, the medicine should be repeated after an interval of three or four days.—L. R. C. P.—*Field.*

NATIVE-MADE IRON IN INDIA AND CEYLON: HOW TO IMPROVE AND EXTEND THIS INDUSTRY.

From an interesting article in the *Pioneer* on "Charcoal Iron in India" we take the following extracts of practical purport to us in Ceylon. Iron ore of very pure quality is to be found very freely in certain Ceylon districts, and there is no reason why a good deal more should not be done to establish a regular and profitable industry:—

Every savage living in countries containing the ore (except the Americans) knows how to make excellent iron. From pure oxides, such as occur in many countries, iron can be extracted so readily, that it could hardly miss being accidentally discovered by a savage who had lighted a fire and made use of pieces of the ore as hot stones to boil his dinner. In India we find the aboriginal populations everywhere expert in the manufacture of iron. In Kumaun and the hills generally this work is left to the Dums; and in West Bengal and Chota Nagpur to the Aghurias, who, from their ugly features and their habit of working at night over the glowing furnaces, are said to have been the prototypes of the ghouls and ogres of fable. The methods of making Iron in India have been often described by officers of the Geological Survey and others. A small clay furnace from 18 inches to three feet high is used, and the fire in it is constantly blown by pairs of bellows, of various construction, working alternately and sending the air in by separate pipes or *tuyères*. Perhaps the commonest kind is the ordinary goatskin bellows, two of which are worked by a man sitting between them. Charcoal is first filled into the furnace and then lighted and blown till it forms a glowing, nearly white hot mass; when alternate layers of finely broken ore and charcoal are placed on the top until as much as can be conveniently worked in the furnace has been added. An opening is made for the slag, or molten oxide combined with the impurities of the ore and fuel, to run out; and then a lump of soft spongy iron mixed with slag is removed and instantly welded into a compact mass. The whole process lasts about six hours. The iron thus obtained is of the softest and toughest description, equal, for making horse-nails and such purposes, to the best Swedish. The great drawback to the process is that it is so wasteful both in the matter of ore and fuel. We learn something about the amount of this waste from a sort of inter-provincial report on the native methods of making iron in this country, and on the prospects of the trade in competition with the cheaper English made iron. The paper is circulated by the Bengal Government; it was printed at the North-Western Provinces Government Press; and though it bears no name either at head or foot, internal evidence shows that it was probably written by an officer of the Punjab Forest Department. It therefore deserves to be called inter-provincial. It seems that, on the average, only about one-third of the total iron in the ore is extracted by the native process, the other two-thirds being lost in the slag; and to make a pound of iron, about 13lb. of charcoal are required. In the round-about process of making smithy iron employed in England (formation of pig-iron, puddling, rolling puddled bars, piling, re-heating, and rolling again) only about 20 per cent of the iron is lost, and the total expenditure of coal or coke—much cheaper kinds of fuel than charcoal—is only about 18lb. for a pound of iron. But for the superior quality of the native iron, the industry would doubtless, for this reason have been swamped long ago by the cheap supplies obtainable from England. Another objection to the native process is that only the very purest ores, carefully washed and sorted by hand, can be employed, because if inferior ore were employed, it would be impossible to exclude the earthy matter

from the spongy iron. This objection, however, is of little force in India, where labour is so cheap and where, as at Lohara in the Central Provinces, we have entire hills composed of stone which contains 98·6 per cent of pure oxide of iron. The objection to the Indian charcoal iron on the score of cost would doubtless disappear, if, instead of the native process, the English method of employing large blast-furnaces producing cast-iron were introduced under proper conditions. The blast-furnace method, though indirect and to some extent wasteful in the matter of fuel, has the great merit that by fusing the iron it effectually frees it from the earthy matters of the ore, and of the ash when coal is used as fuel. The spongy iron must be melted either in the furnace or in a cast-steel crucible, or else we must sacrifice more than half the iron to form a fusible slag as in the native process.

There is no reason why iron equal to the best Swedish should not be made out of Indian ores with charcoal fuel, after the Swedish and Russian methods. The cast iron thus produced could be made into the finest Bessemer steel, because the Indian ores are unusually free from the elements sulphur and phosphorus, which, when in large quantity, are fatal to the Bessemer process as usually worked. Pig-iron manufacture, by means of charcoal fuel, has just been given up as a failure by the N. W. P. Government, which for some years carried on a smeltiug establishment at Dehchauri in Kumaun. Several good reasons are, however, given in the paper above-mentioned for this failure. In the first place the furnace was too large to be worked by natives alone; and the pay of the European overseers was too great to be fairly debitable to one furnace, when these men could equally well have looked after several. The chief reason, however, was that half the ore had to be carried 23 miles from Ramgarh on men's heads or on the backs of mules. In Europe the owner of such a furnace would either have constructed a tramway by which to bring the ore from a distance, or he would have tried to work with the ore on the spot There is plenty of ore at Dehchauri close to the furnace, costing next to nothing to raise; but it was considered too aluminous to work by itself, and therefore the silicious Ramgarh ore was added to it. The writer of the report thinks it a pity that the Dehchauri works were stopped so soon; and certainly, before they were stopped, the experiment might have been made of using the ore found at the place, mixed with limestone and sufficient sandstone to make the slag fuse readily. The ore contains 38·3 per cent of iron; and if 20 per cent of silicious material were added to it, it would still have as large a percentage of iron as the bulk of English clay ores. A much smaller addition of sandstone would probably have been sufficient.

The manufacture of iron and steel is likely soon to be again revolutionized, as it was not long ago by Bessemer; and the new system will probably prove fatal to the production of charcoal iron in this and other countries. In the Bessemer process excellent cast-steel is made from molten cast-iron in a few minutes; the iron being run into a vessel lined with silicious materials, and there getting its impurities—carbon, silicon, and manganese—burnt away by a blast of air which is forced through it. At the end of the process, enough pure cast-iron is added to convert the whole mass into steel, which is then poured into a ladle and cast. Steel can be thus made in enormous quantities, for each converting vessel will work off six or eight tons in fifteen minutes. Two impurities, however,—sulphur and phosphorus, of which phosphorus is the more deleterious, as it makes iron or steel brittle when cold,—cannot be removed by Bessemer's process, since white hot iron reduces sulphuric and phosphoric oxides as soon as they are formed by the action of the blast. For making cast-steel by this rapid process, therefore, iron ores as free from sulphur and phosphorus as possible soon came to be in great demand, while the inferior ores have been little used of late years. Recently, Messrs. Thomas and Gilchrist have succeeded in perfecting a process by which the phosphorus, and to a less extent the sulphur may be got rid of, no matter how much the cast-iron may contain. The Bessemer "converter" is lined with magnesian lime-stone, and the mouth of the vessel above the molten metal is filled with lime. When the phosphorus is oxidized, the oxide at once combines with the lime forming a compound which is not reduced by iron.

The Gilchrist-Thomas process has already come into extensive use on the Continent, where iron-masters are less conservative than in England; but before long we may expect to see excellent cast-steel made in England from the most inferior ore, and then it will be all over with the charcoal-iron industry, except in the most remote countries of the world. India may yet rank, however, as one of the great iron-producing countries if either Government or that private enterprise which is so favourably spoken of nowa-days, would turn its attention seriously to the making of iron by means of Indian coal. There is far more wealth in the iron and coal deposits of the Central Provinces and Bengal than in all the gold fields of the Wynaad.

TEA AND COFFEE CULTIVATION IN BENGAL.

(From the Press Commissioner.)

A report on the tea and coffee cultivation in Bengal for the year 1880 shews that the number of gardens under tea cultivation during the year was 274 against 257 in 1879, and the area under plant was, so far as could be ascertained, 38,805 acres against 28,668.

In the Darjeeling district there was an increase of three gardens over the number reported in the previous year, and of 33,854 lb. in the approximate gross outturn of tea. The year was, on the whole, a favourable one, though the red spider is said to have made its appearance in some of the gardens. The complaints from blight were few compared with those made in the three previous years. Mosquito-blight, though it did some damage in March and April, was hardly noticeable in the later months of the year when it is generally most active. Labour, which is almost exclusively derived from Nepaul, was more plentiful than in the previous year in the hills, but in the Terai it was scarce. The reason of the scarcity of labour in that tract is explained by the manager of a tea garden in the following words:—

"In former times when tea was more remunerative, larger labour forces were kept on the gardens during the cold season; now more economy is evinced in this point in all the gardens. The coolies, who have been long in a garden, have in most cases become well off, and, when the weather is bad and the work heavy, can better afford to sit idle. The large number of estates opened out in the Terai and Dooars lately, of course, much tend to drain labour."

In the Julpigoree district there was also an increase of 10 gardens over the number returned in 1879. The gross yield of tea amounted to 817,765 lb. in the previous year, thus shewing an increase of 406,185 lb. or 98 per cent. during the year under report. As stated in the previous year's report, the gardens in the district are chiefly stocked with the hybrid plant. Manure is used to a very limited extent, the soil being rich with vegetable deposit. Leaf-rolling machines have for some time past been introduced into the district. The use of a tea-drying machine in one of

the gardens is said to have effected a considerable improvement on the results obtained under the old system of drying over charcoal fire, while in another garden, machinery for sieving and equalizing tea worked with success. Labour is chiefly imported from Nepaul and Chota Nagpore, the indigenous labourers numbering between 700 and 800 only. The labourers are reported to be well-housed and properly treated. One application for lease of lands was under enquiry at the close of 1879, and four applications were filed during 1880. There were thus altogether five applications for disposal. Of these two were granted, one was withdrawn, one was negatived, while one was under enquiry at the close of the year.

There was an increase of two gardens in the Chittagong district over the number reported in the previous year, but figures are again incomplete, 18 gardens having failed to supply the information sought. The gardens in the Chittagong Hill tracts have all furnished the returns for 1880, but no figures regarding the yield of tea were supplied in the previous year. A comparison of the results of the year under review with those of the previous year is therefore, not possible. The weather was not very favourable for tea; and the flushes were below the average. The outturn per acre shewed a decrease, but this is attributed to the plucking having been finer than it used to be, the common class of tea hardly paying the cost of manufacture. The soil and climate are well adapted to tea cultivation, very little manure being used. There is an abundance of local labour except at the rice harvest, and the number of labourers imported into Chittagong is small. Improvements in firing and other operations have gradually been introduced, and machinery has been brought into use in several tea estates in the district.

No new gardens were started in the Dacca district, but the average yield per acre shows an increase from 92 lb. to 132 lb.

The number of tea plantations in Hazaribagh in 1880, was the same as in the preceding year, but there was an increase of two gardens in the Lohardugga district. One garden in Hazaribagh and three gardens in Lohardugga furnished no returns for the year; but on those gardens from which returns were received both in 1879 and 1880, the aggregate outturn is said to have shown an increase in the year under report. Early rains in the spring and seasonable weather during the monsoon materially helped to improve the prospects of the industry. The prices, however, showed very little signs of improvement except for the better qualities which are not yet grown in large quantities.

Coffee is only grown experimentally in the Chittagong district, and those who have cultivated a few plants speak favourably of the growth, especially of the Liberian coffee. No returns have been received from the Chittagong Hill tracts, but the crop of the Ceylon or common coffee is said to have been a "fair average one;" the planters have prepared nurseries sufficient to provide plants of Liberian coffee for 100 acres during the current year. No increase is shown in the number of gardens in the Lohardugga district, and there was a decrease of 320 lb. or 50 per cent. in the total yield as compared with 1879.—*Calcutta Englishman.*

COFFEE IN BRAZIL: RIO REPORT.

(From *Kern, Hayn & Co.'s Market Report.*)

RIO DE JANEIRO, 1st July 1881.

Shipments of coffee from Rio de Janeiro during the crop season, 1st July 1880 to 30 June 1881 amounted, as will be seen from the statement below, to 254,889 tons equal to 4,361,126 bags of 60 kilos each against 172,777 tons or 2 961,427 bags during the corresponding season 1879-80 and 210,461 tons or 3,607,903 bags during same period 1878-79, and the crop-year just closed has thus witnessed the largest export from here ever known.

In our report of 1st July 1880 as well as in our printed circular of 1st January 1881, we gave as the estimates of the 1880-81 crop the quantity of 4,000,000 bags of coffee, but we let transpire as our opinion that this figure appeared rather too low.

Now that the greater part of the last crop has been shipped, people begin to perceive how considerably they had estimated the crop and to-day the general belief is that the yield reaches the figure of about 5,500,000 bags of coffee.

To-day it is as little possible for us to guarantee the correctness of this figure as was the case at any time during the past twelve months, but if we may be allowed to express any opinion, we should say the above figure to be pretty correct the more so as most of the opinions we heard express about this subject were of the same tenor.

Once agreed to the correctness of the figure named, the stock in the interior of coffee of the last crop would amount to about 1,366,000 bags.

As above stated the exportation of coffee from this port from 1st July 1880 to 30th June 1881 amounted to about... ...		4,361,000	bags.
wherefrom are to be deducted; the shipments coastwise from Santos and re-exported from Rio, say about... ...	6,000	bags.	
the quantity of former crops calculated to be about ...	500,000	„	
and the quantity of new 1881-1882 crop shipped before this day...	15,000	„	521,000 „
thus leaving a quantity exported during the last twelve months of the 1880-1881 crop of about...		3,840,000	„
and as it was estimated that the quantity of 1880-81 crop coffee exported previous to the 1st of July 1880 amounted to about...		60,000	„
that the local consumption in Rio during the last 12 months was about... ...		84,000	„
and that of the stock existing to-day in Rio of 175,000 bags about 25,000 bags are of the new crop being thus of the old crop there ought to remain on this date in the interior a stock of old coffee of about... ...		1,366,000	„
in order to reach the above named quantity of... ...		5,500,000	„

upon which figure the last crop has been estimated.

With regard to the extent of the new 1881-82 Rio crop, the opinions expressed are, as is always the case, very contradictory, most people however count upon a yield between 3,000,000 and 3,500,000 bags and we take the figure of 3,200,000 bags of 60 kilos we believe to be very near to the truth.

As stated above, so far about 40,000 bags of the new crop have arrived here, which are partly shipped and partly included in our present stock.

The quality of the first arrivals was little satisfactory, and though the last receipts were of better quality, we cannot state the same to be as good as was generally expected.

The planters complain of the unequal ripening of the fruit, whereby the bean will become irregular and defective; as soon as a more correct judgment upon this point can be formed, we will report again.

Supposing that the coming crop would amount to about...		3,200,000	bags
and calculating the stock of old coffee in the interior and in Rio de Janeiro to be to-day about... ...		1,500,000	„
thus making together an available quantity of... ...		4,700,000	bags
and further supposing that on 30th June 1882, there would remain in the interior a stock of old coffee of about... ...		300,000	„

We would have for export during the next twelve months about... ... 4,400,000 bags

or about the same quantity as has been shipped during the crop season just closed.

Shipments of Coffee from Rio de Janeiro.

during the last six years, say: from 1st July to 30th June, viz:

	1875-76 tons.	1876-77 tons.	1877-78 tons.

Liver.—Mme. Sand wrote that in her opinion many obscure cases of disease of the liver were owing to the compression caused by the right elbow, which presses against the side during our usual method of writing from left to right. She also referred to *scoliosis*, or spinal curvature, induced, as she thought by the same cause. As a remedy, she proposed that children should be taught to write straight, forming vertical letters, the paper being placed vertically before the writer. M. Javal has arrived at the same conclusions in more recent times, and bases his conclusions on scientific deductions.—*New York Ho r.*

Liberian Coffee.—A correspondent writes:—"It is quite certain, however, that we have growing and bearing in Ceylon more than one kind of Liberian. I have at Henaratgoda at least *two* kinds: one grows into a well-shaped bush or tree. This kind with me so far is the largest and bears best. The other while young (3 years old) is an ungainly top-heavy tree. In future, I mean to select *seed* from the best trees. It may be, however, that the others ought to be treated differently. Perhaps they may do best if not topped and allowed to grow into a tall tree? The subject ought to be ventilated *soon* so as to know which kind is best, etc. etc. I have not noticed any difference in the appearance of the *cherry* from the two kinds of trees, but the *beans* from each kind ought to be examined and reported on. In my case a few hundred plants bought from——, (grown from imported seed) have produced more of the lanky kind than the seed (also imported) bought from another quarter. On the other hand one of my large lanky trees came with others of the good shape from the same nursery in 1878."

Fishing with Dynamite.—At Maggona, on the Galle road, a man named Juse was accidently killed by using dynamite to kill fishes. An inquest was held on the 24th inst. and a verdict of "accidental death" recorded. It appears that the deceased was a cooly employed lately in the Nanuoya extension work, and on his return to his village he brought with him some dynamite, with which he attempted to experiment in killing fish, and killed himself instead!—*Cor.*

Coffee Leaf Disease and Seaweed Manure.—Mr. F. Cummins, of the P. W. D., who is about to return to Ceylon, writes to us by this mail, as follows:—"Has *seaweed* ever been tried as a manure for coffee? In Cornwall it is considered an invaluable manure for fruit trees. Perhaps leaf disease may succumb to the effluvia it will emit when it rots" Who has made, or will make a trial? During the north-east monsoon, occasionally the Kollupitiya shore is strewn with seaweed which could be easily gathered and despatched up-country.

The Fiji Coffee Leaf Disease Experiment.—There appears to be a fatality attending the Great Amalgam plantation arbitration case between the Government and Mr. W. F. Parr. After considerable delay and difficulty in securing the services of a gentleman to act on behalf of the Government, Mr. Hedges of Taviuni consented to do so. It only remained for the arbitrators to elect an umpire, and all parties were ready to proceed to the Waimanu and go on with the case yesterday. Now, however, another difficulty has arisen. Mr Hedges refuses to consent to the nomination of any person in the colony as umpire and suggests one from Ceylon. To this proposition the hon. R. B Leefe, acting on behalf of Mr. Parr, will not consent, as it will entail very considerable and altogether unnecessary expense, and indefinitely postpone a final settlement. Here the arbitrators are unable to agree and the matter is therefore no further advanced than it was nine months ago. Mr. Hedges appears to have formed a very low estimate of the capacity or honesty of the colonists when he concludes that there is not one to be found qualified to give a competent and unbiased judgment on this matter.—*Fiji Times.* [This is no doubt Mr. J. R. Hedges, well-known here as merchant and planter.—Ed.]

Ceylon Cinchona Bark.—Messrs. James Cook & Co. writing on the 5th ult. make the following remarks on Ceylon bark: what is said in reference to show pieces of red bark, should be specially kept in view, large pieces of this bark should always be carefully separated and packed without injury to the rough exterior:—"The shipments of cinchona bark from some estates are now arriving in larger quantities; in this week's auctions there was an Import marked Stellenberg, 341 packages, one Pile consisting of 177 bales good chips and small broken quill, which sold at 1s 10d, 67 bales small chips and young broken branch 1s 2d, 77 bales root 2s 1d, and 90 bags good but short and broken quills 1s 10d at 2s 4d. It was somewhat surprising to find in so large a quantity of Succirubra from one Estate, no well formed unbroken quill. The shipment was no doubt very even, but it is a mistake not to forward, in the form of good and fine quill, all that could be so sent, as competition from the buyers of show Bark, at times a matter of great importance, was necessarily lost. The Portree, on the other hand, without being exceptionally handsome, comprised some really good and fine quill, and brought as much as 5s at 5s 3d per lb., and the smaller and more irregular quill 3s 4d at 3s 11d, whilst the value to a manufacturer was probably not within 1s at 2s per lb. of these prices, as the good chips of the same Mark sold at 2s 7d at 2s 8d. A further shipment of 35 bales Hamilton the mark to which we alluded in our report of the 26th May was of fair even quality; 9 cases renewed JAR was quilled, other unusual for renewed Bark."

COCOA.—The production in Guayaquil this season keeps moderate, and in the five months ended 31st May, was only 93,774 quintals of all growths, against 181.902 quintals in 1880, 112,248 quintals in 1879, 41,329 quintals in 1878 (the short crop), and 119.595 quintals, in 1877. The total exports from Trinidad from January 1st to July 7th amount to 7,283, 510 lb, against 6,273,190lb., in 1880, 6,697,490lb. in 1879, 7,273,594lb.in 1878, and 5,389,235lb. in 1877.—*Trinidad Chronicle.*

HYDROPHOBIA.—Any one who is bitten by a dog, mad or not, is welcome to try the following nostrum, which is culled from the *Queen's Closet*, dated 1663: *For the Biting of a Mad Dog, or s'in ing of an Adder.*—Take a handful or more of hazel nuts, a quarter as much of rue, with a clove of garlic; stamp all these together; then take the juice and put a little treacle to it, and if he be a man that is stung or bitten, give it him to drink in beer, or wine, or ale; but if it be a dog, give it in the milk; then take that from whence the juice came, and bind it to the place which was bit or stung.—*New York Hour.*

LIBERIAN COFFEE AND TEA IN FIJI.—We have received a communication from the hon. Jas E. Mason of the Alpha estate Taviuni, accompanying a vessel containing the leaf, flowers, and berries of the much talked of Liberian coffee plant. The leaf is 12¼ inches by 6¼ inches, and the berries are three inches in circumference. The trees bear heavily, when planted in suitable localities, and the berry has realized more than 9½s. a cwt. in New York, which encourages the belief that deserted coffee plantations may yet be utilized for other payable products besides cocoanuts. The tea plants on the Alpha estate are also in bearing carefully planted in nurseries to supply the demand which must shortly be created in the colony for a product which will thrive well but is not easy to propagate from imported seed.—*Fiji Times*, July 2.

CEYLON FLORA.—I cannot allow the description given of the Ceylon flora by "H. J. E." in your issue of April 30th last to pass unobserved. He says (p. 560) that neither ferns, mosses, nor creepers, are numerous. I find the indigenous species of plants mentioned by Dr Thwaites in his *Enumeration of Ceylon Plants* to include dicotyledons, 1959; monocotyledous, 648; and Mr. William Ferguson gives in his list, Filices, 225; Lycopodiaceæ, 14; Marsileaceæ, 3; Equisetaceæ, 1; total, 2850; double the flora of Britain, and about one-thirtieth of all species in the world yet described. Ceylon in proportion to its area must be regarded as equal to that of any portion of the globe. It is noted for its Ferns and Balsams, while Orchids abound. Ebony, Calamander, Satinwood, and other fine cabinet woods, are plentiful in the forests. Palms and Bamboos are specially beautiful and luxuriant, few objects in Nature being more grand than a Talipot Palm, Corypha umbraculifera, in flower, and few more graceful than the slender Areca Palm, Areca catechu, or the tall, drooping Bamboo of the mountain forests. The beautiful flowering trees, such as Lagerstromia reginæ, bombax malabaricus, scarlet Cotton-tree, with the varied foliage of several timber trees, give a rich contrast to the deep green of the forests. The brilliant Ixoras, Erythrinas, Bnteas, Jonesias, and Hibiscus, enliven the forests with their splendour. The dense, impenetrable herbaceous plant mentioned is Strobilanthe, called by the natives "Nelloo," of which there are some twenty species, and is what constitutes the most abundant underwood in the forests. The greatest variety of plants is found in the central, southern, and western provinces, which contain all the mountain ranges. To the north and east is comparatively flat pasture country, with poorer soil, lesser rainfall, and scrubby trees and bushes. There are few parts of the world so rich in fungi as Ceylon. *A.—June* 14.—*Gardeners' Chronicle.*

CAROLINA PADDY.—The superintendent of Government Farms has reported to the Board of Revenue on the growth and produce of the so-called "Carolina" paddy received from the Government of India. Mr. Robertson considers the yield of grain is very small, considered in connection with the yield of straw; probably some was lost by shedding from irregularity in ripening, also by depredations by rats, squirrels, birds, etc, losses from which all crops suffer but which are always disproportionately severe when a crop covers but a few square yards of land or ripens when but a small area of other crop is ripe. Crop experiments conducted in the open field on such a *microscopical* scale can but seldom afford any useful information. There has undoubtedly been some mistake either in obtaining or in forwarding the paddy; it is certainly *not* Carolina paddy, and from its low quality it does not appear to me to be a variety deserving of any special attention here.—*Madras Mail.*

PALM WINE.—In most books it is said that the Palm wine is obtained by excising the central bud of the tree, as the Mexicans do the Magney (Agave mexicana), to gather the pulque, and that after a short time the tree is exhausted and dies off, which I believe readily enough. Now I have seen Palm wine extracted from the Borassus flabelliformis, the Coconut Palm, the Arenga saccharifera, and Caryota urens (the best of all), always by cutting the extremity of the spadices, and receiving the juice in large Bamboo joints or earthen pots; the leaves or central bud were never interfered with. The process goes on from year to year for the entire life of the Palm, which does not seem a bit the worse for the bleeding. Some years ago Sir J. D. Hooker published a paper describing very minutely the extraction of toddy from the Borassus, and his experience is entirely like mine. What I want to know is this: Have any of your readers seen with their own eyes the Palm wine extracted by cutting the cabbage of the Palm? Are they ready to make solemn affirmation that they saw this? I believe this notion owes its origin to careless observers, and its propagation to the numerous and hateful family of books made from cuttings pasted together. The only other Palms from which wine is obtained are, I believe, the Palma de Vino (Attalea magdalenæ?), on the lower Magdalena, and the Date Palm. Although I have met millions of both, I never came across a spot where their sap was collected. Are the male and female Date Palms equally productive of wine? I ask the question, as it is the only one from the above species in which the sexes appear on separate individuals.—*Gardeners' Chronicle.*

THE PALMYRAH TIMBER is used for a variety of purposes and it is impossible to exaggerate the extensive havoc that is being carried on from day to day among Palmirah trees. The demand for this timber being steady and animated, every man, who can find a little money, pretends to be a Timber trader, whose business is chiefly confined to palmyrah trees. Not long ago the Palmirah was the most common tree in the Northern Province, one meeting with it on all sides and in large groups. The state of things as far as this is concerned has considerably changed and we think for the worse. Large tracts which were covered with these trees are now bare, waste lands, shewing signs that the timber trader has been busy there. The districts of Pachchellapallai, Wadamaradchy, Poonaryn, the Islands &c. contain numerous instances of the havoc that is being committed among them. The premier division of the Province, Jaffna itself has not escaped the Timber trader. We have an impression that the intense heat and the protracted drought, we suffer from, are in a great measure due to the extensive destruction of this tree. It is not our object to discuss at present the influence of trees on climate and rain; but the fast disappearance of this tree, caused by the brisk trade in it, carried on

between Jaffna and India, urgently calls for measures that will diminish the evils resulting from it. It is idle to suppose that any individual effort to check its destruction will be successful. Palmirah timber has considerably risen in value and there is a struggle to make the largest fortune out of it. We are not in a position to state the quantity which is utilised for local purposes: but the export is steadily increasing. The average number of trees per year being 27,127. Palmirah timber is exported in the shape of rafters. Calculating at the rate of five rafters per tree, not less than 569,675 trees must have been felled from 1859 to 1879, for export alone. Where were these trees felled? How is the ground which they occupied now utilized? All the trees have been felled in the Northern Province and the answer to the other question is that the ground is in most cases left neglected. Our wonder is why do not the people, who find this timber so profitable, take the trouble to grow it and extend its cultivation. Its cultivation is not expensive and it is unmitigated folly to neglect it, while the tree is fast disappearing. To those who have waste lands our advice is—throw in palmirah nuts and in a few years they will be more valuable than you can conceive now.—*Ceylon Patriot.*

Paper Fibre.—Mr. Strettel, Deputy Conservator of Forests, Sunderbuns Division, has drawn attention to the value of the fibre yielded by the stem of the wild plantain of Bengal as a paper-making material. The stems of the fruit-plantain of Bengal yield the same kind of fibre, but have hitherto not been utilized because they contain about 90 per cent of moisture; which can only be got rid of by opening out the tree, and exposing the layers to the sun, or by mechanical force. The former system has been tried, and it has been found that about a fortnight is required to complete the drying process. As one stem (yielding about 100 lbs of green fibre) when opened out, occupies about 100 square feet of ground, and ultimately yields only 10 lbs of dry fibre, a far larger area for drying is requisite than would ordinarily be found available. On the other hand, the percentage of moisture is too great to admit of the stems being carried any great distance in a green state. The cost of carriage to distant crushing mills would make the fibre too expensive; and this fact has doubtless prevented the free use of the ordinary plantain which grows generally all over Lower Bengal in scattered patches. There can be no doubt, however, as Mr. Strettell remarked, that by employing machinery not only can an absolutely dry fibre be produced from plantain stems within eight hours of treatment, but likewise a whiter and better quality can be turned out; for when sun-drying alone is resorted to, the dissipation of moisture is so slow that the fibre loses strength in the process of drying, and likewise becomes discoloured—a fact which materially detracts from its value. The Conservator of Forests, while he thought Mr. Strettell's estimate of the profits to be made from such an enterprise (over three laks of rupees per square of plantain jungle), altogether too high, confirmed that gentleman's report as to the enormous growth of wild plantains in the forests of the Chittagong Hills; and suggested that the opinion of the Superintendent of the Botanic Garden should be asked. Dr. King thinks that the proposal has a good deal of promise about it, and that it might be well worth while for Government to spend a little money in sending a sufficiently large shipment to the London market to be sold for what it will fetch in small lots, so that the new material may become generally known to the paper-making interest. He, however, agrees with the Conservator in thinking Mr. Strettell's estimates too favourable. He further points out, somewhat unnecessarily it would seem, that the Indian plantain must not be confounded with the Manilla plantain, the fibre of which, usually called manilla hemp, is one of the most valuable fibres known, and is worth in London from £30 to £40 a ton. The utilization of this hemp for paper fibre has, however, lately been pressed on the Government of India—a proposal which, as regards feasibility, would be on a par with a suggestion to use silk for the manufacture of grain sacks. The Government of Bengal thinks that there cannot be any reasonable doubt as to the suitability of the wild plantain fibre for paper-making. The local Government will be prepared to give all reasonable assistance to any mercantile firm or individual wishing to try the experiment in the Chittagong Hill Tracts, or elsewhere in Bengal. It will supply wild plantain stems free of cost, on the spot, for a reasonable time at the outset, and will arrange for future supplies at reasonable rates. It will also give such other assistance as may be deemed necessary and proper.—*Pioneer.*

Experimental Pruning.—In another column will be found a paper on this subject by Mr. McL. Carter. He writes further:—Of course the old style of merely clipping off the top and outside stray shoots with shears will never be resorted to again by old hands, and therefore perhaps the comparison is not of much good at the present day; but as I have never read or seen the results of similar trials in any paper, the results of my experiment may be of some service to the rising generation, and guard them from reverting to the old method again."—*Indian Tea Gazette.*

Fermentation.—We much regret that our "devils" made some important mistakes in the printing of the letter on this subject by "Tea House" in our last issue, which we now hasten to correct. For *about* 4 *per cent of ordinary rolled leaf*, read 40 *per cent of ordinary rolled leaf*. Again, for *half inch* (*mvrs*) *sieve* read *half inch* (*mesh*) *sieve*. A correspondent, anent the method advocated by "Tea House" writes: "I find this method answers admirably, as the tips do not get over-fermented."—*Indian Tea Gazette.*

The extraordinary Wastefulness of the Native Systems of Farming may be measured by the following comparison drawn by Mr. Caird. The produce of cotton per acre in India is not one-fifth of that in Egypt and America, and the quality brings but half the price. An acre of cotton-land in Egypt well watered yields 400 lb. of cotton worth £14 an acre: in India the average yield is 70 lb, and the value to the grower not more than 20s. The main distinction between the two modes of management is that in Egypt the cotton-crop is treated as a wet crop at all stages of its growth, while in India, where the climate is hotter, it is never irrigated. This, however, is only one instance of the rich harvest which additional skill and enterprise can reap in India. A far greater promise of wealth is offered by the introduction of new staples, rather than by the improvement of existing staples. Sir R. Temple notices that in the short period of his own service he witnessed the creation and development of a valuable trade in jute, tea, and coffee. The annual value of that trade already exceeds ten million pounds. The tea-trade has been unusually depressed of late, but there is every hope that it will recover and even expand into far greater dimensions. Successful efforts are at this moment being made to introduce Indian tea into the Australian market. An expert was lately sent to visit the principal trade-centres in America, with a view to opening up a trade with the United States and Canada. In sugar, tobacco—which already competes vigorously with American tobacco in the Italian market—cinchona-bark—from which quinine is derived, leather, and various kinds of forest produce, the material for enlarging or creating new trades exists. In every direction a strong impulse is setting in towards the promotion of new employments suited to the various capacities of the people.—*Quarterly Review.*

LIME FROM THE KUMBUK TREE:

LIME, REMARKABLE QUANTITIES OF, IN THE WOOD OF CERTAIN TREES, BUT ESPECIALLY IN THAT OF THE "KUMBUK" (SINHALESE), "MARUTHA" (TAMIL), "TERMINALIA ARJUNA," AND "T. TOMENTOSA" (BEDD.).

"Or, when dyspeptic and exceeding weak,
Will read on salts phosphatic, found in teak."

To the Editor,
Kelvin Grove, Colombo, 22nd Aug. 1881.

DEAR SIR,—The letter from Mr. Cochran in your issue of the 20th inst., giving the analysis of a sample of wood ashes, which showed the remarkable percentage of 56·00 of lime, equal to 100·00 of carbonate of lime, has reminded me of a communication received from Mr. John Dent Young, exactly seven years ago, referring to the fact that on the road between Anuradhapura and Kurunegala the natives burnt the wood of the kumbuk tree for the sake of the lime found in its ashes, which they used for building purposes, and also of an analysis of the samples of ashes made for me by the late Dr. Koch.

Mr. Young at the time wrote to me as follows:—

"I had heard of the process of making lime from the wood of the kumbukgaha, but I never saw any till a few days ago, when I found several people engaged in burning the wood for lime, on the road from Anuradhapura towards Kurunegala. The ashes seem all to disappear and the lime remains nearly pure. It struck me that the matter might interest you, so I send a small sample of ashes and of the lime prepared for mastication. There is no limestone to be found within about 15 miles of the place. If there is anything curious in this, and you wish to have further information, I shall be very glad to collect all I can. I did not forget your commission about the chameleons; they are met with about Mullaittivu and Punakari—Pooneryn, but the natives make them into medicine!! hence the difficulty of getting them."

Dr. Koch's report ran as follows:—

"I have carefully examined the contents of the two parcels which accompanied your letter of the 26th ultimo, and have not the slightest hesitation in pronouncing them both to be composed mainly of carbonate of lime. I found a very slight trace of magnesia in the parcel labelled 'ashes of the kumbuk tree,' but the prepared stuff is as pure a specimen of calcic carbonate as you can procure. I deferred writing to you, hoping you would have looked in some morning and afforded me an opportunity of shewing you under the microscope typical crystals (octahedral and dumb-bell) of oxalate of lime prepared from these specimens."*

You will perceive that by not at the time publishing the above interesting communications I have done injustice to my friend Mr. Young, and to the memory of my friend the late Dr. Koch, and at the same time deprived your readers of information which is most interesting as well as useful.

If you will now, in addition to the above, reproduce the following extracts on this tree, which is widely spread over Ceylon and a large part of India, I think they will form a paper worth a place in the pages of your *Tropical Agriculturist*, viz.:—

(1) The account of it in Sir J. E. Tennent's Ceylon:—

"The Kumbuk of the Sinhalese (called by the Tamils maratha-maram) is one of the noblest and most widely distributed trees in the island; it delights in the banks of rivers and moist borders of tanks and canals; it overshadows the stream of the Mahawelliganga, almost from Kandy to the sea; and it stretches its great arms above the still water of the lakes on the eastern side of the island.

"One venerable patriarch of this species, which grows at Mutwall, within three miles of Colombo, towers to so great a height above the surrounding forests of coconut palms, that it forms a landmark for the native boatmen, and is discernible from Negombo, more than twenty miles distant. The circumference of its stem, as measured by Mr. W. Ferguson, in 1850, was forty-five feet close to the earth, and seven yards at twelve feet above the ground.

"The timber, which is durable, is applied to the carving of idols for the temples, besides being extensively used for less dignified purposes; but it is chiefly prized for the bark, which is sold as a medicine, and, in addition to yielding a black dye, it is so charged with calcareous matter that its ashes, when burnt, afford a substitute for the lime which the natives chew with their betel."

(2) From the "Ceylon Timber Trees" in your Directory for 1863:—

"T. Glabra," W. et A. 314. "T. alata," Moon, Cat. 73. *Kumbuk*, Singh. *Marutham*, or *Maruthu*, Tam. ex Rottler Dicty. pt. 4 p. 31. *Marudummarum*, Ainslie pp. 88, 181, 209, and 266.

I have taken particular notice of this, in many respects, extraordinary and majestic tree, from Belligam Northwards to Jaffna, and from thence to Batticaloa, as well as in the central parts of the island; but whether growing along the banks of the Gindurah, the Kalu, Kalany, or Mahavelli Gangas, in the vicinity of tanks or sandy plains of Jaffna, or on the borders of the Batticaloa Lake,—in every place of which it is well known by either its Singhalese or Tamil name, *Kumbuk* or *Maruthu*,—I have scarcely seen it vary in its general appearance, and in its propensity to become a large tree. The Singhalese name for this tree is as fixed as the hills, but I question if there is another tree in India so involved in confusion respecting its various Botanical and Native names: Sanscrit, Tamil, Telegoo, &c., &c., as well as to the usefulness of its timber and other products.—It has been described under about a dozen species of "Pentaptera and Terminalia" every one of which with their native names and synonyms could very conveniently be included in one and without many varieties too.—On turning to Dr. Birdwood's most excellent "Catalogue of the Economic Products of the Presidency of Bombay," under the chapter on "*Woods*," I find, respecting this tree the following remarks:—"There is much confusion regarding the Botanical synonyms of this tree, which I have not been able to unravel, and consequently the native names, except the local, are omitted."—Pridham vol. II. p. 772, borrowing from Forbes, I think, says that the natives believe that water will always be found by digging near Kabuk (Kumbuk) trees, and a writer in the "Colombo Examiner" Newspaper some time ago, gave an account of one of these trees which "*sprung*" a fountain of water out of its trunk, out of which a number of travellers slaked their extreme thirst and then the water ceased! The Kumbuk tree near the high road beyond Mr. Morgan's at Mutwal, described by Sir Emerson Tennent, is the largest tree, within several miles of Colombo, and is well worth a visit. The late Revd. J. Roberts, in his Oriental Illustrations of the Bible, commenting on Psalm 37—6, alludes to this tree, as follows:—'A truly wicked man is compared to a tamarind tree, whose wood is exceedingly hard, and whose fruit is sour. That *passasu*, i. e., fiend, is like the *Marrutha marram* (Terminalia alata.) This tree resists the most powerful storms; it never loses its leaves (! W. F.) and is sacred to Vyraver, the Prince of devils. I have seen some, that would measure from 30 to 40 feet in circumference.'

* I had the pleasure of looking at a slide prepared by Dr. Koch, and noticed the peculiar dumb-bell shaped objects and the others alluded to.—W. F.

Wood dark colored, very hard, heavy and strong, inch bars bearing 430 to 450 lbs.; used in house building, for boats, canoes &c., &c. Wheels for the cars of idols are often made from cross sections of this wood. —The ashes from its burnt bark produce a kind of lime (chunam) valued as a masticatory with betel leaf &c., and I think that there can be no doubt that the following extract from Buchanan-Hamilton's travels in Mysore &c., vol. 3 p. 202, and referred to by Ainslie 2, p. 270, refers to the bark, of this very tree :— "The *Mutti* (Chuncoa Muttia, Buch : M S S.) in particular grows to a prodigious size. The natives use the ashes of its bark, to eat with *Betel*, in the same manner as in other parts, quick-lime is used."—Must I apologise for thus identifying another name with this Protean tree ?*

(3) The full botanical accounts of two supposed species, but all referring to our kumbuk tree, by C. B. Clarke, in the "Flora of British India" :—

"Sect. II. Pentaptera. *Fruit* with 5 acute subequal wings. *Spikes* usually panicled.

"7. *T. Arjuna, Bedd. Fl. Sylv.* t. 28 ; leaves subopposite oblong or elliptic nearly glabrous beneath when adult, spikes usually panicled, fruits 1-2 in. nearly glabrous ovoid- or oboveid-oblong, the wings not very broad their striations curving much upwards. *Dalz. & Gibs. Bomb. Fl.* 91 ; *Brand. For. Fl.* 224. T. Berryi, *W. & A. Prodr.* 314 ; *Dalz. & Gibs. Bomb. Fl.* 92. T. glabra, *W. & A. Prodr.* 314 ; *Thwaites Enum.* 104 ; *Dalz & Gibs. Bomb. Fl.* 91 T. ovalifolia, *Rottl. in Herb.* Pentaptera Arjuna, *Roxb. Hort. Beng.* 34 *and Fl. Ind.* ii. 438 ; *Wall. Cat.* 3981 ; *DC. Prodr.* iii. 14, *Mem. Combr.* t. 2. Pentaptera glabra, *Roxb. Hort. Beng.* 34 and *Fl. Ind.* ii. 440 ; *Wall. Cat.* 3979. P. angustifolia, *Roxb. Hort. Beng.* 34 and *Fl. Ind.* ii. 437.

"Deccan, Ceylon and the sub-Himalayan tracts of the North West Provinces. Very commou.

"Attains 60-80 ft. *Leaves* usually 4—6 in. (sometimes 10 in.) suddenly narrowed at the base, often cordate, obtuse or very shortly acute at the apex ; petiole rarely more than ½ in., often very short, with two glands near its apex. *Bracteoles* very small. *Calyx*-teeth nearly glabrous both within and without. Young *ovary* very short, covered with crisped brown or rufous hair. Wings of the *fruit* usually truncate or suddenly narrowed at the top —Dr. Brandis states that *T. Arjuna* is common in Bengal ; it is unknown in east and ecutral Bengal but abounds in Southern Behar, Chota Nagpore and on the Sone—*i.e.*, along the whole northern face of the Deccan table-land.

"Var. 2. *angustifolia* (*i.e., Pentaptera Roxb* and *not Terminalia angustifolia Roxb.*). Leaves narrow elongate-oblong suddenly narrowed into the petiole. Southern Peninsula and Concan. *Wall. Cat* 3971.

"8. T. tomentosa, *Bedd. Fl. Sylv.* t. 17; leaves subopposite or uppermost alternate elliptic or ovate glabrous or very hairy beneath when adult, spikes panicled, fruit 1-2 in. glabrous or hoary oboveid-oblong, wings broad striations carried horizontally to the edge. *Brand. For. Fl.* 225.

" Deccan, Ceylon, and the sub-Himalayan tracts of the North West Provinces, Nipal, and Sikkim, ascending to 4,000 ft. ; very common. Burma ; *Brandis, Kurz.*

"Attains 80-100 ft. *Leaves* 4-8 in., petiole ½ in. *Flowers* often attacked by a Cynips producing numerous galls which simulate fruit. *Bracteoles* very small. *Calyx*-teeth with tomentose villous or glabrescent.

"Var. 1. *typica* ; leaves cordate or suddenly narrowed into the petiole, adult more or less hairy beneath often very hairy, petiole with two glands near the base of the leaf, young ovary villous. fruit glabrous. T. tomentosa, *W. & A. Prodr.* 314 ; *Wight Ic.* t. 195. T. glabra, var. tomentosa, *Dalz. & Gibs. Bomb. Fl.* 91 ? T. alata, *Roth Nov. Sp.* 379 ; *Kurz. For. Fl. Brit. Burma* i. 458. T. ovata, *Herb. Rottler.* T. Chebula, *Retz* β. minor *Huerck & Muell. Arg. Obs Bot.* 219. Pentaptera tomentosa, *Roxb. Hort. Beng.* 34. *Fl. Ind.* ii. 440 ; *DC. Prodr.* iii. 14, *Mem. Combr.* t. 1 ; *Wall. Cat.* 3978.—Common throughout India.

"Var. 2. *crenulata* ; leaves narrowed into the petiole often obovate-elliptic adult nearly glabrous beneath, young ovary glabrous. T. crenulata, *Roth Nov. Sp.* 380 ; *W. & A. Prodr.* 314. Pentaptera crenulata, *Roxb. Hort. Beng.* 34, *Fl. Ind.* ii. 438 ; *DC. Prodr.* iii. 15 ; *Wall. Cat.* 3978. P. macrocarpa, *Wall. Cat.* 3982. —Deccan and the sub-Himalaya ; common. Burma ; *Kurz. Kurz For, Fl. Brit. Burma* i. 458 states *T. crenulata*, Roth, to be *T. Arjuna* of Beddome and Brandis. But both Beddome and Brandis have stated that *T. crenulata, W. & A.* is a variety included under their *T. tomentosa*. Kurz has not communicated any example of his *T. crenulata*, nor in his description does he notice the character of the venation of the fruit by which Dr. Brandis has separated *T. Arjuna* and *T. tomentosa*. The synonym *T. crenulata Kurz* remains therefore doubtful. Perhaps as Mr. Thwaites hints *T. Arjuna* (T. glabra, *Enum.* 104) and *T. tomentosa* should be made one species.

"Var. 3. *coriacea* ; leaves as in *T. tomentosa typica*, but beneath with a close hard fulvous tomentum rather than villous, fruit pubescent with minute fulvous hairs. T. coriacea, *W. & A. Prodr.* 315. Pentaptera coriacea, *Roxb. Hort. Beng.* 34, *Fl. Ind.* ii. 438.—Mountains of the Coromandel Coast ; *Roxburgh*, Deccan, *Herb. Rottler.* Malabar Hills ; *Dr. Ritchie.*"

Notes on the Botanical Descriptions above quoted.†

It will be observed that tt. 28 and 17 of Beddome's "Flora Sylvatica of Southern India" are the first quotations made here for these two supposed species. Table 17 is evidently partly a reproduction of Wight's "Icones" tab. 195, also quoted. and Beddome in his description unhesitatingly gives the *T. tomentosa* as the Ceylon tree. In Beddome's description of t. 28, *T. Arjuna*, he has no reference to this tree being a native of Ceylon, whilst Mr. Clarke quotes it as the undoubted tree given in Thwaites' "Enum." p. 104, as the Ceylon one. Of *T. tomentosa*, t. 17. Beddome says, "bark deeply cracked (or in one variety without any cracks),"

* It appears that where there was no lime to be had, the natives used the ashes of the muddi or mutti, kumbuk, as the Sinhalese do between Kurunegala and Anuradhapura. I quote further from *Buchanan's Journey in Mysore* &c. 3 p. 228-9 :—"In low moist vallies here, a kind of white clay, mixed with bits of quartz, is very commonly found under the soil of rice grounds. Its *strata* are often several cubits in thickness, and when it comes to the surface, render the ground very sterile. It is called jaydi mannul, and is used to whitewash the houses of the natives. It is diffused in water to separate the sand and stones, and is then mixed with a little *chunam*, that is to say, the ashes of *muddi* bark (*Chuncoa muddia* Buch. MS.); for in this vicinity there is no lime." Is this the same as the *makie* or *kaolin* of Ceylon?—W. F.

† N. B., that in any remarks made by me on any of the descriptions in the "Flora of British India," I do not mean to disparage the writers responsible for that work, or to say anything that can convey a want of great appreciation of their labors. Each and all of them deserve the grateful thanks of every one who is possessed of this work, for the concise and lucid description generally given, of the orders, genera and species. Residents in India and Ceylon, with the living plants and fresh flowers and fruits before them, may be able to add notes to the descriptions which may appear to differ much from those given in the "Flora of British India," and for which the conductors will no doubt be grateful instead of the reverse.—W. F.

and of *T. Arjuna*, t. 28, he says: "bark smooth, whitish or green," whilst Kurz, "Forest Flora of British Burma," 1. 458, writing of *T. crenulata*, Roth, quotes Beddome's t. 28 (for *T. Arjuna*), and says: "bark thick, brittle, dark grey, *deeply longitudinally cracked*." In Roxburgh's and Wight and Arnott's descriptions of some of their species included in the foregoing, the bark is also described as either *smooth* or *deeply cracked*, and Mr. Clarke therefore, not being able to make use of these most conflicting statements, has perhaps wisely avoided any allusion to them as characters. The old external layer of bark of our Ceylon kumbuk is in every case remarkable by its *exfoliating* in large or small sheets, leaving the under bark very smooth, shining, and of a somewhat mottled green color, and in this respect resembling in appearance the plane tree, *Platanus orientalis*, the birch, *Betula alba*, *Protium caudatum*, *Balsamodendron Berryi*, *Odina Wodier*, and the common guava, *Psidium Guyava*. On the subject of this peculiarity of the bark of the kumbuk, the following explanation of the scaling of the bark of the plane tree is so applicable to that of the kumbuk, that the reason given for this peculiarity may be the same in both cases:—

"The trunk and branches are clothed with smooth light-coloured bark which scales off annually in broad irregular patches, giving the tree a singularly speckled appearance when bare of its foliage. This scaling off of the bark is said to be occasioned by the rigidity of its tissue, incapable of stretching as the wood beneath increases in diameter."—*Gard. Mag. Bot.*, 1,239.

It is a well-known fact in Ceylon that the Hig-gaha, *Odina Wodier*, is the tree which grows most readily by slips or cuttings, and Sir Joseph Hooker, "Fl. Brit. Ind.," 2. 29, gives the following reason for this peculiarity:—"The tissues abound in *starch*, whence it is most easy to increase this tree by cuttings of almost any part." Does the scaling off of the bark in the kumbuk, plane, and the other trees mentioned, indicate that they contain excess of lime in their tissues?

Avoiding the Scylla of the bark distinction, Dr. Brandis has seized the Charybdis of the venation of the fruits, and Mr. Clarke is, I dare say, glad to avail of this supposed tangible character. It will be seen that it is by "the character of the venation of the fruit by which Dr. Brandis has separated *T. Arjuna* and *T. tomentosa*." The fruits of *T. Arjuna* are "1-2 inches (long) nearly glabrous ovoid—or obovoid-oblong, the wings not very broad, their striations curving much upwards." And again, "wings of the *fruit* usually truncate or suddenly narrowed at the top." Several hundred fruits collected from several trees in Colombo have every character to agree with these, some of the wings being truncated, and others not on the same fruit, and a very large portion of them being long ovate, and either gradually or suddenly accuminated to a long or short point, in fact, they assume several shapes and forms, but the sharp-edged wings are very conspicuous in all, and in all those I have seen the striations curve much upwards, and, therefore, if this be a good character, our Ceylon tree must be *T. Arjuna*.

The fruit of *T. tomentosa* is "1-2 inches (long), glabrous or hoary obovoid-oblong, wing broad striations carried horizontally to the edge." (Brandis, "Forest Flora," 225.) In none of the fruits examined by me do the striations run horizontally to the edge, and in this respect the fruits of our Colombo trees are different from those of *T. tomentosa*, but I am not satisfied that the character is a good one, and I therefore believe that the *T. Arjuna* and *T. tomentosa*, as given above, are one species, our Ceylon form of the tree all through the island being so constant in its characters that Dr. Thwaites gives only one, C. P. 1603, number for it.

The question of the large quantity of pure lime in the tissue of this tree is a very important one in respect to lime in the soil where it is found. In this respect its existence may indicate a supply of lime in the soil and thus aid planters in selecting soils for certain purposes, but as it is a plant loving the edges of rivers, lakes, or tanks, it is probable that it elaborates the lime from the water near which it grows.

(4). LIME IN THE WOOD OF TEAK.—(Cutting from the *Ceylon Observer*, No. 85, of 13th April 1878.)—Thoms, of Riga, says the *Academy*, has directed attention (*Ber. deut. chem. Gesell*, January 14, 1878, 234) to the occurrence of a white deposit in teak wood (*Tectona grandis*), consisting essentially of lime phosphate, $PCaHO_4$. His views in regard to this deposit were confirmed, it is stated, by his finding 29·6 per cent. of phosphoric acid in the ash of the wood. A chemist of this country made the same observations sixteen years ago, and they are playfully recorded in a rhyme published at the time:—

> "Or when dyspeptic and exceeding weak,
> Will read on salts phosphatic, found in teak."

5. The allusion to the use of the ashes of the kumbuk tree as a whitewash in the following extract from the "Treasury of Botany" has evidently been borrowed from the passage already quoted from Buchanan's Travels in Mysore, &c.:

"*Pentaptera glabra* is a large smooth-barked timber tree with a trunk six or eight feet in diameter and from fifty to eighty feet high, without a branch. It is common in the teak forests of Pegu, and affords an excellent dark-brown timber, useful for mast-pieces spars, and other purposes connected with shipbuilding. In Canara, on the western coast of the peninsula of India, the natives obtain a kind of lime by calcining the bark and wood, which they prefer to ordinary lime for eating with betel-nut, and also use for whitewashing.—[A. S.]"

I may here mention that I first noticed the large kumbuk tree at Mutuwal, in 1849, in the following manner. I was then returning from Jaffna in a dhoney, and was so satiated with the "oriental luxury" of travelling in this peculiar kind of vessel, that when off Negombo I began anxiously to look out for indications of the land near Colombo, and noticed in a line with the coast what I supposed was a mass of vegetation on the island in the mouth of the Kelani river, as it looked entirely isolated from any other feature. On asking the dhoney-meu what this was, they at once replied: "Oh! sir, that is the big kumbuk tree at Mutuwal, which answers for a land-mark for us when we are out fishing or making for Colombo from the north." I took an early opportunity of visiting this tree, and have ever since taken strangers to see it as one of the "lions" of Colombo. Several years ago the beauty and usefulness of this tree as a land-mark were greatly destroyed by several cartloads of its upper branches having been cut off. In April 1879, I took Mr. Grigson to photograph it as the first of a series of the remarkable trees of Ceylon, copies of which were to be sent to Dr. Bennett, the distinguished naturalist of Sydney. On inquiry from the natives living near the tree I learned that the branches had been cut down for the special lime obtained from their ashes for the repair of St. John's Roman Catholic Church, situated close to the spot. It was also stated that when the wood was burnt no ashes except the lime remained. I again measured this tree on this occasion, and found that it was 45 feet round the base and 24½ feet at 8 feet from the ground. Its bark has been chipped off all round the trunk, and is used by the natives to chew with their betel leaf. In the forks of the higher branches plants of the common orchid *Cymbidium aloifolium*, Sw., and of the curious *Psilotum triquetrum*, Sw., may be seen.

I now send for your inspection Mr. Grigson's excellent photograph of the lower part of the trunk of this famous tree. The picture is altogether a remarkable one, with the giant tree in the foreground, and coconut palms in various stages, and other objects of a native compound, in the back; the tree looks like an ancient pillar leaning somewhat to one side, with ivy-clad sides, and huge buttresses at its base, which has a diameter of 15 to 20 feet. I trust this tardy notice of Mr. Grigson's photograph of our biggest tree in Colombo may be the means of rewarding him for the trouble he took in going so far to have it taken.

To parties who may wish to pay a visit to this tree, it may be useful to mention that it is in a native garden close to the road on the right-hand side, and behind No. 112 Mutuwal Street, beyond St. John's Roman Catholic Church, and about 3½ miles from Sir Edward Barnes' statue. An inquiry for the famous kumbuk tree will at once induce any of the natives in the neighbourhood, to point it out.

If the packet of ashes sent hy Mr. Elphinstone and analysed by Mr. Cochran is the produce of a single tree, surely that tree can be no other than the veritable kumbuk tree (have we two "Richmonds in the field."?), and if so it is curious that its name with its ashes was not mentioned. The kumbuk is considered a purifier of water, and it is therefore a great favorite planted near wells for drinking purposes as well as for baths, and near a very fine specimen of the kumbuk growing in the angle of the Moradana and Jail roads there are extensive baths, while near the road a placard is placed intimating the qualities of the kumbuk tree growing close to the wells. Now if the kumbuk has the power of absorbing the lime from the soil there may be some philosophy in planting them near wells round which their roots penetrate to a considerable extent and depth. One of the finest trees in Colombo is the kumbuk in the edge of the parade ground, and facing the centre road leading through the Police Barracks at Kew Point, Colombo. It is likely that this tree was planted by Moon about 60 years ago, when this point was a kind of Botanical Garden.

It is a common belief amongst the natives, as stated already, that if a branch is cut off the kumbuk tree pure water will flow from the cut for some time and then cease.

It is singular that this famous tree with all its good qualities *real* and *imaginary* should be sacred to Vyraver, the Prince of Devils, but there is no accounting for the contradictions in connection with the religion of the Tamil. I hope to have Mr. Cochran's opinion of the specimens of lime sent by Mr. Young in 1874, and of the ashes of fresh specimens of the wood and bark of this tree.—Yours truly,

W. FERGUSON.

(*Local Extract*)

The kumbuk tree is common enough all over the island. It however loves the banks of rivers and the margins of Tanks where it raises its head a very monarch above the top of the surrounding forest, while in girth, though its inside may not afford room for a small tea party, it attains the respectable measurement of a circumference of 18 to 20 ft. To support the trunk itself and the enormous weight of the out-spreading branches and foliage, it throws out at a height of about three or four feet from the ground, buttresses on all sides, the spaces between which with some kind of improvised roofing, afford shelter and a convenient ambush to the sportsman who watches within their recess for deer and wild buffalo coming to drink. In wild parts of the country such as the interior of the Magampattu, these buttresses are separated from the tree with the axe, and after being squared and sufficiently chipped to thin them, are used for doors. The bark of the tree which is about an inch in thickness, can be stripped in large sheets, and when so stripped are joined at the ends and sunk at the bottom of wells for the double purpose of preventing the earth from falling in, as well as purifying the water. Such wells are common in the Kirene part of the Tangalla district, and it is a well-attested fact that whereas water from wells to which the kumbuk bark has not been so applied, is of a thick bluish milky appearance, and of a strong ferruginous taste, the water from wells protected by the bark is as clear and tasteless as the best spring water obtainable anywhere.

The statement that the ashes of the tree is used by the Sinhalese, in place of chunam, is also perfectly correct, but more than this, the ashes mixed with fine sand make a tolerably good substitute for the ordinary mortar made of lime. Not only is this mortar used for plastering houses in those parts of the country where the ordinary coral lime cannot be procured, but the ashes after lixivation are prepared by having boiled water poured over them, for white-washing and for chewing with betel. It is however very seldom that it is used as an adjunct to the masticatory, as the Sinhalese prefer lime obtained by calcining land or sea shells to that got from the ashes. However, in parts of the country where shells are not to be easily had, the ashes of the kumbuk tree are made to yield a very good substitute. One other peculiarity of this tree is that the living trunk can be set on fire. It burns with a smouldering fire, emitting no flame, and very little if any smoke, while the process of combustion is very slow, though regular, as regards the complete incineration of every fibre. We remember testing this by setting fire to a fallen green tree, which, on re-visiting it a fortnight after, had hardly then a two feet section burnt away. The tree had fallen by the washing away all round of the river bank on which it had stood, a new anicut thrown across the river at a short distance above, having given the current a new set—dead against the buttressed roots of the tree. But whether the tree be green or quite dead, it turns equally well, but the belief among the Sinhalese is that the green tree gives a purer quality and larger quantity of lime. The tree grows most luxuriantly in the ruined tanks of the Magampattu, especially at Tissemaharama, and if some one would take the trouble by an examination of the concentric rings of the trunk to determine the age of the largest (therefore the oldest) tree, some approximate idea of the date when the Magampattu went to decay and ruin may be formed.—*C. Examiner*.

Improving American Tea.—Under this head ng the *Scientific American* gives us the following paragraph:—"Recently on receiving a number of packages of American tea from the experimental tea farm in South Carolina, Commissioner Le Due invited a number of tea dealers in Baltimore and Washington to test the quality of the crop. They pronounced it very good tea, and said it compared favourably with East Indian teas. Last year's receipts from the same place had a *weedy flavour*. This year the same defect is only barely perceptible, *the result being due to cultivation*. By next year it is thought it will have disappeared entirely. It is even now only perceptible to the taste of experts. Letters from Mr. Jackson, the gentleman in charge of the tea farm comment in very favourable terms upon the healthy appearance of the plants and the prospect for excellent results." The italics are ours. Perhaps some of our friends will be able to enlighten us as to the meaning of the term "weedy flavour." As far as our experience goes, we have never seen or heard of any tea of weedy flavour in, or from, the "tea farms" of Assam, Cachar, Darjeeling, or any other tea district in India.—*Indian Tea Gazette*.

THE POTATO DISEASE.

Every one who is taking up potatos states that he finds a few diseased tubers, and is therefore fearful of an inroad of the Peronospora, which is too probable, but not justified by present appearances except in those cases where the now well-known resting-spores have been found. Our own experience is that all these diseased tubers are cases of the disease first recorded under the name of "nape-faule" or wet-rot, which is characterized by the presence of Fu-isporium solani of Martius. Besides this we find a pale grey slimy mucus oozing out in parts, consisting of millions of extremely minute bodies, which we consider some form of Micrococcus, especially as these are accompanied by numerous Bocteria, but whether they are a development or not of the Micrococcus we are unable to determine. Under these circumstances it would be probably dangerous to throw such specimens in the way of pigs, in which it is possible they might generate some unlooked-for form of disease. They should at once be burned.—M. F. B.—*Gardeners' Chronicle.*

STATE OF FORESTS.

The skilful physician knows by examining the surface of the body whether the internal and hidden parts are healthy or diseased; by the appearance of the skin he knows the state of the blood; and he only requires to see the tongue and the eye to know the condition of the stomach and liver. It has to be borne in mind, however, that although there are many analogies between plants and animals, there are also great differences and distinctions. By the appearance of the leaves the general health of the tree is known, but there may he, and often are, incipient diseases at work which have not yet manifested themselves in the leaves. Bark diseases are of that class, and it is very remarkable how many diseases that ultimately prove fatal have their origin in the bark, especially in young and tender trees, as will subsequently be described. The sap is to the vegetable very much what the blood is to the animal, both working within, and producing outward effects; and thus it is that the state of the leaves indicates the condition of the sap and the vessels through which it is conveyed.

It is not, therefore, in early summer, nor yet in autumn, that the leaves should be examined with a view of determining the real health of the tree, because in the former the flow of sap and the flush of growth may he strong and powerful, but not continuous, and in the latter superabundance or scarcity of moisture in the soil are alone sufficient to mislead by the influences they exert upon the sap, and consequently upon the leaves, thereby rendering the efforts of the most experienced observer abortive in his labours of research. The growth of the tree is principally influenced either through the roots, bark, buds, or leaves, and if any of these are disordered the health of the tree is thereby impaired, and unless the disease is of a local and circumscribed nature, it will eventually inflnence and destroy the whole structure.

It is often difficult to determine which is the cause and which the effect of certain diseases; we see the leaf grow yellow and assume a sickly aspect, but we cannot tell what the producing cause is. Insects of various kinds make their attacks, and it would be assuming too much to say that they only sieze upon disordered and diseased parts of the tree, for we know that leaves of the best and healthiest kinds are punctured, and often entirely devoured by various insects, chiefly caterpillars. When the roots are diseased, or in any way incapable of absorbing the moisture requisite for the healthy development of the tree, they do not usually long continue so, for they very soon either regain perfect health or entirely lose their vitality. Root diseases, too, can usually be detected from all others by the manner in which they influence the whole structure of the tree, and the uniform discoloration of the foliage.

Bark diseases, unlike those of the root, are not general, but affect only certain limited parts or spots. It is no uncommon thing to see small patches of the bark quite diseased, and the general surface quite healthy and in its normal state. In young trees, and specially in the larch, disease in the bark is very common, and has been the subject of much discussion. It can in most, if not every case, be either greatly modified or entirely prevented, but in order to make the subject perfectly clear and intelligible would require greater space and time than is here afforded.—C. Y. Michie, Culleu House, Banffshire, 8th Aug.—*Gardeners' Chronicle.*

INDIAN TEA IN AMERICA.

(From the *Indian Tea Gazette*, 20th August 1881.)

The following is an extract from a letter written to the *Indian Daily News* by a Cachar Planter:—

"We were glad to note that our American cousins were being induced to give some orders. If only Indian tea was once taken up and became popular, its future would be secured. The teeming masses of people in the States would consume more tea we should imagine than all the English public, provided Indian tea took the place of China. Australia so far has done well, but the market there would be easily glutted, whereas, if its use become general, it would be almost impossible to glut the American market. The millions of settlers in America and in Canada all use tea at their meals very much as an Englishman takes his beer, so that the inland consumption must be very large. In Australia, every shepherd carries his pannikin of tea, and the amount he swallows in twelve months must be pretty considerable. In the hackwoods of America and Canada, each wood-cutter consumes nearly half a pound of tea weekly, so that, with its millions of people, America could easily dispose of millions of pounds of tea, which would not only clear off all the surplus tea in the London market, but would probably cause a deficit. We wonder if in our time this golden era will take place."

We hope indeed that the golden era *will* take place in our time, and we see no reason why it should not. Taking into consideration the vast flood of emigration that is rapidly pouring into America from Europe, if we can only succeed in *now* introducing our teas into the United States and Canada, those countries will soon become *the* market for our produce. The Indian Tea Industry has now to all appearances, judging from outward signs, a most hopeful future before it. The dark clouds, portraying misfortune and disaster, that have so long been threatening and lowering over us, appear now to be gradually drifting away, leaving a rift through which we can see pouring down the rays of a sunshine of hope, prognosticating a store of better days for us in the not very distant future. We have now simply to take advantage of the opportunity presented to us, and with all our might and main to set to work and *push* our way. "Where there is a will there is a way," and if we will only *now* set to work with a determined will and effort, we are *bound to succeed*. What we require is to push even as the Yankees do. Surely we will not let our American cousins brag their superiority over us in this respect. The prize is within our grasp, and if we wish to secure it, we must lay aside all apathy, all half-hearted measures and with all the energy we possess make a determined effort, and with English pluck and courage added to "Yankee push and cuteness," carry and take possession of the American tea

market by storm, casting China and Japan rubbish in the fosse without the fort. We have an opportunity now presented us to make a breach in the walls of the American Tea Market Fort. If we succeed in making it, the place is ours, and China and Japan will soon fly out of the back door. Once in our possession, we need only plant the flag of the "Indian Tea Industry," and dare any other to displace it. With a home consumption increasing more and more rapidly every year, with new markets, capable of unlimited expansion opened and opening out, the Tea Industry in India should undoubtedly take rank as one of the foremost, one of the safest and most stable investments in this the country and indigenous home of the tea plant.

PETROLEUM AND PLANT-LIFE.

(From the *Monthly Market Report.*)

At the last meeting of the California Academy of Sciences a discussion took place on the subject of the use of petroleum for destroying scale insects on rose-bushes. Dr. Henry Gibbons said that two months ago he put petroleum on the trees in his garden. Since then the trees have grown better than ever before; they have grown faster than ever before, and given better roses. The petroleum seems to kill the scale insects. The handsomest rose he exhibited was from a bush which looked nearly dead a short time since. The petroleum was mixed with castor oil. It is not applied profusely and allowed to run down the roots. Perhaps in a crude state the petroleum would be bad, even to the stalks; but mixed with the castor oil it appears to be advantageous to the plant. The compound does not evaporate nor give out the insoluble portion. Therefore you have a permanent coating, acting on the entire surface of the plant. Dr. Gibbons exhibited a large bunch of beautiful roses of exceeding fragrance and in full bloom, which he gathered from a bush in his garden that two months ago was overrun with scale bugs and nearly dead. Now, since using the petroleum and the castor oil, no sign of any scale insect can be seen in the whole garden. He thought castor oil was the only oil that will mix with alcohol, turpentine, and the benzines. It is soluble in alcohol, and when mixed with crude petroleum forms a sort of varnish and cement, which remains on the bushes and does not fall to the ground. Petroleum, uncombined with castor oil, evaporates swiftly, but when combined forms a useful coating to preserve the plant. Many things have been thus tried. Trees have been white-washed with caustic potash and lime. One of his rose bushes, nearly ruined by scale insects, thus treated, has borne an unusual number of roses, and a single cactus has borne 200 flowers this season. He thought these were practical facts, and quite as valuable as theoretical ones, although he valued both, and was glad to learn of any experience having a bearing of such importance to the agricultural industries of the human family. He cautioned persons against saturating the earth with petroleum, as such a course prevents future vegetation. Like all things else, its moderate use wisely directed is good, and its excessive use is destructive. A grain of opium relieves pain, but its habitual use persisted in brings death. Dr. Bohr said that as the mixture was not soluble in water, if it reaches the earth it cakes the ground and thus shuts out the air, which must permeate the surface, and is necessary to plant-growth. A few applications will make rose bushes grow better if sparingly applied, and kill the scale bugs, but if allowed to reach the soil it renders vegetation thereafter impossible in the spot until it is eradicated. Dr. A. Kellogg thought a simple wash of common lye would at first be sufficient in many cases. Petroleum deteriorates ground for crops. Mr. Verder received a large lot of lemon trees from Australia covered with scale bugs. He applied refined petroleum to the leaves carefully and they all fell off, but every bug died and fresh leaves came out, and the plants continued healthy for many years. He afterwards applied it successfully to orange trees. He thinks there is a misapprehension among those who condemn its use. It should not be allowed to reach the ground.

COFFEE, ITS USES AND MEDICINAL QUALITIES.

By Henry Segur, M.D.

Doctor Bock, of Leipsic, says:—'The nervousness and peevishness of times are chiefly attributable to tea and coffee;' he says that 'the digestive organs of confirmed coffee drinkers are in a state of chronic derangement, which reacts on the brain, producing fretful and lachrymose moods.' I cannot agree that the nervousness and peevishness of the present time are to be attributed to the use of coffee. If people are more nervous or in worse humour now than formerly, we may find other causes arising from the customs and habits of society, much more likely to produce such a state of things, than the use of this particular article of diet. I have no intention of pointing out many changes and peculiarities in the habits of the age, to show many other more prominent reasons for people being in bad humour, besides the use of coffee. My object is to defend coffee from a slander aimed at one of our best friends—a friend more likely to relieve the morbid state of things complained of, than to produce it. Who that has experienced the good effects of coffee can sit quietly and hear it abused, especially by an estimable physician, who has written learned books on the nervous system? The nerves of every honest friend of coffee tremble with the shock of an attack from such a quarter.

Let us examine the effects of coffee on the economy. Taken in moderation it is a mental and bodily stimulant of a most agreeable nature; and followed by no harmful reaction, it produces contentment of mind, allays hunger and bodily weakness, increases the incentive and capacity for work, makes man forget his misfortunes, and enables those who use it to remain a long time without food or sleep, to endure unusual fatigue, and preserve their cheerfulness and contentment. Jomand says: 'An infusion made with ten ounces of coffee enables me to live without other food for five consecutive days, without lessening my ordinary occupations, and to use more and more prolonged muscular exercise than I was accustomed to, without any other physical injury than a slight degree of fatigue, and a little loss of flesh. The mental exhilaration, physical activity, and wakefulness it causes, explain the fondness for it, which has been shown by so many men of science, poets, scholars, and other devoted to thinking. It has indeed, been called 'the intellectual beverage.' It supported the old age of Voltaire, and enabled Fontenelle to pass his hundred years.

The action of coffee is directed chiefly to the nervous system. It produces a warming, cordial impression on the stomach, quickly followed by a diffused, agreeable and nervous excitement, which extends itself to the cerebral functions, giving rise to increased vigour of imagination and intellect, without any subsequent confusion or stupor, such as are characteristic of narcotics.

Coffee contains essential principles of nutrition, far exceeding in importance its exhilarating properties, and is one of the most desirable articles for sustaining the system, in certain prostrating diseases; as compared with the nutrition to be derived from the best of soups, coffee has decidedly the advantage, and to be preferred in many instances.

Liebig says: "We shall never know how men were first led to the use of coffee, but that we may consider the article as remarkable for its action on the brain, and the substance of the organs of motion, and as an element of food for organs as yet unknown, which are destined to convert the blood into nervous substance, and thus recruit the energy and the nervous moving, and thinking faculties."

The medicinal effects of coffee are very great. In intermittent fever I have used it with the happiest effect, in cutting short the attack, and if properly managed is better in many cases than the sulphate of quinine. In that low state of intermittent, as found on the banks of the Mississippi River and other malarial districts, accompanied with enlarged spleen and torpid liver, when judiciously administered it is one of the surest remedies. In these cases it should be given in a decoction, made with four ounces of well roasted and ground coffee, boiled in a quart (16 ounces) of water, in a covered vessel, down to half a pint (4 ounces), and two table-spoonfuls given hot every two hours, commencing six hours before the expected attack, and keeping the patient well covered in bed. It has been found that in typhus fever, coffee increases the elimination of urea, and so far purifies the blood without increasing the destructive metamorphosis of tissue, and that it lessens coma and low delirium. In yellow fever, from a long experience, I consider coffee as my chief reliance, after other necessary remedies have been admiuistered; it restrains tissue change, and thus becomes a conservator of force in that state in which the nervous system tends to collapse, because the blood has become impure; it sustains the nervous power until the depuration and reorganization of the blood are accomplished, and has the advantage over other stimulants in inducing no injurious secoudary effects. In spasmodic asthma its utility is well established, whooping cough, stupor, lethargy, etc.

In the hysterical attacks of some females, for which the physician can form no diagnosis or cause, for the peculiar and eccentric symptoms manifested; a screaming, crying, staring, kicking, with no coherent answer for the medical adviser, at the same time with an evident tendency to act the persecuted saint—give her a cup of well-made, strong, black coffee, she becomes quiet, revives, smiles benignly, as if she had swallowed a panacea that had suddenly delivered her from the clutches of the imps of Satan, and wafted her from all the miseries of a condemned and tortured spirit, to the Elysian fields of Houris. We have used it as a remedy in croup, diphtheria, nephritis, chronic diarrhea, etc. In poisoning from opium it is well-known as the best remedy, and always on hand. Hayne says:—"That in a case of violent, spasmodic disease, attended with short breath, palpitation of heart, and a pulse so much increased in frequency that it could scarcely be counted, immediate relief was obtained from a cup of coffee, after the most powerful antispasmodics had been used in vain for several hours," etc.

After a hearty meal a cup of coffee will relieve that sense of oppression so apt to be experienced, and enable the stomach to perform its offices with comparative facility.

In fact, coffee carries healing on its wings. It is opposed to malaria, to all noxious vapors; as a disinfectant it has wonderful powers; as an instantaneous deodorizer it has no equal, for the sick room, the fetid odors arising from cutaneous exhalations are immediately neutralised, by simply passing a chafing dish with burning coffee grains through the room.

It may be urged that an article, possessing such powers and capacity for such energetic action, must be injurious as an article of diet of habitual employment, and not without delcterious, properties, but I have never noticed any corresponding nervous disarrangement after its effects have disappeared, as is seen in narcotics and other stimulants. The action imparted to the nerves is natural and healthy, and I must positively deny that the habitual use of the article is injurious.

Habitual coffee drinkers generally enjoy good health and live to a good old age. Some of the oldest persons I have ever known, have used it from earliest infancy, without feeling any depressing reaction, such as is produced by alcoholic stimulants.

In Porto Rico our fairest part of creation, at the tenderest age, have been induced to forget the delicious draught from the maternal fountain, by the substitution of a decoction of coffee, which soon becomes the daily beverage.—Mayaguez, Porto Rico, 1881.—*American Journal.*

FERTILITY.

TO THE EDITOR OF THE "FIELD."

SIR,—Your correspondent R. W. M. (See page 299, *T. A.*) accuses me of being too hasty in putting forward my views on the subject of fertility.

I have been conducting experiments now for more than forty years, and the results have furnished me with data that may surely justify my giving an opinion upon a subject of great difficulty and importance, without incurring the reproach of undue haste.

One of my hobbies has been, I admit, to give a scientific explanation of the principles of a rotation of crops. I wish I could think that I had ridden the subject to death.

The question with regard to the source of the nitrogen in leguminous plants is not likely to be settled during my life, at all events; but I have more faith in the answer being obtained from my own fields than elsewhere.

The idea that red clover obtains its nitrogen from the air, and not from the soil, is so firmly established in the minds of agriculturists, that, even if the evideuce of this plant obtaining its nitrogen from the soil were perfectly clear and distinct, a long time would elapse before this view would be generally accepted. At the present time I have no such *absolute* evidence to bring forward, but the general tendency of all the Rothamsted investigations, taken collectively points in this direction.

It may possibly happen that, in considering the soil to be the source of the nitrogen of leguminous plants, practical farmers may arrive at an explanation of many things in agriculture which at present they find very perplexing; and I should not be surprised if their verdict were given before science has, by its slower but more certain methods of investigation, established its own conclusions.

All I can say is that the conclusions to which I have come are different from those which I should have preferred, and I shall not regret, when time has settled the question, if the result should prove that I have been mistaken. J. B. LAWES.

CINCHONA IN COORG.

MERCARA, 22nd August.

The steadiness and attention which this product is meeting in this country augurs well for its future success, and the day is not far distant when there will be large supplies of a rich bark, holding its own in London against that sent from other parts of the world; for in the course of two or three years at the most, there will be many acres of cinchona trees of sufficient growth to be stripped or barked.

Cinchona is not a new industry here, for as far back as the year 1865, a healthy movement was made by a private firm to plant different parts of the

country with it, and it was carried out to a certain limited extent; but the next year and those following, it lapsed into disuse and became neglected. It lacked encouragement and was never thought to have such a brilliant future in prospect, and it has now attained, and coffee was giving sure and quicker profits; so that until 1877 the few hundred C. Succirubra trees which were left and had survived, and that without any care or attention were simply regarded as curiosities, and samples of what the soil could produce, if it ever became necessary to encourage them. (I do not here allude to the Rev. Mr. Richter's 'cinchona garden,' which has steadily been cultivated since 1863.)

Then, when the reaction set in in 1877, these trees were looked upon as an authority, they had become superb specimens of their kind. C. Succirubra standing from thirty to forty feet in height, with thickness of girth in proportion, and growing in a wild, partly desolate tract of the country, where the yearly rainfall was sometimes above three hundred inches and seldom less than two-fifty—it was naturally reasoned that, thriving so well there, similar trees would grow as well at the same altitude, and where the rainfall averaged only one hundred inches—which is about the mean of the coffee growing districts. Extensive orders for young plants were given to the Government gardens near Ootacamund in the first place, and as the supply from these was only limited, private planters on the Neilgherries were requisitioned, and from thence up to the present year the orders for both plants and seeds have been always upon the increase.

Where orders had not been previously registered it was with very great difficulty, and sometimes impossible to procure young plants from there, the demand is so great. Upon one estate here 20,000 C. Succirubras, twelve inches high, were purchased at the rate of R20 per 1,000 on the Neilgherries; the cost of transport into Coorg excluded, a journey of nine days by bullock carts. Of the trees planted in 1877-8, I can speak with confidence of their being magnificent specimens of their kind, ranging in height from fourteen feet downwards, vigorous, healthy, and commencing to flower. Whether the seeds will be valuable and productive from such young trees remains yet to be proved; but blossoming thus early is a good indication of the adaptability of both soil and climate. —*Madras Standard.*

COVERED *VS.* BARE GROUND.

(From the *Australasian*, 6th August 1881.)

"Covered ground *versus* bare ground" has been a much-discussed subject in English and American gardening periodicals. It will be remembered by many of our readers that Mr. Peter Henderson, nurseryman of New York, has proposed to cover all flower-beds with club moss or some similar plant, as a means of lessening radiation and evaporation, and of thus maintaining humidity in the soil, and especially on the surface, whilst vastly improving the appearance of the beds. He would treat specimen plants in pots and tubs in like manner, and both he and others have insisted that the plan is a natural one, and that it is therefore justifiable on that score. Nature, it has been said, covers the ground under trees with their leaves, and thus protects the soil from becoming frozen in winter or parched in summer. Under single trees grasses grow right up to the stem unless the branches sweep the ground, and thus choke other vegetation. The advocates of the system of carpet bedding base its claims on somewhat similar grounds; they aver that beds showing naked soil between the plants can never compare favourably with those that are clothed with verdure, or even with coloured vegetation. To all this it must be replied that much will hinge upon the manner in which the idea is carried out. In this country it would be a good thing could evaporation be lessened at the hottest season of the year, but it is hardly possible that it would be so lessened by covering the surface with the plants commonly employed in carpet bedding, as they all push their roots to the depth of a foot or more, and would thus still further reduce the amount of moisture instead of preserving it. Of the club moss it may be said that it is not a deep rooter; it has, however, a large evaporating surface, and when the air is quiet it maintains around it a humid atmosphere, which is grateful to other plants. Beds clothed with this moss and duly watered are very grateful to the eye when all around is parched, but they can be kept verdant only when sheltered from the north by a building or a high wall, and thus in this part of the country the plan is susceptible only of limited application. We have as yet heard of no objection to the covering of large pots and tubs with club moss; liquid manure can be given as readily as when the surface is bare, it only serves to deepen the verdure of the moss, whilst causing it to grow all the stronger. Where moss cannot be employed, coconut fibre makes a neat mulching: a little of this placed over a dressing of rotten dung will be found to improve the appearance very much.

ARROWROOT IN VICTORIA.

That a very excellent kind of arrowroot may be profitably raised in Victoria has been long since proved by the Rev. F. A. Hagenauer, superintendent of the Aboriginal Mission Station, Ramahyuk, Gipps Land. The plant from which the farina is obtained is the *Canna edulis* (variety coccinea), also called *Tous les mois.**

The following interesting memorandum is an extract from a letter sent recently by Mr. Hagenauer to Mr. W. R. Guilfoyle, director of the Melbourne Botanic Gardens:—

"This plant is one of the freest-growing kinds, and any farmer can grow and cultivate it without any trouble, and almost at any time from the early spring till late in summer. If the land is good, ploughed, and harrowed, the sets should be planted a few inches under the ground, but the old stem to be out of the soil, so that it may be seen. It ought to be planted in rows about 3 ft. each way, so that the sacrificer could be used at the first part of the season, and the ground kept clean—the success is almost certain. At the beginning of winter it is ready for manufacturing the flour, which is done exactly as that of the potato starch; either the bulbs should be crushed or grated, and with the application of clean water it should then be strained through a sifter or cheese cloth; the flour settles freely to the bottom, after which it is to be washed, and, when pure, to be dried and packed for sale. I have no doubt that there will be a good export market, as the plant does not grow in Europe, and yet the produce is freely used there for sick people, for children, and for family use in general." . . . Mr. Hagenauer further adds:—"Should there be any inquiry for quantities of seed bulbs, we can supply a good quantity for 12*s.* 6*d.* per cwt, delivered at Sale railway station, if application is made in good time."

Aloe Fibre.—We have to acknowledge with thanks the receipt, from the Inspector General of Prisons, of a sample aloe fibre twice exhibited by the Convict Establishment at the Polytechnic exhibition held at the Medical College. The twine is very strong and serviceable.

* "Maranta arundinacea" is the plant which yields the most Indian arrowroot of commerce; this species does not, however, succeed well in America.

Tea.—Messrs. W. M. Jas. and H. Y. Thompson, the 38, Mincing-lane brokers, in a letter to *The Times*, remark that the deliveries of Indian tea in England will "soon amount to 50 million pounds per annum, and there can be little doubt, considering the growing and high estimation in which Indian teas are held by buyers throughout the country, that a very much larger quantity, if the standard of quality be high, would rapidly find its way into consumption. Apart from our export trade, the delivery of China tea is about 116,000,000 lb. annually. It is fully expected that India will supply us this year with one-third of our total requirements. For many years past Indian teas were only used for the purpose of blending with China, but it is now known that some of the largest retailers are selling them pure, with advantage to their trade, their customers disliking the admixture.

Coca.—Another Specific against Starvation.—What the leaves of the coca (*Erythroxylon coca*) are to the South American, the nut of the cola (*Cola* or *Sterculia acuminata*) are said to be to the West African. Weston, the American pedestrian, was, we believe, the first to bring into practical public notice the uses of the coca-leaves, although their alleged properties had previously been described by scientific writers. These properties are now said to be possessed equally by the cola-nut, the seeds of a tree indigenous to the West Coast of Africa. The seeds are about the size of a pigeon's egg, several of them being contained in a single husk. The nut is eaten by the natives, who declare that it has the power of satisfying for a considerable period the cravings of hunger, and of stimulating them to withstand prolonged labour without fatigue. The nut, which is of a bitter flavour, is also said to act like olives in enhancing the flavour of whatever may be eaten afterwards. If the virtues attributed to the nut are really possessed by it, it would be an advantage to introduce its use among the working classes, who require some stimulus to increased exertion when, as we heard recently from Australia, they are ready to strike for higher wages than 12*s.* for eight hours' labour a day.—*Colonies and India.*

Cotton-seed as a Fertiliser and as Cattle Food.—A series of trials of the value of cotton-seed as food for cattle, and still more as a fertiliser, has been made in the United States, and the results are reported to be highly satisfactory. One member of the Cincinnati Convention of Cotton-seed Crushers says he has found it 'scarcely inferior to guano as a fertiliser, and invaluable as food for cattle.' Another finds, as the results of experiments upon land in Connecticut, 'that cotton-seed meal is the best fertiliser ever used on tobacco lands.' During three years it increased the productiveness of the land three-fold. He also found it superior to any other food for cattle. A cotton grower at Selma, however, has made a statement of a very extraordinary character. He says that by using cotton-seed meals as a fertiliser upon poor cotton lands, he has increased the yield from 18 to 145 bales, or eight-fold. It wood be very interesting to get a confirmation of this report, for, unless relationship between the fertiliser and the fruit it stimulates has something to do with this remarkable increased produce, it is difficult to place a limit upon the results of using such a marvellous fertiliser in the production of human food. Before, however, any opinion worth having can be formed of the value of this discovery, it will be necessary to learn not merely the present price of cotton-seed meal, but what the price will be under increased and growing demand, and to ascertain also the probability of a steady supply under the enormous demand which must follow a confirmation of the above reports.—*Public Opinion.*

Silk-growing in New Zealand.—In a letter which we published last week a correspondent drew attention to the opportunity which New Zealand offers as a field for sericulture, and suggested a plan by which the industry might possibly be taken up in conjunction with tea-planting. Tea and silk in connection with China is a natural combination of ideas, but it is doubtful whether the comparatively limited area of New Zealand affords the same facilities for the prosecution of the two industries as the far vaster extent of China. The plains of Lombardy are eminently adapted for the culture of the silk-worm, but tea could never be grown there as a commercial enterprise; and although the natural features and climate of different parts of New Zealand are sufficiently varied to give promise of success in the culture of tea, possibly, in the highlands, and of silk in the warmer valleys, it is questionable whether the two industries could be carried on in combination. As regards tea, we believe several Ceylon planters have testified to the adaptability of parts of New Zealand for the cultivation of this shrub; and as regards silk, public opinion in the Colony is generally in favour of the idea of introducing the industry. Some years ago the Government of the Colony offered a bonus of 50 per cent on the value realised for the production in the Colony of the first £1,000 worth of cocoons or eggs, and the recent Royal Commission on the Encouragement of Local Industries has recommended the renewal of the offer. Mulberry trees thrive in the neighbourhood of Auckland, and systematic cultivation of the silkworm would, no doubt, if carefully and tentatively introduced, prove a valuable addition to the resources of the Colony.—*Colonies and India.*

The Nutmeg: a beautiful tree in a garden, and although of long infancy, is the most remunerative of all on attaining maturity. It should be planted only on rich soils, well drained by a shifting drain between the rows: now opened nearer to one row, and in due time filled in with manure and covered; and then opened nearer the corresponding row, and in due time also filled in with manure and covered. And between these shifting drains—which help to winter the roots of the tree and rest it after producing a smaller growth—cloves, &c., might be introduced without injury to the larger cultivation. The planting distance will have to be regulated by the richness of the soil: the intervals being say about 8 or 9 or 10 feet, and calculating upon an annual production of 1,200 feet upwards, per full grown tree, and the average weight of the kernels or nuts 90 to 100 per lb., there will be obtained from a tree of 1,200 fruit over 12 lb. nutmegs average value R1·50 ... ... R18
4 ,, mace... ... ... ,, 75 3

Per tree R21

being very rich remuneration indeed for any amount of care bestowed on the cultivation. Of the pulp of the fruit has been prepared one of the richest *compotes* we have ever tasted, but the pulp generally as well as the leaves should be returned to the soil by imbedment in the drains or otherwise. Many years ago the nutmeg was planted somewhat extensively in the neighbourhood of Galle and failed: for instead of the plant being put into permeable rich soil, it was struck into the hard cabook of the undulating hills near Wakwella; and recently we have discovered the death from want of care of some splendid trees grown not far from Colombo. The property had changed hands from European to Native, and the trees died for want of continued attention, so that unless would-be growers of the nutmeg select a rich soil, and bestow unremitting care in the growth, they cannot reasonably hope to obtain the rich returns now yielded by the cultivation in other countries.—*Ceylon Examiner.*

FARM MEMORANDA.

Flies and Horses.—The incessant torment which flies inflict upon horses during such hot weather as we recently endured may not have occurred to the minds of many. Though a minor misery, yet it is so real that I venture to ask you to allow me to describe a plan which I have found thoroughly successful in preventing it altogether, while perfectly harmless. It is simply the application, before harnessing, of a mixture of one part of crude carbolic acid with six or more parts of olive oil. This should be rubbed lightly all over the animal with a rag, and applied more thickly to the interior of the ears and other parts most likely to be attacked. This application may need to be repeated in the course of the day, but while any odour of the acid remains, the flies decline to settle, and the horse is completely free from all their annoyance. The nervous, irritable state into which horses get from the attacks of these insects is also not an infrequent cause of accidents; and these, therefore, may also be obviated. Whether the dreaded tsetse of Eastern Africa would also fight shy of similarly anointed animals I cannot say, but it deserves a trial, and if successful would be an incalculable boon. It might also prove obnoxious to mosquitoes.—J. James Ridge, M.D., London.—"Enfield" (in the *Daily News*.)

Liver for Fowls.—Some little time ago we had a long spell of parching east winds here. Vegetation, which should have been growing rapidly at the time, was at a standstill, and all kinds of insects and grubs which fowls devour with such relish were nowhere to be found. The most inexperienced poultry-keeper knows that the want of these soon begins to affect the hens, especially in the production of eggs, which becomes scarcer and scarcer until the supply almost ceases. This was the case with my fowls during the period in question, and probably I should have had no eggs until the weather and earth had become humid, had I not, when I saw how matters stood, begun giving a little raw chopped liver daily. Not more than three or four days after the hens had this they one and all started laying, and did not stop again until rain came, when no more liver was given. I have tried many kinds of flesh food for fowls during such a time, but have found nothing so good as the liver. Their recommencing to lay during the very kind of weather which stopped them I attribute wholly to the liver, as no other change of food was made. As liver is so cheap and can be easily procured, probably it may be to the advantage of some of your readers to know this, and as we may have much dry hot weather shortly, I consider the matter well worth publicity.—(Correspondent of *Journal of Horticulture*.)

Agricultural Experiments at Woburn.—These experiments were instituted last year for the purpose of ascertaining the value of dissolved and undissolved phosphates. The results already obtained show that wheat cannot be profitably grown on the light soil at Woburn, and probably not on similar sandy soils elsewhere, for a limited number of years, even when the best artificial manures containing both mineral and nitrogenous constituents are applied to the land in much larger proportion than could be done in actual farm practice, on account of the cost of the manures. On strong wheat land, containing a large proportion of good clay, such as that at Rothamsted, Dr. Lawes has grown both wheat and barley on the same land continuously for about 30 years.—*Home Farm*.

FRUIT EVAPORATION.

(From the *Australasian*.)

Our readers will doubtless remember the description given some three years ago in these columns of the Alden patent process of drying fruit in the United States of America. It was claimed for this process that raisins could be prepared of superior quality to those ordinarily sold at much less than the usual cost; that apples, peaches, plums, and apricots could be dried or "evaporated" in a superior manner, and that the Alden process was in general use throughout the United States. We now learn from our Adelaide contemporary, the *Observer*, that a Mr. Pulleine, from Tasmania, has been describing to a meeting of the Chamber of Manufacturers a similar process, which he is of opinion could be utilised in these colonies. By its aid tons of fruit that now go to waste could be prepared in a marktable form. The approximate cost of a machine that would turn out five tons of fruit per day would be £500. A youngster ten years old could turn out about a bushel an hour; fuel in Tasmania costs little; a ton of coke costing 16s., would last eight weeks, at the rate of 14 working hours a day. Mr. S. Davenport (who took the chair), Mr. T. Hardy, and three other gentlemen were requested to report on the subject. According to Mr. Pulleine, the driers of apples and peaches in the States have not been as particular as was desirable in securing uniformity of sample. The boxes have been extensively "salted," *i.e.*, the best layers have been placed on the top; these practices have, in the long run, an injurious effect upon the trade, creating distrust and lowering prices. On this and the other matters we will allow Mr. Pulleine to speak for himself. Thus, speaking of this condition of the trade, he says:—"This I attribute to the fact that the articles are purchased by merchants in outlying districts, who are at the mercy of the producers to a great extent, and this evil can only be remedied by having a packing factory, where the fruit packed for export would be under the immediate supervision of a thoroughly practical manager, who would see that goods sent out were uniform in quality, brand, and package. The price of evaporated fruits cannot be positively fixed, and like other articles of commerce, the value on the market is subject to the great question of demand and supply and the quality of the article, which conditions, as in cereals, are influenced by favourable or unfavourable harvests. It must, nevertheless, be borne in mind that fruit skilfully evaporated, packed, and pressed, will retain its original quality unimpaired for an indefinite period, having by that process been rendered imperishable. The prices of evaporated fruits for the season 1879-1880 were:—In New York—Apples, 7d to 8d per lb.; peaches 10d to 1s 3d. In Oregon—Apples, 5d to 5½d; peaches, 10d. In London, September, 1880—Apples, wholesale, 7d to 8½d; retail, 10d to 1s. I am however convinced that the best samples on view at the Exhibition would command a higher value. The time occupied in my process depends partially on the atmospheric condition, but in this colony there would be little variation. Different varieties of plums and apples take slightly different treatment, but approximately the time occupied is:—Apples, 2½ to 3 hours; pears, 2½ to 3; plums, 3½ to 5½; blackberries, 2½ to 3½; grapes, 9 to 10; hops, 3 to 3½; apricots, 2¾ to 3½. It is my intention to experiment on vegetables, meats, &c., and I have already achieved results of assuring nature. I may state that this colony has, in my opinion, advantages above any other, especially in the atmospheric condition necessary to successful evaporation, and I am satisfied that should this industry be established on a sound basis, in a very short time South Australia would not only produce a sufficiency of raisins, currants, and other fruits for home consumption, but would be in a position to export to other colonies. Though temporarily a resident in Tasmania, which produces fruit of undoubtable quality, I cannot but recognise the immense resources of this colony in

possessing a climate so admirably adapted to the successful cultivation of the grape, the Zante currant, and the fig, all of which as articles of food enter largely into the every-day 'bill of fare.'"

POTATO CULTURE IN AMERICA.

Having an immense extent of land out of which it is easy to select enormous tracts especially favourable to the production of potatoes, and possessing also many kinds recently raised that are very productive, it is not to be wondered at that potato culture has in the United States grown to be a large and important part of agricultural work, and the crop produced one of considerable importance to the interests of the country. Whilst there is found there less disease, there is to be found a potent enemy to the plants in the shape of the Colorado beetle, and this is so far destructive that its ravages suffice to prevent potatoes becoming a glut, and thus staving off that inevitable result of a glut, a price that is simply ruinous. Were the American potato fields as near to us as are those of Germany, there would be little reason at any time in this country to fear a potato famine, but the cost of freightage and transit is heavy over such a long journey, and thus, whilst able to send us an abundance of corn, the importation of potatoes, except for seed purposes, is necessarily limited. In these vast and thinly-peopled regions, where labour is as costly as land is cheap, all forms of labour-saving contrivances have to be adopted, and thus we find that the *modus operandi* of potato culture differs materially from ours, and is perchance, if less costly, not less productive. A heavy soil is never selected for potatoes, but rich sandy regions that abound near rivers and lakes afford specially favourable positions for potato culture. There, as here, the objections to the use of raw manures with potatoes are strong, but there at least they act consistently, and not only object, but do not employ it with the crop at all. Here our growers largely object to the use of raw manures, but generally employ it with the potato crop. But recently a large grower spoke most favourably of the value of a turned-in clover crop in the spring as a healthy potato manure. Sown with wheat or barley in the spring, the corn crop is taken off and the clover left standing till the spring, is turned-in deeply early in March, and the potatoes planted at once. The green nature of the clover causes rapid decomposition, and upon this vegetable matter the potato plants greedily feed, and produce a finer and healthier crop then when grown with raw manure. Allowing for the difference of season, just what some growers do here, the American growers—especially those in the northern counties of the great state of Ohio—do largely, the clover being turned in late in May and the planting done early in June. When the growth of clover is heavy it is the practice to roll it over in the direction in which it will be ploughed, and thus the plants are more easily buried. The Americans claim for this dressing that in their hot sandy soils it keeps the ground cool and moist, and supplies the plants with abundant food during the season of growth. One reason for such late planting is found in the fact that by it one crop of the beetle is avoided, and such an escape is an important item where 40 or 50 acres are concerned. Later varieties, it is found, do not form tubers any the earlier for early planting, and that, as a rule, these do not swell to any appreciable extent before the cooler nights of August and September. In a locality where labour is scarce it is also important to get the corn crop all in before potato planting, and thus in every way late planting seems to be most profitable. Americans have invariably set us examples as to labour-saving appliances, and in the cultivation of potatoes on a large scale they not only want to plant quickly, but cheaply. Here it is a customary rule either to plant the sets in every third furrow, burying as the plough proceeds, or else to dibble in every third division of the ridges as left by the plough, but in both cases the soil is somewhat hard and tough for the young growing plants. In Ohio the ground, after ploughing, is well pulled with the harrow, and the line-marker—an implement on wheels that marks four or five lines at once—follows the harrow, and as soon as the ploughing is done, the other implements have followed so closely that it is only necessary for the marker to start crosswise over the ground for planting at once to proceed. This is done by men following and dropping a set where the marker has intersected the lines that run the other way, and as the lines are about 30 in. apart, there is thus a plant 30 in. from its neighbours all over the field. When the set is dropped into the intersection, it is gently pressed in with the planter's foot. Then a horse coverer, consisting of an implement having a couple of cultivator teeth, is drawn over the line, leaving a slight ridge of soil. Cleaning is done by the harrow, which is drawn over the field in both directions until the plants are several inches high. Then follows "hilling," which is synonymous with our earthing, but in this case, as the earthing is done by the moulding plough both lengthwise and then crosswise, each plant forms a hill of itself, and this plan is the most favoured in the United States, and for which not only is it claimed that a better crop is obtained, but also that lifting is simpler, more expeditious, and shows cleaner results. It is worth nothing that in this "hill" system not more than one-half the quantity of seed is needed that is required on our customary field plan, and that also the plants have abundant space for the fullest development.—A. D., in *Gardeners' Chronicle.*

FLAX CULTURE.

(From the *West Australian Inquirer.*)

We proceed to give, as succinctly as possible, the means by which the successful cultivation of flax may be pursued. Before entering fully into the subject we would remark that it is creating no small stir in the adjoining colony of South Australia. A lengthy and highly-interesting Paper on the cultivation of flax was read by Mr. Septimus V. Pizey, at a meeting of the South Australian Agricultural and Horticultural Society, full of useful information and brimming over with bright anticipations of success as an industry if developed in that colony. The article is too long to copy *in extenso*, but will amply repay perusal by our agricultural readers. It is published in the *South Australian Register* of July 16. We conceive that no apology whatever is necessary for taking up so large a space in exhibiting the vast benefits placed within the grasp of our farmers by imitating our neighbours in the pursuance of a comparatively new class of husbandry for which the natural advantages of Western Australia are equally favourable for illustrating. Those who may think that our climate is too dry and warm for cultivating flax have only to be told that it has lately been found to thrive luxuriantly both in Fiji and Queensland.

The author of an article in the *Victorian Review* quotes another writer on the subject, who says:—

"We will only observe 'where there's a will there's a way;' men's minds are much more difficult to cultivate than land. Stubborn fields can be made to bear flax and hemp more easily than an indifferent, prejudiced, routine-led neighbourhood can be taught to appreciate their value when grown. Again the profitableness of flax and hemp are more than acknowledged, they are unquestionable; with the sole exception of not furnishing a stimulating beverage, it (flax) lends its aid directly and indirectly in fur-

nishing the whole life-long journey of the human race, from the cradle to the grave; supplies various items of clothing, writing materials, bedding, fuel, medicine, external as well as internal; manure, material to aid the painter's art, animal food of the highest nutritive qualities, and, above all, when duly and properly managed, affords that inestimable blessing to a population, a constant source of remunerative employment. Again, if the patrons of agricultural science will not generously aid, flax and hemp will not be grown; we shall remain dependent upon others for much we might and ought to produce ourselves; we shall continue to pay away large sums which we might retain in our own pockets, and many a constant wages will remain unearned by willing labourers, because neither the material nor the skill to work it are produced and placed within his power."

Again, a quotation from an intelligent contributor on flax culture in the North of Ireland—

"From Belfast to Colcraine is now one enormous bleachfield, to go from the south to the north is like passing from darkness into light. The stranger ascending the Church Tower in Belfast sees around him little but the chimneys of the linen mills which have converted the city—a hundred years ago a mere collection of unpaved lanes and wretched cabins—into one of the wealthiest in Ireland. The contrast has been too great not to strike the really intelligent, though often, alas! misguided natives of the other provinces, and they have, in many instances, betaken themselves, apparently in earnest, to the culture of a plant which has proved so true a friend to their northern brethren. In Cork, especially, the movement shows a strength and persistency greatly beyond what usually characterises the run of Irish industrial enterprises."

Some thirty years ago the writer in the *Review* was largely engaged in agricultural pursuits, and cultivated flax for four years successively—sent samples to the great Exhibition of 1851, receiving medal and certificate of merit; he also sent bales to the great house of Marshall, of Leeds (who alone purchase flax to the extent of a million sterling annually), who pronounced the flax as of most excellent quality. The discovery of gold stayed his further progress at that period (1852), since which time he has been engaged in squatting pursuits. He can therefore write with some degree of confidence, and honestly assert that the soil and climate of many parts of Victoria are peculiarly adapted for the cultivation of flax. And if the climate of Victoria and South Australia is suitable for this industry, Western Australia, in its southern and eastern parts, must be equally so. We cannot do better than give the writer's own words in describing the modes of operation in the growing and preparation of flax. He says:—

"When cultivating the plant I have sown flax seed after grass, after wheat, upon new land, and upon land under fallow; or rather, instead of fallowing, strictly speaking, and allowing the land to lie idle the whole year, flax seed has been sown in the spring, and wheat the following autumn. When sown on new land or after grass, one ploughing only has been given, immediately preceding sowing; but after wheat or other grain crop the ground has been ploughed deeply as early as possible, and again in the spring, with repeated scarifying and harrowing, so as to get the soil into the finest possible tilth before sowing the seed. Of course I am assuming that the agricultural reader is one who is fully alive to the propriety and profitableness of farming his land properly for whatever crop he purposes raising. The earth, as a quaint old writer puts it,—'is as a coy maiden—the more she is tickled the more she loves you—so the soil, the more it is tickled by the plough going deep, with scarifier and harrow to boot, the more she will yield the farmer.' Having got the land in proper order, sow two bushels of clear linseed; that quantity per acre gives fine flax and good seed. The ordinary linseed of commerce is not the seed from which the finest flax is raised. Flax seed is imported yearly into Ireland from Riga (in Russia), and Holland, for seed purposes—from the former it comes in casks, officially sealed as being true and good. The land should be sown (the reverse way to the last harrowing) broadcast and as evenly distributed as possible, then harrowed over (the same way as sown), with a very light grass seed or brush harrow, finishing off with a light rolling carefully, and if this can be got through while the land is dry and friable so much the better. The time of sowing, as early as possible in the spring of the year. No fixed dates can be given, the intelligent cultivator will be guided by his experience of the locality and nature of soil. As it is sown thickly, so it springs up, and the rapid nature of its growth, in this country, does not allow weeds to interfere, if the land is moderately clean. The proper time to commence pulling the crop is when the leaves begin to fall from the plant, and the stalks are nearly all yellow; experimentally, it has been pulled at various stages—when quite green, partially so (as is the Irish plan, by which they lose the seed), fully ripe, and when nearly so. The latter is found to be by far the best practice, having regard to fine fibre and good seed.

Thus we have extracted the gist of the matter contained in the introductory portion of the paper in the *Review*, and trust our agricultural readers will be at once induced to make a start, if it is on ever so small a scale. Let them try with half an acre as an experiment; at the very worst the straw can be used for bedding for horses or for thatching, and the seed given to the pigs. There is no doubt in our minds that if once the attempt be made it will be continued, and, if properly made, that success will attend the effort. We shall give some further particulars of the industry in a future issue.

A SUBSTITUTE FOR WATTLE BARK IN TANNING.

TO THE EDITOR OF THE "AUSTRALASIAN."

Sir,—I notice in your issue of July 5 a letter signed "Kangaroo," asking for a substitute for wattle in reference to tanning skins. I have tried "balar," commonly called black oak, which has proved very satisfactory. Quantities: one bucketful of bark to two of water, to let simmer for six hours, and skins to remain in the liquid from 10 to 12 days.

Poolamica, July 28. Charles Wenyeve.

INSECTS ON WATTLE BARK.

Sir,—A great many of the wattle trees on my farm are covered from base of trunk to extremity of large branches with millions of eggs of some kind of insect (I send you specimen). Would you please say what they will become when fully developed, and oblige Romsey.

[An experienced entomologist, Mr. Robert Scott, of Richmond, has obligingly furnished us with following notes on the specimens:—I have examined the piece of wattle bark from the Lancefield district. The small objects which cover its surface appear to be the protecting scales or covers containing the larvæ of some insect of the Coccidæ, or "scale insect" kind. Many species of Coccidæ are found in Australia on gum and wattle trees, &c. The larvæ are very soft and easily injured, and it is difficult to get them separated from the scale uninjured and in a state suitable for examination. I managed, however, to examine a few under a good microscope. So far as I can judge from the form of the scales (which

differs in allied genera) and the appearance of the larvæ, which are yet in an early stage, they would seem to belong to a species of Aspidiotus, or some allied insect of the Coccidæ kind. The genus Aspidiotus comprises several species, which, in America and Europe, are injurious to fruit trees. Gishurst's compound has been found a very effective means for the destruction of all kinds of "scale insects."

I have read a paragraph in the *Herald* respecting the supposed appearance in New Zealand of the Colorado potato beetle. I have seen several species of beetle here which were suspected to be the potato beetle, but I have never yet seen the true beetle amongst them. If you or any of your correspondents wish to see the real Doryphora decem-lineata, I can show you one, and an inspection of a specimen is often better than even a good coloured plate.—R. S.]

WATTLES FOR TANNING.

SIR,—Being anxious to collect some good seed, I am at a loss to know how to tell that which is the best. That black and golden varieties are the best I learn from the report of the Wattle Bark Commission, and while the broad long leaf enables the golden to be easily distinguished, nothing that I met with in the report enables me to distinguish the black from the silver or other varieties. I find that bark strippers are not at all agreed about the names of this tree. In my ramble, I meet with a black bark, a green bark, a bark covered with white spots, rough and smooth barks—trees on creek banks, flats, and ranges. Excepting the golden the leaf in all appears to me alike. I have been told that a white flower distinguishes the silver wattle, and that the bark with white spots is silver wattle; but I observe this latter bearing a yellow flower, while the white flower I have not seen at all. Pertinent to the information I am seeking, does it matter whether the seed be taken from a young or an old tree, from the bank of a river or mountain side, or a tree with extensive or sparse blossom on it?

SCHOOLBOY.

[The real black wattle, or true tauning variety, is the acacia delbata. The silver wattle, which is considered inferior to the black, is the acacia mollissima, which can be easily distinguished by the silver appearance of the under part of the leaf, and the glaucous appearance of the bark; the flowers of the latter are a bright yellow, that of the former a dirty yellow. The silver wattle is in general found on the banks of creeks, the black wattle on high dry ground. The black has rough bark, the silver being comparatively speaking smooth. The seed, so long as it is good, may be gathered from any tree.—ED.]

QUALITIES OF VARIOUS SOILS.

SIR,—In your issue of June 28 a "Selector" asks for an opinion upon the probable virtues of soil formed from the *débris* of granite ranges. Although neither an agriculturist nor directly connected with the tillage or cultivation of land, I have pretty large opportunities of observing the effect of various modes of agricultural treatment as applied to various soils, and also of noting their various natural products; it may, therefore, not be deemed presumptuous on my part to offer an opinion. I feel bound, then, in the first place, to take some exception to your own remark that "the character of the timber attests at least a fair amount of fertility in the soil." I believe it is a pretty generally accepted proposition that timber trees depend but little upon the mineral constituents of the soil for their nourishment and growth, an opinion which appears to be borne out by the well-known fact that, whereas a given weight of grain, straw, or other such-like vegetable substance yields on burning a considerable residuum of unvolatilised ash; timber, on the other hand, yields almost no residuum. Certainly some slight qualification of this general statement is necessary in the case of the Australian eucalypti, inasmuch as they contain an excessive amount of potash as compared with other timber trees. But this fact will hardly affect the general argument. At all events, observation has led me to the conclusion that depth of soil, aspect, and shelter are much more potent factors in the production of timber than character of quality of soil. It is true that trees of large size, or of value for the purposes of the sawyer or splitter, are rarely or never found in localities where the soil is thin and the rock near to the surface; but it is equally true that timber of the finest quality is commonly produced on soil too poor to be of any use for the growth of ordinary farm crops, provided only that the other conditions are favourable. The gullies and ravines that furrow the lower slopes of our mountain ranges are the principle habitat of the larger eucalypti; and it would seem that if only the soil be deep enough to afford the roots complete protection from the summer heats and a permanent supply of moisture, and if the aspect and situation be such as to insure shelter from violent storms, all the conditions necessary for the growth of timber are fulfilled, and that the quality of the soil has really not much to do with the matter. Of the trees mentioned by your correspondent, stringy bark, white gum, yellow box and wattle are all to be found growing on the slopes of Mount Alexander, where the soil is granitic and of very poor quality; also on the poor granitic soils in the parishes of Langley, Baynton, and Cobaw, to the north-east of Kyneton, and on the granitic and schistose soils of that portion of the Macedon State Forest recently thrown open for selection. They are also to be found growing equally, though I think not more, luxuriantly on the rich volcanic soils forming the upper portion of the Macedon Range, and on similar soils in many parts of the Bullarook and Wombat State Forest; and again in the fertile soils of the tertiary formations of South Gipps Land and the Western Port district. Red gum I have never known to grow except in the near neighbourhood of rivers and watercourses—the best specimens usually in situations liable to occasional partial inundation. I think, also, that red gum is not to be found in Victoria at an altitude greater than about 1,200 feet above the level of the sea, although on this point I cannot be certain. Adverting now to the subject-matter of your correspondent's letter, he requests an opinion upon a statement which has been made to him to the effect that a couple of crops will thoroughly exhaust the fertility of granitic soils, and leave them incapable of producing even grass. Well, as farming is conducted in Victoria, and is likely to be conducted for some generations to come, I think the above statement may be accepted as literally true. Whereas our volcanic soils will generally stand cropping for 10 or a dozen years before they begin to show signs of failure, and the best tertiary soils may be reckoned on for probably an equal length of time, it is a fact that the best granite soils will not yield more than a third crop, and generally not more than a second. And, further, whereas the richer soils will, after an exhaustive course of grain cropping, still continue to bear grass of at least some value, the exhausted granite soil after like treatment will remain for some years as bare of useful herbage as a macadamised road. Of course there are degrees of poverty even in granite soils. For example, in Cobaw, Langley, and Pyaloug, Glenhope, Baynton, Elphinstone, and Harcourt, these soils are poorer than the granite soil in the parish of Kerrie. In the latter locality it is more tenacious, probably from the fact that it contains a larger proportion of feldspar, while

in the former the silica appears to preponderate. And of course the more tenacious soil is more retentive of the soluble organic matters shed upon it in the ordinary course of nature. It may be mentioned also that the soil in the parish of Kerrie is somewhat of a red colour, while in the other localities spoken of it is of a cold grey tint. The redness is probably due to the ferruginous character of the granite from which it is derived; but as I am not aware that oxides of iron enter to any considerable extent into the composition of vegetable tissues, I cannot see that their presence in the soil is of any importance or value to the agriculturist. Granite soils, however, owing to their porous nature, generally carry a good sward of early spring grass, but it is of poor quality, and, although valuable for the early fattening off of spring stock, is of very little use for dairying purposes. Neither does it stand the summer heat well, but is soon scorched up, and by the end of January or beginning of February will hardly afford a bite. I am not prepared to say that under rational treatment these sandy granitic soils may not become valuable and be made to yield a fair return of food for the use of man. But I feel certain that under the existing conditions of agriculture in Victoria their cultivation for the growth of ordinary grain or root crops is but a tempting of Providence.

Kyneton, July 2. SURVEYOR.

TARAXACUM IN THE BOTANICAL GARDENS, NORTH-WEST PROVINCES.—The subjoined resolution has been passed by the local Government upon the annual report on the Botanical gardens:—The report deals with the gardens at Saharangur, Mussoorie, and Chajuri; but the two latter gardens are comparatively unimportant, and only a small measure of success has been obtained in them. Their sites are said to be unfavourable, and a proposal will shortly be submitted for abandoning them as soon as a suitable site can be obtained elsewhere. The sum sanctioned for expenditure was R30,000, of which R24,524-33 were actually spent; the decrease being due chiefly to the fact that for a considerable portion of the year the Superintendent was absent on furlough. The receipts amounted to R6,658-5, against an estimate of R6,000, so that the net cost of the gardens was R17,865-14-3. Attempts continued to be made to acclimatize vegetable and flower seeds, but the success attained was small in the case of the former. Flower-seed is more easily acclimatized. The success obtained in the cultivation of *taraxacum* and preparation of the extract is satisfactory. There is no field where there is more room for doing good service in the gardens than the production of indigenous drugs. At present dispensaries and medical practitioners are dependent for the supply of these drugs on the dealers in the native bazaars; and it is often impossible to be sure that the article supplied is genuine and of good quality, or that from long keeping it has not lost its peculiar virtue. The Surgeon-General was nearly two years ago requested to consult with the Superintendent of the gardens as to the drugs which are found to be of value in practice, and the production and storing of which might be attempted. The result has not yet been communicated to the Government, but the Superintendent might himself take measures to procure information on the subject. If valuable indigenous drugs can be produced of good quality, there is certain to be a demand for them on the part of dispensary committees, who will gladly use them instead of the more expensive European equivalents or substitutes, in the same manner as they now use the cinchona febrifuge. On the whole, the working of the Saharanpur garden seems to have been very satisfactory, and the results are creditable by Mr. Duthie and Mr. Gollan, the head-gardener, who was in charge for half the year.—*Pioneer*.

LEDGERIANA SEED FROM JAVA.—We hear that a local mercantile firm has imported a small quantity of this precious seed from Java which is to be offered by auction, made up in lots of a few grains (weight) each! Much more valuable than gold is pure Ledgeriana seed at this moment, and planters with trees over five or six years old on their estates should look out carefully to see if any of this richest species may be amongst them. No one was more surprised, we believe, that the owner of one such tree the other day, to learn that a piece of bark he sent to Colombo for analysis, gave over 8 per cent of quinine, the tree itself being at once pronounced by competent authority to be a Ledgeriana.

SUGAR.—The Austrian *Organ des Central Vereins für Rübenzucker Industrie* gives an account of a patent taken out in the German Empire by Herr G. A. Hagemann, of Copenhagen, for two processes of coating beet sugar with cane sugar, in order to remove the disagreeable smell and taste, which render the former as a rule unsuitable for direct consumption. (1) While the sugar is still in the centrifugal machine, but after most of the beet molasses has been removed, it is covered with cane molasses, or with a concentrated solution of cane sugar. The cane molasses must, when necessary, be diluted or warmed, and is best applied by means of a syringe or some similar instrument. (2) The beet sugar is placed in a suitable stirring-apparatus, and cane molasses or a stirring of cane sugar is applied. When all the grains are coated, through the stirring with cane sugar, the work is complete. By the above methods beet sugar is said to acquire the smell, aroma, and colour of cane sugar.

COFFEE LEAF DISEASE.—A Ceylon contemporary states that Mr. Ward will shortly forward a further report on his recent investigations to Government for publication, describing the nature of the fresh evidence he has collected as well as its practical utility. Mr. Ward, it is said, has discovered the means of ascertaining the exact period at which we may expect each successive attack of leaf disease, by which means planters will be enabled to prepare for its appearance. No signs are, however, made of any remedial steps that are likely to be successful, Mr. Ward still adhering to the opinion that, so far as our present knowledge extends, the only known means for attacking the enemy is the destruction of fallen leaves, the cost of doing which planters declare to be more than they can undertake. With regard to the experiments with carbolic acid and lime it is said that the trial was made at a time when the fungus was not freely developed on the leaf, and that Mr. Ward is confident that no good can be expected unless its application takes place at the right moment. The fall of leaf on an estate in the Agras treated by the Schrottky process is said to be due as much to the presence of grub as to leaf disease. As to a report that leaf disease was bad in Haputale, our contemporary says that it is true that the disease had made its appearance with more than usual vigour on some of the lower Pass estates, but the attack has passed away without making very serious impression on crop or trees, whilst the estates in the upper part of the Pass have scarcely felt the attack, and at the present time the prospects of the district are as good as they ever were. A correspondent of a contemporary also calls in question the statement made in our columns regarding the prospects of estates in Dimbula, and says that though those places which have been entirely neglected or have been over-manured are not likely to pay for some years, which have been steadily cultivated will give good crops. He also thinks that it is too early to speak decidedly of the results of carbolic acid and lime as a cure for leaf disease. The application of lime to the soil has done much good.

THE YIELD OF TEA PER ACRE IN CEYLON AND INDIA.

We are very pleased to learn the result (See page 355) of his first year's experience from the Manager of the Galboda Tea plantation situated in the Ambegamuwa district. (Ceylon). This district already stands pre-eminent for the strength of the liquor yielded by the tea it produces, and considering its well-distributed heavy rainfall, it ought to give abundant crops of leaf. Our criticism of the Kandaloya estimate was more in the nature of an enquiry as to whether an average of 400 lb. per acre had yet been gathered over any considerable area in Ceylon, than of doubt, in reference to this yield being obtained on the plantation in question. Most certainly Dolosbage and Yakdessa—with a nearly equal rainfall, but lower down and hotter—ought to equal, if not excel, Ambegamuwa in the quick succession of abundant tea flushes, and, therefore, after Mr. Hughes' experience at Galboda we do not think there will be any reason to doubt the harvesting of five maunds per acre from well-cultivated tea on Kandaloya. Mr. Hughes mentions one important condition in estimating production at this rate in Ceylon, a condition which is fulfilled both in the case of Galboda and Kandaloya. namely, that the tea should be grown on virgin forest soil. Where tea is planted on land already cropped for many long years with coffee, or on chena land, it is obvious that although the return may prove remunerative—considering the less expense in opening—yet that it cannot be expected to equal the yield in the case of virgin soil. It is true that in India the return has reached as high as ten, and even eleven, maunds or 800 lb. to 900 lb. of dry leaf per acre; but this, of course, was entirely exceptional; just as much so, as a ton, fifteen and ten cwt. per acre of coffee were in Ceylon in the days (1854 to 1866) when the average yield for the whole country, with the old districts in their prime, never exceeded *five* cwt. per acre. Mr. Stalkartt, one of the oldest Tea planters in Northern India, and a great advocate for working up a small area well rather than treating a large extent indifferently, assured us three years ago in England that he got from some of his best gardens 7 to 8 maunds steadily; but the said gardens were, perhaps, 30 to 40 acres in extent, and seldom exceeded 50 acres, so that the manager was really able to give special attention to the cultivation of almost every individual bush. For the districts in India, as a whole, the average yield is much lower. Thus, in 1875-76 the average yield over all Assam from tea in full bearing was 229 lb. per acre; in 1876-77 it was 228 lb.; in 1877-78 it rose to 286 lb. Darjeeling, in the latter season, gave an average of 350 lb. per acre, and Chittagong 395 lb., the highest district average recorded in the official returns. In season 1879, we have a return of twelve of the principal Indian Tea Companies, and the average yield of their properties ranged from 191 lb. over 2,000 acres (old and young tea) belonging to the British Indian Company, to 346 lb. the average over 6,000 acres belonging to the Assam Company, and 485 lb. (or 6 maunds) per acre (the maximum) which was got from 740 acres old and young tea by the Borelli Company. Another analysis shews that the Borelli Company got 491 lb. per acre over old and young cultivation, and declared a dividend of ten per cent in 1879. The dividend of the Assam Company in 1878 was 27 per cent, and next year it was 10 per cent. This latter profit was made from tea which cost 1s 5⅝d per lb. all over, including sale charges, and which sold in the gross for 1s 7⅝d, the profit being, therefore, 1⅞d per lb. on an average, or 16s 4d per cwt. as coffee planters would put it. In 1878, the clear profit of this Company was a fraction over 6d per lb. In 1876, the Dehra Doon Company with 351 acres under cultivation gave an actual outturn of 197,210 lb. of manufactured tea, or 562 lb. per acre. A Darjeeling planter writing to the *Tea Gazette* insists upon it that the average for that district for *field* cultivation is 370 lb. per acre, while, as regards *garden* cultivation, the yield has been up to 11 maunds (880 lb.) per acre! He adds as follows:—

Besides making some of the finest tea in the world, we in Darjeeling can make it in quantity. Here is the yield of two of my small gardens—

One of 34 acres in 1875 gave 384 mds
The other 25 ,, ,, ,, 265 ,, } about

11 maunds per acre. In 1876, these gardens gave 10 maunds per acre; but I have another garden, 980 acres, which gave less (5 maunds per acre). This reduces the average much. However, in 1876, 143 acres old and 30 acres young plant gave 1,161 maunds, or 530 lb. an acre. That properly cultivated, well filled up and manured land, can yield very largely there is no doubt. In Assam, I believe, it has given 17 to 19 maunds per acre, and the highest yield in Darjeeling from a small area (5 acres) of land, yielded this year at the second flush at *one pluck* (there are at least 12 plucks in the season) 1,050 lb.: this is 210 lb. per acre. The great thing is to make all the plucks yield like this one. A careless day's pruning or plucking lessens the average, sometime as much as 25 per cent. for the next yield.

The editor remarks:—

Some of our correspondents seem to think 6 maunds a good yield per acre, but we know of a factory in Upper Assam which yielded last year (1876) 11½ maunds per acre, and others in the same district which yielded 10 and 8 maunds.

And another planter "Mac" is still more emphatic:—

I do not see why 1,000 lb. of tea should not be the average arrived at per acre. When one comes to look at it, it is only 4,000 lb. of green leaf per acre. True, it represents the young sprouting leaf, still I don't think it is too much. One bush of indigenous—or almost pure—was fenced off, and plucked separately. It was not otherwise attended to specially, and it produced 13¾ oz. of made tea. With similar bushes planted 5″ x 5″, this represents 1,500 lb. per acre. As this bush was not specially treated, I do not see why 1,000 lb. per acre should not be made with ordinary care.

Colonial Money is equally explicit as to what may be done:—

I have never thought 10 maunds per acre as at all impossible. It has already, I know been done on parts of gardens in India, but on the whole of a large garden, never yet. I hope to accomplish it on the gardens I work, as they are in a favourable tea locality but they are young yet. This, merely to show that to my mind there is nothing improbable in ten maunds to the acre, off even one thousand acres.

And now to close these extracts, taken from the "Tea Cyclopædia," we may give one which, to a

certain extent, shows how these large returns per acre are to be got by means of "garden" cultivation and liberal manuring :—

Certainly, hoeing is not practicable in thickly-planted lands. If Dash will take the trouble to use the *English fork*, not the kodalee fork, he will be able to dig deep and well. There is trouble always at first, but the garden year by year comes beautifully into order. By thick planting, judicious pruning and plucking, and digging, two of my gardens of 35 and 25 acres respectively, gave in 1875, 11 maunds of tea per acre. Cow-dung is very good, but Dash says that he cannot get enough of it. Oil-cake, he says has got into disrepute. Most likely it was not the fault of the oil-cake, or the tea tree, but that of the manager, who because he had manured, thought that he could pluck everything off. No manure will enable the tree to stand *unmerciless plucking*. The same manure may not always give a good result. Manuring should be changed, or a compost made. Trees manured with cow-dung this year should have oil-cake next, vegetable mould next, bone dust and so on ; simply to change the position of the soil over the roots, and to bring fresh food for the plants ; for they are like an oyster—they cannot go beyond a certain distance in search of food ; it must be brought to them. This is the reason for a light hoeing or forking. Deep digging, I believe, is necessary twice a year—once in April, or May, and again at the break-up of the rains—September and October ; to prevent the earth caking round the roots of the tree in the cold weather and so preventing them from acting.

In connection with a coffee and cinchona plantation, a "garden," say 30 to 50 acres, of tea, liberally treated and well looked after, ought to pay well, if the requisite skilled labour and close supervision in manufacturing could be afforded. Otherwise the only chance for the owners of such gardens and of patches of tea generally would be the establishment of a central factory, at which the newly-plucked leaf could be disposed of. The Kandaloya Company might, in this way do a good turn to neighbouring planters with small areas of tea, and who cannot afford machinery on their own account. At any rate, it will be interesting to watch the continuous yield of leaf in our Western districts and to compare it, from time to time, with the results obtained in India.

THE VOYAGE OF THE GREAT AND SMALL EAST INDIAN BEES TO CYPRUS :

LETTER FROM MR. BENTON.

The following are extracts from a letter received by last mail from Mr. Benton :—

Larnaca, Island of Cyprus, Aug. 5th, 1881.

John Ferguson, Esq.

Dear Sir,—After my letter to you mailed at Aden, I was again taken quite ill with fever. While on the Red Sea our steamer passed very suddenly from an extremely hot atmosphere into currents of cold air, which seemed to stream southward from the Mediterranean. This change of temperature, which occurred within a few hours' time, not only affected greatly those who were ailing, but made many who were quite well suffer considerably. In my weak condition you can easily imagine that it was trying for me. Mrs. Benton had written to Aden to have me get off at Suez and come by way of Cairo and Alexandria, instead of Port Said, Jaffa and Beyrout, in order that I might avoid going into quarantine upon my arrival here from the Syrian coast, three days in quarantine being required of all passengers arriving from Syria. But at Suez I was too weak and sick to land, and so came on to Port Said, and found a French steamer just about to leave for Beyrout. Upon my arrival in this last-mentioned place the large bees, *Apis dorsata* (bambara), were still alive, having withstood their long hot journey wonderfully well, showing great tenacity of life, so great as to surprise me. The box of little ones *Apis florea* (dandawal messo) was also in good order I had fed both kinds with sugar during the journey. In Beyrout both were permitted to fly. The large bees, which I call the Great East Indian bees, seemed restless even when the air was cool toward night, and many came out and died, while the small ones were more prudent and only flew when the air was quite warm. As a result the former dwindled away, while the latter were still in good order when I arrived in Cyprus two weeks later, after having waited that long for an Austrian Lloyd's steamer, the English steamer having been discontinued temporarily on account of quarantine. But an accident happened, soon after my arrival here, to the queen of my little bees and now they are no more. However, the work which I did in ascertaining something of the bees of India and what could be done with them practically is appreciated by European and American apiarists, as many letters I have received, as well as the Bee journals from various countries, bear testimony. The matter is not likely to rest where it now is, since in the interest of theoretical Bee-culture, even in case no practical result can be directly attained, it is desirable to obtain some living colonies of *Apis dorsata*. If I do not return to Ceylon I shall at least make an effort to secure additional colonies of these *bambaras*. It is thought by many that a cross between these bees and our ordinary honey-bees, *Apis mellifica*, may produce favourable results. The Germans more particularly have a great deal to say about this—are, in fact theorizing a good deal over it. But for my part I do not have much faith that a cross can be produced. It seems to me, that, though the large bees and our bees belong to the same genus, the species are too widely distinct to be likely to cross. I have not yet given expression to this opinion, but thought I would wait a little until one or two wiseacres of Germany who have never seen a living specimen of these bees, and I do not believe a dead one either, have had their say. When their important views have been made known, I shall claim the right to a few words in addition to what has already appeared from my pen, which at present consists of a few letters dashed off while on the steamer coming this way. I was intending to do some real solid work in the way of writing during the latter part of my journey, instead of lying in bed with fever, or on an easy chair, so weak I could scarcely move. It was quite a disappointment to me, as well as to many who were awaiting with great interest some information of the strange new bees. I have been, and am now very busy here among my Cyprian bees, getting off shipments to Europe and America, but if I get time I will write something more for you and try also to send you a translation from the German, which, I think, would give a fair estimate of the importance attached by prominent German bee-keepers to the work of getting *Apis dorsata*. The *American Bee Journal* of June 8th, a weekly magazine devoted exclusively to bee-culture, said in its editorial column:—"We have just learned that Mr. Frank Benton has secured four colonies of *Apis dorsata* as a result of his researches in the East Indies. He has had a very difficult and dangerous task to perform, and but for his indefatigable energy and indomitable courage he could never have accomplished it. Bee-keepers throughout the world owe him a debt of gratitude, and will not we hope, be slow to repay it."

It was very funny, after an absence of nearly six months, to be merely permitted, during three days' time, to converse with my wife, who had been awaiting somewhat impatiently my delayed arrival! But such was the quarantine regulation.

[Referring to the people of Cyprus, and some women lace-workers, he says:—In the Greek Church they have an immense number of saints, and their days must all be observed. One woman has just told me that next Monday will be Saint Somebody-with-a-long-name's day, and if she should work on the lace or sew, she would lose her eyesight.]

I shall write to Mudaliyar Jayetilleke very soon. I hope his bees, as well as the others I left in Ceylon, are thriving, and I await with much interest later developments in this direction.

As yet I have no news from those at the Government Agricultural School in Java, but hope to hear soon. With kind regards to all, I am, very truly yours,

Frank Benton.

STORM OF HAIL, RAIN AND WIND IN HAPUTALE.

Under the Haputale Pass, Sunday, 4th September 1881, 4,300 elevation above sea level.—It has been with some difficulty I have at last found a dry spot in the bungalow to put pen to paper, to advise you of the grandeur of the storm of wind, rain and hail which we have just had. Between 1 and 2 p. m. we were aroused to the fact that there was some terrific force approaching from the Pass by the roar of wind and water: so strong was it that coolies on the estate roads had to hide wherever the least shelter of rock or bank was at hand. To have tried to make way, either with or against such a storm, would have been dangerous. The hail was blown with such force that the bungalow verandah was literally strewed with what looked like Ceylon white sapphires, each from a quarter to half an inch in size, and had the same appearance as if a tamby had been scattering his cut crystals about to the delight of the children, but they could not understand why they melted in their hands. The hailstorm lasted for some eight or ten minutes only. The rain gradually softened down and fell moderately; and in an hour from the time it commenced all was quiet; but the thunder is still audible from the Kandapola direction. This one hour's rainfall will, it is to be hoped, help towards seuding out a large blossom, as hitherto we have not had the rain to complain of your respected "Haputale Ella" correspondent wrote about. It is the opinion of many here that had we had more rain—not light showers—last month our spring crop prospects would be brighter than they are. However, there is still time for a very good blossom, if the two monsoons don't run into each other now.

COFFEE LEAF DISEASE.

It is a subject of remark that wind-blown patches of coffee, and even whole estates exposed to the force of the south-west monsoon, seem to ripen their crop, after the usual August attack of leaf disease, better than the more sheltered areas. How is this? One explanation offered is that, after being stripped of their leaves during the burst of the monsoon in May and June, such wind-blown trees get a young flush which is then in a condition to resist the periodical attack of the fungus, and so the trees are nourished at the most critical period in reference to the ripening of crop. In the Kandy districts, August is now regarded as the month in which the worst attack of *Hemileia vastatrix* is annually developed. In the case of well-sheltered coffee, when a bad attack is experienced the leaves nearly all drop off, and, of course, there is no time to make up for the loss during that crop season. So much has this view of the case impressed some planters, that they are determined to try the effect of a partial stripping of leafage during April and May next year, in order to induce a young flush at the critical period for disease. The planting community are now anxious to see the report on Mr. Marshall Ward's further investigations, which is about due. It has been stated that the only discovery of practical importance made is the means of determining with more or less precision, some time beforehand, the date at which an attack of the pest may be expected, but then, unless the diseased leaves can be collected and burned, this is not likely to aid much in stopping the prevalence of the disease.

So far, sulphur and lime is still the favourite mixture for application, and with reference to the statement made by several experimentalists that the application of this mixture, under Mr. Morris's instructions, positively injured the coffee bushes, we find a possible explanation of this injury in a similar experience in the treatment of the vine. Here is a "Horticultural Note" on the subject from the latest number of the *Australasian*:—

Experience often lends a useful warning to gardeners. Good and useful as is the lime and sulphur solution as a dressing for peach trees and vines affected with mildew or aphis, it appears that it should not be employed without taking reasonable precautions against its getting to the feeding roots. The roots of trees in the open ground would, usually, be out of reach, of harm, but those in pots must always be in danger; that, at least, is to be inferred from the following English extract:—"It is my usual practice to fruit what vines I have that remain unsold, and this year I had left a fine batch of Alnwick seedling. Having some of that valuable mixture for peach trees—Scotch snuff sulphur vivum, and quicklime in equal parts—with it I painted some of the young canes, planted them, and shortly after commenced syringing. This washed the mixture down to the roots, and instead of the vines growing they died, and on pulling them up the roots were all black and dead. The same fate undoubtedly has followed the application of other mixtures when reasonable precaution has not been taken."

Sulphur, it will be remembered, has been found a specific against the *oïdium* fungus by French vignerons, and now it seems a check has been placed on the ravages of the still more terrible enemy, the insect *phylloxera*, and a great industry saved from ruin. We read as follows:—

In *The Australasian* of January, 1875, we gave the substance of an article in *Revue der Deux Mondes* on the "Phylloxera Vastatrix," written by M. Planchon. In this article the writer gave a full and graphic description of the scourge that was rapidly destroying the French vineyards, together with some of the remedies that had been tried. In the *Revue* of June last there is an article on "The American Vine in France," from the pen of Mdme. la Duchesse de Fitz-James, a vineyard proprietress in the Gard. The writer points out in her opening remarks that the area under vines in France had increased from 1,046,000 hectares in 1788 to 2,500,000 hectares in 1868, when the further extension of viticulture was stopped by the appearance of the phylloxera vastat-

rix bringing ruin to thousands of vignerons and others engaged in the wine trade. At this period the vine alone produced one-fourth of the total agricultural revenue of France, and that without occupying more than one-seventh of the poorest of its cultivable soil. Madame de Fitz James recounts her experience in attempting to deal with the phylloxera by means of insecticides, and after spending 15,000 francs with but little satisfaction, she, finding that the remedy, to be even moderately successful would require to be applied three or four times a year, resolved to transform her French vines into American phylloxera-resisting vines by grafting. The methods by which this transformation are effected are twofold. 1st. Grafting the American vine on the already attacked French vine. 2nd. Procuring American rooted vines and grafting the French vines on them. The first plan is the more economical, but the vigneron has to wait some time before he receives any return for his outlay and labour. By the second method a larger capital is required, but a much quicker return is secured. The operation of graftiug, it appears, lastens the fructification of the vine, so that a very much quicker return is received from the grafted vines than from those planted in the ordinary manner. In grafting, the scion is placed very low down on the stock and well moulded up, while all suckers from the root are carefully removed in order that they may not absorb the sap to the detriment of the graft. The American graft soon takes root, and in a short time is able to support itself, while the old French roots gradually succumb to the attacks of the phylloxera. In this manner immense areas of French vineyards are being transformed from French vines into American phylloxera-resisting vines. Care must be taken to select the kinds best suited to the climate, and which have proved proof against the attacks of the phylloxera. The energy and skill of the French vignerons have overcome the utter ruin that threatened them so lately. They have sought and obtained a remedy for the scourge that was ruining their vineyards in the source of the evil—the American vine.

From whence is the remedy for the Ceylon scourge to be obtained? By degrees no doubt the widely-extended cultivation of new products, more especially of cinchona, must check the rapid dissemination and virulence of the coffee fungus, and although the change in the life-phases of the latter, so eagerly anticipated, is long of coming, we suppose it is still possible that a prolonged interval of dormancy may be experienced. There are many features in common between "Rust on Wheat" and the fungus on the Coffee leaf, and we find in recent numbers of *The Field* some curious and interesting information in respect of the former:—

THE BERBERRY AND RUST IN WHEAT.

TO THE EDITOR OF THE "FIELD."

Sir,—I have for some years inhabited an old chateau in Brittany. In the garden attached to the house is a berberry tree. My neighbours (French peasants) want me to cut it down, as they say it is the cause of smut in their wheat, which is seriously affected by that disease this year. Have any of your readers ever heard of this superstition—as I believe it to be—and is it one peculiar to Brittany?—Banshee. [Professor Buckman, writing in Loudley's "Treasury of Botany," says, in an article on the berberry: "Another popular notion with respect to this shrub is that it is the cause of blight, or rust, in corn. This has arisen from the circumstance that the berberry is itself frequently attacked by a species of epiphyte (the Æcidium berberidis), in which the leaves appear to be covered with spots of a brightish red colour; whilst wheat is subject to another epiphyte (the Uredo rubigo, or rust). There has, however, been no connection traced between these two, and there can be no doubt that the peculiarity of colour is at the bottom of both the popular errors now described; at all events, with regard to the last, we can point to fields and districts where rust is common on wheat, and yet there is no berberry near, while in other spots close under a berberry hedge this disease of wheat has scarcely been heard of."—Ed.]

Sir,—Will you allow me to make a few remarks on this subject, respecting which you had a note in your last issue. It is quite true that the berberry was formerly regarded as being concerned in the propagation of rust in wheat, and that after a time this opinion was abandoned. But within recent years the theory has not only been revived, but practically demonstrated. Prof. Oliver remarks: "There is a prejudice amongst farmers that the berberry causes wheat grown near it to become blighted; but the fungus which attacks the berberry has been, until recently, regarded as belonging to a genus different from that which infests wheat, and the prejudice consequently was supposed to be without any reasonable foundation. Observations, however, by Oersted and De Bary prove, notwithstanding the differences which have been regarded as generic between the two fungi, that they are merely alternating generations of one and the same species."

I may add that such unimpeachable authorities as Sachs and Prantl speak most unhesitatingly on this point, the latter observing, with reference to Puccinia graminis (the rust of wheat), that the uredospores (formerly called Uredo linearis) form red streaks on the leaves and haulms of cereals and grasses. In the autumn other spores (teleuto-spores) appear in similar streaks, but black; these germinate in the following spring exclusively on the leaves of berberry, where the æcidia appear in red swollen patches (formerly known as Æcidium berberidis); the æcidiospores are conveyed to grasses, and there give rise to a mycelium with uredospores—the rust again, in fact; and so the cycle is completed. Rust of wheat is, therefore, one of those organisms which require an alteration of host plants to enable them to go through the complete cycle of their life-history, and to this phenomenon De Bary has given the name of heteræcism. Familiar parall l examples amongst animals are afforded by the liver-fluke, which in one part of its life-history inhabits the body of a mollusc, and during another part it takes up its quarters in the internal organs of certain herbivorous animals as sheep, rabbits, and cattle; certain internal parasites of the dog again carry on a part of their life in the intestines of the human subject. Such plant and animal parasites then require an alternation of hosts, and if either host fail, the parasites will probably perish.

As fungal spores are excessively minute, they are easily transported by the wind, and a wheat field may get rusted very many miles from the neighbourhood of growing berberry plants. And even should the berberry be utterly exterminated it would be rash to infer that rust would also disappear, for fungal parasites have a wonderful power of adapting themselves to surrounding conditions, and a new alternating host plant might gradually be brought into use. Thus, even now certain grasses get rusted by species of Puccinia, which find alternating hosts in one case in living plants, in other cases in the buckthorn of our hedgerows. That a wet season is not necessary to the abundant production of rust is well shown by the character of the straw this summer, which, in this locality at all events, is badly rusted.

W. Fream.

College of Agriculture, Downton, Aug. 1.

Meantime we must look forward to Mr. Ward's Report in the hope of further light being thrown on the nature and working of the Ceylon pest. Is there an alternating hostplant in the case of *hemileia vastatrix*?

CHAMPION BLUE GUM.

"I have a blue gum tree on the road through Carlabeck to Nuwara Eliya measuring at least 35 feet in height, and by measurement 60 inches in girth at the ground, and 45 at about 6 feet high. This cannot be more than 5½ years old from seed, though it may be less."—*Cor.*

CEYLON LIBERIAN COFFEE IN AMERICA.

Messrs. Aitken, Spence & Co. have received a telegram from New York Sept. 8th advising the sale of a small shipment of Liberian coffee from Kalutara at 18 cents per lb., equal to 84s per cwt. This was, we understand, valued at 93s before the fall in coffee took place.

ABOLITION OF TOBACCO MONOPOLY AND FORCED LABOUR IN THE PHILIPPINES.

The cost of telegraphing to Manila the royal decree abolishing the tobacco monopoly is said to have amounted to 17,000 reals. Since its promulgation the Manila papers have published the preamble to the decree,—the statement of objects and reasons appended to it as laid before the King of Spain by the Minister for the Colonies, in which the injustice of the monopoly and benefits of its abolition are thus set forth :—

"*Sire.*—Extreme necessity in a country without taxable wealth, and without sufficient revenue to meet expenditure, obliged Don Jose de Basco F Vargas, the then Governor of the Philippines, to establish in 1781 the Government tobacco monopoly in those islands, the resulting disturbances among the natives having had to be put down by force. Hence the present system has been in being for a century. Its results show that though necessary at first, it has now become indefensible from any stand-point. Economically the monopoly has kept the productiveness of the Philippines within narrow limits, and politically, the means employed to maintain it are inadmissible. To exact labour from the native : to oblige him to grow a fixed number of plants ; to compel him under penalties not to neglect for a moment careful attention in their cultivation, and, when the time comes for him to gather the product of his labour, to send Government officers down to reap the fruit of his toil by handing over, in payment or as the price, a sum which seldom reaches 20 per cent of the real value of the crop in the market—all this is injustice, which, though it has been in being for a long time, cannot be continued without great risks. Even if there be no other reasons for it, these are sufficient to decree freedom to cultivate tobacco, and the abolition, of its monopoly, whatever might be the resulting deficit in the estimates.

"There need be no fear that the mode of life hitherto followed by the native will foster in him habits of laziness on obtaining freedom to labour for himself. Setting aside the circumstance that the history of mankind in many proven instances, is against such an apprehension facts in the Philippines are more telling than conjectures. Free cultivation, such as that of hemp, coffee and above all, that of sugar cane, the toilsome nature of which has become proverbial, is now in a surprisingly flourishing condition. As to tobacco cultivation, it has been noticed that in those provinces where the same is carried on with the fewest restrictions, both population and productiveness have increased visibly, but in Cagayan and Isabela for instance, more fertile and rich than the other provinces and completely under the monopoly, not only does tobacco growing fall off but the country is becoming depopulated so that the authorities in the islands have had to devise means and measures to re-people it. Hence in thus doing justice neither expediency is sacrified nor is the future imperilled. Morally, politically, and economically considered, tobacco cultivation freed from monopoly may be left to develope and shape its course stimulated by anticipated gain and justifiable hopes from honest and well directed enterprise. Its consequences, sire, in the fruitful and thinly peopled islands of the Philippines cannot fail to be both immediate and satisfactory. At least such has been the case with a similar measure in Cuba. Free labour, landowning without serfdom, industry without monopoly, and production without restrictions will exercise novel and decisive influence, and combined with patriotism they may lay the foundation for our colonial regeneration. The current of colonisation and labour now throughout the world, and capital unemployed either from doubt or apprehensions will flow into the extensive and almost uncultivated countries situated between the Suez Canal and the future Panama Canal, and lying in the track inevitably to be followed in circumnavigating the world. There, whatever may be the future in store for our native land, a country and a race of people discovered and civilised by us will always proclaim to the world that, in the beneficent reign of your Majesty, vigorous measures were spontaneously taken for their future prosperity and welfare. Relying on these convictions and hopes, the Minister signing this, in agreement with the Council of Ministers, has the honour to submit for your Majesty's approval the subjoined draft decree.—Madrid, 25 June, 1881.

(Sd.) FERNANDO DE LEON Y CASTILLO."

There is every prospect of the intended Spanish Colonial Exhibition being held in Madrid in 1882. No less than six plans for the proposed Exhibition building have been sent into the Colonial office there.

The *Comercio* in noticing the conveyance of emigrants for the Colony in new Ireland by the Marquis de Campo's steamers from Barcelona to Singapore, states that probably a steamer was about to leave Manila for Port Breton with supplies.—*Straits Times.*

THE WEST INDIES.—Jamaica advices are to the 9th July. Five men and three women had been struck by lightning in a pasture opposite Stanton Estate, in Morant Bay, of whom two men and a woman were killed, and three others, seriously injured, were taken to the hospital. The weather at Barbados continued favourable for the growth of the young canes and other crops. The *West Indian* of the 8th July, says :—"The change of weather has brought sickness with it, several cases of fever having occurred, which have created quite a yellow fever panic, although only a few of the cases were of that type, most of them being attributable to the setting in of the rainy season, to exposure to wet or chills, bringing on colds accompanied with fever and dysentery." The weather at Demerara had been in every respect favourable during the fortnight, and reports from all parts were most encouraging as to the crop now on the ground. Little doubt was entertained that if seasonable showers continued until the 1st of August the crop from the 1st of July this year to the 30th of June, 1882, would be the heaviest ever reaped. Produce was in good demand at remunerative prices. A smart shock of earthquake was felt in Grenada on the 4th inst.—*London Times.*

Correspondence.

To the Editor of the Ceylon Observer.

LIBERIAN COFFEE CULTURE.

Dear Sir.—Have any of your readers tried Liberian coffee in land where the ordinary kind had gone out through "grub," but where the soil was still good, and climate and elevation suitable? And can they tell us how they have succeeded so far?

I have never heard of grub in connection with the Liberian species; and the flavour of the rootlets may possibly be too strong for this delicate feeder; or may be the tree itself is stroug euough to disregard what, in the case of Arabica, is more fatal for them.

LEAF DISEASE.

TEA CULTIVATION IN CEYLON AND INDIA.

Deyanewatte, Passara, 1st Sept. 1881.

Dear Sir,—I notice India carried off 34 silver medals for her teas, and Ceylon 11 (eleven) silver medals for teas. Now, considering that, since the writer (as Special Correspondent for the *Ceylon Observer*) reported progress in Assam in 1876, the exports of Indian teas have increased from 17,000,000 to 50,000,000 of lb., and the quantity of tea made hitherto in Ceylon is nothing in proportion to that of India (judging from the number of medals awarded to our tea manufacturers), *Ceylon has certainly beaten India in quality.* This circumstance should greatly encourage those engaged in the tea enterprise in Ceylon to push forward the industry: *considerable credit* being due to the Ceylon Commissioner.—I remain, dear sir, yours faithfully, HENRY COTTAM.

CURING CINCHONA BARK:—COLOMBO CHARGES.

Haldummulla, 2nd Sept. 1881.

Sir,—As prominence is given to the charge to be made for curing cinchona bark, in the case Corbet *v.* Ceylon Co., I will ask why planters are willing, or in this case are made, to pay so exorbitant a charge? Five cents a lb. is 5 per cent on the rupee we so vainly hope to realize for cinchona bark. The curing charge on coffee is 3½ to 4½ per cent of the value, but for this many operations are wanted and expense entailed. What expense does curing cinchona bark entail? A drying on the barbacue? Not always that. I send down a bag of 100 lb. cinchona bark, and I am to pay R5 (!) for 25 minutes' drying on a barbacue!!

The Chamber of Commerce had better arrange a rate that will pay its members and not be so frightful an extortion. Two cents would be ample, and this on 50 bags of cinchona would represent R100.

Let the sale charge be so much per cent on the value realized—say 2½ per cent to cover any fancied curing. Fancy, all the rubbish from an estate being ordered down, realizes for it a very good price 00·25

Curing charges ... ... 00·05

R00·20

Cost of barking, &c. 20 cents. Weeding; management; interest on money; items which duly appear at the year's end. Why are there so few agents?

TWO-AND-HALF PER CENT.

CINCHONA "STUMPS" FOR INDIA.—RAILWAY CHARGES ON CINCHONA PLANTS: A HINT TO THE TRAFFIC MANAGER.

2nd September 1881.

Dear Sir,—What do you think of cinchona "stumps" lately sent from here to India, and being received in good order!

I sent 2,000 Calisaya "stumps" last month to a gentleman in India, and he writes:—"They arrived in beautiful order. Nearly all of them were throwing out fresh shoots." The plants were stumped in the nursery and then dipped in cowdung water and packed in a rough box with a little moss and earth: a few holes were bored in the top and sides of the box.

Why do the railway authorities charge so much for the carriage of cinchona plants? They make people pay in advance for the carriage of the plants, and therefore I think they ought to charge only the rates given under rule No. 34 (I take this from the Directory), viz. 35 cents for every 100 lb, instead of which they charge them under No. 33, at the rate of 55 cents for every 100 lb. Look at the absurdity of the thing! I sent five coolies with plants to be forwarded from Gampola to Nawalapitiya on Monday last, and the charge for the five cooly loads was R1·72! I could have sent the plants up as cheaply by coolies; of course I saved time in sending the plants by rail.

I think cinchona plants ought to be charged under rule 34: else why make prepayment compulsory?—Yours faithfully, R.

YIELD OF TEA IN CEYLON:—4¾ MAUNDS PER ACRE OBTAINED IN AMBEGAMUWA.

Gallebodde, 2nd September 1881.

Dear Sir,—I have only to-day noticed the article in your issue of the 25th ultimo, on the probable yield per acre of tea in Ceylon, as having special reference to the Kandaloya Tea and Cinchona Company about to be started. You allow it does not seem too much in Dolosbage and Yakdessa to count on each acre giving five maunds of dry tea, but you seem to think that an estimate to this amount may possibly be too sanguine, and that 300 lb. or 3¾ maunds per acre is a safer figure on which to base calculations. It may, therefore, be of interest to you and such of your readers as take any thought of the prospects of tea in this island, to know that there was made on this estate for last season, *i. e.*, the 12 months ending 30th June 1881, an average of 380 lb. or 4¾ maunds of tea from each acre. This I can assure you was done without in any way over-plucking the bushes, and I may add that in the current season I expect to considerably exceed this outturn. I think I have seen it stated that on a few of the tea gardens in India, enjoying no doubt exceptional advantages with regard to soil and climate, the yield has reached to even 10 maunds per acre. Though perhaps we can scarcely look to such an outturn in Ceylon, I think it will be found that where tea is planted in virgin soil at a *medium elevation* with a sufficient rainfall an annual average yield of 5 maunds to the acre is not by any means more than may be reasonably looked for. The tea on this estate, of which I have given you the statistics above, was planted in July 1878 on forest land, so that it cannot yet be considered in full bearing; and I think that one cause of its successful yield may be attributed to the fact that in the commencement no expense was spared in importing the best seed procurable from India.—Yours faithfully, J. ROYDON HUGHES.

CURING CINCHONA BARK:—COLOMBO CHARGES.

Colombo, Sept. 7th, 1881.

Dear Sir,—Replying to the letter of "Two-and-Half Per Cent" in yesterday's issue of the *Observer* I would point out that the 5 cents per lb. does not only include "curing," but transport from railway to mills, fire insurance, packing, baling, cases, shipping, and all other minor expenses incidental to the careful preparation and shipment of cinchona.

Parcels are sometimes sent to Colombo, not only in a very damp state, but very much mixed, and it is part of the owner's business to divide each quality carefully, so that it may realize its full value, and not suffer in price for the want of proper attention this side.

"The rubbish from an estate" can hardly be expected to pay cost of barking, weeding, and general management, as your correspondent would have it do; and if it realizes 25 cents per lb. all round he ought not to complain.

Messrs. Baker & Hall give their *personal* attention to all produce sent to their mills, and it is only reasonable to suppose their charges are less than those of the other leading Colombo firms who applied for the Receivership of the Corbet estates, otherwise they would not have secured the appointment.—Yours truly, SHIPPER.

Experimental Stations.—Travancore planters are setting their Ceylon brethren a most commendable example in their determination to establish a couple of experimental stations according to the proposal of Mr. Macdonald Cameron. The Kandy Association ought to take to itself shame that its little neighbour "across the ferry" should be first in this most desirable course of procedure.

Progress in Perak.—Mr. Low, Resident at Perak, is good enough to inform us:—"I have just gathered 16 pods of ripe seeds of the *Hevea Braziliensis*, two of which I have sent to Mr. J. A. Swettenham in Colombo. The plants were put out in Nov. 1878 and were then 3 inches high." He adds in reference to the "Tropical Agriculturist":—"It is a very handy record of the valuable information for which the *Observer* is so prominent."

Rubber in Bengal.—In the annual report of the Royal Botanical Gardens, Calcutta, for 1880-1881, we have the following information regarding the introduction of rubber:—"Of the economic plants, the *Ceara* rubber continues to grow vigorously and to give promise of success. The *Pará* rubber and the Madagascar rubber have entirely failed. The other exotic rubbers are very large trees or climbers, and though, as Dr. King states, the collection of rubber from them in their native forests when they have grown to maturity may be profitable, the cost of planting and protection for several years, until they come to maturity, will probably prevent their cultivation in this country from becoming a success. Of the other economic plants, the mahogany and *guango* or rain-tree appear to be the only exotic trees which grow well in Bengal, and for which there is a demand."

African Rubber for India.—Some months ago it was stated in a London journal that the best results were anticipated from a small parcel of seeds of a new East African indiarubber plant which Dr. Kirk, of Zanzibar, had collected during a journey from Dar-es-Salaam and sent to India. "So successful has been the cultivation of South American rubber-bearing plants in India, that any efforts to increase the variety of trees producing this valuable material deserves recognition. Dr. Kirk says that the particular plant of which he procured the seeds occurs in great abundance along the road towards Nyassa. An important observation made by him is that the supply seems to be but little affected, except in the immediate neighbourhood of villages, by the reckless mode of tapping employed by the natives when collecting the material. Dr. Kirk adds that in many parts a native may still collect three pounds of rubber in a day. With careful cultivation and proper modes of collecting the produce, this plant ought to prove an invaluable addition to Indian commercial products." Has any one heard how the new seeds are succeeding in India?

Anchor-Brand Tea, Maskeliya, Bunyan Estate, 4th September.—Enclosed received from ——. You will see what his home relatives think of my "Anchor-Brand Tea":—"We have just enjoyed a cup of your excellent tea. It is *first rate* and I congratulate you on it; so different from what we usually meet with." Maskeliya will be to the fore again, only give us time. Crop beginning to ripen in patches. [Well done! The Pilgrim Pioneer turning out first-class tea at his time of life, is surely an encouraging proof of what Maskeliya and a great many more districts are yet to do with tea as well as cinchona.—Ed.]

Compressed Asphalte.—Although the value of bituminous asphalte for paving has long been recognized, it has always been felt that one of its defects is a want of density, while another is its slipperiness under the influence of slight moisture. To remedy the first of these defects heavy road rollers have been used, while for the second sharp sand or some other similar material has been introduced into the body of the bitumen. The most recently devised method of treating it in order to remove these drawbacks, and apparently the most successful, consists in combining limestone with the bitumen and moulding the compound under pressure. The limestone is crushed, heated, and mixed with the bitumen at a temperature of 252 dgs. Fahrenheit, the stone having a great affinity for the bitumen when heated. The combination is then pressed into rectangular blocks of convenient size in moulds under a pressure of about 50 tons. The blocks are then submitted to a cold-water bath until they are cold and ready for use. They then form a paving material of great density, and in which the angular points of the limestone are always being developed under traffic. A permanently rough surface is thus produced, which, combined with the cracks formed by the joints of the blocks, presents an excellent footbold for horses. A portion of the roadway in Queen Victoria-street, adjoining the Mansion-house station of the Metropolitan District Railway, has just been laid with this material, which has been in use for some time past in the United States with excellent results.—*Ibid.*

Cinchona on the Nilgiris.—Some months ago, we stated that Mr. Robert Cross had made a collection of some thirty specimens of cinchona bark from the various Government plantations on the Nilgiris, and had forwarded the same to the Madras Government, in view to their being sent home to be analysed. The samples were forwarded through the Secretary of State to Mr. J. E. Howard, and the results are reported in a communication, which we publish in another column. To the cinchona planter the results are of the highest significance, and deserve close and attentive study. The variations in the yield of the most important constituent of the Bark, quinine are such as to be unaccountable on any hard and fast rule applicable either to climate, soil, or condition of cropping. Subtle comparisons might be made and deductions drawn, but these must be more or less hypothetical and will hardly be profitable. A few general conclusions cannot fail to be interesting: these are that bark renewed under moss is the richest in quinine, that bark nearest the roots is richer than bark higher up the stem, and that there must be a limit to cropping to avoid exhaustion. We have on several occasions pointed out the error that the Madras Government was committing in cropping the enormous supplies of bark annually sent home. Mr. Cross alluded to this suicidal action, and he is now ably supported in his condemnation by the leading manufacturer and analyst at home. Mr. Howard suggests the appointment of a successor to Mr. Broughton as Government Quinologist, and we might add, the appointment of a trained Superintendent as a successor to the late Mr. McIvor, if it is the intention of the Government to retain the plantations.—*South of India Observer.*

THE CINCHONA ENTERPRISE IN CEYLON AND JAVA.

The Director of the Ceylon Botanic Gardens is generally credited with considerable faith in the future of Succirubra or Red Bark Cinchona which he has recommended planters to put out freely at suitable elevations. Apart from his position as Botanist, it must be remembered that Dr. Trimen is a high Pharmaceutical and Medical authority, and his opinion on the probable future demand for druggists' "bark," and on the many uses to which it may be turned, is worthy of careful attention. Certainly, Ceylon planters of the common red bark have had great encouragement in recent sales. On Portree estate, Dikoya, for instance, 4,000 trees of this species, which were coppiced, gave no less than 6 tons—13,440 lb.—of marketable bark, or at an average rate of 3⅜ lb. per tree, while the prices realized were most satisfactory, exceeding 4s and 5s per lb. for a considerable proportion of the bark. It has taken most people by surprise that our export of cinchona for the current season should have kept up so well. It was supposed that nearly every tree worth cropping had been stripped or coppiced in consequence of financial exigencies during 1879-80, and that there would be a great falling-off in exports during the succeeding season. But instead we have an excess, although, no doubt, a good deal is made up of prunings and immature bark from cankered trees. We cannot see how the million pounds of export can be exceeded during the coming season, although the large area planted in 1877-78 ought to begin to tell in 1883. It is not an easy task, however, to forecast the future of cinchona exports, and it is still more difficult to say what the state of the market and the probable range of prices will be; but our own inclination is to believe that prices will keep fairly well up for cinchona bark generally for the next six or seven years. Supplies from South America cannot be expected to increase: new uses for bark and its products are being multiplied; and the consumption of quinine and the alkaloids is steadily advancing in America and India, if not in Europe.

We append the translation of Mr. Moens' report on the Java Government cinchona enterprize for the 2nd quarter of this year. Though brief, it is not without interest and instruction. In the first place it will be observed that the Netherlands Consul in Bolivia (whose name has been given to one of the inferior Calisayas) is mindful of the interests of his Government in its great Eastern Dependency, in sending out large quantities of fresh seed of five different varieties of cinchona. British Consuls in Bolivia and Peru do not seem to take the same interest or to remember that they could benefit India and Ceylon in the same way that Mr. Schuhkraft does Java. But it is to the result of Mr. Moens' further analyses that chief attention will be given, and if there is one thing more than another to be learned from the present report, it is that to the proper cultivation of cinchona the skill and labour of an analytical chemist are even more necessary than are those of the planter. The extraordinary discrepancies between trees in the same field and even the same row shew us that nothing save analysis will suffice to guide in propagation and cultivation. A very good illustration of this fact is afforded by a recent experience in Dimbula, where, in connection with some flourishing hybrids, two or three gentlemen who have visited Java and studied under Mr. Moens, and who have since paid close attention to the subject, were asked to say, of varying types, which was the best. The result of analysis, however, proved that the trees they selected were decidedly inferior, while the one tree they pronounced *bad* yielded 6·77 of quinine! On the other hand Mr. Moens shews how his selection by eye corresponded, in several instances, with the result of analysis; but it is evident that the Java Director would not feel inclined to depend on outward appearance alone, even in the case of his own practised judgment. How much more necessary then is it for Ceylon planters to have the aid of analysis. In this connection Mr. Talbot's motion for the next meeting of the Planters' Association has a fresh interest. We fear that the Superintendent of Hakgala Gardens is already appointed, and that he is not a chemist; but, under a system of grants-in-aid of analysis, there is no reason why Government should not come to the rescue without placing any perceptible burden on the revenue. Indeed, if, as is rumoured, the Cryptogamist is to retire at the end of his three years' engagement on 31st December next, the Association might well urge that the salary so saved should be devoted to a Government analytical chemist for the encouragement of the cinchona enterprise. A good deal of valuable and profitable work could still be done at Hakgala, while attention to private demands would keep an able chemist very fully employed. It is strongly felt upcountry, it seems, that, to secure reliable work, a competent officer should give his sole attention to the one branch after the fashion of Mr. Moens in Java, and Mr. Gammie in Sikhim. Meantime we append the latest Java report, which should be carefully studied in connection with the table of analyses by our planting readers: one impression this table and previous returns of the same kind have left upon us is, that, while Ledgeriana is at its best under Mr. Moens' care, the inferior calisayas as well as crown and red barks do not succeed nearly so well in Java as they do in India and Ceylon. We beat Java in the commoner descriptions, and it remains to be seen whether, with due care, our Ledgerianas of the same age may not be found to be richer in "quinine," than those of which Mr. Moens is so justly proud.

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA FOR THE 2ND QUARTER 1881.

Although in May it seemed as if the dry monsoon were setting in, in June it began once more to rain almost daily. The plant growth was assisted by the warm moist weather, and the plants looked flourishing. During the second quarter 22,850 *C. Ledgeriana* and 58,900 *C. succirubra* were planted out. From the Netherlands consul at La Paz, Mr. Schuhkraft, large quantities of seed of five different varieties of cinchona were again received from Bolivia, which are already beginning to germinate well. The supply of labor was ample. To day laberers f3,405·60 was paid. Although the weather was not very favorable for drying the harvesting was carried on fairly well. Altogether about 70,000 Amst. lb. of bark have been gathered, of which 37,000 were sent to the Netherlands, 7,000 reserved for the use of the head of the local medical department, and 26,000 remain in the packing houses of the establishments. The dispatch was hindered during the last two months by the severe epidemic of fever prevailing in the Preanger Regencies: so many of the cart drivers were sick that there were scarcely enough persons obtainable to drive the carts. A commencement has been made

with the thinning out of the plantations of *C. Ledgeriana* descendants. The trees are, where necessary, stripped of their lowest branches and the whole dug out where they deviate entirely from the Ledgeriana type. As the time approaches nearer and nearer when these young Ledgeriana plants must contribute to the harvest a number of investigations have been begun. Some of the results already obtained are given in the statement B (33-40) appended hereto. The trees giving the analyses 38, 39, and 40, were selected by eye out of the same garden, and sorted into best, middling, and bad: they were all derived from the same parent tree. The bad have now been entirely uprooted; from the others the bark will be taken by partial stripping. In the same manner 36 and 37 were selected from one garden, and here also the yield of quinine corresponds to the valuation of the bark as judged by the exterior of the tree. In both cases the bark analyses came from ten trees of each sorting, and was obtained by cutting a small strip of bark from each tree. To obtain the barks used in analyses 33, 34, and 35, strips were cut from a row of trees of the same plantation, without previous sorting. In 33 and 34 the quinine yield is very satisfactory, but in the case of 35 it will be necessary to find out the bad tree and uproot it. Proceeding in this manner, gradually rooting out the inferior trees, the yield of these plantations will be larger and better. Analyses 1-9 are all connected with the renewing of succirubra bark: the first 6 by the cutting in shavings, the following three by partial stripping, according to McIvor's method. The new formed bark had in both cases undergone an analogous change. No. 10 is the analysis of a succirubra bark from Rungbee (British Sikkim), cut from a well developed 13 year tree. The low yield of cinchonidine and the large quantity of cinchonine are in correspondence with the composition of the British India quinetum prepared from this variety, in which also the cinchonine predominates. *C. Pitayensis* belongs to the tolerably good varieties of cinchona, but stands far behind *C. Ledgeriana*. During this quarter 24 plants of this variety have been raised from seed obtained from British India. Analyses 12 and 13 are of the variety which, under the name of *C. pubescens*, is greatly on the increase in British India. It is apparently a hybrid of *C. succirubra* with *C. officinalis*, and the yield of quinine does not correspond with the high expectations which were indulged in regarding this cinchona. In British Sikkim the cultivation of *C. officinalis* has been discontinued, as the climate was not considered favorable for it. The trees which still remain in the Government gardens moreover do not look healthy, but nevertheless the yield of alkaloid of the bark, cut from some of these trees, is exactly the same as that of the much healthier plants of this variety cultivated on the Nilgiris. The micrantha bark, from one of the trees raised from the first American seed and about 18 years old, had the composition which is known and customary for *C. micrantha*. In 1872 seed of Bolivian Calisaya was obtained from Mr. Schuhkraft, from which only 13 plants were obtained. These resemble *C. Ledgeriana* very much in exterior, but they have not yet blossomed. Of 3 of these trees an analysis was made, which on the whole was disappointing. The large quantity of cinchonidine in two of these plants is very remarkable. Analyses 23-29 are of barks of original Ledgerianas already analysed and serving as seedbearers, which were last year also utilized for the obtaining of grafts. As the knowledge of the exact quinine yield of these trees is of the highest importance, in order that they alone may ultimately serve for the propagation by grafts, a second analysis was considered necessary. On the whole the amount of quinine has increased little since the first analysis; in the case of one (No. 24), which formerly had but little cinchonidine, the quantity of that alkaloid had increased to a remarkable degree.

J. C. BERNELOT MOENS,
Director Govt. Cinchona Enterprize.

Bandong, 1st July 1881.

Statement A shows a total of 2,729,220 trees in the Government plantations at the end of June 1881, viz., in the nurseries 626,100 (320,100 Ledg., 230,000 suc., 76,000 of.), and in the open 2,103,120 (556,760 Ledg., 572,300 Calis. and Hass., 552,700 suc. and culop., 404,900 of., 16,200 lanc., 260 micr.). Of the Ledgerianas in the nurseries 10,105 are cuttings and grafts, and of those in the open 61,000 are ditto, besides about 6,500 original Ledgerianas.

CEYLON TEA AGENCIES IN BRITAIN.

(From an Aberdeen Correspondent.)

The *Weekly Observer*, received this week, contains a letter from Mr. W. T. Mackenzie, and contributions from other three pens, all on the subject of Ceylon tea. I am glad to see the subject is about to be met by the joint action of those interested. Mr. Mackenzie's letter is misleading, in particular his estimates. They may have a close relationship to his wishes, but are very wide of fact. Single instances of a hunt for Ceylon tea among grocers' shops in London resulting in finding only "inferior stuff at 8s. per lb." really affords no basis for conjecture as to the demand: nor does Mr. Mackenzie's statement "I know of many people who would drink Ceylon tea if they knew where to get it." Resisting the temptation to poke fun at Mr. Mackenzie, I will confine myself to letting the light of fact fall on his somewhat utopian fancies. Taking his last query first I would say: of Ceylon-connected families in Scotland, very nearly all know where to get the tea. For nearly a year, I have been advertized in the *Observer* as introducing Ceylon produce in the North, for the past three months by a very specific advertizement in the *Observer*, by circular, copy of which was sent to every one in Scotland who gets the *Weekly Observer*, by numerous advertisements in local papers. The following is a copy of one at present running in two local papers:—

Restricting Mr. Mackenzie's query to Scotland, I can answer him that not above a dozen Ceylon-connected families have as yet given me their custom for tea or coffee. In illustration of how unwilling folks are to break their connection with grocers, I had a Ceylon proprietor—one of the few who have got well out of coffee—tell me he liked Ceylon tea very well, but as his family got all their groceries from Mr. So and-so, he of course had to patronize him for tea. That I have some Ceylon folks as regular customers I gratefully acknowledge, and their number being so few, those who have *continued* to support me are deserving of mention. They are Mr. J. Hope Mackenzie, of Tarradale House; Mr. Charles Ritchie, late of Chrystler's Farm; Mrs. Walston Dykes (Hamilton); Miss Black (Buxburn); and Mrs. W. D. Gibbon: the last-mentioned lady having also kindly used her influence among her friends in my behalf. A certain well-known visiting agent now in Aberdeen told me he brought a lot of tea and distributed it among his friends. He received abundant thanks and great praise of the tea, but says he:—"My friends will drink it, like it, and praise it, as long as they get it for nothing, but they won't buy it. Some of them have told me it is done, and I have told them where they can get more of the same estate's tea, but not one of them has been for any." These are his words, not mine. It is obvious that special agencies for Ceylon produce alone will not do. The tea must find its way into the recognized channel—the grocers. At present grocers cannot get it. What is bought at the sales, I am informed by representatives of London tea houses, is resold as an Indian tea. Even supposing my efforts to create a demand in Aberdeen should result in affording me a living, still the experience in a town of over 100,000 inhabitants has been so remarkably slow as not to warrant the adoption of similar agencies. Mr. Mackenzie concludes his letter by saying "a Ceylon tea retail agency once started is bound to succeed." This has not been proved by the one I have kept open for ten months. Had it not been for my connection with the *Observer* and the kindness of Mr. John Ferguson—who in this matter, as in all others that concern the interests of planters, has greatly interested himself—I would have retired from the cause. After opening with a flourish of trumpets praising Ceylon tea, grocers who could

not get it would have rejoiced had I given up. Of course they would decry the thing they won't sell and set themselves still more stoutly against it. The error lies entirely in adopting special agency. By very extensively advertizing and free distribution of samples, a trade to support one agency in a town could be made, but the expense of advertizing would be capital thrown away, as to draw the trade out of the hands of grocers would cost what would be far out of proportion to ordinary advertizing results. Besides, if you do establish agencies whenever the tea comes to be taken up by grocers the agencies will collapse. In a former letter I gave my idea as to how Ceylon tea growers might do. I suggested blending of teas, putting up in small packets and placing it in the hands of those who will take it up, who have already a connection with consumers and who would not be dependent on the sale of the tea for a living. Care would have to be taken that the qualities at different prices be kept uniform, Not only is there difference in Ceylon teas from excellent all the way down to what will not drink alone, but single estates' tea varies a little. The defects of badly manufactured tea must be concealed by judicious blending with good tea. Now that so many estates are going in for tea there will be lots of 'prentice work—seeking purchasers. You cannot expect to come up to Loolecondera or Windsor Forest at once, and if 3rd and 4th class teas be retailed as Ceylon tea, they will damage the trade. At present grocers prefer to sell their own blends. Before you can get them to take it up and give a price for it, you *must create a demand*. The cheapest way of doing so is by getting bakers and confectioners to add it to their trade; their progress would be slow for a time, but they would not be hopelessly sinking money as agencies would. This would be a beginning throughout the country, and in time grocers would be glad to take to it. One other quotation from Mr. Mackenzie's letter. He says:—"Of course, the whole secret would be in advertizing, and this should be done not only at home but in the local papers here, with, at the foot of each advertizement, a note:—'Please cut this out and enclose it in your next home letter.' Say 100 only responded to this and each house used 2 lb. of tea a week, there are 10,000 lb. per annum disposed of at once." I am sure I am under the mark when I say not a family in a hundred uses 2 lb. of tea per week. The great majority require only ¼ lb. per week. Retail sales of over 1 lb. are so few as to be of no consideration in determining the size of packets. The quantities consumers will buy may be guessed from an order for bags I have in the printer's hands. They are ordered by weight, but multiplied by the number in 1 lb. The numbers are as follows:—120 bags 1 lb. size, 560 in ½ lb. size, and 2,160 in ¼ lb. size. Packet teas are not usually put up in less than 4 oz., but I sell 2 oz. nearly as often as 4 oz.

The main argument in favour of a Syndicate adopting packets, is that by doing so they get a better price, as packets are sold at a much smaller profit than loose tea. Should, however, a Syndicate discard that idea and seek agents—not special agencies—to sell from bulk, the possibility of unprincipled dealers offering other teas as the Syndicate's tea or as Ceylon tea may be prevented by each agent being furnished with a large show card, having a *notice*:—"Our teas can be had only from those furnished with this card."

Having sunk my money in the cause of Ceylon tea in Aberdeen, I shall expect the sole agency for the Syndicate's tea in this town. There is no doubt of ultimate popularity for Ceylon tea. Grocers will continue to believe in their blends and push such as they have the most profit on till a demand be created; and this must be brought about by those who have a connection with consumers. Special agencies are out of the way and are certain to disappoint their promoters, so very slow is the progress made. I will be happy to give proof in figures to any Ceylon gentleman who has interest in tea that nearly 10 months of a special agency has not been sufficient to reach a paying point. But for my *Observer* connection and the kindness of Mr. Ferguson,—that brought customers from England, led to calls and purchases by planters on leave, and brought me these few *constant* patrons already mentioned,—I certainly would have had to give up. My sales contiuue to increase slowly, and with them my hopes of ultimate success.

CHAMPION YOUNG GUM TREES.—It will be of interest to compare the growth of gum trees in Ceylon with that of Australia and New Zealand, as shewn in the following letter to the *Australasian*:—"D. J." writing from "Khull's Range," deems it worthy of public record that he grew a blue gum tree in four years from seed, which is now 18ft. high, and 13½in. in girth. Now as I happen to have several thousand of the same age (four years next September from seed), I went out and measured the largest, and found as follows:—Height, 35ft.; girth at butt, 31in. There is one 34in. in girth, but two years ago the top was broken off, and since then its strength has developed in the shape of corpulence. I have seven score of trees nearly approaching to the above in size, and all (about six thousand) look healthy. They were all transplanted from the seed bed, but this season I had intended, and am fortified by your remarks, to plant out seed where I mean the trees to grow. I planted out same year red gum, stringybark, ironbark, peppermiut, and swamp gum; but although these all thrive, they do not grow anything like the Eucalyptus globulus or blue gum; but incline more to be ornamental than useful. Without venturing to claim for my tree a championship amongst four years old, I, just for the sake of inviting comparison with other growers, throw down the gage for championship of the aforesaid tree. R. O. S.

Whakatane, Bay of Plenty, N. Z.

A NEW ENEMY OF THE CINCHONA TREE.—A Dimbula planter has brought us a specimen of a poochie found in the heart of a cinchona tree, where he had eaten a long passage for himself, the entrance being concealed by a mass of web and sawdust. This grub is evidently the larva of a moth belonging to the family *Hepialidae*. The following description of the habits of the larva of *Hepialus lignivorus*, taken from the "Naturalist's Library," vol. 37, page 107, agrees very much with the doings of the larva under notice:—"The larva forms a lodgement or chamber in the centre of a stem of a species of casuarina or the she-oak of the colony [Sierra Leone], and feeding upon the bark and sappy wood directly above the entrance, eating round the stem and carefully hiding its dilapidations by weaving fragments of wood and bark, which it gnaws off, in a strong web; forming at once a fortification and disguise of considerable bulk and thickness round the stem, under which in a winding cylindric passage, the larva constantly keeps its body while at work, alternately gnawing and weaving; but retires to the chamber in the stem to repose. Across the mouth of the chamber it spins a close web, and changes to a pupa in January, soon after which the concealing fabric, to form which the larva took so much pains, falls away. It remains in the pupa state about twenty-five days." We trust that these grubs will not show a general partiality for cinchonas in preference to casuarinas.

FROM RIO TO NORTHERN BRAZIL:

CEARA' AND ITS INDIA-RUBBER TREES.

RUBBER TREES AS WEEDS AMONG THE COTTON.

COFFEE IN NORTH BRAZIL.

We draw the attention of our planting readers to the following long and instructive letter from our correspondent, Mr. Scott Blacklaw. His visit to the Ceará rubber neighbourhood although not productive so far of much practical information as to the industry, is nevertheless very interesting for the glimpse it gives of life and progress in a comparatively little known and neglected part of the great South American Empire. "Neglected," we say, and yet how gladly would Ceylon exchange its lot, at least in one respect, with the province of Ceará, namely, in the matter of railway progress. There we find the planters of 100,000 acres of young coffee with the railway already within 25 miles of their plantations, while it will be ten miles nearer before the year is out! Mr. Scott Blacklaw is right in supposing that, with such facilities, the produce of the Ceará division of Brazil must henceforward be taken into account in estimating the coffee production of the world. As regards rubber, what is to hinder the same planters cultivating this "weed" *ad libitum*, will be a question naturally asked. Our reply may be that possibly the growth of Ceará rubber in Ceylon is greater than in its own habitat, at least the figures given by our correspondent would be deemed very poor for rubber trees of the same age here. Mr. Scott Blacklaw's arrangements for procuring fresh seed of various descriptions from North Brazil may turn out of special service to Ceylon hereafter. Meantime, here is his letter to which we have been referring :—

LISBON, 28th July 1881.

DEAR SIRS,—I am not sure, but I think my last to you was from Pernambuco, or somewhere near it. The journey from Rio de Janeiro, calling at Bahia, Maceio, and Araloas, had occupied some days. My usual luck of having a day on which no business could be done on shore accompanied me to Pernambuco, and on Sunday, the day we arrived, I did nothing but finish a few letters.

All the places I had hitherto called at, and even Pernambuco—being on the great highway that holiday-seekers pass along continually—have nothing about them that you and your readers do not already know. I got ashore early on Monday morning and I took a run through the city and suburbs in tramway cars. Tropical life is here seen to great advantage, and my old friends the jak and bread fruits take up their places among majestic palms and flowering shrubs and plants with variegated leaves form the surroundings of the beautiful villas in the suburbs through which the cars run. Some of the streets of the town are pretty, being in the business part paved with hard stone blocks, and side walks laid with broad flags. The curse of slavery exists here also, as one may see by the great swarms of negroes doing the rough work—and one may not that nearly all the negro women have the tatto-ed faces showing African birth and up-bringing.

The principal commerce here is sugar, cotton, and the produce of the cocoanut tree, also form important items in the lists of transport. Cacao has also a place, but coffee is sometimes with a balance on the side of import!

Here, at Pernambuco, I was almost dissuaded from proceeding further on my journey to the north of Brazil by the account I got of the Indian-rubber seed enterprize. Orders had been sent from here six months ago to Ceará, and Pará, for seeds of the rubber. "These orders were extensive, and must have all been supplied ere this" &c. &c. I was, however, doubtful of the latter, for the Ceara seeds ripen only in September and October, and unless ordered twelve months ago could not yet be supplied unless with old seeds, which would be unsafe to plant. My ticket in the coasting steamer was taken to Ceará, and to that place I would go.

Nothing amused me so much for a long time as to see, on nearing Pernambuco harbour, at daylight on Sunday morning (26th June) a boat came alongside, in a rough sea, and, on a rope being thrown to it, an old man, of over sixty years, catch hold of the rope, and climb the steamer's sides, right up to the hurricane deck, without the vessel slowing in the least. This was the pilot, and now on Monday evening (27th June) before I get on board, this same active man had his position on the bridge. In a few minutes we were off. Outside the harbour, the pilot, without the steamer slackening speed, slides down the rope, into his two-oared boat, and we soon enjoy the fresh Atlantic breeze.

We sail along the coast, and reach the mouth of the river Parahyba next morning (Tuesday, 28th June), and we have, before breakfast a beautiful sail up the river, to the town of Parahyba. As we are only to be here a few hours, no one goes ashore. We land some passengers engaged on railway construction. Even here there are railways. Land near the river is very flat, and should do well for sugar cultivation. Here and there, through the trees, a patch of cane could be seen near some rude hut, covered with cocoanut tree leaves, or "cajans" as I remember you call them.

At the mouth of the river is an old Dutch fort they tell me the Dutch, at one time, had all the northern coast of Brazil, but of such slender construction that the pressure of earth behind the walls is bringing the latter down. No guns are to be seen; so it appears to be abandoned. There seems to be a great extent of land here available for sugar cultivation; but the scarcity of labourers will make the extension of agriculture in any form impossible, unless under small farming.

The town of Natal, the capital of Rio Grande do Norte, was reached by 2 a.m. on Wednesday, 29th June. The entrance is dangerous. The ship did not go in, but sent a boat with the mails and passengers. The boat returning at 9 a. m., breakfast bell sounds, and paddles begin to move almost at the same time. We sail along the coast, which is dry and barren-looking, land lying flat, and white, down to the sea, with only here and there a red-looking precipice. At 2 p.m. we lose sight of land; have wind and current in our favour, and on Friday, 1st July, at 9 a. m., we cast anchor at Fortaleza, the capital of Ceara. We have been eleven days from Rio de Janeiro. Viewing from the sea the regularly-built town of Fortaleza and the beautiful flat stretching away for twenty or thirty miles to the foot of the hills; the many patches of corn and rice fields ready for harvest, showing a prospect of plenty for man and beast; the hills covered with virgin forest, through which tall granite rocks are peeping; and coffee, sugar, and cotton plantations showing themselves on the lower portions of them; one cannot help asking one-self on this bare land to which the heavens were shut for the three years 1877-78-79, which famine and its attendant miseries carried off 200,000 out of a population of 950,000 and 99 per cent of the cattle died?

Yes! Here is the town to which refugees from the interior flocked, and were laid in the cemetery at the rate of 1,000 a day. I have it, from one of our own countrymen, who had the paying for interments for one day in December 1878, in the absence of the Government official, that they exceeded that number.

Having been arranging my small things in the cabin, about the time the steamer stopped, I did not notice the arrival of a swarm of boatmen on rafts called *jangadas*. These rafts are formed of six round trees fastened together, with bolts, and treenails. They have masts, and sails, and a small platform raised eighteen or twenty inches above the level of the water, with a seat for two passengers and room for luggage. I was introduced to the hotelkeeper, who had come on board. He was shown my luggage, and he gave all in charge to a servant of his own. After a little delay we were allowed to leave; the hotelkeeper called on me to come on shore. The sea was rough. I had not seen any of these rafts cross the breakers, and ours was the first to leave. I did not like to show fear, so I jumped cautiously on board—and in two minutes we were ten yards from the ship; the sail was hoisted, and the strong breeze made the mast bend. I must say my feelings were not those of comfort and security. The mast formed a sort of back to my seat, and I clutched it. The hand-bag with all my valuables in it, and my umbrella. I found were quite encumbrances to me. The breeze freshened as we got near the breakers, but I noticed the end of a board sticking up in the middle of the raft, and on enquiry I found this was a long, broad board, arranged to slide up and down between two of the logs, more than four feet of its length being down in the sea, and the boatmen told me that, but for this board, the raft would upset. This explanation caused me to breathe more freely, and it came in good time, for we were already riding over the large waves which were breaking on the sand. The steadying board was pulled up, the sail was lowered, and the two boatmen jumped into the sea, breast-deep, almost at the same instant, and in a very short time the raft grounded. On the sands was a swarm of men who did not care for wetting their clothes. They soon came two and two with hands and arms arranged in form of a chair and carried the half-scared passenger safely to dry land—the latter quite unable to conceal his surprise that on such a rude craft, and in such a surf, he is landed without a wetting, not so much as a drop of water having reached even his boots.

Ceara has tramway cars also, and these run down to the seabeach. As I had nothing to do until the luggage came ashore, I agreed to walk to the hotel. The town is regularly laid out, and built with wide streets running at right angles, and in the populous parts there are large open squares which form market places. The streets are paved with granite blocks, and side walks are laid with thick flags of free stone. None of the houses have more than two stories. The hotel is owned by an Englishman, and he kindly gave me a nice airy room at the top of the house, from which I could see the sea, and a great part of the town.

I had received in Santos, and Rio de Janeiro, a few letters of introduction to several people in the different towns at which I was to call. On presenting one of these to the head of an English house in Ceará, I happened to meet a coffee planter, who was at one time partner in a large house in Fortoleza, and owner of some 26 coffee estates on the hills, some 90 or 100 miles from the seaport. I willingly accepted his kind invitation to accompany him up to his estates, and, as trains only run every two days, we arranged for Sunday, 3rd August, as the day we should go up to the hills of Baturité.

I was not sorry to have Saturday to collect information and pay visits.

Sunday, 3rd August, made its appearance with heavy rain, which continued up till an hour after daylight.

At 6·30 a. m. I was at the railway station, where I met my friend. The railway was opened only since the famine of 1877-78 and 1879.

It was made by the Government to find work for the people, who had flocked from the interior to the capital, during the time of famine. It is a metre gauge, and is solidly built. The stations are large permanent buildings and the rolling stock is all American. They have the Baldwin locomotives, and the long passenger carriages with passage through the centre of the train. The stations are very close to each other. About 25 or 30 miles from the capital, a railway branches off to the north, to a place called Maranguape, famous for good soil, and flourishing cotton and sugar plantations. This branch is not long: say 12 to 15 miles. I found my fellow-passengers very communicative and exceedingly kind. I got much information from them relative to the different tropical plants treated by the farmers of Ceará, and one Fazendeiro not only told me all about the rubber tree but showed me, on his own plantation close to the railway, the Manisoba (Ceará rubber tree) growing spontaneously in his cotton, and although it was not the season for picking the seeds he promised to collect a few and have them ready for me by my return on Tuesday Two days after, while waiting a few minutes at the station, this same gentleman showed me quite a forest of the rubber trees, on a small hill a quarter-of-a-mile off. Those I saw in the cotton fields were 12 to 15 feet high, and had stems 3 to 4 inches in diameter, a foot from the ground, and were only two years old. They had grown up as weeds on the cotton fields. They used to be cut down along with other jungle weeds, but bearing of the importance of cultivating them he left plants growing at distances of 25 to 30 feet apart. The old trees have a nice green appearance, but the young all look sickly, and their leaves have a yellow tinge with a great many black spots resembling those left by the *Cemiostoma caffeeitum* on coffee leaves.

All accounts agree as to the excessive hardiness of the tree, and the ease with which it can be propagated by cuttings. The people in Ceará say it grows exactly like mandioca. You throw a branch on the ground, cover it over with earth, and it will grow into a tree. This station, which is called Baburú, is the only place along the line of railway at which the rubber tree is to be seen.

From Bahú station, the railway begins to ascend. The trace runs along the face of the hills on an easy gradient. The cuttings at some places against the sides of the hills are deep, and some of the embankments very high. The train goes cautiously along the face of the hill, peeping in at every ravine as it passes, as if looking for an opening, till at last with a bound, through a cutting 30 metres deep, the ascent is won, the mountain range is cleared; and were it not that I was outside on the carriage platform all the time, I could almost have imagined myself in another country. We arrive on a wide stretching plateau of undulating ground, Indian corn and rice fields plentifully scattered over it. We have left the coast range of hills behind us. The level country stretches away to the south, and west, while to the north, are the high hills of the Serra de Couceição, and the Serra de Baturité, the town of Baturité lying nestling at their foot.

An hour's ride by rail, after crossing the "Serra," brings us to the village of Euuôa. Here the railway at present ends. It is 90 kilometres from Fortaleza. From this point a branch line is being made for 12, to 15 kilometres, to the town of Baturité, the largest town in the interior,—and the Government intend extending the main line in a southerly direction: Could funds admit of it, an extension of the railway

now being made from Parahyba westward, would be made to join this one going southward. Canôa at present is an important place making hay while the sun shines, which it will not do for long, for the branch railway from here to Baturité is to be finished by the 4th December, when it is expected the Emperor will open it, on his way to the Amazon. After that time Canôa will be left a quiet, sleepy village, which will open its eyes to the full, only every two days, at the sound of the Baldwin locomotive fog horn, for here in Ceará the railway trains do not run every day.

A sumptuous breakfast had been prepared for my friend and myself at the railway contractor's bungalow on the new track a mile from the village. We saddled at 2 p. m., passed through the town of Baturita about 3-30, and we commenced to climb the Serra shortly after. A few rapid streams have to be forded, for there seems a general absence of bridges. The roads are of varied gradients, some of them one in five on a long stretch, and when a sharp spur has to be crossed, it is modified to one in three. The *ascent* is nothing, but I look forward with uneasiness to my return (descending) journey. The coffee estates are at length reached, commencing about 1,800 feet above sea-level. The soil is a dark chocolate, lying amidst granite boulders, resembling the *gneiss* in Ceylon, but with a larger admixture of *mica*. The surface soil is not very deep, and the subsoil is hard, and *granitic crust*, or *laterite*, can be struck at three or four feet deep.

The coffee plantations resemble those of Ceylon, being planted along the sides of large ravines, and always on steep ground.

The cultivation is very primitive, indeed. The trees are planted at distances of five or six feet apart, and their height not over eight or nine feet, although allowed to grow up naturally without any pruning. The close planting must be the cause of their small size, for, beside an opening, such as at a road, or a stream, the trees are the size of those in St. Paulo, planted 11 feet apart.

Weeding is done only three times a year: once after picking in October and November; once in March, or April; and once before picking in June and July. Picking commences in July, just as the rains have ceased and they have dry weather, with occasional showers up till February, the year following. This is very advantageous for picking a large crop with few hands. I saw picking carried on on several estates. The labourers are all free-natives of the Province. Men, women and children work at coffee picking. The fruit is not first thrown to the ground, and then swept in a heap as in St. Paulo, but each picker carries a wide basket, tied round the waist, and the branches are all stripped clean. Ripe, half-ripe and green are all picked at once. What has already fallen is considered as lost, and so it is, for the weeds are lying rotting under the trees. It would be an improvement if they would weed oftener, and have the weeding that is done immediately before picking a light one; and sweep clean under the trees before coffee began to ripen and fall and so save not only what has fallen before, but also what the pickers drop during picking. *Curing* is also done in a very primitive way. No dispulping is done in the cherry. The coffee is dried in the usual way on earthern drying grounds. When sufficiently dry it passes through a series of beaters resembling those used for beating and cleaning yarn. The machine consists of a number of wooden pestles which are raised by teeth projecting from a wooden shaft, which is generally a continuation of the axle of the water wheel and these pestles fall into a long wooden trough into which the dry coffee is put. The coffee thus having its husk broken, is passed through a pan which separates the chaff. Some pass the coffee through a separator to take out the peaberry, but many do not. The coffee is a bad sample, owing to the large quantity of green coffee picked along with the ripe.

Labourers are plentiful on the Ceará plantations. Slavery exists only as a domestic institution, as servants in houses only. The field hands are all free. Before the famine, they were not so plentiful as since. Wages are now 640 reis a day (1s. 4d. Eng.) and hands provide their own food. Before the famine, wages were 500 reis a day (1s. Eng.) and food. The price for coffee picking is 640 reis (1s. 4d. Eng.) for 128 litres; say per 3½ bushels. The current year's crop is a good one, and on nearly all plantations I have seen, the trees were heavily laden with fruit.

There has not been a large crop of coffee for some years. 1879 was the last of the famine years, and in 1880 there had not been a great quantity of rain, and trees had not fully recovered. The estimate for Ceará this year is 125,000 sacks of 60 kilograms. This is a very important factor in the coffee returns of the world. Until now I did not believe that the production of coffee in Ceará was worth noticing. I should say, including young coffee fields not yet in bearing, there were over 100,000 acres under cultivation. There is still room for extending in other mountain ranges, although on this particular range nearly all available coffee land is taken up. Sugarcane is grown in the hollows, and bananas in the ravines. Mandioca is grown in both young and old coffee, between the rows which must lessen the production of coffee very much. The estates seem to suffer a little from wind, although the planters say wind does not trouble them. The dry branches observed on many trees must be the effects of the drought two and three years ago.

Transport of everything is by mule-pack, the present railway terminus being 25 to 30 miles distant. By the end of the year it will be 10 miles nearer.

I passed all Monday very pleasantly riding over the estates owned by my friend, and these were at an average elevation of 3,000 feet above the level of the sea. The thermometer was 70° at night, 70° in the morning, and the day being cloudy, was the same at midday.

On the top of the range is a village with hotel, and church, and some neat clean-looking houses. It being over 3,000 feet above sea level, is largely frequented by those from the northern part of Brazil, in search of health; particularly those having beri-beri.

From what I said of the roads in my uphill journey, you may imagine how I felt on my return. At one place we have to descend the point of a spur at a gradient that ought to be counted by degrees, say 50° zigzags, about 15 feet long, and the corners of these, cut away by the heavy rains, making almost a straight rugged track, all the way down a height of about 1,000 feet. The spur seemed to have been formed by two large earth-slips broken away from the mountain's side, and this spur being the solid piece left between the two. At the corners of the zig-zags, on each side of the spur, were large precipices. On that to the left, at the distance of 100 yards, was a roaring cataract, breaking over the side of the mountain in three or four falls. Spray was thus thrown over the path, making the way slippery in even the best of weather. Leaving the house of my friend at 4 p. m., Canôa was reached by 9·30 p. m. The ride from Baturité, to Canôa was pleasant in the moonlight.

No beds are used in this part of the world. After a light supper, I enjoyed my sleep in the hammock until daylight. Tuesday, 5th July I returned by rail to Fortaleza, got the small parcel of seeds of Manisoba (Ceará-rubber tree) from my Sunday friend at Bahna in passing.

I had time to make arrangements with influential people in Ceará for the supply of any quantity of seed I may require, and have it sent on to my

order after the picking season came round, which would not be before September, or October. The steamer "Lisbonense" of White Star line was to have sailed for Liverpool via Pará and Lisbon this evening, but was delayed for a day. I took my paasage in the "Lisbouense" for Liverpool. I caunot finish the piece about Ceará without expressing my thanks to the people of Ceará for their exceeding great hospitality. From the highest to the lowest, I received nothing but kindness and civility, both in town, and in country. All seemed anxious to oblige the stranger, and to give every information in their power.

Pará lighthouse, or rather the lighthouse at the mouth of the Amazone, 80 miles below Pará, was sighted at 10-30 p.m. On the 9th, while waiting for a pilot to come and take us up the river, we picked up an English shipwrecked crew, who had been two days in a small boat without food or water. The vessel, a coal brig, had struck on some sunken rock, but all hands were saved and came home to Liverpool with us.

At Pará, I also made complete arrangments for a supply of Ceará-rubber tree seed, cacao seed, and anything also that I may send for.

We sailed from Pará on the 12thJuly. A 16 days' run brought us to Lisbon. The passengers were all Portuguese with the exeeption of the shipwrecked crew and captain and engineer of a new steamer, brought out from the Clyde, to coast at the mouth of the Amazon. The saloon was crowded, and we had a head wind, and heavy sea, all the way across. Writing was a thing almost impossible.

I take two tins of Ceará-rubber seed to Liverpool with me. I am afraid we will not suceeed in getting Ceará rubber trees to grow from seed. They told me in Ceará that, if kept dry for more than a month, they would not germinate. I shall send the two tins to Ceylon on trial.

Further than the small quantity of this seasou's seeds, I did not briug any of the Ceará seeds. Last year's I considered not worth the trouble, as they will probably be a failure, as seeds generally are which have lost one whole season in planting. Some bags, however, consigned for Ceylon came in our vessel, but were not enclosed in tin, being loosely in bags. —I am, yours very truly,

A. SCOTT BLACKLAW.

NEW PRODUCTS: ALOE FIBRE, CASTOR-OIL, AND OLIVES.

Auchintoul Estate, Balangoda, Sept. 7th, 1881.

DEAR SIR,—As I presume everything appertaining to new products is of interest. I beg to enclose a report, received by the last mail, from London; but would remark that the sample in question was not prepared by me. The brown shade, of which the valuer complains, must have been caused by over-fermentation, in water largely impregnated with iron, and can be remedied by exposing the fibre to the rays of the sun for a day, on growing grass, taking care to water it regularly; or by leaving it without watering for two consecutive moonlight nights. With regard to value, as the strength is equal to Manilla hemp, worth from £30 to £40 per ton, and the specific gravity one-sixth less, it necessarily follows that the fibre should increase per ratio, or, say £36 to £48 per ton.

My *modus operandi* is as follows: I have there large pits in a ravine, with a watercourse on either side: the one to supply clean water, and the other to carry off the impure: the aloes are cut and tied in bundles of about twenty-five, and placed in the pits with water just sufficient to cover them; the sluices on each side are then closed, and the aloes allowed to remain until the fermentation has reached the desired point, viz., till they feel soft and pulpy, and the bright green has given place to an olive colour; then the sluices are opened, and a current of fresh water passed through the pits, which checks fermentation, and enables the men to proceed with the cleaning, without endangering their health.

Cleaning.—The leaves are now taken out of the water singly, laid on boards and scraped with *galvanized* iron or zinc scrapers, until the vegetable matter is removed, when the fibre is rinsed in clear water, and put out on the dry grass to dry: the refuse is collected in tubs, and at the end of the day's work well tramped on, washed, and also put to dry.

Results.—An ordinary cooly prepares about three pounds of dry white fibre and two of dry refuse per day. Cutting, bundling, and carrying, will depend upon the distance. In any case, each ton of green leaves costs 50 cents laid down in the pits.

Castoroil (*ricinus communis* of Linn.) deserves attention. In Farre's Materia Medica, two varieties are given, a large, and a small. The former yields from 25 per 30 per cent and the latter from 38 per to 40 per cent of oil. The trees, which come into bearing in four months and then give from three-fourths to one pound of clean seed each, are best propagated from seeds, put out direct. I have planted in holes six feet apart, 18 × 18 × 9 four seeds in each, filled up loosely with mana grass, so as to give light, air, and shade, and have had very few failures. I am also experimenting on a variety of medicinal plants, and will give you the results in due course. if you eare for them. I may mention that the jungles here abound with the "Varloe" or Ceylon olive, the half-ripe fruit of which, preserved in brine, are quite equal to the Spanish. Have auy of your readers tried them?

There does not seem to be any *gold* in this district, except what may be extracted out of "New Products"!, and even this is a difficult process.—Yours faithfully, W. MCDONALD YOUNG.

MARKET REPORT.

Aloe Fibre.—Your sample has been submitted to manufacturers, who say it is a fibre of pretty good quality as it does not weaken by being immersed in water, which New Zealand Flax was found to do. They value it at £24 to £25 per ton. It is of the same quality as Seichal hemp, but the sample you send is too small to be of any use as a criterion, as manufacturers would require at least 10 tons as a sample before they could give you the real market value of the article. In the sample you send, one part is quite white, and the other of a brownish shade; the former is the more valuable, and might rank with Manilla hemp.

THE SILK INDUSTRY IN CHINA.

Under this heading the *China Review* notices a Government report on silk published by order of the Inspector General of Customs. It seems that according to Chinese tradition mulberry trees were first planted and silk weaving inserted by Si Ling-shi, the wife of Whang Ti, about 27 years B. C., since which time sericulture has always been under the special patronage of the Empress. Many references are found in Chinese books to sericulture, and it is noteworthy that in the time of Confucies silk was cheaper than linen. Silk thus because the staple manufacture of the Empire, exerting a great influence on all the relations of Chinese life until the introduction of cotton from India in 1260 A. D. From that date sericulture steadily declined until it was revived by the present dynasty. In fact, were it not for the official looms, the industry might have died out altogether. After tracing the origin of the name of silk, and the

introduction into Europe of silkworm eggs in the year 551 A. D., the writer in the *China Review* continues :—

The times are changed, and to the purpose, when we find printed under the auspices of the Chinese Government these series of reports on silk, which supply, with more or less fulness of detail, accurate and special information from one and all of the provinces wherein treaty ports are located. It is also significant of the high standard to which the silk industry has now reached, of its importance and extent, of its recovery after the misfortunes of the Taepiug insurrection, that M. Rondet, President du Jury pour l' Industrie de la Soie in the Paris Exhibition of 1878, should come back to the original " Land of Silk " for fresh information, for fresh guidance.

These reports originated in a request from this gentleman, the greatest authority on silk, addressed to Mr. Hart, Inspector General of Customs. Under cover of Mr. Rondet's letter, a series of queries on silk were drawn up by the Chamber of Commerce of Lyons and which appear to be the lines on which the different Commissioners and Assistants at the various ports have worked. That the information is not altogether new was not to be expected, and that there should be frequent repetition was what only was to be looked for under the circumstances. It is our opinion that these reports will do much to clear up what has been insufficiently understood in the silk trade of China, and as a consequence much misapprehension will be removed. Numerous practical suggestions to the silk spinner and to the merchant, for the further development of the trade, will be found embodied in their pages. Mr. Kleinwachter's report, with its illustrations, strikes us as the most exhaustive and able of the series.

As the reports of the other Commissioners necessarily go pretty much over the same ground, the same enquiries having been addressed to all, there is therefore no necessity to allude to any special report. We should, however, fancy that the extracts from the Chinese Miscellany of 1849, "On the Growth and Treatment of Mulberry Trees, and the Method of Breeding and Rearing silkworms," translated from the Chinese, gives the sum total of what is known by the Chinese on the subject. It was a happy thought to append this to a report. Mr. Chalmers, reporting from Pakhoi, mentions that when the caterpillor of the camphorwood tree has attained its full size, it is cut open and its silk extracted in a form strongly resembling catgut, which makes excellent fishing line. We mention this because, that a process almost identical is employed by Biscayan and Portugnese fishermen for obtaining fishing line from the ordinary Silkworm. Mr. Rocher's report shows how speedily the domesticated silkworms revert to the wild state in obedience to the well-known natural law. The fact he mentions, may also throw light on the origin of silk culture in China. He had noticed during his investigations that the country people were collecting a particular kind of cocoon, which is very little known by Chinese, and still less by Foreigners. He explains its origin, as follows :—

"The first place I noticed the existence of this wild worm was at Huch'i-kuang, a barrier situated in the province of Chiangsu, at the entrance to the west side of the T'ai-hu. All the mulberry leaves along the river were covered with this kind of gauze, and not a single green leaf was to be seen, each tree, as well was as the ground underneath, was covered with millions of live cocoons. From there to Houchou I found mulberry trees more or less in the same state. As far as I have been able to ascertain, there is no doubt that this worm, except that it is smaller in size, is a degenerate form of the ordinary silkworm, and this may be explained by the fact of the country people having been obliged to leave their homes at at the approach of the rebels, just as they were busily engaged in breeding worms, and the butterflies being left to themselves, laid their eggs anywhere, so that in process of time the worms partook more of a wild nature. What leads me to believe that the above statement is correct is that before the invasion of the country by the rebels, this kind of wild-worm was unknown."

The paper concludes by showing that the present flourishing condition of the industry is almost entirely due to intercourse with foreigners. We are glad to learn that the eggs recently imported by Mr. C. Powell Jones are good and should hatch this month. We hope that the enterprize will prove successful in his hands as well as at St. Benedict's Institution, where the worms which were exhibited at the recent Polytechnic Exhibition were reared.

Col. R. H. Beddome, the well-knowu Conservator of Forests of the Nilgiris, arrived by the B. I. steamer "Ethopia" from Tuticorin this morning He is to spend about a fortnight in the island with the special object of reporting on our cinchona enterprise.

Tea from the Yatiyantota District.—We have lately been referring to the superior quality of the tea from the Ambegamuwa district, and some we have recently tasted made on Dalhousie estate, Maskeliya, appears to be very good ; but we have now to notice a sample from a comparatively low elevation, Mepitiyakauda estate, Yatiyantota. which, in flavour and strength, seems to us above the average of Ceylon teas. With careful preparation of the leaf, there can be no doubt that tea plantations in the hot wet districts between the Kelani river and Gampola ought to pay well.

"Haputale to Give Half a Ton an Acre All Round when the Railway Reaches it!" (Our correspondent's heading.)—Haputale, Malvern, 5th September.—On Saturday we had a nice shower of rain, and yesterday a *copious* shower—in fact, enough for this elevation. We expect good blossoms this month with fair weather. This last season, I gathered about 5 cwt. an acre from this place all round, but on *two or three acres* that had been well manured, with castor-poonac and a little crushed bone, I gathered half-a-ton ! Let this fact go *Home*, and let the *city men* say, if *they* will have a railway or not. The end that was manured looks *now* almost as well as the other portion of the estate.

Water Power in India.—In the case of the Egerton Mills, a prominent characteristic of the undertaking is the utilization of the mechanical power which is supplied to India in the descent of the water brought by the monsoon to the Himalayan ranges ; a power which, under the developments of modern science now so rapidly progressing in this direction, may be expected to afford a motive force to machinery which will go far to compensate for the absence of coal and other fuel in the upper regions of the continent of India. The Egerton Mills will be worked by a turbine set in the channel leading out of the Bari Doab Canal. The stream conducted through this channel will, after performing its duty of providing motive power to the machinery, be returned to the canal and utilized for its original purpose—namely, irrigation. We are glad to know that the co-operation of the Punjab Government in affording liberal terms for the utilization of water-falls on the Punjab canals has given an important impetus to the establishment of this undertaking, which will no doubt be followed by others of similar character in North India, wherever this economical supply of motive force is attainable.—*Pioneer.*

Correspondence.

To the Editor of the Ceylon Observer.

CHAMPION BLUE GUMS.

Langdale, Liudula, 9th September 1881.

DEAR SIR,—The girth of the blue gum mentioned by me was measured, but the height was only a rough guess from memory. I find it should be something more like 50 or 60 feet than 35. In Carlabeck garden there is a gum, name unknown, measuring 56 inches girth at a foot, and 50 at 6 feet high and about 45 feet high; but this is a much older tree, probably 7½ years old, from seed. This tree has now plenty of fruit on it, being the only gum I ever saw in bearing.—Yours truly, E. H.

THE APPLICATION OF LIME TO TROPICAL PLANTATIONS.

[*To the Editor of the "Tropical Agriculturist."*]

September 5th, 1881.

DEAR SIR —I see that one of your correspondents asks for information regarding the application of lime. As one who takes a strong interest in the higher cultivation of coffee and believes that its future in Ceylon depends much upon a right conception and use of the principles of manuring, I hail such enquiries with satisfaction, and hope that similar ones will draw forth such knowledge of the subject as has been acquired of late years in this country. If my mite is of any assistance to your correspondent, he is heartily welcome to it.

I have had some experience in the use of lime and have seen both good and ill results, according to the judgment displayed in its use. Anyone wishing to apply lime to his land should first consider well what is the object he wishes to attain, and the nature of the soil he is to work upon. The effects of lime are various. In the first place, it acts upon the soil mechanically: if *heavy*, opening it up and making it free; thus giving a stiff clay more the character of a good loam and enabling the roots of anything grown upon it to penetrate it more freely in search of food: if *light*, it tends to consolidate it. Secondly it acts chemically bringing into action the latent plant food, neutralizing injurious acids, and forming with the organic matter it may meet with carbonic acid water, in which, as Professor Graham says, plant food is dissolved before being taken up by the roots.

Now, concerning the practical application of these principles, about which I am in a better position to write than as regards the theory of them. If the object is to open up a stiff soil, *i. e.* one in which the clay is in too great a proportion, such as is seen in many portions of Dimbula, the lime may be applied while quick and forked in ou the surface, the whole ground being first covered with the lime. If, however, the soil is a good strong loam such as with cultivation usually yields remunerative crops, the best plan will be first to fork the surface of the ground and then to scatter the lime broadcast over the trees and ground. The first shower of rain will then slake the lime and carry it down to the bottom of the forked soil, part of it acting upon the soil in its passage, and the remainder working its way downwards to a still lower level and opening up the unstirred ground. If the soil of the estate is of a light character or semi-exhausted by previous cropping, I consider that the best form of lime is then that of ground coral or gypsum, as, if the lime were applied in its quick state, it would speedily exhaust all the supply of organic matter in which such soils are usually somewhat deficient.

It should be remembered that lime is a substance finding its way quickly to the lowest accessible level, and if forked in direct, on fairly open soil, it rapidly descends with the first rains, leaving the upper surface but slightly affected.

Again, lime should not be looked upon as a manure in itself, but as the foundation for subsequent manuring, its effects being to bring into action more speedily the demand for such matter and thus tending rather to exhaust a soil. Its presence in the soil is most beneficially felt when such manures as bones come to be applied afterwards, the soil also being in a much better mechanical condition for the roots to operate upon the manure.

If, however, it is not intended to follow up the lime with manure, then, except in the case of stiff soil, I consider that its application is best omitted.—Yours faithfully, CULTIVATOR.

CINCHONA, COFFEE, AND OTHER PRODUCTS AT A HIGH ALTITUDE.

Agrapatana, 6th September 1881.

DEAR SIR,—Is it worth while, or toolate in the day, to give a look over the far-famed district of Upper Dimbula, with its cinchona and coffee? The former we may regard as a financial success on several properties, *i.e.*, looking to the success some superintendents have attained lately in planting up new clearings, as also in planting among coffee: every open space, between the lines, landslips and even straight up and down banks are stuck full of cinchona from two to four feet apart; mostly of the large-leaved officinalis, although we meet now and then with calisaya and succirubra. The two former are no doubt the best varieties for the higher altitudes. Yet succirubra is not to be despised, for there are many very fine samples to be seen on almost all estates in the district, but generally at a lower elevation than the more recently planted clearings.

On going over several, we cannot but be struck with numbers going out from canker and disease, especially on flat and swampy and wet situations. This disease, once started, takes its course; very soon affects its neighbours, and goes on killing thousands.

Don't you think, Mr. Editor, that on its first appearance, to uproot all affected plants and immediately cut substantial drains, and apply sulphate of lime (or gas lime) would be a remedy? It would kill fungus and open up and sweeten the sour soil, so that it could be planted up afresh.

But even after this, how are we to prolong cinchona for a number of years? Not surely by the scraping or shaving process now being carried out upon young trees of from 12 to 20 months old. Such a system looks almost contrary to vegetable life, especially on such young trees—"killing the goose that lays the golden eggs." Healthy trees that have matured seed for the second or third time will bear this process and give handsome returns; and it appears to me to be the better method for the ultimate good of estates *i.e.* in preference to stripping or uprooting nothing but sickly and the weaker trees from crowded portions.

Also our "bread and butter" must not yet be altogether neglected. *Coffee* intermixed with cinchona is well worth the planting at these high altitudes, for on some coffee I saw at over an elevation of 5,000 feet, five years old, coffee is bearing an average crop of 4 to 4½ cwt. per acre, at the same time intermixed with the small-leaved officinalis five years old and looking remarkably well (of course under a system of good cultivation). We might now notice coffee upon poor ridges on some estates, suffering from leaf disease (h. v.), bug, black rot and poverty, with but little crop, and whether it would not be to the proprietor's advantage to plant up the same

with cinchona. The ordinary labour force, a day or two now and then, would easily plant the whole up with but very little increase of expenditure. Some of these young estates have often a few lines of cinchona planted along the road-sides, generally in a very slovenly and careless manner, with a sickly strangled look about them; we might say fit subjects for gangrene and disease.

In case of a failure of cinchona and coffee upon some parts, is there no other product that would pay? The forests here are full of the wild pepper (or what is said to be), and surely piper nigrum, the pepper of commerce, would grow and do well, say upon the Government reserve, alongside of all main streams and in wet swampy places where cinchona and coffee will not thrive

Rubbers.—Are none of them suitable for this climate? Tea has had a fair trial, but I cannot say how it pays. Perhaps not flushing enough to pay handsomely.—Yours faithfully, ENJOYENT FULE.

STOCKS OF CEYLON PRODUCE IN LONDON.

Colombo, September 1881.

Dear Sir,—I notice your article on coconut oil of yesterday's date but can you supply for general information, how stocks of coffee, coconut, oil, cinnamon and other Ceylon produce are made up by Reuter's Staff in their telegrams?

It must have riled cinnamon estate proprietors that they had been receiving low prices that barely covered the expense of peeling and preparing their produce, indeed making a dead loss, calculating interest and outside expenditure, whilst we are told this has been caused by the home custom officials making such a blundering mistake, as to create a "big stock," said to be over 7,000 bales, when, on an inspection asked by those interested through the dock companies of the real quantity on hand it shewed this: their present stocks to be only 4,097 bales Ceylon and 2,767 bales China comparatively worthless (about 2d to 3d per lb.) this China stuff being inadvertently added to the stocks of good Ceylon cinnamon (2,767 bales in excess of actual quantity). No one but those connected with the late decline in cinnamon can well feel the result of such mistakes caused by purchasers at home believing 3,000 bales of an overstock to be still for sale in London.

It is little satisfaction to be told it is a home official mistake. Continued small shipments shewing difficiences of over 2,000 bales on this side, as at date of last sale, or 1,200 up to 30th August in cinnamon, and over 1,600 bales in the case of chips. These actual deficiencies of shipment and 3,000 bales of a mistake to stock naturally made home speculators see their way to business. Great deficiency even for next peeling will I believe still be shewn by the failure of rain, through a dry season or no monsoon at all.

To come to coffee. Does the quantity in stock include all shipments afloat? Take Reuter's telegram of 23rd August. We there find 19,000 tons in stock, week's landings 900 tons, and week's deliveries 1,100 tons. Take their wire of 30th a week after. We find again 19,000 tons in stock, week's landings 700 tons, week's deliveries 1,000 tons. In the former week we have an over delivery of stock of 200 tons. The total stock may be correct, but in the latter week we have still 19,000 tons in stock, with an over-delivery between the former and latter week of 300 tons without affecting stock to the least. For my part I cannot and cannot understand it.

Again take coconut oil. I am told some time ago, stocks in London were made to include what was afloat. Well, even if this was so, we have during the last six months a gradual decline in quantity shipped reaching up to 30th August, nearly 1,000 tons less than last year. No doubt the home stocks are large, and as you state, it is almost certain, owing to the continued dry season in the low-country affecting cinnamon as well as coconuts, there will up to February and March of next year at least be a specially short supply of copperah and makers of oil will find this out after the present pickings of June and August have been made into copperah. In looking at home stock we see nothing to make this article go up and down as it appears to do. Up today, and down tomorrow, seems to be the motive power of some wire drawers, shewing there are other causes acting against one of our principal staples. To shew this I'll take Rose, Wilson & Rose's market report of 4th August last, shewing stocks 2nd August 1881, 8,928 tons afloat from Cochin, and Ceylon, by last advices 3,790 tons or say 12,718 tons with the London price of £26 10s. Turn to a like return of 1872. We have 13,531 tons with London price £35. In 1873 we have 14,757 tons price in London £32 at £32 10s. In 1874 we have 12,461, about the same stocks we have at present with a London price of £35 at £35 10s. In 1875 and 1876 we have about 8,000 tons for former with £36 10s and £36 15s. but only 6,000 tons in 1876 with £37 its price, shewing for 3 years continuous stocks averaging heavier then present stocks, we then had prices averaging £34 per ton or £7 10s more than this year even with less stocks than at present.

These figures speak for themselves, and I trust, in the interests of coffee, cinnamon and coconut proprietors, that we shall have renewed activity for our principal staples, and that deficiencies in crops will be made up to them by better prices all round, but when stock's reports are incorrectly given and speculators take advantage of such reports, Ceylon produce exporters have great reason to complain.—Yours truly,

CEYLON.

CINCHONA IN HAPUTALE: 96 LB. WET BARK FROM ONE TREE EIGHT YEARS OLD!

Craig, Haputale, 8th September 1881.

Dear Sir,—I uprooted one Cinchona tree today, with the following result, in wet bark, weighed by myself. The tree was planted either in 1873 or 1874. Elevation 5,150 feet.—Yours truly A. McK.

Quill bark	...	...	... 48 lb.
Twig bark	...	...	... 28 lb.
Root bark	...	...	... 20 lb.
			96 lb.

The tree was stunted in height, considering the dimension of the stem. At the surface, the girth was 42 inches.

We suppose the tree to be succirubra? And taking 32 lb. as the weight of dry, marketable bark, we have thus one tree giving at least £4 worth of crop!—Ed.]

CINCHONA CULTIVATION IN DIMBULA AND SELECTION OF TREES RICH IN QUININE BY THE EYE.

Agrakanda, Lindula, 10th Sept. 1881.

Dear Sir,—I notice in your leader of September 8th, the following remarks:—"A very good illustration of this fact is afforded by a recent experience in Dimbula, where, in connection with some flourishing hybrid, two or three gentlemen who have visited Java and studied under Mr. Moens, and who have since paid close attention to the subject, were asked to say of the various types, which which was the best. The result, however, proved that the trees they selected were decidedly inferior, while the one tree they pronounced bad yielded 6·77 of quinine."

As 6·77 of quinine, 9·03 of sulphate of quinine, is the exact amount of Mr. David Howard's analysis

of a hybrid on this estate, I may be pardoned if I am mistaken in supposing that you refer to it, and I hope you will forgive me for venturing to correct you. Two gentlemen, who, by the way, have never studied under Mr. Moens, but certainly have paid close attention to the subject, selected by the eye 10 trees out of 190 on this estate. Of these ten they again selected four which proved on analysis to be by far the best of the ten. One of the chief guides in this second selection was the outturn of dry bark, for it is obvious that a tree yielding 50 per cent. of dry bark will pay better than a tree yielding only 33 per cent, the percentage of quinine and the size of the tree being the same in each case. These gentlemen, however, are of opinion that there is no comparison between the selection by the eye of C. Ledgeriana and chancebred hybrids, and that consequently in the case of the latter there is a far greater necessity for the assistance of the analyst.—I remain, dear sir, yours faithfully.

MOWBRAY C. BULLER.

[We think "we told the tale as 't was told to us" by an authority who is very anxious to urge the appointment of a Government Cinchona Analyst. Neither the name of the estate nor of the gentlemen concerned was given to us; but if it should turn out to be the same case as Mr. Buller refers to,—as doubtless it must, unless two stories have been mixed up together—it will be very satisfactory to find that local ability to recognise good types of cinchona by the outward appearance is so clearly proved.—ED.]

MASKELIYA, (CEYLON) 7th Sept.—The recent spell of planting weather has been succeeded by sunshine, doing some damage to the lately put out plants. The effects of leaf disease, wind, and grub are here and there visible, though in the opinion of some "prospects for next year have never been better"! This year, however, estimates will not be exceeded. Cinchona proves a success, and, considering the age of the trees, the proprietors of Hamilton are to be congratulated on the prices recently realized by their bark. Young cinchonas in the upper end of the valley grow apace, but it is to be regretted that the Calisayas are chiefly of the inferior kinds. General satisfaction was felt by those present in Dikoya court today, when an attempted murderous assault on a resident in an outlying valley secured for its perpetrator six months' free board and lodging. *On dit*: that, owing to the unusual officiousness of the medical auditors, the Secretary has resigned his post. We hope that the rumour is untrue, as the district will have some difficulty in getting another like him.

GAMMIE'S SULPHATE OF QUININE.—The following is from the *Pioneer* of the 30th ult:—That "excellent substitute for quinine"—whose virtues are familiar to readers of the advertisements in the various *Gazettes*—is likely before long to find its function gone. The Government cinchona factory in British Sikkim have recently succeeded, for the first time in this country, in manufacturing from the cinchona bark some sulphate of quinine, samples of which have been pronounced under analysis to be capable of bearing comparison with the pure sulphate of quinine of commerce. Preparations are being made for undertaking the manufacture on a larger scale, and Dr. King hopes in due time to be able to supply the entire quantity needed by the Government in India. Another new production of the same factory which claims to be an improvement on the cinchona febrifuge is a "Crystalline febrifuge." The peculiarity of this preparation is that it consists of the mixed sulphates of the crystallisable alkaloids only: by rejecting those that are non-crystallisable, it is expected that the nausea which sometimes follows the taking of the febrifuge will also be eliminated.

LOWER UNZIMKULU, NATAL.—An old Ceylon planter writes:—"I have some beautiful coffee nurseries out here: no leaf disease; and the small patches of an acre or so of old coffee growing round about are simply splendid. Trees bear in a way out here never seen in Ceylon for years, I suppose. 3 lb. of cured coffee per tree is very often picked. The trees are never manured and never pruned, except being cut down with a blunt axe now and again when they get too high. I have a few officinalis alive from the seed I got from Abbotsford just before I left; but the climate does not seem to suit it. I think succirubra would thrive better and mean to try it. I hope the favourable blossoms I read about in the *Observer* have set equally well. I will have 50 acres of bush ready to burn off at the end of the present month."

THE PROSPECTS OF THE INDIAN TEA CROP.—The local paper, says the *Englishman*, is jubilant over the prospects of tea planters in the Darjiling districts, and "doubts if they have ever been so bright as they are now." Our contemporary is confident that the outturn "will be fully equal to that of last year," as although the weather was unfavourable at the beginning of the season, it has been all that could be desired during the last two months, which has "enabled planters to make an unusually large quantity of really good tea in July." Furthermore the prices realised have been satisfactory. After all these favourable circumstances the writer arrives at the conclusion that "with an increased and increasing Home consumption, as well as with a new market opened out and capable of indefinite expansion, we think that even the most desponding will agree with us that the bad times for Darjeeling tea are over, and that a very bright future is before allengaged in the industry." Let us hope that he may prove right.

"THE JAMAICA TOBACCO PLANTATIONS COMPANY."—The capital of this Company is fixed at £100,000 in £1 shares, application for 50,000 of which is now invited in the usual way:—"The prospectus states that the Company is formed for the purpose of acquiring and developing two Freehold Tobacco Estates in this Island of Jamaica—namely, Morgan's Valley and Retreat, comprising together an area of 1,656 acres, of which about 210 acres are now under tobacco cultivation, and the Leasehold Estate of Malmsbury Valley, of which 40 acres are under tobacco cultivation. These estates were originally selected by Cuban planters as suitable for tobacco growing; and although there are only 260 acres, or thereabouts, under tobacco cultivation, the yield has, it is affirmed, hitherto been satisfactory. Considerable working Capital is required for the purpose of extending the cultivation and doing full justice to the productive capabilities of the properties. The vendor, not being in a position to provide this, has agreed to sell the estate to the Company. The Directors speak highly of the tobacco, referring for support to a Parliamentary Report of Sir Joseph Hooker. The prospectus goes on to estimate that this year's crop will exceed 1,200 bales of fine tobacco. One half of this quantity would produce, it is calculated, over four million of cigars of average size. The profits on these (based on the best information the Directors could procure) should exceed £12,500 or sufficient to pay a dividend of £25 per cent upon a capital of £50,000; if however, all were sold in the leaf, it should yield about £12 per cent. In addition to tobacco, a portion of the land is also suitable for the production of coffee, of which some has been planted, the berries being of fair quality; and an increased dividend is anticipated from this source. A portion of the estate is covered with logwood, and there is a considerable quantity of pasture land. The Directors propose, if favourable opportunities offer, to acquire and bring under tobacco cultivation other estates in Jamaica."—*Gall's News Letter.*

HORTICULTURE.

(From the *Asian*, 30th August 1881.)

The Vegetable Garden.

The vegetable garden in Bengal, and especially near Calcutta or any other large town, is, as a rule, a sadly neglected department. Very few private individuals, even if they have the requisite amount of space at their command, care to take the trouble to grow their own vegetables. Why this is so it is certainly difficult to explain, for, with the majority, but little care is required to grow them well. Many, doubtless, are under the idea that during the season our markets are so well supplied with every kind of vegetable, and at such moderate prices, that it is not only cheaper but far less trouble to procure daily whatever may be required. Undoubtedly this is, to a certain extent, true; but is this the only thing to be thought of, what can be said with reference to the quality of vegetables procured from our markets? Admitted that most of them are grown to a very high state of perfection as far as size is concerned, but that is all that can be said in their favour; the quality is invariably of the poorest description. The reason for this is very plain to any one at all conversant with the subject. Not only are the varieties grown of the oldest and most inferior description, but, as a rule, are produced from acclimatised seed, which, in many instances, has been growing in the same locality for years. Even in Europe it is an admitted fact that nearly every kind of vegetable deteriorate by being grown successfully on the same soil. How much more is this likely to be the case in this country, where they have also many other difficulties to contend against? As a rule, native gardeners are under the impression that size is the one object to be attained, and there is a certain amount of rivalry amongst them to produce enormous specimens of cabbages, cauliflowers, celery, &c., but further than this their ambition does not go. They are content to grow the same varieties as their fathers, and possibly their grandfathers, grew before them. Take the following for instance: The only variety of cabbage grown for the Calcutta markets is the drumhead or cattle cabbage; the only turnip, the "Flat Dutch"; the only lettuce, green hammersmith; the only pea, a variety known as "patna pea," which is the common white English field pea, and the same with nearly every vegetable, only one or two of the oldest varieties are to be found. But why should our market growers care to make a change? They certainly can see no reason for doing so, for they find that, not only are they able to dispose of what they now grow readily, but also that to secure good prices for their produce size is the only desideratum, and yet how often we hear it remarked "that vegetables in this country have not the flavour they possess at home." I believe this to be an entirely mistaken idea, and such a conclusion can only be come to by the consumers of bazar produce. If these grumblers could or would grow their own supplies, and grow them as they ought to be grown, and not leave them entirely to the tender mercies of the *malee*, they would soon give a different verdict, for providing good seed of good varieties is procured and properly cultivated, not only will our vegetables be in no way inferior to those produced in Europe, but in many instances will be infinitely superior, for during the cold season here we have a climate probably equal to any in the world for the successful cultivation of nearly every description of European vegetable.

Seeds.

The first step towards success in the vegetable garden is the proper selection of seeds. If no attention is paid to this important point, no matter how much care may be bestowed on their cultivation, good crops can never be obtained. Some recommend the use of acclimatised seeds, but I should say, with the exception of the cauliflower, have nothing whatever to do with them, except as a "dernier resort" in the event of failure of imported seeds. Others, again, are in favour of American seeds, but these are almost invariably composed of second class varieties, and the only point that can be urged in their favour is their superior germinating power. English seeds, when procured from a source that can be relied on, invariably give better results than any other, their germinating power, provided they have been properly packed for this climate, being almost equal to those imported from America, and their produce is in every way superior.

Sowing.

This is an operation that should never be entrusted to a native gardener, unless done in your presence. Honesty is a virtue hardly known or practised amongst them, and a very common trick is to substitute worthless bazar seeds for those that have been entrusted to them to sow. For very early crops, which must be sown before the expiration of the rainy season, it is necessary to make beds raised three or four inches above the surrounding soil. These may be of any length required, but should not be more than three feet, or at the most, four feet wide. They should have a narrow drain running between them to carry off any excess of moisture. For later sowings, when the rains are over, the old native method of laying out the ground is certainly the best. This is done by dividing it off into beds three or four feet wide, with a raised path running between them about one foot wide, and three or four inches high, which must be well beaten down. This serves a two-fold purpose—giving free access to the vegetables for weeding and watering, and also retains a much larger amount of moisture at the roots of the crops than when the sowings are made on raised beds. Care must be taken that the soil in the beds has been either trenched or dug to the depth of at least eighteen inches, or for root crops even two feet will not be too much. After being well pulverised, a liberal supply of well-rotted manure should be added; the quantity will, of course, depend on the kind of vegetable to be grown in the bed, for their requirements differ to an enormous extent. Take, for instance, the cabbage or cauliflower, for which a soil can hardly be made too rich; but supposing peas were grown in the same soil, the probability is they would delight their happy possessor, with the vigour of their growth at least for a time, till he found that all their strength had been expended in the production of haulm, for in such cases, although they may possibly bloom freely, the pods rarely set at all. But not only is it necessary to regulate the quantity of manure according to the crop to be grown, but it is also equally essential that the description of manure best adapted for the requirements of each particular plant should be employed. It is, of course, a well known fact that the properties of various animal manures differ very considerably in their component parts, some being rich in ammonia, others in lime, potash, &c. In like manner also each particular vegetable possess one or more properties, generally to a much greater extent than the soil naturally is able to sustain. If, therefore, we employ a manure possessing those ingredients necessary to the life and well being of the plant, it naturally follows it must be benefited thereby, but, on the other hand, if a manure is used whose principal part is one found but in a minute degree in the class of plants to which it is applied, and which in most cases would exist naturally in the soil to a greater extent than is actually required, it follows that the crop is in no way benefited, and in many cases would be seriously injured thereby, besides the manure being entirely wasted.

After manure has been added, and the soil broken up as finely as possible, the surface should be turned over daily for at least three or four days before the seed is sown. This exposes it to the beneficial action of the air—a point that is of more consequence than many are disposed to believe. It is a too common practice in this country to allow that portion of a garden allotted to the cultivation of vegetables to remain a desolate waste through the whole of the hot and rainy season, during which time not only will an immense quantity of weeds accumulate, but it also thereby harbours an unknown quantity of insects of every description, much to the detriment of any crops that eventually may be grown in the soil. Instead of this, if the ground is regularly turned over once or twice a month, not only will it prevent an accumulation of weeds and insects, but the soil will receive more benefit in this having every particle of it exposed to the air, than it would from a heavy dressing of the best manure that could possibly be procured. The next point to be considered is the condition of the soil at the time of sowing. If it is too dry the seed will fail to germinate for want of moisture, and watering immediately after seed has been sown is also very prejudicial to success, as this causes the soil to become caked and hardened, thereby preventing the seed pushing through. When the soil is too dry, the best plan to adopt is to give it a thorough drenching one or two days previous to the time of sowing. On the other hand care must be taken that the soil is not too damp, otherwise, in all probability, the seed will rot instead of germinating.

Sowings may be made broadcast or in drills, but for the majority of those vegetables that are sown in the place where they are intended to remain, the latter is decidedly the better plan, as it not only economizes the use of seed, but also gives the growing crops a neater and more uniform appearance. When possible, it is advisable to shade the ground after the seeds are sown. This not only induces them to germinate more quickly, but also with greater regularity.

WATERING.

This is another point in the cultivation of vegetables that is deserving of more attention than is generally bestowed on it. A mistake too frequently made by many gardeners is to give crops a slight watering nearly every day. This, instead of benefiting them, is often prejudicial to their growth; in lieu of this if the soil is thoroughly drenched every third or fourth day, it will be found to have a much better effect.

LIQUID MANURE.

Probably nothing conduces more to the success of the majority of vegetables than being liberally supplied with liquid manure. It is far more stimulating and quicker in its effect than heavy dressings of dry manure. The reason for this is obvious, as it is supplied in such a way that the plants are able to absorb it at once. It may be made from fresh droppings of the cow, horse, sheep, goat—in fact of nearly any animal. All that is required is to allow the water to remain on it for four or six days, so that, when it is used, it may be perfectly clear. Its strength of course must be regulated according to the requirements of the crops for which it is intended.

ARTICHOKE (*Cynara scolymus.*)

Firminger, in his "Manual of Gardening," states that in the neighbourhood of Calcutta only what is called acclimated seed can be used with any prospect of success, as it is very rare indeed, that a single head can be obtained from plants raised from "imported seed." In direct contradiction to this, another well known authority, "Landolicus," says, "the seed of the artichoke is best imported from France, England, or America." "Country seed is easily obtained, but can never be relied on, as it frequently yields worthless flowers." My experience certainly coincides with the latter. On more than one occasion I have had plants raised both from English and acclimated seed growing side by side, under precisely the same treatment, and the former has invariably produced the finest heads.

Although the plant is naturally a perennial, it can only be cultivated as an annual with any amount of success in this country. It is therefore necessary to sow the seed as early as possible. This is best done in seed-pans or boxes about the middle of August. The seed, if good, will germinate in ten or twelve days. As soon as this occurs they must be allowed as much light and air as possible. It is therefore advisable to place the boxes or pans out into the open air during the continuance of fine weather, and only removing them under shelter when it is raining heavily, as the plants, in their young state, are very delicate, and, if subject to any excess of moisture, are apt to damp off. If the seedlings come up too thickly, they should be thinned out and planted in other gumlahs. As soon as the plants are five or six inches in height they may be put out in the ground prepared for them. Great care must however be taken in removing the plants that the tap root is not broken, otherwise they will receive a check which it is difficult for them to recover from.

The soil in which they are grown can hardly be made too rich. The plan most generally adopted is to dig trenches at a distance of three feet apart, and after thoroughly pulverising the soil to a depth of two feet, a heavy dressing of rich manure should be given. The plants may then be placed in the trenches at intervals of two and a half or three feet, and must be kept well shaded till established. Water must be liberally supplied through the whole period of their growth, and they will also be much benefited by frequent dressings of strong liquid manure. In Europe the artichoke is generally propagated by offets or suckers from year to year, and occasionally this method is adopted here. With a little care old plants may be kept through the rainy season. There is, however, but little advantage gained by doing so, as, although the heads may form earlier, they are always inferior to those produced by seedling plants when well grown.

ASPARAGUS (*Asparagus officinalis.*)

One of the most delicious of all European vegetables, and although extensively grown in this country, the produce is of very inferior quality as compared with that grown in Europe, not only in point of size, but also flavour. This is probably more owing to the want of care bestowed on its cultivation than to the difference in the climate. There is certainly no vegetable that will repay good cultivation better than asparagus. This was clearly proved at a recent show held at Tunbridge Wells, where special prizes to a large amount were offered for the best exhibits of this esculent, the leading class being for three bunches, each containing one hundred heads. The first prize exhibited in this section weighed upwards of thirty-seven pounds, or an average of about two ounces for each head. Although it may be out of the question for us to attempt to grow anything approaching this, still much can be done to improve the pipe stem style of growing that is so generally seen amongst us. The mode of growing it in this country is thus described by Firminger:—

"The seed should be sown in August, or as soon after as possible, under shelter from the weather, in seed gumlahs in very loose, mellow earth, both rich and sandy, for, if the soil be at all retentive, the roots, which are very delicate, would, at the time of

planting out, be sure to be broken, and the plants much checked in consequence. By the time the rains are over the young seeding plants should be about ten inches high.

The most economical mode of proceeding then is, in a plot of ground selected for the purpose, to dig cylindrical holes a foot wide and two or more feet deep at a distance of a foot and a half apart. In these, to a depth of about ten inches, throw a compost of equal part of mould and well-decayed manure; plant one plant in each, spreading the roots horizontally in a fan form, and taking care not to break them in doing so. Well water them, and continue to do so constantly, never allowing the soil to become dry; as the plants advance in height, keep filling in soil well enriched with manure. In three or four months' time the holes will thus become filled up to a level with the surrounding ground. About the end of April or beginning of May they will bear flowers, the removal of which before forming seed, though considered by some a needless trouble, will conduce to strengthen the plants. It is however of great importance that no portion of the foliage should be plucked, but rather be encouraged to make as vigorous a growth as possible. When the rains commence the plant will require no further attention; they will send up at that time several shoots from which cuttings might be made for table use; but it is far better to spare them and allow them to grow into branches, and not make any cuttings till the following year. In the cold season the stems will die entirely down, and the plants remain dormant till March, when they will make indications af again sprouting. At this time preparations may be made for what is called forcing them for the table. The earth should be removed till the roots of the plants are reached, and a good rich dressing of manure supplied; after this they should be well watered daily. In about a fortnight's time fine green heads will begin to show themselves above ground which may be cut for the table."

The preceding is but a modification of the old English method of cultivation, and is decidedly better than another system frequently adopted here, which is to crowd the plants into a bed frequently at a distance of not more than nine inches apart. People imagine that by so doing a larger crop is obtained. This is an entirely mistaken idea, for no matter how rich the soil they may be grown in, or how liberally supplied with manure, the produce will invariably be inferior, and for a very good reason, namely, want of sufficient room at the roots. Even the space between the plants, recommended by Firminger, has been found by experienced cultivators in England to be quite inadequate to the requirements of the plants, most of whom are now adopting the continental system of culture. This method is so simple, and has proved so successful, that I would strongly advise a fair trial being given it in this country. The following, taken from the *Garden* of February 12th, 1881, fully describes the process:—

"Although the details of the system of growing good Asparagus require some little space to describe on paper, the essential differences between that and the system commonly employed in England are so very clear that they may be shortly stated. Each plant is treated as an individual—as a vigorous subject, requiring much space in which to grow, if strong growth and strong shoots are required. Long experience has taught cultivators that a smaller space than *four feet apart* will not suffice to give the very best results. At first sight people in the country might suppose that this means a waste of ground, but it really is not so. At first, when the plantation is young, waste of ground is avoided by taking a light crop off between the lines, say one of kidney beans or early pot-toes, but after a good year's growth, and when the asparagus gets strong, its roots really occupy the whole space, and the result is so much more satisfactory than in the common way, that the ground affords a better and more satisfactory return. There are two principal ways of growing this crop—one devoting a certain portion of the ground to it as usual with us, the other alternating plants between rows of small fruits, or placing a plant where there is room for one. This last way is important, because it may be carried out in small gardens everywhere, and by its means we should become more readily convinced of the value of giving plenty of room. Single plant here and there in open spaces, wherever room can be found for them, would, from the sufficient space allowed to each plant, soon convince all of the value of the system.

Planting.—Healthy young plants are always chosen, and they are planted about the time, or a little before the time, when growth commences in spring. They are invariably planted in a shallow trench, somewhat like a celery trench, not quite so deep, and not manured as that is, supposing the ground is in fair condition. In a trench about eight inches deep the plants are placed on little low hillocks, and they are carefully attended to for the first year. The plants, be it noted, are four feet apart in the line, and the same distance between the trenches. It will be noticed that the second essential difference between the common way that is in use with us, and the way it is now desired to make known is, that in garden soil of fair quality no manure is used at the time of planting. There are soils in which drainage and preparation might be required; but assuming that the soil is as good as garden soil generally is, no preparation is given beyond the opening of the trench, and the planting of each root in a little fine surface soil. The great expense which has been supposed to be necessary in the culture of this plant is at the commencement at all events avoided. It is when the plants begin to get strong and well established that a little manure is applied. There is thus a great economy in two things—in plants and in manure, which, under the usual system with us, is used to the most wasteful extent, so much so indeed as to seriously limit production by causing alarm as to expense. A most important point is the regular staking of the plants, the stakes being placed clear of the root, and in a slanting position across the shoots of each plant to which they are loosely but firmly tied."

Broad Beans (*Faba vulgaris*).

It cannot be said that the cultivation of this fine old vegetable is attended with unqualified success in this country. Frequently, from some unexplainable cause although plants may thrive vigorously and bloom freely, they obstinately refuse to set a single pod.

They succeed best in a deep, stiff, loamy soil with a moderate amount of well-rotted manure added. The seed should first be steeped in warm water for about twelve hours, otherwise they will take a very long time to germinate. The sowing should be made in October as early as possible after the rains in drills about eighteen inches apart; the seed should be planted about two inches deep with a space of four inches between them. As soon as the plants have ceased blooming, pinch off about two inches of the top; this will induce them to set more freely, and an occasional syringing during the time they are in bloom will also conduce to the production of pods. Some authorities recommend sowing the seed in boxes or pans, and as soon as they are two or three inches high, transplant them into the open ground. One advantage gained by this method is, that the crop grows more uniformly, and it is also stated that the fruiting is thereby considerably accelerated.

Runner Beans (*Phaseolus multiflorus.*)

Scarlet runners, as they are more generally called, cannot be grown successfully here, although they thrive

vigorously, and produce their old familiar flowers freely. They can rarely be induced to set a single pod. Probably if grown as a dwarf plant and kept constantly pinched back as recommended by "Landolicus," a better result might be obtained.

French or Kidney Beans (*Phaseolus vulgaris.*)

These may be divided into two classes, namely, climbers and dwarfs; the former, however, like the scarlet runner, will never set its pods freely in our climate; dwarf varieties therefore should only be selected, and these, if well grown, will thrive with every success. They should be sown in a moderately shady position; if fully exposed to the sun they not only grow slowly, but almost invariably become infested with a kind of fly which destroys them in the course of a few days. The first sowings may be made early in October, or as soon as the rains have ceased, and other sowings at intervals of ten or fifteen days should be made up to December. They should be sown in rows two feet apart, and about three inches dividing the seeds, which must be covered with about one inch of soil only. The seed, if good, will germinate in four or five days, and the plants be in full bearing in six to seven weeks from the time of sowing. They should be grown in a free, open soil, moderately enriched with well-decayed manure.

Beet (*Beta vulgaris.*)

This this one of our most valuable vegetables, and is probably more popular in this country even than in Europe. It is cultivated here without any difficulty. A free, open soil suits it best, and to grow it to perfection a trench should be made about eighteen inches deep, at the bottom of which a layer of four inches of rich manure should be laid. This should then be covered up with about nine inches of soil, and the seeds sown in a row down the centre. As soon as the plants are three or four inches in height, they should be thinned out to a distance of nine inches apart, when they may be supplied with a liberal dressing of liquid manure. Treated in this way they form large roots and are ready for table in ten weeks from the time of sowing. For an early crop, a small quantity of seed should be sown in pans about the middle of August, and if they come up too thickly, should be transplanted into other pans, where they must be kept till the end of the rainy season, when they should be planted in trenches as mentioned above. These, however, never make such fine roots as those grown in the open ground.

Borecole or Kale (*Brassica oleracea acephala.*)

This is the most hardy section of the whole Brassica family, and is extensively cultivated in Europe for winter use. In this country no object would be gained in cultivating them, as they would come into season about the same time as all the other members of this group, and their quality is decidedly inferior compared with the cabbage or savoy. There are, however, several very showy and effective variegated leaved varieties, examples of which would tend to enliven the monotony of the kitchen garden, or even mixed with flowering plants during the cold season. These are also as well adapted for culinary purposes as the ordinary varieties.

The Broccoli (*Brassica oleracea botrytis asparagoides.*)

The broccoli, which is really only a hardy class of cauliflowers, is very extensively cultivated in Europe. This is, of course, owing to the fact that it is hardier and better able to withstand a low temperature than the latter; it is, however, very inferior to it in point of quality. In this country, where it can only be grown at the same season as the cauliflower, it is certainly unnecessary to attempt its cultivation, although probably it could be successfully grown under the same treatment as recommended for the other members of the Brassica family.

Brussels Sprouts (*Brassica oleracea bullata minor.*)

A well-known variety of the cabbage family, which, instead of forming a single head, produces numerous sprouts, each about the size of a hen's egg, one from the axil of each leaf. When well grown this is one of the most delicate flavoured vegetables we possess. To ensure really good sprouts, it is necessary that they should be grown without a check from the time of sowing up to the period when they have made their full growth. Many experienced English cultivators recommend that the seed should be sown in the places where the plants are to remain. This, although possible in England, could never be attempted here in consequence of the rainy season being at its height at the time that it is necessary that the seed should be sown. The best plan to adopt, therefore, is to raise the plants in small pots in the manure recommended for early cauliflowers, or the seed may be sown very thinly in a seed-bed under shelter; and as soon as the plants are large enough they should be transplanted with a large ball of earth adhering to them, so that the roots are not injured. Their after cultivation should be the same as that of the cabbage, as, however, the lower leaves mature they should be carefully removed, as this will induce the plants to sprout with greater regularity.

The Cabbage (*Brassica oleracea.*)

Probably, with the exception of the Pea, no vegetable can boast of so many named varieties as the cabbage. It cannot, however, be said that these are all distinct kinds; on the contrary very many of the supposed new varieties that are being continually introduced are nothing more or less than synonyms of old well known sorts that have been in cultivation for years, although some of them, by careful selection, may be considered as decided improvements on those which they have descended from, and which they so closely resemble. As evidence of this I may mention that some two or three years since the Royal Horticultural Society of England undertook an exhaustive series of experiments with the cabbage, in which upwards of one hundred varieties were grown for trial, the result of which was that it was proved beyond dispute that there were really only sixteen or eighteen distinct kinds, and the remainder of those tried being either identical with the types selected, or mere cultural improvements on them. I regret I am unable to turn up the Society's published report, as it would possibly interest some of my readers.

In England the advantage gained by growing several varieties is, by careful selection to have them in season as long as possible. In this country, however, where we have but one growing season for them, and that but a very short one, no object is gained in growing several varieties. The main points in selecting a particular kind adapted to the climate should be that it is of quick growth, good flavour, and one that hearts quickly.

The following are the best amongst the new varieties, and are well adapted to this country:—"Carter's Heartwell Early Marrow," "Sutton's Imperial," "Sutton's Matchless," "Improved Enfield Market," and "Daniel's Defiance," the latter probably the finest of all, of quick growth, hearting freely, and producing immense heads often weighing from fifteen to twenty pounds each, of a very delicate flavor. In addition to the above there are—"Enfield Market," "Winningstadt," "London Market," "Schweinfurt," "Nonpareil," Wheeler's Imperial" and "Coconut," most of whic are well known as being quick growing kinds and of good quality.

Culture.—The cabbage is a very gross feeder, and to grow it successfully it must have liberal treatment, and more especially so in this country where its growing season is much more limited than in a colder climate. The first sowings may be made towards the

end of August in seed-pans placed in a sheltered position, but allowed as much light as possible as soon as they germiuate, otherwise the plants will probably become drawn and damp off. As soon as they become at all crowded, they should be thinned out and either transplanted into other gumlahs or into the open ground in a raised nursery bed, under the shelter of a hoogla or mat. It is certainly a doubtful question if much advantage is gained by making early sowings in seed-pans as described above, although it is a practice very generally adopted. One objection to it is the extra trouble necessary to raise good strong plants, and another that plants grown in this way never thrive so freely, or produce such a good crop as those raised in the open ground, and transplanted to the place where they are to remain direct from the seed-bed. The ground in which the plants are to be growu can hardly be made too rich; the manure best suited to it is night soil, but in this country it is of course entirely out of the question to employ it on account of the prejudices of the *malee*. The next best is goat or sheep maunre, and where procurable should be used in prefereuce to any other. Many cultivators recommend the old Chinese method of planting, that is to make regular rows of holes, each eight inches in diameter and of the same depth, at a distance of eighteen inches apart. These holes should be filled up with a rich compost made of equal parts of mould and manure. This is certainly an economical method, but should never be employed when plenty of manure is available. A much better plan is to make trenches, twelve inches wide, remove the soil to a depth of nine iuches, then have the bottom of it well turned up to the depth of ten or twelve iuches. After this four or six inches of manure should be added, which must be well forked into the soil, the plants should then be planted in the centre of the trench at a distance of two feet apart, and the same space should divide the rows. The young plants will require to be shaded for three or four days, and should be liberally supplied with water till well established.

The Cauliflower (*Brassica oleracea botrytis cauliflora.*)

The most popular of all European vegetables in this country, the *Phool Kobee*, is prized alike by all classes of society, oven entering into the heterogeneous mass of the mild Hindoo's curry, when it comes within the scope of his slender purse.

The cauliflower is generally known here from acclimatised seed, aud when really good seed is procured will produce heads of the greatest perfection under good cultivation. It is geuerally believed that it is impossible to produce good heads from plants raised from imported seed, and even Firminger mentions it in his "Manual of Gardening." From my own experience I should say this is quite a fallacious idea, although it must be admitted the plants require more care and attoution than those raised from imported seed. To grow it well it requires the richest of soils, with a liberal supply of root moisture throughout its whole growth. To insure this heavily mannred ground is of the first importauce, aud liberal dressings of liquid manure should be frequently applied. The first sowiugs should be made about the same time as that mentioned for the cabbage, and as soon as the seedlings are large enough to handle, they should be transplanted into a bed of light, rich soil, at a distance of four inches apart each way. As soon as they have made four perfect leaves, they may be again transplanted into a bed of richer soil than the one first employed. This time they should be placed six to eight inches apart; here they may remain until they are strong enough to be planted out in the quarters where they are intended to remain. Should, however, time and labour be available, a third transplanting will even be beneficial to the plants. The object gained by frequent transplanting is, that it prevents a too luxuriant growth of the foliage, aud induces them to heart more freely and quickly.

When very early cauliflowers are required, I have found the following a very successful method of producing them:—Fill a quantity of three-inch pots with light, rich soil, and in the centre of each sow three or four seeds of any good acclimatised variety. As soon as these have germinated, select the strongest plant and remove all the others. When they commence growing freely, weak liquid manure may be given. As they iucrease in size, they should be continually shifted into larger pots. Seed sown in this way at the end of August will, by the end of the rains, have produced strong plants, nine to twelve inches in height, which should then be in six-inch pots. As soon as the weather has become quite settled, these should be planted out in trenches in the open ground as previously described, when, in the course of seven to eight weeks, they will produce fine heads. Many will probably think this is a laborious process, but the fact that by so doing you may have cauliflowers on your table quite a month before your neighbours, is a victory well worth winning. Our native gardeners have great faith in the efficacy of mustard cake, or *Khullee*, as a manure for cauliflowers, and in fact for every member of the cabbage family. It undoubtedly is a very powerful stimulaut, and very quick in its action. They generally apply it when the plants are about half grown, by removing the soil for about six inches round the roots, and apply about half a pound to each plant. This is then covered with the soil, and a copious watering given.

The best of the English varieties are—"Veitch's Autumn Giant," "Erfurt Dwarf Mammoth," "Walcheren" and "Lenormand's Paris Market."

Rus in Urbe.

THE PHYLLOXERA.

(From the *Gardeners' Chronicle*, 20th August.)

From a report from Her Majesty's Consul at Bordeaux we extract the following:—

Of the 2,200,000 hectares (a hectare = 2½ acres nearly) which composed the vineyards of France. 500,000 are destroyed, 500,000 others are greatly attacked: it is a loss of more than three milliards to the country. The Gironde is one of the departments which has suffered most: one-third of the vineyards are destroyed, another third are badly attacked. For the very important vineyards of the Gironde, where submersion is possible, it is a sure remedy, which is generally employed, and with invariable success. In the cases of vineyards already destroyed, the remedy seems to be to reconstitute them by planting American vines as stocks for grafting French cuttings on, which plan has been the subject of satisfactory and conclusive experiments for the last few years, especially in Languedoc. Where the vines are not too far gone, a judicious use of sulphide of carbon is a certain means of preservation, and, in most cases practicable, owing to the moderate cost.

Submersion.—The good effects of submerging vineyards have been fully demonstrated, especially in the Gironde, as the rivers deposit a quantity of fertilising matter being of a muddy nature, which manures the land whilst destroying the insect; and thus there is reason to believe that the gain in produce may pay for the cost of the operation. As the means of applying the water varies with the local way of procuring it, it is impossible to lay down rules as to how this should be done. Of course it can only be employed on low-lying flat land. Embankments are constructed

to keep the water in, and a depth of from 40 to 50 centimetres is considered sufficient, the time for the operation being early in the winter—November or December—and the water remains on the land about forty days. I am informed that a vineyard in the South, belonging to Mr. Faucon, treated by submersion every winter for ten years, is in the most flourishing condition; and that whereas in 1869 the crop only yielded 25 hectolitres, it has since come up to 2,500 in the year 1875. Mr. Faucon appears to have been the first person who tried the system of submersion.

Insecticides.

Sulphide of Carbon.—The drawbacks to the employment of this specific are its dangerous nature from inflammability, the difficulty of diffusing it equally in the ground, and that, if used in two great quantities, it destroys the vine as well as the phylloxera, but, used with prudence, its good effects are incontestable. During winter or towards the commencement of spring, but before vegetation commences, one or two treatments should be given; if two, not more than 15 grammes in each, with an interval of eight to ten days between the two doses; if only one treatment, from 25 to 30 grammes. In spring and summer it is not advisable to apply the sulphide, except in very bad cases. The soil should not be disturbed for at least a fortnight after treatment.

As the roots of vines extend in all directions underground, the sulphide should be introduced so as to extend as evenly as possible throughout the vineyard; thus it should be injected by holes bored at equal distances—for instance, if the vines are planted 1 metre apart, one hole between each two vines; no hole should be nearer than 30 centimetres to the vine.

In this country the instrument used for injecting is the *Pal Sujecteur Gastein*, which is a kind of large syringe with a long nozzle, and contains the sulphide, the quantity being regulated by washers, limiting the stroke of the piston.

Sulpho-Carbonate of Potassium.—This insecticide, which, from the quantity of water required on using it, is so expensive as to be excluded from general use, although it is still in request where patches of disease manifest themselves, has the advantage of containing potash in considerable proportions (about 28 per cent), which fertilises the ground, whereas the sulphide of carbon possesses no manurial qualities.

The cost of employing sulpho-carbonate is about 600 francs per hectare, whereas the sulphide of carbon costs about 200 francs. A poisonous solution is formed by mixing it with water, and it is thrown into basins hollowed out round the foot of each vine. These basins should be carefully prepared, so as to allow of the mixture reaching the whole of the insects underground. The quantity of sulpho-carbonate to be applied to each root varies according to age and vigour of the plant—for young plants from two to four years old, from 20 to 30 grammes according to size, diluted in 10 litres of water to each vine. When the solution has been absorbed by the ground, 10 litres of water should be thrown on it to drive it deep into the soil. In summer, when young roots are superficial, and may carry insects on them, or if the solution has not been absorbed, no water should be added. The ground should be filled up round the roots as soon as possible after the operations, and should not be disturbed for a few days afterwards. Many other insecticides have been tried, but the above appear to be the only means proved to be practicable and efficacious by long experience.

Plantation of American Vines.—Experience has shown that American vines, although not exempt from the attacks of the phylloxera, are hardier, and their roots possess much more resistance; consequently a system of using American roots with French vines grafted on them has been carried out lately, when new vineyards have been planted, or to fill up vacancies in existing ones. The species of American vines most in vogue for grafting upon are, I am informed, Riparia, Clinton Vialla, Solonis, Elvira (which, without grafting, produces white wine of good quality), and also the Facquez (which gives a vine of the type of "Vin du Midi"), Herbemot, &c.

Various methods of planting and grafting are used, which I shall endeavour to explain as clearly as possible. 1. American cuttings are planted in the vineyard, and after a year, at the time when the sap has risen, and before the buds begin to swell, the grafting takes place. 2. By planting the American cuttings in a nursery to root, and after a year lifting them, grafting and planting out in the vineyard: this plan is more certain. 3. By taking two cuttings, one American, the other French, grafting the latter on the former and planting in a nursery. After a year all those which have succeeded are lifted and transplanted in the vineyard; this is the quickest method.

The graft is always below the surface of the ground, and, when done, loam or clay is covered round it in a cone to protect it, without using any mastic. A clever workman can, with an ordinary grafting-knife, and assisted by another man to tie up, graft from 250 to 300 plants in a day.

Several machines have been invented for grafting; the one most recommended is the "Machine Petit," invented by Mr. Petit, engineer of Langon, Gironde. This machine is for performing the operation ("*greffe en fente Anglaise*") in a house or shed: it is placed on a table, and contains two blades—one for making the diagonal cuts, and the other for splitting. Price 35 francs. "Machine Berdageur," said to be not so complete as the former, but less expensive. Price 12 francs. "Machine Leydier," for the "*greffe Champin*," which is a more complicated form of graft, "*en fente Anglaise.*" "*Moule à greffe Teysonneau,*" (12 francs), for grafting "*en fente Anglaise,*" either on a table or in the ground; but when grafting on a plant rooted in the ground is practised it is usually done by hand, as there is difficulty with any machine cutting so low down, and the knives get spoilt by the clay, stones, &c. With one of these machines, when the plants are out of the earth, and can be operated on on a table, two men could get through more than 1,000 in a day.

Japanese raphia, previously soaked in a solution of sulphate of copper to prevent it rotting, is much used for tying the grafts. Vineyards planted in virgin seasand are said to be free from phylloxera.

Mr. Armand Lalande has published a pamphlet entitled *Le Phylloxera dans la Gironde*, which is well worth reading; and I may mention the following works, which have been recommended to me:—*Manuel pratique de Viticulture*, par Gustave Foer, containing much useful information and plates of various methods of grafting; and *Traité théorique et pratique du Greffage de la Vigne*, per Amié Champin—a very complete work on grafting.

CINCHONA IN COORG (SOUTHERN INDIA).

Mercara, 24th August.

As the elevation of the coffee cultivated portion of this country in place exceeds 3,900 feet, or is less than 2,750 feet, this altitude is most favorable for the growth of certain kinds of cinchona, &c. C. Succirubra has been proved to grow quicker and more luxuriantly than any other variety, although hybrids C. Condaminea and C. Officinalis are met with. The pure plants of the latter varieties thrive but sparingly and give little encouragement to cultivate them on a large scale.

In 1879, Colonel H. S. Thomson, the late Superintendent of Coorg, directed attention to the many waste lands of gently undulating hill-slopes that encompass the town of Mercara, which, situated on a plateau, commands an almost horizontal view of several miles to all points of the compass, excepting to the south-east, where the abrupt descent of the ghat commences. These hill-slopes in former days were covered with dense forests—and still possessing a fertile soil, were abandoned to neglect, and had become wholly a prey to the lantana shrub, which had spread and overrun acres upon acres of these tracts of land. Orders were given and executed to have the lantanas rooted out and burnt—a most difficult task—and to have the ground planted with cinchona, which has in part been done.

An expensive experiment is now being made with C. Ledgeriana, and seedlings, three inches high, were procured in June from the Neilgherries at the very high rate of R500 per thousand, the great risks incurred by an eight day's journey in bullock carts of such delicate plants, and the cost of transport hire excluded. The *Indian Agriculturist* of the 1st August quotes the price of C. Ledgeriana seed grown in Java at £36 per ounce, which is still more extravagant. C Ledgeriana promises to be a rapid grower, and to quickly repay the money expended on it if the bark proves of such superior quality, for many of the purchased plants have grown to above six inches in height in less than three months, and have also given many cuttings, which have struck: placed in sand, in a glass house, and a temperature at 75°. The elevation where it is proposed planting them out is at 3,650 ft., on a gentle slope with a northerly aspect, and with a moderate annual raiufall of 120 inches. An attempt will also be made on an estate, some miles west of Mercara, that has a slightly higher elevation, greater declivity of ground, richer soil, but with the tremendous rainfall of 275 inches. If these C. Ledgeriana should live ont the first year of planting, that is 1882, there can be little danger apprehended afterwards. The roots will then have established themselves and have struck to drier ground than the surface. As C. Succirubra succeeds well in this situatiou, the C. Ledgeriana being a hardier plant should thrive equally well. Few nurseries have been successful in rearing any large quantities of seedlings, and those that have been so reared unless guarded with extreme care during the transplanting months of November and December, perish in thousands.—*Madras Standard*.

GOLD AND PLANTING IN SOUTH INDIA.

TO THE EDITOR OF THE "SOUTH OF INDIA OBSERVER."

Sir,—In a recent issuo of your valued paper, referring to the gold enterprise in the South-East Wynaad, you drew attention to the great number of estates that were being abandoned, and which had formerly been good paying properties. To show that the cultivation of coffee, cinchona and tea is not being entirely neglected, I send you a detailed statement of the extensions which have been undertaken in the Ouchterlony Valley proper this season,—extensions, I believe, on a larger scale than in any one former season since the opening up of the cultivation. Upwards of six hundred acres of new land have been opened, besides which a large number of cinchonas have been planted out in the old cultivation, and the necessary annual supplying has not been neglected. The following are the details of the plants put out:—

Coffee—new extension ...	200,000
Do supplies	105,000
Cinchona—new extension	650,000
Do planted in old coffee ...	450,000
Tea—new extension	220,000
Do supplies	60,000
Making a grand total of...	1,685,000

These figures, at any rate, shew that in spite of the gold mania, there are still those who believe that the cultivation of coffee, cinchona and tea is a sound investment for the future. O. V.

[Our remarks applied to S. E. Wynaad, and there we have since been informed the neglect of coffee cultivation is very extensive. We are obliged to our correspondent for pointing out that the Ouchterlouy Valley is an exception.—Ed. *S. I. O.*]

THE GIANT BAMBOO IN CEYLON

forms the subject of a full-page engraving in the *Gardeners' Chronicle* for 27th August, accompanied by the following remarks:—

There is no group of plants, nor even that of the palms, which is more strikiug to the botanist who first sees tropical vegetation than the bamboos; the singularity of their habit, the remarkable rapidity of their growth, the persistence of many species for long periods of time without flowering, and the extreme beauty of form presented by the larger kinds, all contribute to interest the mind and strike the imagination. The effect is enhanced by the knowledge that these towering and umbrageous masses of foliage, rivalling or overtopping the slow-growing and solid trees of the forest around, are in all respects as truly grasses as the humble poas and fescues of our dowus and meadows.

Perhaps the very largest known bamboo is that of which meution was made in an article on Ceylon by "H. J. E." in a recent number of the *Gardeners' Chronicle*. An illustration of one of the magnificent specimens in the Royal Botanic Gardens, Peradeuiya, there alluded to, is now given (fig. 54), and being taken from an admirablo photograph, it conveys an accurate idea of the vast dimensions and perfect symmetry of a well growu plant of this fine species.

The species is Dendrocalamus giganteus, Munro, (Bambusa, Wallich), and is described in the late General's well known monograph. Though thriving with such vigour in Ceylon it is not a native here, but of the Malay peninsula. There appears to be some doubt as to its precise home. Brandis gives Moulmein, but Kurz does not include it in his *Forest Flora of Burmah*, and states that it is confined to Malacca and the adjaceut islands. It appears to be a local species, and the majority of visitors from the Straits who come to Peradeniya are unfamiliar with it.

It appears to have been introduced into the Calcutta Botanic Garden in 1831, whence specimens were received at Peradeniya in 1856. It seems to have flowered at Calcutta in 1861 or 1864, and to have survived the process. Colonel Munro was able to examiue the fruit and thus to fix its generic position as a Dendrocalamus. In 1864 the great cyclone destroyed four out of the five plants then in the Calcutta garden. The original plant at Peradeniya is still a thriving and handsome specimen; it was soon largely propagated from, and the numerous specimens in the gardens and in many parts of Ceylon are its descendants: the subject of the portrait was one of the earliest propagated. No specimen has as yet flowered in the island.

Any detailed scientific description would not be in place here, but a few particulars will be interesting, and attention may be called to some facts of morphology. We have here essentially a perennial tufted

grass on a large scale; the hard solid subterranean rhizome is excessively branched, and each branch terminates in an aërial stem or culm. In this species these are crowded very closely together, and are added to every year, the oldest ones being principally in the centre, but the rhizome branches are so intermiugled and interlaced that there is little regularity in this matter.

The clump figured must contain several hundred culms of various ages, and the mass measures 98 feet in circumference about a yard from the ground. Each culm is cylindrical, and grows as vertically straight upwards as its older companions will allow; the squeeziug and jostling which occurs is wonderful, and the enormous compressing force will in cases force a culm out of shape slightly. As with other bamboos they take their full diameter almost immediately, and while yet soft, the silicic hardening not being completed till they have reached nearly the full height. The outer ones towards the top get somewhat pushed over by the immense weight of foliage of those within, and are sometimes broken off in consequence. The usual dimensions of the culms are from 26 to 29 inches in circumference, the largest I have measured attaining 33 inches, or nearly a foot in diameter. They are not thickened at the joints, perfectly smooth, of a pale dull green colour as a basis, but this is overlaid with a sort of "bloom" of whitish blue, and the effect of this is to give a pale greyish tint to the stem. Their actual length is over 100 feet, but that is about the height of the clump figured; each joint is 15 to 18 inches in length, and the thickness of the wall about 1 inch; the lowest ones are shorter, with a rather thicker wall. When young each node gives off a large thick, leathery, yellow sheath, topped with a rudimentary leaf-blade, but they are quickly detached, and fall off or often slide down the stem, slipping over one another, so as to form quite a mass at the base of the culm. These sheaths are beautifully polished within, but are set outside with minute brown hairs, separable by the slightest touch and somewhat irritating to the skin. No sheaths are seen in the photograph, which was taken when no young culms were rising. A dense narrow collar of short, stiff, crowded, very hard, blunt rootlets comes off just above each partition in the lower part of the culm; these increase as we pass down in length and number till at the very base they pass into the innumerable rootlets originating from the rhizomes themselves, which in incredible numbers permeate the soil in every direction, and effectually prevent the growth of any other large plant in the immediate neighbourhood.

This, and the litter caused by the quantity of fallen leaves, are the principal objections to these magnificent objects in a botanic garden, and by choosing suitable sites for planting them, these are rendered of no great consequence. During the very high winds that are experienced in Ceylon at the changes of the monsoons and at other times, a few stems are occasionally broken off, and the grinding, creaking, and clattering noises which go on overhead among the straining stems in windy weather are apt to alarm any one standing beneath.

I may add that in the view the river is the Mahawelliganga, which, by a bend, surrounds three sides of Peradeniya gardens, and on its opposite bank we get a glimpse of a coconut plantation. The little bamboo on the bank under the giant is the common small wild one of Ceylon, Beesha stridula, the "Bata lē" of the Sinhalese, but a poor specimen. The palm on the bank is a young plant of the common "Kitool," Caryota urens; whilst the small tree, only a portion of which is included on the left hand of the picture is the "Gadoomba" Trema or Sponia orientalis, a useless plant, and a good example of what the late Dr. Seemann used to call a "tree-weed."

I should add that I am indedbted for this photograph to Mr. Skeen, of Colombo, whose artistic taste has brought together a beautiful series of studies of tropical tree-forms, mostly taken in the Royal Gardens and the neighbourhood of Kandy.—H. Trimen.

"ALLEVIATION OF AGRICULTURAL PRODUCTS IN BRAZIL."

The attention of the press has of late been largely directed to a consideration of the measures needed to enable our greatest staple to withstand a competition which is yearly becoming more severe in the European and United States markets.

Of these measures there are some, such as improvements in growth, gathering, preparation and selection, which are within the power of the planters themselves; others, as the abatement of the debasing of the better qualities by mixing here with inferior ones, and the trade tricks of false nomenclatures abroad, are rather matters of commercial arrangement; but there is a third class, in regard to which action is sought from the Government. The excessive cost of internal transport, and the heavy imperial and provincial taxes upon the export.

It is in truth, undeniable that, thus burdened with excessive rates of internal transport, rates which, even on the railways, are tenfold those of European lines, and with 13 per cent export taxes, levied, not on the plantation value, but on the price at the shipping mart, the coffee of Brazil enters heavily weighted into the competition abroad, and that at home the limits of profitable production are injuriously narrowed.

The Government is asked, therefore, to abolish the imperial export tax, and to reduce the freight upon the State railways. Nothing could be more simple in thesis, but, unfortunately, the discussion has not yet reached the point of demonstrating the practical manner in which the relief is to be obtained.

In fact, the fiscal system of the State opposes itself to such a relief of agriculture, as 17,000,000 mils. to 18,000,000 mils. of the revenue is derived from the taxes on exports, and the reduction of the D. Pedro II. railway freight to half, which would still be four-fold the rates of European lines, would entail a further loss of revenue to about 6,000,000 mils.

It may be argued that the increase of production would in time compensate indirectly for the losses from these reliefs, by the augment of importation and of other sources of revenue. But there is no warrant for relief that the compensation would be realized before many years, and meantime it would be necessary to provide revenue from other sources to fill up the void. But from whence are these resources to be derived? Certainly not from the overtaxed imports, the bounds of whose taxable productiveness appear already reached, if not passed, importation tending to decline. Certainly not from any probable great increase in stamps or in the other items of direct or indirect taxation which figure in the estimates.

It is clear, indeed, that most, if not all, of the grave deficit caused in the revenve by even a partial remission of the export taxes and railway freights would have to be met by new direct taxation, and what that taxation is to be we have still to learn. But this is the x whose equation it is necessary to discover, and the solution is the more difficult to find as the taxes on exports, impolitic and anti-economic as they are, represent the only contribution to the State expenditure from the immensity of land held by individuals in Brazil.

It is true that the taxes paid by the producers who add to the general wealth, and furnish means for the support of the State, should rather fall on those

who neither cultivate their lands nor permit their cultivation by others, but this solution of the problem of relieving agriculture from unfair and impolitic burdens has not been in favour with our governments and parliaments, notwithstanding it is of the most evident advantage to the State to discountenance the conservation of the lands in vaste, and to stimulate their settlement and cultivation, affording homes to the abounding native proletariat, and solving the problem of independent immigration.

The question of lower railway tariffs is also unquestionably intimately connected with that of the settlement of the waste lands, inasmuch as it is the lamentable rarity of a producing and consuming population along them which renders necessary the extraordinary tariffs they maintain.

We indicate the difficulties which lie in the way of alloviating the burdens of agriculture in the hope that during the active discussion attending the presentation of candidates for the suffrages of the agricultural interest, it may be remembered amid the loudly-cried panaceas of hypothecary banks, Chinese labour, and the enserfment of native or foreign proletariats by laws of location of services, that cheap transport, abolition of export duties, the encouragement of immigration, and the general advance of the country in population, prosperity and power have their natural solution in that of the problem of obtaining the settlement and cultivation of waste lands, paying nothing to the State for its protection, contribution nothing to the general wealth, embarrassing the progress of every improvement, and spreading their enormous masses to the very confines of the maritime cities themselves.—*Anglo-Brazilian Times.*

THE LOSSES FROM TEA BLIGHT.

(From the *Englishman.*)

So far the year 1881 seems likely to be a good one for Tea, and those interested may be congratulated on the fortunate combination of circumstances that has led to this state of affairs. First, low stocks at home induced a rise in prices; this was followed by reports of a late season from the tea districts; the Indian crop also was of better quality than usual, and, to crown all, that from China was reported inferior. A rise in prices, and indeed a very great rise, was the natural result, though reduction of outturn due to finer plucking placed many estates so far behind that it was at one time a question whether even the high prices would save them from loss. Quantity however is being now made up in most places, and if tea does not fall heavily in value, the results of the season may be above the average. The importance of permanent causes of loss is, however, not diminished by this spurt of prosperity, and there is one matter of great moment that calls for the attention of all concerned in tea. We allude to the serious havoc annually caused by blight. This is often equal to a handsome dividend, and there seems so far to be no attempt to cope with it.

It is all very well for Government to send an entomologist to the Tea districts to study and report on the various insect blights. It is, no doubt, a step in the right direction to ascertain the times and seasons of their development, when and where the eggs are laid. Other enlightened Governments go a great way in this direction, and we should not be behind. We are therefore glad to see that Mr. Wood-Mason has been deputed for the work, and he no doubt will find out a great deal both useful and interesting, but that he will discover a cure even for one of the three most conspicuous of Tea blights, we very much doubt. A vast amount of time may be necessary to learn all about an insect, and when the knowledge has been attained, we may be as far off as ever from a cheap and certain means of exterminating it. The knowledge is the result of careful and prolonged investigation, whereas the cure (if there is one), is ten to one a discovery, the "happy thought" of some obscure assistant who has the matter in view, and tries it in the nick of time. Considering the enormous losses caused by each of the blights if bad, a loss estimated at some nine or ten lakhs of rupees per annum, it seems a matter for surprise that some steps are not taken by those most interested (*i. e.*, the large agency houses) to combine and offer substantial rewards for cures, or even such discoveries as may conspicuously mitigate the evil. Where the losses are so steady and so severe, the amount lost per annum might be well taken as that of the total prize found, in which case the interest of almost every planter would be at once enlisted in the matter, and experiments would become so general that the chances of discovery would be enormously increased. Practically the money value of a cure for "red spider" that would save 90 per cent of what is now lost by it, would be worth some R150,000 or R200,000, and that of a cure for the other blights not very much less; for both the "Tea Bug" (or mosquito) and the little "green fly" can, where bad, do equal damage.

There is much that Government can do in this matter of the study of blights affecting tea, but for the discovery of a cure the agency houses and proprietors generally should look quite as much to their own combined efforts to offer an inducement to the men who are specially qualified to watch and work at the task, but who now feel that, if they do find a cure, or even a means of conspicously lessening the damage and loss, they must keep such knowledge to themselves, or present a very valuable discovery to the world for nothing.

THE MANGROVE A FUEL PRODUCER.

(From the *Madras Mail.*)

A correspondent writes:—

The protective merits of sea-weed against littoral erosions have at different times suggested to those interested in the question the planting of mangrove trees along the banks of such of our tidal currents as evince a propensity, under certain conditions, to be eroded by the action of the stream. Nowhere in this Presidency, except at Masulipatam, have the good results of the plan been more manifest. Thirty years ago, the tidal stream that runs by the side of Masulipatam was subject to frequent inundations from the volumes of water that, under the appellation of *freshets*, sometimes changed the bed of the current and produced inundations attended with loss of property, and not unfrequently of life too as well. Mr. Rhodes, who was then the Judge of the district, conceived the happy idea of planting the whole length of this stream with seeds of the mangrove, and, under his immediate direction, measures were taken which resulted in the stream being confined very much to its own bed, and a provision for fuel being also secured at the same time that supplied the wants of the whole town. The mangrove—I cannot just now recollect its botanical name—is a capital fuel and fodder-supplying agent; and the cattle at Masulipatam take readily to its leaves. The branches are used as fuel, certain seasons of the year being chosen for the low jungles being cut down to a certain height and sold by auction to local merchants. A very extraordinary feature connected with the mangrove is that its seeds germinate while on the tree; they drop into the oozy banks and send up, with marvellous rapidity, a growth which, but for the measures taken to restrain

it, would be injurious to health by excluding the sea and southerly breezes from entering the Fort and town. Mr Rhodes remained long enough in India to see to how admirable an extent his efforts succeeded. The result of his experiments at Masulipatam suggests the carrying out of the same experiment at Negapatam and elsewhere, wherever the conditions exist which favored the Masulipatam experiment. I do not for a moment venture to hint at any exhaustion of the *Srihuricott* jungles north of Pulicat, from which our fuel supplies are derivable; but I still think that there are certain tracts adjoining the Buckingham Canal and the natural salt water lagoons which would favor experiments with the mangrove. Given an oozy bottom and salt water, and the mangrove attains a luxuriance to put to flight any apprehensions that exist on the ground of a failing fuel supply. Wood, every householder knows, commands prices now nearly double the rate at which it stood before railways and workshops employing steam-power came into existence among us, and the securing of a fresh source which would leave cattle dung and palmyra leaves to their more legitimate use ought to commend itself to all who watch with anxiety the impoverishment of the land by scarcity of manure. The necessity of increasing our fuel supplies is being brought home to us each day with increasing force. It is not necessary to point out how many thousands of acres belting our tidal streams are lying waste and unproductive, and which, if laid out in the manner we wish to see them done, would cheapen one of the greatest necessaries of life. The limit of the fuel-producing capacity of the country has been nearly reached; the fuel bearing acreage is now almost stationary, and perhaps decreasing; and prudence no less than duty requires that any system which proposes to deal effectively with an evil that threatens the comfort of thousands requires to be carefully examined. We shall have to fight a very uneven battle with the future, if a precaution now imperatively needed be delayed till worse evils come upon us.

THE ACTUAL COST OF MANUFACTURING TEA.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

DEAR SIR,—Though not a Darjeeling planter, I beg to set you right in your remark relative to machinery after "Pundeem's" letter on "The actual cost of manufacturing tea."

The garden is supposed to make 500 maunds of tea only; now machinery does not pay, I hold (except drying machinery), on a garden of only this yield.

Putting aside all the items referred to by "Pundeem," I will try and explain what I mean, by giving two estimates—one for machinery, and one for manual labour—for a 500 maund garden, and you will be able to see what I know as a fact, even mauy old planters never think of.

Hand rolling at 2 men per maund *leaf* at 3 annas per man=6 annas per md. leaf = R1-8 per md. tea.

We will say that a fair average all round through the season is 10 mds. leaf per day for a 500 md. garden, so we will deal with this amount.

Rolling 10 *mds.* = 3-12-0 at 6 aunas per md. for hand rolliug.

Rolling 10 *mds.* per machiuery costs 3 annas paniwallah, 3 annas wood-cutter (this is very low estimate), Engineer's pay R30 per month, for which he works in the year on an average only 3 months at most: we must multiply his daily pay, *viz.* 1 rupee per day by 4 (on account of only 3 months' work in year), which is as follows:—1/ × 4 = 4 / + 3 as. + 3 as. = R4-6. Again, we expend 9 annas for oil, and again wear and tear of machinery, but we will for simplicity leave this out, and we have the following:—

	R.	A.	P.
10 mds. rolled by hand	3	12	0
10 ,, ,, by machinery	4	15	0

The oil will be a constant loss all the year round, and for engine house repairs, sundry wear and tear, &c., also.

I now beg to shew how a 1,000 md. garden is benefited by machinery.

Cost of rolling, say average daily yield is 20 mds.—

20 mds. hand rolling at 6 annas per md. = 7 8 0

20 ,, machine rolling by above account = 9 annas oil, Engineer's pay = R30 per month; but he works 4 months (nominally), so we only multiply 1/ by 3 (or ¼ of a year), we then have 3/ + 9 as + 3 as. paniwallah, × 3 as. wood-cutting, = total of R3-15.

Please notice, that as the men required for attending to rolling machine would be the same in both cases, *viz.*, for 10 mds. as for 20 mds., these items cancel; when only 6 or 8 mds. leaf arrive daily: no need of a machine or engine.

Sylhet, August 14th 1881. A. C. J.

N. B.—I have never seen the above calculated or referred to, though many letters appear relative to hand-rolling *vice* machine, by old planters and Calcutta men.

P. S.—In additiou to the foregoing I beg to state that I have rather over-estimated the number of men required for rolling. I know that 1½ mds. good leaf can be easily rolled by 3 men, and I have seeu 1 md. rolled per mau, and have doue it, but paid 3 as. 9 pie to the man. W now have R2-5-6 rolling expenses for 10 mds. at 3 as. 9 pie per md. leaf, but even then if we cut Engineer's pay down to R12 per month, the hand rolling comes cheaper for the 500 mds. yield, as we have then Engineer's pay per day = 6 as. 3 p. × 4 = 1-9 + 3 as. paniwallah. + 3 as. wood cutting + 9 as. oil (this should be also multiplied by 4), as it has to be used even in the cold weather; but say we only multiply by 2, theu we have total of R3-1-0.—A. C. J.

TEA: A FEW NOTES ON CULTIVATION AND MANUFACTURE.

(From the *Indian Tea Gazette*, 3rd Sept.)

I lately drew attention to some facts regarding the natural time for pruning the tea bush, and will now teuch upon some facts regarding cultivation and manufacture.

I.—CULTIVATION.

The ordinary cultivation by the hoe reduces the outturn by an unknown quantity.

Loss incurred by "Deep hoeing."—Planters wonder how the outside branches of the bushes give over flushing and go to seed so much sooner than the centre of the bush. Oue reason is, that when the garden "gets a good hoeing," every feeding root of the plant, within reach of the hoe, is sliced off. To remedy this and increase the outturn, gardens may be dug with pickaxes in the cold season, and only scraped during the rains with hoes: or cultivated all the year round with digging forks, and so save the feeding roots as much as possible, while giving at the same time better cultivation.

Method of Terracing.—Old, as well as new, *tila* gardens can easily be terraced by aid of a triangle and plummet, which would enable the soil to be cultivated without loss by hoeing; the loss by wash is small compared with the loss caused by hoeing the surface soil off the tilas iuto the swamps below, leaving the plants ou the bare faces of the tilas without nourishment or cultivation.

II.—Tea Manufacture.

From the following report on a challan of tea, valued in London at 1s. 3½d., in October last year, when prices were low, it might be that there is an *unnecessary amount of technicality in the manufacture of tea* as carried on at present. The challan of tea was characterised as "rather strong, rather brisk, and shows an improved quality of liquor."

System of Plucking.—The usual two leaves and a bud were plucked in one piece, *i. e.*, a full grown soft leaf, a half grown leaf, and the tip, and were manufactured in the following way :—

Withering Process.—The leaf was thrown on mats on the floor, &c., of the leaf house a few inches thick, and was turned over several times during the day and night, and then put in the sun next day, as required for rolling, till the leaf only became limp : in the absence of sunshine the leaf was softened in the chulas, while the stalks were yet brittle.

Rolling and Sifting.—The leaf was half rolled, and as much of the finer tea as broke off was sifted out with a half inch mesh sieve and manufactured separately ; the unbroken leaf was rolled and again sifted.

Fermenting Process.—In the course of these rollings and siftings, the leaf, by exposure to the air in a cool rolling house, assumed a pinkish reddish colour, and was then put over the fires to dry. By this process there was no nice discrimination required to catch fermentation at a proper stage.

Advantages of the method.—Tea manufactured in this way gives nearly the same liquor day by day, because it does not depend on any of the critical chemical periods incidental to fermentation. The quantity of Pekoe kinds was in excess of the usual amount, and these teas were not deflowered by breakage after manufacture, but the Pekoe Souchong would have been better of the rolling force of machinery.

The Hybrid and China varieties of tea grown in India, as manufactured by this simple process, suits the requirements of the brokers as to colour of infused leaf, &c., and are fit for being drunk pure. Might not some such tea be more suitable for the new markets than fermented teas, which require to be mixed with China tea to make them palatable? A pinch of tartaric acid, say ½ tolah weight, dropped into a tasting cup of the planter's morning infusions, will cause a deposit of the tannin, and may perhaps show the strength of the tea.

John Tod.

Silchar, 24th August 1881.

VEGETABLES FOR THE TROPICS.

(From *Sutton's Tropical Garden Guide.*)

Artichoke, Globe (*Cynara Scolymus*).

Even as an ornamental plant this is very beautiful. The silvery whiteness of its leaves renders it very striking. The soil should be dug fine about 2 feet deep, plenty of liquid manure should be given as soon as the plants are fairly started. Sow in June in a pot, and plant out when about a foot high.

Asparagus (*Asparagus officinalis*).

Sow in August or September, and till rains are over give shelter to the seed gumlahs, which should be formed of loose, rich, and mellow earth. A good method of planting out is to dig round holes about 2 feet deep, fill in half with good leaf mould and compost, then plant the roots carefully, and gradually add mould as the roots grow until up to surface of surrounding soil. Let the foliage grow as strongly as it will, and water until the rains set in. No shoots should be cut the first season, but when the stems die down and become quite decayed in March, a good dressing of manure should be applied to the roots by removing the upper soil. Plentiful watering after this will ensure fine heads during April.

Beans, Broad (*Faba vulgaris*).

Sow about the middle of October. Before planting immerse the seed in warm water, and allow it to soak for some hours. If this precaution is not adopted the thick rind will often prevent germination. To prevent the bean-stalks falling about, it is well to plant them in double rows 4 inches apart, with 2 feet space between the double rows. It is sometimes desirable also to nip off the top of the stalk when three parts grown, otherwise it will often go on flowering without setting any pods. It is well worth while to sow the seed in seed-pans, and transplant into the open ground. This method brings the crop a full week earlier, and ensures a good crop.

Beans, French (*Phaseolus vulgaris*).

Of these there are two classes—runners and dwarfs—used in England. In the tropics, however, the dwarfs alone are useful, as the runners grow so rapidly that they will not set their pods. The dwarfs also are more convenient, as they require no sticks. Sow for early crop the beginning of October, and continue to do so every 14 days for succession. The beans should be sown about 1 inch deep, in rows 2 feet apart. The spot selected should be shady and cool.

Beet (*Beta vulgaris*).

This delicious root is well adapted for cultivation in India and other hot countries, and is perhaps the most universally used of all European vegetables. It is best to sow on land which was heavily manured for the previous crop. The end of September is the best time to commence operations by sowing in drills 1 foot apart. When plants are well up, single out to 8 or 10 inches apart in the rows. Unless the young plants are well protected with nets, not a single one will escape the ravages of the sparrows. At the beginning of November a second sowing may be made with advantage. Give plenty of water and liquid manure. Small handsome roots are better than large coarse ones.

Broccoli (*Brassica Botrytis asparagoides*).

This is easily cultivated, and can be grown to great perfection. The soil should be trenched 2 feet deep, and a good supply of manure should be given. Dung of horned cattle is best, but nightsoil is excellent. Grow only the white varieties. The ground should be laid out in beds for irrigation. Sow any time during the rains, but the possibility of the plants being eaten up by insects during July and August makes it advisable to differ sowing till the beginning of September. Sow thinly on a bed of finely prepared soil, and when a few inches high transplant 30 inches apart. Water should be freely given about once in four days during dry weather.

Brussels Sprouts (*Brassica bullata gemmifera*).

This is a very delicate vegetable, and thrives well in India. The treatment should be the same as for cauliflower.

Borecole (*Brassica acephala sabauda*).

A very hardy and excellent vegetable ; highly ornamental. Sow same time and in same manner as cabbage.

(*To be continued.*)

ROYAL BOTANICAL GARDEN, CALCUTTA.

(*Extracts from the Report for 1880-81 by the Superintendent, Dr. Geo. King.*)

Rheea.—A large patch of ground is still, by desire of the Government of India, kept under rheea for

the purpose of supplying roots to persons who may wish to undertake the cultivation of this fibre. The prices which have on two occasions been offered for machines to clean rheea fibre have hitherto failed to create much interest in the matter in commercial circles in Calcutta, and the native zemindars are for the most part disinclined to meddle with new and unfamiliar cultiva ion. For reasons stated in my last report, I am not however sanguine as to the possibility of rheea cultivation becoming a commercial success in Bengal; and I am not sure that the caution of commercial men and zemiudars in this matter is altogether to be reprobated.

Paper materials. –In compliance with an order of Government which I had hitherto been unable to carry out, I deputed the Curator of the garden during the cold weather to examine the long grasses that grow on the banks of the Adjai and Damooda rivers with the view of testing their suitability as materials for paper fibre. Mr. Pantling was absent on this duty for some weeks. He made a careful examination of many miles of the banks of both these rivers, as well as of those of the Brahmaputra between Chilmurree and Goalundo. On all three rivers Mr. Pantling found the prevailing grasses to consist of the three species of Saccharum known as *S. spontaneum*, *S. Sara*, and *S. fuscum*, the vernacular names of which are respectively *kashee*, *sara*, and *khuree*. Each of these grasses forms a stout reed from 5 to 10 feet high, and having a rather thick hard stem. This stout hard stem being quite unsuitable for paper-making, only the leaves and the leaf-sheaths can be taken into consideration. Fortunately I was able to show these materials to a gentleman connected with one of the largest firms of paper-makers in England, who came to India during the past cold weather for the express purpose of finding out what can be obtained from India in the shape of a paper fibre. The cost of collection and freight being taken into account, this gentleman's verdict was against all three fibres. At my request the Commissioner of Orissa was good enough to send me further supplies of some of the wiry grasses of the coast; but the same objection holds to all these, namely, that the proportion of hard, useless stem is so great as to preclude them from consideration as practicable sources of paper fibre. Something has been done in Burmah in the way of carrying out Mr. Routledge's proposals for the utilization of young bamboo shoots as a source of paper fibre; but as yet no very satisfactory results have been arrived at. As Esparto and Alpha grasses, at present so largely used in the manufacture of paper, are rapidly becoming scarce and dear, the necessity of some substitute for them is daily becoming more pressing. My own opinion is that, of Indian fibre-producing plants, the plantain is the one which promises best; and I think some attention might be well spent on its utilization. *Baobab* has been proved to be too slow of growth, and *Malachra capitata*, which has been recently suggested, does not seem to promise much.

India rubber.—The Ceará rubber-trees (*Manihot Glaziovii*) continue to grow vigorously, and a few of them are now beginning to yield seed. The demand for young plants and for the seed of this species continues to be considerable; and of all the recently-imported rubber-yielders, it is the only one that promises any kind of success in this part of India. The Pará rubber (*Hevea*) and the Madagascar rubber vine (*Vahea*) have utterly failed. Of *Urceola elastica* and *Castilloa elastica*, two well-known South American rubber-yielders, I have not hitherto been able to get more than two or three sickly plants. Of the great rubber creeper of the East African Coast (a species of *Landolphia*) seeds have—thanks to the kind exertions of Dr. Kirk, Consul-General at Zanzibar—been received at the garden, and some of them have germinated. But I fear, even if it were to turn out to be suited to the climate of Calcutta, *Landolphia* would prove rather an unmanageable crop, for it is described to be an enormous creeper, climbing to the tops of the highest trees. With regard to all these exotic rubbers, it must be remembered that (with the exception of Ceará) they are either very large trees or climbers; and although it may pay well to collect rubber from them in their native forests where they have grown to maturity without cost to the collector, it is quite a different matter when their planting and protection have to be paid for, and their coming to maturity has to be awaited for years.

Other economic plants.—The locust bean or carob and the various kinds of *Eucalyptus*, of which the cultivation was pressed on Government, have been tried for years, and have all been found totally unsuitable to the soil and climate of Bengal. They may now, I think, cease to be reported on; so also may be baobab as a fibre-yielder and *Prosopis pubescens* as a cheap source of tanning material. Mahogany and guango or rain-tree are two exotic trees which really grow well in Bengal, and for which the demand is steady. Arrangements were therefore made some time ago for regular annual importations from Jamaica of seeds of each. Last year, however, all the mahogany seed received from this source was quite bad.

SANDAL-PLANTING IN MYSORE.

(From the *Indian Forester*, July 1881.)

Looking at planting in its two aspects—of the production of strong healthy nursery plants, and of getting these planted out so that there shall be no interruption of growth—sandal-planting is not an easy operation. The seed, a ball of soft, sticky, albumen, the size of a pea, in a fleshy fermentible pericarp, is very liable to go bad; but in ordinary soil it germinates with difficulty, so much so that it was supposed at first that the seed required, as in nature, to pass through the intestines of birds or animals; but here it was overlooked that a bird's gizzard would be certainly destructive to the seed, and the digestion of animals most probably so, while it is a matter of observation that sandal comes up naturally in many places where there are no animals to help it. It is a fact that soaking the seed for one or two days in a mixture of cow-dung and water has been found to hasten germination; but this is observable in other seeds. The difficulty of getting sandal to germinate in the early days of forestry may be put down to bad seed and ignorance of the way to sow it.

As soon as the young sandal has come up its troubles begin: at first, during the rains, with a species of rot in which the root may be observed attacked by a fungoid looking growth. The leaves turn yellow and drop off from below upwards, and the sandal seedling appears as a little stick with only the terminal bud left. It the attack is mild the plant makes fresh root growth, and the terminal bud new leaves; but if not attended to, plants perish very rapidly in this way. I have seen a nursery of 20,000 seedlings destroyed in ten days during heavy rain. The remedy is drainage. The foresters, as soon as the disease appears, "lift" the tile-pots, taking them out of the beds and standing them on one side, high and dry, with the air playing round the pots. When the heavy rain is past the tile-pots go back into the beds.

During the monsoon, to some extent, but more usually afterwards, many plants are lost from grubs eating the fleshy cellular portion of the tap-root. Sandal has a tap-root like a miniature radish, and it is attacked in the same manner as that and other fleshy roots.

These dangers past, it was observed in the early nurseries that something was wrong during the dry season. Here and there was a plant growing *à merveille*. One thought with horror of its tap-root for the next planting season. Elsewhere, in odd corners, a few plants pushed on steadily: the generality looked pinched and miserable, in different soils, variously manured and properly watered. When the planting season arrived there was a small proportion of good plants left; and yet, was it not worth planting sandal even on these terms?

The remedy for bad germinations and subsequent poor growth in the nurseries has been found in humus, or the nearest thing to it, in the way of a vegetable manure, which the climate produces. The seed is sown on the tile-pot beds just covered with a mixture of sand and leaf manure. From then, till the plants are transplanted, a year afterwards, the beds are kept constantly *covered* with old leaves, dead grass, or any litter at hand. The leaves and litter, if properly watered, decay rapidly and require to be replenished at intervals of a few weeks. Last year this plan was tried in a few nurseries, and gave good results where persistently carried out. But it raised opposition; to the careless it gave trouble, to the neat it looked very like a messy craze. During the present season it has been followed in 17 nurseries, in different hands and in different parts of the country. It is easy to account for its beneficial effect: as a matter of observation it leaves nothing to be desired in the appearance of the nurseries. The portion of each nursery under sandal is shaded with boughs so as to afford a broken half-shade similar to that in which sandal comes up naturally in thickets and hedges. Each tile-pot now contains a bunch of fine plants with the rich dark foliage of healthy sandal. There are this hot weather (1881) above a lac of tile-pots stocked with sandal, and in many nurseries it would be difficult to find an empty pot.

Let us pass now to the planting out and management of the tap-root. In young plants the tap-root is usually longer than the height of the plant above ground. It is very sensitive to injury, and this was the cause of the failure of the early attempts to plant sandal. If cut so as to only remove two or three inches, *leaving ten inches above perfectly undisturbed in its pot*, the plant will usually die. The plan now adopted to keep the tap-root of manageable size is to have a layer of bits of broken tile strewn so as to lie flat at the bottom of the tile-pots, much as one pots plants in a flower-pot, and doing so may be presumed to afford the same advantages in the way of drainage. By this means the tap-root is stopped growing down more than ten inches, the depth of the tile-pots; it divides and accommodates itself within the tile-pot; lateral roots develop, and we obtain a form of root suitable for planting.

Transplanting begins as soon as the ground is thoroughly moistened by the first rains; it takes usually about ten inches of rainfall to do this. The tile-pots are lifted, walked away to the newly-filled pits. One tile is gently removed and the cylinder of earth and root resting on the other tile slipped into the ground. The earth is filled in, and the remaining tile, gently pushed back from the roots it has protected and confined during the last year, is pulled out, and goes back with the return coolies to the nursery to be re-set, and begin its work again. Watering should be stopped in the nursery a day or two before the tile-pots are taken out, so that the earth cylinders may be as hard as possible, and the transplanting rules provide for a little watering, for a day or two after the plants are put out. It is worth noting that the best planting—the minimum of root disturbance—is during the driest weather (for the season) a curious adaptation to the weak point of the climate.

Some one may ask why not use flower-pots instead of tile-pots. In the first place flower-pots are more expensive—all potters cannot make them; and, secondly, many of the advantages of tile-pot nurseries would be lost. *i. e.*, the shape of the tile-pot cylinders giving roots with the maximum of depth and the minimum of width—the compactness of the nurseries and consequent saving of water for each bed is a honey-comb of 100 tile-pots in a space of 50 inches × 50 inches—the case with which the tiles can be removed from the cylinders of earth and used again in the nursery next year. The system of planting from tile-pots has been already described in the pages of this journal. In Mysore, during the past season, two and a half lacs of plants were put out from tile-pots at a saving of fifteen rupees per 1,000 plants. Of this, 5,000 odd was sandal, and the percentage of hot weather failures among the sandal was 35 per cent. It must be remembered that this was the first year of sandal-planting on a large scale, and this figure will probably be much reduced in the future. As usual, nothing was spent on watering or weeding after the plants were put out. Repeated failure is not a very serious matter on these terms; R5-8 per 1,000 plants represents the cost.

Each tile-pot contains usually more than one sandal plant, sometimes as many as half a dozen, depending on how the seed comes up.

There is thus a survival of the fittest for rot, grubs, and the first hot weather to work on; and then, when space is required for growth with the first monsoon after planting out, all but the best plants in each pit are cut out.

A word in conclusion about sandal plantations elsewhere. We have heard about those of Madras, and would be glad to learn more: their forest reports always late, have latterly not been sent to Mysore. It is believed that the plantation on the Neilgherries cost considerably more than R30 per acre of 500 plants, and that that near the Cauvery falls is really *in situ* sowing with a suggestion of English ploughs and elephants—costly enough, and impossible for work among hills or in existing forests. R30 per acre of 500 plants is now the maximum cost of planting in Mysore, but it is hoped that sandal may do with pits 2 feet instead of 3 feet cube, and then the cost of planting will fall to R16 per acre of 500 plants.

Sandal-planting has been begun, I believe, in the Nizam's Dominions and in the Central Provinces, of both of which places seed has been sent from Mysore. There are some sandal plants now growing in the Botanical Gardens, Brisbane, from Mysore seed. Possibly the existence of frost may mark the northern limit at which sandal can be profitably grown in India. A specimen of sandal from the Nizam's Dominions, compared with Mysore wood, showed a denser structure, and was nearly scentless; but no particulars of the elevation at which it was grown were received. Probably good sandal could be grown anywhere in Southern India between 1,500 feet and 5,000 feet elevation, and a moderate rainfall. The higher limit would be approximately the climate of Brisbane: below the lower in Mysore, the trees looks straggling and forced, but it does not matter. There is now in the Bangalore Museum a log grown fully scented, which was found growing on the banks of the Cauvery at only 1,200 feet elevation. There is a large trade in sandal between Penang and China, which began above 44* years ago. Example

* Forty years ago the sandal wood trade reached a development which is accounted for by the high value attached to this wood by the Chinese. Speculators fitted out ships and cut down the forests of the Malabarian Islands. The natives naturally resented this devastation. They were answered by the rifle.

of Western Australia find it pays them better to export sandal at £7 a ton than to till the ground, and the sandal trade has been credited with atrocities in the Southern Ocean and with the present backward state of Western Australia. This wood, however, is inferior stuff. Indian sandal stands as far above all other kinds in the China market as does Indian opium. It is stated that the profits of the middlemen are enormous, and that £200 a ton is a common price for first class Indian wood in China. Be this as it may, is there any other wood in the world which will fetch a *steady nett* price at the place of production of £45 a ton?

KAD-HANDI.

MAIZE.

(From the *Indian Agriculturist*, 1st Sept. 1881.)

This cereal is second only in importance to rice. It is grown largely throughout the American continent, from Canada in the north to Patagonia in the south: throughout the islands of the Pacific, in the West India Islands, in Australia, throughout the whole of Africa, in Spain, Portugal, Southern France, Italy, Hungary, Turkey, Greece, Asia Minor, Persia, Central Asia, India, China, and the islands of the Indian Ocean. To use the words of the author of *Tropical Agriculture*, "no grain could secure such favours from all parts of the world, except from its intrinsic value. Its flexibility of organization makes it easy of adaptation to climate and soil. Though it prefers moist and rich soils with strong heats, there are varieties of it which can be raised in tropical climates at a height of more than 9,000 feet above the level of the sea. The warmest regions of the Torrid Zone produce maize in abundance where three crops can be taken in a season, while the short summers of Canada have a variety suited to them. This cannot be said of rice which requires great heat and cannot endure a climate of a high latitude."

The uses of Indian corn are numerous. It serves as food for nearly one-third of the human race. As a fodder for cattle, horses, sheep, swine, and poultry it is invaluable. The dried cobs and stalks serve as fuel, and in South America a kind of beer is largely distilled from the corn.

In Germany, Austria, and Hungary, a very superior kind of paper is made from the leaves and sheaths of the cob, and it is to be hoped that the day is not far distant when English capital will be forthcoming with a view to establishing this industry in India. "Maize paper" has none of the brittleness peculiar to ordinary straw paper. Maize paper appears to be the most unexceptionable of all the papers *not* made from rags. Not only is it remarkably tough, but it is devoid of all the silicious matter which proves so embarrassing in ordinary straw paper causing great brittleness when folding and rapidly destroying the face of printers' type. The extreme toughness of the paper makes it particularly eligible for bank-note paper, and for the purpose of envelopes. The colour is somewhat yellowish, but it is easily bleached.

In India, maize is a summer or *kharif* crop. Where irrigation is available it is sown in May or the end of April, but otherwise not until the monsoon sets in. After the first showers of rain, the ground is ploughed up, the surface of the soil being scarified by a native plough. Manure insufficient in quality and quantity is ploughed into the soil, and the seed sown in parallel rows about one foot apart. A heavy beam of wood called a *sowga* drawn by two bullocks is passed over the field to close the furrows, and the seed is left to its own devices. As soon as the plant has attained a height of about five or six inches above ground, the field is hand-hoed; this operation being repeated twice or thrice. About the beginning of October the crop is cut, and large sheaves are heaped up all over the field, after standing for a week or ten days the cobs are broken off, the stalk and the grain *shelled*. The native method of shelling is truly barbarous; three or four men sit round a heap of the cobs and beat the heap with short heavy sticks, an immense amount of grain is thereby lost and damaged. The average yield seldom exceeds 25 to 30 maunds per acre. The amount of seed sown does not fall short of 28 lb. per acre.

In Algeria the main yield on unirrigated land is 20 cwt. per hectare (2·471 acres), whereas in American maize cultivation has attained its highest development, an ordinary crop is 60 bushels and 100 bushels, or 75 maunds is not an uncommon yield. 130 bushels or 7,800 lb. per acre have been raised.

The New York State Agricultural Society require a yield of 80 bushels of corn to the acre to be entitled to a premium.

The results of two experiments on the Saidapet Model Farm are herewith given.

No. I.

MAIZE EARLY AMERICAN.

General nature of soil	Sandy loam.
Area of land sown	2·83 acres.
Cultivation of soil before sowing...	Twice ploughed, harrowed and ridged, and again ridged over manure.
Kind and quantity of manure used	42 loads of farm-yard dung.
Pounds of seed sown	181 lb.
Date of sowing	21st September.
Cultivation during growth of crop	Twice hand-hoed.
Rainfall and number of wet days recorded during growth of crop..	31 wet days, 24·00 in.
Date when harvested	29th December.
Number of cobs	7,390.
Weight of straw when dry ...	5,824 pounds.

The foregoing, it must be remembered, is the produce of only half the ground, as the maize was sown in lines alternately with lines of cotton.

The weight of manure is not given, but allowing 20 maunds per load, it would be a little over 10 tons per acre.

No. II.

MAIZE "YELLOW FLINT."

General nature of soil	Sandy loam.
Area of land sown	1½ acre.
Cultivation of land before sowing	Ploughed, harrowed, and ridged.
Pounds of seed sown	19 pounds.
Date of sowing	25th September.
Cultivation during growth of crop	Twice hand-hoed.
Rainfall and number of wet days recorded during growth of crop	31 wet days, 24·00 in.
Date when crop was harvested ...	5th January, 1876.
Number of cobs	4,050.

The remarks made with reference to the area of land actually cropped apply equally to both experiments.

Professor Symmonds enumerates seventeen varieties grown in North America. "They may be distinguished by the number of rows or grains on the cob, and the size, colour, shape, &c., of the kernels." He

---

In 1842 the crews of two English vessels landed at Sandwich Islands, one of the most luxuriant in the Archipelago of the new Hebrides. The Islanders, when resisting the destruction of their woods, were set upon by the whites, who killed twenty-six, and driving a great number into a cave, suffocated them with smoke till not one remained.

evidently gives the first place to "Golden Sioux" or "Northern flint corn," having a large cob with twelve rows of moderate sized grains very oily. This is regarded as one of the best varieties for fattening animals or for human food. By skilful tillage 130 bushels have been raised to the acre weighing 9,216 lb. in the year; when dry, 75 lb. of ear gave a bushel of corn shelled. The soil best suited is a light sandy loam. clay is not good. The following is an extract from a letter from a gentleman, a planter in Natal, on the subject of maize cultivation :—

"The kind of maize we prefer out here is that known as the 'American Horse-toothy Mealy.' With proper cultivation we can easily raise as much as 70 to 75 bushels per acre, and the meal produced is excellent food for both man and beast. We go in for deep ploughing and liberal manuring. The rows of corn are struck out 4'-6" to 5' apart, and the plants 12" to 15" apart in the rows. As soon as the plants appear above ground, say 6 or 7 inches, we give them a top dressing of ashes and lime or superphosphate,* heaping a little earth round each plant, and converting as it were the surface of the field into so many small hillocks. We then run a horse hoe between the rows keeping the land free from weeds, and the same time preventing the soil from caking or hardening. We do this about two or three times. In about ten weeks the crop shows sign of maturing, and is generally off the ground in about 90 to 100 days from date of sowing."

With regard to maize cultivation, Professor Symmonds gives the following hints :—

"After thorough preparation of the soil by deep and subsoil ploughing, and the addition of such amendments as analyses may prove to be necessary, the corn should be planted out at slight depths in *hills* 4 feet apart in every direction, which will admit of more thorough cultivation in both directions than if planted in rows. I cannot but suggest that in the final preparation of the soil before planting, it could be better to run the subsoil plough at a full depth in sticking out the rows; this having been done in both directions, will leave the intersections visible for the planting of the corn From the peculiarity of this plough the soil will be left in a more divided condition than if turned over by the surface plough alone. In these intersections the corn may be planted. When three inches high, the lifting subsoil plough which will affect the soil at the surface for two feet on each side of this line of travel, should be run in one direction half way between the rows of hills, thus disintegrating the soil in the centre to the full depth, disturbing it at the surface to the very plants, gradually lessening as it approaches them, so that none of the young roots are abraded by its action. It will now be seen that immediately under the corn is a deep disintegration readily accessible to the roots, while the space between the hills is thoroughly pulverised and deepened as it recedes from the hills, so that the roots will not be inclined to travel surface-ways. At the proper time for a second ploughing, the lifting subsoil plough may be run in the opposite direction half way between the rows, thus rendering the soil pulverulent to a great depth at a later stage of the growth. The after cultivation may be conducted by the universal cultivator set the whole width of four feet, or so near it, as not to disturb the plants, and to such depth as will keep the entire surface free from weeds and open for the admission of the atmosphere. The running of this cultivator once in each direction will be found to be more efficient than the ordinary use of the hoe, and at the same time securing flat cultivation.

"At the first application of the cultivator or lifting plough, stimulating manures may be applied to each hill with safety, and we have known many instances where 100 bushels of shelled corn per acre have been produced by the application of two ounces of improved superphosphate of lime to each hill at the first hoeing or first cultivation. The result seems to be larger when stimulants are thus applied, than when placed in the soil before planting. Indeed when guano or any other stimulating manure is used, it should be at the first disturbance of the soil after the corn is above ground rather than before the planting of the seed. Some growers prefer to plant the corn in hills as already named running a *Universal Cultivator*, with the two rear share-teeth reversed between the rows when the corn is three inches high. This throws a light furrow from each row, in which special manure may be applied; a small subsoil plough should then be run with the flat side towards the corn, the wings of the plough removed, so that the lifting action of the nose will only be applied to the soil. This should be repeated on each side of the row so as to disturb the soil to a depth of ten inches before the roots are sufficiently grown to be abraded, and this loosening will thoroughly mix the manure with the soil. The rear teeth of the cultivator may then be reversed and run again between the rows so as to replace this narrow furrow, leaving the soil flat. In place of a second hoeing at the usual time, the horse-hoe may be run in the opposite direction, clearing the ground of weeds and leaving the soil clean and pulverulent."

The high yield and general excellence of American maize may be ascribed to :—

I. Careful selection of seed.

II. Judicious and complete preparation of the soil previous to planting the corn.

III. Deep ploughing and careful after cultivation, such as elimination of weeds, &c.

IV. Liberal manuring with organic manure followed by top dressings of mineral manure.

In Indian agriculture these conditions are conspicuous by their entire absence.

Selection of Seed.—Obviously the best method is to select the best and healthiest plants in each field, and from these plants take the largest and best filled cobs, two or three years' careful selection with even the most *degenerate* country-seed would result in a quality (provided all other conditions be maintained) bearing four, five, and six cobs to each plant.

Preservation of Seed.—The natives of this country do not attempt to keep their maize seed in store more than one year, and during this time it is kept *on* the cobs, and the cobs covered with ashes in earthen air-tight vessels—to prevent insects and ants attacking the grain, the months and covers of the vessels should be smeared over with carbolic acid.

Mr. Robertson, Madras Agricultural Department, suggests that "to prevent crows and squirrels, &c., destroying the seed, tar it before sowing. Take 1½ pint of water, 1/12 pint of tar mix together, and when cool pour the solution over the seed. After dusting sand, ashes, or sawdust, to prevent the seed adhering together, the grain is ready for sowing."

Ploughing and Cultivation.—The best plough for India is the Kaisar, and the changes which have been rung on it by different patentees in various parts of the country. The Kaisar, the Ryot, the Kasthkar, &c., are all modifications of M. M. Ransomes Sims and Head, primitive and Egyptian ploughs costing in England about £1-10. The patentees have, however, modified their inventions to suit the requirements of the ryot and his cattle, they give a deep tilth with a light draught and are very effective, tearing out weeds, roots, &c., with great ease. This form of plough varies in cost from R5-5 to R9. Five or six

* Note.—In the last report on *rabi* operations, Cawnpore Farm, full information is given as to cost and mode of preparation of superphosphate.

ploughings with this implement is equal in effect to twenty grubbings with the best native plough.

Constant and repeated weeding is required for maize. Maize should get at least 20 tons of farm-yard manure per acre supplemented by about 2½ to 3 cwt. of mineral manure applied as a top dressing after the first hoeing and previous to ridging up with a ridging plough. A ridging plough with double mould board on the principle of the "Kaisar" can be made up for R9.

Good bone dust manure costs about R7-5 per maund, varying of course with the price of sulphuric acid, which in Upper India is seldom less than 8 annas a pint. A mixture which has been found to answer remarkably well consisting of wood ashes, bone dust (calcined bones) and common salt in the ratios of 6-3-1 respectively, is much cheaper (about R4 per maund): though not so powerful fertilizer as if composed solely of bone dust. The bones are calcined then pounded, and afterwards treated with sulphuric acid and hot water; wood ashes and salt are then added and the substance fit for use. About two ounces of the manure to each plant will produce excellent results, four, five, and even six cobs to each shoot.

With careful cultivation and judicious treatment, the Indian species would soon exhibit the excellence of the American maize or South African mealy.

The cost of cultivation and produce per acre, would, in the hands of an intelligent cultivator, approximate close to the following figures:—

Cost of cultivation,

	R.	A.	P.
Government Revenue	1	0	0
Seed 20 lb.	0	8	0
Manure 20 tons	12	4	0
Ploughing, ridging, weeding, and after cultivation	10	0	0
Harvesting crop	10	0	0
Mineral manure 3 maunds @ R4 per md.	12	0	0
	45	12	0

Value of produce.

Grains 60 maunds at R1-5	90	0	0
Straw fodder 120 maunds at R0·25... per maund	40	0	0
	130	0	0
Balance in favor of cultivator 130 minus 46=	84	0	0

Attempts have been made to introduce the American varieties into this country, and not without success: though it could be as well to bear in mind that one or two years of rational cultivation would soon bring the native maize in point of excellence up to the finest imported species. One of the greatest mistakes made and *the* rock on which most agricultural experiments in this country have split, has been the attempt to introduce and force upon the natives, foreign species at the expense of the indigenous staple.

Mr. Fuller's experiments with fodder crops at Cawnpore have shown that the sorghum only requires careful cultivation to equal, if not surpass the once far-famed *Teosinte* or *Reana Luxurians* according to Mr. Fuller, reana cannot hold its own with "sorghum."

When these foreign species are introduced and distributed to intelligent natives, it is seldom that precise and accurate directions are given as to the method of cultivation, or if instructions are given no native would for one instant dream of carrying them out, the consequence being that with shallow cultivation and deficient manuring, the highly organised species degenerates at once, and the much talked of *Valaiti Tukhm* is found on developing into a full grown plant to yield a produce little superior to, if as good as the ordinary country staple, and the native never dreaming or caring to admit even that the fault was *his*, for the future, discredits the imported seed, and "will have none of it." Every Indian staple, maize, rice, wheat, sorghum, sugar, and cotton, one and all under a system of rational cultivation, can be rendered capable of the highest development, and that in a relatively short space of time. Let the new Department of Agriculture bear this in mind, using its best endeavours to attain this end, and an agricultural reform of great importance will then have been effected.

25th July 1881.

SERICULTURE is progressing steadily in the United States, under the care of the ladies who have taken it in hand, and at a recent meeting in Philadelphia they were enabled to announce that the culture of silk had at last become a promising and profitable industry. Trees and cuttings of mulberry have been sent out to 15 States, and eggs to 20, and a firm of silk merchants has offered premiums amounting to 500 dollars for the best pound of cocoons in the different classes. The climate of the United States is so diversified that it will be strange indeed if some locality is not found as well adapted raising silk as Japan or India. —*Sydney Mail.*

NEW PATENTS.—Amongst the many patents lately taken out, we note the following inventions, specifications of which have been filed under the provisions of Act XV. of 1859 in the office of the Secretary to the Government of India in the Home Department:—

No. 63 of 1881.—George Archer, Tea Planter of Darjeeling, in British Sikkim, for drying tea, coffee, cinchona bark, and other vegetable products, named "The Vacuum Stove." No. 69 of 1881.—James Macbeth Robertson, Tea Planter, residing at Arcuttipore Tea Estate, Cachar, for drying or roasting tea leaves, entitled "The Typhoon."—*Indian Tea Gazette.*

BRAN OR GROUND FEED is best fed to cows, upon moistened hay, it being mixed with the hay all will be eaten together and raised and masticated. But if it is not fed with cut hay, it should be fed dry and in a small quantity each time, for if fed alone it is not raised and re-masticated, but goes on to the third and fourth stomachs. If fed in slop it is swallowed without any mastication, and mixed with little or no saliva, but it fed dry it cannot be swallowed until it is mixed with saliva, and the saliva assists in digestion. When food is masticated the act of rumination causes the saliva to flow and mix with food. We have experimented, and find that when fed alone dry ground feed is better digested that when fed wet. —*National Live Stock Journal.*

THE SUPPLY OF CINCHONA PLANTS.—This season has not been equal to the demand. Planters have enquired in all directions with only partially satisfactory results. In Ceylon stumps are in favor, and more than one correspondent of the *Observer* recommends them as preferable to plants, which sometime die down in patches wholesale in the most unaccountable way. The roots should be trimmed with a sharp knife, and the stumps cut off about 8 inches above the roots before planting. A planter in Wynaad has assured us that a device of his to supply a deficiency of plants has answered admirably. The plan was as follows:—He trimmed off the lateral shoots on the young planting of the previous year, and removing all but the two tenderest leaves at the tip, but in cuttings into the pits in some cases two to each and others three. The cuttings were put down before the monsoon, and the following year he found that most of them had struck root and were in excellent condition. In some cases both, and in many all three, cuttings had rooted. We commend the plan to those who have failed to secure a supply of plants.—*South of India Observer.*

CINCHONA IN BOLIVIA.

In the *Proceedings of the Geographical Society* for last month, there is printed a paper on Eastern Bolivia and the Gran Chaco. I make the following extract with reference to cinchona from it, as likely to be of interest to your readers :—

"The cinchona plantations are at a height above the sea from 1,300 to 6,000 feet, and are formed, to some extent, with the young plants from the forest, but chiefly from seed, the small plants being transplanted, when three to four inches high, to the bottom of holes six feet apart and some six inches square by a foot deep, the month of the hole being covered by a piece of bark : the young plant is thus protected till it reaches the surface level, when the bark is thrown off, and it is able to bear the force of the sun. A year and a half from the time of the seed being sown, the plant attains a height of six to seven feet, and at the age of six years the trees are cut, each one yielding some 5 lb. of dry bark. The cost of forming a plantation of upwards of 50,000 plants a year old may be calculated at the rate of 2½d per plant.

"The bark grown on the steepest slopes appear to be the finest, and the immediate proximity of the high cordillera is evidently advantageous, probably owing to the greater amount of moisture in the air, the more clouded atmosphere and the frequent showers. Farther east the quality is much inferior. The finest calisaya district extends northward along the slope of the mountains from lat. 16° 30'. This region also produces coffee of the finest quality, but little known abroad, owing to the high cost of transport, the production consequently not exceeding the demand of the nearest centres of population : indeed very fine coffee is grown on all the eastern Andean slopes North of the 18th parallel, in the district of Guarayos, and on the ranges in other parts of Chiquitos, that produced on the lower plains being somewhat inferior. The privileged region of the 'Jungas,' or warm ravines of the La Paz Cordillera, produces, besides coffee, the plant yielding the *coca*, so largely consumed by the Indian races of this part of the continent. The duty collected on this article alone by the Bolivian Government amounts to £40,000 annually."

CALCUTTA BOTANICAL GARDEN.

We have received the annual report for 1880-81 of the Royal Botanical Garden, Calcutta, by the Superintendent, Dr. Geo. King, with the order of Government thereon, from which we notice that

Dr. King does not think that the cultivation of *rhea* is likely to prove a commercial success in Bengal. The prizes offered for an efficient machine for cleaning the fibre have hitherto failed to create much interest in the subject, and it is unlikely that zemindars and ryots will undertake the cultivation of the plant until there is a cheap and effective means of bringing it into a marketable condition.

Trials have been made with various grasses with a view to discovering one yielding a paper-fibre, but hitherto unsuccessfully.

Dr. King recommends that attention should be given to the utilization of the plantain, which, so far as the manufacture of paper is concerned, promises to be the best of the fibre-producing plants in India.

The Government has undertaken to assist persons willing to experiment with plantain. As regards economic plants we learn that

The *Ceará* rubber continues to grow vigorously and to give promise of success. The *Pará* rubber and the Madagascar rubber have entirely failed. The other exotic rubbers are very large trees or climbers, and though, as Dr. King states, the collection of rubber from them in their native forests when they have grown to maturity may be profitable, the cost of planting and protection for several years, until they come to maturity, will probably prevent their cultivation in this country from becoming a success. Of the other economic plants, the mahogany and *guango* or rain tree appear to be the only exotic trees which grow well in Bengal, and for which there is a demand. Among persons who have received or sent plants and seeds are Dr. Trimen and Capt. Bayley. The Kew Gardens also sent dried Ceylon plants for the herbarium. At the Lloyd Botanic Garden, Darjeeling, potatoes of the best English and Australian varieties are being raised to be distributed with a view to improving the local produce.

CEYLON COCOA AGAIN TOPPING THE MARKET.

We are indebted to Messrs. Sabonadiére & Co. for the following detailed report and memorandum of sales from the Brokers, of Pallekelle and Ambecotte cocoa, which are of special interest to all planters of this new product. Here we have a considerable shipment of cocoa, and the pre-eminence attained by previous samples is well maintained. It is evident that Ceylon producers, assisted by their mercantile agents and shippers, are in a position to keep the first place for excellence in preparation, whether it be of coffee (Arabica and Liberica), cinnamon, coconut oil, or cocoa, and also, we trust, as the future will shew, in respect of tea, cinchona bark, cardamoms, India-rubber, tobacco, &c., &c. We trust that the high prices obtained for first-class qualities, will amply reward local enterprise in new products :—

Report on 196 *bags Cocoa, ex "Booldana" from Colombo.*

You will observe that the unclayed cocoa fetched the best prices. There is really nothing to say about this cocoa. It is often wise to leave well alone. You get enormous prices for these small lots, because the berries happen to have inside a colour which the chocolat makers like. The demand from this quarter is, however, a small one, and easily satisfied, and therefore, when your shipments are on a larger scale, you will have to be satisfied with lower prices. Amba, 27 *bags*, we think the finest cocoa in the parcel, it being bold and plump. Otherwise, with the exception of the difference in the size of the beans, the cocoas are really all much alike ; the break of the beans being very similar.

We fancy the cocoa is liked best unclayed. The claying seems to make the husks much harder and heavier.

We don't think we can do better than to advise you to try and send future shipments as like Amba 27 *bags* as possible.—(Signed) I. A. Rucker & Bencraft.

CINCHONA BARK.

The history of the Bark market during the last twelve months or so, has, as our readers all know, been very considerably influenced by the shipments of a comparatively newly discovered species, known as "Cuprean."

The quantities so far shipped have been excessively heavy, and we are informed by those who are well versed as regards all matters connected with Bark that if current reports are true, there are at the present moment enormous quantities of this Bark ready for shipment. It is probable, however, as regards shipment, that a policy of forbearance will be maintained. For reasons which we shall touch on presently, it is necessary, that the present prices of this Bark should be defended, and it is, therefore, proposed in order to support the market that the shipments should be equalized, so many packages per month being dispatched. All matters relating to Bark are interesting to most of our East Indian friends. They will be especially glad to hear that according to the generally reported estimate, Cuprean Bark cannot be put on the London market under a cost of 1s 6d per lb.

If this be correct, numerous sales lately made in London, cannot leave otherwise than a small margin for profit, and it becomes evident that a not very heavy further decline in the value of some Cuprean bark, would make shipments anything but remunerative.

We take the following from the "Chemists' Journal:" The statements therein made, we cannot personally endorse, but if they prove eventually correct, it will probably become evident that the influence of this Bark, on the future of the market has been considerably over estimated. Dr. Robbins evidently thinks that the commercial death of this article will be as sudden as was its birth, and that the former is nearer at hand, than many have been inclined to calculate.

"The recent discovery of cinchona bark on the lower mountain ranges adjoining Buccarramanga, in the State of Santander (U. S. Columbia), seems to have been purely accidental, no one supposing the Cinchona Bark of any value would grow at such low altitudes as that in which this 'Cuprea' was found. The good trees, however, are generally found about 2,000 to 3,500 feet above sea level, and in this respect, while it approaches nearly all the varieties of the Succirubra family, it differs from the greater part of the other South American Barks. As far as external appearance is concerned, it differs by reason of its weight and hardness from all other barks of the cinchona family. Dr. Robbins, of the firm of McKesson & Robbins, has visited the field, and his description of the amount of handling this bark undergoes is interesting. Dr. Robbins states that the bark he purchased was first cut, stripped, and dried, carried two days on men's backs, and then five days by mule to Buccarramanga into warehouse, from there five days by mule into warehouse, five days canoe again into warehouse, then by river steamer four days into warehouse, then by railroad and small boats, and eventually put aboard ocean steamer bound for New York. The *Drug Reporter* states that explorations have been made in every direction outside of this limited 'Cuprea' district without satisfactory result, and while it is impossible to foresee what discoveries may be made in these extensive South American regions, the Buccarramanga bark district is a pocket mine, the material is in sight, is being rapidly exhausted and when exhausted will be seen no more."

Messrs. Howards quote Quinine Sulphate at 10s; Quinidine Sulphate at 7s, Cinchonidine Sulpnate at 2s 6d, and Cinchonine (Mur.) 1s 4d.—*I. A. Rucker & Bencraft's Price Current, August 25th.*

POTATOES FOR EXPORT TO TROPICAL COUNTRIES

have formed the subject of discussion in the *Australasian* lately. We read:—

The common potatois produced in the greatest perfection in the cooler parts of Victoria and the colonies of New Zealand and Tasmania, and in no other part of the Southern Hemisphere—excepting possibly Chili—in anything like corresponding abundance and perfection. When we look at the map of the world, and consider how centrally the three abovenamed colonies are situated in relation to the rich and extensive regions that border the Indian Ocean and the Polynesian islands, and that in no part of that immense extent of territory can a potato be produced at all comparable to the product of Warrnambool, we may realise what a market there would be for the potato and similar perishable products if they could be economically conveyed to those countries in good condition. But there is the difficulty. The potato is simply a reservoir of moisture and nutriment for the young plant, and if exposed to the influence of heat, and more especially if in a moist climate, germination sets in, and the tuber rapidly decays. It is, therefore, very difficult to keep on board ship, especially in hot climates. And yet in no other situation is it so valuable, for of all vegetable productions there is nothing to equal the potato for dietetic properties in hot climates. The remedy I propose for the drawbacks connected with the exportation of potatoes, &c., is packing in dry sawdust, which would enable these perishable products to be sent to any part of the world and kept for a considerable time. Sawdust, being the most effective of non-conductors, prevents any increment of heat, and likewise excludes the moisture in the atmosphere; the principle of germination is thus rendered dormant, and decay prevented. Grapes—a far more perishable commodity than potatoes—have been conveyed from Europe to Melbourne, packed in sawdust, in good condition; therefore, we may reasonably expect that potatoes could be preserved in the same manner. This process could be tested for a mere bagatelle. Let any enterprising party take a couple of hundredweight of sound potatoes; pack one-half in kiln-dried sawdust, let the other half be packed without that protection. Then let the two packages be sent per steamer as far as Cooktown, to he there detained till there is an opportunity of sending them back to Melbourne. A comparison of the two samples will show the value of the sawdust packing, and give an idea at a very small outlay of the cost of so preserving them.

For permanent markets, any settlement where there is a number of Europeans could be depended on—the Cape Settlements, Mauritius, Aden, the Indian Empire, Hong Kong, the Dutch Settlements. With New South Wales, Queensland, and New Caledonia there is a considerable trade already established, which would be immensely increased could the potato be made less subject to decay. Immense quantities would also be used for provisioning shipping if it were found that they would keep over a voyage, as potatoes are the best anti-scorbutic known.

That sawdust will have the effect of preserving them for a considerable time I have no manner of doubt, as it is well-known that they will keep for a season in a dry cool place; packing them in dry sawdust would provide that requisite in any country or climate. I believe the same principle would be of great service in the Indian horse trade. Suppose a few tons of carrots were packed in sawdust on board one of the vessels engaged in that trade; they could be dug out when wanted, and the horses would not only be kept in better health on the voyage, but would land in better condition and be more readily saleable.

Blue Tier, Tasmania, July 12. JAMES GRANT.

LIFE IN IOWA, UNITED STATES.

A Ceylon mercantile colonist, who left Colombo some years ago, has sent a friend an interesting account of his wanderings since, from which we are permitted to extract as follows :—

"I visited Adelaide, Melbourne and Tasmania, and after sundry curious experiences of bush life in the latter place, returned home to England in December last. Tasmania is certainly the most primitive spot in the world, in many parts the only means of travelling being one's own legs. For three or four days at a time, I have had to camp out, carrying *all* I required for the journey on my back; so little has the country been opened up.

"The country is one of the most beautiful I have ever seen, but so densely wooded and intersected by so many considerable rivers, that the making of new roads seemed to me a Herculean task.

"I myself camped on the banks of one river, in company with another man going the same way as myself, for a whole week before we were able to ford it. I cannot see how the island will ever be any good till more bridges and roads are made.

Attracted by sundry pamphlets on farming in the United States, I left England again in February last. I visited Tennessee first, where there is an English Settlement got up by Mr. Thomas Hughes, author of 'Tom Brown's School Days.' He calls the settlement 'New Rugby.' It has been noticed a good deal in the home papers, and, perhaps, through this channel you may have heard of it.

"I cannot say I found the prospects particularly promising there, the soil being comparatively poor, and, moreover, thickly wooded, making the expense of clearing considerable.

"I came here in April last, and have since bought a small farm of 160 acres, costing me, with house and some additional improvements I have made, about 2,000 dollars.

"I do not manage the farm myself, but let it to a tenant who pays me one-third of the crops as rent. At present, I am living on the farm, working for my tenant, to see how I like farming. I am distant about 7 miles from Le Mars, which is my post town, and a very rising place, on the strength of which I have also invested in some town property which brings in a fair rent. The latter, I believe in, more than farming, as a means of making money, so far as my experience goes at present."

NEW PRODUCTS IN CEYLON.

(*From a correspondent.*)

8th Sept. 1881.

I shall, with your permission, from time to time, give you my experience with new products, as a kind of supplement to the very interesting and instructive monthly reports of your Western Province correspondent.

Liberian Coffee.—I have about a couple acres varying in age from two to three years. The older trees are in full bearing; and their branches, heavily laden with berries in all stages of growth, are a very cheering sight. A great mistake has been made with these trees. They have been allowed to grow more than one stem. To one accustomed to the sight of the Arabian coffee with its branches trimmed to grow regularly, the tangled mass of vegetation which these bushes present is anything but pleasing. When I took charge of this estate, most of the younger trees were severely affected with leaf disease. A coffee planter of about 30 years' standing and with three or four years' experience in Liberian coffee cultivation, passing this field of coffee, put his hand over each affected tree and said "That tree is no good; it will never recover from so severe an attack." I did not despair. I had some ashes on the estate, very old and exposed to the rains of more than one monsoon. These I spread and forked in about the roots of the affected trees, and, as if to give the lie to my friend's experience, the trees have now a goodly show of strong healthy leaves. I believe the effect of the ashes would have been better had they been fresh.

Cacao, I have planted on a small patch of about two acres. This patch had been planted the year before and the plants had all died, with the exception of one solitary plant. The loss of these plants has been attributed to crickets and drought. The land was over grown with scrub, which I cleared. The grass on the ground I allowed to remain, as I believe it injudicious to quite bare the ground and expose it to the baking heat of a tropical sun. I cleared a space of about three feet diameter round each hole, and planted the seed at stake. Each seed was shaded by a basket of cocoanut leaves, like those very common in the lowcountry for carrying fruit in. This monsoon, or at least the earlier portion of it, was particularly dry, and from this cause I lost from 15 to 20 per cent of the plants. I supplied the vacancies with seed. A very small percentage was lost through the ravages of cricket, grub and white ants. The second time, I supplied this field with plants grown in small, bottomless pots. I did not, as is usual in the hill-country, break the pots to get out the plants, but got them out by a few gentle taps on the sides, which brought the plants out without in the least disturbing the roots. The pots are available for further use. The cacao plants are put out 12 feet apart in regular squares and are quincunxed with Liberian coffee plants. These I put out both to economize space and to act as shade for the cacao, as this field has hardly a shade tree on it. I am of those who believe that cacao, with all fruit-bearing trees, does not want overhead or dense shade. All the shade it wants is about the roots and stems, and this the cacao gets in the hillcountry where it is planted in the coffee. I have, however, not calculated solely on the shade the Liberian coffee will afford, but attempted to grow castor between the cacao plants. This, I thought, will serve the double purpose of shade and be profitable besides. The cricket or bloodsucker, I don't know which, took a wild delight in cutting down each castor plant as it shewed itself above ground. I sowed seed a second time, but with a like result. I intend now to put down the seed of a wild plant with narrow leaves and which grows into a graceful bush of about 10 or 12 feet high, which will afford the light shade after my own heart. All the weeding this field will get from me is the keeping of the circles round each plant clean by a mamotying once in two months, a general hoeing twice a year.

Tea is yet in the nursery. I intend planting all the plants I have in the Liberian coffee field between the lines, so that I will not have to incur separate expenditure for cultivating the product, for which this elevation is decidedly too low. Warmth and moisture are said to be necessary for the profitable cultivation of tea. We have the warmth without the moisture. In weather like the present, we may have a few flushes, and if I can make sufficient tea for my requirements I shall not complain.

Cinchona.—A few plants of succirubra I have put down in a narrow belt of jungle. I am sorry we have no forest reserve on this estate, to enable me to try whether dense shade will not make up for elevation. The shade afforded by the narrow belt, which is but a few feet wide, I am afraid, being insufficient, will sorely try the plants I have put down; but so far they do not seem to have suffered from the elevation. I have a nursery with a few hundred plants in it.

which I intend planting in the belt before alluded to.

Cardamoms I have no hesitation in pronouncing a decided failure planted in the open in the lowcountry. I was deceived by the prospectus of the Ginidoniuie Compauy. It pointed to Udugama as a place where cardamoms have been grown successfully in the open. In your book, *All About Cardamoms*, page 33, I read :—"Irrigation under shade, where possible, would, I believe, be of great advantage to the plant, for it luxuriates near the running water, but no amount of water can make up for the absence of shade." What would make this book doubly valuable is one or more articles on the cultivation of cardamoms in the island, say one from the hill-and the other from the lowcountry. I trust an early number of the *Tropical Agriculturist* will contain these.

Tobacco, according to an article from the *Asian*, appearing in the first issue of the *Tropical Agriculturist*, is very easily and profitably cultivated. The ground is prepared with not too much of manure; the plants put down watered for a couple of days only ; then weeded occasionally till the crop is up for harvesting. Tobacco is, I believe, cultivated very differently in this island. The ground is *very heavily* manured by means of movable pens; the plants are watered one or twice daily till they are fit for cutting. Besides this, the ground is dug often as the plants are growing up, each digging being followed by a manuring with dry cowdung. I have tried tobacco on a small scale ; and it 's just as well, as I find that up to date, with plants varying in age from two months to two weeks, I have spent a great deal more than what the plants are likely to fetch. I shudder to think that more expenditure must be faced, which, when totalled up in the end, will be more than double of what the plants will realize. I had no experience to guide me, and all I knew about tobacco was what I gathered from the pages of your Handbook for 1876-78. My first mistake was to follow the instructions in the Directory :—"Sow the seed three weeks before the monsoou rains." Seed sown in April was not fit for planting till July ; and when the plants were fit for planting my ground was not. As the ground I had dug up or prepared in April was in July kneedeep with grass and weeds, I went over the ground again, that is weeded or dug it up. I did not manure it, for I had not the cattle. After digging, I sprinkled, rather thickly, wood ashes over the whole ground, and smoothed and lined it for planting. At each peg I sprinkled a handful of fresh wood ashes and mixed it thoroughly with the soil. The plants were then put out, shaded and watered every day it did not rain. When the plants were about 6 inches high and looked as if they had fairly established themselves, the ground was dug up and the shade removed. After they had put out a few more leaves, saucer-shaped, shallow "rain gauges," *à la Montclar*, were made round each plant with soil, into each of which a coconut shell of poudret e was put and thoroughly mixed with soil. After the plants had attained a height of 18 iuches or so, the ground was again dug up and each plant manured with a little dried cowdung Those plants that flowered had their tops pinched off. Now, I don't believe it is at all necessary to dig the ground up, or manure the plant so often, nor do I think it necessary to water the plants, unless when the ground is dry. I think the tobacco plant had enough, and more than enough, of manure in the ashes and poudrette I applied, to give it a vigorous growth for its short term of life. But I have now schooled myself to bow to experience. An experienced Sinhalese tobacco cultivator, whom I employed, thought that frequent turning up of the soil and manuring essential to a proper growth of leaf, and he exultingly pointed to a few trees here and there which had gone wrong as a proof that his style of treatment was necessary, and that my delaying it had spoilt the plants. I trust that either Mr. Macartney or Mr. Bisset will give us their experience in the cultivation of the Sumatra variety in the Trincomalee district, as this variety is said not to require irrigation. If a few hints are given as to the kind of soil most suitable, preparation of ground, what manure used, if any, and the style of cultivation adopted, I am sure they will be conferring a great boon on many who, like myself, are cultivating new products in

THE LOWCOUNTRY.

A LEGAL-PLANTING QUESTION.—A planter writes :—"Can a man be run in for abandoning his land to the injury of his neighbour? I remember there was a case on this subject some years ago, but forget the result, though I think it was in favour of the injured party, and the Supreme Court laid down the law pretty clearly for the future."

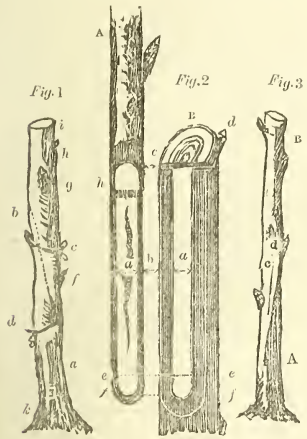
COCOA.—Of 4,650 bags offered, a large portion was Grenada, which sold at 1s to 2s advance, at 63s to 67s for common to fair, 67s 6d to 73s 6d for good to fine. Of 1,306 bags Guavaquil, 300 bags sold at 68s to 76s for common to middling grey. Trinidad 89s to 105s for good to very fine red. A parcel of 196 bags Ceylon attracted attention on account of its very good quality, and was sold by auction, chiefly at 92s 6d for fair, and 99s to 104s 6d for fine ; a few lots superior 109s to 111s 6d.—*S. Rucker & Co.'s Weekly Circular*, 26th Aug.

IT appears from the Statistical Abstract of the Colonies, laid before Parliament, that up to the end of 1879 about 79 million acres had been reclaimed out of the Crown estates in Australia, Tasmania, and New Zealand. There remained unalienated nearly two billion of acres, or fully 14 times the total quantity taken up by emigrants and colonists from the beginning. The Crown has other splendid estates elsewhere; some 9½ millions in Ceylon, about 4 millions in Natal, 52 millions in Cape Colony, and something over one million in Jamaica and Trinidad.—*Madras Mail.*

TEA CULTIVATION IN JOHORE.—In order to test the capabilities of his country for the production of tea, the Maharajah of Johore has had a small garden formed, which at the end of last year was visited and reported upon by a gentleman experienced in such matters. The little garden is described as being in charge of a Chinaman who does not treat the plants as is done in India, but apparently *more Sinico*, and his mode of manufacture varies similarly. The soil of the estate is of a reddish yellow colour, soft, without clay or stone, and of a friable nature, so that the frequent showers of rain easily percolate through it. When their age is taken into consideration, the growth of the plants is most rapid and luxuriant. The seed was sent from Assam by Dr. Barry, and is, no doubt, what is known as Assam hybrid. The leaf of the plant is soft and bright, and most healthy in appearance, being almost entirely free from blight of any description. The climate of the district is apparently all that could be desired for tea. Provided prices are only tolerably favourable, it is thought that tea cultivation in Johore will prove remunerative. A great element in its favour is that the labour-supply, both Chinese and Malay, is good, fairly abundant, and to be relied on. By a late mail from Singapore we learned that the Maharajah of Johore was making a tour in Java for the purpose of making himself acquainted with the methods adopted there in the cultivation of tea, coffee, &c., with a view to the improvement and development of his own state. He is stated to have been received with much distinction by the Governor-General of Netherlands India.—*Colonies and India.*

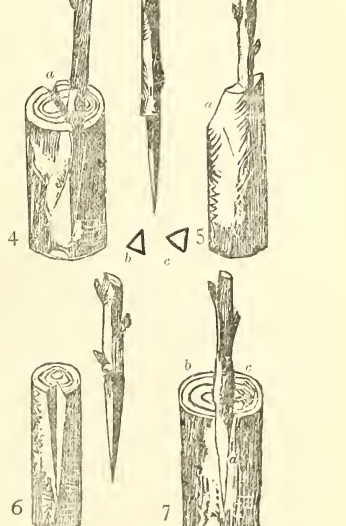
GRAFTING DECIDUOUS FRUIT TREES.

The following are woodcuts referred to in the article on this subject on pages 315 and 316 :—



In continuation of this subject dealt with on pages 315 and 316, we reproduce from the *Australasian* an article treating of three other systems, known respectively as cleft, notch, and crown or rind grafting :—

Cleft-grafting, fig. 4, is not a neat method; it is, nevertheless, much used in New South Wales, in orange nurseries, and it is possibly the only method of working vines that is ever resorted to. If the orange stock and scion do not differ in size more than those represented in fig. 2 in our issue of 23rd ult., the latter generally grows over the top of the stock, so that eventually the two are united all round, and a smooth trunk, bearing very slight indications of the union, results. In the case of vines the stock is usually large, because grafting is rarely resorted to except for the purpose of exchanging one kind for another after a trial of several years. The method of performing cleft-grafting is as follows :—The stock is split at *a* by a chisel and mallet; before the chisel is withdrawn, a wooden wedge rather larger than the scion is inserted to keep the split open until the scion is in its place. The wedge is then withdrawn, a tie is put around the stock, and grafting-clay over all, not omitting the top. In grafting large stocks two scions are sometimes placed on the opposite sides of the stock. In preparing the scions for insertion when two are to be used, they must be cut of somewhat different shape from single scions intended for large stocks. If the operator will insert one shoot representing a scion and withdraw the wedge, he will see that the other edges of the cleft will nearly go together, leaving the opening across the top somewhat tapering, as well as the perpendicular cut. The single scion then must be cut wedge-shaped in both directions—when two are to be used in one stock they will require to be tapered only in one direction. There must be no bruising of the bark either of the stock or scion. In order to avoid this, a very thin slice may be taken off the bark edge of the scion or off the edges of the cleft in the stock before the scion is inserted. In grafting vines it is important that a bud be left nearly close down upon the stock, as represented in fig. 4. Figure 5 is another method of cleft-grafting with one scion. The stock is frequently cut sloping as at *a*, a small shoulder being still left at the summit when the cleft is made and the scion inserted. This method is not much used in the colonies, nor indeed on the continent of Europe, whence it was derived. Figure 6 represents a substitute for cleft-grafting; it is triangular notch-grafting—a neater mode, and inasmuch as no hollow is left in the stock, as in cleft-grafting, it is preferable. This plan is, however, not generally used. A skilful hand will get over a great many vines in a day by the process of cleft-grafting. Experience enables him to dispense with tying and claying. He merely cleaves the stock, inserts the scion, and having withdrawn the wedge, trusts to the embrace of the stock to keep the scion in place; he then earths up, or rather levels in the soil, for if a straight piece of stock can be met with below ground, he heads the vine down as low as he can; and this system of keeping the graft below the surface has much to recommend it in a dry, warm climate.



Crown or rind grafting, which is shown by fig. 7, is almost universally employed in re-grafting large apple and pear trees. It is much to be preferred to cleft-grafting, inasmuch as the wood of the stock is not rendered unsound by cleaving. It is easily performed; the lower end of the scion is cut sloping, as in whip-grafting; the head of the stock is cut over horizontally, and a slit *a* is made just through the inner bark. A piece of wood, bone, or ivory in shape somewhat resembling the thinned end of the scion, is introduced at the top of the slit between the alburnum and inner bark, and pushed down, in order

to raise the bark, so that the thinned end of the scion may be introduced without being bruised. The edges of the bark on each side are then brought close to the scion, and the whole is bound with matting and clayed. When the stock is large, in order that its top may be soon healed over, and in case of a single graft, *a*, failing, two others are introduced at *b* and *c*. It is to be observed that although the scion may be pared flat on the side intended to be placed next the wood of the stock, yet the latter being circular, the flat cut face of the scion can only be in part closely applied to it; for a perfectly flat surface can only touch the circumference of a cylinder longitudinally along one line. Therefore, if the central portion of the flat cut face of the scion touch the wood of the stock or layer of cambium, the edges of the inner bark can scarcely do so, and the organizing cellular substance of the stock must accumulate towards the edges of the scion before it can reach its inner bark. Instead of the scion being made flat, it would better accord with the principles of grafting if its wood were made slightly hollow, so that its inner bark might be in immediate contact with the layer of cambium from which the bark of the stock was raised. If this cannot be done, care should be taken that the scion be at least cut flat, and by no means with convexities.

TREES AS A PROTECTION FROM HOT OR VIOLENT WINDS.

(From the *Indian Forester*, July 1881.)

The effect of forests in tempering and checking the force of the wind is frequently allnded to hy writers on forest economy; and if I quote a few of the passages which I have met with, it is because I thiuk that will be the most conclusive manner of testifying to this important *rôle* of protection which trees and forests perform for the benefit of neighbouring cultivation.

The Americans, who have often heen reproached with the wanton destruction of their forests, are now endeavouring to re-establish them. A notice on the subject, hy Mr. G. P. Marsh, which occurs in the *Revue des Eaux et Forêts* for October 1880, under the title, "*Le reboisement aux Etats-Unis*, begins by pointing out the value of trees to the settler on the prairie as a protection against the wind. The passage, translated from the French, is as follows:—

"None can better appreciate the henefits conferred by forests than the settler on the prairie, whose dwelling is ever exposed, as a ship on the ocean, to the fury of the violent and changeful winds which sweep across the bare and level plains, where no obstacle checks their impetuous career.

"Seated hy the hearth in the depth of winter when his dwelling, buried in snow, looks like a mole-hill in the midst of a vast expanse of moorland, he regrets that, when some 20 or 30 years ago he was selecting a site for his dwelling, he did not plant out with trees a few patches of hundreds of acres of which his holding consists. Had he done so, his house would now be snug and quiet, with a fine clump of trees to shelter it from the north-west wind. His garden would not be dried up by the first dry wind of summer; and he would not see his fruit blown off and destroyed by the wind.

* * * * *

"There are very few among the pioneers of the far West who have had this forethought; but the wisdom of those few is now so manifest, that from one end of the prairie to the other it is felt that the planting of trees is an object of public importance."

As shewing the advantages expected from this planting of trees, the last paragraph of the extract from *The Scientific American*, entitled: "Preservation of Forests," which appeared in the *Indian Forester* for July 1879, may be quoted:—"Any State where these precautions" (planting groves of trees, quickset hedges, trees on road sides, &c.) "should he generally adopted, would soon he so unmistakeably distinguished by the unfailing humidity and freshuess of its fields and the abundance of its crops that the sheer necessity of competition would induce backward neighhours to try the same experiment, and before long the maxim would not only he generally recognized, but generally acted upon, that husbandry and tree culture are inseparable."

This certainly points to practical benefit to be derived by agriculture or other cultivation from the planting of trees in their vicinity; and this, too, without its being necessary to establish extensive forests, or even to distribute the trees with the special object of forming a productive belt

Forests, too, are effectual in tempering the winds, rendering the climate of the place more equable.—(*Baudrillart, Dictonnaire Forestier.*)

A writer in the "*Indépendance Belge*" of 18th June 1865 thus describes the effect of forest trees:—

"1*st*.—They prevent the sun's rays from reaching the ground and heating it.

"2*nd*.—By the expanse of branches and leaves they multiply the cooling surfaces affected by nocturnal radiation.

"3*rd*.—The upper layers of the air, cooled in the tree tops of the forest, sink, by their increased density, towards the earth, and thus is kept up a degree of cold considerable in its intensity, and thereby a well maintained moisture.

"From what has just been stated it may he clearly deduced by scientific reasoniug that forests lower the temperature of their locality and render the climate at once cooler and moister."

I helieve that these views are rather one-sided, and that the fact really is that, as forests absorb or part with heat very slowly, and as the air inside the forests is not renewed so freely as it is in the open, forests have an equalizing and regulating effect on the heat of the local climate, and tend to absorb the heat of hot winds and to give back this heat as the weather becomes colder.

In the "Transactions of the Academy of Science of France" (*Comptes Rendues*) Vol. LX., sitting of the 10th April 1865, a memorandum may he found which establishes the opinion that forests afford shelter from the wind to cultivation in their neighbourhood; and it is pointed out that this action is more effectual the higher the trees.

It has been noticed in many countries that extensive denudation has caused hot winds in summer and hail-storms in winter. Thus the occurrence of hail-storms has been remarked in the vineyards of many parts of France to have been caused by the destruction of a screen of forest vegetation which previously warded off the winds and their attendant storms.

A well-known instance of the protection afforded by plantations of trees is the great work of fixing the rolling sand hills in the departments of the *Gironde* and *Landes*, which was first effected by Bremontier, and is still heing carried on. In this case not only had the wind to be combated, hut the substance of a moving range of sand-hills to be consolidated, so that the wind should not be able to roll it, piecemeal, inland.

The authority of M. Lorentz and Parade (*Culture des bois*) will, I feel sure, be admitted on this subject to he the best that can he adduced. Speaking of the climate of plains, (p. 21, 5th edition) we are told that "the absence of forests or other plantations makes itself felt (just as the total absence of large surfaces of water) by an increased heat and drought in summer, and in winter adds to the intensity of the cold."

As regards the effect of a *belt of trees* in protecting the ground behind it from the wind, the third chapter of the work just quoted, treating of the laying out of compartments or forest for felling, contains much that is instructive. The following passage (pp. 205, 206) is particularly applicable :—"It is an addition to the advantages of the rule we have just been discussing to leave standing on the west and south margins of the forest, when the fellings reach those parts, a belt of trees forming deep forest of a width more or less considerable (100 to 50 feet) according as the place is exposed or sheltered, as the trees are deep-rooted or the reverse, &c. It is well known that near the margins of a wood the trees are generally more branchy and stunted, and more firmly rooted than in the interior, and that having grown up under the constant action of the wind they naturally withstand its violence better."

Monsieur Bagneris, in his *Manuel de Sylviculture*, concludes his remarks on the admitted climatic effect of forests in these words :—"Lastly, the forests break the force of the winds and check their violence." Again (p. 218) on the subject of laying out compartments for felling: "When the side directly exposed to the wind is reached, it is always necessary to maintain intact on that side a zone to be kept up as deep forest and worked by selection fellings. The width to be given to this belt must vary according to the resistance it has to offer; but, to be effectual, it is seldom that it can be made less than a hundred yards wide."

On exposed ridges or plateaux, as well as in narrow valleys swept by the wind, it is often necessary to increase the width.

In the "*Indépendance Belge*" of the 20th June 1865 the use of forests as screens to protect cultivation from the wind is discussed. Their influence—and Arago is cited in support of this view—is one of equalization; and the writer proceeds to say: "It is for man, and particularly for the agriculturist, to know how to constitute such screens as will be free from any drawbacks that might be presented by dense forests of vast extent. Now for this purpose extensive forests are not needed; screens of trees, quick-set hedges, plantations round the homestead and along the roads will afford ample shelter, without occasioning, as forests might, late spring frosts and thereby often endangering the crops."

The circumstances of different localities must necessarily vary so greatly that no rule can be laid down as to the width of the belt of trees; but as regards shrubs and quick-set hedges affording ample shelter, that, I think, depends on the intensity of the danger to be counteracted and the extent of ground to be protected. The resistance of the belt of trees will be in proportion to its density and the firmness with which the trees in it are rooted, the extent of ground it will protect will be greater or less as the trees forming it are tall or short.

I believe that the distance behind the belt to which the shelter extends is about twenty times the height of the screen. No doubt there is some mathematical formula, whereby, with certain data, it might be computed; but the surest and simplest plan will be to rely on actual observation in each case. One may expect that a low wind sweeping over a level plain, and a wind coming in a slanting direction, as from the side of a mountain, would not be counteracted to the same extent by a belt of trees of a given height—so that I should expect to find the extent of ground sheltered to depend very much on the angle of incidence of the wind.

As to the best kinds of trees to be planted, in the absence of existing timber, they must above all be suitable to the soil and climate—of hardy growth, capable of growing up in the exposed situation where they are to be placed. Such as are gregarious and will form a dense thicket are to be preferred, and valuable kinds, if suitable in other respects, should be used in preference to those which are useless as timber. If the winds to be counteracted are constant, evergreen trees, which keep their foliage throughout the year, are to be preferred to deciduous kinds. According as the winds are hot or cold the kinds should be chosen which are best suited in this respect; thus, in Europe, the Scotch fir (*Pinus sylvestris*, Linn.) is found to resist cold better than the maritime pine (*Pinus maritima*, Linn.), which, in the winter of 1879, succumbed to the cold extensively in the north and centre of France.

Sissu (*Dalbergia Sissoo*, Roxb.), which is recommended by both "E" and "Aliste" for very good reasons as suitable for planting in amongst the tea bushes, would be very useful also for the belt of jungle as it is gregarious and hardy, growing in the stoniest soil of river beds exposed to the winds which sweep down the valleys. It is also a quick grower, and the wood is valuable for cart wheels, furniture, gun carriages, &c.; but it does not, as a rule, form compact or dense forest. It would be useful on the outside of the belt by its hardy temperament and firm root hold.

Bamboos have the advantage of growing to their full height very quickly, and when propagated by off-sets they form good-sized clumps in three or four years. "Aliste" remarks that the bamboos in his part of the country are all flowering, and asks if there is no remedy to prevent their dying after running to seed. I believe there is not. I was informed a few years ago that the bamboos in a part of Orissa had all died in this way. In Drury's "Useful Plants," 2nd edition, p. 64, we find that "at the age of 15 years the bamboo is said to bear fruit—a whitish seed-like rice, and then to die." I have noticed that the forest bamboo of the Terai, (*Dendrocalamus Hamiltonii*) is flowering pretty generally this year; but the phenomenon does not universally affect all the bamboos. I have also noticed clumps of this bamboo in a languishing condition which had lately flowered.

The bamboo is very useful to tea planters, and is frequently planted on estates in the Darjeeling Terai. It is also very firmly rooted, and the clumps have a good broad base. This is important at least for the outside of the belt as they may be used in places of deep-rooted trees should the soil not be deep enough for their growth. But whatever tree or shrub is used on the outside, all the low branches must be kept. Stunted trees, with branches feathering down to the ground, will be most useful. At page 68 of the *Indian Forester* for July 1880 this sentence occurs :—

"In exposed situations both the pruning and thinning of trees should be much lighter round those margins of plantations which face the prevailing high winds of the district. By too close packing it often happens that only the face of the very outermost trees are dotted with foliage, so that any injury to one of these admits the destructive winds. This may be guarded against by a judicious early thinning of such margins, so as to secure a belt of low-branched trees—(A. J. Burrows, in *The Garden*)."

The India-rubber (*Ficus elastica*, Roxb.) would be a good evergreen tree for the outside edge where permanent foliage is desired. It will grow in most soils provided they are well drained and permeable; and it also requires plenty of sunlight. Its roots take firm hold of the soil. *Cedrela Toona* might also be grown as suggested. It is a shade-loving tree, and its being planted amongst other kinds would draw it up with a fine clean stem, so that the trees would be likely to give good timber. The toon is capable of attaining a height of seventy feet or thereabouts,

but requires a moist, rich soil and a sheltered situation, otherwise its growth is stunted. The young plants are apt to be broken by deer browsing on the leaves. The new shoots also suffer from the attacks of a grub which eats into the pith.

If the soil is suitable it would be worth while to grow toon, as the timber is greatly esteemed for tea boxes and furniture.

As regards the raising of sissu in a nursery as recommended by "E.," I think under the circumstances it would be a waste of time. Sown broadcast, sissu germinates very readily, and the seedlings grow far more rapidly than the plants raised in the nursery and then transplanted. It would be better to sow broadcast over the whole of the proposed belt and to thin out any plants required for planting in the tea replacing them by toon, &c. Sissu seed is very plentifully produced, and is easy of collection as the pods are indehiscent, and there is no danger in leaving it to get fully ripe upon the trees.

Toon seed, however, should be collected as soon as the fruit begins to ripen, for if the capsules are left to open, all the seed, which is very light, will be lost Toon may with advantage be raised in a nursery, as it requires particular care to screen the seed beds from the sun and to protect the young seedlings for the first few weeks. To effect this, a rough roof of elephaut grass or loosely-woven mats, through which the sunshine can filter as through a cullender, should be erected over the seed beds. The seed should only be lightly sprinkled over with earth. The best time for sowing is early in the rains, as soon after the seed has been collected as the ground gets damp and warm.

The germination of the seed of *Ficus elastica* is rather difficult. It requires a well-drained soil, yet a warm moist atmosphere like that of a greenhouse; the seed should be fresh gathered; the beds should be heaped up in little mounds and the seed sprinkled *on the sides of the mounds*. Pounded brick and charcoal have been tried as soils for the seed-beds. I would recommend a compost more apt to retain moisture, a mixture of pounded brick, charcoal, decayed leaf-mould and moss gathered from the branches of trees; and that the mounds be made with this.

Water should be given often enough to keep the seed-beds moist, but they should not be deluged with water, nor should very cold water be given but having the same temperature as the soil.

The *Ficus elastica* grows readily from cuttings, if struck in soil that has been well hoed up, and the cuttings are put in during rainy weather when the soil is warm say July or August, in a sunny place.

Wherever possible it would of course be preferable to utilize existing trees; for, however quick-growing the kinds planted may be, it will take a long time for them to attain their full height, or, in other words, their maximum protective effect. But it seems that the garden "F." alludes to is situated on an open space *as yet* too slightly wooded. To judge, however, by the opinion of a correspondent of the *Indian Tea Gazette* who writes from the Nilgiris, planters do not always select the site of their plantations with a careful regard to the local conditions affecting climate. He says: "I am inclined to the idea that a want of special knowledge has contributed greatly to the non-success of tea growing here. In many instances very exposed windy situations have been chosen instead of the low-lying humid valleys; and sometimes, I think, fixing the site of a bungalow on a nice spot, and having the tea cultivation close by, has had something to do with it." It is interesting to see that tea planters who occupy a most important area in many districts and have a great landed interest in the country, take interest in forests for the sake of the protection they afford, as well as for the produce they may yield.

F. B. MANSON.

AMERICAN CULTIVATION OF JUTE.

Attention is being directed in America to the advantages of cultivating jute instead of importing it from India, whence 82,471 tons was taken to the United States in the year ending 30th June 1880, the value being above five million dollars. The demand is, of course, not so much for paper manufacture as for textile fabrics and cordage. The South requires eighty million pounds of butts for bagging to cover her five million bales of cotton, as much more to sack her cotton seed, cake, meal, rice, and grain, while the great West and North, and California will probably require two hundred million pounds of the fibre for sacking grain and vegetables.

The *Paper World*, our contemporary published in Holyoke, says that California has been raising enough jute for several years to furnish bagging for her other crops, and Louisiana and many other Southern States contain lands which are unquestionably admirably adapted for jute growing. In Louisiana the crop is considered a sure one, and can be raised as easily as corn. The yield of jute is estimated at from 2,000 to 4,000 pounds of fibre per acre, and the price of jute butts is from three to six cents. The plants are not molested by insects and worms, and, indeed, are said to be less subject to disaster and bad weather than any other crop raised in the South.

Professor Waterhouse, of Washington University, St. Louis, says:—"All that is now necessary to the certain success of the undertaking is the invention of a cheap and rapid means of disintegrating the fibre. In the preparation of the fibre, nothing but chemical or mechanical agencies can successfully compete with the cheap manual labor of India, and convert the culture of jute in the United States into a great and prosperous industry."

Our contemporary tells us that "the few jute factories which have been established in the United States are doing a profitable business. They import the raw material from India. The import duties on jute and its manufacture are as follows:—Jute tow $20·00 per ton; gunny cloth 3 cents per lb.; bags, composed wholly or in part of jute, 20 per cent *ad valorem*; bagging, valued at 7 cents or less per yard, 1½ cent per lb.—over 7 cents per yard, 2½ cents per lb.; jute yarns 20 per cent *ad valorem*; butts $6 per ton. On all other manufactures, in whole or in part of jute, 30 per cent *ad valorem*. With such a premium on the domestic culture of jute, and with the certainty that it will yet be in enormous demand, there can be little doubt that American ingenuity will devise some process which will effect the cheap and rapid disintegration of the fibre mentioned by Professor Waterhouse.—*Indian Agriculturist.*

THE SALE OF INDIAN TEAS IN AUSTRALIA.—The Calcutta *Englishman* says:—Very favourable reports regarding the progress of Indian tea in Australia have been received by the Tea Syndicate from Messrs. Henty and Co. of Melbourne. Careful analyses of India and China tea have been carried out by Messrs. Cosmo, Newbury and Dunn, with results most favourable to the former, and fifteen thousand copies of a circular, containing the analysts' report, along with other information, were being issued throughout the Colonies. A large firm of tea dealers had, further, espoused the cause of Indian tea with enthusiasm and were determined to advertise heavily and establish agencies in every important town in Australia. In Sydney alone no headway had been made, but success there, too, will no doubt follow. The unprecedentedly low quality of the season's China teas is greatly in favour of the Indian leaf, as it will not only help to turn the public taste against the trash, but necessitate a larger use of Indian tea for mixing purposes.

SESSIONAL PAPERS.

NEW PRODUCTS COMMISSION:

PAPERS LAID BEFORE THE COMMISSION.

Enclosure in No. 1.

The Earl of Kimberley to the Officer Administering the Government of Ceylon.

Ceylon.—No. 142. Downing-street, 28th April, 1881.

Sir,—With reference to my despatch No. 32 of the 2nd of February last, forwarding a letter from Kew Gardens regarding the planting industries of Ceylon, I have the honor to transmit to you a copy of another letter which has been received from Sir Joseph Hooker. You will see that Sir J. Hooker wishes to explain what it is in the power of the authorities of Kew Gardens to do in the way of rendering help to the introduction of new plants into Ceylon, as he has been obliged to refuse very many applications for assistance.

Sir J. Hooker further makes a suggestion, which seems worthy of your consideration, that the Commission, which was recommended in my despatch of the 2nd of February, might perhaps think it worth while to attempt the direct importation of the seed of the Para and Ceara rubbers.

I have, &c.,
KIMBERLEY.

Mr. Thiselton Dyer to the Colonial Office.

Royal Gardens, Kew,
14th April, 1881.

Sir,—On January 12th last I addressed to you, at the desire of Sir Joseph Hooker, a letter offering some suggestions made with the object of encouraging new planting industries in Ceylon. Sir Joseph Hooker was glad to learn from Mr. Herbert, in a letter dated February 3rd, that these suggestions met with the approval of the Secretary of State, and had been communicated to the Ceylon Government.

Since this time, applications have continued to pour in from Ceylon at the rate of two or three a week (many coming through private channels in this country), to say nothing of personal interviews, for the purpose of obtaining from this establishment seeds and plants, in large quantity, of new staples.

It is impossible not to feel regret at the manifest disappointment caused by the unavoidable refusal with which each successive case has been necessarily met. I venture to trouble you with the following remarks, for the purpose of defining our position in a matter of this kind, and with the hope that they may be transmitted to Ceylon, so as to obviate the misconception which seems to exist there as to what it is in our power to do.

The most pressing demand is for seed of Para and Ceara India rubber, of which planters in Ceylon do not hesitate to write to ask us to send them "bushels." Now you are aware that the introduction of these valuable plants into the Island is entirely due to the munificence of the Indian Government, which went to immense expense in procuring them from the New World. *Vide* foot-note in appendix, p. 399. There being no tropical Botanic Garden suited for their reception in India, it was at Sir Joseph Hooker's suggestion that Ceylon was made the depôt for the young plants in the East. The Island has therefore participated the benefit of their introduction, without in any way sharing the enormous expense,

Practically, the whole stock of Para India rubber plants—some 2,000 in number—which has ever been in the possession of the Royal Gardens, has been transmitted to Ceylon. Having successfully effected the introduction of the species into the East Indies, it is not within our means to take any further step in the matter. The collection of the seed is costly and difficult, and our experience is that, even when freshly brought to this country, scarcely more than three per cent. has germinated.

With regard to the Ceara rubber, a reference to the Kew reports for 1876 and 1877 will show that the whole stock of plants with which we had originally to work was only 55, all told.

Those sent to Ceylon have succeeded remarkably well; they have fruited profusely, and Dr. Trimen appears to have distributed every seed in his possession. With the successful introduction of this species into the East, we consider our duty in the matter closed.

Plants of the Para rubber were sent out from Kew in 1876, and of the Ceara rubber in 1877. The introduction is a very recent one; it appears from Dr. Trimen's memorandum on the subject (Sessional Papers, 1880, No. VII.), that both plants can be propagated with facility from cuttings.* With reasonable assiduity there can be no doubt that planters who take up the new cultivation might raise large stocks in a very short time.

I need not refer to the other plants, for the seeds of which we have been asked. I think it must be evident that the function of this establishment must be limited, as regards the Colonies, to the communication to their respective Botanic Gardens of such new and important plants as we are able to distribute. The Colonial Botanic Gardens will, in their turn, propagate and distribute the plants received from us. But even this operation cannot be performed in a wholesale way. The development of new cultures requires time. And if, when the suitability of climate and soil to some new staple has been established through our instrumentality, planters are at once impatient to embark on its cultivation on a large scale, they must not look to this establishment, nor indeed to the local Botanic Garden, for aid in carrying out undertakings of a magnitude which makes them matters of purely commercial enterprise.

The Commission, the appointment of which has been suggested, might perhaps think it worth while to attempt the direct importation of some seed of the Para and Ceara rubbers. With regard to the first, which travels so badly, the only chance of success would be by packing the seed in slightly moistened earth. The quantities in each case should not be large on account of the risk of heating. The seed of the Ceara rubber plant would probably travel better and might be transmitted in linen bags. The only chance, as far as I am aware, of aid in the matter would be through the Consul at Grand Para and the Vice-Consul at Ceara. I am sure also that the accomplished and courteous Director do Passeio publico at Rio de Janeiro, Monsieur Glaziou, would give every assistance in his power to Dr. Trimen.

I am, &c.,
W. T. THISELTON DYER.

Enclosure in No. 2.

The Secretary, Planters' Association, to the Hon. the Colonial Secretary.

Kandy, 14th May, 1881.

Sir,—I have the honor, on behalf of the Sub-Committee appointed to communicate with Government as to the best means of introducing seed and plants of such new products as offer inducements to cultivators, to ask if Government would be prepared to consider the recommendations of the Sub-Committee, after enquiry, and to forward any lists

* Which is also our experience at Kew.

of requirements that might be made up to the sources from which supplies are most likely to be drawn.

The Sub-Committee would point out that seeds of the better varieties of cinchonas are almost unobtainable in Ceylon by private applicants, and that these might be obtained from the Indian Government plantations at Darjeeling and at Ootacamand, and also from the Dutch Government at Java. They would also beg to instance that it is equally impossible to obtain seeds of any of the species yielding India rubber, and they cannot but think Government influence could secure a supply from South America and elsewhere.

I have, &c.,

A. PHILIP,
Secretary.

REPORT OF THE COMMISSIONERS.

The Commissioners having duly and very carefully considered the questions referred to them for report, are of opinion that it is not the function of the Government Botanical Gardens to supply seeds and plants of new products in quantities, but that it consists in and terminates with their successful introduction and acclimatization.

The Commissioners recognize the fact that the above object has been and is now kept in view in the administration of the Botanical Establishment in Ceylon. They therefore have requested the Director of the Botanical Gardens to refer to the records of Péradeniya Gardens, and to furnish a statement of the new economic plants or varieties that have, from time to time, been introduced into Ceylon, shewing the success of each so far as the records at his disposal and the existing plants in the Gardens afford information; and the same having been furnished, is attached hereto. (*Vide* appendix D.)

On a careful consideration of the letter addressed by the Secretary of the Planters' Association to the Colonial Secretary, under date of 14th May, 1881, the Commissioners are of opinion that great benefit would result if, having due regard to the interests of private enterprise, the organization of Government in regard to the various colonies and in foreign countries were made use of for the purpose of facilitating the purchase in those places of seeds and plants of new cultures required in Ceylon.

The Commissioners would have been glad to have had before them an outline of a scheme approved by the Sub-Committee of the Planters' Association; but, failing this, they submit for the consideration of Government the following scheme which appears to them to meet the requirements of the occasion:—

1.—That the Planters of Ceylon should form a standing committee, or should appoint some permanent body to communicate with Government, and that the Planters' Association should be communicated with and asked if it will undertake this duty.

2.—That this committee shall from time to time send in to the Colonial Secretary lists of such plants and seeds as are required, the quantity needed, and the names of the applicants, with a certificate that each application is *bonâ fide*, the seeds and plants for the personal requirements of the applicant, and not for purposes of re-sale or export.

3.—That in the case of sufficiently large demands, Government shall be prepared to ascertain whether it be possible and desirable to obtain seeds and plants in such quantities; and, if so, at what price they can be supplied to the committee.

4.—That Government shall inform the committee of the result of its enquiries, and on receipt of payment shall take steps to procure the plants and seeds desired, and forward the same to the committee for distribution.

5.—That the disposal of the plants and seeds to the applicants must be wholly managed by the committee, as also all correspondence and other communications with the individual planters.

Government cannot undertake any of the expenses in the matter. The cost therefore of freight, &c., will be taken into account in estimating the amounts to be charged to the applicants.

Neither the Royal Botanic Gardens, Pérádeniya, nor the Royal Gardens, Kew, can take any direct part in the above scheme, which should relieve them of a strain they are not constituted to bear.

Whilst admitting that the coffee interest has suffered very serious discouragement of late years, and that, in consequence, some of the older and more exhausted of the lands have been abandoned, the Commissioners would nevertheless demur to the opinion expressed in Mr. Dyer's letter of 12th January, 1881 , to the effect that coffee in Ceylon has seen its best days, and also to his statement that estates of 800 acres had been left uncultivated, which the Commissioners believe to be unfounded in fact.

HENRY TRIMEN.
Colombo, 11th July, 1881. GEORGE WALL.

APPENDIX TO REPORT.

MEMORANDUM ON THE PART TAKEN BY THE ROYAL BOTANIC GARDENS IN THE INTRODUCTION OF USEFUL PLANTS INTO CEYLON.

The following notes on plants of economic value introduced into the Botanic Gardens during the past 35 years have been put together at the request of the Commission. They shew that the introduction of foreign plants of a useful character has been kept steadily in view by the Superintendents and Directors as a part of their duty, and actively prosecuted by them, and that the public utility of this Department of the Government service has in this respect, as well as in others, been fully vindicated.

In drawing up this Memorandum, I have been mainly guided by the existing contents of the Gardens, and by the (unfortunately brief and scanty) notices in the annual reports, so far as I have been able to consult them. Previously to 1844, the date of Dr. Gardner's arrival as Superintendent, I have no records whatever, and but very few during his short but active incumbency. This, however, is less to be regretted, as it is certain that, for the previous 20 years, next to nothing was done at the Gardens, which languished under the rule of a succession of mere gardeners. In the period, however, from 1817–25, when the establishment was under the care of Mr. Moon, there can be no doubt that much more activity was shewn, and many valuable plants introduced. I have however no present means of ascertaining these, though a list of them could perhaps be compiled from Moon's "Catalogue of Indigenous and Exotic Plants growing in Ceylon," published in English and Sinhalese at Colombo in 1824. I may remark that here, as in all similar establishments, scientific knowledge and sound utility have gone hand in hand, and a "practical" head of the Gardens has meant stagnation of enterprise and the decline of influence and ability to be of public usefulness.

Food Plants.

Coffee.—I am not aware what, if any, share the Gardens took in the early attempts at the systematic culture of this staple (which was introduced long ago by the Dutch); but I find that in 1845, at the height of the coffee mania, Pérádeniya was largely supplying the rapidly increasing estates with plants ready for planting out at the then cheap rate of 6*s*. (Rs. 3) per 1,000.

Of *Liberian Coffee*, now so much grown, the first plants were received at the Gardens in 1873 from Mr. Bull. These died. The same year arrived plants of the very closely allied *Cape Coast Coffee* from Kew. In 1874 Mr. Bull sent 12 more plants of Liberian coffee, and in 1875 a stock from Kew was received. The cultivation was greatly helped forward by the Director, in 1876,

distributing a printed paper containing the answers obtained in Liberia to a series of questions he had sent home.

A consignment of *Mauritius coffee* was received in 1876; and in 1879, by the initiative of His Excellency the Governor, a large quantity of seed of *Jamaica coffee* was obtained, and the resulting plants distributed to applicants free of charge.

Tea.—*China tea* was introduced or re-introduced to the Gardens in 1845, and *Assam tea* in 1847; but it was not till about 1860 that its cultivation began to be seriously thought of. In 1865 Dr. Thwaites drew up an elaborate paper of instructions for the Commission of Enquiry which was sent to India by the Planters' Association; in this year 200 lb of seed were distributed from the Gardens. The *Assam Hybrid* the kind now principally preferred, was obtained here in 1867, and seed began to be distributed in 1870.

Cacao.—This is one of the old introductions. In 1845 it was being advertised for sale at Pérádeniya at 4*s.* a dozen plants. The value of this culture was frequently insisted upon by the Director, and in 1873 he printed simple instructions for its cultivation. Last year a very important consignment of eleven of the most highly prized varieties from Trinidad was received, which will in due course doubtless prove of great use.

Other food-plants of value, introduced at various times to the Gardens, are the *Sago Palm*, the *Sugar Palm* of Java, *Arrowroot*, new varieties of *Tapioca* and of *Paddy* and other grains. Also many tropical fruit-trees; as the *Durian*, several varieties of *Oranges*, the *Langsat*, the *Litchee*, the *Sapodilla Plum*, the *Java Almond*, the *Brazil Nut*, the *Queensland Nut*, and the *Amoy Pumelow*.

Drugs.

Cinchona.—In nothing has the immense utility of the Botanical Establishment been shewn more completely than in the history of this cultivation. So soon as there was a probability of the successful introduction of the plant into India, the Director of Pérádeniya actively engaged in the enterprise on behalf of this Colony. Supported by the Government, he, as early as 1860, selected the present Hakgala garden as the site of a plantation, and obtained the services of an experienced gardener from home. In the same year, the first plant (a yellow bark) was received from Kew, but unfortunately dead. Seeds of grey bark from India followed in 1861, and more plants of yellow bark from Kew in good order. Mr. Markham sent seeds of crown bark in the next year, 1862. In 1864 there was a large number of young plants at Hakgala, and Dr. Thwaites was urging the cultivation of Bark on the planters. Little desire was, however, shewn on their part to grow anything besides coffee, although it was determined to give the plants gratuitously, on condition only that they should be carefully cultivated. In 1865 about 180,000 were thus distributed; but in subsequent years there were fewer applications. By the year 1872, however, it had become acknowledged that the enterprise would prove profitable, and the Government then fixed the sale of plants at 5 rupees per 1000. Applications were very numerous for the next six years (1873-78), culminating in 1876, when 1,224,000 plants were sent out. By this time cinchona planters had mostly formed their own nurseries, and the issue from Hakgala has gradually diminished to very small quantities.

Though it is the case that the Hakgala garden has by no means kept pace in any respect with the great and expensive Indian and Java establishments, or, in the introduction of the best sorts, even with some private enterprise here, yet it must be remembered that nothing more was ever contemplated at Hakgala than fairly to start the cultivation by rapid propagation of plants for distribution to the planters, and that, as no provision was ever made there for the conduct of experiments requiring special knowledge and leisure, it was impossible that any contributions to Quinology could result from its foundation.

The fact remains that the lucrative industry of Cinchona planting was wholly the creation of the Government Botanical Department; and a course has been since successfully steered which, whilst affording very great assistance to the planters, has never attempted to enter into competition with them, nor at any time made addition to revenue to be the main object or an object of importance, as is the case in South India and Jamaica and in Java.

Ipecacuanha.—This important drug was introduced here from Kew in 1866, and a further stock in 1871. From Calcutta a number of plants were obtained in 1874. A small number are annually disposed of.

Other medicinal plants brought into the colony through the Gardens, and of more or less value commercially, are:—*Calabar Bean, Cajuput, Benzoin, true Rhubarb, Camphor, Cascarilla, Coca, Sarsaparilla, Balsams of Peru and of Tolu, Cubebs, Calumba-root, Jalap, Cebadilla,*

Condiments and Spices.

Cardamoms.—I am not aware when the valuable Malabar variety was first introduced, but it has probably been cultivated by the natives for a long period. Dr. Thwaites advocated its systematic culture in his report for 1868, and about 1873 it began to be taken up. The Gardens now supply large quantities.

Nutmeg.—This dates further back than the existence of the Gardens, but it is included in the sale list for 1845—the seeds offered at 2*s.* a dozen, and plants at 12*s.* a dozen. Within the last two years there has been a revived demand for this ; and as the Gardens possess a number of trees in full bearing, large orders can be met. During this year and the last, between 14,000 and 15,000 seeds have been distributed to the newly-opened low-country estates.

Clove.—The history of this is very similar to the last, but the revival of its cultivation is less marked than in the case of nutmeg, and our supply exceeds the demands.

Other spices introduced into Pérádeniya at various periods are :—*Jamaica Allspice, Madagascar Clove, Jamaica Ginger, Grains of Paradise, Lesser Galangal.* The indigenous peppers, cinnamons, &c., are also kept in stock.

Perfumes.

Vanilla.—From 1853, or earlier, the Director of the Gardens has not ceased to push the cultivation of this, and at one time a large quantity was grown at Pérádeniya, 64 lb. of the pods being sent home for experimental sale in 1866. A few estates now grow this in considerable quantity, and the Gardens continue to keep up a moderate supply.

Of other perfumes, the Gardens contain *Ilang-ilang, Patchouli, Cuscus grass* and *Lemon grass.*

Fibres.

Cotton.—Experiments were made on the growth of good varieties of cotton in the Garden in 1852-53 ; and in spite of the unsuitable character of Pérádeniya for the plants, a small supply of different varieties was kept up for many years here in case of demands. In 1860–62 there was some attempt at taking up the cultivation in Ceylon of the good sorts, but this soon ceased. At present the " Sea-Island " is the only variety remaining in the Garden.

Manila hemp and *China grass* or *Rheea fibre* were introduced in 1852 and 1853, and are still kept up in the Gardens. *New Zealand flax* is now grown at Hakgala, having been long since introduced to Ceylon.

Of Dyes, *Arnatto, Indigo, Red Sanders wood, Safflower, Logwood,* and *Turmeric* are growing here. The *Cochineal*-Cactus and insect were introduced in 1853, but did not succeed, and more recently the cultivation of *Saffron* has been attempted.

Of Oil plants, the Gardens have introduced the *Oil Palm,* the *Earth nut,* and the *Tallow-tree* of China ; and grow *Gingelly* (Tel) oil and other native kinds.

Timber Trees.

Sandal wood was first grown at the Gardens in 1869, but this was probably a re-introduction, the plant having been lost. It does not succeed in Pérádeniya, but plants sent thence to the drier districts are doing well.

Mahogany was introduced before the period to which these Notes refer, and several old trees are in the Garden and scattered over the Island. They rarely fruit, but fresh supplies of seed have been recently obtained from the West Indies.

The Gardens have introduced also the *Sal* of India, the *Rain-tree* of Venezuela, and the *Bucare* of Tropical America (" Bois immortelle" of the West Indies), as well as many other foreign timber trees, and several very useful Bamboos.

Of *Fodder plants,* the *Teo-sinte* grass and the *Paspalum (P. conjugatum)* have been introduced at Pérádeniya. *Lucerne* has also been experimentally tried. Whether the valuable *Guinea Grass* and the *Mauritius Grass* owe their existence here to the Gardens at an earlier period, I have no present means of ascertaining. The *Algaroba* or *Mesquit Bean* of South America has been recently acquired.

There are also some very important plants which do not come well under any of the above heads.

Tobacco.—The Shiraz, Manila, Maryland and Lattakia varieties, introduced in 1853, 1859, 1860, and 1868, respectively, have all been carefully cultivated at Pérádeniya, although the climate and other causes rendered it impossible to keep up a stock on the slight chance of its being

enquired for. The kinds are still grown in small quantity, but have now become mixed, and are no longer of much value.

Gutta Percha.—Several sorts have been introduced, the original kind from Singapore in 1869.

India Rubber.—The *Assam* rubber tree seems to have been introduced to Péradeniya so far back as 1835. For the more valuable South American kinds—the *Para*, the *Central American* and the *Ceara* rubbers—Ceylon is indebted, as in so many cases, to the liberality and public spirit of the Indian Government, and the energy and promptitude of Kew. These were introduced in 1876.* Since then some African and Malayan species have been obtained, and are growing very satisfactorily.

To render this list as complete as possible, I may mention the *Divi-divi*, the *Vegetable Ivory*, and the *Cow-tree* of Venezuela, as trees, useful in various ways, which have been at different times brought into the Gardens.

Nor should the further facilities for the cultivation of truly tropical species by the establishment of the garden at Henaratgoda be passed over in a notice of what has been done to foster the acclimatization of useful plants in the Colony. This adjunct was opened in 1876, and has proved of great utility in enabling the Botanical Department to keep up a stock of species which with difficulty grew in Péradeniya.

Appended to this Memorandum is an advertisement from one of the local Newspapers of the plants and seeds on sale at the Gardens in June, 1881. Such advertisements are now prepared quarterly by the Director, and have, it is believed, considerably tended to the spread of "new products" in the Colony. It will be seen that many of the above enumerated species are included in this advertisement.

From these imperfect notes it will be readily seen how unfounded is the cry that these Gardens have done little or nothing towards the introduction of plants suitable for commercial culture; and also (even if it came within their functions), how impossible it would be to attempt to grow permanently in them large quantities of each and all of these numerous staples.

Péradeniya, 9th July, 1881.

HENRY TRIMEN,
Director.

---

* I am desirous of taking this opportunity of putting upon record something of the history of the introduction of the valuable Para Rubber into the East, which has been effected at a large cost and with much trouble. When the Government of India had determined upon the enterprise, a commission was given to Mr. Wickham, then living at Santarem, to collect seed at the rate of £10 per 1,000. He succeeded in obtaining 70,000 seeds in the Ciringals of the Rio Tapajos, which he packed with the greatest care and with a full knowledge of their evanescent vitality; and coming straight home with them arrived at Kew on 14th June, 1876. The following day the whole number were sown; not more however than "about $3\frac{3}{4}$ per cent. germinated, some as early as the fourth day after sowing; and many in a few days reached a height of 18 inches."—(Kew Report, 1876). At Sir Jos. Hooker's suggestion it had been previously arranged between the India and Colonial Offices that owing to the want of any accessible and properly constituted Botanical Garden in any part of India suitable for the growth of this completely tropical species, the seedlings should be sent here to Ceylon to be cultivated and propagated for subsequent distributions to Burmah, and other hot and moist districts of the Indian Empire. Owing to the plants' rapid growth, wardian cases of a special form had to be made for their transmission, and, on August 12th, thirty-eight of these, containing 1,919 plants, were despatched from Kew in charge of a gardener (W. Chapman). In due course they were received at Péradeniya in very good order.

Mr. Cross's share in the introduction of Para Rubber was a very small one. He also had been sent by the Indian Government to South America to bring home live plants in case the transmission of living seed should prove impossible, and he arrived at Kew on 21st November, 1876. He brought with him about 1,080 seedlings without soil, of which, with the greatest care, scarcely three per cent. could be saved. About 100 plants propagated at Kew from these were subsequently sent to Ceylon.

The cost of procuring the seeds of Para Rubber, freight, and other expenses appears to have been no less than £1,505 4*s.* 2*d.*, the wardian cases alone costing £120, and the gardener and his passage, £163. The whole of this large expenditure was borne by the Indian Government. An undertaking involving such an outlay as this, it is obviously beyond the power of the Executive of this Colony to carry out; but in this case, it is Ceylon which (from climatic causes chiefly) appears likely to benefit most largely from the successful action of the Government of India.

Seychelles.—We have received through the courtesy of a correspondent, a photograph of a plant of Liberian coffee, apparently about 7 feet in height, the branches of which are laden with fruit. The plant was sent from Kew in 1877.—*Gardeners' Chronicle.*

Dried Grasses.—Messrs. Hooper inform us, in illustration of the demand for these ornamental grasses, that they have just received a consignment of 8 tons of Stipa pennata! and this only represents a portion of their stock, a large quantity being also stored in their warehouse in Germany.—*Ibid.*

Fruit Packing ought to have attention bestowed upon it, as being an indispensable operation, which is but too often indifferently performed. It cannot be too frequently stated that, to ensure safe transit, the packing must be firmly done, the material used must be sufficiently elastic, and the boxes shallow, or, if deep, divided by trays. Perhaps the best materials for fulfilling the second condition are paper shavings and perfectly dry moss; the latter of which was generally used for packing fruit in the old coaching days, and is not yet superseded by anything superior. —*Ibid.*

Artificial Fertilisation.—A fact recorded by Mr. Williams in the report of the Dundee Horticultural Association is so important, that we think it well to give it greater prominence. A flower of Victoria regia naturally fertilised, says Mr. Williams, yielded twenty-five seeds; another, artificially fertilised with its own pollen, gave sixty seeds; another fertilised with pollen from another flower on the same plant, a hundred seeds; while yet another, fertilised with pollen from a flower on another plant, gave 300 seeds —twelve times that of the naturally fertilised flower. —*Ibid.*

Eucalyptus Citriodora.—Of late years it has been the fashion to grow both in greenhouses and out-of-doors the blue gum tree, that has (deservedly or not) got the character of being an antidote against malaria; but its inability to bear our winters out-doors, and the rapid growth it makes inside, where it quickly outgrows its limits, renders it of little use. But those who are fond of plants with fragrant foliage cannot fail to like E. citriodora in the condition we recently saw it at the Durdham Downs Nursery, in the shape of compact plants from 1 foot to 15 inches high, in small pots; they were raised from seed sown the present spring. It has handsome lance-shaped leaves; the perfume is something like the lemon-scented Verbena (Aloysia citriodora).—*Ibid.*

Costa Rica.—General Thomas Guardia, the President of Costa Rica, has signed a decree to the effect that a waggon road from the capital to Rio Sucio having been sanctioned by the Republic, it is necessary to provide for the cultivation of the lands and the erection of habitations on either side of the road, so as to facilitate traffic along the said highway, and therefore that all persons, foreigners as well as natives, who may wish to become owners on either side of the road, shall signify their intention, within six months from the 22nd of April last, to the Governor of the Province of San Jose, and that this officer shall thereupon draw up a document, stating the locality of the said free concession, and this certificate shall serve as a provisional title, and after two years from the date of this provisional title, the grantee shall appear before the Judge of National Revenue, and prove that he has commenced to cultivate his lot, whereupon the Judge shall deliver to the grantee a freehold title, free from payment or price, except the fees for the measurement of the land, and the expense of the title deed; and that a space of twenty yards shall be left open between each allotment of land, so that the various cultivators may have accommodation roads between their lots for facilitating their various cultivations.—*Madras Mail.*

Madagascar Plants.—We learn that the national herbarium at Kew has acquired another important collection of dried plants from Madagascar. The collection was made by Dr. G. Parker, and comprises about 400 species, many of them novelties. Among other things is a miniature palm, 2 or 3 feet high, and having pinnate leaves. We understand that Dr. Baillon is engaged writing a *Flora* of the island. —*Gardeners' Chronicle.*

Gooseberry Fungus.—In thanking you for your most interesting article on Æcidium grossularis, and asking you to supply your readers now and then with similar exhaustive treatises on the fungoid diseases of our plants, I can corroborate the writer's assertion as to the sporadic visitations of that pest. It appeared last year very extensively in a neighbour's garden, where it had never been noticed before; this year it has changed its habitation to mine, though it has not developed itself to any great extent. The same seems to be the case with Æcidium urticæ, which was very common in some parts of Norfolk last year, but of which, after the most diligent search, I have only succeeded in finding one specimen this year.—F. M. D. P.—*Ibid.*

How to Estimate Height of Trees.—Now, with regard to height, you may say, "It is all very well to measure girth, but how are you going to measure height?" Who is to tell us whether a tree is 130 ft. or 140 ft. high? I can give you two rules of thumb, which will at least assist calculation. This is one. Supposing your tall friend to staud out well in the open; set by the side of him a stick of ascertained height, say of 6 ft. Watch at the proper hour the length of shadow cast, both by your 6 ft. rod and by the tree. Then calculate in proportion the height of the shadow-casters; *e. g.*, if the tree's shadow be twelve times the length, take its height at 72 ft. Or, take three laths, join two of them at a right angle, and make each lath containing the angle to be of the same size. Then unite the equal sides with a third, subtending the angle. Now hold it level and opposite the tree. Walk away until your eye looks up the third and long side precisely to the summit of the tree. You may now consider yourself to be standing at the apex of an enlarged triangle, of which the ground line is one side and the erect tree another. You measure the ground line, and in so doing you measure the height, for it equals the perpendicular which you thus get.—*Australasian.*

Standard Peach Tree Culture at Whitehill.—At the gardens on the beautiful estate of Whitehill, near Hawthornden, belonging to R. B. Wardlaw-Ramsay, Esq., is to be witnessed at present a sight seldom if ever seen in this country. Peaches at Whitehill have for some time been famous, but this season, especially as regards the prolific crop, eclipses all former years. The fruit range, which is erected upon an elevated plateau, surrounded by pretty and well designed flower beds, consists of four peach-houses and three vineries, all span-roofed. The central house which is several feet higher than the others, is the standard peach-house, of which I wish more especially to speak. It is about 32 feet by 18 feet, and about 20 feet high. It was erected about twenty-five years ago, and in it were planted out as standards four peaches and one nectarine. They are now about 18 feet high and about 12 feet through, and are literally covered with beautifully coloured fruit, and when the afternoon sun falls upon them, to stand underneath these trees and look upwards, a sight is seen which will rarely be forgotten. It is estimated that on these trees there are not less than from 2,300 to 2,500 fruit, and on one of the peaches there are not fewer than 600 well finished fruit. Mr. Leyden, the courteous head gardener, pulled one of the peaches, and it was found to weigh 7¾ ounces, and measured 10 inches in circumference.—John Methven, Edinburgh.—*Gardeners' Chronicle.*

THE RUBBER INDUSTRY.

Planters of Rubber of one or other kind in Ceylon are now to be counted by scores and hundreds, and we have been pressed for some time to afford them fuller information than any yet available, by republishing in pamphlet form the opinions of different authorities under the title of "All about India-rubber." Such a compilation is in hand; but we have not concealed from ourselves the fact that cultivators in Ceylon will have to make up from their own experience a truly reliable guide for Rubber planters. All that has hitherto been written is theory, rather than practice, and in respect of the cultivation of this product, as well as of many other tropical products, to Ceylon should belong the credit of leading the way and showing the world of would-be cultivators "how to do it." By far the most practical paper that has yet appeared is that of Dr. Trimen which was included in our last Handbook. This was based partly on Mr. Cross's Report, and in some respects Mr. Cross has not been found a reliable authority by local planters. Some of his statements are now generally discredited, but, although not borne out by experience in Ceylon, they are no doubt in accordance with what is seen of the plant in its native habitat. Mr. Scott Blacklaw described Ceará rubber as a weed in the coffee plantations in Northern Brazil, and he gave a word of warning as to the value of some of the seed imported thence to England. We are glad to learn that Dr Trimen will shortly be able to publish some more useful information for Rubber planters the result of his cultivation and experiments in Peradeniya Gardens, and we shall endeavour to supplement the papers already available by the results so far as they can be obtained of local experience. One planter has very courteously placed his experience at our service, in the following practical form:—

"CEARA RUBBER.—*Germinating the seeds.*—File each seed carefully on both sides, until the kernel is *just* visible. The two ends may be rounded off a little, but the operation requires care. When the filing is finished, have ready a solution of kerosine oil and water (one to ten) and immerse the seeds in it for a second or two. This prevents ants and other insects from coming near them. This operation over, the seeds should be thrown into a tin box containing some coir fibre refuse, procurable in Colombo. Cover them well over with a further supply of the same material and shut down the box. In two days' time, they will be found, on examination, to have commenced to germinate. Take them out and put them (germ downwards) into Wilton's transplanters filled with good soil, on a table, with its legs in saucers of water. Three or four days more will suffice to let the seedlings develope into nice, healthy little plants, and ten days from the date of the commencement of the operation they can be finally transplanted. When the seeds are in the box of coir refuse no water is required, and even when put into the transplanters very little moisture is needed.

"The young plants are remarkably strong and love the sun. They are, however, very impatient of moisture, and should therefore be placed under cover during a shower of rain. The filing operation may be done on a grind-stone; but to ensure *perfect* success each seed should be rasped carefully with a file.

"Some planters lose as many as 60 and 70 per cent, and in one instance, which has come to my knowledge, five plants only were secured out of 300 *seeds*. I am indebted to a gentleman in Colombo for the above simple but effective way of germinating the seed, and can confidently recommend its general adoption. Not a single seed need be lost if the directions are carefully followed.

"*Planting out.*—It being important that the Ceará species of rubber should be induced to grow coconut fashion with a tall, clean stem, it will be found necessary to plant them pretty close to each other, say 500 to the acre; and so far as my experience goes, plants grown from seed are more likely to develope into this style of tree than those propagated by cuttings. The latter grow faster, perhaps, and blossom earlier—a matter of some importance in cases where a supply of seed is required: but, for a permanent plantation, I am of opinion that every tree should be raised from seed.

"Mr. Cross's statement, that the Ceará rubber may be expected to grow and flourish in soils where hardly anything else will live, is not supported by Ceylon experience. On the contrary, there is no tree I can name that enjoys more thoroughly richness of soil, and the difference between plants in good and bad land is very marked.

"*Collection; Value and Quantity of Produce.*—Nobody is yet in a position to say which is the best way to tap the tree when it reaches maturity; but, from experiments I have made, I believe it will be found impossible to improve upon the method adopted by the natives of Ceará. They bare the trunk of the tree and allow the milk to trickle down the stem. Two or three days afterwards the gum or caoutchouc is pulled off in strings and sent to the market. As may naturally be supposed, the rubber reaches England in a very impure state. Hence its value is less than the Pará kind, which is prepared with the greatest care. My reason for thinking it impossible to improve upon the native method of collection is because the flow of milk from a Ceará tree is very slow, and any other system would increase the cost, a contingency which must be guarded against. It may, perhaps, be found possible to purify the caoutchouc in Colombo before shipping it to England. Labour is cheap and the machinery necessary for the operation is by no means complicated. As regards the yield per tree, a very small quantity will pay, provided the cost of production is restricted, and an inexpensive method of collection adopted."

The Rubber industry is yet destined to be one of considerable importance in Ceylon, and we trust to be able to aid intending planters as much as possible, by laying before them "All about India-Rubber." The title may be deemed misleading, since so much has yet to be learned about Rubber, but of course we can only give such information as is available up to the time of publication.

In this connection we may draw attention to the Papers already published (pages 393 to 399) referring to the New Products Commission—if it may be so called. Dr. Trimen's "Memorandum on the part taken by the Royal Botanic Gardens in the introduction of Useful Plants into Ceylon" is especially interesting, and he shews there very clearly how much indebted we (in Ceylon) have been to India for the introduction of the Pará and Ceará rubbers. In such matters however, Ceylon may well be considered an integral part of India, and the authorities here ought always to be ready to reciprocate by the supply of any seeds and plants from our Gardens required by the Government of India.

CEYLON TEA IN AUSTRALIA.

It will be seen from the full report of the last Melbourne sale of Ceylon teas that the highest price (1s 9d) was realized for a parcel from Rookwood estate. Loolecondura failed to maintain its former pre minent reputation, and we suppose it is with reference to parcels from this and from other estates which sold as low as 7½d and 6½d per pound that an authority in the Melbourne tea trade writes to us:—

"Your planters want stirring up about the manufacture of their teas. The liquor is right; but some of the leaf is miserable in appearance; some dust sent us was finer than oatmeal, and with the prejudice on this side it gives a bad name to Ceylon teas generally." We have received the following from a Colombo merchant:—

"The Australian mail delivered this morning brings particulars of the sale at public auction in Melbourne on 16th August of 625 packages of Rookwood, Loolcondura, and Deanstone tea, sold by Messrs. Greig & Murray under instructions from Messrs. James Henty & Co

"Rookwood tops the list with 1s 9d for pekoe, and 1s 5d for broken pekoe; pekoe souchong fetching 1s 0½d. The average for this estate is 1/2·58 per lb., on 6,385 lb.

"Loolcondura averages on 15,878 lb. 1/1·08, or 1½d less than Rookwood. Prices range from 1s 3d for Broken Pekoe to 6½d for Pekoe Dust.

"Two lots of Pekoe Souchong from Deanstone realized 7½d and 7½d respectively, the former price being paid for chests, the latter for half-chests. This tea was not well made, and had become musty.

"The average for the three estates is 1/0·65 per lb. in bond, on a total of 25,863 lb."

Our Colombo friend is also able to inform us that, on the 12th ultimo, Messrs. Fraser & Co. sold 40 boxes of Ceylon Tea, each 25lb., pekoe souchong, from Agar's Land Estate, at 1s 0½d per lb.

It is interesting to know that the finest lot from Rookwood was valued by a competent tea dealer at from 1s 10d to 2s per lb. For all the other lots of Rookwood the prices realized were slightly above valuations. So, generally, with the Loolcondura and Deanestone lots, the sale-prices being slightly over or very close to valuations. Of the 14th half-chests of Loolecoudura pekoe dust which went for 6½d, one broker says "as fine as sand"; and opposite the two Deanstone lots we have the remark: "bad sample, musty flavour." We trust great care will henceforward be taken to maintain the good reputation of Ceylon Teas in the Australian market.

CEYLON TEAS IN AUSTRALIA.

LARGE SALE IN MELBOURNE.

(*From Our Own Correspondent.*)

MELBOURNE, 29th Aug. 1881.

A large number of the trade attended Messrs. Greig & Murray's auction rooms, Melbourne, on the 16th Aug. attracted by the sale of Ceylon teas. The whole of the lots submitted, consisting of 30 chests, 514 half chests, 85 quarter chests, were sold at prices ranging from 6½d for dust to 1s 9d per lb. in bond for Pekoe. For details, see below.

Buyers objected to the dusty-looking appearance of the bulk of the teas and the very large leaf of others; but the Rookwood pekoe was generally admired, and I expected it would have realized 2s per lb; but a large grocer near me, at the time of the sale, said it was not strong enough in the pot to obtain that figure.

Whilst on this subject, I cannot too strongly impress on your Ceylon planters the prejudice that exists in Melbourne against dusty, broken, or large leaf samples of tea, and that outside the blenders there is really no sale for such class of teas.

The Calcutta Tea Syndicate are determined that Australians shall have plenty of Indian teas, for I notice another sale of some 847 half chests advertized for the 2nd September. On the catalogue are some 200 half chests of Ceylon teas from the Dunedin estate to be sold on the same day.

Indian teas are steadily growing into favour with Melbourne people. A new firm has just started here for the exclusive sale of Indian teas in ½ lb. or 1 lb. packets, 18 and 20 lb. teas and 40 lb. half chests. The business will be wholesale or retail. I presume India will include Ceylon teas.

You will regret to hear that Mr. Josiah Mitchell died at his residence, Skelsmergh-hall, Kyneton, on the 25th Aug. This gentleman was an authority amongst us on all matters pertaining to agriculture. Mr. Mitchell also showed Mr. A. M. Ferguson, Commissioner for Ceylon, considerable attention, and they visited many parts of Victoria together. The *Argus* of 26th Aug. which I post to you contains a full account of Mr. Mitchell's career.

CEYLON TEA IN MELBOURNE.

Tuesday, 16th August 1881.—Ex "Almora," "Malwa," &c., from Ceylon, choice Ceylon Teas 625 half-chests, from the well-known gardens of Rookwood, Loolecondura, and Deanstone. Greig & Murray will sell by auction at their rooms, on Tuesday, 16th August, at half-past eleven o'clock, under instructions from Messrs. James Henty & Co., agents for the above Ceylon Tea Planters.

CEYLON TEA.

Ex "Almora," "Malwa," &c., per lb. in bond from Ceylon

65 quarter-chests Rookwood Pekoe 22lb. Perfect leaf black neat wiry full of golden tips. Choicest malty very rich and full ripe Pekoe flavor. 1s 9d.

29 half-chests Rookwood Pekoe Souch. 45lb. Very even but small choppy greyish leaf. Strong rather pungent brisk full flavory. 1s 0½d.

70 half-chests Rookwood Pekoe Souch. 45lb. Greyish black neat even small fairly twisted leaf. Brisk full ripe rich very strong flavor. 1s 0½d.

20 quarter-chests Rookwood Bro. Pekoe, 25lb. Handsome small black neat leaf full Orange Pekoe tips. Richly fired dull deep malty Pekoe flavor. 1s 5d.

37 half-chests Loolecondura Pekoe. 40lb. Greyish black fairly curled very even leaf few tips. Thick full heavy pungent brisk Pekoe flavor. 1s 1½d.

30 half-chests Loolecondura Souchong. 40lb. Well made greyish black even leaf. Pungent and strong full brisk Pekoe Souchong flavor. 1s 1d.

2 half-chests Loolecondura Bro. Pekoe. 49lb. Very small neat blackish brown leaf. Very full ripe brisk with strong deep infusion. 10½d.

14 half-chests Loolecondura Pekoe Dust. 55lb. Very small brownish open leaf. Rich deep full Pekoe flavor. 6½d.

29 half-chests Loolecundura Souchong 40lbs. Evenly twisted greyish black wiry leaf. Pungent strong rasping brisk flavor. 1s 1½d.

31 half-chests Loolecondura Bro. Pekoe. 40lb. Showy black small neat leaf full Orange tips. Great strength and character a splendid mixing tea. 1s 3d.

38 half-chests Loolecondura Souchong 40lb. Greyish black well twisted and curled leaf. Very rich full pungent and strong Pekoe flavor. 1s 0½d.

32 half-chests Loolecondura Pekoe. 40lb. Neat even greyish black small leaf few ends. Full rich strong briskly fired and very flavory. 1s 1½d.

33 half-chests Loolecundura Souchong. 40lb. Greyish black well made very even leaf Choice tea in the cup great strength and character. 1s 1⅞d.

29 half-chests Loolecondura Pekoe 40lb. Handsome showy small leaf full of golden Pekoe tips. Fragrant full bodied liquor rich strong Pekoe flavor. 1s 2⅜d.

31 half-chests Loolecundura Souchong 40lb. Greyish black well curled and twisted even leaf. Very pungent and strong brisk showy infusion. 1s 2½d.

24 half-chests Loolecondura Pekoe 40lb. Rather small but very even blackish leaf few ends. Flavory delicate infusion brisk and ripe. 1s 1⅜d.

40 half-chests Loolecondura Bro. Pekoe 44lb. Rather small but very even broken leaf. Strong and pungent full ripe P. koe flavor. 11½d.

15 half-chests Loolceandura Bro. Pekoe 46lb. Very small neat brownish black leaf. Strong thick heavy deep infusion—a fine mixing tea. 8d.

30 half-chests Deanstone Pekoe Souch. 40lb. Rather bold and loosely twisted evenish leaf. Brisk full flavory. 7½d.

30 chests Deanstone Pekoe Souchong 80lb. Bold blackish rather loosely twisted leaf. Fairly strong full flavory leaf. 7¾d.

A sale was announced for Friday, 2nd September 1881, at half-past two o'clock of Indian tea, just arrived from the celebrated districts of Darjeeling, Kangra Valley, Assam, and Dehra Doon; also Ceylon tea for sale by auction, ex "Rollo," etc. and R. M. S. "Bokhara," from Calcutta and Ceylon. 725 half-chests Indian tea, 10 half-chests each 40 1-lb. packets, Indian tea, 80 cases each 2 22-lb. tins India tea, 31 boxes Indian tea. 200 half-chests Ceylon tea by Fraser & Co., under instruction from Messrs. Jas. Henty & Co., Agents to the Calcutta Tea Syndicate, and in connection with the Government of India.

The particulars of the Ceylon tea were as follows:—

Ex R. M. S. "Bokhara," from Ceylon.

100 half-chests Ceylon Pekoe Souchong Black even wiry leaf, Pekoe tips very strong full rich ripe, dark-red infusion.

33 half-chests Ceylon Broken Pekoe Small even black broken leaf, Pekoe tips very powerful rich ripe Pekoe flavour.

67 half-chests Ceylon Broken Pekoe small even black broken leaf, Pekoe tips Very powerful rich Pekoe flavour. Grown on the celebrated Dunedin Estate.

LIBERIAN COFFEE IN THE WEST INDIES.

We have received from Messrs. S. W. Silver & Co. of London a copy of the pamphlet "On the Cultivation of Liberian Coffee in the West Indies," by Dr. H. A. A. Nicholls, a notice of which, extracted from the London *Times*, has already appeared in our columns. As our readers will have seen from that notice, Dr. Nicholls is not able to add much to our knowledge of the subject, his book being intended for planters in the West Indian islands. One or two points however we may notice. For instance, Dr. Nicholls is not an advocate of clean weeding. He says:—

"I think a thin carpeting of low plants has a beneficial effect by protecting the ground from the scorching rays of the sun, and by preventing the surface soil from being washed away during heavy rains. The system adopted at St. Aroment is to keep a space of about two or three feet round the tree constantly clear of weeds, and to "cutlass" the rest of the ground. The "cutlass," or "matchete," is a long, broad, heavy knife, and the weeds and grass are by it mowed or chopped close to the ground. In the hands of a strong man the cutlass is a most useful and powerful agricultural implement; and for the expeditious clearing of the "bush" in the West Indies it is almost indispensable.

He is in favor of alternating the rows of coffee with plantains and other food plants. As to topping, and gathering of crop, he says:—

"I have not yet satisfactorily determined whether Liberian coffee trees should be "topped," for as the plant is so much larger in every respect than the creole coffee, to endeavour to dwarf it to a convenient height for picking is scarcely likely to be followed by success.

"Unlike the creole coffee, the main stems of the Liberian species bend very readily, and do not split or break even with rough treatment; but the bending of the boughs will not permit the berries to be gathered from the upper branches of my biggest trees. I have, therefore, had constructed two ladders connected at the top by strong hinges, so that they may be inclined to each other at various angles; the degree of separation of the lower ends being regulated by a chain permanently fixed to one ladder, and capable of being hooked to the other. The contrivance answers admirably, for by using the ladders between the rows the berries are picked from the highest branches of the trees with the greatest ease."

He cannot speak from experience of the preparation of the coffee for the market, but he says that Dr. Imray found Gordon's breast-pulper unsatisfactory for the large berries, and the old "rattletrap" has been found to succeed much better. As we have mentioned, however, the Fairfield Ironworks have made to the order of Messrs. Aitken, Spence & Co. a special machine for pulping the large-berried coffee, and we believe Messrs. Walker & Co. have also prepared a special machine which has worked well. In an appendix Dr. Nicholls gives a letter addressed by him to the *Dominican*, in which he says:—

"For some time past stories have been in circulation in the Island to the effect that the cultivation of Liberian coffee is a mistake, inasmuch as there is very little sale for the produce on account of the coarse flavour of the bean. I have endeavoured as far as possible counteract these mischievous stories, for I fear they have deterred persons from embarking in the new cultivation; but as I am considered to be interested in the matter, my contradiction has not as yet borne much weight.

"By last mail I received a letter from Mr. Morris, the able botanist, who has lately been appointed Director of the Public Gardens and Plantations in Jamaica; and, as will be seen from the following extract from this letter, the question of the great value of Liberian coffee is now authoritatively answered in the affirmative. Mr. Morris writes:—"From the enclosed extract from the *Ceylon Observer* you will notice that Ceylon-grown Liberian coffee has lately obtained 93s per cwt. in the New York market. This is a most encouraging result, and, as we are so favourably situated as regards the American markets, the West Indies ought certainly to compete successfully with the East Indies in the future culture of this coffee."

"I enclose the clipping from the Ceylon paper kindly sent by Mr. Morris for my information, and the news it contains is so important and welcome to coffee planters generally that I will ask you to be good enough to publish it *in extenso*."

The extract referred to is from the *Observer* of 21st Jan. 1881 recording the sale of Putupowla coffee in New York at 20c. per lb. We have no doubt Liberian coffee will succeed in Dominica and other West Indian islands and will be able to withstand the white fly, hurricanes, &c., which proved so fatal to the Arabian or creole coffee.

NEW PRODUCTS.

Lowcountry General Report.

LEAF DISEASE ON LIBERIAN COFFEE—THE DIFFERENT VARIETIES OF THIS COFFEE—HOW TO PLANT CACAO IN THE LOWCOUNTRY—WHITEANTS—WEATHER.

WESTERN PROVINCE, September 1881.

During the month of August, no twenty-four hours passed without more or less rain; and now, on the 12th

September, it is pouring in bucketfuls, the rain having increased daily in volume and duration for ten days past.

The weather being so favourable for planting, all the open land has been occupied, and all failures filled in. The coffee plants were, as usual, attacked by crickets, immediately on being put out; but after the first week their ravages gradually ceased and are now almost entirely at an end. About five per cent of the plants were cut, but more than one-half of those are growing again. Indeed, on this occasion, the cutting has been chiefly of leaves, instead of stems, but the former is probably the worst evil of the two, as the loss of leaves is almost certain to be followed by disease.

Hemileia, I am sorry to say, is appearing at more points than is at all agreeable. On plants that have lost their lower leaves from any cause before they begin to branch, it is almost certain to appear, and recently I have found it bad on those that were in most vigorous growth. I stump every plant on which I find it, so as to give them the chance of making a fresh start. Some of them, however, have become too weak to make an effort, and die off, while others shoot out at once; but since I began stumping none so treated are sufficiently advanced to show whether the disease has been carried forward to the fresh shoots. Many of the older trees suffer more or less from the disease, but it is not so virulent on them as on the young plants; but once settled it remains always. Some of the varieties are absolutely proof against its attacks, but others are peculiarly liable. The stout, thick, leathery leaf is unaffected, while the long, smooth, thin leaf is spotted all over. Trees with close foliage are less liable than those with the branches wide apart on the stem, and the leaves wide apart on the branches. Trees partially shaded are more liable than they are in the open field, and even the shelter of a rock seems to render them more susceptible. When a young plant under one year old is attacked, the fungus seems to ripen very rapidly and the yellow dust covers the back of the leaf in large quantities—in fact, if any use were found for it in the arts, it might be collected to pay, at 10s an ounce. On the older trees, it never covers the whole leaf, but appears in spots, while no yellow dust is found. A few days ago, while inspecting a six feet tree a good deal spotted with the disease, I observed on a newly fallen kahata leaf the same spots and perforations as on the coffee. On further examination, I found all the kahata trees on the place affected with the same disease. It may be something other than the *Hemileia*, but the effect is the same. I will send you a leaf or two of each for scientific inspection and comparison.

The growth of the plants put out from nine to eleven months ago is highly satisfactory. Seed sown in June last year; plants with three pairs of leaves, put out in October, November and December, are now from 15 to 30 inches high, and the most forward have as many as five pair of branches. There are probably fewer varieties than the imported seed sown. Still there is a very decided difference in the height at which they begin to branch, though much less in the size and leaf. Generally the largest pair of leaves are those that precede the first pair of branches, and I have them here 12 inches long and 7 inches wide.

I have not sufficient experience as yet to offer an opinion as to which of the numerous varieties are likely be most profitable to the cultivator. The first object will be to reject all that shew themselves most susceptible to leaf disease; and this will include all that have smooth thin leaves, all that have the lighter shades of green, and all that are of peculiar open foliage. Other characteristics may appear undesirable hereafter, but this is the extent of my present knowledge. Some months ago, I described a dwarf variety, that turned up on another plantation, and which would be amply provided with room at three feet apart. But this is not the only small variety. Some early bearers are not larger than the Arabian species of the same age, and others are even smaller. On the whole, I should say that 100 superficial feet is too large a space even for the largest kinds, and the space allowed should be regulated by the size attained by the selected variety. As for the pioneers who have planted with such plants as they could get, they must make the best of the results of ignorance. I have here several plants that have produced pure white or variegated leaves in the midst of otherwise healthy growth. I do not suppose this to be a settled variety, for some of them have returned to the normal green after sporting the white on several leaves and even on several branches. I have here one curious plant with variegated leaves green and white, six inches long and little more than an inch wide, no doubt a permanent variety, for the results of which we must wait.

I by no means pronounce the soil and climate here unsuited to the cultivation of cacao, but we must pay for our ignorance and presumption in one way or another. I ignorantly presumed that I could cultivate Liberian coffee and cacao on the same ground with advantage to both. The truth turns out to be, that cacao *needs* shelter, and has no objection to absolute shade. Liberian coffee utterly rejects shade, and retains or regains its upright position in the fiercest wind that blows. If any friend of mine wanted to plant cacao in the low lands of the Western Province, I would say: clear your land, put down plantains at 12 feet the first year, and put out your cacao in the interspaces in the second year. The plantains will wear out in four years, and the cacao will then be able to shift for itself. After all, there may be some necessary fact that my experience has not caught: for I had congratulated myself that some of my trees were out of danger from the enemies of their infancy, when all at once the patch of finest trees I had, began to drop their leaves, and within a week branches that had extended to four feet from the stem had not a leaf left. That it was not to failure of the roots that this phenomenon was due appeared within a few days, for the lower part of the branches became clothed with fresh and luxuriant foliage. Some of the branches I pruned down close to the stem; some I cut entirely down to the stem; and some I left untouched. I will report the results in each case as they appear. They were the largest trees I had, due to the most sheltered situation, and their failure at this stage I dare not attempt to account for, as trees much less sheltered and nearly as far advanced have not so suffered. Finding that I would have plants over after all the open land was planted, I felled between three and four acres in July. Rain came the day it was finished, and it has rained every day since. I, however, caught an opportunity of getting a tolerable fire through it, and cleared it up; but the wet and stormy weather now in force has left some of the heaps unburned till the arrival of forty-eight hours of dry weather. After all, the whole work has been done twenty per cent under the lowest tender for contract. I would have been glad to have it ready for planting in this weather, but I still hope to complete the operations on it before the end of this month. I am lining so as to put 605 plants to the acre, This will make the new piece uniform with a former planting in the event of its being finally settled to quincunx the latter—an operation I am now convinced will be advantageous in the face of the failure of so much of the cacao.

I am sorry to say that the last planted cacao has suffered even more than the former plantings from whiteants. In six weeks two-thirds have disappeared,

and the danger is by no means over. I have still five or six hundred fine plants in nursery, but I cannot put them ont, till I can put quicklime into the holes with them. The vermin do not like to meddle with this substance: at least, while it retains its caustic quality, and till that departs they will be pretty safe. I read of cacao trees bearing heavily elsewhere within their third year. I have here a few fine flourishing plants over two years, that have flowered abundantly for nine months past without forming a pod.

13th Sept.—For the last four days rain has been heavy and frequent, and work is almost at a standstill, half-a-day yesterday and none to-day.

COTTON will be king once more. That crop is magnificent, fully 7,000,000 of bales, it is said. The only deficiency is in the Southwest. It is the Southern, not the Western merchants who will be the great patrons of New York during the coming year.—*New York Hour.*

MR. A. J. THOMAS'S TRANSPLANTER.—We should ere this have called attention to the latest form of transplanter, that patented by Mr. A. J. Thomas of Agra, Lindula, and manufactured by the Fairfield Ironworks Co. A specimen can be seen at our office, with pan and bag of tins, and we have heard planters who have used this transplanter speak very favourably of it. As far as simplicity is concerned, certainly it can scarcely be surpassed.

ANCHOR BRAND TEA.—The Hon. Mrs. Deane writes to her nephew of Kintyre, Maskeliya:—"It was very good of you to send me the tea, I consider myself a judge of tea, and really that is very good. I doubted at first what it would be like, as the leaves seemed rather large, but on drinking some found it quite *delicious*. It has none of the coarse rank taste which you so often find in the Indian teas." This opinion, from one so well qualified to peak of teas, should beeu cheering to the pilgrim pioners on Bnnyan estate: it shows what goodering and supervision can accomplish.

SALE OF PURE CALISAYA LEDGERIANA SEED.—Under instructions from Messrs. Aitken, Spence & Co. Mr. C. E. H. Symons sold by auction today 45 boxes and one parcel, each containing 2 grams (*i. e.* 31 grains) fresh Calisaya Ledgeriana cinchona seed just arrived from Batavia. The whole was sold for R2,438, or an average of R54·18 per 2 grams. According to these figures the first boxes realised at the rate of R774 the ounce; the second at the rate of R929, and the tuird small lot at the rate of R1,361 the ounce, or equal to R21,792 per pound! Perhaps about a rupee per seed.

"THE CINCHONA PLANTERS' MANUAL" is the subject of high, but we consider not undeserved praise from the Calcutta *Englishman*, as may be seen on page 411. There can be no doubt that it is the most complete and practically useful book available to the cultivator of cinchona. Our Ceylon planters should understand that Mr. Owen has not written from his own knowledge and experience alone. He has had the advantage not only of aid from Dr. Trimen (as is acknowledged), but of consulting every Government Report (whether from India or Java), and all the modern books published on the subject. He carefully consulted the files of the *Observer* for the past four or five years, and he had, besides, the great advantage of the written opinions on controverted points of planters in nearly every district of Ceylon, India and Java, including Mr. Gammie, Mr. Rowson and Mr. Moens himself—which were given in answer to a circular we issued with a special list of questions prepared with reference to the Manual. There is, therefore, good reason for saying that, at this moment, there is no more reliable or more practical work on the subject than "THE CINCHONA PLANTERS' MANUAL."

PERUVIAN BARK AND COCA.*

"Replenish the earth, and subdue it: every tree in which is the fruit of a tree yielding seed, to you it shall be for meat." From far off down the ages comes the echo of the voice which spoke through the Hebrew seer, and comes to us with all the freshness of a new message, as we close the utterly prosaic pages before us. Mr. Clements Markham has laboured long, earnestly, and successfully at his difficult task, and before attempting to follow him in his researches, we would state briefly what that task has been, and what has been accomplished. Mr. Markham set before himself no less an object than the introduction of the cultivation of Peruvian-bark trees on an extensive scale into British India and Ceylon. The object he had most at heart, undoubtedly, was to supply in the very heart of fever districts "a cheap and efficacious febrifuge to the people of India," but his scheme has succeeded beyond, not his own hope probably, but certainly beyond the wildest expectations of onlookers. The enterprise, begun twenty years ago, has for observable result that there are now 847 acres under cinchona cultivation in the Government plantations on the Nilgiri Hills, besides 4,000 acres of private plantations on the Nilgiri, in Wainad, Coorg, and other hill districts of Southern India. In British Sikkim, the Government chinchona plantations cover an area of 2,242 acres. The annual bark crop from the Government plantations of British India alone is already 400,000 lb. In Ceylon, 5,578 acres were under chinchona cultivation in 1877. In 1879-80, the quantity of bark sold in the London market from British India and Ceylon was 1,172,000 lb. The labourers, who, with desperate toil and herculean energy, have given to the millions of India the trees which are emphatically for the healing of the nations, have deserved more recognition than their services have as yet met with, —but of this more by-and-by; at present, we will follow Mr. Markham for a moment in his earlier wanderings, while collecting chinchona plants and seeds in South America. His narrative, though stiff as a Blue-book (the reader who opens it at random will assuredly believe it to be stuffed with dry statistics), is full of interesting matter. Before entering upon the narrative of his search, Mr. Markham pauses to give an account of the early use of the plants he seeks, and the origin of the name now applied to them. He tells us the Indians though probably aware of the fever-healing virtues of their Peruvian bark, were prejudiced against its use. There is some evidence that European travellers were healed by it as early as the year 1600, and it was in 1638, more than seventy years after the conquest of Peru, that the Countess of Chinchona, wife of the Spanish Viceroy of Peru, "lay sick of an intermitt nt fever in the palace of Lima." It was this same Count and Countess of Chinchon, remarks Mr. Markham, who at an earlier date entertained Prince Charles and the Duke of Buckingham at the alcazar of Segovia. Subsequently, when appointed to the Government of Peru, the great event of their viceroyalty was the cure of the Countess of Chinchon of a tertian fever by the use of Peruvian bark. The Countess returned to Spain (we are still quoting from Mr. Markham's account) in 1640, and brought with her a supply of the "quina" bark which had worked her own cure, determined to use it for the sufferers from tertian ague on her father's and husband's estates," in the fertile but unhealthy *vegas* of the Tagus, the Tarama, and the Tajuna." The powder was long known as "the Countess's Powder" (*Pulvis Comitessæ*), and Linnæus in her honour called it by her title. The Jesuits appear

* *A popular Account of the Introduction of Chinchona Cultivation into British India.* By Clements R. Markham, C.B., F.R.S. London: John Murray. 1880.

to have been the great promoters of the further introduction of the bark into Europe, and the new medicine shared the fate of all medical or other innovations. A storm of prejudice was raised, 'it would kill more than it would cure,'—may be taken as a rough estimate of conservative thought concerning it in the seventeenth century, while even those who admitted its efficacy and valued it as a boon were profoundly ignorant of the tree from which it was taken. This being so, we confess we turned with considerable curiosity to the next chapter, in which we learn how the people of Europe really became first acquainted with the chinchona trees. Mr. Markham tells us the first description of the quinquina tree is due to the memorable French expedition to South America which, on May 16th, 1735, sailed from "Rochelle," to measure an arc of the meridian near Quito, and thus determine the shape of the earth. MM De la Condamine and the botanist Joseph de Jussieu were amongst the principal members of the expedition. Both made laborious efforts to collect and take home young plants, but the fate which for some inscrutable reasons attends so many early efforts befell theirs. The plants La Condamine had for eight months preserved with loving care were washed from the deck of his little vessel by a wave, and Jussieu, "after fifteen years of laborious work, was robbed of his large collection of plants by a servant at Buenos Ayres, who believed that the boxes contained money." Poor Jussieu! the blow struck him heavily, and he returned to France deprived of reason. But glancing over the narrative of his work, we notice that "he was the first botanist who examined and sent home specimens of the coca plant, the beloved narcotic of the Peruvian Indian."

Further on, Mr. Markham devotes a chapter to the history of the cultivation of the coca, a chapter which seems to the present writer full of interest. Mr. Markham states that the coca leaf is to the Peruvian Indian what betel is to the Hindu, kava to the South Sea Islander, and tobacco to the rest of mankind. So much, perhaps, was already pretty generally known; but we imagine that, at least outside a very limited medical circle, it was not known that "its use produces invigorating effects which are not possessed by the other stimulants." While reading carefully the history of the marvellous virtues of this plant given by Mr. Markham, the present writer came accidentally across a recent prescription, in which a preparation of it was given in minimum doses, the efficacy of which was tested, with good result, on headache caused by mental worry. On further inquiry, we found its use was the subject of careful consideration and even administration amongst some of our ablest physicians. The Peruvians, says our author, look on it with feelings of superstitious veneration, and the old Incas sacrificed it to the Sun. The plant can be cultivated from 5,000 to 6,000 feet above the level of the sea; but we have no space to follow the interesting details of its cultivation, we can only add Mr. Markham's testimony to its medicinal use. He says:—"Applied externally, coca moderates the rheumatic pains caused by cold, and cures headache. When used to excess, it is, like everything else, prejudicial to health; yet of all narcotics used by man, coca is the least injurious, and the most soothing and invigorating." And he adds, "I chewed coca, not constantly, but very frequently, from the day of my departure from Sandia, and besides the agreeable, soothing feeling it produced, I found that I could endure long abstinence from food with less inconvenience than I should otherwise have felt, and it enabled me to ascend precipitous mountain sides with a feeling of lightness and elasticity, and without losing breath."

But we have left ourselves small space to touch on what, after all, is really the subject-matter of the work before us,—the author's labours in the, as it has proved, successful attempt to introduce the cultivation of chinchona trees into British India. The work, as he tells us, was accompanied by this difficulty, from which similar undertakings have been free,—the plant to be transplanted had never been cultivated. "When tea was introduced into the Himalayan districts, it had been a cultivated plant in China for ages, and experienced Chinese cultivators came with it, but the chinchona had remained a wild forest tree." In 1852, the proposal to introduce chinchona plants into India was made officially. In 1852, and again in May 1853, Dr. Boyle drew up a long and valuable report on the subject; and at the same moment Mr. Markham was actually exploring some of the chinchona forests of Peru, in ignorance of any desire on the part of the Indian Government to procure chiuchona plants, and his objects, he tells us, were of an antiquarian and ethnological character. But the subject of chinchona cultivation being in 859 brought under his notice by Mr. Henry Beedes, of the Indian Office, he gave the subject due consideration, saw the inestimable benefit that might be conferred on India and the world generally, and resolved to undertake its execution. Mr. Markham was, indeed, well qualified for the gigantic task he set himself. He knew the region, the people, and their languages, and having to consider whether the undertaking should be a private or a Government one, he wisely, as we think, submitted his proposal to Lord Stanley, then, in 1859, First Secretary of State for India, and was entrusted with the commission he executed so thoroughly, namely, to introduce chiuchoua cultivation into India. The plan for which he applied for sanction was as follows:—

"To make a collection of plants and seeds of all the chinchonæ known to commerce, through the instrumentality of qualified agents. This would entail the despatch of five agents; to Bolivia or Caravaya for the Calisaya plants, to Huanuco in Peru for the grey barks, to Loxa in Ecuador for the brown barks, to Huaranda in Ecuador for the red barks, and to Popayan for the Colombian barks. These five agents were to work simultaneously under my general superintendence, and a special steamer was to be supplied to convey the collections of plants and seeds from the five ports of Islay, Callao, Payta, Guayaquil and Buenaventura, direct to India across the Pacific Ocean. If the scheme failed at one or more points—which, considering the enormous difficulties, was quite probable—my plan was to repeat the work in the next season, and, if necessary, in the next and the next, until complete success was secured."

He adds subsequently:—

"The measures which I thought necessary from the first, and which I have since continuously striven to bring to perfection, were:—1. The introduction into India of *all* chinchona species known to commerce, because it was uncertain which would eventually prove to be best adapted for cultivation in the new country. Even species which do not yield quiuine were collected, because, the other chinchona alkaloids also possess febrifuge virtues. 2. The establishment of Government plantations wherever suitable sites could be found in India, to form centres for the distribution of plants and seeds, and for ascertaining the best methods of cultivation. 3. The manufacture in India, of a form of the febrifuge combining, in the highest attainable degree, efficacy and cheapness; so that there may be abundant supplies within reach of all classes of the people."

Mr. Markham was eminently happy in the fellow-labourers who assisted him in his huge work; through

lands everywhere bright with flowers, amid magnificent mountain scenery, they found the primeval chinchona trees; it was no easy, summer day's task. In dense forests, on the verge of giddy precipices, with hornet's stinging, ground choked with creepers, and fallen masses of twisted bamboo, they steadily, for many a day, fought their way, and the record of their work is well worth reading. Their collection was made at last; but their work did not go on undisturbed by vexatious interruptions, even danger of arrest from local magnates, though carried on with the free permission of the Peruvian Government; and probably, no one who has not personally assisted at such a task knows the infinite labour and care required to transport in safety a large mass of plants, seeds, and seedlings from one country to another. In April, 1860, Mr. Markham commenced his work; in February, 1873, he is able to record that his original plan had been carried out in its entirety, and the species of the five regions whence the barks of commerce are derived were converted from a wild to a cultivated state, and brought together in the plantations of British India,—the health-giving trees into the land which numbers "a million and a half of deaths from fever annually." At least half these deaths may, says Mr. Markham, be prevented by putting some cheap form of the chinchona alkaloids into every *pansari's* shop in the country, and thus countless multitudes be saved from death or grievous suffering. It remains but to add, in this brief, imperfect sketch of Mr. Markham's work, to which we can but call attention, that the English Government with the short-sighted negligence which but too often accompanies its sanction to scientific research, has left unrecognised and unrewarded many of Mr. Markham's most able helpers,—men who risked, not only their lives, but what was, perhaps, more valuable, permanently their health and strength in the undertaking; while the justification for such negligence is certainly not to be found even in the market value of the work accomplished, since we find "on the Nilgiris the whole expenditure has been repaid with interest by the sale of bark in the London market, and the Government is now deriving large profits of many thousands a year from bark harvests."—*Spectator.*

SCIENTIFIC AGRICULTURE AND AGRICULTURAL EDUCATION.

There is no subject which is attracting more general attention in civilized countries in the present day than that of Technical Education. In this utilitarian age, the direct value of the Education imparted to the mass of the rising generation is being very closely criticized, and the cry is spreading on every side that a great deal has yet to be done before it can be said that European, American or Colonial youth are taught or trained in the way best adapted for the work lying before them in life. Perhaps of all branches of technical Education, that which is the most important, namely, the direct teaching of practical and scientific Agriculture has been about the last to receive the attention it deserves. In England this is especially the case. On the Continent of Europe and in the United States of America, a great deal has been done by the establishment of Agricultural Schools and Colleges, Schools of Forestry, &c., to meet the requirements of a large proportion of the population; but in England, Colleges or Schools of Agriculture may be counted on the fingers of one hand, and as a consequence the British Colonies (which look to the Mother Country as their Educational guide) have been slow to realize the importance of affording a special training for their young people in the one supremely important section of Colonial industries. The depression of the past two or three years has done much to open the eyes of the British public to the backward condition of agriculture in the majority of English farming districts, and to the need of a special training, if future generations of landlords and tenants are to be enabled, with Tennyson's farmer, "to do their duty by the land." The one question which often lies at the centre of all others in social economy or political administration, is how can the greatest amount of produce be secured at the least expense from an acre of ground? The attainment of this result is a matter of science and art, and in regard to Britain it is pointed out that a wide distinction should be drawn between the science of agriculture and the art of farming. In the latter we are told the British farmer occupies no mean position, even though his art be based on empirical principles or on old precepts which will scarcely stand the strain of scientific investigation. But the great want of England is scientific agricultural research. Save for the work of Messrs. Lawes and Gilbert at Rothamstead, and more recently of Mr. Jamieson for the Highland and Agricultural Society, little or nothing has been done by way of experimental inquiries. Very different is the case on the European Continent, and especially in Germany. There, we are told, numerous experimental stations, largely subsidized by Government, are exclusively occupied in working out researches which may eventuate in results of vast practical importance. We may feel sure, however, that scientific research into abstruse agricultural questions will never be encouraged as it ought to be in England until the British farmer, like the British engineer or doctor, receives an appropriate scientific education. It is pointed out that even the well-educated men who take to farming in their youth as a means of future livelihood know little or nothing of the sciences which more particularly bear on their profession. In politics, literature, or art, they may be well able to hold their own; but their knowledge of chemistry and physics, of botany and physiology, is miserably bare, if not a total blank. Of course, there are exceptions due to the Agricultural College at Cirencester and a few similar institutions; but it is now felt that, if the want is to be at all adequately supplied, an "agricultural curriculum," so to speak, must form part of every school worthy of the name in England, and especially of all Colleges and Universities. The problems of medicine are complicated enough, but even they, we are reminded, appear simple when compared with those of agriculture, and yet the tilling of the ground with due knowledge and art must always be one of the most important of human duties. There is no resisting the argument, therefore, that the youths of Britain who are destined, whether as cultivators, tenants, or landlords, to live by the land, should be furnished with the knowledge best calculated to promote scientific agriculture.

If, however, the mother-country does not awaken to an adequate sense of the necessities of the case, she will most certainly be speedily distanced by her daughters at the ends of the earth. In Canada and throughout Australasia, a perfect *furore* has set in for the establishment of Technical, and, especially, Agricultural Schools. Bills to establish "Schools of Agriculture" are among the most popular measures of Colonial politicians, and already much has been done in the far South. New Zealand occupies the foremost position with its Agricultural College, to which is attached a model farm, a learned Director, and a well-organized teaching staff; Victoria has an Experimental Farm with a School attached; and South Australia and Queensland have Experimental Gardens and Forest Establishments. New South Wales lags behind, but she is speedily to make amends, and very shortly Agricultural Schools or Colleges will be found in all the Australian Colonies. The plan adopted may be judged from the following extracts from Australian papers referring to the New Zealand establishment :—

"Our neighbours in New Zealand are wisely aiming at tilling the field of youthful thought and sowing seeds of knowledge in the praetice aud science of agriculture. With this laudable object in view a school of agrieulture has been establshed, in connexion with the Canterbury College, on a farm of 500 acres, 12 miles distant from Christchurch. The school buildings comprise lecture-theatre, library and museum, chemical laboratory, separate bedrooms for 20 students, with all the other requisite conveniences, together with quarters for the director. Stables, granary, cowhouses, dairy, piggeries, &c., have been erected on the farm. The best of labour-saving machinery and implements have been selected, and the dairy utensils, include the most recent improvements connected with the manufacture of cheese and butter. A portion of the farm is devoted to experimental purposes, to test the merits of different methods of cultivation, the effect of manures on various crops, the qualities of native and exotic grasses, the suitability and comparative worth of new varieties of cereals, roots, fodder, and other plants. The studeuts will take part in the work of the farm, and will thus acquire a practical kuowledge of all kinds of farm work, the management of stock, and the making of butter and cheese. Land surveying and levelling will also he taught, and the course of instruction will include the theory of agriculture in all its bearings—the origin and physical properties of soils, the effects of air and rain on fallowed soils, use of manures, draining, cultivatiou and harvesting cereal and other crops, &c. Also chemistry as applied to agriculture; biology, physiologieal botany and entomology, geology and physical geography, veterinary medicine and surgery, mathematics and book-keeping. The course of instruction is to extend over three years, and there will be three terms in each year. Six scholarships have been established, which entitle the holders to board, lodging, and instruction at the school free of all cost. These scholarships will be open to public competition. Candidates may reside in any part of the New Zealand, and must be between 15 and 19 years of age."

The Director says :—

"To the end that the instruction imparted in the school should be, in the first place, eminently practical, farm work, on the part of the students, must be compulsory, and its proper performauce be made a conditiou of studentship that must be rigorously enforced. It is found in America difficult to enforce this condition without some payment for results; and for this, as well as for another obvious reason, I would strenuously advocate the adoption of payment for work done by the students during the second and third year of the course, and alson for harvest work done during the first year, providing that such work be efficiently done. I think payment should be made by the hour, or by the piece, according to quality and amount of work done." Twenty students will be received, and these with three practical farm-hands are to do the entire work of the farm. What this work will consist of is very clearly detailed in the sketch time-table for the first year. We quote from the report :—Monday : 8 to 10, ploughing or other work with horses; 10 to 11, dairy (utensils); 11 to 12, lecture (agriculture); 2 to 3, lecture (chemistry); 3 to 4.30, arithmetic ; 4.30 to 5, milking. Tuesday : 7 to 7.30 milking; 8.30 to 10, laboratory; 10 to 11 lecture (biology); 11 to 12, arithmetic ; 1 to 3, ploughing or other work with horses; 3 to 4, field class (botanical); 4.30 to 5, milking or pig-feeding. Wednesday : 7 to 7.30, milking or pig-feeding; 9 to 10, arithmetic ; 10 to 12, ploughing or other work with horses; 1.30 to 2.30, farm class; 2.30 to 4.30, hedging or other farm work. Thursday ; 7 to 7.30, milking, &c.; 9 to 10, arithmetic ; 10 to 11, laboratory ; 11 to 12, lecture (agriculture); 1 to 2, dairy (utensils); 2 to 3, lecture (chemistry); 3 to 5, ploughing or other work with horses. Friday ; 8 to 10, ploughing or other work with horses; 10 to 11, lecture (physical geography); 11 to 12, arithmetic ; 1 to 3, hedging or other farm work; 3 to 4, arithmetic ; 4 to 5, milking, feeding pigs, &c. Saturday ; 9 to 11, examination. Thus the time of the students will be about equally divided between outdoor and indoor work, and the object plainly is to be turn out thoroughly practical men. An experimental field is to be provided, so that the effects manuring may be closely noticed. A meteorological report will be published weekly, and chemical analyses of such substances as manures, soils, and mineral substances will be undertaken. The farm year is to be divided into three terms, two of these being contemporaneous with the college to which the school is attached, and on the whole it would seem an excellent work is about to be performed."

It is not alone though in Anglo-Saxon communities that we find special attention now given to the need of providing Agricultural Education and of the State encouraging the development of scientific Agriculture. In Japan a Minister of Agriculture and Commerce was recently appointed, and one of his first duties was to organize an exhibition of national Japanese industries. In China it has been determined to establish Colleges for technical as well as general education, and the Chinese authorities are to send no more students to Europe or America for their education. In India perhaps the most notable event of Lord Ripon's *régime* has been the re-establishment, with a considerable flourish of trumpets, of Lord Mayo's Agricultural Department, and much attention is promised henceforward to all that concerns the development of agricultural industries, the improvement of existing tillage, and the provision of a suitable training for the youth belonging to the classes of representative landholders or cultivators. How all this bears upon the present condition of agriculture in Ceylon and the attitude of the Government, we must leave for a future issue, when we shall endeavour to make suggestions calculated to benefit the great agricultural industries on which the prosperity of the island so entirely depends.

Correspondence.

To the Editor of the Ceylon Observer.

THE ARTIFICIAL DRYING OF COFFEE.

Samarang, Java, August 22nd, 1881.

DEAR SIRS,—As you are likely to have heard, it being mentioned in the Singapore papers, a method for drying coffee in an artificial way was invented by me in the beginning of this year. My making a secret of this invention, which is going to make such a great revolution in the prospects and future of the coffee planting, made me have many a struggle before getting listened to by the planters here in Java. I, at last, found some who consented to see an experiment which greatly satisfied them all. The fact of a method for drying coffee, being invented was mentioned in all the Java newspapers and at last, in May, a commission was sent by the Chamber of Commerce at Samarang to assist at an experiment which I was invited to make. The result of that visit and the official report given by that commission is literally to be found in the circulars which I took the liberty to send you by this mail.

You, being editors of the *Ceylon Observer*, a paper which takes so much interest in everything concerning coffee planting, made me take the liberty to send you some circulars, about 200, with the kind request to distribute them amongst the coffee planters in Ceylon and the principal planters in British India, and to mention the inventiou in your esteemed paper. I trust you will have the kindness to receive all letters which the planters in Ceylon might write to me and to forward them to my address.

Apologizing for the liberty I have taken, being unknown to you, and thanking you before hand for your complying with my request, I have the honour to be, dear sirs, yours obediently, T. MAANEN.

The pamphlet, after stating the difficulties attendant on the drying of coffee in the ordinary way, and also the drawbacks of the Guardiola system, says :—

"In order to provide in all those difficulties, I lately took some experiments on Pendem estate, belonging to Messrs. A. M. & F. Engelken, for drying coffee on an artificial way, and was fortunate enough to obtain, after many trials during the last season, a complete success. Therefore, I am now able to make you acquainted with the results of my experiments and with the inestimable advantages to be obtained by my drying process.

1. The construction is very simple and may be done by everyone within 4 weeks, if materials are at hand.

2. No yearly repairs are wanted.

3. No complicated machinery.

4. The drying process can be surveyed by any workman.

5. The quantity of wood depends on the quality and size, but will not exceed 5 or 6 cubic metre for drying 50 piculs of coffee,—any wood may be used and the roots of bamboo will do the best.

6. Two or three men are wanted for drying any quantity of coffee.

7. The heat can be regulated as required.

8. The whole costs for installation will be about 2000 to 2,500 guilders = £170 to £200— which may depend upon local prices of materials.

9. By my process about 50 to 100 piculs of dry coffee, ready for shipment, may be obtained in 22 or 24 hours at 104 to 140° Fahrenheit (100 piculs 6,200 kilogram).

10. The coffee is perfectly dried by my process. The evaporation goes on very equally and the coffee is not exposed to injurious vapours or extraordinary heat. The quality is not in the least affected and the whole is better dried than on masoned drying floors."

After pointing out the advantages of this system, Mr. van Maanen says : "For an amount of £200,— for each estate, I am inclined to give you every information wanted, drawings a. s. o., on condition that no one else shall profit by your knowledge of the process. Every information about the experiments is to be got, besides by myself, by the Chamber of Commerce at Samarang and by Mr. A. M. Engelken at Pendem estate, Solo, Java."

Then follows a report by Messrs. Engelken and Croes on the merits of an experiment made at Pendem estate with this process ; this is followed by the report of the Commission appointed by the Samarang Commercial Association, which we have already published in the *Observer*.

CEYLON, INDIAN, AND EUROPEAN OLIVES, AND CEYLON "WERALUS."

Colombo, 12th Sept. 1881.

DEAR SIR,—In a letter in your issue of the 9th instant, headed "New Products, Aloe Fibre, Castor Oil, and Olives," occurs this passage respecting the last named :—"I may mention that the jungles here abound with the 'Varloe' or Ceylon olive, the half-ripe fruit of which preserved in brine are equal to the Spanish. Have any of your readers tried them?" This subject was discussed in the columns of the *Ceylon Observer* several years ago, and that of the real olives one or two years ago, but perhaps it would be well to give a sort of final notice of the Weralu at least. In 1857 I examined in the British Museum several specimens, and a very fair figure of this plant, in the collection made by Paul Hermann in Ceylon in 1670-77, and in his *Museum Zeylanicum*, a somewhat barbarous catalogue of the volumes containing his dried plants, said to have been first published in 1717, my copy being the 2nd edition of 1726, he refers to this plant at pp. 9, 10 and 22, and to the specimens of it in volumes 1, pp. 50 and 57, and 2, p. 33, in every place of which the old Dutchman spelled the word 200 years ago as it is pronounced by the Sinhalese, and ever has been, viz. *weralu*, and hence no doubt the origin of Weraluga stenna, a well-known place where I resided when surveying in Ambegamuwa in 1841. I believe that the Sinhalese have eaten the olive-like pulpy matter of its drupe when ripe and pickled, time out of mind. Hermann alludes to the drupes as of the size and shape of an olive, and as to the pickling of them by the natives in 1670, he refers thus :—"Fructus immaturi condiuntur, muria ab incolis, addito pauxillo oleo olivarum, ad concitandum saporem olivis propinquiorem" (*Mus.* p. 9.) Burmann, *Thesaurus Zeylanicus*, 1737, p. 93 and plate 40, gives a fuller description of it, and the figure of the leaves and flowers gives a fair idea of the plant.

It is the Elæocarpus No. 206 p. 92 of the *Flora Zeylanica*, of Linneus, 1747, in the appendix to which the description of this genus is first given = 10 the meaning of which is *elaia*, an olive and *karpos*, a fruit, the fruits resembling those of the olive, but otherwise far removed from it. In the *Species Plantarum* it was named Elæocarpus serratus Linn. the specific name indicating the serratures on the margins of the leaves. It belongs to the Lime or Linden family, Tiliaceæ and its wide separation from the true olive is indicated by the fact that in Thwaites, *Enum Plant. Zeyl.* the weralu is given as order 31, and the order Oleaceæ-Jasminaceæ, as No. 104, although the sequence of the orders in this work may not indicate this wide separation. Roxburgh *Fl. Ind.*, 2,

596, wrote:—"Without success I have tried to extract oil from the fruit. They are dried and used in curries by the natives and also pickled."

The fleshy exterior of the ripe drupes of the weralus are freely eaten by the natives, and by Europeans who are fond of acid fruits. The taste is about midway between those of an unripe plum and a sloe. No pickle is better known in the streets of Colombo than that from the weralu fruits, and it is hawked about by Sinhalese boys when the fruits are in season.

Moon *Cat.*, pt. 2, p. 36, No. 565, gives the following Sinhalese names for weralus, viz.: æmbul (sour), kana (eatable), kahata (astringent), gal (rock), and tittra (bitter), and for Elæocarpus serratus he gives the third of these kahata, but this is evidently a blunder as no such distinction is made respecting the common and edible one which is simply the *weralu* par excellence.

The endcarps of several species of Elæocarpus are used as necklaces and rosaries by the Brahmans, several strings of the different kinds being often worn by the same person. They are scented with sandalwood and sold all over India and Ceylon. I can imagine how much of the time of the Director of the Royal Botanic Gardens at Peradeniya is taken up in answering questions like that put by your correspondent, and the labor lost in doing so.

Two species of Olea, one of Ligustrum, and four of Chionanthes belonging to the real Olive family, are indigeneous to Ceylon, and the Olea fragraus, a native of China, was said to be in Peradeniya Garden in Moon's time. The leaves of this latter plant are said to be used in China for scenting tea with. "Olea cuspidata, Wallich. a tree abundant in Afghanistan, Beluchistan and Western Sind, has been supposed to be a wild form of O. Europea, but is regarded by Dr. Brandis as a distinct species. It is not known to have been ever cultivated, yet its fruit which is of small size and but sparingly produced, is capable of affording a good oil." (Fluckiger and Hanbury.)

The O. Europea has been introduced to different parts of India, but I am not aware that it has borne fruits.—Yours truly, W. F.

SILK IN CEYLON: PRACTICAL HINTS FOR SILKWORM REARERS.

DEAR SIR,—Perhaps, with reference to the remarks in your issue of Saturday, the following hints may be useful to any of your readers who are attempting to rear silkworms. *Firstly*, keep the worms as much as possible at a temperature of 70° and 75°. *Secondly*, always give them their food dry: avoid waste, but let them always have some food to go on with. The youngest worms must be fed on the small, succulent leaves from the tips of the branches. *Third y*, as far as possible allow fresh air to circulate round the trays in which they are kept, but avoid sudden changes of temperature. *Fourthly* feed the worms regularly and do not disturb them during moulting. *Fifthly*, avoid crowding the worms, and keep each batch separately, according to age. *Sixthly*, guard against the attacks of rats, mice, green lizards, bronze and "house" lizards, birds (especially robins and titmice), earwigs, spiders of all kinds, and horuets. *Lastly*, put not your trust in eggsimported by anyone but yourself. It is the custom in Ceylon as elsewhere, to purchase experience with other people's money, and recent importations of eggs from China have, so far as I know, not been more successful than the African palm nuts offered some while ago. If there is one thing more than any other in the rearing of silkworms that requires regularity, it is the hatching of the worms as much as possible at one time. It is the custom in large rearing establishments to keep only the worms that hatch out on three or four days, so as to obtain the systematic feeding and regular growth of many thousands, without which success is impossible. If follows then that if the worms emerge only by tens their rearing necessitates an enormous amount of extra time, trouble and expense, and must lead only to still greater irregularities in the following generations, (if there are any).

Irregular emerging from the eggs is a sign of great debility in the parent stock: the rearing of worms under such circumstances is almost worse than useless, and the greatest care and discrimination will be required to prevent the present attempts at Sericulture meeting with the same fate as has attended others.—Yours faithfully, NO FRAUD.

ENEMIES OF CINCHONA.

Dikoya, 16th September 1881.

DEAR SIR,—By this post I send you in a small box the remains of a poochie, regarding which, I think, any information you can give will be useful to cinchona planters.

I found him in the heart of a healthy young succirubra tree to which my attention was first drawn by observing a clotted mass of eaten wood-like saw dust round the tree. Taking this off, I found a hole large enough to put a little finger into, going into the tree about 10 inches above the ground. On cutting the tree down, above the hole. I found that the poochie had worked downwards, and on rooting the tree up, I found he had worked his way down to the very bottom of the stems, or a couple of inches below the surface of the ground. Perhaps the portion of the stem which I first cut may be of interest to you, so I send that also by parcel post.—Yours faithfully, K.

[The "poochie" sent is precisely the same as that described in our issue of the 7th instant, when a specimen was sent to us from Upper Dimbula. It is believed to be the larva of a moth belonging to the family *Hepialidae* which has hitherto shown a great liking for casuarina trees.—ED. C. O.]

THE GOVERNMENT AND THE CINCHONA ENTERPRIZE IN CEYLON.

Maskeliya, 20th September 1881.

DEAR SIR,—With reference to Mr. Talbot's resolution before the P. A, it would be well that Government should be made to understand that the appointment of an analyist is the only way they can now make up for the neglect which the cinchona enterprize (an enterprise on which the fate of the Colony may be said to depend) has met with at their hands.

Hakgala is in such a state that money spent on it can do the planter no good in any way. The stock-in-trade there may be said to consist of an *imposing* gate, avenue, and bungalow, a couple of honest propagating houses that pretend to be nothing better than they are—dingy, unwholesome, dens—an acre or so of sickly Java Ledgerianas, about a year old, and a few miscellaneous dying succirubras and officinalis. Dr. Trimen is probably anxious to effect a reformation, but the money so spent can never make up for the years wasted, and any ordinary estate in the Island will always have better cinchona to show than Hakgala. Grafting from stocks of ascertained value seems to be the only practically useful work to be done, but the non-existence of such stocks is an obstacle. If, therefore, Government refuse to engage an analyist, let them never quote the expenditure on reclaiming Hakgala as being any help to the cinchona industry.—Yours truly, NEGLECT.

THE "ENGLISHMAN"'S REVIEW OF "THE CINCHONA PLANTERS' MANUAL."

We have to acknowledge the receipt of "The Cinchona Planters' Manual," by T. C. Owen, published by Messrs. A. M. & J. Ferguson, Colombo.

It is one of the most complete works of its kind that we have come across, and far surpasses both in manner and in matter any similar manual that has yet been offered to the planter. The writer goes to the very root of his subject, the first part of his book being devoted to an exposition of the physiology of plants in general. Part II. contains two chapters, one dealing with the chemistry of the alkaloids derived from cinchona bark, their relative values, and the proportions in which they exist in different parts of the tree; and the other giving a detailed account of the various species and varieties and their characters, regarded both from a botanical and a practical standpoint. Part III. treats exhaustively of cultivation and harvesting, and their accessories; Part V. deals with the diseases to which the plants are subject; while in Part VI. the writer gives us a series of elaborate estimates of outlay and returns. In Ceylon, we observe, the diseases are less serious than in the case of either coffee or tea, the most formidable being canker. But in Java the trees are said to be liable to the attacks of a pest identified by the writer with the red spider of tea-bush notoriety. We regret to add that he suggests no remedy for the evil.

If the estimates given in the Manual can be depended on, cinchona cultivation holds out prospects which the tea planter may well envy. They show at the end of five years, for the *Officinalis* variety, a profit, on the uprooting system, of R1,344 on an outlay of R1,179, and on the mossing and renewing system a profit of R3,047, on an outlay of R1,822, per acre; and for the *Succirubra* variety profits of R860 and R2,509 on outlays of R993 and R1,795 respectively. As regards the first of these results, Mr. Owen says:—

"The profit of R1,343 per acre includes the cost of land, R150, and the proprietor finds himself in this position. He has purchase money and expenditure returned to him, with profit as above; he has 100 acres of cinchona land planted up by self-sown seedlings; a quarter of this acreage being two and a half years old, and ready to cut during the middle of the ensuing year, one-fourth the year after, and one-half the third year; shewing a profit at the end of nine and a half years greater than that shewn at the end of the first five years by the saving of original purchase of land and opening expenses, R27,945, besides other little savings in upkeep and first building, always provided that the land is found capable of producing a second crop."

No estimates of results are given in the case of *Calisaya* or other species, for want of data to go upon.

CUPREA CINCHONA.—Further information concerning the "cuprea" cinchona bark has been contributed by Dr. Charles A. Robbins, of New York, to the *Oil, Paint, and Drug Reporter*. He has visited Santander, United States, Columbia, where the bark is collected. He says that the tree grows on the lower mountain ranges adjoining Buccaramanga, at a much lower altitude than any of the known marketable kinds, the good trees not generally growing at a level below 2,000 or above 3,500 feet. The first lots of bark that were shipped were obtained from the higher altitudes, 2,000 to 3,000 feet, and was in most cases of fine quality. A good deal of that which has recently been collected is of very inferior quality and it is stated that the greater part of it will not yield half as much quinine as the first shipments to London, which sold at 3*s.* 6*d.* to 3*s.* 8*d.* per lb.—*Phar. Journal.*

ABSTRACT OF PEKING GAZETTE.—July 16th.—(1) Memorial from Ming An, Governor of Kirin, reporting that he has succeeded in obtaining from amongst the hills ten large plants of wild ginseng weighing about two taels nine mace five, and ten small plants weighing about one tael four mace five. The ginseng supplied to His Majesty last year was paid for out of the public funds by the memorialists, but the expense of procuring it is so large that he cannot continue to draw upon the public funds for the necessary amount. The four ounces odd that have now been procured involved an expenditure of Tls. 404, and he would suggest that now that the sale of cultivated ginseng is no longer prohibited, and duty is levied upon it, the sum required to procure the wild ginseng for the Court may be drawn from the duties levied on the cultivated plant, should His Majesty demand a further supply.—Rescript: It is noted.—*North China Herald.*

JOHORE TEA has been characterized as "Good blackish leaf, strong, Pekoe flavour." This, to begin with, is encouraging, and it may be that at no distant day we may see tea plantations on the Malay Peninsula. The experimental tea gardens belonging to H. H. the Maharaja are flourishing excellently. A tea planter from India who recently visited them, stated, that the "soil and climate was all that could be desired', for the successful cultivation of the tea plant. Samples sent to London have been reported on as above and valued at from 1/7 to 2/1 per pound. Indian teas are increasing in favour, the deliveries in London reaching nearly 50,000,000 lb. annually. Apart from the export trade, Messrs. Thomson, the tea Brokers, state that the deliveries of China tea are about 116,000,000 lb. The quality has deteriorated. Java tea is not esteemed in the home market, and the same may be said of much that is exported from Japan. There are thousands of acres in Johore admirably suited for this industry, and judging from the quantity and quality of Gambier leaf and the general superabundance of foliage everywhere on the territory, there seems to be nothing wanting to guarantee success to the planter except cheap Indian labour. The nearness of Johore to the Singapore market is in itself a great advantage to the planter.—*Straits Times.*

FIBRES.—In the annual report, which has just reached us, of another valuable institution in Calcutta, the Royal Botanical Garden, it is mentioned, on the authority of the Superintendent, Dr. King, that the cultivation of *rhea* is not likely to prove a commercial success in Bengal. The prizes offered for an efficient machine for cleaning the fibre have hitherto failed to create much interest in the subject, and it is unlikely that zemindars and ryots will undertake the cultivation of the plant until there is a cheap and effective means of bringing it into marketable condition. During the past twelve months various kinds of grasses were examined with a view to test their capability of yielding a paper fibre, but the results in no case appear to have been hopeful. Dr. King recommends that attention should be given to the utilization of the plaintain, which, so far as the manufacture of paper is concerned, promises to be the best of the fibre-producing plants in India. Sir Ashley Eden, who is always ready to encourage local enterprise, expresses his readiness to assist any mercantile firm or private persons wishing to try experiments with the plantain in the Chittagong Hill Tracts, or elsewhere in Bengal, by supplying them with wild plantain stems, free of cost, at the out-set of the experiment, and afterwards at reasonable rates. The manufacture of paper is an industry that it is very desirable should be encouraged in India, and, we hope, some one will come forward to avail himself of the assistance of the Bengal Government.—*Times of India.*

A NEW KIND OF PALM has been discovered in some of the South Sea Islands, or else cultivation has improved the already wonderfully productive powers of the cocoanut palm. In a leading article a few days ago a contemporary spoke of the "copra-bearing palm" as one of the natural products of those islands. Ready-made copra, hanging in graceful clusters from the tree, would indeed be a striking proof of the effects of scientific agriculture.—*Colonies and India.*

CARDAMOMS.—During the past month, Bengal cardamoms, the produce of *Amomum aromaticum*, Roxb. and meni seed, the spindle-shaped fruits of *Lophira alata*, have been offered at the London drug sales. The latter belongs to the natural order Dipteraceæ, and occasionally presents one of the wings of the calyx, to the development of which the order owes its name. An oil obtained from these seeds is said to be used by the natives of tropical Africa under the name of "meni" oil.—*Pharmaceutical Journal.*

MEDICINAL PLANTS IN JAMAICA.—The cultivation of chinchona bark is being vigorously carried on in Jamaica under the able direction of Mr. D. Morris. The true *Cinchona Ledgeriana*, the most valuable of all the Peruvian barks, has been grown from seed supplied by Mr. Moens, of Java; and there are now in Jamaica some 60,000 seedlings raised from this seed, beside 20,000 more from seed obtained from Dr. King, of Calcutta. This quantity will, it is hoped, enable the Jamaica plantations to compete successfully in a few years with those of the East Indies. The Columbian barks lately introduced into Jamaica are also thriving. The cultivation of jalap in Jamaica, again, promises to be a success. About 2,000 lb. of this root are being now sent to the London market, partly in the form of split and dried tubers and partly in slices. Should the latter meet with acceptance at a fair price, the cultivation promises to be remunerative, as the roots can, in this way, be dried without artificial heat, and 2d. per lb. cost of production saved. The roots are said to lose about 70 per cent. in drying. The roots are being analysed, and the results will probably soon be published.—*Colonies and India.*

THE WATER POWER OF NIAGARA RIVER.—The recent visit of the American Society of Civil Engineers to Niagara Falls has drawn renewed attention to the works for utilizing some of the enormous water-powee of Niagara river which are now in progress under thr auspices of a new Company. The canal was originally constructed by Horace H. Day, of New York, in the year 1850, at a cost of $250,000. The canal debouches from the river above the falls, and discharges into the reservoir below them, being about three-quarters of a mile in length. Its dimensions at present are about 35 ft. in width, by 10 ft. in depth; but the new Company have land enough secured to enlarge it, when necessary, to 100 ft. wide. There is a fall of 2 ft. in the length of the canal. It is arranged to extend the reservoir, as required, to a mile in length along the river bank, its width being 70 ft., and depth same as the canal. Four wheels, owned by private individuals, were in operation formerly. The new Company, formed some four years ago, bought the old undertaking at a mere song, and is now developing the scheme into a thoroughly organized water-power Company. They have nearly completed a wheel pit, not far from the lower extremity of the present reservoir, 40 ft. long by 20 ft. wide, sunk in the solid rock 86 ft., from which a tunnel, 10 ft. by 6 ft., has been bored for discharging the waste into the river. It is proposed to ultimately place three wheels in this pit, but for the present only a 50 in. Risdon turbine is in position, under a head of 86 ft., developing some 1,100-horse power. The water is led from the reservoir to the wheels by huge iron pipes. The total available head is about 220 ft., which, after deducting the 86 ft. at present employed, leaves some 134 ft. yet available. The possibilities of power appear at first sight to be inexhaustible.—*Iron.*

QUEENSLAND PEARL FISHERIES.—From a report recently issued on the pearl fisheries of Queensland by Lieutenant de Hoghton, of Her Majesty's ship "Beagle," we learn that 11 firms are engaged in the trade in Torres Straits, of whom ten have their headquarters at Sydney, employing nearly 100 boats in the work.' The amount of pearl-shell exported in 1878 was 449½ tons, valued at from £60,000 to £70,000. The price of the shell fluctuates a good deal, ranging between £120 to 280 per ton. The divers principally consist of Kanakas, Maories, and Malays, only some 20 white men being engaged in the operations, with a few Australian blacks. Generally speaking, the divers make an excellent thing of it, their earnings seldom being less than £200 a year, while in very good years, such as 1878, they have been known to make £340 each. Although there are a good number of sharks in these seas, the loss of life on the part of the pearl fishers is very small, averaging about two per annum; and it is a curious fact that the sharks almost always beat a retreat as soon as the fishing operations commence.—*London Times.*

ARTIFICIAL HONEY.—When "artificial honeycombs" made of paraffin wax and filled with "glucose"—*i.e.* the sweet syrup of common corn—are manufactured in large quantities in New York, and "eagerly bought up as the best clover honey," it is hard to say where Yankee ingenuity and human credulity are to end. But cannot many of our Colonies take the hint thus offered to them, and step in to supply the demand for honey with the real article? In the garden isles of the West Indies, on the flowery slopes of Botany Bay, amid the groves of Tasmania, in Canada itself—with all its "terrible winters"—the "busy bee," if properly housed, would manufacture illimitable quantities of best honey in purest wax cells without the necessity for machinery to copy the combs in solidified paraffin, "so beautifully as to defy detection"—to quote the words of the *Graphic*, which reports this latest Yankee dodge—and without calling into requisition hot irons to close the cells. Wooden nutmegs, oleomargarine, and glucose honey, are all very well in their way, but when it is worth while to make imitations of any article there must be a market for the real thing and the real thing will always bear the palm.—*Colonies and India.*

THE ENGLISH COMMUNITY IN IOWA.—A per pawith this title, by Mr. Robert Benson, in *Macmillan's Magazine* for May this year, gives on account of the English settlement referred to by a correspondent in our issue of last Friday. It appears from this that the founder of the colony (which now numbers 500) was Mr. Close, the well-known Cambridge oarsman, who in 1877 bought 3,000 acres in north-western Iowa, his reasons for choosing that part in preference to Canada or other American states being that there was plenty of railway carriage, the land was prairie and would grown both staples, Indian corn and wheat, and as the eastern half of the state was thickly populated and the land there was worth £8 to £15 an acre it was to be expected that the next year of immigration would overlap the eastern half and equalize prices. 120,000 acres have already been cultivated by this colony, representing a capital of about £250,000. The land is divided into farms of 160 acres each, every 40 farms or so being placed under a steward. A farm ready for the tenant would cost now from £340 to £400. Labour is plentiful, the wages being £3 10s a month and board. Nothing but success has met the colony so far, but the test will come when there is a bad harvest from burst, or drought, or storms, or other causes; on when a good harvest in Europe corresponds with one in America. Meantime however persons with moderate capital can scarcely do better than follow the example of the former Colombo merchant whose experience is given in Friday's paper, and buy a farm in Iowa.

TEA AND SILK FARMING IN NEW ZEALAND.

For the Tea Industry.—(1) The necessary supply of one-year-old tea plants and fresh seed from China, Ceylon, Assam, the Neilgherries and Darjeeling, delivered at the nearest port to the proposed plantations at cost price, or free. (2) Facilities for the importation of labour from China, India, or elsewhere; and reasonable legal protection to the planter against the non-fulfilment or evasion of labourers' engagements. (3) A proportion of forest land to the acreage purchased or rented, at a reduced figure, or free. (4) The admission without duty by the Customs of all material, implements, tools, and machinery necessary in tea cultivation, manufacture, and packing, for a short term of years. (5) Freedom from duty or excise impost for all tea grown and prepared within the colony for the first ten years.

For the Silk Industry.—(6) The necessary supply —four hundred plants per acre—of five-year-old white mulberry bushes grafted on black mulberry stocks, or other approved kinds and seed from Sydney or elsewhere; also the needful quantities of any other silkworm-feeding shrubs, such as the castor-oil plant, the terminalia and jujube trees, the ailanthus, &c., delivered at the nearest port to the proposed plantations at cost price, or free. (7) Facilities in regard to labour, land, and freedom from duties, as in the tea industry. (8) And such encouragement as would lead to the speedy settlement of skilled reelers from France and Italy, silk throwsters from England, and the purchase in time of all the elaborate mechanism required in the higher branches of the silk industry.—W. COCHRAN.—*Chambers's Journal.*

CASUARINA CULTIVATION.

TO THE EDITOR OF THE "MADRAS MAIL."

SIR,—Referring to an extract from *The Eurasian and Anglo-Indian Advocate* which appeared in your issue of 20th July, regarding the cost of planting casuarinas, the writer says:—"It is estimated that under very unfavourable circumstances as much as R100 per acre will be required for the first year." On referring to his estimate for planting six acres I find, after deducting an item 'cost of watering and all sundries' which I will suppose is expenditure incurred after the first year, the cost of raising, planting and tending for one year, on six acres, to be R156 or R151 per acre.

The writer of the extract also says:—"Land for casuarina cultivation may be had for R10 per acre. I shall say R20 to be on the safe side." On going to his estimated abstract of receipts and expenditure, I find R1,400 as gross expenditure on 6 acres; but on referring to detailed account, I cannot find any charge for cost of land. Again, a profit of R7,600 on an outlay of R1,400 would, by my calculation, be 542·8 per cent instead of 550 per cent. Will the writer of this, or the editor of the paper referred to, be so good as to explain, and if I am wrong put me

Travancore, 3rd Sept. RIGHT.

THE CULTIVATION OF CASUARINAS.

At the meeting on the 3rd ultimo, of the Madras Agri-Horticultural Society there was read an article on "The Profit of Casuarina Cultivation," published in the *Madras Mail* of the 20th July last, as an extract from *The Eurasian and Anglo-Indian Advocate*, in which it is reckoned that 18,000 trees may be grown on six acres of land to produce 8 annas each in four years, at a gross expenditure of R1,400 resulting in a net profit of R7,600, or a return in four years of 550 per cent. The Honorary Secretary, who has had considerable personal experience in this matter, stated that such estimates are liable to cause much mischief by inducing people to speculate without the means. "The most successful casuarina planters in the neighbourhood of Madras, where the land is specially adapted to the industry, plant only 300 trees to the acre, and consider themselves very fortunate if, after being twelve to fifteen years without return for their money, they can cut an average of anything over forty tons of firewood to the acre; or if, in other words, they get their wood to market so as to give a net return, at R6 per ton, of R240 per acre. Multiplying this sum by 6 we have a return of R1,440 for six acres, against the writer's estimated expenditure of R1,400. Thus, the business is only really profitable when worked on a large scale; when the trees are allowed to grow for much more than four years; when there are very good acres to make up for those that fail; and when water is close enough at hand to allow of the expenses being reduced to the lowest possible amount." We have been informed that no area under 100 acres will pay Europeans, and that these 100 acres must be good land. Natives who plant small plots make profit because they use only the unpaid labour of their own families. Last year as an experiment a correspondent of ours cut an acre of seven year old trees—an average one. Its produce was just under 7 tons, and the net value of the wood was about R5 a ton, so the acre yielded but R35 after seven years' waiting for returns.—*Madras Mail.*

SILK IN THE PUNJAB.

The cocoons from imported seed are said by the manager of Messrs. Listers' filature to have been as fine as any in the world. This is an extremely satisfactory result, and one that the Lieutenant-Governor hopes will be maintained. It is to be regretted that the country seed should have become generally diseased, but his Honor does not think that it is necessary to take any special steps in this matter as proposed by the Financial Commissioner and the Commissioner. From the facts stated by the Deputy Commissioner that very few country cocoons were exhibited this year, and that Messrs. Lister gratuitously distributed foreign seed to all breeders who agree to sell the produce to them, it appears certain that the foreign seed will supersede the country seed without any effort being made in this behalf. It is not likely that the moths and worms of the two classes are allowed to mix, but unless this is the case, the infection cannot spread.

The return attached to the Deputy Commissioner's report shows that the produce of 2 maunds 26½ seers of seed was 347 maunds, 2 seers of cocoons. The rough outturn of silk is put at 80½ maunds, but at the rate used by the Deputy Commissioner, viz. 10·41 seers of silk per maund of cocoons, the amount would appear to be 90 maunds 12 seers. This seems to be a satisfactory result, but it is not possible to compare the figures with those of previous years, as the former statistics of one or the other of the districts are always incomplete in some particular. The Lieutenant-Governor trusts that this information will be carefully recorded in the future, and an effort should be made to gauge roughly the proportion which the cocoons exhibited bear to the whole number produced in the two districts.

The development of mulberry plantations during the past year has been satisfactory. The Irrigation Department has been addressed as suggested by the Financial Commissioner, and requested to plant mulberry trees as far as possible on the banks of the Bari Doab canal and its main distributaries in the Gurdaspur district.—*Indian Agriculturist.*

TOBACCO-GROWING IN THE EASTERN PROVINCE OF CEYLON.

TO THE EDITOR OF THE "CEYLON TIMES."

SIR,—Mr. A. Shaw, a Sumatra Planter, whose services we secured at great expense to cure our Tobacco, is now engaged on that work. It is necessarily a lengthy process anywhere, but we have found it more so here—our climate during the months that the curing is going on, is very dry, and fermentation is therefore not so quick and strong, as it otherwise would be. That this is any disadvantage, except that it makes the curing a little more expeusive, and that we lie out of our money the louger, we are not prepared to say.

Last year we had more difficulties to contend with than we will ever have again. Still, we got a considerable acreage planted with tobacco, from which we have secured a large quantity of leaf. Regarding its quality, I can only at this stage, quote from Mr. Shaw's report. "Much of the tobacco grown this season, which I am now engaged in curing, is of excellent quality." "The great point, therefore, has been gained in Trincomalee in proving so satisfactorily, that the soil and climate are suitable for producing tobacco of the wished-for quality." The tobacco is now being sorted and pressed into bales for export to London and Amsterdam—a few bales being sent elsewhere on the continent through Messrs. Frendenberg and Co.

I see no reason why tobacco should not grow equally well at Tissa—if my ideas of its soil and climate are correct. It certainly is worth a trial, as there is no crop more paying. Your correspondent wished to know why we were planting up last year's tobacco lands with coconuts. The natives of Trincomalee cultivate tobacco more extensively than anything else, year after year on the same land, using cattle manure alone; in Sumatra, after the first crop, the land is manured with lime and guano. We desire to get as much land opened up here as we can, as the more we open the healther the place will be, and having plenty of land we can afford to plant up our first year's clearings with coconuts. Awaiting the result of the sale of our first tobacco crop before we plunge. Besides which coconuts are a very paying product here. And we are not over burdened with money, and I think we shall find it cheaper to fell and clear new land than to manure the old. The upkeep of the coconuts, is next to nothing, the planting we do simultaneously with, and at the expense of, the tobacco.

A. H. MACARTNEY.

TOBACCO CROPS OF 1880 AND 1870.

J. R. Dodge, special agent for the collection of statistics of agriculture, has issued from the Census Office a report showing the tobacco crops of the United States for the census years 1880 and 1870. The comparative statement in the report shows an apparent increase in the production of 80 per cent during the decade, the product in 1880 being placed at 473,107,573 pounds, and that of 1870 at 262,735,341 pounds. This apparent increase, Mr. Dodge says, exaggerates the real advance in tobacco cultivation; at the preceding census the crop was a small one, and the fear of taxation may have operated to prevent a full crop of tobacco in 1870. The crop reported in 1880 was one of medium production, not in excess of present requirements for home demand and export. Fifteen States produce now, as in 1870, more than 99 per cent of the tobacco of the United States, although it is reported in twenty-two other States and six territories. Of these fifteen, only Missouri, Illinois, Indiana, and Massachusetts produced less than in 1870. Kentucky occupies the first position, producing 36 per cent of the total product of the country. Virginia then holds second place; Pennsylvania has advanced from the twelfth to the third; Wisconsin from the fifteenth to the tenth; and North Carolina, Connecticut, and New York have each gained one point in the rank of tobacco States. Those that have retrograded in relative production are Massachusetts, Maryland, West Virginia, Indiana, Illinois, Missouri, and Tennessee. The average yield per acre is shown to be 731 pounds, varying from 1,599 pounds in Massachusetts to 471 pounds in North Carolina. This variation in the rate of yield, the report states, is due in differing degrees to the use or neglect of fertilizers, the habit of growth of different varieties and vicissitudes of season.

The following table shows the total product in pounds and yield per acre in 1880 in fifteen leading tobacco-growing States:—

States.	Total Yield.	Average.
Kentucky	171,121,134	756
Virginia	80,099,830	553
Pennsylvania	36,957,772	1,340
Ohio	34,725,405	1.001
Tennessee	29,965,652	707
North Carolina	99,286,448	471
Maryland	26,082,147	683
Connecticut	14,044,652	1,620
Missouri	11,994,077	773
Wisconsin	10,878,463	1,234
Indiana	8,872,842	742
New York	6,553,351	1,327
Massachusetts	5,369,436	1,599
Illinois	3,396,700	699
West Virginia	2,296,140	564

THE STATE OF PERAK.

(*London and China Express*, 26th August 1881.)

As evidence of what the result would be were the Malay States under British rule, there is an announcement in the *Straits Settlements Gazette* of the increase which it is thought desirable to make in the price of land in the district of Larut. The order referred to has of course been made at the instance of the Regent and Council, who direct the Resident to see that it is carried out. This goes without saying so far as its appearance in the order is concerned; but one is very much inclined, on seeing Legislation of that kind, to imagine that the circumstances as just put, ought to be reversed. This, however, has nothing much to do with the alteration made, except so far as to show that the British Resident's presence, coupled with his *advice*, is bringing about a state of things very different to that which existed only a very few years back. As to the advisability of the change, that is a matter in which there is likely to be a good deal said, because it may with justice be contended that anything resembling a diminution in the easy terms offered by the Government must to some extent stop the otherwise very rapid development of the country. This opening up in that part of Perak, south of the Kreean and Kuran rivers, must have been more successful than was anticipated. But what the object can be in putting a higher price on the land is rather difficult to see, unless it is to divert enterprise more to Perak proper, in which very little has as yet been done beyond prospecting.

On the other hand, there cannot be, comparatively speaking, very much land left in Larut. Ever since the mines were opened there the influx of Chinese has been very large, while since the war the cultivation of rice and sugar has increased to a very great extent. The low-lying portion of the country included in the water-shed has always contributed to the rice products; the yield in some parts being so

great as to utterly eclipse the neighbouring lands, and now that the opening of the fresh water canal from above the tidal influence of the Kreeau supplies the one want, the whole of the lands have no doubt been applied for. Further up the river, also, much enterprise has existed for a considerable period, and Selama and its neighbourhood, besides producing large quantities of tin, is in a high state of cultivation. On the banks of the river again, near Province Wellesley, a very extensive sugar estate exists, the energetic Chinese proprietor of which has gone in for machinery, so that there is a continuous line of settled cultivation from the mouth of the river for some considerable length of its course, and again near its source. Now is this enhanced price for the land a wise act on the part of the Regent and his advisers? It will, of course, if it does not put a stop to the opening up, add considerably to the funds in the Treasury; but is this pecuniary advantage likely to be nullified by the uncertainty which will arise in the minds of capitalists with reference to the acts of the Perak Government? When other States are contending for the patronage of capitalists, it is questionable whether it is a wise policy to pursue. Time will show; but if the result is disadvantageous, more harm than a return to the easy terms can remedy will be done. Surely it would be far better to adhere to one set of conditions, and not change it because it has been beneficial. We should have thought that was the greatest argument in the system adopted. There may be local circumstances which justify the alteration, and we can only hope there are, otherwise the change is assuredly a penny wise and pound foolish one.

DECAY OF EUCALYPTUS AT CHANGA MANGA.

(*Indian Forester*, July 1881.)

I see that Mr. J. C. McDonell draws attention to the destruction of Eucalyptus at Changa Manga Plantation. It is a pity that he does not state what species have suffered, or whether only one kind has been affected. I was reading lately a paper "On the Timber-supply of Australia" by the Hon'ble Mr. Krichauff. He says:—"I heard at different times the gum trees died without any apparent cause in many parts of the colony, especially in the south-east. I observed once, many years ago, that our blue gums died suddenly over an area of perhaps fifteen or twenty acres, in the Bugle Ranges in the midst of a well-wooded district. Last summer, however, my attention was called to the following alarming fact:—On a very large tract of timbered country on the Hundred of Strathalbyn, said to be about fifteen or twenty square miles in extent, not a blue gum remained alive. All other gums—white, yellow or red—were luxuriant, while the blue gums, from the largest tree to the smallest sapling, were dry, and the bark, already cracked, ready to fall down this winter. It was remarkable and perplexing to observe the exactly straight boundary line on one of the outskirts of this tract of land which I visited. Within a few yards all blue gums were dead, and outside this line they were as vigorous as ever. My time being short, I could not examine the trees properly to ascertain anything further; but such an examination ought yet to be made. At all events, inexplicable as it is to me, I thought it right to mention it, so that one or other of my hearers or readers may venture an explanation, or the enigma may be solved by comparing the observations of a number of persons at different localities and times, and perhaps as regards different kinds of trees."

In the instance quoted it is the blue gum (*Eucalyptus Globulus*) which alone suffered. Was it also this species at Changa Manga?

Above, the blue gums were growing in their native climate along with their accustomed associates; the blue gums suffered but the others flourished. The cause might have been supposed to be frost or drought, but that blue gums were said to be unaffected on the other side of a boundary line.

Again, one would expect that, if the cause were drought, the older trees with roots penetrating more deeply would have resisted longer than young saplings. The other trees, too, even though of hardier constitution, would have probably suffered to some extent.

Thus, though without the opportunity of observing the facts, it is rash to hazard an explanation. I should imagine that the damage was caused by an inroad of animals, perhaps rats and mice, or other rodents. I should examine the roots of a tree that had shown signs of suffering, to see if it had been gnawed, and also search for any other indications of the presence of animals, such as their holes, droppings, &c. Or the evil might be due to fungus; and perhaps this is more in accordance with the fact of the boundary line separating the invaded tract from the flourishing tract alongside. The intervening few yards of cleared land forming the boundry line might readily be crossed by such animals as rats and mice, but the mycelium of fungus would take some time to cross it, or be stopped for want of nourishment.

White ants are generally credited with forbearing any living tree, and besides they are certainly not exclusively partial to blue gum. So I think we must seek the cause of death in some peculiarity of the species. The malady may have attacked other vital parts, for instance the cambium; but the roots, I think, are most vital—the most likely seat of the evil.

The *Revue des Eaux et Forêts* for November 1880 contains an interesting paper on the "Maladie ronde" which ravages the pine forests in Sologne. The writer comes to the conclusion that the malady, which attacks the Maritime and Scotch pines, is due to the mycelium of certain fungi, notably the *Rhyzina undulata* (Fries.)—F. B. M.

SILK GROWING IN AMERICA.

The rapid growth of the silk manufacturing interest in the United States was recently made evident in these columns by a review of the census statistics gathered by Mr. Wyeoff. Commenting upon the same facts, and the superior quality of American manufactured silk, the Philadelphia *Public Ledger* gives a large amount of interesting information touching the production of raw silk and its possibilities in the United States.

"It is as easy to raise cocoons as sheep—easier. The intermediate stages between the cocoon and the factory have yet to be undertaken, but cocoons and eggs are both raised in this State, in North Carolina, and in Missouri, for sale and export. The shearing of the cocoons or the filature is the step that has to be taken on an extended scale. The great cocoon market for the world is Marseilles. The silk filatures are grouped in the departments around Lyons, and the French raised cocoons are consumed in the immediate neighbourhood in which they are raised; but the foreign cocoons, coming from all countries, are distributed from Marseilles, and there they are purchased to the best advantage. Consul Peixotto points out in a private letter to the American Minister at Paris, in answer to some enquiries made through Mr. Noyes by the Philadelphia silk school, that American-grown cocoons can be sold at Marseilles as readily as any others, as soon as the quality and especially the uniformity of the cocoons become known in the markets. By the efforts of this school American grown cocoons will doubtless soon be placed on sale in this

imporsant depôt to direct the attention of American silk raisers to this point. There have been already given in the *Ledger* such details of silk growing under the management of this school as will satisfy any one that all that is needed is such a point to which the numerous little harvests all over the country can be gathered and forwarded. Here is one experience from Gwynedd, Pa., representing six weeks' care of one crop. There were raised in one farmhouse, just as an experiment and to see how it would work, thirty pounds of cocoons and fifteen ounces of eggs. The cocoons are worth at a market two dallars a pound; the eggs, from three to four dollars an ounce. From a North Carolina farmer comes a letter on a larger scale. He has put up one hundred and fifty racks this year, four feet long by three wide, and each rack is to accommodate two thousand worms He expects to raise this summer one thousand barrels of cocoons (North Carolina cocoons, pure white, took a premium at the Centennial); but this grower raises also from the French eggs the large flesh-coloured cocoons, of which about one huudred and ninety weigh a pound, and from the Japanese eggs also a fine cocoon.

"But why, asks the protective and otherwise thoughtful reader, need the cocoons be sent abroad to be sold, and this golden fleece sheared by French hands? Why can they not be kept at home, seeing that the silk manufacturer can, or at least could, take all that can be raised for years to come? That is the point which is now occupying the minds of *sericulturists*—seriously occupying them. Cocoons and eggs and all that they know. They know that the mulberry will grow wherever the apple tree does, and that the osage orange does about as well as the mulberry. They know that the season begins on the 11th of May and lasts six weeks, and that it is possible, by skilfully retarding some of the eggs to make two seasons in the year. What they have not yet reached is the perfection of reeling, although they are experimenting upon it. The hand reeling of Italy and France is an old story. Silk has been reeled by hand here, and is still, and if the farmer's daughter puts her reeling at the same price as her knitting or crochet to fill up the unemployed time, and not for an occupation to live by, hand-reeling would pay to that extent. For an extended business the great filatures are needed, where American cocoons can be reeled at home by machinery, the only thing that can come into competition with the cheap day labour of the Italians, French, and Japanese hand reelers. A young American engineer is at this time in France, experimenting on the reeling of silk by electricity, which is the motive power destined to lighten labour as well as streets. This is the one missing link that is needed to complete the chain between Hortsmann's fringes and ribbons and the New Jersey silk dress goods and handkerchiefs, the Connecticut sewing silks, &c., and the cocoon racks in American farm-houses. The Philadelphia school that has done so much in gathering up these threads of detail, and in sending out its cocoons and instruction over the country is a real credit to the city and the State."—*Indian Agriculturist.*

TEA PLANTING IN THE MALAY PENINSULA.

(*London and China Express*, 26th August 1881.)

Tea planting in the Malay States is about to receive an impetus by the opening out of two estates in Johore, the managers for which will in a short time proceed to Singapore. This has no doubt been caused by the favourable report issued on a small sample of tea received in England, and now that a beginning is to be made on a large scale, it will not be long before the cultivation is widely extended. We have very frequently pointed out that there is a great field for tea in the Malay States, and it is somewhat surprising that nothing has been done for so long. The soil in the interior is admirably adapted for the plant, and the experiments which have already been made in Province Wellesley were so successful, that a following up of them was well justified. The Maharajah of Johore very naturally desires to have his country opened up, and H.H. has with admirable foresight announced his intention of facilitating by every means in his power agricultural enterprises. This policy if steadily adhered to must attract capitalists, and as the territory is rich there is no reason why it should not contribute largely in time to the European markets. The Maharajah of Johore is an energetic and enlightened ruler, and has done much to make his State a model native one, although we have on occasions differed from his policy when we have deemed it our duty to do so. Many of his efforts have perhaps been curtailed from want of an inexhaustive exchequer; but nevertheless much has been accomplished. As a very much favoured *protégé* of the British Government, his Highness has many opportunities which are denied to the less patronised Malay princes, and this will probably tell a great deal in such enterprises as tea, coffee, cinchona, and sugar cultivation. The influence he can bring to bear on the authorities ought to be directed successfully towards obtaining labour which will be the one great want on the estates. A good opportunity now presents itself for settling the question of Indian labour in the Malay peninsula. Johore leading the way, and obtaining a licence to import coolies from India will be a good precedent for the States where there are British Residents, and it is hardly likely that the request of the Maharajah when he makes it will be refused.

With regard to tea planting itself, it may not be out of place to draw attention to one or two points which will materially influence the results of the cultivation. First and foremost, something more than ordinary care must be bestowed on the selection of land. Virgin forest, slightly elevated or undulating, with a good depth of surface vegetable mould, and a light subsoil, should be chosen. The situation must be such as to be within easy reach of water carriage, but at the same time not likely to be submerged by inundations. Next comes the important question of choice of the variety of plants. As to this, experience in the Darjeeling Terai district has shown that nothing succeeds so well as the hybrid. This and no other must be selected, the seeds being obtained from some of the gardens situated at the foot of the hills. The ordinary methods of clearing, planting out, and general cultivation it is not necessary to touch on, as they are matters well known to every planter of any experience. But there is one point which must not be forgotten with regard to the climate, namely, that its great humidity and equable temperature will necessitate a slightly different treatment in plucking to that practised in India. There is hardly any doubt that when the tea plants have grown to a sufficient height to allow of plucking that the "flushes" will be almost continuous, and that tea may be manufactured nearly all the year round. This is an enormous advantage in one sense, and if properly worked ought to place the Malay States in the foremost rank of tea-producing countries. But there is a danger of too much plucking, and it is against this that even now we would give a word of warning. The moderate success of the Java gardens has undoubtedly been due in a great measure to this constant drain on the plant. It is absolutely necessary to check the growth, or let it rest occasionally, and to do this the plant must be allowed to grow without being plucked for at least three months out of the twelve, at the time

when the flushes are ascertained to be weakest. So much for the plucking. Now with regard to the extent of cultivation. This is a rock on which many enterprises have split in India, and we should be sorry to see the promoters of tea gardens in Johore come to grief from the same cause. The expenses of clearing the land, planting, and cultivation, will necessarily be very heavy, on account of the dearness of labour, and a return must not be expected within three years. That period of time must therefore be at once provided for as outgoing. We would therefore suggest that any one garden be not opened out to a greater extent, under any circumstances, than 200 acres. This will afford ample means of testing the full capabilities of the place, and will tax the resources of ordinary associations quite sufficiently. When that amount yields well the garden can be extended gradually in a way to leave a good interest on the capital from the balance between the returns and expenditure. Nothing like failure from exhaustion of capital must be risked, for the speculation, with care, is certain to be a success. If this is exercised, and Indian labour is allowed to be introduced, it will not be long before English markets have a good supply of tea from the Malay States. There is an ample field for it here, as well as in Australia, and locally. The demand for tea is growing all over the world, and as new countries are opened up, so will the consumption increase, especially for those kinds which are well grown and carefully manufactured.

AGRICULTURE IN TRAVANCORE.

(*Colonies and India*, 20th August 1881.)

Manufactures being few and insignificant, agriculture is the principal industry of Travancore. Almost every one secures for himself a small area of land, sufficient at least for the site of a dwelling, and small garden around it. Indeed, in some parts of Malabar there are scarcely any compact towns, each house being separate, and situated in its own grounds. Agriculture is carried on with some measure of practical skill and success derived from lengthened experience, but with most primitive instruments, and needing much improvement as to manuring, rotation of crops, and the preparation of produce for the market. With a view to national progress in these respects, two students have recently been sent by the native Government to the Agricultural College at Madras, who, it is hoped, will be able on their return to introduce more scientific methods of husbandry.

The principal native agricultural products are rice, coconut, and other palms and farinaceous roots for food, besides coffee, which is cultivated by European planters with the aid of native labour. Fruit-trees also are grown more or less by every one, and invariably planted as the beginning of an estate when waste land is cleared.

Rice is grown chiefly on irrigated or swamp land, though dry or "hill" rice is also grown wherever the soil is sufficiently rich to give a crop, and the rain sufficiently abundant to bring it to perfection. Most of the landed wealth of the country consists of rice or "paddy" lands, which vary greatly, however, in quality and produce, and consequently in value. The price of "paddy" lands varies according to the soil, facilities for irrigation, distance from the centres of population, and the returns they are capable of yielding. Some are worth only 30rs. to 40rs. per para,* others cost up to 70rs. (say, £24 to £56 per acre). The Government compensation for rice lands taken for public purposes is only 14rs. per para. Land may be said to be worth generally about 15 years' purchase. The proper soil for rice is found in valleys or plains irrigated by water-channels, often with a supply for the dry season in a tank at the head of the valley. The varieties of rice suited to different soils and seasons are numerous. The produce of rice lands in Travancore ranges from fivefold up to thirty-fold. There is a popular complaint that the land is deteriorating and the return less than in former days, which the old people ascribe to diminished attention to sacred rites and duties, but which arises from exhaustion of the soil through want of proper cultivation. In the southern districts, where tillage is more careful and manuring better attended to, and the sun hotter, the clouds and rainfall being less, the increase has sometimes been known to be fortyfold; but farmers think they are well off with fifteenfold at each harvest—*i.e.* twice in the year—and throughout the greater part of the country seven or eightfold, or in the south twelve to fifteenfold must be put down as the usual return. Of course, in unfavourable seasons the crop may be almost nothing. As it costs at least two paras† of grain in wages to sow one para of seed, a return of at least three times the seed sown is necessary to repay expenditure. A tenfold increase would be 80 paras, or 32 bushels of "paddy" or rice in the husk. When cleaned of the husk, this is reduced to half the quantity—say 16 bushels—weighing on an average 64½ lb. per bushel when raw. Old rice would be lighter, down to about 59 lb. The produce, therefore, of an acre of good rice land may be averaged at 1044 lb. Paddy is usually sold at 12 chuckrams per para. The Government rate for commutation of taxes payable in kind is 7 chuckrams. When slightly boiled and beaten from the husk, the price is 32 chuckrams per para, or about 2⅔rs. per bushel. The total acreage of rice land under cultivation in Travancore is not exactly known, but a fresh survey and re-assessment are about to be undertaken. The survey of eighty years ago places it at about 400,000 acres; but since then much waste land has been brought under cultivation, and the total acreage cannot probably be taken at less than 500,000 acres. Whereas at the beginning of the century Travancore exported large quantities of paddy and rice (in 1843 no less than 231,000 candies of 654 lb. each), and imported but a small quantity, the case is now totally reversed—exports being only about 70,000rs. to 80,000rs. in value, and imports (duty free) having risen from 4½ lacs of rupees seven years ago to 13¼ lacs in 1879. The produce of the country is, therefore, not sufficient for home consumption at the present time. This arises not only from the diminished production already referred to and from increase of population, but also from the general improvement of the circumstances of the lower castes, who can now afford to eat more rice in place of, or in addition to, fruits and vegetables, coarse roots, and inferior grains.

Supposing the cultivated area of rice to be 500,000 acres, and the joint produce of the two crops fifteenfold, or 1,566 lb. per acre; this divided amongst a population of 2½ millions would give 312 lb. of rice per head per annum for consumption. Imported rice to the value of 13¼ lacs of rupees would give (at a chuckram per pound) 15 lb. per head additional. The consumption in Ceylon of rice (and fine grain) is estimated at 5 bushels, or over 300 lb. per head, besides fruits, vegetables, and roots; and in Burmah,

* A para of land is equivalent to from one-eleventh to one-eighth of an acre, according to locality. It is assumed here to be equal to one-eighth of an acre.

† A para of seed is a variable quantity, the term being applied to the amount of grain necessary to sow a para of land. It may be taken at two-fifths of a bushel.

"where the peasantry have enough and to spare," 507 lb. per head.*

The cultivation of the coconut extends over the whole of Travancore, which has hence been facetiously called Coconut-core! Forty-four years ago the total number of cocoanut trees was 11,100,000, and the increase since has been so considerable, much waste land having been planted with this valuable palm, that the present number cannot be estimated at less than 15 millions. These are almost invariably too closely planted to obtain full advantage of sun and air; but supposing they stood at the moderate distance of 20 feet apart (which is 109 to the acre), the area covered would amount to 137,000 acres. The soils best suited for the coconut are the sea-shore, the banks and alluvium of rivers, and level lands exposed to the sea-breeze; these conditions abound in Travancore. Inland on the mountains the coconut will grow, but not bear fruit. The young plants generally require watering for the first two or three years, and must be protected from the inroads of cattle until they rise some feet above the ground. Ashes are applied as manure at the beginning of the wet season, and the ground opened about the roots of the trees, which come into bearing some eight or ten years after planting. A coconut plantation is one of the most easily managed and most remunerative products of the country. The natives have but to put down the nuts and guard the trees more or less while attending to their other employments, and in due course a permanent and profitable plantation is created. Europeans, however, seldom attempt such an investment, and few who have done so have succeeded in it. For new plantations, waste lands are usually taken up. Within the last twenty or thirty years much land otherwise worthless has been reclaimed along the sandy sea-coast, and many trees have been planted on either side of new roads opening up into the interior. The price of 100 ordinary trees in the southern parts may be stated at about 400 rupees. These would produce, at a low estimate, say 2,400 nuts, value 34 rupees annually. The produce of the tree is very much dependent on soil and climate. The average of good trees in full bearing has been stated at 120 nuts in the twelve months, while in low and sandy soils it will amount to 200, and in gravel or laterite under 60. Ripe coconuts are quoted in the Trevandrum market list at somewhat under two rupees per 100. The kernels are dried into "copra" for the manufacture of coconut oil. The copra is largely exported to other parts of India, as well as the "coir" or fibre surrounding the husk, which is sent to Europe and America.

The annual value of the products of this palm exported—nuts, dried kernel or copra, oil and fibre—amounts to 42 lacs of rupees, besides oil, nuts, timber, and leaves for home use. It has been estimated that 60,000,000 of nuts and 15,000 candies of oil are annually consumed in the country. The timber is not exported, but split up and used for rafters, and the leaves are in great demand for thatching.

The trees are sometimes tapped for a few months to procure the sweet juice, which, boiled while fresh, gives a palm sugar, and kept a day or two till it ferments becomes toddy, a slightly intoxicating drink, somewhat like beer. The toddy also is distilled into arrack or native spirits.

Other palm trees are also cultivated. Next to the coconut comes the palmyra, which is grown only in the drier districts towards Cape Comorin. The palmyra, with its sweet sap and sugar, leaves, timber, and fruit, furnishes a living to a great number of the Thanar caste in Travancore and in Tinnevelly. The number of trees in 1880 was about 6,000,000. It is probable that no considerable increase has taken place since, as old trees are in demand for their timber, and the slow growth of this palm discourages planting. From 160,000 to 24,000 cwts. of the sugar (jaggery) of this palm are annually exported, worth something over 3½ rupees per cwt.

The beautiful areca palm is planted in damp, clayey soil on the banks of tanks and rivers. Unlike the coconut it will thrive at a distance from the sea and on the hills. It is grown very largely in North Travancore, whence the nuts are carried to the south by Syrian and other traders. The trees will grow two or three feet apart. The areca begins to bear in five years, and continues to produce for twenty-five years. The nuts are sold wholesale at six or eight chuckrams per thousand, and retail in Trevandrum at from eight to thirty-two for a chuckram, according to season and demand. 3,500 candies are annually exported to Bombay and other ports, the value of which is about 4½ lacs of rupees.

Roots, vegetables, and fruits form a considerable proportion of the food of the population in Travancore. The forest and hill people dig out wild stringy yam-roots from the jungle as food in the hot season. Every native grows something, if he can, around his own dwelling for home use. The principal cultivated root crops are yams *(Dioscorea)* of various sorts, the small tubers of which are planted out in the beginning of the rainy season and dug again within a year. Some of these roots grow, under favourable circumstances, to a large size, up to four feet in length and one in diameter. Sweet potatoes, the root of a convolvulus, give good returns within three months after planting, and quantities of esculent arums (*Amorphophallus* and *Colocasia*) are grown in fields furnishing a large supply of food.

Tapioca, introduced from South America, is now largely cultivated in Travancore, and admirably suited for still more extended use. As the price of rice has risen of latey ears, tapioca has become the more essential as an article of food. It will grow in any soil, and needs but little care except to preserve it from the depredations of cattle. After the roots are dug, the stem is cut into pieces about 4 inches long and planted some 3 feet apart with a little ash or other manure. The root requires occasional weeding and earthing, and arrives at maturity in nine or ten months. Well boiled it is eaten with fish curry. It is sometimes given to cattle. In a green state the root does not keep long, but it can be sliced and dried in the sun, or grated and made into farina. A field of this valuable and nutritious root is planted at but little cost; its yield is very large, and its cultivation highly profitable. The produce has been estimated in Ceylon at 10 tons of green roots per acre: this weighs one-fourth when dried, and, if the dried roots gave half their weight of flour, it would amount to 2,800 lb. per acre. With some care and attention any amount of the granulated flour might be prepared for home use and export; but, though this plant grows almost wild, the people do not take the trouble to prepare it.

Other culinary vegetables are amaranthus, cucumber, brinjal, peas, &c. Fruits commonly grown are the jack, of which there are two or three millions in the country, guava, papaw, anona, pine-apple, and plantains in great variety. The spices grown are pepper, ginger, turmeric, and chillies. The exports of ginger amount to about 4 lacs rupees; of tamarinds 2 lacs; of turmeric nearly 1 lac; of pepper 3 or 4 lacs; and of coffee, from 4 to 8 lacs. Good crops are often obtained from sesamum and horse grain,

* The quantity required for an adult living wholly upon rice is usually reckoned at 3 nāri, about 1½ lb. per day, or rather more. The Famine Commission compute that for a working adult male 1½ lb. of flour or rice is sufficient, and for children from half to a fourth of the quantity, according to age.

and much might be done in the production of fibres for cordage and papermaking.

The size of farms is various; three or four hundred acres is an estate of considerable magnitude, which not two in a hundred will possess. The lesser farms do not exceed from seven to fourteen acres, and are often considerably smaller; indeed, taking the average as given in the Sirkar accounts, we should only have about two acres as the extent held by every farmer. As was well put in the report on the former survey, "A farmer with three hundred paras of paddy land, four hundred coconut trees, fifty areca, and twelve jack trees, with vines yielding five or six tulams of pepper, will be in very easy circumstances; but scarcely twenty husbandmen in a hundred will have such property; indeed, the lower classes rarely possess sufficient rice land on which to support their family; they trust, however, to the produce of their garden lands to make up the deficiency."

MATHEINE.

(*Brazil and River Plate Mail*, 1st Sept. 1881.)

What is Matheine? It will not be sufficient reply to this question to merely state that it is a new drink, which, in the future, must take equal, and in some respects, even higher rank than tea, coffee, chocolate, and the other well-known domestic beverages that "stimulate but not inebriate" the imbiber. It is, in fact, so important an addition to our social resources that we feel it to be a duty to make a more particular record of its characteristic merits. To some of our readers Matheine will present itself as an old friend in another guise; for it is the product of a process discovered by Mr. A. K. Mackinnon, (who, in connection with the Kopf Company, has introduced so many new and excellent food preparations) from the dried leaves of the Ilex Paraguayensis, with which South American communities are so familar under the name of "yerba maté." In the *Revue Scientifique* and other journals of Europe, public attention has been directed to the special advantages of this South American drink. It has been represented, and truly represented, as possessing all the cheering and refreshing properties of tea and coffee, without producing any of the unpleasant effects upon the nerves too frequently attendant on an over liberal use of these popular beverages. But the mode in which it is used is so opposed to established custom in our own and other countries of Europe that journalistic advocacy must have failed to bring it into general consumption on this side of the Atlantic. The common practice in Brazil and the River Plate, where it is extensively used, is to pour boiling water on some of the powder (consisting of dried leaves and twigs of the yerba maté shrub), and then to suck the infusion through a tube, which is passed from mouth to mouth, as the "calumet of peace," under certain circumstances, is said to have passed round a circle of North American Indians. This difficulty has, however, been altogether removed by Mr. Mackinnon. Matheine, which is in a liquid form, can be utilized with the greatest facility while it may be fairly described as a boon to the weakly and infirm, and of the utmost service to hardworking people in every grade of society. Professor Wanklyn gives the following analysis of this substance: Moisture, 6·72; ash, 5·86; soluble organic matter, 25·10; insoluble organic matter 62·32. Another analytical chemist, Signor Parodi, now resident in Buenos Ayres, gives a qualitative analysis, viz.: Cafetannate of theine, Cafetannic acid (free), Chlorophyl and Wax, Resin, Gum and Vegetable Albumen, Lignine; and the ashes contain Salts of Potash and Lime, Oxide of Iron and Manganese and of Silica. Another analysis demonstrates the presence of Theobromine, which is the active principle in cocoa. However, we are bound to say that, up to the present no satisfactory analysis has been made. We take the following, as to its properties, from an announcement of the Kopf Company:—

We know that the infusion of this interesting shrub possesses the properties of tea, coffee, and cocoa. It is sedative and stimulant; prevents the waste of tissues; increases the activity of the brain, and hence is invaluable to brain workers; causes the secretion of milk, and, therefore, of great value to nursing mothers; this which shows its nutritive power is amply exemplified in the fact that the gauchos (native horsemen) undertake long journeys on horseback, at times as much as 60 and 80 miles in a day, with no other ailment but three or four maté cups of their favourite infusion.

To military men this substance would be invaluable, as it would enable them to undertake fatiguing marches better than any other beverage known. Sportsman, angler, and traveller would alike benefit by its use in lieu of strong alcoholic beverages.

To South Americans, not less than Europeans, Matheine should prove exceedingly acceptable. The yerba maté infusion, as actually taken by the former, namely, by suction through a tube with a perforated bulb, is liable to serious objection, as the finer particles are swallowed, and in process of time accumulate and form irritating concretions in the stomach, to the serious injury of the health of the individual. In its liquid form this is altogether avoided. We should add that the proportion is one to two teaspoonfuls to an average sized teacup of boiling water, with milk and sugar to taste.

FLAX CULTURE.

(*Sydney Mail*, 27th August 1881)

A resident in the Camden district writes:—"I have been requested by several farmers (some your subscribers) to ask you for information regarding flax culture. They are inclined to experiment in new crops, for ever since the failure of wheat in the district they have had recourse to growing hay, which of late has been bringing hardly a price to pay. The questions I would like answered are:—1. Do you think flax could be grown in this district with success? 2. Is there any demand for it in Sydney? 3. What prices would linseed, flax, and flax straw or fibre command respectively? 4. And what would be an average yield per acre?" In reply, we may state that it affords us great pleasure to hear that the Camden farmers wish to move out of the old overworked furrows to seek new ground. Nearly all the information sought appeared in these columns last July, when we strongly recommended flax culture as suited to this colony. With regard to question 1, any fair soil upon which wheat can be raised will produce good crops of flax. A retentive subsoil is necessary, for flax likes moisture; but it is not so liable to fail from drought as cereal crops are. The Camden district should prove a good home for the flax industry. It does well in Europe, especially in Flanders, and has done well in England and Ireland. It may be grown on any good deep loam, but this must be finely cultivated. The soil must be thoroughly open, perfectly clean, and reduced to a fine tilth to produce payable crops, and this is a matter which is recognized by the farmers of older countries, where linseed and flax production is an important industry. The flax farms are like gardens, and from the first part of the culture to the last the crop is one which requires close attention and plenty of labour. When flax was tried in Victoria, where 30 acres of bushland were offered to those who attempted its cultivation, only 17 acres were placed under the crop, and these returned an average of from 8 to 17 bushels of seed and from 7 to 9 cwt.

of flax per acre. But the cultivation was crude. Flax has been tried in South Australia and proved moderately successful. Its career was checked by the intervention of the Government, who closed the mills on sanitary grounds; but now, as explained in past issues in these columns, the failure of wheat in South Australia has caused a reaction in favour of linseed and flax. Linseed culture is also undergoing a fair trial in Victoria. In Australia, as in other countries, the production of fibre as well as seed must be the rule to render the crop profitable. This was well explained by an Ulster man, recently, in the columns of a Melbourne contemporary. We quoted his comments at the time, but as it seems they have escaped the notice of some of our readers we reproduce them. He says that in the North of Ireland the flax-scutchers give the farmer £12 per ton for the flax, harvested and dried in the usual way and delivered at the mill. He puts the average crop down as two tons per acre, and the cost of erecting buildings, plant, &c., for an establishment capable of manufacturing £250,000 worth of fibre per year, at only £3,000. When flax was cultivated in South Australia, the price paid for raw flax with seed attached was £5 to £5 10s. per ton. The loss of weight in scutching is fully 50 per cent. Apart from the utilization and production of the fibre, the profits from seed production depend greatly upon the quality of the soil, the care in harvesting, and, last but not least, the demand. On good soils well worked as much as 20 bushels of seed to the acre may be obtained, but we fear there are few inland localities in this colony will yield so much. On the coast, where the river flats are rich, good crops might be raised. The value of seed at present in this city is £16 per ton. about 8s. per bushel. An old colonist recently contributed to the July number of the *Victorian Review*, a paper well worthy of attention, on flax-growing. In this he says:—

"When cultivating the plant I have sown flax seed after grass, after wheat, upon new land, and upon land under fallow; or rather, instead of fallowing, strictly speaking, and allowing the land to lie idle the whole year, flax seed has been sown in the spring, and wheat the following autumn. When sown on new land or after grass, one ploughing only has been given, immediately preceding sowing; but after wheat or other grain crop the ground has been ploughed deeply as early as possible, and again in the spring, with repeated scarifying and harrowings, so as to get the soil into the finest possible tilth before sowing the seed. Having got the land in proper order, sow two bushels of clean linseed; that quantity per acre gives fine flax and good seed. The ordinary linseed of commerce is not the seed from which the finest flax is raised. Flax seed is imported yearly into Ireland from Riga (in Russia) and Holland, for seed purposes; from the former it comes in casks officially sealed as being true and good. The land should be sown (the reverse way to the last harrowing) broadcast and as evenly distributed as possible, then harrowed over (the same way as sown) with a very light grass seed or brush harrow, finishing off with a light rolling carefully, and if this can be got through while the land is dry and friable so much the better. The time of sowing, as early as possible in the spring of the year. No fixed dates can be given; the intelligent cultivator will be guided by his experience of the locality and nature of soil. As it is sown thickly, so it springs up, and the rapid nature of its growth, in this country, does not allow weeds to interfere, if the land is moderately clean. The proper time to commence pulling the crop is when the leaves begin to fall from the plant, and the stalks are nearly all yellow; experimentally, it has been pulled at various stages,—when quite green, partially so (as is the Irish plan, by which they lose the seed), fully ripe, and when nearly so. The latter is found to be by far the best practice, having regard to fine fibre and good seed."

There is a market in Victoria for the flax fibre. One manufacturer is prepared to take 100 tons annually, and give from £30 to £40 per ton for it.

HORSE-BREEDING IN WESTERN INDIA.

(*Asian*, 13th September 1881.)

A valued correspondent who has had some years' experience on the subject, has written to us regarding horse-breeding in Western India; and as the subject is an important one, we will let him speak for himself. He writes: "I propose to offer my opinion in reference to the breeding of stock in the western parts of India. You have made an impression on me and my mind of horse breeding in that part of the country from a paragraph in your columns lately. Erroneous conclusions have been drawn by other people that the quality of mares in these provinces have been overrated; and, as further change will probably take place by the opening up of the line of railway through some part of these provinces, especially that of the Rajputana State Railway from Ajmere to Palumpur, I think those who may pass that way should take the opportunity to see some of the mares and stock in those parts. I have but little doubt that they will say that they have not been overrated, and it would afford me much satisfaction to discover that horses from this part of the country were distributed over a larger compass than they are, and if so, whether the Government of India would not then discover a new source from whence to get a supply suitable for the artillery and cavalry remounts without costing so much money and waste of time as the present system has led us to. The present mode of purchasing horses appears to me an hazardous undertaking, and often very disappointing to the Australian horse importers, inasmuch as from some batches of these horses I have seen lately, I say they have greatly improved. Yet I have seen some of these inspected and turned away, and sold to private individuals, who, in the course of six months, have profited considerably by their purchase. The quality of these imported horses, as I have seen from my personal examination, is much improved, and they are, to all appearance, better bred and more active than formerly. The best representatives come to Calcutta, yet there are often good mares rejected which would suit well for breeding purposes, as it is difficult to procure good mares for this purpose. These should be purchased and sent to the Government depôt for breeding purposes, and then I venture to suggest these Australian contractors would, in time, benefit the country. We should also furnish proper stallions to mate with them, and not some of the sort I have seen, which are likely to disappoint us, and I believe have done so. These are errors which should not be overlooked, for the business of breeding is expensive, so let us try and lay down the foundation for a new branch in this line. I will temporarily relieve myself from giving you further particulars of my opinion about a system which does not immediately concern me, as I might be told by some of the officers who conduct such matters that I know nothing at all about it. I am, however, a bit in the horsey line! To return to Ajmere, the terminus of the railway I have mentioned. I believe I am correct in saying some one has resolved to establish a breeding depôt near that station, and I am not surprised at it, and I hope they will succeed. For, be it known, in the western parts of India the climate is so well suited for the rearing of stock, as I have proved, that I believe the Government of India have, from experience, at last, found this out, for I notice there are two or three stallions located there, one of

them a fair specimen to breed from. It is possible, I suppose, to trace the breed of the horses and stock in Rajpootana, and its varieties from which they were formerly raised by the native Princes, and I have heard such names as Kuch Bhoj, and Thulla mentioned, and that they were considered the finest horses in India for military purposes years ago; but that great injury was done to these breeds which had not been repaired until this past eight or ten years. It is quite easily conceivable to those with any knowledge of horse flesh that these animals are particularly well framed, with good knee action, very powerful, and will stand any amount of hard work, as many have been convinced when travelling by dâwk through part of the sandy country. I have seen a team of four walers actually give it up after a few miles when three country-breds, we will call them Marwaree ponies, in comparison to the walers being on such short legs, attached to the same carriage would go on twenty miles without hardly a halt. I believe something similar to this occurred when one of these native Princes had the honour of a visit from one of your late Viceroys who was riding behind some of his own slashing looking walers, which had to be taken out to enable His Excellency to complete the journey, behind the horses reared and bred in Western Rajpootana. We see and hear of many gentlemen who yearly pay visits to the fairs of Pokhur and other places, and purchase cheap nags, which have found their way into some of your native cavalry regiments about the North-West Provinces, and which look more inviting and fit for hard work than those alongside of them on parade. It should, however, be known that these gentlemen visiting these fairs do not get the best breed horses, or of ages much beyond three, and in many cases younger horses which are sent to these fairs are not fair specimens of the Marwaree horse, and are sent often because considered of no practical value, and oftener, because religious duties or village disputes are urged as an excuse to get rid of them, and to settle matters. This is not, however, the case with the horses reared and bred solely by the native princes, who positively decline to sell any that have been reared from their own known breed and stock, however profitable it might be to them, and consequently a great number have accumulated. An accurate register of these I could never procure, but that they are the best and most uniformly shaped class of country-bred any one would wish to see, except, if one considers it a defect, that of the peculiar position of the ears, or I might say curve or twist at the point of the ear, and the carriage of their necks, which I think should be thought altogether unworthy of notice in selecting horses for cavalry purposes. We cannot obtain horses of certain shape and form to the perfection many would like to see them, so that I have come to the conclusion that you were perfectly right in your remarks in stating this subject of breeding was receiving a temporary check just at the very time when everything should be done to encourage, and nothing to disgust. Otherwise these horses, however excellent, will not be made use of, when the time might come that we should require them. The native Princes are not so easily moulded into new habits; they have, however, transplanted, with their own Marwaree breed, horses and mares that will, I hope, again and again be bred from, and the breed be more improved, as they have spared no expense in procuring animals. I regret to say that a serious loss has happened to these States by the death of the valuable stallion "Crown Prince," whose shape and make we all well remember, with undeniable blood, when we saw him at Delhi during the assemblage. There are, however, a few others of the right stamp for breeding purposes, notably "Euro," of English parentage, but bred in the colonies, and "Cock-a-Hoop," the former being by Lucifer out of Zenobia by Kingston, and the latter by Victorious by Newminster out of Mother Carey's Chicken by Declare. In fact, the Maharajah of Jodhpur has the most useful selection of horses and mares of all breeds collected together by any single person in India, some of which would greatly surprise your horsey men had they the opportunity to ride behind them in carriage, or on their backs out a pigsticking, or for a long tedious journey by road."

SUGAR GROWING AT PORT MACKAY, QUEENSLAND.

(*Sydney Mail*, 27th August 1881.)

Before entering upon a description of the sugar mills and the processes employed in the manufacture of sugar, it will be well to glance at the capacity of the Mackay district for the growth of the sugar-cane, and afterwards to offer some remarks on the climate. And in order the more effectually to do so, I shall have to present your readers with a few statistics, which I have gathered from official sources, as well as from gentlemen in Mackay whose experience and position render the facts given highly trustworthy. These will help to demonstrate how far Mackay is to be regarded at present as the greatest sugar-producing district in Queensland. No figures, however, will adequately convey the impression which only the face of nature is fit to produce; so much does the eye take in that defies calculation to give, and statistics, after all, are only approximatively true. The prosperity of a district may be tolerably well-known from the high social condition of the town, and Mackay may be cited as a good example in proof. It is however necessary to place before the reader a few facts that will show this in other ways.

A ride across the country opens the observer's eyes to the richness of the land, which he sees spreading out in broad plains and gentle hills, backed by an uneven line of forest-covered mountains in the distance. That the soil of the district is capable of profitably growing sugar-cane was proved as long ago as 1864, when Mr. J. Spiller began planting on the banks of the Pioneer. His example was soon followed by others, who were only waiting for signs of success. From that time to the present there has been a rapid increase in the manufacture of sugar, while elaborate machinery, capable of producing 14,930 tons, has been successively erected within a short distance from town, mostly on the banks of the river; and, now, attracted by the fame of the district, the Colonial Sugar Company, with a capital of £250,000, have commenced work at a place called Homebush, and will plant cane this year. This accession of strength will enormously add to the sugar-producing capacity of the district, and will doubtless induce other companies to do the same, for only a very small proportion of the country is under cultivation.

The extent of land under cane last year is set down at 6,678 acres, to which another thousand acres must be added up to March of this year; it is now probably much more. Of this, 5,486 tons of cane were crushed, yielding 9,470 tons of sugar, 287,250 gallons of molasses, and 88,617 gallons of rum. The probable yield of sugar during the present year, according to good judges, will be between 10,000 and 11,000 tons. But this inadequately represents the capacity of the Mackay district, for there is now within a distance of 25 miles from the town of Mackay, mostly in the hands of people able and anxious to grow cane, but debarred from doing so by the want of a market for it, over 160,000 acres beyond the acreage now under cultivation, equal to the production of at least 60,000 tons of sugar over and above the 23,310 tons which

the present cultivated land should yield. In addition to this, in the whole district, under exactly the same climatic influences, and with a soil similar to the land now being worked, there are at least 500,000 acres more, within easy reach of navigable waters, which would produce, after every reasonable deduction, at least 125,000 tons more sugar per annum, which added to the capacity of the alienated lands would bring the entire district up to 200,000 tons per annum, at what is regarded as a very moderate estimate of its capacity; and this in a district proved by 14 years' experience to be exceedingly well-adapted for the production of first-class sugars, at a cost, say, of £12 per ton on board ship.

The capacity, therefore, of this district for sugar production appears to be much greater than has hitherto been recognised. What hinders sugar progress at present is the want of one or more firms, who would meet the demand for milling power by erecting in the most suitable localities, mills which, commencing with a production of 200 or 250 tons per annum, might be increased by adding to their power, with the increase of crops, up to a production of 1,000 tons each per annum. One such mill, it is said, by the use of Mackenzie's ejecter pan, could be started at a moderate cost, and it is confidently asserted that such a mill could, after the first season's operations, be worked on such a scale and at such a cost as would ensure a return of from 20 to 40 per cent to shareholders.

The sugar mills in the district gradually increased in number from the time (1868) when Mr. Davidson erected his first mill, to 17 at the present time, all of which are in full work, and just able to cope with the cane grown. A very large mill, capable when finished, of producing 2,000 of sugar in a season, is now being erected at The Palms, under the superintendence of Mr. Donaldson. It is owned by Messrs. Sloane, of Melbourne, who have other property in the neighbourhood, and will eventually be fitted with two vacuum pans, besides all the latest improvements in sugar-making. Of the mills at work, the most complete and admirable in all respects that have as yet come under my notice are those at the River Estate and at Pleystowe, the former owned (along with the Pioneer) by Mr. Spiller, and the latter by Messrs. Hewitt and Co., over which I was courteously shown by their respective managers. At the River Estate mill, this month, an influential company of ladies and gentlemen assembled, at the invitation of Mr. H. Brandon, manager of the A. J. S. Bank, on behalf of Mr. J. Spiller, who is at present absent from ill-health, to witness the christening of a locomotive engine to be used on the railway constructed on the estate, as well as to see a trial made of Siemens'-electro-dynamic machine, recently put up in the mill for illumination with the electric light. The christening ceremony was performed by Mrs. H. Brandon. The railway excursion among the cane fields up the hills was highly interesting and successful; and when the electric light was first put in action, the astonished kanakas excitedly exclaimed, "No more night—all now same as day!" At the close of the proceedings, the company were entertained at lunch at the house of the manager, Mr. Percy Crees.

With regard to the amount of sugar manufactured in the district from the commencement to 1878, I find 33,700 tons given as an aggregate yield. Since then we have 6,928 tons up to the end of March 1879, and 9,470 tons to the end of March 1880. This quantity, added to the 11,000 tons expected as the return for 1881, makes a total of 61,098 tons of sugar produced in the Mackay district from 1868 to the end of the present year. In three years it is anticipated that 20,000 tons will be the annual product of the district from existing mills, and in manufacture this sugar will require 240,000 tons of cane. But with an estimated capacity of producing 200,000 tons, (some say 250,000 tons) it will be seen what an immense room still remains for further industry.

I am not yet in possession of estimates of value but those for 1878, during which year the export-value of sugar, molasses and treacle, golden syrup, and rum manufactured in the district of Mackay amounted to £168,036, of which £155,682 was for sugar. Other exports swell this sum to £193,491.

As all the mills are now furnished with centrifugals, and generally with vacuum pans, the sugar manufactured is of a very superior quality, and commands a price at the port of from £21 to £28 per ton; it varies in character from fine household crystalled white to different shades of rich yellow. Three qualities are generally made at each mill, but the varieties produced in the district are very numerous, it being found impracticable as yet to maintain perfect uniformity of character for any length of time. As far as my own experience goes, the white sugar, or that which is first turned out of the centrifugals, is as good a household article as could be wished; though for certain purposes, such as preserving fruit, the highly refined sugar of the Colonial Sugar Company is indispensable. It is, however, remarkable that in the very place where it is made, its retail price should be from a halfpenny to a penny per pound more than in the Sydney market.

With regard to the yield of sugar per acre, it is often very difficult to arrive at accurate results. Want of experience, the use of imperfect apparatus and a disastrous cane disease, have operated against ascertaining what are the capabilities of the soil, and the comparative productiveness of the various kinds of cane in cultivation. For Queensland generally, the yield, estimated for the ten years ending 31st March, 1879, was 25 cwt. 3qrs.; and for Mackay 27 cwt. 0 qr. 23 lb. Considering the disadvantages above enumerated, this must be regarded as a prolific yield, being much higher than Jamaica and India, and but little below that of Java. But this estimate is much below the one I formed at the plantations, where 32 cwt. per acre appeared to be nearer the truth. In some instances 2 and 2½ tons have been taken off, but this must be looked upon as too exceptional a yield to be held up as a fair sample; yet, in so admirable a climate as this is made out to be, it is highly probable that with improved methods of culture the produce may be kept at near two tons. It must be remembered that at Mackay (and generally in Australia) no manures have yet been used to enrich the soil; while in other countries this is an expensive item, and tells heavily in the cost of production.

So fertile is the soil at Mackay that the planter may go on for years reaping crops which seem inexhaustible, but this fertility cannot last for ever; the soil, to be kept in vigour, must have that restored to it which has been taken away; and it would now be well for planters to store up manure for the evil day that is sure to come.

The amount of rum produced in the three distilleries of Mackay during 1880 was 88,604 gallons. The respective plantations distilled as follows:—Alexandra, 24,122 gallons; Te Kowai, 24,428 gallons; Pleystowe, 24,054 gallons. The latter bears a high reputation in the market.

A comparison of Mackay with other sugar-producing districts of Queensland, gives it greatly the advantage. A few figures will show what I mean. In 1880, Cardwell yielded 525 tons of sugar; Maryborough, 4,157 tons; Bundaberg, 619 tons; Brisbane, 850 tons; Logan, 2,150 tons; while Mackay, probably owing to its superior climate, gave no less than 7,263 tons, its yield per acre being also higher.

The small planters, of whom there are a good many

in the district, and who have almost entirely abandoned growing maize in favour of sugar-cane, sell their produce to the mill-owners. The price paid is 11s. per ton for cane yielding juice having a density of 10. of Béaumé's saccharometer, the millowner cutting and carting the cane; or 10s. per 100 gallons of juice at 10° Béaumé. This is considered good payment, and the selectors are anxious now to grow cane to the exclusion of almost everything else; but there are many influences which cause the price to vary.

Sheep.—In the year 1788 there were only 29 sheep in Australia; at the present time there are no fewer than 62,000,000.—*Indian Agriculturist.*

The Toad destroys from twenty to thirty insects in an hour, and the mole is continually destroying grubs, larvæ, palmer worms, and insects injurious to agriculture; no trace of vegetation is ever found in its stomach.—*Ibid.*

Gas Tar.—An American farmer says that a gill of gas tar mixed in a pail of whitewash, and applied with a brush to the houses and roosts of poultry will destroy or drive away any lice that may infest them. This is easily tried and has the merit of doing good, whether in the direction intended or not.—*Ibid.*

Bees.—Indiana reports of the bee industry for 1879 (the latest given) show 145,327 colonies, yielding 1,107,627 pounds of honey, or 8·18 pounds per colony. The season was regarded as yielding only half the average annual produce. Lake stands at the head of all the counties, with 59,934 pounds of honey.—*Ibid.*

Watering with Solution of Iron.—We learn from several agricultural journals that by watering plants with water in which sulphate of iron has been dissolved, most extraordinary results may be obtained: beans for instance will grow to double their size, and acquire a much better taste; the same is the case with pears and other fruit. Water kept in a tub with a quantity of old nails in it may also be used for watering with good effect.—*Ibid.*

Maize.—Paris, 13th Aug.—Messrs Porion and Mehay have discovered a means by which the residue of distilled maize can be employed either to fatten stock, or act as a manure, besides extracting an oil suited for the manufacture of soft soap. The plan rests on the well-known fact, that the oil contained in the grain, remains constantly fixed to the undissolved solid parts, and the azotised matters rest also for their greater portion similarly united. The composition of the cake prepared, exhibits but slight variation, and can be used in the end, either for food or a fertilizer; 2 cwt. of the refuse yield 6½ lb. of a colored oil, and 22 lb. of feeding cake. M. Ladurean of Lille has tested the products; in point of aliment, these products are equal to good linseed cake, and as a manure are on a par with groundnut refuse.—*Madras Mail.*

Cotton.—A single discovery has been made by accident in connection with some experiments upon cotton seed, which may have a widely extended influence upon agricultural operations. With a view to ascertain the situation of the oil-cells in the cotton seed, Professor Thomas Taylor, the microscopist, was requested to make an investigation, and he found that one row of these cells constitutes a protection to the germinating point. The Professor resolved further to ascertain how far these defences protected the embryo from agents usually destructive of all organic life. In using sulphuric acid, he found that one result was completely to remove the adherent cotton, so leaving the brown shell of the seed clean without being visibly affected. Some of the seed that had been thus treated was sown, and, to the surprise of every one, it came up at least five days earlier than the seed in its natural state. Several experiments were subsequently made, which confirmed the fact that the treatment with sulphuric acid stimulated the vitality of the seed. The gain of five or six days' start in the avoidance of early frosts or in the raising of early cotton, for which premiums are offered in some of the Southern States, cannot be over-estimated. Another advantage is that owing to the cotton hitherto adhered to the seed, the sowing has had to be broadcast, which has been very wasteful. Now the clean seed can be sown by means of a drill, with the result of producing a regularity of growth which will tend greatly to facilitate the subsequent cultivation. The Americans are shrewd enough to apply this treatment with sulphuric acid to other seeds slow of germination. And we cannot but think that our English agriculturists will take advantage of this suggestion. If we have no seeds, like the palm, which take three years to sprout, at any rate there are frequently seasons when the power to hasten a natural operation will be an immense advantage.—*Indian Agriculturist.*

Locusts.—Mr. Barrows, the purser of the steamer *Alvo*, tells a sad story of the plague of locusts now spreading starvation in the agricultural districts of the Columbia. He says that between Carthagena and Barranquilla the lands were as utterly barren of live vegetation as though some great fire had swept through them, burning and blasting everything in its track. "The once magnificent groves of coconut trees were to be compared to nothing but a forest of bare poles, without a single green twig or leaf. Millions upon millions of locusts filled the air like great clouds, and the atmosphere in some places was quite hazy in consequence. The ground presented a remarkable appearance; and as the train travelled along, the insects were so thick that they looked like small yellow waves as they jumped up and down. Not a stalk or a blade of grass was any where to be seen. The locusts alighted upon us until our clothes were covered with them. When we tried to remove them, they showed their ravenous condition by attempting to bite our fingers. The farmers are it a state of terror, as they are perfectly helpless before the plague."—*Madras Mail.*

Tobacco.—The quantity of tobacco consumed in the world must be enormous. Some curious statistics relating to tobacco smoking in France appear in the Belgian *National*. It appears that there are 5,671,000 smokers, each person smokes an average of 9lb. a year. For every fifteen smokers, eight smoke pipes, five cigars, and two cigarettes. The total consumption of cigarettes is estimated to be 294,000,000,000 per annum, that is, 800,000,000 a day, 33,000,000 an hour, 550,000 a minute, 9,166 a second; finally, if all these cigarettes were placed end to end they would reach 514 times round the globe. This is for France alone, and we imagine there are countries where more tobacco is used than in France, Germany for instance. France makes a considerable profit from the monopoly she enjoys in connection with tobacco, and there is no valid reason why tobacco should not be heavily taxed. It is clearly a luxury, and not a very good one at the best. The question of making this article a monopoly in India has often been discussed, and has invariably been laid aside on account of the difficulties attending the administration of such a monopoly, and because of its being looked on in India as a necessity of life. We do not see much difficulty, provided the several native Governments would likewise make its cultivation subject to such rules as control opium cultivation. Its universal consumption, which is urged against the proposal, is, in our opinion, the very reason why tobacco is a suitable article for monopoly. Excepting salt, it is the only article on which a tax would be of universal application, and it would enable the Government to lighten that on salt. This latter, although very light, is open to the objection of being a tax on a positive necessity of life.—*Friend of India.*

THE DEADLY LINDEN.—A St. Louis physcian says the linden tree is dangerous to health, being like the deadly upas tree of the east. The St. Louis doctor has been making investigations, and he says: "Just in the spring, when the sap was about to rise, I wounded my trees in several places, and collected the exuding gum carefully. I found in it a new and singular alkaloid, to which we gave the name of 'lindoline,' and which fully justified my fears. It is a most deadly poison—somewhat akin to the curare or wooreli poison of South America. A very small inoculation upon the skin of a cat, made with a needle simply dipped in the lindoline, killed the animal in eighteen seconds. It acts as a nerve excitant of great power, and has a real value in the materia medica as an antidote to morphine poisoning and other cases of that kind; but it must be greatly diluted in order to do anything of this kind, as it is intensely virulent. I am quite sure that a pinscratch touched with lindoline would kill a man in a couple of minutes. Of course, like all poisons of this kind, it is not one-tenth as effective in the stomach as when inoculated, still even there it is deadly."—*Madras Mail.*

THE MORETON BAY CHESTNUT IN THE DARJEELING TERAI.—SIR,—The plants of the Moreton Bay Chestnut (*Castanospermum australe*) at Bamanpokri (Darjeeling Terai), three in number, have this year flowered for the first time. I send you a bunch of flowers herewith. They grow like the jack fruit on small special branchlets on the older parts of the stem and branches; but these special branchlets seem to produce no leaves. I would have sent you a better specimen, but that I want to procure seed in order to raise more seedlings of the tree. Two of the trees which are closest to the teak plantation, and are thus in the shade, seem to be dying slowly; whereas the other, which is about 60 feet distant, but well exposed to air and sunlight, is in a flourishing condition. At page 34 of your list of "Trees, Shrubs, &c.," you state that 1869 is probably the date on which these trees were planted. I should be glad to know if in its native habitat the *Castonospermum australe* flowers at so early an age as eleven or twelve years. I fear this early flowering is an indication that the tree is unable to adapt itself to the climate of the Terai.—F. B. M.

NOTE.—It is a handsome orange yellow flower, resembling that of 'Cassia.' We cannot say whether flowering at an early age is the characteristic of the tree. Perhaps some of our readers can help us.—ED.—*Indian Forester.*

TOBACCO.—Since the commencemeut of tobacco growing by the Government, and more recently by the enterprising proprietors of the Poosa Farm, with a view to prepare the weed for European consumption, much has been done. We learn that 13,723,660 lb. of tobacco, worth only £126,322, were exported from India in 1878-79. In the following year a less quantity was exported, but the total value had slightly risen. This would seem to indicate an improvement in the quality of the exports. The fact that the value of non-Indian tobaccos has been falling during the interval, puts the prospects of the Indian trade in a still more favourable light. The few who have really studied the subject know that, in the estimation of London agents and merchants, the Indian leaf only requires the labour of skilled curers to compete successfully with the produce of America and the Manillas. The native agents here are the persons who are chiefly responsible for the abominably bad way in which the leaf is prepared. This shows clearly that the general quality of Indian tobacco is improving. The recent withdrawal of the Spanish Government from the Manilla monopoly should further advance this trade, and if only the native growers would procure good seed, and bestow more attention on curing, there is no reason why Indian tobacco should not be equal to the very best in the world. —*Friend of India.*

TEA-BUG.—The following telegram from Mr. J. Wood-Mason to the Chief Commissioner of Assam, and dated June 8th, 1881, is extracted from the *Assam Gazette*:—Have discovered by observation of specimens of this formidable pest kept in confinement that the female deposits her eggs singly in the substance of the tenderest shoots of the plant in the *internodes* or portions of the stem between the pekoe and the two or three leaves succeeding from above downwards, and in the buds developed in the axils of plucked leaves and in the parts thereabout; that the presence and position of each egg is from the first indicated on the exterior by two unequally long glistening white bristle-like prolongations of its shell, and later by discolouration of the point pierced. Have discovered by dissection that she is provided with a serrated ovipositor of the shape and sharpness of a sabre, wherewith to pierce holes in the soft tissues of the plant for the reception of her eggs. These observations have been verified in the field upon numerous blighted bushes; but, though eggs have readily been found by the unaided eye on blighted portions of bushes, not a single one has yet been seen on any perfectly uninjured shoot. The vigorous and unremitting plucking of the blighted portions of bushes might mitigate the evil, and I would suggest that this message be sent to newspapers, and published in the *Gazette* for general information.

QUEENSLAND.—At Oxley Point reserve plantations of red cedar (Cedrela Toona) have been successfully established; the young plants are now from 3ft. to 6ft. high. A large number of seedlings have been distributed gratis to intending planters; "applications varying from 20,000 to 2,000" have been received. The varieties of sugar-cane in the Oxley-reserve have thriven exceedingly well; many new varieties have been received during the past year, making in all 78 new varieties which are under successful cultivation. The director, has considered the sugar-cane an object worthy of his special attention on account of its great commerical importance. Rice from British Burma and from the Madras Presidency has succeeded. Surprise is expressed at the indifference shown by colonists to the special inducements offered by the Government to those wishing to go into coffee cultivation. The garden possesses a large stock of seed and plants ready and available for such cultivation. The Moresby Ranges are specially pointed out as adapted for the culture of coffee, cocoa, and several spices. Applications have been received for tea, but they are chiefly from abroad. Large numbers of seeds and plants have been distributed during the year, and no less than 104,000 cuttings and roots, chiefly of economically useful plants. The Mango, the Jack fruit (Artocarpus integrifolia), the China date plum (Diospyrus kaki), the Alligator pear, the Cherimoyer, the sweet sop, and the oval kumquat have all fruited abundantly, showing their perfect adaptability for culture in Queensland, but more especially in the northern portions. "The American and other varieties of grape vines from this establishmeut, distributed to Toowoomba, Warwick, and Stanthorpe, have yielded large quantities of superior-flavoured fruit, adapted for both wine manufacture and the table, proving to be a valuable addition to the many varieties already in cultivation here. During the late season I visited the majority of the principal vineyards, with the view of satisfying myself as to the existence or not of the Phylloxera vastatrix, and I am happy to be in a position to report that without exception I found every vineyard I inspected perfectly free from not only this pest, but from any disease whatever."—*R. B. Gardeners' Report.*

LIBERIAN COFFEE: WYNAAD NOTES.—It is worthy of note that, as far as can be at present judged, the Liberian coffee planted in Wynaad is entirely free from leaf-disease. The ordinary variety is beginning to show the usual golden tints to a disheartening extent, and some young West African plants, strong and healthy to all appearance, are, I regret to see, becoming affected. But the young Liberians raised in the same nursery are firm, green and healthy, without a speck. This is very encouraging, and will make the cultivation of Liberian coffee a matter of serious consideration to those who still believe in coffee. But King coffee is growing old in Wynaad. It is the opinion of many that his day is past, and that he must now give place to the more lucrative cinchona, or the speculative gold mine. It is certain that, in a few years' time, the appearance of the country is bound to become entirely altered. The hill sides will be thick jungles of cinchonas, and reefy patches will either be peopled by busy miners or (more probably, say the dubious) show ghastly holes and caverns, telling of failures, and proving that "all is not gold that glitters."—*Madras Times.*

TEA CULTIVATION.—As competition for labour in some of the tea districts, is becoming keen, from the difficulty of finding labourers, the *Indian Tea Gazette* asks why a Company should not be formed, aided if possible by Government, to buy up waste jungle land not yet cultivated, in the neighbourhood of the gardens, and help the people to emigrate to it from the more thickly populated districts of Bengal? Our contemporary thinks that the scheme might, and probably would pay, provided only that the people could be persuaded to emigrate, as the land in many cases would be suitable for rice crops, when it would in the course of a few years become very valuable; or, if it were unsuited for rice, it might grow sugar-cane, while the timber on the land should nearly if not quite pay for the cost of clearing. It would, of course, be an immense boon for planters to have a resident population around them, for one of the most tiresome, and in many cases expensive matters connected with the tea industry is the importing of laborers to work a garden. The people, however, seem loath to move, and appear to prefer abject poverty in their own district to comparative comfort in a land not far removed from their home, but still, to them, a strange one.

LINDULA, Sept. 14th.—Weather all that can be desired. Most estates busy planting out cinchonas. Crop beginning to ripen up. Coolies not plentiful; advances given out freely. Leaf disease has almost disappeared. If it comes as rarely every year, I do not think it will affect future crops, as the trees are getting fresh leaves in a most surprisingly short time. Trees with crop on look healthy and strong. Grub is *not* spreading. There is less of it in the district, as far as the appearance of estates goes, than we have had for the last four years. The beetles and grub do *not* travel from east to west, but west to east. When they have got to the end of the coffee due east, they attack south. Will anyone deny this? Grub will disappear as it did before. Old planters' tell me it was bad in one or two districts about 35 years ago, but afterwards disappeared. Again they came about 18 years ago and again died away. We have them again, and it is quite reasonable to expect that in another couple of years the words "white grub" will be in no one's mouth. Our roads want thoroughly doing up. If you travel from the Agras as far as Kotmale, you will not find more than four very small gangs of coolies. This is more like the years in which we used to get lots of rain in September. Coolies are, as a rule, very healthy. No thanks to the doctors, for we never see them. The Medical Ordinance must be revised. This will be one of the most important questions for the new planting member to bring forward. Mr. R. A. Bosanquet's name is talked of as the right man to be sent to Council. Just had a small washing of coffee. It turns out between 70 and 75 per cent. This I consider very good for the early pickings. Cinchona trees "shaved," and no covering used, feel the effects of continual rain. The side facing the south-west turns black, and, if the tree is not a large healthy one, it dies. Only in very exposed places they die. If there is a little shelter from the S. W. they do well.

THE VARIATIONS OF CLIMATE IN HAPUTALE, CEYLON: 11th Sept.—The weather reports for August, sent you from Haputale, have been so conflicting that the enclosed weather table, as registered by six estates, proves that the reports sent you from the various correspondents were strictly true, although by no means applicable to the whole of Haputale. Steady rain from late last night till now (2 p. m.), and appears pretty general over the whole of Haputale.

PLANTAIN FIBRE.—There appears now no doubt as to the suitability of plantain fibre for paper manufacture. The Bengal Government is encouraging the cultivation of the wild plantain for the purpose, and

Dr. King has recommended a trial shipment to the London market to make its value known to English manufacturers. The wild plaintain, and for the matter of that the cultivated sort, the fruit of which, both ripe and unripe, is consumed by the masses in this country, grows luxuriantly on the hill slopes, and the fibre might be a source of additional profit, for the tree annually dies down, and the fibre is simply thrown away. The plantain, according to Laborie, is largely cultivated on coffee plantations in Domingo as a shade just in the manuer that cinchona is now put among tea and coffee trees.—*South of India Observer.*

COLONIAL FISHERIES.—Your recent notice of Mr. Musgrave's work on the "Fishes of Jamaica" should induce circulars being sent to all the Colonies to contribute information on local fisheries, in readiness for the International Fisheries Exhibition, which is to be held in London in 1883. Dr. Day will, no doubt, take a lively interest in this matter. The author of the "Fishes of India" should be able to exercise great influence among our many Indian friends; and it is to be hoped that, through the exertion of Sir J. MacDonald and Sir W. V. Whiteway, our great fish-producing Colonies, Canada and Newfoundland, will make a better show than they did at Berlin two years ago. Australia, too, ought to be able to illustrate the wealth of her fisheries there. New South Wales sent a commissioner to Berlin to report upon any features in the fisheries exhibition there which might help her Government in passing regulations for the development of her fisheries, and an exhibition in London, ought to be the medium not only for affording similar instruction to all our Colonies, but for making the public better acquainted with the marine wealth of Britain beyond the seas.—*Colonies and India.*

CALCUTTA TO THE NILGHIRIS.—The journey by road from Metapolliam to Ootacamand is expensive by express tonga, much more expensive than that from Umballa to Simla; for while the fare for the latter journey is R40 (80 or 90 miles); the charge for the former is R30 or R36 for 32 miles; and this notwithstanding there is supposed to be opposition between two or three companies. The road for the first few miles to Kullar, the foot of the "Ghaut," is not very good; but the asceut is smooth, much smoother than the ascent to Simla; and the scenery is very pretty indeed as one mounts the face of the hills, and the varying foliage, tropical at first, but gradually displaying more and more of the European type. Here and there tea and coffee gardens are noticed, and further up cinchona is being planted in profusion. Indeed, planters here seem to look upon tea and coffee with a feeling expressed in the word *Ichabod*, and they are now going in for *gold* or cinchona. Practical men, these planters! They make diligent search over their estates, and they discover quartz, auriferous quartz, of course, at all events the specimen shown is generally valuable. Do they set to work at once and crush it? Oh, dear no! they sell or try to sell the estate or the right of working it, to a capitalist if they can find one, or a company if they cannot. By this means the planter saves a modest pittance, while he poses as a benefactor to the community. And we will wish them all well. May everybody who buys an interest in a mine, find that interest at least 50 per cent. As regards cinchona, it is a fair speculation. I am informed that digging "pits" costs about R17 per thousand. It will take five or six years before any return comes in, and there is the risk that the price of bark will have lessened owing to the quantity which will then be produced, but a glance at a share list, which shows that the dividend of a Cinchona Company was 100 per cent in 1880, engenders a natural expectation that there will still be a margin for profit.—*Pioneer.*

SULPHURIC ACID AS A CURE FOR COFFEE LEAF DISEASE.—We learned from Mr. Geo. Wall before his departure that some experiments he made on coffee leaf disease with very weak dilutions of sulphuric acid—watering the soil around affected trees—were eminently satisfactory. We believe Mr. Marshall Ward has been trying the same application, and no doubt the result will shortly be made known. Sulphuric acid diluted with water to the extent mentioned by Mr. Wall would be a very cheap application, if it proved efficacious in checking the leaf fungus.

THE RAIN-TREE.—At a meeting of the Committee of the Agri-Horticultural Society of Madras, held on the 3rd ultimo, it was stated that the Rain-tree (*Pithecolobium saman*) in the Gardens, which is believed to be under nine years, from the seed, continues, in spite of its having been necessary to amputate some of its largest limbs, to grow enormously. Measured on 30th July last, it gave in girth 9 feet 4 inches at the ground, 6 feet 3 inches at the height, 3 feet and 5 feet 9 inches at the height, 5 feet had spread about 85 feet from north to south; and a total height of about 46 feet. A reference to the former measurements shows that the girth at 3 feet from the ground has increased in the last three years 2 feet 2 inches. The age of the tree is, if anything, over-estimated; but search is being made for traces of the receipt of the seed, which it is believed came from Ceylon about 1872. A casuarina tree standing alongside, which was the specimen of its order when that part of the ground was laid out as the Botanical Garden, and is therefore knowu to be about ten years old, now measures at five feet from the ground only 2 feet 8½ inches, though it is about 82 feet high.—*Madras Mail.*

THE KALUTARA LIBERIAN COFFEE ESTATES.—The Liberian coffee enterprise in the district continues to flourish, and give every promise of assured success. A large clearing has been planted in Gikiyanakanda estate, and the plauts are thriving beyond expectatiou. Cocoa is, I fear, not so successful: the soil is not rich enough for it, and the white ants attack the tree. Tea and India rubber both succeed admirably. The Ranwalagalakanda lots have not yet been put up for sale, as it was important to ascertain what line the proposed new road would take with regard to them. I have suggested that a road should be traced from the bridge at Tabuwana, the termination of the present road, to the foot of the estate Arapolakanda through Crurie and Torwood to Nebada, and thence to join the present minor road at Matugama, passing along the foot of the Ranwalagakanda lands. A connecting road from Nebada to Warakagoda will afford an outlet to the river for those estates on the Ranwalagalakanda range, and relieve the District Road Committee of the extremely heavy upkeep of the hilly road through Gikiyanakanda. The great advantage to be secured by estate owners in the district is I conceive, the extreme facility of transport to Colombo by water. Coffee can be transported from the store on the river side to the store at Colombo without any further handling. The present estates are at some distance from the river, but there are large tracts of forest land adjoiuing the Kuda and Maguruganga which will, I doubt not some day, and I trust before very long, be taken for the cultivation of Liberian coffee and other low-country products. It is a great mistake to think that Sinhalese labour is unsuited for the purpose. I have found as many as 200 Sinhalese coolies at work cheerfully under Mr. Foulkes at Gikiyanakanda in the new Liberian coffee clearing, and he finds no difficulty it securing as much labour as he requires. The appearance of the estate is sufficient testimony to the quality of the labour.—*Mr. Wace's Administration Report on the Kalutara district for* 1880.

WEST INDIES, DOMINICA, 10th August.—The coffee crop is likely to a large one for the island, and the exports of cacao are expected to be above those of last year. The lime crop is late in consequence of the drought during the few fine months of the year, but the cultivation of the lime tree is constantly being extended, so the exports of juice, both raw and concentrated, become larger every year.—*Colonies and India.*

AUSTRALIAN GUMS.—If evidence were wanting of the suitability of the soils on these Hills to the successful cultivation of Australian gum trees, we need go no further than Dava Shola. On Mr. Money's Cinchona Estate in this locality, the blue gum has lately been planted both as a break-wind and as standards for a living fence probably to be rendered impervious with wire. The gums were planted not more than twelve months ago, and now are over six feet in height, and two inches in diameter. The rapidity with which they grow, makes them admirably adapted for shelter. The gum will probably be the great timber tree of the district, and take the place of the more valuable sorts of jungle wood now used by the natives for building purposes.—*South of India Observer.*

THE SUPPLY OF CINCHONA PLANTS.—This season has not been equal to the demand. Planters have enquired in all directions with only partially satisfactory results. In Ceylon stumps are in favor, and more than one correspondent of the *Observer* recommends them as preferable to plants, which sometime die down in patches wholesale in the most unaccountable way. The roots should be trimmed with a sharp knife, and the stumps cut off about 8 inches above the roots before planting. A planter in Wynaad has assured us that a device of his to supply a deficiency of plants has answered admirably. The plan was as follows:—He trimmed off the lateral shoots on the young planting of the previous year, and removing all but the two tenderest leaves at the tip, but in cuttings into the pits in some cases two to each and others three. The cuttings were put down before the monsoon, and the following year he found that most of them had struck root and were in excellent condition. In some cases both, and in many all three, cuttings had rooted. We commend the plan to those who have failed to secure a supply of plants.—*South of India Observer.*

TEA IN NATAL.—Tea cultivation in Ceylon is now attracting attention, and is making headway in the colony. We see no reason why it should not pay in Natal. It is already grown here, and succeeds on a small scale. We made a trial recently of the Natal product, and to our taste it is preferable to the Assam we are in the habit of using. It is strong, and like all Indian teas, does not do to be infused long. We today publish an article on the subject by a practical Indian planter, who is confident that under efficient management tea growing in Natal is a branch of industry that will yield a very good return on the capital that may be invested in it. Several parties are already growing a few plants, and they all agree that they are well suited for Natal, and that they would persevere if only they could get leaf manufactured. Heat and moisture, with soil that retains water are desirable. We commend our correspondent's remarks to the attention of our readers, and our columns are freely open for discussion on the subject. With sugar an established success, were tea proved equally so, there is no limit to coast industry, whilst abundance of suitable land is still procurable. The local, Cape, and South African markets would consume for some time to come all that is likely to be raised here at prices more remunerative than for export. Natal last year imported tea to the value of £6,264 and the year previous £9,793, whilst the returns from the Cape Colony aggregated in 1878 1,252,850 lb and in 1879 879,599.—*Natal Mercury.*

TEA CULTIVATION AT MESSINA.—We learn from the *Indische Mercuur* that during last year an Italian landed proprietor, Count Amajo, opened on his estate near Messina a large tea plantation. It is growing excellently, and experts pronounce the leaves in no way inferior to the China variety.

JUTE, I think, would be a capital thing for the Ceylon natives, as it could take the place of their coffee in their defunct and non-yielding gardens. It is chiefly round their homesteads that the ryots and people of India grow it. How much is a Beegah?—*Cor.* [A third of an acre.—ED.]

AGRICULTURE is a recognized part of the University curriculum of many American, Scotch and German Universities (Cornell, Kentucky, Massachusetts, Edinburgh, Halle, Göttingen, Munich, Leipsic, Berlin, Bonn, Vienna, Eldena, Giesen, Kiel) and distinct degrees in Agriculture are now granted in some of them.

TOBACCO CULTIVATION IN IRELAND.—Among the Irish business to be brought before Parliament next session will be a bill to repeal the Acts in force prohibiting the cultivation of tobacco in Ireland. During the recess arrangements have been made for the collection of information and statistics on the adaptability of the Irish soil for the growth of the plant. It is not proposed—should the cultivation of tobacco be resumed in Ireland—to exempt it from duty.—*Overland Mail.*

CHICORY.—"What is one man's food is another man's poison" is an adage, it is to be feared, which will scarcely solace coffee-planters for the information given us by the *Sydney Mail*, that 50 lb. weight of chicory seed has been distributed among cultivators in the south-eastern district of South Australia, with the view of extending the growth of that plant. It is impossible to take up a journal published in our coffee-producing colonies without reading testimony to the general belief that their industry is seriously affected by the extensive adulteration of coffee by chicory, and consequent demands that efforts should be made to induce the Home Government to check it. There may be other uses to which chicory is applicable, but there is no doubt that the soft flavour imparted by it to coffee makes the adulteration of the latter more favourably regarded than it otherwise would be, and therefore this effort in the direction of "new products" in South Australia will be certain to call forth complaint in Ceylon, and other coffee-growing Colonies, which even now have difficulty enough to sustain the competition to which they are exposed with countries where labour is almost compulsory, such as the Brazils and Java.

NEW PRODUCTS IN THE WESTERN PROVINCE OF CEYLON. The cultivation of new products such as Liberian Coffee, Tea, Cocoa, and India-rubber, has been largely extended, and has been so successful that the enterprise has attracted the attention of even the villagers, to whom every encouragement in such cultivation is being given. There are still large extents of Crown land available for the cultivation of new products in the Western Province, and there is no doubt that, when better means of transport are secured to the Districts selected, these lands will be sold greatly to the advantage of Government as well as of the purchasers. In the development of these new resources new roads are especially required. In the Kalutara, Kegalla, and Ratnapura Districts there is already a large and steadily increasing area under cultivation of some new products, and the roads for which the planters have applied, if they can be opened in an inexpensive manner, will, I consider, be reproductive to both planters and the Government. A thorough reconsideration of the Road Ordinance of 1861, and a more liberal adherence to its provisions in favour of minor roads, is however necessary before much progress can be made in the matter of district thoroughfares.—*Hon. F. R. Saunders' Administration Report for* 1880.

THE AUSTRALIAN TEA MARKET.—The Calcutta *Englishman* gives a timely warning to the Indian tea planters, of the need of regular supplies of teas being sent to the Australian Colonies, if full advantage of the promising opening there is to be taken. The Indian tea planters complain very much of having only the London market to depend on, having seriously suffered from panics there, which, from time to time, has brought down the price of their staple to a ruinously low figure. The advice, therefore, which is given below, ought to commend itself to the Bengal tea-growers, as well as to the tea planters of Ceylon :

BRAN OR GROUND FEED is best fed to cows, upon moistened hay, it being mixed with the hay all will be eaten together and raised and masticated. But if it is not fed with cut hay, it should be fed dry and in a small quantity each time, for if fed alone it is not raised and re-masticated, but goes on to the third and fourth stomachs. If fed in slop it is swallowed without any mastication, and mixed with little or no saliva, but it fed dry it cannot be swallowed until it is mixed with saliva, and the saliva assists in digestion. When food is masticated the act of rumination causes the saliva to flow and mix with food. We have experimented, and find that when fed alone dry ground feed is better digested that when fed wet. —*National Live Stock Journal.*

THE BARK OF DEAD OR DYING CINCHONA TREES.—A planter writes :—"Can you, or any of your readers give me information as to whether the bark of a cinchona tree that dies, and is then pulled up and barked, still retains its valuable properties, or is the bark valueless? I have heard several expressions of opinions on the subjects but some said it was valuable, and others the exact opposite." The following is from the *Cinchona Planters' Manual* on this subject :—"The period of approaching decay has been indicated as the time for coppicing or up-rooting the clearing. Mr. Broughton's dictum on the subject was that diseased trees contained little, and dead trees no alkaloid. He also shewed that the larger and more vigorous the tree, the more valuable the bark. The result of some experiments in connection with this point, shewed bark from fine vigorous trees yielding 6·76 and 6·94 of total alkaloids; similar trees of the same age, and of mean growth, gave 4·34; and trees of stunted growth 2·40 only; the amount of quinine and the other alkaloids all diminishing in the same proportion. In spite of this, we find no difference in value between the bark of our dying and healthy trees. The reason probably is that the disease is a sudden one, and the tree shews signs of decay, putting on an unhealthy appearance, whilst only certain spots are affected; the bulk of the bark being as valuable as on the thoroughly healthy tree. There is indeed a very generally held opinion, that any thing which arrests the growth of a cinchona tree causes it to increase the secretion of alkaloid, and the change which takes place when the trees mossed is accounted for. Whether there is any truth in the idea or not, it is impossible to say, suffice it, that no proof has been brought forward in support of the theory, whilst the investigations of scientific men do not favour it. Dead bark, that is bark that has been deprived of its juices, and become inert on the living tree, is valueless. Instances have been given of dead bark having a value. This can probably be accounted for by the growth of the tree having been suddenly arrested, by up-rooting for instance, and the bark allowed to dry on it. In this case, there is no more reason for a loss of value in the bark than if it were stripped and dried in the usual way. This being the case, it is more important that diseased trees should be harvested at an early stage, before any portion entirely loses its vitality; and consequently, coolies should constantly go over the plantation to remove such trees, and to take the bark from fallen branches, &c."

OSTRICHES.—Two hundred ostriches from the Cape have been landed at Buenos Ayres, where ostrich-farming will be commenced.—*British Trade Journal.*

ADULTERATION IN PARIS.—The examination of samples of food at the municipal laboratory in Paris during July showed that of 412 samples of wine only 15 were good, 185 being tolerable, and 209 bad; of 13 samples of water only 1 was good, 1 being tolerable and 11 bad; of 164 samples of milk 31 were good, 21 tolerable, and 112 bad; and so with other articles of food, perfumery, &c. We read that "the examinations of bread, pastry, meat and coffee gave satisfactory results." But we suppose the analysts did not reckon chicory as an adulterant, or they would scarcely have been so satisfied with their samples, which must have contained more or less of that abomination.

CEYLON TEA IN GLASGOW.—A correspondent writes :—"If the enclosed cutting from the *Glasgow Herald* has any interest for you, or your readers, perhaps you will publish it. The figures are no doubt from *Ferguson's Directory*" :—"Owing to short coffee crops planters in Ceylon have of late years turned their attention to the cultivation of other products, among which tea figures conspicuously, and the export from Ceylon of this article is yearly increasing. In 1877 only 2,105 lb. were exported, while in 1880 the export had increased to 140,000 lb. Last year the area of tea planted out amounted to 9,300 acres, which will produce about 3½ million pounds of tea when in full bearing; and as the planted area is yearly increasing we may expect before long to hear a good deal about Ceylon tea, which appears to be a successful rival of Indian tea as regards its qualities as a beverage. At the Melbourne Exhibition Ceylon teas were awarded 36 prizes, of which 11 were first-class, and the decision arrived at by the Victorian Government analyst was that in some important respects Ceylon tea was the best in the world, and that in Ceylon the best quality of tea could be produced with the minimum exhaustion of the fertilising matters in the soil. Regular supplies of this tea are now being received in Glasgow by the Strathellie Tea Estates Company of Ceylon, and judging from the demand it appears to be highly appreciated."

AGRICULTURE IN KEGALLA DISTRICT.—The cultivation of tea, Liberian coffee, cocoa, and other new products is becoming very popular in the district. In the neighbourhood of Kegalla, Liberian coffee has been grown successfully in native gardens, and I have no doubt that in the course of a few years the cultivation of this variety by the natives will be extensive. The climate and soil in Three-korales seem specially adapted for its growth. Mr. Molligoda has planted up about 50 acres of Liberian coffee in the neighbourhood of Kegalla, and judging from the appearance of the trees, now six months old, the estate promises well. European enterprize has converted the hitherto comparatively untried region about Ruwanwella and Yatiantota into thriving and industrious districts. Tea is chiefly cultivated, and is the most paying product. Next come Liberian coffee and cocoa, which thrive well, and will, I have no doubt, yield a handsome profit. The African palm also grows well. With the view of encouraging the cultivation of new products, I have requested each Ratemahatmaya to prepare a small nursery near his house for the planting of seed to be supplied to them from the Government Botanical Gardens. The seedlings will be given to the leading landowners in each village. In this way I hope that, under the fostering care of the chief headmen, the trial of new products will be within the reach of the poorer cultivators. Parcels of Liberian coffee, cocoa, and tea seed have been received from Dr. Trimen.—*Mr. C. A. Murray's Report for* 1880,

SCIENTIFIC AGRICULTURE AND AGRICULTURAL EDUCATION.

A home writer pleading for an agricultural education being provided at the public schools and universities, advances as one argument the responsibility of Englishmen for the well-being of India. Here we have a great Dependency in which Agriculture is pre-eminently the occupation of the people. On the one hand, ignorant intermeddling with, or neglect of, agricultural matters may bring on bankruptcy and ruin; while, on the other, due enterprise and encouragement guided by science, would increase the harvests of food and other produce far beyond any present conception. The successful administration of India (and we may add of Ceylon) must now every year depend more and more on the broad, intelligent and scientific handling of agricultural questions, and to secure this result, the laws and facts of geology, of botany, and of physiology, will have to be carefully studied and applied. It is particularly pointed out that it will become incumbent on the Government to have their subordinate officers—civil servants included—educated and trained to form reliable judgments on agricultural questions. Men of brains they should always be, and no doubt a classical, and especially a mathematical training, will still be required; but young Englishmen for the different branches of the Indian Service ought not to leave their native land without some knowledge of the ordinary rules of cultivation and, at least, of the elements of the sciences on which the success of agriculture, as well as horticulture in the long run depends. The latter branch, more particularly, deserves attention, for large districts in India, as in Ceylon, are now chiefly dependent on their planting industries, and one great duty of the servants of Government ought to be the promotion and encouragement by every means in their power, of the cultivation of new products, whether in garden or field, by the native villagers and land-holders themselves.

This brings us to consider more particularly what the Government of India are doing to promote these objects. We need not dwell on the Botanic and Economic Gardens or the Agricultural Exhibitions established at different points; on the great cinchona culture experiment with its brilliant success both on the Nilgiris and in Sikhim, and the important manufacture of the febrifuge which has followed; nor on the constant endeavour of the Indian authorities to encourage the development of their resources in new products, or to introduce other industries, such as jute, tobacco, india-rubber, silk-growing, &c., from abroad. Model Farms are being worked successfully in several divisions of the country, notably in Madras, where Mr Robertson has also a school of agriculture under his charge, which ought be to a model to the other Presidencies, and more especially to Ceylon. From a recent review of the work done under the auspices of this useful institution, in the *Madras Times* we quote as follows:—

To what a high degree of proficiency the Madras School of Agriculture has attained is shown by a pamphlet, which we have received, containing the "Question Papers of Class I. in the Madras School of Agriculture." Eminently practical in their character, and admirably suited to test the thinking-powers and the capacities of the students generally, no one can rise from even a cursory glance at them without feeling convinced that a thorough knowledge of the various subjects mentioned in the papers cannot but constitute a scientific agriculturist in a very large sense of the term. Economically considered, the country has been too long a sufferer to the agricultural charlatanry which it has been a victim to, and Mr. Robertson has never ceased to point to means of escape from the dangers of a neglected agriculture. Field chemistry and geology are points which Mr. Robertson very justly lays much stress upon. They are subjects which the ordinary ryot treats with huge disdain, and the various papers set for examination show that the Superintendent of the Government Farms is anxious, beyond all things, to impress on the minds of his young pupils that Nature has no superfluities, either organic or inorganic, and that certain processes whose utility may not be apparent to us at first sight or thought either, are as necessary to the comfort of animal life as is the food that such life is supported by. Mr. Robertson leads with some very practical questions as to benefiting the soil by hoeing, deep tillage, and the conditions under which crops benefit by the latter. He has omitted no pains, apparently, in the analysis of waters, and expects his class to be able to determine the difference between Hydrostatic water, Capillary water and Hygroscopic water, Manures, and the several gases that go to form a fertile field, in short all the elements of plant food, are points on which he must have well grounded his class to expect it to be proficient. Flax and wheat, sugar, cotton, and maize, are crops whose scientific cultivation he urges the necessity of, while the growth of tobacco, hemp and fibre of all descriptions on principles better calculated to develop them to their fullest capabilities could not have been omitted in his lectures. Coffee loses none of its importance by the side of cereals and fodder-producing plants. Farm implements and gear generally are matters Mr. Robinson thinks his class ought to be adepts in; and, looked at from every point of view, the portion of questions set by him shews that there is no part of a farm, no concern of it, however petty it may be, that has not a recognised and highly important function to discharge. Doctor Western's papers on veterinary science follow those of Mr. Robertson. They are of a highly professional character, and extend to all matters connected with animal life on the farm either in health or disease. He is critical in the use of terms employed in the pharmacopœia of veterinary lore; and the general tenor of his paper denotes the inestimable value he sets upon cattle and the condition of perfect freedom from disturbing influences he would see them in. Mr. Hamilton's questions on chemistry are proof of the high standard of perfection to which the class must have attained to be expected to answer them. A discriminating intelligence alone could enable a student to pass through them successfully, and we feel certain that the questions demanding an explanation of the different kinds of acids known to the field chemist are meant to be something more than tentative. Mr Wilkins follows with a string of every pretty questions on botany, and we would fain hope that the replies received were significant of the value the class attached to that branch of Nature's choicest gifts which the science of botany illustrates. Wiser than our ancestors in not a few respects, it is an unmistakable evidence of triumph of modern botany that we no longer labour with them in the ignorance which once existed with reference to a thousand discoveries that the science has made known in these latter days. Dr. Knes's questions on zoology are searching and interesting and at the same time the habits and characters of the animals he calls upon the students to classify cannot be contemplated with indifference. We have left ourselves but little space to notice the papers on Physical Geography,

Arithmetic and Book-keeping, Mensuration and Building set severally by Mr. Ganapti Iyer and Seetharam Moodelly Garco, and have only to add by way of concluding remarks that the little volume contains matter which we would give the students of class I of the Agricultural School the full credit of being thoroughly acquainted with.

Here we have a model Agricultural School established for some years, at our very doors, giving instruction and guidance to the Ceylon authorities if they only choose to profit by the same; and, seeing that the local Educational vote has been liberal beyond the ability of the Director to dispose of it, so far as the promotion of the all-needful elementary vernacular education is concerned, we would strongly advise Mr. Bruce to urge the commencement of an Agricultural School and the revival of the Model Farm. Inquiry has lately been made as to the position of the "Soyza Model Farm" enterprise, and during the present Session of Council we have no doubt the whole question will be opened up by one or other of the native members. Whatever may be the result, Government cannot plead impecuniosity in respect of this matter, for ground, buildings and even lecturers may be said to be available. But we need not pursue this subject further for the present. To return once more to India we have as the crowning evidence of the interest of the Government in Agricultural Improvement, the re-establishment of a special department, and from the official resolution on the subject, we repeat a portion for the information of our readers:—

Agriculture and Commerce Department. The new Department will, as a matter of course, control all operations for the relief of famine; but that part of its functions will be necessarily intermittent, and its main work will lie in the branches of the public administration which most closely affect agricultural development and the interests of the agricultural population. In making the following distribution of work, the Governor-General in Council has therefore, been influenced by the desire to free the new Department as much as possible from unnecessary calls upon its energies, in order to directed efforts, so far as present circumstances admit, to the fulfilment of its most really essential duties.

5. Having regard to these considerations, the Governor-General in Council is pleased to direct the all matters connected with the subjects noted below so far as they affect the provinces of British India shall come under the cognizance of the new Department, *viz*:—

1. Land Revenue, including Settlments and Takavi advances.
2. Surveys, including Geological Surveys, and excluding Archæological and Marine Surveys.
3. Agriculture and Horticulture, including Fibre and Silk, Fisheries, Cattle-breeding, and Cattle-disease.
4. Minerals.
5. Meteorology.
6. Famine.

As a temporary arrangement, the Home Department will be charged with the superintendence of the Forest Department; and subject to reconsideration, the Agricultural Department will temporarily conduct the whole business of the Government of India connected with Emigration.

But it is not alone through a separate Department that the Government of India—thoroughly awakening to their true position as great land-lords—are prompting agricultural development and improvement. Every Indian civil officer from the Lieut.-Governor down to the youngest Assistant Collector feels that no more important duty can be undertaken by him than the task of aiding and fostering the beginning of new industries among the people, or through the occupation of waste and unoccupied districts. In some instances a rich harvest has been already yielded; for as the *Pioneer* remarks:—

Our tea plantations and cinchona gardens furnish marked examples of what can, under judicious and energetic management, be effected in the direction indicated; and cinchona will for years to come be pointed to as a blessing which official European enterprise has extended to a country where for ages fever held sway, and was but little less paralysing in its effect than gaunt famine. Tobacco may be pointed to as another industry, which at the present time deserves especial attention; for although much has been already effected in the North-West Provinces towards establishing it in the market, there is still considerable room for further experiment, especially with regard to the long-vexed question whether the leaf, as grown and cured in this country, cannot be rendered a remunerative branch of our export trade. But even if this degree of perfection be not attained, there yet remains, judging from the large quantity of tobacco which the trade returns show as imported into India and Burmah yearly, an immense sphere for local consumption.

Then again, turning to the raw products and handicrafts of India, where the aid of Government might be beneficially invoked, notwithstanding the extent to which machinery has in some instances sapped a wide field for manual labour, it is beyond doubt that the manufacture of paper, sugar, candles, furniture, and leather, is yet capable of great expansion. It is satisfactory to learn that paper mills are likely to be started before long in British Burmah, where a well-known London firm has during the early part of the year been prosecuting inquiries on the spot, with a view to ascertaining the best adapted fibre of the widely scattered bamboo for the manufacture of paper. The enterprise, which we trust will succeed, will afford another extensive industry for the absorption of native labour.

Notwithstanding the vast and varied interests entrusted to their charge: the huge debt and the frequent political and military complications—from which our island is free—it must be admitted that the Government of India are far ahead of the Executive of Ceylon in their patronage of agriculture and their readiness to foster new industries. The time has now come when our local authorities should acknowledge the need for considerable changes in the attitude of the Civil Service towards this question. It may take some time to introduce marked improvements, but at least steps in advance should begin to be made; and some more of these we shall endeavour to indicate on another occasion.

DARJEELING TEA AND CINCHONA ASSOCIATION (LIMITED).

Messrs. Schoene, Kilburn & Co., the Managing Directors, have kindly sent us a copy of the report of the above Company for the half year ending 30th June last. We read:—

The outlay, as you will observe, has been very large, reaching the sum of R61,525-8-5; but the quantity of bark cut has also been much larger than it was for the corresponding period of 1880. This increased outturn has been further maintained up to the present time, and the returns shew 834,158 lb. of green bark

cut to the 21st August, against 483,863 lb. to the same date last year.

Prices, we regret to say, have been somewhat lower, and the sales are as follows :—

157	packages at an average of		1*s* 8½*d*	per lb.
91	,,	,,	1*s* 6¼*d*	,,
112	,,	,,	1*s* 5½*d*	,,
160	,,	,,	1*s* 6⅝*d*	,,
81	,,	,,	1*s* 7*d*	,,
46	,,	,,	1*s*	,,

The last lot was of inferior quality, and besides the above there are 557 packages in transit and partly arrived in London. The outturn of tea to the 21st instant was 5,030 lb. against 934 lb. for the corresponding period last year : 1,700 lb. have been sold at an average of R 1-4-3 per lb.

The property is stated by your manager, whose report we append hereto, to be in good order ; and all the works, including the new extensions of both cinchona and tea, seem to be progressing favourably.

The approximate proceeds corresponding to the first half-year may be seen by the note at the foot of the accounts ; and with this before us we would suggest that at your meeting the usual *ad-interim* dividend of 10 per cent should be declared.

We quote from the Report of the Manager (Mr. Hogarth) as follows :—

Buildings.—The buildings on the estate are in good order. The tea-house at Poomong has been completed, and a Portland Cement floor laid down : the *chulas* for drying the tea have also been made, and the verandah for accommodating the machinery at the east end of the house has been built. At Namring a wooden godown with an iron roof has been erected : the cook-house and stable are now completed, as is also the stable at Poomong. The pucca drying godown at Namring is hardly sufficient but can easily be increased, if necessary, next cold weather, by adding to the length.

Chinchona Cultivation.—Up to the 30th June 113,414 lb. of bark were packed, and 108,014 lb. despatched, as against 51,051 lb. despatched to corresponding date last year, shewing an increase in despatch of 56,963 lb., which I think you will consider is very satisfactory. On the south and west portions of the Poomong spur all the Chinchona roots have been taken out, and barking is being carried on, on the east side of the spur. At Namring last year's extensions of Calisaya and hybrid plants have done very well, and I do not doubt, but that ultimately, they will turn out a success, and form a very valuable addition to the Company's property. This year's extension consists of 35 acres. At present it all looks healthy, and I have no doubt will turn out as well as last year's planting.

Tea Cultivation.—Up to the 30th June 2,796 lb. tea were made as against 411 lb. made up to same date last year, shewing an increase of 2,385 lb. : the whole tea garden has recently been hoed, and is at present in a very fair state of cultivation : last year's clearance is doing well, and the plants all look healthy. There are very few vacancies : the new extensions consists of 70 acres of good hybrid plants on the west side of the Poomong spur, and appear inclined to do well. I think there is every prospect of 100 maunds tea being made this year. No machinery is at present used, but when we require it, the supply of water will probably be found ample for a water-wheel either a turbine or a water-wheel, whichever should be deemed advisable.

Labor.—I have been able to keep more coolies than I expected, the musters of the two factories of Poomong and Namring amounting daily to over 700 souls. This I consider, is attributable, to be owing to the large extensions in both tea and cinchona a considerable number of coolies is required to keep the young plants free from jungle, as well as to carry on the ordinary work of barking and tea manufacturing. I should, however, have been glad to have been able to obtain an even larger supply of labor, as it is excessively difficult to keep the jungle down : the health of the coolies on an average has been far better than it was last year.

General Remarks.—The two factories are in very fair order. Several improvements have been made in the roads : in the plantations sundry new roads have been made, thus facilitating access to the different works. In addition to the planting out of tea and chinchona, large nurseries of Toon Cryptomaria seed have been made, which at present have germinated well. The Toon will be planted out at the lower elevations on the Rungjo Flats : the Cryptomarias will be planted higher up. I have also just received some seed of the "Pinus longifolia." I trust these will all turn out well, as they will prove a very valuable addition to the timber on the estate ; and, as timber is yearly growing more scarce in this district, it is very important that our wood should be preserved, and new timber grown as much as possible.

PUBLIC SALE OF CINCHONA IN COLOMBO.

COLOMBO, Sept. 22ND, 1881.

Messrs. Robinson & Dunlop put up for public sale at their offices this afternoon the undermentioned lots of cinchona bark, which sold at the rates per lb. quoted :—

				R.	c.
Stair—Lot 1	18 lb.	Succirubra Quills	..	0	75
,, 2	62 ,,	,, Stem Shavings		1	25
,, 3	49 ,,	,, Root	..	0	87
,, 4	670 ,,	,, Twigs	...	0	32
,, 5	60 ,,	,, Officinalis Stem Bark	...	1	40

The above bark was grown from trees 5 to 6 years old, at an average elevation of 5,000 feet.

				R.	c.
Mayfield—					
Lot 6	220 lb.	Succirubra Stem Shavings	...	0	90
,, 7	240 ,,	,, Branch Quills		0	33
,, 8	150 ,,	,, Twigs	...	0	28½
,, 9	60 ,,	,, Root	...	0	82
,, 10	40 ,,	,, Renewed Stem		1	50
,, 11	120 ,,	,, Officinalis Stem Chips	...	0	90
,, 12	26 ,,	,, Root	...	0	65
,, 13	25 ,,	,, Twigs	...	0	33
Aberearney—					
Lot 14	450 lb.	Succirubra Stem Quills analysis 1·96	...	1	7
,, 15	120 ,,	,, Bold Brauch Quills	...	0	50
,, 16	1320 ,,	,, Branch Quills		0	43
,, 17	300 ,,	,, Twigs	...	0	27
,, 18	120 ,,	,, Root	...	0	91
,, 19	230 ,,	,, Stem Pieces			91
,, 20	450 ,,	,, Shavings	...	1	22

From trees 4 to 7 years old. Elevation 4,200 feet. Analysis of stem bark by Mr. Symons, gives 1·96 yield of Sulphate of Quinine.

Portswood—Lot 21	210 lb.	Officinalis stem,	c		
Lot 22	280 lb.	Bold Twigs	..	0	28
,, 23	40 lb.	Small Twigs	..	0	15

From trees 3 years old, grown at an elevation of 6,500 feet.

Though prices were considerably below those of last public sale, this sale went very well considering the small quantities in some of the lots offered.

NETHERLANDS INDIAN NEWS: COFFEE.

(Straits Times.)

"BATAVIA, 2nd September.—All is quiet in Acheen to the satisfaction of the supporters of Civil Government there. The exodus of fleeing and disgusted Chinese from there to Penang seems to have ceased, at which, we heartily rejoice, from the services rendered to our forces and officials there by this indefatigable and industrious race of mankind."

The coffee crop in the Residency of Pasaruan appears, this year, to be likely to surpass the boldest anticipations. The local journal there surprised us this week with the tidings that the yield in that province will exceed the high estimate made, by about 50,000 to 80,000 piculs, and that, in any case, the crop may amount to 350,000 piculs. In spite of the rather lower prices realized by coffee of late in European markets, the revenue resulting from such crops will be very considerable. Let us hope that the Netherlands Government will employ a portion of the millions thus obtained in supplying what the Colony is so much in need of, namely, diminution of taxes, extension—speedy and great extension—of means of communication and thorough improvement in our defences."—*Java Bode.*

SALE OF JAVA CINCHONA BARK IN HOLLAND.

On the 21st July 1881 there were sold by auction at Amsterdam 26 chests and 824 bales of Java cinchona bark, as follows:—

		Per ½ kilo.
65 b.	succirubra stem 1st qual. ...	151 to 201

1 ,,	do root ...	171 ,, —
1 ,,	pahudiana stem ...	95 ,, —

The quotations being so many cents of a florin (equal to 1s 8d sterling) per $1\frac{1}{10}$ lb., we see that the highest price secured for red bark (stem and root) was less than 3s 3d per lb.; for crown bark (stem and root) it rose to 5s 3d; and for the inferior yellow barks (*Calisaya Javanica*, and *Calisaya Schuhkraft*) as well as the hybrid *Hasskarliana* and the inferior crown species *lancifolia* the maximum was only 2s 6d per lb. On the other hand the first and second qualities stem Ledgeriana realized up to 761 cents per ½ kilo, or 11s 6d per lb. When we compare these prices with the London quotations at the same period we see that for fine quill of East India and Ceylon crown barks, as much as from 4s to 7s was obtainable, and even up to 5s for red bark quill. There is nothing very wondeful therefore in the 11s 6d per lb. for Ledgeriana bark; but without particulars as to the age of the trees from which it was stripped, it is impossible to institute comparisons of much practical value.

The purchasers of the Ledgeriana seed at the local sale on the 20th instant will however feel a special interest in the above prices obtained for the Java bark. The results of the sales of seed are reported to us as follows:—

			R
25 boxes	..	at R50 ..	1,250
5 ,,	..	,, 55 ..	275
1 ,,	..	,, 56 ..	56
1 ,,	..	,, 57 ..	57
10 ,,	..	,, 60 ..	600
1 ,,	..	,, 61 ..	61
2 ,,	..	,, 64 ..	128
1 parcel		..	11
45 boxes and 1 parcel			R2,438

Each tiny box contained about 31 grains in weight of seed, or say 4,000 seeds, of which 70 per cent are expected to germinate. We should say 50 per cent to be safe, and we then find more than 3 cents per seed paid; but if only 1,000 plants come to a marketable age in the nursery, we have no doubt that the purchasers can easily turn over their money. We have heard of a rupee per plant being offered adn refused for Ledgerianas less than eighteen months old in the Central Province.

THE GOLD MINING COMPANIES OF SOUTHERN INDIA.

A handbook of the Indian Gold Mining Companies, posted up to July last, has been published by Messrs. Higginbotham & Co. It contains a list of the Companies; an alphabetical list of Directors; a list of the Mining Engineers; and the rules for Gold Mining leases in Madras, and in Mysore. The list of the Companies gives, in most instances the names of the Directors, the Secretaries, the Bankers, the Solicitors, the Consulting Engineers, the date of issue, the capital, the values of the shares, and the cost and area of the properties. We would have been glad if the compiler had gone a step farther, and favoured the public with a digest of the prospectuses of the Companies. It is likely to be interesting hereafter to compare promise with performance; for while on the one hand, the results of some of the Companies may exceed the sanguine expectation of the earliest pioneers of the industry, on the other it may be found that hope told a far too flattering tale to the promoters of several of the schemes. We have, however, been enabled to compile two useful tables from the information before us. In the first, we give

a list of the Companies connected with Wynaad, and some particulars about them :—

THE WYNAAD COMPANIES.

Name.	Capital.	Price of Property	Paid in Shares.	Area Acres.
Balcarres ...	£180,000	100,000	50,000	1,198
Carta Para ...	50,000	½ nett pro	...	300
Central Wynaad ...	100,000	62,000	33,000	1,560
Cherambadi ...	100,000	32,000	16,000	200
Cootacovil ...	100,000	60,000	32,000	300
Devalah Central ...	120,000	70,000	20,000	986
Devala Moyar ...	200,000	132,000	61,795	2,055
Devalah Provident ..	75,000	30,000	...	120
Dingley Dell ...	100,000	70,000	30,000	600
Ind. Consolidated ...	400,000	275,000	130,000	1,920
Indian Gold Mines ...	110,000	...	...	...
Do Glenrock ...	100,000	50,000	33,000	3,000
Do Grange ...	100,000	50,000	33,000	300
Do Kingston ...	130 000	91,500	43,333	270
Do Mammoth ...	150,000	70,000	...	1,500
Do Phoenix ...	150,000	85,000	33,000	800
Do Trevelyan ...	150,000	96,000	50,000	930
Needlerock ...	125,000	85,000	32,000	250
Nilgiri Gold ...	120,000	85,000	30,000	200
Parcherry ...	150,000	98,000	50,000	299
Rhodes Reef ...	190,000	120,000	50,000	50
Simon's Reef ...	170,000	55,000	...	...
S. East Wynaad ...	100,000	60,000	...	2,400
South Indian ...	100,000	47,000	...	1,200
South Wynaad ...	100,000	65,000	32,500	677
Tambracherry ...	160,000	120,000	52,000	6,000
Wala Wynaad ...	75,000	45,000	15,000	500
Wentworth ...	120,000	80,000	40,000	2,027
Wynaad ...	R650,000	...	...	1,000
Wynaad District ...	£100,000	40,000	25,000	270
Wynaad Glen ...	60,000	...	...	80
Wyn. Perseverance...	80,000	50,000	26,666	600

The nominal capital of these Company amounts to no less a sum than £4,030,000. To this we may add a list of the Companies working in the Kolar District :—

THE MYSORE COMPANIES.

Name.	Capital.	Price of Property.	Paid in Shares.	Area Acres.
Balaghat ...	R 3,60,000	1,20,000	60,000	150
Colar ...	£ 150,000	40,000	...	320
G South'n Mysore	75,000,	45,000	...	150
Kaiser-i-Hind ...	R12 00,000	7,50,000	3,25,000	640
Madras ...	£ 135,000	85,000	25,000	320
Mysoro ...	,, 135,000	55,000	...	750
Mysore Reefs ...	,, 120,000	75,000	30,000	320
Nine Reefs ...	,, 100,000	60,000	33,000	300
N. Ooregum ...	,, 120,000	75,000	40,000	320
Nundydroog ...	,, 100.000	50,000	33,000	...
Ooregum ...	,, 125,000	75,000	...	259

The nominal capitals of these Mysore Companies amount to £1,216,000. So the combined nominal capitals of the Indian Gold Mining Companies above named, plus the £6,00,000, of the Southern India Alpha Company (now practically absorbed in the Indian Gold Mines Company of Glasgow) may be set down at £5,365,000.

One characteristic of the majority of these Companies will forcibly strike most persons who look through the Handbook, namely, that their head-offices and Boards of Directors are in London, and they are almost entirely administered at a distance of five thousand miles from their names. (One Wynaad Company, the Wynaad, has its head office in Bombay; as also has one of the Mysore Companies, the Kaiser-i-Hind; and another Mysore Company, the Balaghat is administered from Madras.) The explanation of this is that as the promoters could not reasonably calculate upon getting the money they wanted in India, they had to resort to the place where the money was to be had for the asking. Doubtless, if the British public had looked askance at the schemes, few of the Companies would have been started. But while admitting that the promoters were wise in their generation in going far afield for the sinews of war, we consider that risk is run by attempting to direct the affairs of the Companies from London. The local management of mines has been found to work best in Australia and elsewhere; and we see nothing in the new industry in India to justify the supposition, that this plan, which commends itself to common sense, can be safely departed from in this country. Moreover, very few of the Directors can be regarded as men who possess a practical knowledge of gold, or any other mining. There are one hundred and fifty-two of them, and the majority are retired officials. The gentleman who seems to have been most in request, is Captain W. B. McTaggart, formerly of the 14th Hussars. This ex-warrior, is a director of six Companies, namely, the Nilgiri, the Nine Reefs, the Nundydroog, the Mysore, the Madras, and the Great Southern of Mysore; and in regard to five of these Companies he also occupies the position of one of the vendors of the land acquired. He is the son of a Madras merchant; but we are unacquainted with his other qualifications to direct the working of half-a-dozen companies, whose capitals total up to £665,000. Presumably, a director should be none other than a man who is competent to direct; and we do not readily understand how such competency can be obtained without a practical knowledge of the business that needs direction. One might imagine from the list of directors in the Handbook that "any fellah" is good enough to join the Board of an Indian Gold Mining Company whereas, if people who know a good deal about gold; mining in Australia and America are to be believed, the Directors of Gold Mining Companies ought not to be "guinea pigs," but men who have established a reputation for shrewdness and practice in the business of gold mining. The old proverb warns us that a "little knowledge is a dangerous thing" and not a few of the gentlemen whose names are before us might declare with truth, that since their minds are blanks with regard to mining they are not hampered with the dangerous modicum of knowledge referred to. But those Directors who are dummies are so many causes of weakness to the Companies under notice; for, as they become sooner or later conscious that they are at sea on the subject of mining, they are tempted to allow the entire management of the Companies to drift into the hands of individuals, whose ability to undertake the task may be open to question though there may be no indisposition on their part to learn the business that they have undertaken; but in the absence of suitable training, the requisite experience may cost a good deal to acquire, and the shareholders will have the honor of paying the piper.

This is already being discovered in India, for some of the above-mentioned Companies have appointed to the charge of their mines, men whose qualifications for the responsibilities imposed upon them are less obvious than their relationship to Directors or Secretaries. The title of Mining Engineer is readily assumed; but there is reason to believe that some of the men who are now called Captains of mines would not pass muster for miners of the first class in Australia. In such cases the Directors have exercised the patronage which has fallen into their hands in a more good-natured than judicious manner; and there

may be in consequence a good deal of disappointment. But how are the Directors, who are not themselves to the manner born to mining, to know a first class miner, when they see him; or to detect the mediocre ability of a second or third class man? As time goes on, and their own false starts, and the blunders of the equally ignorant Directors of their Companies are brought home to them, they many learn a thing or two; but meanwhile the capital at their command will be dribbling away, and the public will become more clamorous for results. The shareholders will ask for dividends, and they will not be quieted by technical reports from the miners that are characterized by "much cry and little wool." There are, on the gold fields, some Mining Engineers, who may be safely trusted to go a-head economically, and conscientiously, without direction; but on the other hand, there are some engineers, so-called, who will need good deal of looking after, yet who may calculate with some safety upon the comparative freedom from direct control, which the five thousand miles between themselves and their Boards will give them. It is not necessary to assume that the latter class of men will not do their best, or will not act honestly by their employers; but their best may be far from satisfactory to those whose interests they are engaged to promote. This brings us round, then, to our former argument, that the Gold Mining Companies of India should be managed in India.

The Handbook contains the following list of Mining Engineers, and properties on which they reported favorably:—

Grove, W. Central Wynaad.
Harris, Edwin Grange.
Harris, John Kingston Kaiser-i-Hind, Mysore Reefs, Nine Reefs, North Ooregum.
Harvey, C. J. Cootacovil, Glenrock, Nilgiri, Tambracherry.
Lain, Thomas Mammoth, Tambracherry.
Lindon, E. V. Cherambadi, Madras.
Massey, J. D. Parcherry.
Pogler, Oliver Devalah Central, Devala-Moyar, Dingley Dell, Consolidated, Kingston, Needlerock, Wentworth, Wynaad Perseverance.
Rogers, John Nundydroog.
Simons, W. Vazie Carta Para, Devala Provident, Dingley Dell, Simons Reef, South Wynaad Wynaad, Wynaad District, Wynaad Glen, Ooregum, North Ooregum.
Smyth, R. Brough, Devalah Central, Devalah-Moyar, Trevelyan, Rhodes Reef, South-East Wynaad.
Sowerby, W. Central Wynaad.
Tapp, Henry Cherambadi.

Of the above Companies one, the Indian Mammoth, is in liquidation. The Devalah Central, the Devala Moyar, the Devalah Provident, the Indian Glenrock, the Indian Phœnix, the Indian Trevelyan, the Rhodes Reef, South East Wynaad, the South Indian, the Tambracherry, the Wynaad Perseverance, the Colar, the Mysore, the Mysore Reefs, and the Ooregum Companies have obtained a settlement on the London Stock Exchange.—*Madras Mail.*

CALCUTTA TEA SYNDICATE.

We have received a number of documents relating to the operations past and prospective of the Calcutta Tea Syndicate. First is a circular dated 12th August, referring to a recent sales of tea in Melbourne, and giving an extract from a letter of Mr. Sibthorp's from Chicago on the prospects of Indian tea there. Then comes an extract from a letter of Messrs. Jas. Henty & Co.'s on the recent discussion on tea adulteration and stating what steps were being taken to make Indian tea known throughout the Australian colonies. A memo is attached to this letter, on the irregularity of weight of the packages of tea from India, and consequent loss to importers. We then have the report of the Syndicate committee on the operations of the season 1880, and the revenue account and balance sheet of the Australian venture. The report summarizes the results of that venture and states what was being done in America. We see that the Indian Government have given a grant of R6,000 towards he expenses of the American experiment, as they had given R10,000 toward the Australian one. Lastly we have a report of a general meeting of the members of the Syndicate and others interested in the Indian tea industry, held on the 5th September in Calcutta. The chairman, Mr. J. J. J. Keswick, gave a short history of the movement which gave rise to the formation of the Syndicate, and the success which had attended its efforts in Australia. He also stated what was being done in America by Mr. Sibthorp, and urged on his hearers not to relax their hold on these new markets. He was followed by Mr. Inglis, who said:—

The indirect gain to all concerned in introducing Indian Tea to new consumers would be enormous. It must be remembered that America (including in that term the United States and Canada) consumes over 80 million pounds of tea, nearly the whole of which is at present supplied by China and Japan. If India could only get the supply of 10 per cent. of this quantity or say 8 millions, it would be an immense relief to this market, and would have the best effect on prices. Then again looking to Australian and New Zealand, we find they took over 22 million pounds last year from China, and I don't think we in India should rest content until we get the supply of at least one half of this quantity (Cheers). Of the two markets the American will, I think, be the most difficult to secure, and it will require a very persistent and well sustained effort to obtain the same reception for our teas there which they have already met with in Australia. But the effort is well worth making and cannot fail to succeed.

Mr. Lesslie Worke, who spoke next, said:—

I observed in a recent circular issued by the Syndicate that only 400,000 lb. had been promised by the agency houses for shipment to Australia. I can quite understand the attractions which the London market has thus far offered—fortunately for the tea industry it has yielded up to date very handsome averages, but I think when we remember that we have not been able to get through half the season without something very closely approaching a panic being seen in that market, we must feel that in it we are leaning upon a broken reed. So long as we have solely London for our teas, we have only one string to our fiddle, and it requires a very clever man to do well when he is reduced to so sore a strait. It is therefore clearly our duty and our interest to use all the influence we have as agency houses in supporting the Syndicate in its efforts to develop the Australian connexion, and we should certainly not rest satisfied with a smaller export this year than the 1¼ million pounds spoken of by Mr. Inglis (Cheers).

The next speaker, Mr. Carritt, said:—

The tea industry may with advantage take a lesson from the Calcutta jute industry. Not very long ago our jute mills were in a more deplorable condition than was our tea industry last year, and but for the successful efforts made by the mills to open out fresh markets in the Colonies and America, many of the mills now running would be closed. Their efforts were not without difficulty and some discouragement, as we shall no doubt have, but if our efforts are rewarded with like success the prize will be well worth the labour. Not only are the Indian jute manufactures carried to the Colonies and foreign countries, but they are frequently even sent to Great Britian to the very fountain head from which their opposition came.

This seems to me almost like sending Indian tea to China.

Other speakers followed in the same strain, and Mr. Magor, the secretary, in tendering thanks for the confidence placed in himself and his colleagues, said :—

It is no idle boast to say that Indian tea is superior to that of China and Japan (cheers) and that consequently it only requires to become known to extend its consumption. To make it known is the end and aim of the Syndicate, and with this object in views, it must be obvious to all that the present opportunity should be availed of for keeping the market well supplied to meet all demands. Mr. Magor said you will have learnt from the Chairman that all tea which has been sent down has met with a ready sale and has gone into consumption, thus stimulating an inquiry which will give an impetus to the trade before leaving it to private enterprise to develop. With regard to America, it is a moot point whether we should endeavour to meet the public taste by an imitation of Japan teas, or make any alteration in our manufacture to suit their market. He was of opinion that our tea will have a better chance if it stands on its own merits (cheers.) They had no doubt about its quality—the only drawback is the prejudice that already exists in favour of a much inferior article. We must no forget, however, that Japan teas, which have now such a hold on the American taste are of comparatively recent introduction, and have had to make their way against the competition of the older China growth, in the same way as we shall have to compete with them. He did not under-rate the difficulties of overcoming these prejudices, and he did not anticipate that we shall command immediate success, but he was quite satisfied that, as the teas become known, they will make their way against all competition, and it may be our pleasing duty to elevate the taste (for tea) of a great nation like America (Loud cheers.)

NEW SUBSTITUTES FOR COFFEE.

(*Translated from the "Indische Mercuur."*)

In a German paper it is remarked that the leaves of the coffee tree are really better adapted for use than the coffee leaves themselves. They are specially rich in caffein and tanniu. According to a chemical analysis of Professer Henlouse the leaves of the Sumatra coffee contain 1·26 p. c. of caffein, besides tannin, but very little sugar and fat. The amount of soluble constituents is much greater in the coffee leaves than in the beans. As caffein and tannin are by far the most important constituents of coffee, the use of coffee leaves as a substitute has much to recommend it. The leaves should be simply dried—as is the case with tea leaves, and could be brought into the market in this condition The preparation of the dried leaves could be done in such a way that they could be roasted in the same manner as coffee, with the addition of about 10 p. c. of sugar, and be also made from the ground powder by means of boiling water. A coffee substitute, consisting of a mixture of roasted coffee leaves and roasted corn, can in a certain sense entirely take the place of coffee, as this mixture, in consequence of its containing caffein and aromatic products of roasting, which owe their origin to the tannin, approaches very closely to the composition of true coffee, whilst in the ordinary substitute a few traces is to be found of these substances. The history of coffee substitutes is more than ordinarily interesting: the first attempt at the manufacture dates from the second half of last century. In the year 1790 there were already in Magdeburg coffee substitute manufactories, which prepared the chicory root. This industry extended to such an extent that in 1840 there were already 11 coffee substitute manufactories with 2,500 workmen. What success has attended the manufacture of coffee substitutes in other countries may be judged from the fact that in France alone six million kilograms of chicory root are consumed, not to mention all the other materials from which coffee substitutes are manufactured to an equal extent. The continental theory of Napoleon I. gave a specially strong impetus to the manufacture of artificial coffee, as it did also to the manufacture of beetroot sugar and soda. From the narrative of travellers we know that coffee substitutes are used by other nations also. In Arabia a kind of coffee is prepared from the roasted seeds the so-called Durrah plant and sold under the name of Sudan coffee. Several negro races prepare other seeds in like manner, and the Tunguses even the seeds of a poisonous plant, viz. the henbane. In our August number (*I. M.* 1880) we spoke of several new European coffee substitutes, and we shall not therefore refer to these, except to say that they have none of the effects on the nervous system which true coffee produces. It therefore seemed not uninteresting to notice the use of roasted coffee leaves, as in these are found the substances (especially caffein) which exactly constitute the peculiarities and characteristics of coffee.

TEA AND SILK FARMING IN NEW ZEALAND.

Some six years ago we directed attention to the island of Ceylon as likely to become an important tea-producing country in the future, and to Australia as a vast field for sericiculture. Since then the strides taken by the former country in tea-growing and manipulation have been simply extraordinary. This will be admitted when we mention that at the late Melbourne Exhibition the tea-planters of Ceylon carried off 11 first awards out of a total of 49 bestowed, and altogether, they secured 36 honours for the 78 samples they exhibited, out of a total number of 270 awards earned by 506 samples shown by the various tea-producing countries. It is with a feeling of pleasure, therefore, that we congratulate our *protege* of 1875 on having taken so distinguished a position in the great Colonial gathering of 1880 and 1881. It is not our purpose at present to re-direct observation to the progress of the sister occupation in Australia, although we understand that silk culture there has been fairly successful; but rather to allude to an important proposal, having for its objects the farming of tea and silk as a twin industry in New Zealand, which is at present being discussed in this country.

Practical persons have for some years been studying the scheme in all its bearings, and are assured that the North Island possesses many of the necessary advantages, and that the province of Auckland offers nearly all of them. There the temperature rises to between 90° and 100° Fahr, nearly every summer, with occasional leaps to 110°; the mean of the coldest month is 51°, and that of the warmest 68°. Snow is seldom seen, except upon the mountain summits, and even slight frosts are a curiosity on account of their rare appearance or their evanescence. Moderate showers spread over 186 days of the year, fall annually to the extent of 47 inches; the hot blighting winds and dust storms of Asia, so devastating to vegetation and so baleful to the silkworm, are unknown; and the mulberry, ailanthus, castor-oil plant, and numerous semi-tropical shrubs and trees flourish profusely in the open air. For China and Japan tea these advantages promise the perfection of climate, and the rarity of frost favours the belief that the indigenous Assam shrub might also be successfully cultivated. We have used the guarded expression that Auckland offers nearly all the advantages desiderated for tea and silk farming, the exceptional circumstance being the want of cheap labour. Were it proposed to cultivate and prepare either product by itself, we should feel pretty well assured that in no sparsely

populated country, however suitable otherwise, could either tea-farming or sericiculture, conducted separately, pay. But, pursued together on the same estate, under the same general management by much the same staff of employes, the scheme assumes rather an inviting complexion. Indeed, if the economy likely to be effected by the efforts of a highly-trained staff, using every scientific and mechanical aid to produce two or more important and valuable commercial articles instead of only one, be appreciated; if we bear in mind the moderate price of land generally in New Zealand, and Auckland's homogeneous and equable climate, so favourable to abundant and varied crops; if we recollect how trifling must be the expense of inland carriage to a shipping port in a country no part of which much exceeds 100 miles from the sea, as compared with the serious outlay incurred for transport by the tea and silk of China and India to the coast; if we give due weight to these advantages, and then reflect upon the enormous local demand for at least one of the products, the belief seems most reasonable that the higher outlay for wages will probably be far more than counterbalanced by reduced expenditure in other directions.

Several objects actuate the promoters of this enterprise, and their proposals may be thus epitomised :— "It is proposed to establish a syndicate with adequate capital, under the title, probably, of 'the New Zealand Tea and Silk Company (Limited),' for the judicious employment of capital and labour at the Antipodes by the acquisition of an area of say 30,000 acres in Auckland, or elsewhere in New Zealand, to be used partly for the land settlement of special classes of immigrants, and partly for the inauguration and prosecution of sundry important industries, particularly those of tea growing and preparation, and sericulture, and, with the subsidiary design of offering agreeable and remunerative work to deserving females of education, who have been deprived through misfortune or fraud of their incomes, and of trying to improve the habits of the aboriginal population by engaging them in congenial employment whenever practicable." In explanation, we may say it is expected that one of the first results of the successful introduction of tea and silk farming as a combined industry into New Zealand would probably be a copious influx of immigrants more or less connected with the industries in question or with allied trades. For the accommodation of such, and in order that some immediate advantage might accrue to the syndicate, the acquisition of a much larger surrounding or adjoining acreage than would otherwise be necessary is proposed. It is suggested that portions of this reserve land should be sold, let, or used in the most profitable manner as the state of trade at the time might dictate, and on other parts selected farmers of ability and some means, with labourers and others of good character, should be settled. Food would thus be provided for the infant colony, and at the same time there would be a battalion of reliable assistants upon which to draw during any sudden crisis. In short, it is suggested that in addition to the functions of tea and silk farmers, the syndicate should assume those of a land settlement company.

The purely industrial feature of the scheme consists in the gradual plantation of an area of 3,000 acres with tea and mulberry shrubs at the rate of 100 acres or more of each per annum. Simultaneously with this work, other products, such as olives, grapes, oranges, lemons, small fruit, honey, sugar, &c., are intended to be reared, all of which, being usually considered more remunerative than even the most lucrative crops of the ordinary farmer, would soon furnish a material item in the income of the syndicate. During the time occupied by the tea and mulberry bushes in arriving at a yielding age—in the one case four years, if from seed, and in the other two years, if transplanted at five years old—the necessary buildings would be erected, the water services surveyed and arranged, water-wheels and other machinery constructed, and the general cultivation and improvement of the estate attended to and gradually increased. In the course of the second year the first silk harvest would probably be gathered, and the net returns, if all went well, might amount to £80 per acre for the yielding area of mulberries; a requital which, as far as the leaf crop alone is concerned, would probably be doubled after the bushes had been five years *in situ*. Until the fourth year there will be no appreciable income from the acreage under tea, and as this shrub has not yet been grown on a commercial scale in New Zealand, the promoters very properly think it better in the meantime not to hazard any opinion as to the probable return. But for the reasons already given, united to the circumstance that the present large local consumption of 1,500,000 lb. a year would render any export of the product for some years unnecessary, thereby effecting a saving if freight, commissions, and dock charges, they look nor a very gratifying result from this source also.

To the philanthropic the intention of employing educated female labour in the more delicate manipulations is an appeal which has only to be known to meet with a hearty response. The successful employment of Maori workers, where practicable, would also be a philanthropic object well worthy a trial. But apart from this interesting, although subsidiary, feature of the proposed undertaking, we think it may be said to contain the elements of success, and it deserves the careful consideration of those who are anxious for the development of our Colonies. Further information may be had of Mr. William Cochran, of Overdale House, Dunblane, Perthshire, N. B., who is at present performing the duties of interim secretary.—*British Trade Journal.*

JAMAICA.

JAMAICA, one of the oldest of British Colonies, and next to Ceylon, the finest and most valuable of the tropical islands possessed by England, has for many years past suffered under much neglect and undeserved depreciation. Although the favourite seat and exercise-ground of British philanthropy, it has never attracted the attention it deserves as a field of colonisation and of British industry. Its manifold and unparalleled resources have remained almost unexplored, and its riches left to nature and the "irrepressible nigger." No Colony has paid so dearly for the luxury to which England treated herself some fifty years ago in the abolition of slavery, and none has been so slow to recover from the sacrifice which the nation then offered to humanity. For many years past Jamaica has been the Cinderella of the British family—the despised and abused sister, whose case has been given over as almost hopeless, and whom Government and the public alike have tacitly agreed to hand over to the emancipated Africans as their peculiar heritage.

From such a destiny, from lapsing into a second Hayti, there seems at length to be some small prospect of rescuing this beautiful and interesting island; a possession more valuable to England, if she knew it, than a dozen Cyprus'es. The wonder is that a Colony like this, with its many singular advantages, its wealth of natural products, and its commanding geographical position, should have been so long ignored by the restless spirit of British enterprise. As a field for such industries as are suitable to a tropical land, it may be safely affirmed that there is no portion of the earth which deserves so much attention as Jamaica.

Unlike any other of the West India Islands, it offers to European settlers a temperate climate of singular fineness and salubrity among the mountains, while its plains teem with all the treasures of the tropics. It thus combines the resources and the advantages of several distinct zones. There is nothing which is grown in any tropical country which may not be produced in the greatest luxuriance in Jamaica. There are many fruits and flowers peculiar to temperate climates which are produced in Jamaica alone of all tropical countries. While the sugar-cane, the pimento tree and the mango flourish in the low country, English flowers and fruits delight the dwellers in the Santa Cruz mountains. From Kingston to Newcastle is a pleasant ride of two hours, but in those two hours you pass from a temperature of 90° in the shade to one of 60°—from palms and bananas to furze and pine. The excellent "Handbook" recently published under the auspices of the Jamaica Government will enable the public to form some idea of the extraordinary riches which nature has showered with bountiful hand on the island. Sugar, coffee, tobacco, rum, pimento, and fruits are at present the chief articles of export, but they are not produced in anything like the quantity which the island is capable of yielding under vigorous and enlightened cultivation. A great many articles, the growth of which is recently attempted, may be added to the number of the island's products. The cinchona plantations are found to be well suited to Jamaica and are beginning to give profitable returns. Cocoa or cacao, as well as the cocoa-nut, may be grown as easily as in Trinidad or in Honduras—the more sheltered valleys of the interior being admirably adapted for the former, while nothing can exceed in luxuriance and healthiness the cocoa-palms on the north coast. The breeding of cattle for export is already one of the most lucrative of occupations, while the climate has been found to be singularly favourable, for a tropical one, for horses. The mineral wealth of the island has scarcely yet been tested, but Jamaica is known to be rich in copper, cobalt and lead. The fish on the coasts, as well as in the numerous fresh-water streams in the interior —an uncommon feature in a tropical island—are most abundant and in great variety, though the creoles and the negroes have the bad taste to prefer, as elsewhere in the West Indies, the imported salt cod from Newfoundland to the produce of their own native shores.

Amidst such an abundance of good gifts, it may surprise us to discover a reason why Jamaica has not advanced more rapidly in the development of her resources. There is a reason, however, which those who have any knowledge of the island will be at no loss to name. The island has not prospered—is not prospering, by reason simply of the diminution of its labouring population. It never will prosper so long as its improvement depends upon indigenous industry. Its very fertility and salubrity are fatal to all progress, if that progress is subject to such influences as those which have hitherto retarded the prosperity of Jamaica.—*The Colonies and India.*

CEARÁ AND PARÁ RUBBER SEED.—Mr. A. Scott Blackadder writes from Dollar, Scotland:—"You will see by my advertisement that I have made arrangements for getting seeds from Pará and Ceará in any quantity. I fear, however, the Pará rubber cannot be raised in Ceylon, from seeds brought from Brazil. They say in Pará that, if the seeds are longer than 3 months in a *dry* place, they will not germinate. I have no doubt of the Ceará seeds growing, if sent to Ceylon, in tins, dried from Ceará. A few bags of Ceará rubber seeds came to Liverpool, in the same steamer in which I was a passenger. I fear they will be of little use, as they were loose in bags, and of last year's picking."

110

A LEDGERIANA CINCHONA tree four years old on Warwick estate, New Galway, is now in flower, and Dr. Trimen has seen the blossom and pronounced the tree a true 'Ledger.' There are a good many more trees and plants very much the same on this property, but of course they have yet to be verified.

A NEW FIELD FOR ARABIAN COFFEE.—A correspondent of the Calcutta *Englishman*, signing "Planter," writes, as follows, of the prospects of Arabian coffee in Bengal:—This plant (Arabian coffee) thrives well and fruits abundantly in Bengal. The Agricultural and Horticultural Society of India at Alipore have some specimen plants in full bearing, the branches are bending with their load, and from a calculation made by me, I am prepared to satisfy any enquirer that no more profitable industry than this can be undertaken in Bengal. The return in profit is said to be enormous to any person who will go into it.

GOLD, GEMMING AND PLUMBAGO IN THE WESTERN PROVINCE.—The discovery of precious stones in new districts has led to increased activity in their search, and has afforded employment, and a precarious means of living to a large number of natives both in the Ratnapura and Kalutara District. The law regarding the rights of the Crown and the proper means to be adopted to stop gemming on Crown lands has for a long time been in an unsettled state. I am happy, however, to be able to say that at last a partial remedy has been discovered by criminal prosecution under the 19th clause of the Ordinance 6 of 1846, relating to malicious injuries to property, and the wholesale depredations which were committed, by persons, not stealthily but in gangs of several hundreds, have now been checked. There is, however, no doubt that a special Ordinance is necessary, embodying the provisions of the Proclamation by Sir Edward Barnes dated 9th December, 1826. Sir R. Morgan stated in Council in 1872 that this Proclamation had still the force of law and was a very useful measure, but it has been found impossible to give effect to it; and as I believe that almost the only printed copy extant is in my possession, I shall be glad if greater publicity can be given to it by printing it as an appendix to this report. (*Vide* B.) The discovery of gold in the neighbouring continent of India has re-opened discussion of the question whether gold in appreciable quantities exists in Ceylon. For my own part, I have little doubt that it does so exist in the Sabaragamuwa District of the Western Province. In 1869, when stationed at Ratnapura, I collected some gold from the stream which ran through the Government premises, and forwarded it through Sir Charles Layard to Mr. Brough Smyth. That gentleman, whose opinion is authoritative, stated that the small pieces of gold were real "nuggets," and had not travelled far and that he had no doubt a careful search or prospect in the neighbourhood would be repaid. When visiting Ratnapura in the early part of this year, I procured some more gold collected from the same spot, and sent it through Mr. W. Ferguson to Mr. MacDonald Cameron, and the report of that gentleman was equally favourable. The attention of Government, I believe, has been already called to the necessity for framing rules to regulate and define the rights of private persons to gold found on private or on Crown lands, and it is not necessary therefore to say more on this subject. The Government has been successful in a suit taken before the Privy Council in appeal from the Supreme Court of Ceylon for the recovery of a valuable piece of land containing plumbago at Pelpitagoda in the Kalutara district, and, as before stated, 75 tons of this land have been sold for 35,851 rupees, an average rate of 968 rupees per acre. This would seem to show that the plumbago is of superior quality.—*Mr. Saunders' Report for* 1880.

TEA.—Nearly all the local tea Companies in Assam have declared, or are about to declare, an *ad interim* dividend. A Darjeeling correspondent remarks that "this is a satisfactory contrast to the state of tea in this district at the same period of last year. At that time it was almost morally certain that very few concerns would do more then pay their way until the manufacturing season came round again. This year, it must indeed be a badly managed concern, which, unless it is very handicapped by having to pay heavy interest on borrowed money, or by other exceptional circumstances, which ought not to give a very handsome return on the season's expenditure."—*Madras Mail.*

JOHORE.—A correspondent writes :—"As some of your readers may feel interested in Johore, the enclosed letter has a passage or two which you may care to publish for their benefit :—'I was pretty well disgusted with Johore at first. I got such fever, nearly finished me up twice. A newcomer from Ceylon says, he had Wellawaya fever and all other fevers in Ceylon, but be never felt anything to come near the severity of Johore. Liberian coffee does first-class in the lowcountry. Cocoa is being tried with apparent success. Tea is also promising. You may have seen about some samples sold in London, at a high figure. All that is nice enough, but what 's the good of it when we have not a plentiful supply of labour over which we can have complete control ? So you see, the burden of my letter is an indefinite supply of labour.'"

THE GOLDFIELDS OF INDIA.—Mr Samuel Jennings is the secretary to the South Indian and Glenrock Gold-Mining Companies, and naturally, in some respects, his book assumes the shape of a eulogy of those particular undertakings. After observing that the direction of a reef is ascertained by tracing the line of outcrops on the surface, and its dip only by driving levels to intersect it at depth, he adds, "In fact, no so-called reef can be properly said to have been proved until such levels have been driven, or shafts sunk upon it." Further on, he remarks upon the deceptive nature of quartz surface boulders, which, instead of leading to true reefs, prove on examination to be no other than mere boulder rocks "carried to their present position by some tremendous convulsion of nature; and subsequently and by degrees partly buried in the earth." Mr. Jennings leaves his readers to infer how many companies may be working upon barren soil. From first to last he bears out our expressed opinion that gold does exist in India in workable quantities, and that a few fortunate companies in the best selected districts will reap considerable profits, while the majority will fail. Several of those promoted in England, we are aware, had but one initial intention—to sell worthless land at a fabulous price. It may happen, however, that the victimised shareholders may compel the vultures to disgorge. "Free gold," about the existence and discovery of which every prospectus is full "is but seldom met with." This assertion will not encourage investors, more especially when his further observations upon the conditions under which it is occasionally found are also read. Again, investors will do well to remember that assays, "can never be relied upon to indicate with any certainty *how much* profit may be calculated upon." But perhaps the most important lines in the book are those which exhibit the superhuman difficulties to be overcome ere Indian gold-mining will be fairly upon its legs. Judging from the remarks about labour, roads, railways, communication, and other obstacles to be conquered, some years may elapse before twenty shillings' worth of gold may be brought to the coast at a less expenditure. Of course some plots will prove richer than others; but, for the time being, shareholders as a body must hope for no return.—*Overland Mail.*

THE FOOD of the blue-bird, for instance, according to the *Journal of Science*, consists of 90 per cent. of insects and only 10 per cent. vegetable matter; whereas that of the sparrow consists of only 6 per cent of insects, the rest being fruit or grain.—*South Australian Register.*

PLANTING IN BORNEO.—Mr. Loyalty Peake writing from Matang, Sarawak, on the 2nd instant, gives the following news of his pioneering work in the Far East:—"I am still working away at cinchona nurseries, and hope to get the clearing burnt off this week. We shall shortly be forming a Cinchona Company here, with 1,000 shares at 100 dollars each. It will pay well with land and felling so very cheap. The Borneo Company will shortly commence gold crushing on a large scale. The Chinese have been making it pay for years. I spent a very pleasant fortnight over at Johore last month and had a good look at everything. I have managed to get hold of a few Tamils here, but they are not a good sample : Chinese are much better workers, but you must give them contract work to make it pay."

TEA.—Dr. Aitkin observes:—"The introduction of tea, as the beverage of a man of letters, is a curious circumstance in dietetical history. I cannot but regard it as a very valuable discovery, and I think the literary tribe are much indebted to those who contribute to familiarise them with the 'cups that cheer but not inebriate.' I scarcely ever knew a person fond of study who was not also fond of tea, unless he had contracted a relish for less innocent refreshment. It is not my purpose here to enter into a medical discussion of the qualities of this herb ; but, from experience, I can affirm that unless taken too strong, or of too high a quality, its effects are perfectly salutary, and peculiarly favourably to sedentary habits."—*Home paper.*

TAMBRACHERRY ESTATES AND WYNAAD GOLD MINING COMPANY.—The directors of this company, in a circular just issued, state that after mature consideration they are resolved to consider the sum of £20,000 in the light of profit on the sale of the portion of land disposed of to the Cootacovil Gold Mining Company (Limited). Out of this sum they recommend the shareholders to declare a dividend of 10 per cent., which will absorb £16,000, and to appropriate the remainder to cover preliminary expenses in England and India. The directors, after taking the best legal advice, find they are precluded from carrying out their original intention of returning a portion of the proceeds of the above land in the shape of capital, and no other course appears to be open to them excepting that proposed, without bringing the company under the act as "limited and reduced," which is undesirable.—*Overland Mail.*

CEYLON BEES.—The bee is undoubtedly a wonderful insect; but Ceylon claims to possess, in the *Apis dorsata*, the "most wonderful bee in the world." This insect is known among the Sinhalese as the Bambara, a name which is curiously suggestive of the familiar title given to the wild bee of this country ; and its nests are hunted for by the natives in the thick jungles of the island, where, however, no attempt is made to domesticate it. An enthusiastic American apiarist, Mr. F. Benton, has succeeded in taking captive two or three colonies of this bee, which he hopes to take to America. In his search in the forest, attended by a party of bee-hunters, he astonished the natives by the manner in which he handled whole swarms of the insect, before a single irritated specimen of which a Sinhalese honey-collector has been known to flee for miles : for the Bambara is so savage that a strategic movement to the rear is advisable when a swarm, or even a single individual, is ruffled by improper handling, though escape from its sting is hardly possible. If the bee deserves the encomiums which Mr. Benton bestows upon it, it will no doubt receive fuller recognition than has hitherto been accorded to it.—*Colonies and India.*

Trinidad.—The condition of the newly-opened line of railway to Couva was described as exceeding unpleasant, owing to the uneven subsidence of the earth-work, which has not as yet had time to settle down. The *Port of Spain Gazette* said that the sleepers of American cypress were already showing signs of decay, and even now wanted relaying.—*The Colonies and India.*

An Enemy of Liberian Coffee?—A correspondent in Pussellawa writes :—"I am sending you, by this post, a poochie, which I shall thank you to tell me the name of. I found it about three weeks ago on the stem of a Liberian coffee tree in its cocoon, out of which it came this morning." The "poochie" is a moth, *Suana cervina*, belonging to the family Bombycidæ. It is an enormous female with her wings not fully developed, and her body greatly distended with eggs. The silkworm is also a member of the same family.

Extirpation of the Prickly-pear.—Government are anxious to extirpate the prickly pear; yet it is frequently planted as a hedge by the ryots. The Collector of the Chingleput District has notified that, if the ryots wish to avoid having to spend their time or money in removing this nuisance, they should endeavour to meet the wishes of Government. The village officers and leading ryots should themselves use for fences the plant called *Kiloovay Mooloo* or *Korookapully* instead of the prickly pear, and advise others to do so. Both these plants grow quickly, and the latter answers the purpose of fuel.—*Madras Mail.*

How To Detect Unwholesome Tea.—A correspondent writes :—"Tea drinkers now-a-days will do well to apply the following simple test to the tea purchased of their grocers. Turn out the infused leaves, and if any are found a good brown colour, with fair substance, the tea will be wholesome, but if the leaves are black and of a rotten texture, with an oily appearance, the tea will not be fit to drink. The purer the tea the more the distinctively brown colour of the leaf strikes the attention. I am sorry to say that the mixing that is frequently adoped by the trade to reduce prices results in the two kinds of leaves being supplied together. I need hardly add that it is important to see that the leaves have the serrated or saw like edges without which no tea is genuine."—*Trinidad Chronicle.*

Ceylon Direct Supply Agency.—We have received a circular which informs us that this agency, whose office is at 10, Cullum Street, Fenchurch Street, London, has been established for the purpose of supplying the public with tea (and other Ceylon produce) direct from the plantation in Ceylon. The C. D. S. A. teas are packed in 1 lb. foil bags, and the superior qualities in ½ lb. and ¼ lb. samples as well, each quality being distinguished by a coloured label. These teas are also packed in useful hinged lid tins of 5 lb. and upwards, or may be had in original half or quarter-chests of 38 and 20 lb. We wish all success to this agency, the manager of which is Mr. J. D. Van der Straaten.

Ceylon Tea in Sydney.—Mr. A. M. Cameron writes from Sydney, under date 7th Sept., as follows:—"I hope something will be done in the way of trying Ceylon tea in these pound and half pound packets here; but it must be of the *best* quality. There has been so much inferior—*very* inferior—Indian teas sent to these parts, that, while it is surely depreciating all Indian tea in the market, there is a good chance of the success of Ceylon tea. But, as I have said, it must be of very good quality. In my opinion, it will be a mistake to get the people here to confound Ceylon with Indian teas in general. Ceylon tea, for its own sake, ought to be kept distinct. I am willing to do what I can to sell it here, by auction, or otherwise, if I am favored with any consignments; but, as I have said, it must be good stuff, such as I can recommend to the best houses and residents here."

Wallaha, September 28th.—A revolution in cinchona : No such thing as hybrids!—at least, so says authority. Dr. Trimen and Col. Beddome paid a visit to this district, and have declared all supposed hybrids to be distinct species, by name Pata de Gallinaryo. They only visited one estate, Eildon Hall. Their visit seems to have been kept a profound secret (more's the pity, as other estates could have shown several different kinds).

South Coorg, 23rd Sept.—South Coorg has a worthy representative of the same family as your "Kumbuk tree" viz., the "Terminalia Coriacea," the Mutti Mara of the Canarese, and Kara Maradoo of the Tamils. On the Titty mutty, it is the principal forest tree and grows to an immense size, planks 3 feet wide all hard wood being readily obtained. The koorambers use it when burnt in place of chunam along with their betel. It also in some cases affords them a supply of water, slightly bitter and astringent, but most acceptable when no other can be got. The timber is entered as first class by the engineers in our D. P. W. The wood is beautifully veined and when worked up is almost equal to walnut, and I believe some of it has been sold in London as Indian walnut. For doors or windows it is not much used, as it contracts very much in the dry weather. At present it is loaded with seed but they are not ripe. Divi Divi (Cæsalpinia coriaria) grows splendidly at Hoonsoor, but unfortunately nothing will grow under it. I believe a shipment of the dried pods was sent home, but a second not having followed I fear the price was not satisfactory. I am glad to see that the merits of the *Coorg* coffee is being recognised by planters out of Coorg and Munzerabad, and I have no doubt that Ceylon planters would much benefit by the trial of a few bushels of guaranteed Nalkenaad tree seed, and that once tried there would be a regular demand for the same. To make sure of having seed that can be depended on as being true to the kind, it is requisite (in my opinion) to give an order a full year beforehand, so that the trees may be selected in December or January, and marked with pieces of tin attached by wire to the stem. When marked, the ground must be carefully manured and dug up for 2½ feet round the stems and then thatched with hill or swamp grass all over the dug space, and to a depth of from 4 to 6 inches. When the blossom buds are sufficiently forward, the trees should then be well watered so as to bring the blossom out, and the watering kept up as required till the spring showers. If any trees adjoining those marked show any symptoms of having benefited from the water their blossom buds must be rubbed off before bursting so that there can be no chance of hybridization from those inferior trees. When the crop is ripe, equal care must be taken that none but the cherry from the marked trees is picked, and to ensure this the superintendent must see every tree done and remain with the coolies the whole time they are at this work. When pulped the beans should be mixed with dry ashes or powdered charcoal and then spread a bean thick on coir or date mats in one cool airy store which can be locked, and there remain till it is required for the nursery, or till packed and sealed for transport. Plants raised from a December seed nursery will be from six to eight inches high by the end of June, and just what is required for ball planting. In proof of the superiority of Nalkenaad plants over all others, I have only to name the Watta cooly estate Samphaji, where the only trees of the 1858-59 planting now left are a few that were brought by a Coorg planter as a sample of what he had for sale. The Ghauts once the very centre of coffeedom in Coorg are now on the wane, no one caring to open there, the bamboo having so many advantages, chief of which are climate and soil alike suited for coffee and cinchona.—An Old Bamboo.

THE INDIARUBBER INDUSTRY in Mozambique seems to be developing rapidly. In 1873 only £443 worth of India-rubber passed through the Custom House. In 1876 it reached the value of £22,198, and last year, according to figures given by Mr. Cousul O'Neill, it exceeded £50,000. It would seem, however, to have reached its climax until communications with the interior are properly opened up, the careless cutting of the trees by the natives having resulted in the destruction of enormous tracts of india-rubber forest. —*Echo.*

COOLIES IN JAMAICA.—Some 400 coolies, adults and children left by the ship "Syria," Captain Blaker, for Calcutta on Monday last. We learn that some £6,000 were taken away in Bills, and nearly as much in gold coins, and a considerable quantity of jewellery. From the Government Savings Bank three men withdrew the sum of £1,200, and several others took little fortunes in the shape of gold coins as well as Bills. Truly the West Indies are lands more propitious of blessings to the East Indian foreigner than to their own sons. Jamaica is a land dropping with milk and honey for the coolie labourer.—*Gall's News Letter.*

AN AGRICULTURAL DEPARTMENT IN JAPAN.—The institution of an Agricultural Department by the Japanese Government is announced. The matters submitted to it for consideration by the assembly of local officials charged with the development of agriculture in their respective provinces are reported to be—(1) revision of the methods employed in preparing agricultural statistics; (2) exchange of seeds between the different prefectures, and their transport; (3) supply of manure; (4) establishment of a society for investigating fishery affairs, and the protection of marine productions, fish, seaweeds, &c.; (5) subject of rewards granted for meritorious services calculated to improve agriculture.—*London Times.*

WYNAAD PLANTING AND MINING ASSOCIATION.—At a committee meeting held on the 14th September, a communication from the Government of Madras and Collector of Malabar was read, the order from the Madras Government being as follows:—"As recommended by the District Officers of Malabar, the Governor in Council resolves to sanction the extension of the Coffee Stealing Act to the low land tracts traversed by the coffee in transit to the coast. The Government, however, consider that it will be sufficient to apply the act in the main roads from Wynaad to the coast. The Collector will accordingly report, at an early date, if this is not enough; and what roads should be specified in the notification." This was recorded with great satisfaction, and it was resolved that the Honorary Secretary address the Collector of Malabar praying that the act may be extended throughout the whole of the district and that a recognised form of pass be made obligatory; the said form to bear a revenue stamp of one anna and to be procurable at all Cutcheries and Post Offices. The rest of the business related to telegraphic communication, repair of roads used by the gold-mining companies, and sale of arrack. It was resolved that the annual meeting should be held on 5th Oct.

DATE COFFEE.—We see the Ceylon planters are beginning to cry out against the so-called Date Coffee, and no wonder; but if people prefer ground Date stones to ground Coffee seeds, as they say they do, we do not see that Government can interfere further than to insist upon things being called by their right names. Date stones, as we believe, contain not an atom of the peculiar alkaloid on which the value of Coffee as food depends. One enthusiast—or is he a wag?—fired by the success of the Date Coffee, proposes to grind the Orange pips, which are as plentiful as Blackberries in Spain, into "Orange Pekoe"! —*Gardeners' Chronicle.*

PALM SUGAR.—It is not to be supposed that the price of coconut oil will always remain as low as it is at present, and we hope and believe that there will soon be an improvement, but as a similar depression in the oil trade may at any time happen again, it might be worth while to try if part of the produce of the coconut tree cannot be profitably converted into sugar. Perhaps it would not pay, but the same thing used to be said about beet root sugar, and yet the beet root is now largely cultivated in France for the purpose of sugar making. It is not, therefore, unlikely that if as much attention were given to the manufacture of palm sugar as has been given to that of beet sugar, similar success might be attained. Indeed it used to be said that sugar could never be profitably made in this country from the cane, and yet it has been done, and still continues to be done at Baddegama, near Galle. In the Kalutara district, coconut trees are grown more for toddy than for nuts. Most of this is used for making arrack, and some for conversion into vinegar, but a considerable quantity of it is made into jaggery, which is the only kind of sugar in common use among the poorer classes in this country. The farms in France are generally of small size, and the French farmers have not much capital, but they do manage to grow beet root and make sugar of it by having sugar factories conducted on the co-operative system. Considerable quantities of palmyra jaggery are sometimes exported from the Madras Presidency to England for making refined sugar, and we do not see why cannot jaggery—and kitool and palmyra jaggery too for that matter—should not be exported from Ceylon for the same purpose. Most of the sugar now consumed is made from the cane, but palm sugar is probably of more ancient use than any other kind.—*C. Messenger.*

GOLD ON THE NILGIRIS.—Assays of Nilgiri quartz quartz were made by Mr. F. Claudet, Assayer to the Bank of England.

	ozs.	dwts.	grs.		
The best result was..	2	12	12	gold.	per ton of quartz
and...	1	12	0	silver.	
The worst result was...		10		gold.	
...		9		silver.	

The other three assays were made by Messrs. Johnson Matthey & Co., Assayers to the Bank of England, and H. M. Mint:—

	ozs.	dwts.		
The best result was...	3	5	gold.	per ton of quartz
do. ...	1	10	silver.	
The worst result was...	0·250		gold.	
do. ...	0·100		silver.	

Mr. C. Harvey saw some of the quartz from these hills in England, and said that it was some of the best stone he had seen from India. I have been shewn the results of panning pounded quartz, and of sand in the rivers, near these reefs, and also in one case of the surface soil, on a very reefy looking bit, contiguous to a reef; and the results, judging from what I have seen in other places, were simply splendid in every instance. I have also been shewn several very fine specimens of gold that were taken from these hill reefs. With the immense natural advantages that there are on these hills, in point of climate, water, position, and local labor, it is a wonder that the investing public have not been induced to turn their attention to these parts, or that our wealthy Australian cousins have not paid us a visit. When once this new industry is started up here,—and surely some one will be enterprizing enough to try it soon, however slow they may be in getting results in the Wynaad,—it will give a tremendous impetus to every branch of work up here, and it would not be long before we had the train running up to Coonoor, with or without the help of Government.—*Cor. Madras Mail.*

HORTICULTURE.

(*Asian.*)

Celery (*Apium graveolens*).

Few vegetables are more benefited by good culture than the above. If it receives any check during its entire growth, the result is that it either becomes tasteless or stringy, or bolts, and not unfrequently both. The first sowing should be made in pans in July; the seed at this period will, however, frequently take from five to six weeks to germinate. As soon as the plants are large enough to handle, they should be transplanted to a nursery bed, where they may remain till large enough to be planted in the trenches. They must, however, be carefully protected with mats during the continuance of heavy rains; the main sowing should be made in the open ground by the first week of September. The seed at this time will germinate more quickly, and the plants will not be more than ten days or a fortnight behind the first sowing. When the plants are five to six inches in height, trenches must be prepared to finally plant them into. The trenches should be from nine to twelve inches deep, and about fifteen inches wide, the soil from which should be placed evenly on each side; then add four or five inches of thoroughly decomposed rich manure. This must be well dug in and thoroughly incorporated with the soil. The plants may then be planted at once. Care should be taken in taking up the young plants from the nursery beds not to injure the roots in any way; they should therefore be removed with as much soil adhering to them as possible. The principal attention they will require for the next two months will be to supply them with water and rich liquid manure as frequently as it is possible to do so. Earthing up should not be commenced until the plants have attained a height of at least 18 inches. A dry day should be selected for the operation. Before commencing, all the small lower leaves and any side shoots they may have formed should be carefully removed; then proceed by cutting down a portion of the soil on each side of the trench. Break this up finely and place the soil round the base of each plant with the right hand, which should be held in position by the other. Do not press the soil too firmly around the heart, and avoid letting pieces of the soil fall inside the plants, otherwise in all probability they will grow crooked. The market gardeners who supply the Calcutta bazars adopt another method for blanching the plants, which is to mould up the plants in the ordinary way to a height of about four inches only, and as soon as the plants have reached maturity, tie up the remainder of the stem in a plantain leaf. Another plan, and one which on account of its simplicity will certainly recommend itself to public favor, is to place ordinary drainage pipes, about 15 inches in length and four or five inches diameter, over each plant as soon as it has made its full growth. By either of these systems the heads will blanch more quickly than by the old plan of earthing up, but they invariably lack that sweet, nutty flavour which should be present in all good celery.

The best varieties in cultivation are:—

White Varieties.	*Red Varieties.*
Sandringham Dwarf White.	Wright's Grove Red.
Wright's Grove White.	Cole's Defiance Red.
Cole's Superb Crystal White.	Manchester Prize Pink.
Seymour's Superb.	Sulham Prize Pink.

Capsicum (*Capsicum.*)

The ordinary varieties of the capsicum are so well known and so extensively cultivated in this country that they hardly need be mentioned here; for, no matter how small a garden may be, and possibly without another vegetable in it, wherever a native *mālee* is employed two plants are certain to be found there—these are the common chili and tooloe (*Ocimum sanctum*), a plant held in great reverence by the Hindus.

There are, however, several new varieties introduced during the past few years which are deserving of a place in every garden—not for the value of their produce, but rather for the extremely ornamental character of the plant. The best of these are: "Monstreuse," "Prince of Wales," and "Princess of Wales;" the former has enormous fruits, frequently four inches long and six inches in diameter. Any of these are easily raised from seed sown in October in light, rich, sandy soil. As soon as large enough they should be planted singly in pots filled with a light rich soil well enriched with old manure or leaf mould. As soon as established they should be placed in a position where they are fully exposed to the sun throughout the day.

Cardoon (*Cynara cardunculus*).

A plant closely allied to the artichoke and much resembling it in its foliage. It is extensively cultivated on the Continent, but is but little known in England, and is but rarely, if ever, seen in India. Firminger thus describes the method of growing it:—"The seeds are sown at the same time and in the same manner as those of the artichoke. When the young plants are about nine inches high, they are put out at a distance of three feet apart in ground that has been well enriched with manure; they are then treated in the same way as celery. When the vegetable has become blanched by being earthed up, it is ready for use, and is taken up and stewed like "sea kale."

The Carrot (*Daucus carota*).

This vegetable requires a deep, rich, light, sandy soil, and one that has been heavily manured; the season previously suits it best. In preparing the ground for them it should be trenched to a depth of two feet for long varieties, and about twelve inches for the short kinds. Care must be taken that the soil is carefully broken up and pulverised finely. If the soil has been liberally manured for the previous crop, and the soil moderately rich, no fresh dressing should be given, as fresh manure has a tendency to cause the roots to become forked. When, however, the soil is poor, a liberal supply of very old leaf mould or cow manure should be added. This must be placed about six inches below the surface, as it will then have the effect of drawing the young roots downwards. To promote a vigorous youthful growth, and enable the young plants to grow freely, some recommend that the drills be drawn deep enough to allow of a small quantity of well-rotted manure being placed at the bottom, and after covering this with a little fine soil the seed should be sown.

The first sowing of the horn varieties may be made on a raised bed early in September, and successional sowings every ten days thereafter. Sowings of the long kinds should be commenced in October, to induce the seed to germinate quickly. Before sowing it should be steeped in water for six or eight hours; it must then be thoroughly mixed with ashes or dry sand, and sown in drills nine inches apart for the small kinds, and twelve inches for the larger sorts. As soon as the plants are three or four inches high, they should be thinned out to a distance of six inches between them. The crop must be kept clear of weeds, and the soil frequently stirred around the roots; they must also be kept liberally supplied with water during the whole period of their growth.

As soon as they have attained maturity, they should be carefully taken up without damaging the roots, and after cutting off the tops to within an inch of the crown, and allowed to dry in the sun for two or three days, should then be stored in dry earth or sand for future use.

Cress (*Lepidium Sativum*).

In the open ground sowings cannot be made safely till the expiration of the rains in October. A small quantity of seed should be sown at short intervals to keep up a regular supply. By adopting, however, the process usually employed in England for forcing it,

we may have it in season all the year round. The seed should be sown in pans or boxes filled with a very rich soil; after being well watered the seed should be scattered thickly over its surface. It must be covered with a pane of glass till the seed germinates. If kept in a shady position it will grow quickly and be ready for use in from ten to twelve days from the time of sowing. Cultivated in this way it is much more delicate in flavour than that grown in the open ground.

AMERICAN CRESS (*Barbarca præcox*).

This is easily grown in any damp, shady situation in a good sandy soil, sown at the same time as the ordinary cress. In flavour it somewhat resembles the water cress, but is decidedly inferior to it, so that when conveniencies exist for growing the latter, this may certainly be dispensed with in a garden.

WATER CRESS (*Nasturtium officinale*).

This, although naturally a perennial, can only be successfully cultivated as an annual in this country. The situation best adapted to it is a water-course or drain where there is a regular stream of clear running water. This is, however, next to impossible to obtain here during the cold season. The method therefore generally adopted is to sow the seed in gumlahs, the soil in which must be kept constantly moist. As soon as the plants are two inches high, they should be transplanted closely into other pans three-fourths filled with a compost made of equal parts of sand, coarsely broken brick and leaf mould. These should be placed at the edge of a tank, the top of the pans being kept on a level with the surface of the water. Of course as the water sinks in the tank it will be necessary to have the pans occasionally lowered. Another plan which I have seen successfully tried on several occasions, and which possesses many advantages in its favour, is to construct a small raft or frame of any common jungle wood. On this securely fasten a tray or box, about six inches in depth, of any size that may be required. This should be filled to within two inches of the top with the same compost as recommended for culture in pans, and the plants transplanted into it in the same way. The only precaution necessary is to see when the apparatus is complete, that is so balanced as to keep the surface of the soil slightly below the water level. It may then be moored at the side of the tank or allowed to float about, when, if properly made, forms a pretty ornament. The great advantage of this is that after the plants are once established, they require no further attention. Where a tank is not available, they may also be grown in pans sunk in the open ground. Great care must, however, be taken to keep the soil in them constantly covered with water, and which, to produce a good crop, must be changed daily.

CUCUMBER (*Cucumis sativus*).

All attempts to cultivate the many splendid English frame varieties of this delicious vegetable in this country have, I believe, invariably proved fruitless. Whether it is owing to any peculiarity of the soil or atmosphere remains to be proved. Firminger seems of opinion that it is principally owing to the ravages of a kind of beetle with which they frequently become infested, but this certainly is not the only cause, for even if plants are grown under glass, and carefully protected from every insect, the result is the same. The seeds germinate freely enough, and the plants grow vigorously till they have formed five or six leaves; they then, from some unaccountable cause, obstinately refuse to proceed further, and gradually dwindle away. Strange to say all the varieties of English melons, vegetable marrows, and in fact nearly all the members of the *Cucumis* or *Cucurbita* family, when grown from imported seed fail in the same way.

There are, however, two varieties of cucumber indigenous to this country. These, although considerably inferior in quality to the English varieties mentioned above, are still, when well grown, quite equal to those grown in the open air at home. They may be grown at almost all seasons of the year, and require but little attention, provided they are planted in good rich soil, and have a trellis or tree on which to climb fully exposed to the sun. They should be cut for use when very young, as, if allowed to reach their full size, they generally become tough and tasteless.

ENDIVE (*Cichorium endivia*).

This is not a very popular vegetable, although it is certainly deserving of more attention than has been bestowed on it in this country. The curled varieties especially are particularly useful, being greatly appreciated by many when cooked in the same way as other green crops, or when well blanched, it makes a salad almost equal to the best lettuce. The seed may be sown from August to December. For an early supply the first sowing should be made in pans, and as soon as the plants are two inches high, they must then be transplanted into beds of rich soil, to which a liberal dressing of very old manure has been added. They should be placed at a distance of twelve inches apart in the rows. As soon as they have made their full growth, they should be closely tied up to blanch in the same manner as lettuces. Some recommend that the plants after being tied up should be covered with a flower pot to induce them to blanch quickly, provided they are properly looked after. Undoubtedly this is the quickest and most certain method of blanching, but if they are at all neglected, and the pots not removed daily and carefully tried, the consequence is that the plants invariably decay.

INDIAN CORN (*Zea mays*).

This plant is so well known to every native gardener that it is hardly necessary to mention anything regarding its cultivation here. The sorts generally found in our gardens are the small seeded varieties so extensively grown as a field crop in almost every part of India. These are, however, very inferior both in point of size and quality to the many splendid varieties imported from America; these, whenever procurable, should be grown in prefereuce to any other.

The best time for sowing is at the commencement of June, before the rains set in, but successional sowings may be made till September, although the produce will be inferior to that of the first sowing. Firminger recommends that the seed should be sown in rows twelve inches apart, and the grains eight inches in the rows. From my own experience I should say the crop would thereby be considerably too crowded; even a distance of eighteen inches each way will not be found too much. An American writer thus describes their method of cultivation: "Plant in hills about three feet apart; place a shovelful of manure or a handful of poudrette in each—five or six grains to a hill is sufficient. When up thin them out, allowing three of the strongest plants to remain. Thorough cultivation is necessary to secure a good crop."

JERUSALEM ARTICHOKE (*Helianthus tuberosus*).

This is a very useful vegetable, and is much cultivated in some parts of India where potatoes are not procurable at the time it is in season. The tubers should be planted in April or May in the open ground, in rows two feet apart and eighteen inches between the tubers, and about four inches deep. If grown in a good rich soil no manure should be given them, as it often has the effect of causing them to form too much stem, instead of producing good tubers. They will be ready to take up by the end of October, and as soon as they are dry, should be carefully stored in sand or earth, as, if exposed long to the air, they invariably shrivel up and become useless.

KNOL KHOL OR KOHL RABI—TURNIP ROOTED CABBAGE (*Brassica oleracea caulo rapa*).

A popular variety of the cabbage tribe principally valued in this country on account of its coming into season earlier than any other European vegetable. There are two distinct classes of this plant, namely, the green and the purple varieties, some of them growing to an enormous size. These, however, are not suitable for the garden, being very inferior in quality in comparison with the smaller kinds, the best of which are early white Vienna and early purple Vienna.

Its cultivation is the same in all respects as that of the cabbage, except that when planted out they should only be placed at a distance of eighteen inches between the rows, and about twelve inches from plant to plant. The soil in which they are grown can hardly be made too rich, and as soon as the plants commence growing freely, they should be supplied with frequent dressings of strong liquid manure, the great object being to induce the plants to make a rapid, vigorous growth, otherwise they invariably become tough and fibrous. They are best suited for the table when about the size of a cricket ball.

LEEK (*Allium porrum*).

The leek is but little cultivated in Bengal, and is rarely to be found in our markets. This is certainly not owing to any difficulty in its cultivation, for, providing good seed is procured, it can be grown most successfully with proper treatment.

Seed should be sown early in October or as soon as the rains are over, in a light, rich soil. When the plants are about six inches high, they should be transplanted into trenches prepared in the same way as for celery, but they need not be more than eight inches wide. The plant should be placed in the rows at a distance of not more than five or six inches apart. In planting, the seedlings should be placed at least three inches deep in the soil, and as they increase in growth, should have some light, rich soil drawn round the stems to insure their being properly blanched. They must be kept liberally supplied with water, and are also much benefited by frequent dressings of strong liquid manure.

THE LETTUCE (*Lactuca sativa*).

Lettuces are especially partial to an open, deeply worked, and well enriched soil, and to an abundant supply of moisture throughout their whole growth. Not only is this necessary to insure a free growth, but also to secure such an amount of crispness and natural succulency as alone constitute the highest merits of this important salad plant. The lettuce is divided into two distinct groups, namely, the cos and the cabbage varieties, both of which thrive equally well in this country, although probably the cabbage varieties are best adapted for very early crops being of a harder nature. Sowings may be made for an early crop in pans or boxes in August or September, and as soon as they have formed four leaves, should be transplanted into well raised beds. They must, however, be protected from heavy rains, otherwise they are liable to damp off. For main crops after the rains are over, sowings should be made in the open ground in drills twelve inches apart. As soon as the plants are sufficiently strong, they should be thinned out in the rows, leaving nine to twelve inches between the plants of the cos varieties, and fifteen inches for the larger kinds of cabbage. The plants that are removed from the drills should be transplanted into a bed of rich soil and carefully shaded for three or four days. These will form a good successional crop to those left in the original bed, although they will not be equal to them in size, as the finest lettuces are always produced from the plants that are allowed to remain in the place where the seed is sown. As soon as the plants are large enough a few should be tied up at intervals of three or four days to blanch them. This operation must only be performed when the plants are quite dry; it is therefore best done in the afternoon of a bright sunny day. After being tied up care must be taken not to water the plants overhead, otherwise the water settling between the leaves frequently causes the hearts to rot.

The red ant is particularly partial to the seed of this plant, and in gardens much infested with this insect it is almost impossible to raise plants in the open ground. In such a case it is necessary to sow the seed in pans or boxes filled with coarse soorkee or gravel, to which may be added a small quantity of leaf mould. These must be placed in such a position that the ants cannot get to them; this is easily managed by procuring gumlahs about the size of ordinary seed pans; fill those with water and then invert an ordinary six or eight-inch flower pot in each, on which must be placed the pans or boxes. If care is taken that the gumlahs are kept constantly filled with water, this will form an effectual barrier to ants or any other insect.

THE MELON (*Cucumis melo*).

Innumerable attempts have been made in this country to cultivate the many varieties of melon now so much grown in England, but invariably, I believe, without success. There are various reasons adduced as to the cause of this:—some attributing it to the climate, others to the ravages of a particular kind of beetle, which, strange to say, has a happy knack of always turning up wherever a plant of the melon or cucumber family grown from imported seed is to be found, and yet they leave plants raised from indigenous seed entirely unmolested. Possibly this insect acts on the same principle as the mosquito which is well known to have a peculiar penchant for new comers. I do not think either of these reasons sufficient to account for such an invariable failure—in the first place as regards climate. In England they are generally grown at an average day temperature of eighty-five and a night temperature of about seventy degrees. In most parts of Bengal at certain seasons of the year there would be but little difficulty in keeping a glass house or frame at the above temperature, and with reference to the insect theory, it is certainly, if not actually, a myth—at least considerably over-estimated, for, admitting the presence of the pest, still it is quite easy to protect the plants from its ravages.

Till such time as some better reason is brought forward to thoroughly convince the most sceptical of the impracticability of its culture, we ought certainly to persevere, as possibly by some happy chapter of accidents it may eventually fall to the lot of some fortunate amateur to discover a method by which we may be able to have a Hero of Bath or "Scarlet Gem" on our tables at a tenth of the cost it takes to produce them by our more fortunate friends at home.

There are one or two kinds of melon (*Kurbooza*) extensively grown in Bengal. These probably originally came from Cabool. They have, however, become quite domesticated here, and require but little care in their cultivation beyond being planted in a light, rich, sandy soil and liberally supplied with water. Closely allied to the melon we have the phootee (*Cucumis momordica*). This is cultivated in the same manner as the preceding, but is very inferior to it in flavour.

THE MUSHROOM (*Agaricus campestris*).

Although mushrooms are found growing wild in many parts of Bengal, it seems doubtful if any of these are the true *Agaricus campestris* so extensively cultivated all over Europe, although probably they are closely allied to it. Very few attempts have been made to cultivate the mushroom artificially amongst us, although we have every convenience at command, the only difficulty being to procure good spawn. This may be overcome by importing it from Europe at the commencement of the cold season, and probably even it might be artificially produced here by the same method as adopted in Europe.

The following taken from "Burbidge's Propagation and Improvement of Cultivated Plants," graphically describes the whole process of cultivation both in growing from spawn and also to produce the same artificially:—

"The great essentials to the development of the common Mushroom are a moderate heat of 60° to 80°, accompanied by a humid atmosphere, and a moderate amount of light. According to some authorities they absorb a large amount of nitrogen; but the direct application of nitrogenic manures to the soil does not appear to influence their growth in the open ground. The common or edible mushroom is readily propagated from spawn, that is cakes or bricks made of horse dung, cow dung, loam, and chopped hay well mixed togcther and made into flat bricks, and to these cakes the mycelium of the mushroom is added, either from a pasture where mushrooms are found in abundance or more often from previously made spawn. After the cobweb-like mycelium has spread through the compost in every direction, but before the more perfect threads have time to form, the whole is formed into bricks or cakes, and then dried; and curiously enough the mycelium thus treated retains its vitality for a long time, and soon develops itself when placed in a moist, firm compost or bed of horse droppings and soil, in a warm and humid atmosphere; the flat cakes are about ten inches long, and five wide, and vary from 1½ to 2 inches in thickness. By some spawn cakes are made of cow dung, horse dung (that from horses at grass being best), sheep dung, loam, and chopped hay, the latter being used to bind the whole firmly together. After these are made they are laid on laths to become partially dry before the spawn is added. They are then taken and placed in alternate rows of heated manure, and as each brick is added a hole or two is made in it with a pointed stick, and the cavity filled with previously made and tested spawn. The bricks should not touch each other; and when a stack has been made, cover the whole with a layer of the heated droppings, which, by gently heating the cakes, causes them to be completely pervaded with mycelium.

Spawn may be made in a covered and dry, but not too airy, situation. The corner of a barn or that of an out-house or even of a stable are favorable places for its development. The bed in which it is to be generated should be made early in May, and the following are the materials employed, which may be reduced to smaller proportions if necessary—fifty-six barrow loads of fresh horse dung, six barrow loads of good garden soil, and one barrow load of fresh wood ashes which have not been wet, with half a barrow load of pigeon's dung fresh from the pigeon house. The whole should be watered lightly with cow's urine or water from manure heap. When the mixture has been properly made, after various turnings it should be placed to the depth of a foot along a wall; the width may be left out of the question, but it requires a certain bulk in order that it may heat gently. The bed must be trodden firmly, and at the end of ten days the consolidating process must be repeated, and ought to be continued two or three times a week until early in September. The manure thus prepared is cut with a sharp spade into blocks of about a foot each. These are then left to dry in any airy place from which sunshine, and above all, damp, are excluded. These bricks are placed on their sides and turned from time to time. Spawn thus made will keep good from ten to twelve years if it is placed in a dry position free from frost. The spawn being thus prepared we pass on to the next stage, namely the production of mushrooms. To grow a crop quickly it is necessary to engender a moderately lasting artificial warmth in the materials employed. Get if possible to maintain them as free as possible from decay, and with a moderate latent moisture only. The place best adapted for their production is a rather damp godown or out-house; in this should be arranged a row of shelves at a short distance from the ground, on which the material in which the Mushrooms are to be grown should be placed to the depth of eighteen inches and firmly beaten down. The compost best adapted for this purpose is prepared as follows:—Fresh horse droppings six parts, cow dung two parts, sheep dung two parts, garden soil four parts, and fresh wood-ashes one part. Before these are mixed they should be allowed to dry in the sun for two or three days to take off the excess moisture. After being mixed, and the beds made on the shelves as described above, they should be allowed to remain for five or six days, till fermentation commences. As soon as a moderate heat is perceptible, the spawn should be added; this is done by making holes in the surface about twelve inches apart and three inches deep; in each of these a small piece of spawn, about two inches square, is inserted. After having first been dipped in tepid water, these should be slightly covered with the compost and the whole beaten down firmly. After a month the beds should be covered with about two inches of light, rich soil, and the whole again beaten down, and then well watered; it will then require no further attention beyond occasionally watering the walls and floor of the house to promote a damp atmosphere. If properly managed the beds should commence bearing freely in about eight weeks from the time of spawning them.

THE ONION *(Allium cepa)*.

The principal difficulty in the cultivation of the onion in this country is to procure seed that will germinate even in Europe. When it is more than a year old, it will but rarely grow satisfactorily. It is hardly surprising therefore that we should be frequently disappointed in our attempts to produce a crop from imported seed. Acclimatised seed, however, germinate freely, and when a crop is grown to be drawn when young for salads, etc., it is preferable to use this, as there will then be no fear of a disappointment providing fresh seed is procured.

The onion is a very gross feeder, and requires deep cultivation; a light, rich sandy soil suits it best; the ground should be trenched to a depth of at least two feet, adding at the same time a heavy dressing of manure. Sowings may be made early in October in drills nine inches apart. After covering up the seed, the beds should be trodden or beaten down firmly. As soon as the plants are six inches high they may be thinned out to a distance of six inches apart in the rows. The crop must be kept plentifully supplied with water, and frequent dressings of liquid manure will materially conduce to the production of a good crop.

The young plants removed from the seed bed should be drawn carefully without injuring the roots, and transplanted into other beds. If carefully managed these will produce almost as good crop as those left in the seed bed. In planting out, however, it is necessary to notice that they are not put too deeply in the soil, otherwise this will prevent the proper formation of the bulb. As soon as they become ripe they should be pulled up and placed on mats to dry, fully exposed to the sun for a few days, taking care to remove them inside at night. When they have become thoroughly dry, they should be carefully cleaned and stored in sand in a cool dry place.

There are an immense number of varieties now grown in Europe; many of these however in consequence of their taking a long season to attain maturity are not adapted to this country. It is, therefore, advisable to select those sorts which are of a quick growth, such as "white Spanish" or the Tripoli varieties.

PARSLEY *(Apium petroselinium)*.

This, although a perennial, can only be grown successfully as an annual in this country. Sowings may be made in pans under shelter in August; by the end of the rains these will have formed strong plants, and should then be planted out into beds of well manured

soil at a distance of six inches apart. A second sowing may be made in the open ground in October; this will not require to be transplanted, but the plants should be thinned out to the distance mentioned above. A slightly shaded situation suits it best; the seed will be found to germinate much more freely, if it is steeped in water for three or four hours and then well mixed with dry ashes or sand before sowing.

The Parsnip *(Pastinaca sativa)*.

This vegetable is but very rarely grown in Bengal; the principal difficulty in its cultivation seems to be to induce the seed to germinate, as when once the plants are above ground they require no more care than the carrot. A mistake too frequently made by many is in sowing the seed too early before the soil is in a suitable state for it to germinate in. It is always advisable to delay sowing till the first week of November, when, if a light, rich, friable soil is available, a good crop may generally be grown without difficulty, for it is more frequently owing to the seed rotting in the soil from an excess of moisture than from any actual defect in the seed that produces so many failures in the attempt to grow this vegetable. The seed may be sown broadcast or in drills at a distance of nine inches apart, and as soon as the plants are four or five inches high, they should be thinned out to the same distance in the rows. They must be kept liberally supplied with water, and an occasional dressing of liquid manure will also be found beneficial.

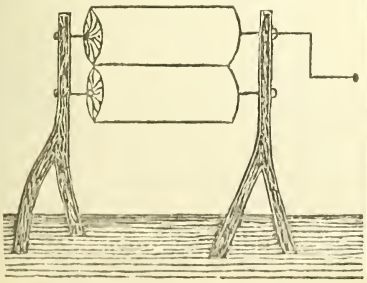
Rus in Urbe.

THE PLANTAIN TREE AND FIBRES.

The following paragraphs and illustrations of Mr. Liotard's memorandum were omitted by the *Journal of the Society of Arts* in its abstract, given by us on page 297 of the *Tropical Agriculturist*. We reproduce them here from a Madras Government paper. The first part as far as "rainy season" should come in after line 13, col. 1, page 298, and the second part, "In thoroughly conducting * * * each hand," should come in after line 43 of the same page and column.

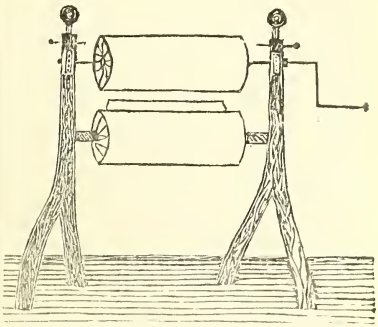
When cut and divided strip by strip, each class of the strips should be separately subjected to a process of crushing. For this and subsequent processes some simple, cheap, and efficient mode of treatment is requisite; and the machinery to be used must, moreover, be light and portable. As a beginning I would suggest the following processes which I have tested practically with good results.

In the first place the fresh cut strips (about two inches wide and on an average five feet long) should be simply passed through a pair of rollers, like those employed by Bengalis in expressing juice from the sugar-cane; or the contrivance sketched below might be adopted:



The rollers might be two feet in length and eight inches in diameter, and should be of any strong wood which can easily be procured. Stone rollers might not be easily procurable; iron ones would, if not very clean, discolor the fibre, and both will in any case have the disadvantage of being more costly and less portable. By using the rollers the strips will be crushed, but not so as to injure or tear the fibre. If necessary, the strips can be passed twice through.

The strips being crushed, the next thing to do is to entirely remove all the cellular tissues and coloring matter which, by the crushing, will have been loosened. A simple way of doing this would be to use a pair of wooden rollers of the same size as those just mentioned, but constructed thus:



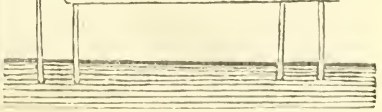
The lower roller would be a fixture, with a blunt wood or horn blade fixed into it, so as to stand against the space between the two rollers with a very slight slant on one side. The upper roller would be turned by the hand. The crushed strips should be placed between the rollers from the side on which the blade slants. Then the upper roller being turned will draw the strip through between itself and the blade, thus scraping away most of the pulpy matter which will have been loosened by the previous set of rollers.

After being passed a first time, the peg on both ends of the upper roller should be lowered into the posts in order to lower the upper roller so as to leave a minimum of space between it and the blade. The strip should then again be passed through, once or twice, when it will come out quite free from all pulpy matter. In every case the strip should be passed through with some care.

When cleaned in this way, the fibrous material resulting will be well suited for paper-making, and will only need drying to fit it for baling and despatch.

But for cordage and textile manufactures we should go a step further; we should comb the fibrous material, or (as it may more properly be called) the clean fibrous strip. This can be done by laying the strip flat on a board with pegs arranged *close* together thus:

The puller stands on this side.



The strip, on being pulled over the pegs, will be divided by the first and sub-divided by the second row of pegs. The result will be very fine strips of fibre which can be dried, baled, and despatched as marketable stuff. The cordage or textile manufacturers will then easily be able to extract single *individual* fibres out of the stuff for their industries.

I must explain that the pegs must *not* be of iron, as they would discolor the fibre; they should be of bamboo, the second row being finer than the first, and both rows being close in together so as conjointly to produce the effect of a fine comb. One single row does not answer so well as two rows.

The whole operation, from the cutting of the trees to the combing of the clean strips, should be done in one day. No water should be used at all, and the product of each class of layers should of course be treated separately.

The fibrous material, whether simply crushed and cleaned in strips for paper-making or also combed for cordage and textile manufactures, should be dried, not by being spread on the ground, but by being laid out in the sun, or in any airy place, on ropes, as the washermen lay out their clothes. The material will be dry in a very short time, but it should on no account be exposed to wet or to the night dew, and should be perfectly dry before being baled. And it follows from this, that the extraction of the fibre from the plantain tree had better be done during the day than during the rainy season.

* * * * * *

In thoroughly conducting the trials on one, or two, or more species of the plants, the following particulars could no doubt be carefully noted:—

the name and rank of experimentor,
the species operated upon,
the locality and district,
the weight of the trees cut down,
the weight of dry fibre obtained,
the cost of the operation.

Samples of each class of fibre would be preserved for valuation. The object would be the production of a marketable fibre from indigenous plantain trees by some cheap and ready process of extraction such as is here indicated, in view to serving—

(1) paper-makers, and
(2) cordage and textile manufacturers.

That these suggestions will produce good fibre I have no doubt, as I have tested them practically on the Native variety of plantain known in Bengal as the *kanch-kella*, which does not produce such good or so much fibre as the varieties I have now referred to.

The working charges will not, I believe, be prohibitive, for the implements I have suggested are anything but costly, and they can easily be carried about the plantations, thus obviating the necessity of otherwise carrying the plantain trees themselves which are heavy to transport. The cost of manual labour can be reduced by making three men work two pairs of rollers and passing four strips at a time. This can be done by placing one man to turn one pair of rollers with each hand, and by having each of the two other men to pass a strip with each hand.

ENCLOSURE No. 2.

Letter from H. W. J. Wood, Esq., Secretary to the Bengal Chamber of Commerce, to the Officiating Under-Secretary to the Government of India, Simla, dated Calcutta, 2nd June 1881.

I am directed to acknowledge the receipt of your letter, No. 132, of the 21st of April, on the subject of fibre obtained from the plantain tree by the process described in the memorandum drawn up by Mr. Liotard of your department.

2. As the Committee of the Chamber of Commerce have no practical knowledge of the matter, the samples of fibre, together with your letter and its enclosure, were referred to the Agri-Horticultural Society for report; and the Committee of the Chamber place before you the opinions of those whose practical experience will no doubt be accepted by the Government as a guide in any future experiments that may be conducted with the view of making a valuable addition to the industrial resources of the country:—

"I have submitted to our Committee your letter of the 19th instant, and the papers accompanying and the minute specimens of plantain fibre therein referred to. They are of opinion that they are very prettily got up, are much too good for paper making, but might be useful for cordage. It is, they add, impossible to quote values on such small specimens."

"If Mr. Liotard can prepare a *large* quantity of fibre similar to the specimens *at a moderate cost* it should pay well, probably as a substitute for Manila hemp."

ENCLOSURE No. 3.

Extract paragraph 1 from a letter from the North-Western Provinces and Oudh Government, No. 910, dated 9th June 1881, to the Secretary to the Government of India, Home, Revenue and Agricultural Department.

In reply to your letter, No. 6-125, dated 21st April 1881, regarding the cultivation of Manila hemp in these provinces, I am directed to say that inquiries concerning this plant had previously been made by the Department of Agriculture and Commerce, North-Western Provinces and Oudh, from Captain W. T. H. Cox, a planter in the South Wynaad, who has for some time past been cultivating it on a large scale. His report is not satisfactory, since he has found it impossible as yet to grow the plant at a profit, from the difficulty of cleaning the hemp for which no machine appears to have been invented. If the cleaning is done by hand, as in the Philippine Islands, the process is found to be too expensive to leave a margin of profit.

* * * * * *

From C. L. Tupper, Esq., Officiating Secretary to the Government of India, Revenue and Agricultural Department (Agri and Horticultural), to the Secretary to the Government of Madras, dated Simla, 8th July 1881, No. 6.

In continuation of the letter from this Department, No. 122, of the 21st April last, I am directed to forward copies of the papers noted in the margin, on the subject of the extraction of fibre from the *Musa textilis*.

2. As it appears that Captain Cox has found difficulty in cleaning the hemp, I am to suggest that, with the permission of the Government of Madras, he should be furnished with a copy of the memorandum by Mr. Liotard. Should Captain Cox try the process therein described, the Government of India would be glad to be favored with some account of the results.

VEGETABLE PHYSIOLOGY.

(*Gardeners' Chronicle*, 10th September 1881.)

At the close of the last century Sprengel published a most suggestive work on flowers, in which he pointed out the curious relation existing between these and insects, and showed that the latter carried the pollen from flower to flower. His observations, however, attracted little notice until Darwin called attention to the subject in 1862. It had long been known that the Cowslip and Primrose exist under two forms, about equally numerous, and differing from one another in the arrangements of their stamens and pistils, the one form having the stamens on the summit of the flower and the stigma half way down; while in the other the relative positions are reversed, the stigma being at the summit of the tube and the stamens half way down. This

difference had, however, been regarded as a case of mere variability; but Darwin showed it to be a beautiful provision, the result of which is that insects fertilise each flower with pollen brought from a different plant; and he proved that flowers fertilised with pollen from the other form yield more seed than if fertilised with pollen of the same form even if taken from a different plant.

Attention having been thus directed to the question, an astonishing variety of the most beautiful contrivances have been observed and described by many botanists, especially Hooker, Axel, Delpino, Hildebrand, Bennett, Fritz Müller, and above all Hermann Müller and Darwin himself. The general result is that to insects, and especially to bees, we owe the beauty of our gardens, the sweetness of our fields. To their beneficent, though unconscious action, flowers owe their scent and colour, their honey—nay, in many cases, even their form. Their present shape and varied arrangements, their brilliant colours, their honey, and their sweet scent are all due to the selection exercised by insects.

In these cases the relation between plants and insects is one of mutual advantage. In many species, however, plants present us with complex arrangements adapted to protect them from insects; such, for instance, are in many cases the resinous glands which render leaves unpalatable; the thickets of hairs and other precautions which prevent flowers from being robbed of the honey by ants. Again, more than a century ago our countryman, Ellis, described an American plant, Dionæa, in which the leaves are somewhat concave, with long lateral spines and a joint in the middle, which close up with a jerk, like a rat-trap, the moment any unwary insect alights on them. The plant, in fact, actually captures and devours insects. This observation also remained as an isolated fact until within the last few years, when Darwin, Hooker, and others have shown that many other species have curious and very varied contrivances for supplying themselves with animal food. —*Sir J. Lubbock.*

A NEW ALKALOID.

(From the *Pharmaceutical Journal*, 27th August 1881.)

Under the name of cinchamidine, another alkaloid has been added by Dr. O. Hesse to the already long list of those derived from cinchona (*Berichte*, xiv., 1683). It has been obtained by precipitating the mother-liquor from the purification of homocinchonidine sulphate with ammonia, re-crystallizing the precipitate repeatedly from boiling alcohol, dissolving in excess of hydrochloric acid and fractionally precipitating the solution with neutral sodium tartrate. The last portions precipitated consist essentially of cinchamidine, mixed with another basic substance that is removed by treatment in sulphuric acid and solution with a few drops of solution of potassium permanganate; this does not attack cinchamidine, which is afterwards precipitated with ammonia and re-crystallized from alcohol. Cinchamidine crystallizes from boiling dilute alcohol in colourless lamellæ and flat needles, and from strong alcohol in short thick prisms, dissolving with great difficulty in ether, tolerably easily in cold alcohol, freely in chloroform, an insoluble in water. It has a composition represented by the formula $C_{20}H_{26}N_2O$, melts at 230° C., forms salts with acids which are mostly beautifully crystalline, is lævogyre, and dissolved in excess of dilute sulphuric acid neither shows fluorescence nor gives a green colour with chlorine and ammonia. Dr. Hesse states that cinchamidine crystallizes together with cinchonidine and homocinchonidine, raising their melting points, and he thinks that possibly its sulphate occurs sometimes in commercial homocinchonidine sulphate, and the base more frequently and in larger quantity in commercial "cinchonidin purum"; this would possibly explain some unexpected analytical results obtained by Claus, which gave for supposed cinchonidine results corresponding more closely to $C_{20}H_{26}N_2O$ than $C_{20}H_{24}N_2O$.

On the other hand it should be mentioned that the existence of Hesse's "homocinchonidine" as a distinct substance has been more than once challenged, and Skraup states (*Monatsh. f. Chemie*, ii., 345), that having examined a specimen of cinchonidine" obtained from Hesse, he found that its difference in crystalline form from "homocinchonidine" was due to its containing 1 to 2 per cent of quinine, and that by an admixture of quinine with "homocinchonidine" it might be obtained crystallized in the form indicated by Hesse for his cinchonidine. He therefore contends that as Hesse's "cinchonidine" differs from "homocinchonidine" only by an impurity, the latter name must be abandoned.

According to Mr. Merck's last circular there is still some uncertainty as to the active principle of quebracho bark, and solid and liquid extracts appear to be preferred. What is known as Penzoldt's fluid extract (see vol. x., p. 50), or tincture, having the proportion 1: 2 to the bark used, is evaporated to form a dry extract, of which 1 part represents 20 parts of the fluid extract. In the preparation of "Penzoldt's extract," a resinous body is obtained as a by-product, which is said to be a valuable remedy in diarrhœa. The bark, according to Hesse (*Pharm. Journ.*, [3], vol. xi., p. 589), contains a series of alkaloids, and of these, Mr. Merck prepares three: Frande's "aspidospermine," in crystalline prisms; an alkaloid crystallizing in fine needles; and an amorphous alkaloid, forming non-crystallizable salts. This last mentioned is said to represent the "aspidospermine" of commerce.

A NEW BEVERAGE.

There seems to prevail a perfect mania at the present time for the manufacture of new beverages. We have already zoedone, vivone, vita novo, and other brain and nerve invigorators and non-alcoholic sparkling tonics; and as if these were not enough to satisfy the cravings of "drinking humanity," we now learn according to a French authority, one M. L. Couty, after a special visit to South America, has contributed to the *Revue Scientifique* an article giving the results of his examination of the food question in that continent, especially with respect to a nutritious beverage known as "Mocte," which he believes is destined to replace coffee and alcohol to a very great extent. The leaves are derived from the *Flex Paraguayensis* which grows to a height of from three to six metres, and covers acres of ground throughout Paraguay, Rio Grande, Parana, and the province of St. Catherine, which represent a zone larger than France and Germany united. The leaves, which are thick and oblong, are picked only every three or four years. They are dried by artificial means in the woods by the peasants themselves, who send them in a rough state to the factories. Here they undergo a separating process by means of sieves, and then they are packed ready for sale. The leaf is boiled for a minute or two and a liquid is produced less limpid than tea and not so dark as coffee. The aroma is less pronounced than that of good tea. Mocte is less bitter to the taste than coffee, and may be drunk without sugar. It may with advantage pass through seven or eight successive boilings, each time in fresh water, and the last infusions are better than the first; but in this case it must not be allowed to get cold. It is sold at the rate of 7 fr. and 8 fr. per 15 kilogrammes, delivered at Antonine, a shipping port in Parana; and as each kilogramme furnishes 40 litres of a strong infusion, the rate per litre is no more than 2 centimes. But the cost would be far less if there were proper means of traffic from the woods, carriage rates being three times as expensive as the article. Of course a great reduction might fairly be anticipated if railways

or even causeways were constructed; as at present the journeys are made by means of mules along steep and rugged paths. From a chemical analysis of the plant, it appears that it contains the same properties as coffee, an alkaloid with oleaginous essences and resinous gums, but as the quantity of the latter is much greater than in coffee, the nutritive element is superior. This analysis has been confirmed by experience. The inhabitants drink nothing else, and with mocte and meat they live well, without feeling any anxiety for bread or vegetables, although it would be easy to cultivate maize and potatoes if necessary. The cattle tenders often remain shut-out for days from all human habitation with their herds, and are content to forego their usual meals, if only they have a good supply of mocte which appears to be an active element of food and, unlike coffee, produces neither sleeplessness nor palpitation.—*Western Star.*

THE PAPER MULBERRY TREE.

(*Journal of the Society of Arts*, 2nd Sept. 1881.)

The United States Minister of Agriculture, in a recent report, calls attention to the largely increasing manufacture of cloth in China, Japan, and the Sandwich Islands, from the paper mulberry (*Broussonetia papyrifera*). In Tahiti and other South Pacific Islands, a species of cloth is manufactured from its bark, know as "Tappa" or "Kappa," and it is said that the finest and whitest cloth and mantles worn by the islanders and the principal people of Otaheite are made from the bark of this tree; it dyes readily, particularly in red, and takes a good colour. The following is the method employed by the native women of Otaheite in beating out the fibre. The cleansed fibres are spread out on plantain leaves to the length of about eleven or twelve yards, and these are placed on a regular and even surface of about a foot in breadth. Two or three layers are thus placed one upon another, great attention being paid to making the cloth of uniform thickness; if thinner in one place than another, a thicker piece is laid over this place when the next layer is laid down. The cloth is left to dry during the night, and a part of the moisture having evaporated, the several layers are found to adhere together, so that the whole mass may be lifted from the ground in one piece. It is then laid on a long smooth plank of wood prepared for the purpose, and beaten with a wooden instrument about a foot long and three inches square. Each of the four sides has longitudinal grooves of different degrees of fineness, the depth and width of those on one side being sufficient to receive a small packthread, the other sides being finer in a regular graduation, so that the grooves of the last would scarcely admit anything coarser than sewing silk. A long handle is attached, and the cloth is first beaten with its coarsest side, and spreads very fast under the strokes. It is then beaten with the other sides successively, and is then considered fit for use. Sometimes, however, it is made still thinner by beating it after it has been several times doubled with the finest side of the mallet, and it can thus be attenuated until it becomes as fine as muslin. Should the cloth break under this process, it is easily repaired by laying on a piece of bark, which is made to adhere by means of a glutinous substance made from the arrowroot, and this is done with such nicety, that the break can scarcely be detected. In other islands the bark is kept wet and scraped with sharp-edged shells. It is said that the King of the Friendly Islands had a piece made which was 120 feet wide and two miles long. In Japan a species of cloth is made from paper derived from this tree. It is cut into thin strips, which are twisted together and spooled, to be used in the woof of the fabric, while the warp is composed of silk or hemp. About 250 pieces only are manufactured at the principal manufacturing place. The paper mulberry grows everywhere in Japan, and is a valuable tree, as furnishing the bast from which a large portion of the Japanese paper is made; the plants are reproduced in quantity by sub-dividing the roots, and in two or three years are ready to be cut. This work is done in November, and the branches, from seven to ten feet long, are made up into bundles, three or four feet in length, and steamed so that the bark is loosened and can be more readily stripped off; this is washed, dried, and again soaked in water, and scraped with a knife to remove the outer skin, which is used for inferior kinds of paper. The bast, when cleaned, is washed repeatedly in clean water and rinsed; it is then bleached in the sun till sufficiently white, after it is boiled in a lye, chiefly of buckwheat ashes, to remove all gummy matters. The fibres are now readily separated, and are transformed into pulp by beating with wooden mallets; the pulp is mixed in vats with the necessary quantity of water, to which is added a milky substance prepared from rice flour. The couches on which the paper sheets are produced are made of bamboo, split into very thin sticks, and in parallel lines by silk or hemp threads, so as to form a kind of mat. This is laid upon a wooden frame, and the apparatus dipped into the vat, raised and shaken, so as to spread the pulp evenly, after which the cover is first removed, then the bamboo couch, with the sheet of paper. When a number of sheets have been thus prepared, they are pressed to exclude the water, and afterwards spread out with a brush upon boards and allowed to dry. The sheets are only about two feet in length, but sometimes sheets ten feet long are produced.

AGRICULTURAL RETURNS FOR 1881.—The Statistical and Commercial Department of the Board of Trade have issued a summary of the returns collected on the 4th of June last, which shows the extent of land in Great Britain under wheat to be 2,806,057 acres, or 103,381 acres less than in 1880; barley, 2,442,405 acres, or 25,036 acres less than in 1880; oats, 2,901,135 acres, or an increase of 104,230 acres; potatoes, 579,431 acres, an increase of 28,499 acres over 1880; and hops, 64,128 acres, or a decrease of 1,577 acres. The total number of live stock in Great Britain on the same day is given as —Cattle, 5,911,524; sheep and lambs, 24,582,154; pigs, 2,048,034.—*Journal of the Society of Arts.*

SARRACENIA PURPUREA AND FLIES.—Joseph Jackson, Massachusetts, in Coulter's *Botanical Gazette*, states that when out herborising he was surprised on drawing aside the petals to look at the stamens, to see the whole cavity formed by the petals and the peltate expansion of the style filled with flies, as large as the common house-fly, all busy as could be, eating the pollen, of which scarcely a grain could be seen. Fourteen flies were counted in one flower. Nearly every plant examined was filled in the same way.—*Gardeners' Chronicle.*

TEA CULTIVATION IN AMERICA.—Successful experiments are reported on the cultivation of Tea in the United States. A tract of land has been selected in Georgia by the Commissioner of Agriculture as an experimental farm, on which the cultivation of Tea on an extended scale will be carefully and thoroughly tried. Samples of Teas already produced in America have been sent to London, and the report of a Mincing Lane firm is as follows:—"They represent Teas of a high type. The flavour, though not strong, is remarkably fragrant. In appearance they resemble Indian Teas, but the flavour is more like that of the finest Chinese black Tea, or of the hill Teas of India." The cultivation of the plant has been taken up with vigour by one enthusiastic planter, so satisfied is he of success in a commercial point of view, and this after fifteen years' experience of Tea cultivation in India. Fifty acres of land have been planted with Tea, which, if successful, will be at once extend to 100 acres. It is prophesied by this American Tea planter that in a comparatively short time America would be able to supply her own markets with this important article.—*Gardeners' Chronicle.*

LIBERIAN COFFEE IN SUMATRA.

Although published in Batavia in 1879, we had not previously met with a little pamphlet in Dutch by Mr. F. G. Steck, of Medan, Deli, Sumatra, entitled "De Kultuur der Liberia Koffij" (The Cultivation of Liberian Coffee). In his preface Mr. Steck acknowledges his obligations to the book published at this office, in 1878, containing the Liberian letters of the late Mr. Crüwell (whose name the Batavian printer has turned into *Gruwell*); and he adds such facts as had come under his own or his friends' observation in their experiments with this variety of coffee. On looking through the pamphlet, however, we cannot find any important addition to our knowledge of the subject. In fact, in closing his preface, Mr. Steck admits that the information given is meagre, as was to be expected in the case of a new culture, and he asks for corrections and further information with a view to an enlarged edition of his pamphlet. The little work consists of 31 pages, a page and a half being devoted to the situation, climate and soil of Liberia, and the remainder to the coffee tree to which it gives its name. In the division on the laying out of ground Mr. Steck describes at some length an invention of his own for taking levels on steep land. In quoting Dr. Bidie's opinion on the ubiquity of growth of this coffee, Mr. Steck refers to him as an authority on Liberian coffee in Ceylon! We do not remember to have seen stated what is mentained here: that Liberian coffee contains 92 p. c. of caffein, as compared with only 56 p. c. in Java coffee. At the end of the pamphlet the writer mentions what had been done in Sumatra up to the time when he wrote (Sept. 1879) in the way of cultivating Liberian coffee. The estates mentioned are Agnieta, 10 miles from the sea; Agatha, adjoining it; Mariendal, at Deli, about 180 feet above and 16 miles distant from the sea; and Boeroeng Merac, in Langkat, about 52 miles distant from but only 60 feet above the sea. The last two estates appeared to be doing specially well. We hope Mr. Steck will give us the benefit of his further observations soon.

SALE OF CINCHONA BARK IN COLOMBO.

Mr. E. John put up for public sale, at 19 Upper Chatham Street, Fort, at noon today, the following lots of bark which were sold at the prices mentioned :—

	Lot.	lb.				R.	c.
Kataboola—1		378	Succirubra quills		...	0	72½
	2	446	,,	chips	...	0	73½
	3	213	,,	root	...		75
	4	478	,,	twigs	...		17

An analysis by Mr. Symons of lots 1, 2 and 3 mixed in their relative proportions shews 1·320 per cent Sulphate of Quinine. Root bark from 5 year old trees. Other trees 2 to 4 years old. Elevation 3,000 feet.

	lb.			R.	c.
Diokapitiya—					
Lot. 5	219	Succirubra quill	...		65
6	203	,,	paper quill ...		30
7	253	,,	twigs and chips.		27½
Agar's Land—					
8	211	,,	chips and pieces.		57½
9	78	,,	twigs ...		17
Claverton—					
10	435	,,	mixed shavings..	1	10
11	41	,,	silvery stem ...	1	05
12	304	,,	chips and pieces.		97½
13	114	,,	papery quill ...		60
14	193	,,	twigs and chips.		27½
15	58	,,	dust ...		10

Analysis of lot 12 by Mr. Symons, shews 2·186 per cent sulphate of quinine.

	Lot.	lb.			R.	c.
Glenugie, B.—						
B	17	64	Succirubra stem quill	...		85
B	18	232	,,	chips and pieces.		77½
B	19	404	,,	paper quill ...		35
B	20	254	,,	twigs and chips.		24

Other remarks same as A parcel but without analysis.

Glenugie—

Lot.	lb.			R.	c.
17	150	Succirubra stem quill	...		82½
18	559	,,	chips and root...		80
19	406	,,	branch and twig.		25
20	630	,,	papery quill and pieces ...		55

Analysis by Mr. Symons of lot 18 chips and root shews 1·590 per cent. sulphate of quinine. Elevation 4,400 feet trees 4 and 5 years old.

	Lot.	lb.			R.	c.
Morar—21		24	Succirubra mixed quill	...		60
	22	554	,,	shavings ...	1	20
	23	667	,,	twigs ...		23

Analysis by Mr. Symons of the shavings lot 19 shews 2·316 per cent. sulphate of quinine. Elevation 4700 to 5,000 feet. From well grown 4 years old trees. Original plants from Portree.

Strathmore—

Lot.	lb.			R.	c.
24	196	Succirubra stem quill	...		77½

The attendance was good, and the bidding spirited, the whole 69 lots being knocked down within two hours.

CINCHONA CULTURE IN DIMBULA:

LEDGERIANAS 5½ YEARS OLD YIELDING 9·6 OF QUININE AND NOT A TRACE OF INFERIOR ALKALOIDS.

We draw attention to the good news conveyed to us by Mr. Wm. Smith in Messrs. Howard's analysis of bark from Ledgeriana trees on Matakelly, five and a half years old. The result is most satisfactory, the three richest specimens being, we suppose, worth at least 18s per lb. The Yarrow bark analysed gave up to 11·2 per cent sulphate of quinine, but the trees were said to be younger. It is possible that the source of the seed is the same in both cases, namely, the late Mr. McIvor of the Nilgiri Gardens. If not, Mr. Smith's pinch must be from some received by Mr. A. M. Ferguson direct from Mr. Moens. That is a point which can be definitely settled very soon now. The important news is that the most valuable Ceylon cinchona bark as yet analysed has been grown in the centre of Dimbula at an elevation of over 4,000 feet. The highest percentage of quinine shewn in the series of analyses we published the other day from Mr. Moens was 11·20 (*of quinine*, not the sulphate); but he does not here specify the age of the tree, merely referring to the plantation as a young one. In other cases we are enabled to institute a comparison. Thus bark from a five year old tree of the best type yielded 8·45 per cent of quinine, and another of the same type, seven years old, gave 7·20 per cent; but in these cases the inferior alkaloids made up from 2½ to 3⅓ per cent; while in the best Matakelly bark, the 9·6 of quinine was unassociated with even a trace of other alkaloids. This, of course, makes the bark all the more valuable to the manufacturer. If any one in Ceylon deserves success as a cinchona cultivator it is Mr. Wm. Smith, for if he had his way well-nigh twenty years ago he would have planted out in the Dimbula valley all the plants Dr. Thwaites had then to spare for him at Hakgala Gardens; but "partners" would not at that time listen to expenditure on anything but "coffee," at least not on a tree grown for pharmaceutical purposes! 'Whoever made a fortune by growing a drug?' was then the cry; but the few farseeing men of that early day have lived to see their prophecies more than fulfilled. It is also very satisfactory to find Messrs. Campbell and Fairlie so successful in their selection of the best types of the trees as proved by analysis this is a branch of the cinchona planter's education which must be learned by all who wish to do justice to the richest species.

While on this subject let us once for all ask for uniformity among Ceylon planters and also merchants and brokers in their reports, quotations and speech about bark analyses. We hear 2, 3 and 5 per cent trees spoken of when all the time not quinine, but sulphate of quinine, is meant. In Java and India, on the contrary, the percentage is always based on the quininc. To give the proportion of sulphate is useful as a guide to the market value, but, in respect of yield of different barks, let it be the rule to associate "per cent" with *quinine*. In this way, we can compare the best tree in the latest Java report (11·2 per cent) with the best on Yarrow (8·4 per cent) and again on Mattakelly 9·6 per cent. We have no doubt that Ceylon Ledgerianas will yet beat the richest produced even under Mr. Moens' special and scientific care.

PROGRESS OF CEYLON TEA CULTIVATION.

The following is an extract from the *Grocer* of Sept. 3rd respecting the prospects and progress of tea cultivation in Ceylon, and of the market opening for its disposal in the Australian Colonies:—

"CEYLON TEA.—Owing to short coffee crops, planters in Ceylon have of late years turned their attention to the cultivation of other products, among which tea figures conspicuously, and the export from Ceylon of this article is yearly increasing. In 1877 only 2,105 lb were exported, while in 1880 the export had increased to 140,000 lb. Last year the area of tea planted out amounted to 9,300 acres, which will produce about 3,500,000, lb of tea when in full bearing; and as the planted area is yearly increasing, we may expect before long to hear a good deal about Ceylon tea, which appears to be a successful rival of Indian tea as regards its qualities as a beverage. At the Melbourne Exhibition, Ceylon teas were awarded thirty-six prizes, of which eleven were first-class, and the decision arrived at by the Victorian Government Analyst was that in some important respects Ceylon tea was the best in the world, and that in Ceylon the best quality of tea could be produced with the minimum exhaustion of the fertilising matters in the soil."

In the same journal, I came across a letter addressed to its editor by some aggrieved tradesman, who evidently fears that arrangements something similar to those proposed in Ceylon for the disposal of island-grown tea will militate against the profits of the "middleman." The following is its text:—

"IS IT FAIR?

"SIR.—A short while since I had a circular placed in my hands issued by the 'Darjeeling Tea Company' to their shareholders, offering to supply them with boxes of their tea direct, and I was told that this offer was being accepted, not only for their own wants, but to supply the needs of their circle of acquaintances as far as practicable. I would ask you, sir, if you consider this fair to the trade? Unless I am mistaken, the Assam Tea Company attempted to do this some years since, but withdrew the privilege upon remonstrances being made to them by their broker. Perhaps the Darjeeling Tea Company may also see the 'error of their ways,' when they know that such procedure is strongly resented by the dealers.

I am &c.,

"Exeter, August 29. W. S. SAUNDERS."

Now, without wishing to disparage the usefulness to the community of the shop-keeping classes, it cannot

be thought that in these days of co-operative trading the growers of tea should stand particular in considering their interest to the detriment of their own, and I don't suppose this protest will deter or delay the steps contemplated in Ceylon for the profitable disposal of its products.—*London Cor.*

AGRICULTURE IN MADAGASCAR AND MAURITIUS.

MAURITIUS, 6th Sept. 1881.

That Madagascar, in the hands of a civilized and strong Government, would become a wealthy possession, the experience Mauritians have of that island permits of their entertaining very little doubt. Its climate, it is true, is not very healthy; but it is the *ne plus ultra* of a sugar and coffee growing country: while it could export coals, timber, and cattle in immense quantities, and gold has been found there, but owing to the jealousy of the natives the working of the mines has been forbidden; so that it is impossible to give an opinion as to their riches. I may notice, as a sign of the times, that one of our firms (Messrs. Antelme, Patte son & Co.) has lately put a small steamer about 300 tons, the "Imerina," permanently in the trade between this and Madagascar and Réunion. Our connection with the former fine island is daily making headway; and I may say *en passant* that Madagascar is quite worth any trouble that can be taken to obtain a footing there. As a sugar-growing country, it will, before many years, be likely to leave Mauritius in the background, and many of our rising generation are daily leaving this for it.

The Chemical Manure Company is one of our most prosperous public investments. It was founded here some years ago by a French gentleman passionately fond of scientific agriculture; and, unlike many things undertaken *en amateur*, it has proved a great success, and gives its shareholders about 20 per cent per annum. It possesses a capital of R200,000, and its net profits since January last, for the half-year ending 30th June, were R87,008! Of this magnificent result, the directors have, however, only given the shareholders their usual 10 per cent for the half-year; and the remainder has been carried to the reserve fund for future dividends.

SCHOOLS OF AGRICULTURE IN THE UNITED STATES AND BRAZIL.

We are glad to see from *O Agricultor Progressista*, a new agricultural journal published in the interests of the *Companhia Zootechnica e Agricola*, that the director of that society, Sr. Domingos Maria Gonçalves, proposes to require manual labor from all the students attending his new agricultural schools. We were misled by the statement in the statutes of the society that "the laborers, watchmen, shephords, field servants, &c., will be by preference admitted and chosen from among the freemen," which, in the absence of any clause specifying obligatory field labor for the students, led us to infer that the work would all be done by hired laborers. In this inference the director informs us that we are mistaken, as manual labor will be required from every matriculated student in proportion to his strength. This is just as it should be. One of the most successful agricultural schools in the United States—the State Agricultural College of Michigan—was founded literally in the forest, and all the work of clearing and breaking up the land, fencing, draining, road-making, planting orchards, as well as the after work of crop, fruit and stock-raising, has been done by students. The land which was once covered with a dense forest of oak, beech and maple, is now one of the finest and most productive farms that can be found anywhere—and all the work is done by students, who are required to work a specified number of hours every day. Many of the most successful farmers in the state are graduates of this school and some of its graduates occupy high scientific positions. It is not claimed that the labor of the students has any great pecuniary advantages, but it gives them a practical knowledge of scentific agriculture, and contributes largely to their good health and physical development. In relation to the profession in whose interests the school is established, it not only makes its graduate practically familiar with all the details of every day work, but it makes them acquainted with the latest and most scientific methods of agriculture, and teaches them to investigate and experiment for themselves. Such a result as this is greatly needed in Brazil. Instead of calling upon the government for an investigating commission when his coffee trees, or his sugar cane fields are attacked by disease, the Brazilian planter should be competent to take the matter into his own hands. He should know how best to cultivate his lands and to obtain the best results. Instead of tilling a piece of land for a time and then abandoning it as worn out, as is now the practice, he should know how to keep up the fertility and productiveness of his fields, and to add to their value year by year. The profession of agriculture should be elevated to the rank of a science, and this can only be done through just such schools as we have indicated.

FALLING-OFF IN COPRA EXPORTS.

The Chairman of the Levuka Chamber of Commerce referred as follows in his annual address to an article of produce which has recently been the subject of discussion in Ceylon:—

"The article, however, which shewed the most serious decrease is the principal export, viz., copra. The official returns clearly give the following as the quantities raisen in the colony:—

	1877	1878	1879	1880
Tons 4372	5513	2714	5168	

"That is to say that Fiji produced 2,000 tons more copra in the two years, 1877-8, than in 1879 80 This is serious and difficult to explain; on a former occasion I assigned two principal reasons—the Government system of collecting native taxes in produce instead of money and the consequent restrictions crippling the enterprise of the individual native, and a drought in the early part of 1879; but exception has been taken to my arguments by a few. Within the last twelve months copra has fallen over 20 per cent in value in Europe, and unless it rises as rapidly again, which we hardly warranted in hoping, or the quantity exported this year shows a considerable increase, a large section of our producing community will suffer severely. The causes of this serious depreciation are difficult to assign, it is true that the present low value of the article at home may discourage some of those in Africa and the East Indies who were tempted to enter European market by the high prices of 1878-9; should such prove to be the case we may then perhaps look for an improvement."

In respect of trade generally he stated:—

"That the value of the total export trade for 1880 exceeded £229,000, of which £51,000 was produce imported and exported again, which was an indication that with care and enterprize the trade of many other islands in the South Seas might be concentrated in Fiji. The value of the produce raised in the colony was nearly £178,000, but the whole of this apparent increase of nearly 35 per cent on the yield of the previous year cannot fairly be claimed owing to certain exceptional circumstances. There is a decrease in the

exports of beche-de-mere, candlenuts, maize, and copra. We (*Australasian*) share the surprise expressed by the chairman that the export of sugar was less in 1880 than in 1879, but we are glad to learn that it is not likely to be permanent, but that, on the contrary, Fiji seems destined very early to take a high position as a sugar-producing colony. The Colonial Sugar Company of Sydney are establishing works on the Rewa River, which, it is believed, will very shortly increase the export of sugar by one-half, and other extensive mills are projected. It is highly satisfactory to learn that in 1880 nearly 15 times as much coffee was exported as in the three previous years combined. On the whole, the chairman of the principal commercial body in the colony speaks most hopefully of the present and future prospects of the export trade. The imports for 1880 exceeded £185,000, an increase of over 30 per cent on the previous year. These satisfactory statistics indicate very clearly that the Fiji settlers are not deficient in energy or enterprise ; and if they accept the advice of their late Governor; and display equal moderation and good sense politically, a bright and prosperous future may be predicted for the Pearl of the Pacific."

SOUTH COORG.

20th September 1881.

I have now to thank you for the correction made with regard to Coorg trees, as also for the specimen numbers of the *Tropical Agriculturist*, which, to use a stereotyped phrase, " does supply a long felt want," and which ought to make the teeth of this Presidency editors water with sheer envy. Their hobbies seem to be Service and Gold, both of which they seem to ride well.

The monsoon has been most favourable for planting operations during the whole of August, and till the present date. During 27 days on which rain fell in August, I registered 10·54 inches, which is 2·806 above the average of the past five years, and with the exception of 1878 heavier than we have had since 1873, from which my record dates. For September, we have had rain on 15 days, giving a total of 3·19 inches and but very little sun—just the very weather we want for making up nurseries &c.

Plants in old coffee and clearings are now looking well, excepting where choked with weeds; and but very few places are in that deplorable state just now, labour being very plentiful on almost every estate, and still coolies come trooping in. Fortunately for them crop will soon be on, when every one of them can be well accounted for.

Leaf disease is showing up here and there on "chicks," but nothing to speak of, and I think our Nalkenaads will remain untouched. I think our mamoty diggings have a little to do with our freedom from disease, as well as our good caste trees. The whole of the Bamboo estates are now dug regularly and to a depth of from six to nine inches. It is found to be far more beneficial to the trees, and only a little more than our old weeding and burying used to cost. A clean estate can be dug by Canarese coolies at R4 per acre, and a dirty one about R4-12. If done by coast contractors the prices will be slightly higher, probably R5 and R7 respectively. Our dread enemy, the borer, has not been so bad this year as we expected, and now that we have become familiar with him, we take his little freaks as a sheer matter of course, and keep on supplying, and with the grand soil and forcing climate we have here, the raising of supplies is comparatively an easy work. In the Ghauts it is almost impossible to get a supply up, but the soil there is poor and the monsoon well worthy of its name.

Cinchonas are doing well both in Ghaut and Bamboo land, the Ghaut having the advantage. With few exceptions succirubras have been the only sort tried. The only exception I know is a nice little field of Ledgerianas which were brought from the hills and planted out this season. They have been most successful so far. We find the succirubras do splendidly under our shade trees and bid fair to outgrow the figs and jacks. I could point out many over six feet high and only 20 months from seed. How does this compare with Ceylon ? With regard to cinchona under shade, the hill planters gave as their opinion the reverse of what we have by experience proved to be a fact; and, if I am not misinformed, Coorg planters having Ceylon experience gave the same dictum with regard to coffee, and now shade is considered by all to be a *sine qua non* for the latter, and any one holding the reverse would be considered a fit subject for a lunatic asylum in the Bamboo.

SALES OF CEYLON AND INDIAN TEA IN MELBOURNE.

Indian tea, season 1881-82. Ex "Rollo," from Calcutta.

10 half-chests (each 40 1-lb packets) Kangra Valley pekoe blackish even curled leaf, strong rich pungent, ripe delicate pekoe. 1s 2¼d.

31 boxes Assam broken pekoe very handsome small wiry black leaf, full of golden tips very strong pungent, rich dark red liquor 2s 1d

44 cases (each 2 22-lb tins) Darjeeling Pekoe small even wiry black leaf choicest full rich mellow, Darjeeling pekoe flavour 1s 7¾d.

50 half-chests Darjeeling pekoe handsome black small even wiry leaf extremely choice rich ripe liquor 2s 0d.

36 cases (each 2 22-lb tins) Darjeeling pekoe souchong greyish-black even wiry leaf very rich full ripe mellow, Darjeeling flavour 1s 5½d.

50 half-chests Darjeeling Pekoe Souchong black even wiry twisted leaf very choice full pungent mellow pekoe souchong 1s 3d.

48 half-chests Dehra Doon pekoe souchong handsome even wiry curled leaf extremely rich, with most delicious fragrant fruity flavour 1s 1¾d.

25 half-chests Kangra Valley pekoe souchong even curled black leaf full fresh brisk malty flavour 0s 10½d

9 half-chests Kangra Valley souchong black curled leaf full brisk malty souchong flavour 0s 11¼d.

43 half-chests Darjeeling Pekoe handsome black small even wiry leaf extremely rich full ripe mellow Pekoe flavour 1s 5d.

50 half-chests Darjeeling pekoe souchong greyish black even wiry twisted leaf choicest full rich delicated, Darjeeling flavour 1s 3d.

41 half-chests Assam pekoe souchong black small wiry even leaf, pekoe tips very strong fine red hick liquor 1s 1½d.

34 half-chests Darjeeling pekoe souchong Greyish black even twisted leaf very rich, very strong, full ripe mellow liquor 1s 3d.

35 half-chests Dehra Doon pekoe souchong black even wiry curled leaf choicest, very rich ripe, delicious mellow fragrant flavour 1s 1¾d.

40 half-chests Darjeeling pekoe souchong black even wiry twisted leaf very choice, rich mellow, delicate, Darjeeling flavour 1s 1¾d.

50 half-chests Darjeeling pekoe souchong greyish-blackish even twisted leaf very strong full rich ripe mellow, Darjeeling flavour 1s 3¾d.

50 half-chests Indian pekoe small even wiry black leaf, full tips very strong rch pungent dark-red liquor 1s ¾d.

50 half-chests Indian pekoe black small wiry handsome leaf, pekoe tips very strong powerful rich ripe malty pekoe 1s 2¼d.

50 half-chests Indian pekoe souchong even twisted wiry black leaf strong full rich ripe, fresh flavour 0s 11d.

50 half-chests Indian pekoe souchong black even wiry twisted leaf very strong rich full pekoe flavour 0s 11½d.

50 half-chests Indian pekoe souchong even wiry twisted black leaf, pekoe tips very full strong rich fresh Pekoe Souchong 1s 2d.

CEYLON TEA.

Ceylon tea, season 1881-82. Ex R. M. S. "Bokhara," from Coylon.

100 half-chests Ceylon Pekoe Souchong black even wiry leaf, pekoe tips very strong full rich ripe, dark-red infusion Passed.

33 half-chests Ceylon Broken Pekoe small even black broken leaf, Pekoe tips very powerful rich ripe Pekoe flavour 0s 11d.

67 half-chests Ceylon broken Pekoe small even black broken leaf, Pekoe tips very powerful rich Pekoe flavour Passed.

Grown on the celebrated Dunedin Estate.

COFFEE EXHIBITIONS.

The projected coffee expositions abroad, however good they may be in theory, can only be effective in practice, if they are placed under the management, not of the Brazilian consuls, as proposed, but of special agents who possess a thorough practical knowledge of the coffee trade, which the consuls seldom possess.

One of the great embarrassments with which the Brazilian coffee is struggling at present is the discredit into which it has fallen in the consuming markets, and this is attributed to two causes. Firstly, to the speculation of some dealers in Europe who, in order to obtain a better price, unscrupulously pass off the best Brazilian coffee as Java or Mocca, and declare only the lower qualities as coming from Brazil. Secondly, to the bad faith of certain coffee producing countries which try to disparage the Brazilian product in order to exalt their own.

In proof of this latter fact a correspondent of the *Jornal do Commercio* cites a circular lately sent by the Minister of Commerce of Haiti to the consuls that of country in Europe, in which he says the folowing :—

"When there is a considerable fall in the prices of coffee, our principal productiou, of which we export more than 60 millions of lb., it is our duty to point out to the nations to whom we send that precious product, how much superior the Haitian coffee, is in taste and aroma, to that of other countries, with the exception of Mocca. The qualities of Guadeloupe, Porto Rico, Cuba and Jamaica, which can compete with ours in aroma, reach the various markets only in insignificant quantities. It is for this reason that in order to improve the bad taste of Brazilian coffee, which is produced to the huge extent of a million of bags, the Brazilians employ the coffees of Haiti and Java."

That circular is being reproduced in most of the commercial papers of Europe, and it does not appear that any Brazilian consul did think of protesting against its assertions.

Few of them probably either know or care much about the subject, and equally few of them would have the capacity, energy, or commercial experience necessary to manage the projected coffee expositions, or to take other steps to improve the position of the Brazilian products and commercial interests a broad.

Canada has set a good example to Brazil in this respect. Desirous of extending her commercial relations with Brazil, and having decided on the measures to be adopted, she did not put them in practice through her diplomatic or consular representatives in Brazil, but named a special agent for the purpose, selecting a Rio merchant of great commercial experience and a thorough practical knowledge of the subject It being decided that the establishment of direct and subventioned steam communications was the first step necessary towards the development of the commerce between the two countries, the agent of the Canadian Government placed bef re the Imperial Government and the representatives of the nation such convincing proofs of the utility of the enterprise that the former promptly granted and the latter promptly confirmed the subvention.

The Canadian Government then made it generally known in the dominion that they had a special agent in Rio always ready and capable of giving to the Canadian manufacturers and merchants any informations and explanations they might desire, and thus the contemplated development of her commercial relations with Brazil is steadily progressing on a sound and practical basis.

Let Brazil follow a similar plan in the execution of her project to hold coffee expositions abroad, and then this project may prove as effective in practice as it is good in theory.—*Anglo-Brazilian Times.*

We are not amongst those who think that the proposed Coffee Exhibitions to be held in England and America will prove of advantage to Brazil. There can be no doubt that the Brazilian coffee trade is just now suffering very severely from a variety of causes, chief amongst which are the various mixtures now sold on this and the other side of the Atlantic to the detriment of the sale of the pure article, and the action of a few unscrupulous buyers who are selling the finest Rio coffee as prime Java or Mocha, and are declaring that only the lower qualities come from Brazil. It would be difficult, we know, to put a stop to this practice, but it would be far more difficult to compel the British or American consumer to pay 1s 8d per lb. for pure coffee when he can get a very palatable substitute for 10d. Almost every English grocer now has a mixture of his own, which is put up in 1-lb. tins and sold for 10d, and we are informed that where a pound of pure coffee is sold twenty of these tins are disposed of. If the planters and merchants of Brazil think that by establishing Coffee Exhibitions here and in the United States they would be successful in changing the tastes of the consumer, we venture to say that they will find themselves wofully mistaken. And, besides where could such an Exhibition be held here to prove attractive and at the same time remunerative, for we presume that it is not meant that they should be carried on at a loss? We have now a Wool Exhibition at the Crystal Palace, but it has proved nothing like the success that was anticipated, and we are afraid that if a Coffee Exhibition were got up it would prove less attractive still, for it must necessarily be of much smaller dimensions, and there would be nothing like the same variety as at the Crystal Palace Wool Exhibition, Most astonishing of all, we note that "it is proposed to have such exhibitions every year." One year's experience, we have not the slightest doubt, would prove quite sufficient to show the inutility of the scheme; and if we wanted any evidence on this point we should only have to turn to the special trade exhibitions which have been held in London during the past twelve months We have made these remarks solely in the interests of the planters and merchants of Brazil, feeling assured that, so far as this country is concerned, at least the establishment of a Coffee Exhibition would prove a great loss to all concerned, and we would counsel them to keep their money in their pockets —*Brazil and River Plate Mail.*

CEYLON TEA IN AUSTRALIA.

(*From Our Correspondent.*)

Melbourne, 12th Sept. 1881.

On the 2nd September, another successful sale of Indian teas ex "Rollo" took place at auction. The trade run on the Darjeeling Pekoe and Pekoe Souchongs paying

for the same from 1s 1¾d for large rough leaf with little liquor to 2s per lb. in bond for even, wiry, leaf with strength. For some rather good broken Assam Pekoe with tip 2s 1d per lb. B was paid. The Kangra Valley teas were too high fired, and Dehra Doon too herby to sell well.

At the same sale, some Ceylon teas were tried, a small line of broken flaky realizing 11d per lb. The other two lines were withdrawn, higher prices than previous sale being evidently wanted and not obtainable at the time.

I send you the *Age* of 6th September containing a full report of the opening of the Calcutta Tea Association (no connection with the Calcutta Tea Syndicate) new premises in King Street, Melbourne. This Association is formed for the wholesale and retail sale of Indian teas only, and have opened large premises in Charlotte Place, Sydney, for the same purpose. Their advertisement offers the public pure Indian teas in ½ lb and 1 lb packets, 5 lb, 10 lb, and 25 lb. tin cannisters, and chests, half-chests and quarter chests. The planters of Ceylon and India should wish this Company every success in their endeavours to sell Indian tea straight. We have blenders here of India and China teas, but this means adding the superior Indian tea to bring up the *very inferior* China tea.

"The Calcutta Tea Association, 26 King-street, Melbourne, and Charlotte-place. Sydney, are now booking orders from grocers and storekeepers for their pure Indian teas, in ½lb and 1lb packages, 5lb, 10lb, and 25lb. tin cannisters, also, chests, half-chests, and quarter-chests, to be sold at 2s 6d., 3s, and 3s 6d per lb.

"Until the grocers are supplied the public can obtain sample packages from our wholesale warehouses.

"The above teas are the produce of upwards of 50 tea estates, blended so as to make the most perfect tea the world can produce."

THE CALCUTTA TEA ASSOCIATION.

(From the *Age*.)

Under the auspices of this Association the Indian tea interests are now making a vigorous atempt to introduce Indian teas to Australia. To this end large premises have been taken in Kingstreet in this city, and also in Sydney, where the operations of the Association are carried on on a large scale. Yesterday a large number of gentlemen, including the leading business men of the city, visited by invitation of Mr. Inglis, a gentleman largely interested in fostering Indo-Australian trade, and recently representative of India at the Melbourne International Exhibition, the stores of the Association in King-street. The building is a large one of three stories, the ground floor being used as an office and store. In the upper story the blending of the teas is carried on by skilled workmen, under the supervision of Mr. Fraser and a gentleman who has been thirty-four years in the trade. The floor is divided into bins and the products of the various districts, principally Assam, Cachar, Sylhet, Darjeeling, Dooars, Kangra Valley, Nilgiris and Ceylon are united, so that the good qualities of each tea may be apparent in the whole. After being properly blended the tea is sent down to the second story by means of shoots where it is packed for sale, and in this room a number of the youth of both sexes are employed. The tea is made up principally in ½ lb. to 1 lb. packages, but a considerable quantity is packed in from 10 to 40 lb. cases. The aroma of the tea was spoken of by experts yesterday in the highest terms, and the purity of the leaf was the subject of remark. In the blending room is the necessary machinery for reducing the leaf if it is too large, and the whole arrangements have evidently been made by those who thoroughly understand their business. About twenty-five hands are at present employed in Melbourne, but forty at least would be required when the Association is in full work. As showing the excellence of the teas offered to the public by the Association, the following analysis has been made by Messrs. J. Cosmo Newbery and Dunn :—

THE CALCUTTA TEA ASSOCIATION, PER MR. J. A. MOODY.

Marks.	Percentage of mineral ash.	Percentage of extract.	Percentage of Soluble salts.
No. 1	5.36	41 42	3.38
No. 2	5.26	42.41	3.35
No. 3	5.32	40.41	3.26

The above samples have been carefully examined by us. They are absolutely pure, and we may add that even the lowest quality of your tea has a higher extract than any packet teas we have examined.

J. COSMO NEWBERY,
FREDERICK DUNN.

The packet teas examined by Messrs. Newbery and Dunn up to the above date comprised the following :—Royal Mixture, Challenge Mixture, Universal Mixture, Governor's Mixture, Exhibition Congou, Taeping Mixture, Oriental Mixture, Family Mixture, International Mixture. Nonpareil Mixture, Celestial Mixture, Steamer Brand Empress Breakfast, The People's Choice, Pbesant Brand, Cock Brand, Pagoda Brand, and Mikado Mixture. After the party had been shown through the building they were entertained at luncheon ; Mr. INGLIS occupying the chair. After the usual loyal toasts had been duly honored, the Chairman said he had a toast to propose which he thought would be drunk with enthusiasm, but before doing so he should like to say a few words to those present. He stated he had been asked as the representative of the Indian Government at the late Exhibition to invite those present to assist in the promotion of the Indo-Australian tea trade. For years past a great trade was being carried on between Australia and India with horses and now India was trying to start woollen mills, in order to utilise Australian wool. What he asked them to do now was to assist the Calcutta Tea Association in pushing the sale of pure Indian teas in the Australian market. Of course there was a prejudice to combat. People were accustomed to Chinese teas, and might think the Indian tea unpalatable the first time they tasted it, but after taking it he would guarantee they would appreciate its purity and flavor. That there was a prejudice against the tea in the public mind was really not an insurmountable obstacle, as those present knew what an unnatural prejudice had been exhibited at first in England to the Austrian wines sent home, which all here knew were pure and wholesome. Another point in favor of the Association teas which would soon make itself felt was the fact of the operations of the Company being carried on by experts. The teas passed through no intermediate hands, but were in the possession of the Association from the time they left the gardens in India till they were offered for sale to the Australian public. That was a sure guarantee that no adulteration would be permitted. Another point in favor of the teas was that those offered to the public by this Association were products of ten or fourteen gardens, blended nicely together, so as to produce the most pleasant flavor possible. The Association intended to go into the trade with spirit, and did not doubt to conquer in the end. As instancing the manner in which Indian tea had increased in popularity in England, he might mention that in London last May 4,500,000 lb. more Indian tea were sold than in May of the previous year, and the total export from Calcutta to London for the month had been 44,500,000 lb. He would now call upon them to drink success to the Calcutta Tea Association.

Mr. E. S. HARLEY begged leave, as one of the oldest tea brokers in the colonies, to say a few words before the toast was honored. He could assure them that the teas were bound to become popular, although a prejudice might exist against them at first. Anyone who had taken Indian teas for a few days would never go back to Chinese. The starting of this Association was of more interest to the colonies than the generality of the public were aware of, and he sincerely hoped the operations of the Association would be successful.

The toast was then drunk with great enthusiasm.

The CHAIRMAN proposed the health of the manager, Mr. Fraser, and spoke in eulogistic terms of that gentleman's qualifications for the post.

Mr. FRASER responded in a few appropriate words, stating at the same time his firm opinion that the Indian teas would soon hold the foremost position in the Australian trade.

The CHAIRMAN proposed the health of the Press, by whose advocacy alone they could hope for a successful development of the industry just started; and after the toast had been suitably responded to the company separated.

SILK-GROWING IN CEYLON.

With reference to Dr. Vanderstraaten's paper on this subject, we may call attention to the following extract from our "Review of Agriculture and Planting Enterprise in Ceylon" published in our Handbook for 1876-78:—

"There is a spot on the banks of the Kelani river 3 or 4 miles above the Bridge of Boats *en route* to Hanwela 'Orte Saide' or Silk Garden where the Portuguese are believed to have fed silkworms. The Dutch unsuccessfully attempted to propagate the Silkworm and produce Silk at Jaffna. In the British period silk has been tried more than once, more particularly by a coffee planter (Mr. H. C. Bury,) in Haputale, on whose produce a favourable report was received by us a few years ago, from a Coventry firm, but the difficulty of securing carefnl skilled labour and the injurious effects of thunderstorms on the silkworms prevented the continuance of the experiment. Sir Wm. Gregory took a great interest in Silk-growing, as in all other experiments with new products. In 1872 he reported that the 'mulberry tree grows quickly and vigorously in Ceylon, and the worms are reported to be hardy and to thrive well, but the difficulty was to find patient and skilled hands to wind the silk.' Accordingly he recommended the dried cocoon to be sent to Europe to be spun, but the cost of female labour in England is another difficulty. Sir Wm. Gregory introduced and distributed Japanese silk-worm eggs in Ceylon."

Dr. Vanderstraaten writes to us in reference to his paper:—"I was indebted to Mr. Alex. Geddes of Moratnwa for the floss silk exhibited. The white is from the Bombyx mori, a Chinese silkworm; the brown is from the Tussur silk moth (Anthercea Mylitta, or A. Paphia). Mr. Geddes finds that the Tussur moth cannot be domesticated. Mulberries are plentiful all over the island, and can bo freely cultivated from cuttings; in two to three years each tree will supply 5 lb. weight of leaves. As a new industry mulberries can be cultivated with tea. It is a profitable and interesting amusement for women and children. Every year about £1,500,000 is sent from Europe to China and Japan for eggs; principally from Italy, where mulberries are plentiful. It is introduced into orphan schools, reformatories, prisons, leper and lunatic asylums: supplies of eggs can be sold to the general public. The early history of Ceylon from Valentyn in 1663 to Tennant has been consulted. In 1663 the Dutch cultivated it in Colombo and Jaffna. When the English came to Ceylon a garden of mulberries and buildings for the rearing of silk worms were found at Orté Sedé (Portuguese for silk-garden) near the Bridge of Boats at Kelani. The silkworms exhibited at the Polytechnic Exhibition were from Father allPas' supply. It ought to be tried more largely now that the experiment has been successful as shown yesterday."

We are glad to learn that an experiment is being conducted so far with success in "silk-growing" in lower Dimbula, and we learn from another gentleman, who has taken considerable int rest in the matter, that, though his experiment in Colombo was a failure, he is trying again with more chances of success, and is inclined to experiment with the very abundant "lettuce" (*Pisonia alba*) tree leaves instead of those of mulberry. If the silkworms thrive on the leaves of this plant, the industry ought to prosper in and around Colombo.

CINCHONA CULTIVATION IN JAVA.

LETTER FROM MR. MOENS:—SIKHIM LEDGERIANAS THE SAME AS THOSE IN JAVA.—PROSPECT OF A GOOD COFFEE CROP IN JAVA.

By all cinchona planters in Ceylon, the following letter addressed to us by the able Director of the "Government Kinakultuur, Java" will be read with much interest: it is of great importance to know that Mr. Moens consider the Ledgerianas in British Sikhim to be the same as his own, seed having already come from Northern India freely to Ceylon:—

Bandong, 22nd Sept. 1881.

DEAR MR. FERGUSON,—I have to thank you very heartily for your kindness in sending me your Directory, which contains so much valuable information about Ceylon and its Planting Interest. And, by the last mail I also received from you Owen's Cinchona Planters' Manual, which appears to me to be a good book, giving a great deal of concise and useful information about cinchona.

On some chapters we would not have the same opinion. I am quite opposed to uprooting or coppicing, as long as there is any chance of stripping or shaving the trees with success. Of course, I understand that with trees, living only five or six years, all attempts at stripping would be vain; and then nothing is left, but uprooting with an experiment to replant.

I found coppicing not a great success, neither in the Nilgiris nor in British Sikkim: many of the stumps failed to make shoots or died afterwards. With us, as a rule, coppicing has answered much better, but, as I said above, I prefer stripping. The gardens at Neddivuttum which had been stripped seven times, looked quite healthy, and I think Dr. Bidie has seen them formerly in a bad time, and that they recovered afterwards.

From my last report you will have seen the analysis of the so-called "pubescens." It does not contain much quinine, but will be improved a great deal by stripping or shaving. C. Pitayensis, which ought to be called C. Trianae, is a valuable kind, as it contains, besides a good percentage of quinine, as great a quantity of quinidine. Cross has told already that they have only about 50 old plants of this kind in Dodabetta; none in Neddivuttum nor in Sikhim. But private planters, Mr. Liddell and others, have C. Pitayensis in rather large quantities.

The Ledgerianas in British Sikkim I found quite the same as ours, and as drought can be more relied upon there than here, a regular supply of seed will be easier to get from Mr. Gammie, than from our plantations. We have had a normally dry season, with about 3 months with very little rain, and I expect to have a good crop of seed in 1882. There will also be a large crop of coffee, for the same reason. The small crop of last year was *not* caused by leaf disease, but by the continuous wet weather.

I brought some "hard Carthagena" plants from Gammie, but they have died. I do not think it a great loss, and fear that it will be found a very poor bark.

With great pleasure I see that Ledgeriana is found to grow so well in Ceylon, and that there are many more trees of this kind than people knew. The more I see of it, the more I find that we generally planted

it too high, and that it flourishes better from 3,200 to 4,500 feet than above this height. They begin to plant it largely now in Java at 3,200 feet, with great success.

Our Ledgeriana grafts go on to grow better than anything else, and I will take a first crop from them by cutting the lower branches in November next, when they will be two years old, since planting. Till now there are no signs whatever of the gloomy predictions of Mr. Cross going to be realized. Some people *will* condemn things they never saw or tried: I am a great friend of the principle of trying. So Cross with the stripping: what does it matter, whether the trees are placed on crutches for the rest of their life after the first stripping, if they produce more and better bark lamed and on crutches, than healthy on their own feet. It may appear cruel to ill-treat a tree in this manner, but we do not keep them for our pleasure, but to get as much and good bark from them as possible. Mr. Cross has very great merits indeed for cinchona cultivation, more than anybody else, by his successful gathering of different valuable species; but he is not at all an authority on the cultivation of cinchona, and has taken great pains to show this in his report.

I think the publishing of your *Tropical Agriculturist* a happy idea; and most people in Java, who do not, of course, take so much interest in the local affairs of Ceylon, will like to have the planting information in a concise form.

Some days ago, I got a letter from Australia telling that old Mr. Ferguson will pay us a visit, and can be expected at Batavia on the 30th of this month about. I hope he will soon come to the hills, and I shall be glad to go with him over the plantations and to introduce him to planters of coffee, tea, or other products which will be of interest to him.
—Yours very truly, J. C. MOENS.

FIBRES.

A Dikoya planter sends us a sample of fibre accompanied by the remark:—

"Knowing you take great interest in new products, I send you a specimen of fibre I have grown here. Could you ascrtain name of same as the plant grows very freely in the present soil." The fibre is not unlike that of the tree-mallow sent us lately by Mr. Hay from Dolosbage, being soft and white and probably more fitted for papermaking than cordage.

Mr. Schrottky, who saw the sample today, condemned it as too weak, putting its value at £15 a ton (against £400 for rheea grass which is the fibre to be experimented with here) and his opinion is fairly borne out by a merchant with Calcutta experience, to whom we submitted the specimen. He writes:—

"The sample of fibre, which appears to be jute or one of its congeners, is of fair staple, fairly cleaned, but short, containing no No. 1 of the ordinary Calcutta classification, but little No. 2 and to be composed of No. 3, 4, 5, with pieces, worth on the average, about £15 to £16 in London, or about £10 per ton here. You should tell your friends that it is well to avoid cutting off pieces of quality like those in the sample, the cutting diminishing the value of the staple which should be as long as nature produces it. It is only rough ends, coarser in texture than the run of the filament that are cut off, and the pieces I see in the sample do not appear to partake of such roughness. A longer staple would command about £18 to £20 per ton in London, and its equivalent here, and this will help to guide your friends *re* the remunerativeness of the cultivation.

GENERAL PLANTING REPORT FOR CEYLON.

WEATHER.—North of Kandy, the planting season cannot be said, so far as it has gone, to have been a good one, and there are still a number of cinchona and other clearings to plant. In Dimbula, Dikoya, Maskeliya and Ambegamuwa, the rainfall has been up to the average, but it has been very irregular, coming down generally in heavy pours succeeded by a week or so of drought, which is not desirable planting weather. There is every prospect of a wet north-east monsoon, which is likely, on the whole, to do good to coffee and other products, although it may interfere with curing operations.

BLOSSOM—CROP PROSPECTS AND CROP GATHERINGS.—Crop prospects are not as good as they were in the early part of the season. A great deal of the blossom did not set, and some of what came on is dropping off half ripe, ordrying up at the points of the branches. Leaf disease is blamed for the whole of this, and no doubt correctly. The lower districts, and favoured estates in the higher districts are doing well, and it is nothing unusual to see fields, or portions of fields, with from five to ten cwt. an acre. It is quite true that a smaller proportion will ripen than did formerly, but it is encouraging to see coffee trees in these days with such good crops on them. If some districts and estates are doing well, this cannot be said of others, such as many at high elevations, and with a westerly aspect. Many such estates are not giving a cwt. an acre. And Uva, which has been the means of keeping up the total crop for several years, is likely to be short. It is to be feared that next year's crop will not exceed 600,000 cwt., if it reaches that figure.

LEAF DISEASE.—Lately we have heard less about leaf disease becoming modified, or passing away. There are few, but hope that it *will* pass away of its own accord, although thus far there is no appearance of it. People have almost lost hope in a remedy of a practical nature being found to eradicate or even modify it to any considerable extent. Manure seems to be the best remedy for it, but with short crops few can afford to apply it. Meanwhile coffee, the greater part of the year, looks as well as could be desired, and no doubt it would again bear as formerly, were leaf disease removed.

NEW CLEARINGS.—There is hardly such a thing out of Uva as a new clearing for Arabian coffee. Cinchona clearings are being planted and supplied, the latter being a work that never seems to have an end, so many are the failures from sun, wash, canker, insects, &c. In the low-country the areas of tea, Liberian coffee, cacao and cardamoms are increasing, but not so rapidly as they would if money were more plentiful. Those engaged in planting new products have not the slightest fear of failure where soil and climate are suitable. Liberian coffee in particular gives great promise, and before long will astonish those who, knowing very little about it, have taken it upon them to warn others from planting it. There is now Liberian coffee in partial bearing on many estates, and the yield where planted with the proper number of trees per acre is almost incredible. With regard to pulping it, this can be done without any very great difficulty. A Liberian pulper has not yet been perfected, but no doubt one of our engineering firms will soon turn out a satisfactory machine.

LABOUR PROSPECTS.—At the end of last crop there was a good deal of labour in the country, but the strictest economy being the order of the day, all surplus coolies were paid off. Many got work from sub-contractors on the railway, but after a short time a number of contracts were stopped and the coolies thrown out of employment, without being paid in some cases. It is said, after this many left the Island and went to

their villages, and at present there is no surplus of coolies, but scarcity, in many districts where coolies are required for planting, or to assist in taking in a larger crop than usual.

Roads—Railway and Transport.—Roads at present are generally in good order, probably owing to the traffic being little than in former years. On the Dikoya road there has been a great increase of traffic, on account of the railway works, and it is a very common thing for carts going to Dimbula taking this route, which, though longer, is easier than the Kotmale road. There is no valid reason why Government should any longer refuse to undertake the entire upkeep of this road, seeing so much extra traffic is thrown upon it.

The coaches now running on the Dimbula and Dikoya roads are a great convenience, and are well patronized.

Manuring, &c.—Very few estates are now able to afford artificial manure, and many long ago broke up their cattle establishments. However not a few old estates still retain their cattle, it being well understood that to give up manuring where it has been continued for years is almost equivalent to throwing up the estate, and this is especially the case with old coffee. Where it can be done, manuring still pays; the trees are kept in good heart, and a larger proportion of the blossom sets.

Medical Ordinance and Health of Coolies.—Medical Committees have been doing their utmost to keep down expenditure, and reduce the assessment to rates that estates can pay. It is the manifest duty of Government in the present depressed state of the coffee industry to remove this burden from the shoulders of the planters, and let it be borne by the general revenue. It will probably come to this in the end, and the sooner the better. On low-country estates there has been a good deal of sickness during the past six months, but not so much as there has been among the Sinhalese in the villages. Kurunegala has been unusually unhealthy for many months, but is now improving.

new products:—cinchona, tea, cacao, cardamoms.

Cinchona.—The planting up of cinchona in coffee has been more general than ever this year, and where it is not being done, or done on a small scale, the reason is that sufficient forethought was not given to the preparation of nurseries, and the purchase of plants cannot be afforded. Planters have at last come to realize that Arabian coffee alone cannot now be depended on, and something else must be planted along with it. Cinchona answers this purpose best, where the elevation is suitable, but succirubra cannot be planted with more than 200 trees to the acre without injuring the coffee, and the branches must be kept well lopped. When succirubra is over 5 years old, 100 trees per acre are as many as can be had, without serious injury to the coffee. In the case of officinalis, much closer planting is practicable without harm to the coffee, and as many as 1,200 to 1,500 per acre may be planted, if they are thinned out when they reach 4 years old.

Tea.—No cultivated plant seems to grow so well and readily as tea, and there cannot be the slightest doubt that when Ceylon tea planters have attained the requisite skill in the manufacture of it they will be able to compete successfully with Indian teas. We have great advantages over the Indian tea districts in climate, labour, and means of transport, and we shall be able to put our tea on board ship at a lower cost than it is possible for them to do it. What we require is to give increased attention to "manufacture," and be able to turn out really good teas, and then without doubt tea cultivation will be one of the best investments in the Island.

Cocoa.—Nothing is likely to pay better than cocoa, but it will not grow everywhere. Good, deep soil is required, and perfect shelter from wind. Under these conditions it will pay handsomely. It grows well up to 2,000 feet, and even higher. It does not object to a rainfall of 150 inches, and finer trees or pods cannot be seen everywhere than those Mr. Drummond can show on Gang-warily, where there is a considerable rainfall.

Cardamoms.—The area under cardamoms is rapidly increasing. They can be grown from a few hundreds up to 4,000 feet, although they bear best at from 2,000 to 3,000 feet. The cultivation is very simple, and a very moderate capital is required. Should a large quantity be produced, many fear there will be a fall in the price. Those who are fortunate enough at present to have an acreage of cardamoms in bearing are reaping a rich harvest.

TROPICAL AGRICULTURE IN THE SEYCHELLES ISLANDS.

The *Ceylon Government Gazette* gives as a Supplement a report by the acting Civil Commissioner of the Seychelles, Mr. Cockburn Stewart, (formerly Private Secretary to Sir Hercules Robinson in Ceylon) on the agricultural resources of those dependencies of Mauritius, and observations on the same by Mr. J. Horne, Director of Forests and Gardens at Mauritius. These are published at the request of the Mauritius Government in the hope that capital will be attracted to the islands. Unfortunately Ceylon has at present no capital to spare, but some of our planters may wish to try their fortunes in the Seychelles, and shew the Seychellois "how to do it" with regard to coffee, &c. But it will be seen that they will have to undergo fumigation on arrival there, lest some of the insidious spores of hemileia should be concealed about their persons! Mr. Stewart's letter is dated 20th June, and is addressed to the acting Colonial Secretary at Mauritius. He begins by stating that the present is a turning-point with regard to the future prosperity of the islands, on account of the coconut disease having assumed such alarming proportions as to threaten the extinction of that product. It is, therefore, all the more necessary for other products old or new to be extended or introduced. Hitherto the area of Mahé, the principal island, has been unascertained, the report of Mr. Salmon for 1878 putting it down at 110 square miles, or 70,400 acres, of which 40,000 were estimated to be forest. Mr. Stewart has had careful measurements taken, however, which show that the total acreage is only 34,749 acres. He says:—

"Of these 34,749 acres, about 12,000 acres are planted in coconuts, and 9,500, as according to a return which I caused to be prepared, are divided into estates not planted with coconuts, and of which about 500 acres are planted with vanilla, cocoa, coffee, cloves, maise, manioc, &c., and 1,500 is forest. The addition of these figures, viz:—12,000, 9,500, 1,500, gives 23,000 acres. We find that there remain 11,749 acres of non-cultivated and waste land. Of these 11,749 acres, 8,000 are well suited for vanilla, cocoa and coffee planting, which, with the 9,000 acres referred to above as divided into estates not planted with coconuts, gives a total of 17,000 acres of land admirably suited to the production of every known spice, vanilla, cocoa, and coffee."

The three principal products of Seychelles in the future he says will be vanilla, cocoa, and Liberian coffee. Of vanilla there were 150 acres planted, one-half being in bearing. At the last Paris exhibition

Seychelles vanilla obtained the first prize, and the present market value in Paris is 80f. per lb. That the culture is a profitable one may be judged from the following :—

"An ordinary vanilla plantation, or "vanillerie" as it is called here, is about 5 acres in extent, and at a moderate computation represents a production of 250 lb. of vanilla per acre. A clear profit of 10 rupees a pound after deducting all expenses of production, shipping and freight to Europe may be accepted as a fair calculation, thus giving a profit of 2,500 rupees an acre. To refer to actual facts, I may mention that Mr. Serret, a member of the Board of Commissioners, who possesses a vanillerie here, informed me that last year he was offered 100 francs a kilo or about £2 per pound for his first crop of vanilla, which represented 270 lb., and that this year his second crop is estimated at 600 lb., of which 400 lb., are actually gathered. Mr. Serret's estate is 7 acres in extent, with 5½ planted, and is worked entirely by twelve African boys."

As to cocoa we read :—

"There are about 100 acres of cocoa in cultivation, and the quality is pronounced by judges in Europe to be unsurpassed. The cocoa from here took the first prize at the International Exhibition of Paris. The cocoa tree bears in the fifth year after it is planted, though, in some instances, it has been known to bear after three years. It thrives magnificently, and the trees everywhere are healthy and vigorous, and seem admirably adapted to the soil in all parts of the Island. It will grow well at Praslin, Silhouette, Félicité and La Digue."

But Liberian coffee is *the* culture *par excellence* for Seychelles, Mr. Stewart thinks, and he describes 42 trees obtained by a Mr. Cauvin from Mauritius in December 1878, and which at 30 months old were from 8 to over 10 feet high, and were covered with berries. Mr. Cauvin states that they had blossomed in November 1879, May and November 1880, and May 1881. The ordinary coffee also grows well on these islands, 70 acres being in cultivation, the quality being good, and the flavour excellent. Regarding other products Mr. Stewart says :—

"The attention of the Seychellois has again been attracted to the cultivation of cloves, and there are 150 acres under cultivation. I say "again" attracted, for I regret to say that the lazy habits of the people have led to the wanton destruction of acres of this spice. Mr. Horne, the Director of the Mauritius Botanical Gardens, in his admirable Report on these Islands, dated the 20th May, 1875, writes as follows :—"The manner in which the Islanders gather the cloves is both reckless and wasteful; they cut off all the branches of the tree, although they are well aware that several years must elapse before the trees again reach the bearing stage, and in fact that many of them will die altogether. The cloves could easily be gathered from the highest trees by means of a bamboo ladder, and Mr. MacLeod, H. B. M. Consul at Mozambique, writing of Seychelles in 1859, twenty-two years ago, says, "This year two-thirds of the cloves that are produced by the remains of the spice gardens established by Mahé Labourdonnais were left on the ground for want of labour to save them." Since that date they have been cut down for firewood. The value of the Seychelles cloves is about £4 the 100 lb. The last lot sent home realized £6 the 100 lb., but this was exceptional. Pepper grows wild in these Islands, but although attention was called to the desirability of cultivating it by Mr. Horne in 1875, no attempt has as yet been made to make it a productive industry. I am glad to say, however, that I have induced several of the inhabitants to commence to cultivate it, and have promised to endeavour to import two or three Malays from the Straits Settlements who understand its culture and manufacture to show them what should be done to render this plant, which is indigenous to the Island, a source of probable cultivation. Cinnamon is allowed to grow waste, and no attention is paid to nutmegs, allspice, arrowroot, ginger, saffron, and cardamoms, all of which could be extensively cultivated. I am taking every step in my power to impress upon the people of Seychelles the importance of this place as a spice producing country, and using every endeavour to give an impulse to the nascent desire of the more advanced of the population to adopt such ideas. It is impossible to imagine a country more favoured by nature than Seychelles. Though near the equator, the great heat common to the tropical countries is not experienced, and hurricanes so destructive to agriculture in Mauritius and Bourbon never visit these Islands. The country is notoriously healthy and exempt from all epidemic diseases and endemic fever, and well watered streams and rivers, and, as I have endeavoured to point out, peculiarly adapted to the cultivation of every known product of the East or West Indies. Cotton used to grow here, but has for years past been uncultivated. Mr. MacLeod, referring to Seychelles cotton in 1859 says "From 1817 to 1827 a flourishing and lucrative cotton trade was carried on at the Seychelles, and it requires only labour to compete with America in this article which it produces of the very finest silky Sea Island quality." It grows wild on some of the outlying islands, but its cultivation has never been attempted. There is no better tobacco grown in the East than Seychelles tobacco, yet but little is exported, and the preparation is still crude and unskilful, a fault easily remedied by the introduction of two or three Malabars from the Coast of India skilled in the preparation of Coringhy tobacco."

It is difficult, as Mr. Stewart says, to understand how, with all these advantages, the agriculture of the islands should have so long remained undeveloped. The reasons he gives are that the islands were almost unknown, and the land is mostly the property of private individuals unable from want of capital and from natural apathy and indolence to cultivate the lands. The teak tree will grow admirably, and it is proposed to replant the forests with it. At present there is only one specimen, 2½ years old, and 20 feet high. Mr. Stewart then refers to the labour question, the supply having been hitherto obtained from the liberated slaves brought to the islands in 1878 by H. M. S. "Ruby." In conclusion, Mr. Stewart touches on the coconut disease, regarding which a separate communication has been sent to our Government, but is not published here. He says :—

"The cultivation of the coconut tree is one which is peculiarly suited to the indolent habits of the people. A tree is planted and reaches the bearing stage after twelve or fourteen years without any further care. The fruit falls to the ground, and the only trouble required is to gather it. Although I cannot help feeling that the appearance of this disease will lead to the increased prosperity of the Seychelles Group, inasmuch as it has turned the attention of the inhabitants to the fact that their present easily cultivated staple produce will not continue to last for ever without some care and attention, and has awakened them to the consciousness that the cultivation of other products for which their country is so suitable is an assured success, and within the reach of the most of them, still it behoves Government to take energetic steps to endeavour to combat the progress of the disease. I have addressed you separately on this subject by this mail, going into full particulars for the information of His Excellency the Lieutenant-Governor. I will only add, therefore, that the disease is caused by a species of borer which, introducing

itself into the trunk of the tree, gradually works up to the top, when the tree dies, and that I believe the appearance of this insect is due in a great measure to the utter want of care bestowed upon the trees by its cultivators. I cannot but hope that some easy remedy may be found to combat successfully the damage which is caused by this insect to the coconut cultivation of these Islands."

Mr. Horne's letter is a running comment on Mr. Stewart's. We extract the following paragraphs :—

"All purely tropical agricultural products thrive in Seychelles in a most admirable manner. Cloves, pepper, and cocoa grow without any attention or care from the inhabitants all over the country, as if they were indigenous, especially in Mahé. The common coffee, and cinnamon, escaped from former plantations, may be seen growing like native plants in many parts of the forests and in nearly all the islands of the Archipelago. A species of vanilla (*Vanilla Phalaenopsis*) "Liane sans feuille," is wild, and everywhere, in sunshine or shade, this plant may be seen scrambling over the rocks. The semi-spontaneous growth of these kinds of plants not only shows how well the climate and soil of Seychelles are adopted to them, but it clearly indicates the success which will attend their cultivation whenever seriously entered upon. Experiments in their cultivation are not needed. The planters have simply to plant, cultivate, gather, and prepare the produce for the market. The suggestion of introducing Malays who understand the cultivation of the pepper and preparation of the produce for the market is an excellent one. Liberian coffee is likely to take the lead, and it will grow well on every part of these Islands, whether the land has been planted with coconut trees or not—sandy beaches of a saline nature, perhaps, excepted; cocoa will thrive best in the sheltered fertile valleys in the interior of Mahé, Silhouette, Praslin, La Digue, &c. Care must be taken not to introduce plants nor seeds, &c., of the Liberian coffee, nor of any other thing from Ceylon, for fear of introducing the coffee leaf fungus, which has been so disastrous to the coffee plants in that country, Southern India, Singapore, Java, &c. This fungus was introduced to Fiji with coffee sent from Ceylon. The Government of that colony put itself to great expense in endeavouring to extirpate it, and, according to latest information, success was very doubtful. The introduction of this pest would either ruin Seychelles as a coffee growing country or greatly detract from its value as such. A good precaution against its introduction would be to disinfect seeds, &c., coming from any of these countries into Seychelles, with sulphur and lime, &c., and even people's clothes, whether in portmantcaus or on their owner's back. It may safely be concluded from a mass of evidence that no variety of the coffee plant is exempted from the attacks of this fungus, and that of Liberia suffers severely in Ceylon.

"The teak tree appears to thrive in Seychelles; so also will Sal, Sissoo and Toon, which are among the principal useful forest trees of tropical India. These should be freely introduced to the forests of Seychelles. So also the South American Rubber trees, viz: Manihot glazovii (the Ceara Rubber tree) Heveas and Castilloas. Plants of the two former will be sent to the Chief Commissioner as soon as the young plants will be fit for transportation. Three Wardian cases of Nutmeg plants will also be sent at an early date. No opportunity should be lost in making the Crown reserves useful to the community, and making them self-supporting if not remunerative beyond their up-keep and watching. While not unmindful of exotic species, which will flourish in Seychelles, I would draw attention to some of the most useful of the native forest produce, the growth of which ought to be encouraged. These are in order of merit. Bois de Natte (*Imbricaria sps.*) This tree yields a timber which rivals the mahogany—Bois de fer (*vateria Seychellarum.*) This large forest tree yields a most excellent and endurable timber. Capucin, (not yet botanically known) also grows to a large size and yields an almost indestructible timber of great value. Gayac or Faux Gayac (*Afzelia bijuga.*) This tree attains large dimensions and grows in rocky land by the sea shore. Its timber is of great value and repute for a variety of domestic uses. Bois rouge and Moiré are of smaller import, but still worthy of preservation and increase. The same may also be said of the Filoa, which thrives on the poorest of soil, and sometimes attains a height of 150 feet with trunk whose diameter is nearly 7 feet. The Lette (*Verschaffeltia splendida*) is a large growing palm whose trunk is split and the outside slabs are used as palisades in house building. Palmiste Haut Baum (*Stevensionia grandifolia*); the large entire leaves of this palm are used for thatch. Palmiste Choru (*Dickenia nobiles*); the heart of this tree is a most useful and excellent vegetable. Owing to the numbers of it which are annually felled, and as there are none planted to replace those cut, the tree is becoming more and more scarce. The extension of this tree in Government forests is most desirable. Coco de Mer (*Lodoicea Sechellarum*) is, not only on account of its uniqueness and rareness, but also on account of its utility, a subject worthy of attention and care. It should be planted in all the reserves. Cocoa marron (*Curculigo Seychellensis,*) yields leaves useful for cordage, and also for enveloping tobacco, &c. This list might be added to, but I hope it is sufficient to show what is meant. In fact the growth of every wild plant that is of utility, even in remote degree, to the community should be encouraged in the Government forests; and the little raspberry (*Robus rosaefolius*) which yields a fine fruit, and also fine apples, which grow wild and by the acre where nothing else would thrive. Another plant, Bois dur, (*Plectronia bibractiata,*) is the source of the beautiful walking sticks for which Seychelles is famous. On this account it will soon become extinct. It thrives on soil of the poorest description, and it is worthy of preservation in Government reserves suitable to its growth."

NEW PRODUCTS IN THE LOW-COUNTRY OF CEYLON.

GENERAL REPORT:

CACAO AND CRICKETS; LIBERIAN COFFEE; LEAF DISEASE; WHITEANTS; THE RAILWAY AND LOWCOUNTRY TRAFFIC.

Western Province, Oct. 3rd, 1881.

The weather of September was showery up to the 20th, after which we had eight days dry and hot, when it again became showery.

I was rather hasty in assuming, in my last report, that the crickets had moderated their ravages. It was only a lull of a few days, after which they set to work with fresh vigor, and are still going on; cutting leaves even on last year's plants, cutting daily fresh plants, and destroying the buds by which those cut formerly were endeavouring to re-establish themselves. Already twenty-five per cent of the last planting have been cut, and, as they continue to operate up to the middle of November, they have time to do a great deal more injury before they die. For two years I have been trying to observe their habits, with a view of counteracting their operations, but my progress has not been encouraging. I know that they begin to appear about the beginning of March and that they disappear about the middle of May; that they reappear in the latter end of August, and again dis-

appear in the middle of November. I know that placing the young plants in baskets is not an absolute protection, but it is the only means of saving them I have discovered. When the plants are put out in the field, they continue cutting the stems, till they are eight or nine inches high, after which they begin to cut the leaves. A circle of green leaves stuck in round the plants is a partial protection, but only so long as they remain green, and they are quite as bad in new as in old land. Plants once cut, they return to again and again, season after season, and they follow no rule as to where they attack. All parts suffer alike in the course of the season, and the plants are not fairly out of danger till they are over one foot in height. As some lands are entirely free from this pest, I believe it is a speciality of soil that suits them. They burrow deep down (sometimes as much as eighteen inches) and they can only do so in a light sandy loam. It is the same soil that suits the batali, and the earthworm. Our jungle is an impenetrable thicket of the one, and several inches of our surface soil consists of the castings of the other. So far as I can judge, these insects have no enemies. They only leave their burrows at night, and we have no terrestrial insectivore of nocturnal habits. The hedgehog would be an exceedingly useful creature among them; but we have neither that nor any other creature of like habits.

The soil, however, that suits batali, earthworms, and crickets, seems equally suited to Liberian coffee, so that we must, as the old proverb has it, "lay the head of the girse to the tail of the sow," and thus we may work out a tolerable result from the given factors. Besides, a close observation of the facts and constant reflection on them may, by-and-bye, result in the discovery of some mitigating appliances that will, in some degree, stay the waste of plants that has so seriously affected our progress here. The coffee still continues to grow rapidly, making two branches a month: the older trees seem, however, to have called a halt, in their vertical extension, at from five to six feet, and are now giving themselves chiefly to lateral growth.

Leaf disease is not extending. I still stump any plant that I find it on, prior to branching, but my eye spares one in full growth with several pairs of branches, and leaves more extensive than a lady's bonnet; as I find it is the small-leaved varieties on which it permanently fixes.

The whiteants have, in a great measure, moderated their attacks on the young cacao, but the crickets are now cutting a good many of them, and, as the nursery plants are safe and thriving where they are, I am not anxious to expose them in the field till the cricket season is over, and I am in hopes that the liming I propose to give them in planting will deter the ants till the ground settles about them. The white ants always make a minute examination of any newly moved soil, in search of anything that may suit them, and to establish their runs against dry weather.

We have had such frequent, if not very heavy, rains during the last five months, that weeding has been a rather serious matter. We have got pretty well clear of the special jungle weeds, but have in their place the goat weed, and several other troublesome annuals. The worst enemy however and the most persistent is pasture grass, of many species, that if left to nature, would in a few months turn the property into excellent feeding ground for cows and oxen.

I sowed ten thousand coffee seeds about ten days ago in the sheds, and as I treated them with a good dose of quicklime I will be able to report its effects in due time.

I have 3¼ acres of new clearing ready for planting, with twelve chains of cart road, a bambu fence of ten chains, all the ant-hills levelled down, with some draining and embanking; all at the moderate cost in coolie labour of R63. If I had got a good fire, I would have saved five rupees of this outlay. The 27×24 inch holes have still to be filled up, and the batali roots to be extracted, which will bring the whole cost of the 3¼ acres up to R100, or say R30 per acre. I have made this a test piece, to ascertain the lowest figure for which an acre of Liberian coffee could be put down by Tamil labour; but it has cost a good deal of personal exertion, and the consumption of a good deal of extra beer. To enjoy beer a fellow wants to be out in the field all day in this climate, keeping his eye on all that is going on, bullying, coaxing, scowling, warning, instructing and in desperate cases cuffing. Then wending his weary way home, he immediately, on arrival, has a vessel ready that will hold a whole bottle, and empties it at a draught. Jove never so much enjoyed the nectar handed by Hebe, as the old planter enjoys that draught of beer. Far be it from me to advise young planters to forswear tea, coffee, cocoa, and other such innocent beverages, and addict themselves to beer, but I state a fact as it concerns myself; though from necessary economy I am obliged to do without it, for the most part.

It seems as if the various departments of Government do not work together for the general benefit. This estate is beginning to have some traffic with Colombo, and it became necessary for me to consider how it was to be conducted most economically. We have a railway station within 7½ miles, and I have no complaint against the charges made by that institution; in fact, so far as the railway is concerned, there can be no competition, but it has pleased the Provincial Road Committee to establish two tolls within three miles of each other, and if I send an empty cart to bring a load from the station I have to pay at both tolls, first going and then returning R1·38 for a single load, using 7½ miles of minor road. The toll ordinance provides, that a cart passing a toll with a load shall be free when returning empty the same day, but it makes no provision in favour of a cart that passes empty and returns the same day with a load, though I fail to discover any reason for making a difference. The two tolls in question belong to two different minor roads, the junction of which is well within half a mile of the railway station, and the grievance of this neighbourhood could be easily remedied, by moving the one beyond the junction on its own line or franking the one by payment at the other. Till one or other of these courses be adopted by the P. R. C., I will, in common with my native neighbours, conduct the traffic of this estate by cart altogether, and save something over a rupee on each load. It is not the only instance in this province in which the Road Committees wink at toll-renters, establishing themselves at points where they can intercept the traffic, on roads already amply supplied with those institutions, but in this case a not inconsiderable amount of traffic is forced away from the railway by the multiplying of tolls on the roads leading to it. If the Provincial Committee would make a regulation, that, where any two tolls are within five or six miles of each other, payment at one shall frank the other, the public would be satisfied; but if that or some other equally just arrangement be not made, and that soon, there will be agitation on the matter that may not not be successful, but will certainly be troublesome. I can, in some cases, travel nearly twenty miles, and come across only one toll, but here are two to pay within three miles.

Correspondence.

To the Editor of the Ceylon Observer.

THE CEYLON TEA-PLANTING INDUSTRY AND COLOMBO EXPORT TRADE: A GOOD SUGGESTION.

22nd Sept. 1881.

SIR,—I think, now that tea is being produced in large quantities in Ceylon, that some one should set up in Colombo, offering to buy tea in bulk, paying for it according to quality; blending and exporting as deemed best.

I am sure that an institution of this sort would pay well, and save the producer much labour and trouble, having simply to send away his store boxes and have them returned when empty.—Yours faithfully,

TEA IN STORE.

LIBERIAN COFFEE CULTIVATION.

SIR,—There is a letter in the "Times" written by a party with a deliberate intent to injure the progress of the new industry. He concludes by signing himself "Don't," but he gives not one sound reason for abandoning the cultivation of this variety of coffee. He is evidently a grossly ignorant individual, and has very little idea of cultivation. When the maritime provinces were taken by the British, there existed a trade in coffee such as found its way from the *native* gardens. Several years after the capture of the Central Province, the *cultivation* began and took nearly 10 years before it began to attract much capital. The plants and stumps could then have been got for the mere collecting.

In these depressed times, with the price of Liberian seed and plants is too high for the mass, it is a matter of surprise, that the cultivation of this species has made so much progress in three years. Now that the seed is approaching reasonable prices, the cultivation will rapidly increase and *is* increasing, if a comparison is made with the present and last year's planting. I know that mistakes in the selection of land will be made. It was a mistake to suppose that it will suit *any* soil in the low-country; but that there are between 20 to 30 thousand acres available in and around the Central Province chiefly, I have no doubt. In three years to expect a new cultivation to assert itself is absurd. Even the oldest estates can hardly expect much, so soon. The tree takes five to six years to be well developed. The writer seems disappointed in not finding the gentlemen he mentions millionaires already; but if his connection with the island lasts 10 years more, he will see the day when it will export as much coffee as it did in 1875 and 1876, but of this coffee more than ½ and likely a half will be of this Liberian variety, realizing nearly as much as the Arabian; for John Bull's prejudices will be then considerably toned down, as it is now in the matter of China *vs.* Indian teas.—Yours,

PROGRESS.

CEYLON TEA IN LONDON: TAMBIES AND QUININE.

4, Guildhall Chambers, London, 9th September 1881.

DEAR SIR,—It will, perhaps, interest you and your Ceylon readers to hear what was said on the subject of Ceylon tea by an expert tea-taster and valuer. He said:—"The Ceylon varieties show the thin pale liquor, large half rolled leaves, and dull infusion, which formerly marked the Java teas. But vast improvement has been obtained in the latter, now fetching excellent prices. Formerly they were under the ban in the London market, as the Ceylon teas are now. The splendid bright infusion so marked in the Indian tea is conspicuous by its absence in those from your island, which have the dark color of China qualities. Get the planters to pay less attention to the *make* of the leaf. Produce the *yellow tip* so much thought of in the London market, improve the infusion, and let there be fewer coarse leaves in the shipments. Prices are then bound to improve." This gentleman kindly supplied us with sample boxes of Indian teas and one of Java tea. These we are sending on to you by a gentleman returning this month to Ceylon; so that you can see what is required.

Let us cordially endorse all that was said upon the subject of the home sale of your teas by your Northern correspondent. Every word of his letter was to us, working in the same field, pregnant with truth.

A short time back in "Planting Notes" from the Matale direction your correspondent spoke of a tamby hawking quinine about the country at a low figure. The following may perhaps explain his query. We received from India not long ago an indent for 100 ounces of sulphate of quinine. The label was sent as a guide and a sample bottle was to follow. We forwarded the label to the manufacturers, giving the order. We received a sample bottle from them. Shortly after, the bottle from India arrived. On comparing the two, it was clearly apparent that they were very different in quality. Both were taken to the manufacturers, and the matter was very simply explained. The bottle from India contained cinchonidine (worth 3s 3d per oz.) instead of quinidine (worth 5s 10d per oz.). The process was perfectly simple. The cinchonidine label had been removed upon arrival in India, and a sulphate of quinidine label substituted; the swindle being the more easily effected as the waxed impression of the English firm remained intact. Be careful when purchasing quinine from tambies and "see that you get it" is the moral of the above.

It would, perhaps, have been better, if Mr. W. Turing Mackenzie's friend, who made the laborious hunt after Ceylon tea in London, had applied for the information he required at the offices of one of the firms connected with your island. Mr. W. Sabonadicre, Mr. Delmege, ourselves, and others, are established in London, and he could doubtless have obtained the tea from one of these sources. Our advertizement appears weekly in the *Ceylon Overland Observer*, and for Ceylon produce, passages, shipment of goods, and parcels, and all information regarding the island, we are at everybody's service who calls at our office. Trusting we have not taken up too much of your valuable space, yours faithfully,

HUTCHISON & Co.

ANALYSIS OF CEYLON LEDGERIANA BARK.

Mattakelly, Lindula, 29th September 1881.

DEAR SIR,—I enclose Messrs. Howards' analysis of eight samples of bark taken from eight cinchona Ledgeriana trees grown here, being about five and a half years old when the bark was taken.

The results will, no doubt, be interesting to your numerous readers now engaged in cinchona cultivation, and may be doubly so to you, when I tell you, I am indebted to your senior for the seed from which these trees were raised.

The selection for analysis from among the other trees was made by Messrs. F. A. Fairlie and J. A. Campbell, showing that selection botanically may be cultivated to a high degree, as Nos. 1, 2 and 3 on the list will prove.

Since these were picked out for analysis, we have had the advantage of seeing most of them blossom, as well as a good many of the others grown from the same seed; and judging botanically, we expect, at least, the same average richness over the whole. I trust Mr.

Ferguson will he able to recollect the source from whence he got the seed. A historical account of these trees, when we know the source of the seed may be interesting, since as far as I know they are among the oldest amongst their species in the country, while the analysis leaves no doubt of their being pure "Ledgeriana."—Yours faithfully, WM. SMITH.

Analysis by Messrs. Howards London, of 8 samples of C. Ledgeriana bark taken from trees 5½ years old, grown on Mattakelly Estate, Lindula :—

GUM TREE LEAF DISEASE AND THE CONSEQUENCES.

Lindula, 24th September 1881.

DEAR SIR,—While I was in England two years ago, my gum trees were almost annihilated (in fact one or two were killed) by a peculiar leaf disease, which appears in the form of round spots, varying according to the size of the leaf from pin's head to a three-penny bit. *Hemileia* does its work from the stem outwards towards the tip of the branch: but this disease commences at the tip and works in towards the stem. It has all the potency of the true leaf disease, and is, I am sorry, to say this year not only stripping the gums of all their foliage, but playing havoc with my cinchonas, especially unfortunately with my Ledgeriana. That the disease comes from the gums is beyond doubt, for every piece of vegetable matter near a gum is affected, while there is not a vestige of the disease where there is no gum. I have some sixteen varieties of eucalyptus, and as far as I can see they all suffer alike. I herewith send you leaves of gum, rose, oleander, gladiolus, strawberry, plum, and cinchona, to show how similarly, indiscriminately, and virulently this fell enemy is doing his work. You will observe that the spots gradually surround the leaf, as it were, and then make short work of the centre parts. As the eucalypti have been, and are being, introduced into the country by thousands (I might safely say *millions*, for I know of estates where to each cinchona a gum is planted as shelter), I have thought it right to make this fact public.—I am yours faithfully, KÁROLY FÜRDÖ.

[Mr. Marshall Ward, to whom we referred the box of leaves with a proof of "Károly Fürdö" 's letter writes :—"I have carefully examined the leaves sent, and fail to discover any mycelium in them. Why does your correspondent dignify the spotting (which is a common enough phenomenon, and which I have long observed on many plants) with the name of 'leaf disease'?" Of course our correspondent did not mean the spotting was the same as coffee leaf disease, but what is this attack which results in the dying out of gums and cinchonas through the loss of leafage, and which seems to spread from leaf to leaf, unless it be a leaf disease? Have planters in other districts noticed this gum-tree leaf-disease and its effects? It seems more allied to the coffee leaf rot disease of Coorg, than to the *Hemileia vastatrix*. Curiously enough in an *Australasian* received by this mail, we find a paragraph headed "The Blue-gum an Enemy of Insects," as follows :—"That the blue-gum is not an enemy of all insects is determined by the fact of its being itself a prey to more than one species. This, however, may be quite consistent with the power claimed for it, of keeping away rom fruit trees certain insects that commonly infest them. The *Maryborough Advertiser* has found on Chinaman's-flat a Mr. Mills, who is said to protect his apple and other fruit trees from the attacks of insects by calling in the aid of gum leaves. In spite of annual devastation proceeding in his neighbours' gardens, it was noticed that Mr. Mills serenely cultivated his produce without much demonstration, and, in fact, appeared to abandon himself to the luxury of smoking under his own vine and fig-tree in comfort, and in supreme indifference to the raids of the insect world. Yet, at the end of the season, it was always found that whilst his busy neighhours had meagre crops, Mr. Mills's trees were crowded with ripe blooming fruit. Inquiries were made as to the reason of this, when it was elicited that Mr. Mills makes a practice of strewing eucalypti branches in his garden in proximity to his fruit trees; and, further, he makes a rule of bringing large green strips of bark from the bush, which he fits round the stems of his fruit trees and ties thereon. The result is that Mr. Mills garden is singularly free from insects, and thrives whilst others are blighted."—ED.]

"THE POTTERY TREE."

Kelvin Grove, Colombo, 29th Sept. 1881.

DEAR SIR,—When I sent you my notes on the kumbuk tree as a lime-producing one, I overlooked the enclosed cutting, which I made from the *Forres and Elgin Gazette* of 19th May 1880, referring to another tree so remarkable for the quantity of silex in its hark that it is called the "Pottery Tree." The genus Moquilea contains several species, and helongs to the order Chrysohalanacæ, common in the tropical regions of Africa and America, two genera of which Parinarium, and Parastemon, are natives of British India, and are included in the order of Rosaceæ, in the trihe Chrysobalaneæ by Sir J. D. Hooker; but none of this trihe, exist in Ceylon. The *Moquilea utilis* must he a recent discovery, as I cannot find notice of it in any of the hooks to which I can refer. Here then is a new product to he introduced to Ceylon, the specific name of which indicates that it is a useful one.

By the way is it not a mistake to call the *Pithecolobium Saman* "the rain tree" (see the paragraph quoted by you from the *Madras Mail*, at the bottom of the 1st column of the 3rd page of the *Ceylon Observer* of the 22nd inst.)? In Don's *Gardener's Dictionary*, 2, 432, No. 32, a description is given of the *Cæsalpinia pluviosa*, D. C., and it is called the *Rainy Brasilleto*, and I suspect this is the true rain tree and that its name has heen transferred to the *P. Saman*, though I heard reasons given for this latter being called the rain tree in consequence of its drooping leaves enabling the dew or slight rain to fall on the ground beneath.—Yours truly, W. F.

(*Extract referred to.*)

One of the most remarkable of those trees which bear a stony or silicious bark is the "pottery tree" of of Para, on the Amazon, termed "Carapia" by the Brazilians, and known to botanists as the *Moquilea utilis*. It is a magnificent tree, and sometimes grows to 100 feet before hranching. The wood is exceedingly durable, being largely impregnated with flint; but the principal value of the tree lies in its bark, which is used by the Indians for furnishing the raw material of pottery. It is not that vessels are made from the bark itself, as they are sometimes made from gourds and calabashes; but the bark is burned, and the silicious ashes mixed with a proportion of river-clay make a strong and serviceable ware.—*Cassell's Family Magazine.*

GUM TREE "LEAF DISEASE."

6th October 1881.

DEAR SIR,—Referring to "Károly Fürdö"'s letter which appeared in your issue of the 3rd inst., I have noticed the disease on a few trees of Eucalyptus globulus in the Dimbula district; but it has not yet proved fatal in any instance. I attribute the blotches on the leaves to the attacks of a small fly, somewhat resembling the May fly, with transparent, light brown wings. This insect was very numerous on the trees that were attacked, and I feel sure that the flies are in some way connected with the disease, though I have not yet found any larvæ boring in the leaves.

The blue gum is certainly not an enemy of insects, nor the red gum either. I have seen specimens of the former destroyed by cockchafer grubs, by black grub, and by whiteants, and the leaves of both species are liable to the attacks of leaf-rolling larvæ. The trees are often used as resting-places by beetles of various species. The *Cetoniidæ* may sometimes be found on the trunks, feasting on the gum that exudes from the bark.—Yours faithfully, AUSPEX.

NEW PRODUCTS.

SIR,—Permit me to suggest the names of two new products, which may be cultivated with advantage in this islands—I mean—*sanseviera*, or American aloes, * known in Tamil as *maral*; and *Asclepias gigantea*, called in Tamil *erukkally*.

The former grows in abundance in the Jaffna peninsula and the Vanniya district uncared for by the people. It grows to a height of two to six feet, according to the fertility of the soil. Its leaves are very close to the stem, and resemble the leaves of pineapples; and could be propagated by means of shoots or buds. When the leaves are cut and put into water for ten or twelve days, the fleshy portion is removed from the leaves, leaving only the fibre in an unclean state. The fibre is extremely fine, glossy and very strong. It can be used in the manufacture of silk cloth, paper, or coir rope.

The latter (I mean *Asclepias gigantea*) also grows in all parts of Ceylon, chiefly in hot districts, without any care or attention on the part of man. They neither require pruning, weeding, or watering, but grow wildly, spreading several branches. The native physicians utilize its leaves, roots, and juice for medicinal purpose. A white powder resembling lime is found in the leaves, pods, and branches. The juice is very hot and pungent. In Jaffna, people burn the sticks to charcoal, and utilize it in the preparation of fireworks (rockets) and gunpowder. I would suggest to the coffee planters to try the leaves of this plant, as manure for the estates suffering from leaf-disease. In the bark of this stick, may be found fibre of excellent quality which also can be used in the preparation of cloth, ropes, &c., and in the pods extremely soft cotton, which can be utilized for mattresses and various other uses.

LANKASNAHAN.

[NOTE.—An allied species, to the first mentioned the *S. guineensis*, or African bowstring hemp, grew in Ceylon in 1824, and may be still in the Peradeniya Gardens. The *Calatropis* is well-known for its fibre, its charcoal, for its use as floats to nets, its gum, and medicinal qualities. It is the *Mudu-wara* of the Sinhalese and the *Irkulan* of the Tamils. The *Sanseviera zeylanica Willd*, and the *Calatropis* (*Asclepia*) *gigantea* are too well-known plants in Ceylon and India to be considered as "new products." The former is found wild all round Ceylon, and its long strong fibre is well-known as the Ceylon bowstring hemp, but I do not recollect an instance of its profitable manufacture in Ceylon. It is the *Maha-niyada* of the Sinhalese and the *Araley* or *Maral* of the Tamils.—W. F.]

* I never heard this plant called American aloe before: the *Agave Americana* and *Fourcroya gigantea* are so called.—W. F.

THE RASPBERRY-JAM WOOD of Western Australia is highly scented, and will polish equal to Spanish mahogany. For fancy cabinet-ware it will be found especially useful. British manufactures will do well to obtain samples, and judge for themselves as to the truth of these observations.—*Stationer*.

CINCHONAS: UPPER MASKELIYA, 6th October.—Your South Coorg correspondent has no reason to complain of the growth of his succirubras 6 feet in 20 months from seed. The following will give some idea of how they grow in this end of the valley:—Succirubra—6″ plants put out in July 1879, are now some of them 15 feet high; 3″ plants, or, as you may call them, seedlings, put out in November 1879 are now 8 feet high, Officialis,—6″ plants put out in July 1880 are now 8 feet high, girth 4½. Can any other district in Ceylon beat this? If Maskeliya does not hold its own in coffee with other districts, I think it has the pull over them in cinchona growing.

LEAF DISEASE.—A wail comes from the coffee districts around Palghaut. Young estates in this neighbourhood enjoying all the conditions for successful cultivation, soil, good climate everything that can be desired, elevation suitable, and rainfall perfect, are attacked in the most unaccountable way with leaf disease. The young wood which gives promise of excellent bearing capabilities for the next year, is suddenly denuded of foliage, and the wood itself dies back to the primaries all in the short space of a fortnight. No apparent cause can be assigned for this rapid progress of the disease. Everything is being done to counteract the disastrous effects of the disease, especially vigorous manuring, and time alone will decide whether the estates will bear the attack or succumb.—*South of India Observer*.

DIMBULA, 4th Oct.—I send, per accompanying post, a "poochie" which I found eating into the bark of a cinchona officinalis tree. I have never seen one like it before. I am afraid I have injured the head in taking it from the tree. However, I send it, and shall be glad, if you, or any of your readers, can let me know what it is; and whether they are likely to turn into a pest? I get your *T. A.* through my P. D. and read it with great interest. It contains a great deal of valuable information, of which I was totally ignorant of before. [The "poochie" is the larva of a small moth (probably of the family Arctiidæ, genus Psyche) in its portable tube constructed of bits of bark and lined with silk. Although a bark feeder, it is not likely to do much injury to cinchona plantations.—ED. C. O.]

ASHES OF THE KUMBUK TREE.—It seems that the ashes which were analyzed by Mr. Cochran for Mr. Elphinstoue were from the kumbuk tree, as our correspondent "W. F." surmised. On 16th September Mr. Cochran wrote to "W. F.":—"I have estimated the amount of lime in the ashes received from you. The raw sample dry contained 93·75 per cent of carbonate of lime and the prepared resample 98·05 per cent. The first of these closely resembled in appearance the sample I received from Mr. Elphinstoue. I think it is very probable that it too was from the kumbuk tree. It contained rather more lime than your sample; but, whereas yours was fully carbonated, the other contained fully 5 per cent of lime in the caustic state which would by and bye become carbonated, thus reducing its percentage of lime a little." On 21st September Mr. Cochran wrote to say that he had heard from Mr. Elphinstone that the ashes he had sent were those of the kumbuk.

CULTIVATION OF CASUARINAS.

(*From a Correspondent.*)

Permit me, (the writer of the article on Casuarina Cultivation which originally appeared in the *Eurasian and Anglo-Indian Advocate*, and which you republished in your issue of the 20th July), to make a few remarks in reply to strictures passed on my statements by the Secretary of the Madras Agri-Horticultural Society. That gentleman, who claims to have considerable experience in this matter, says, that on the average only 300 trees can be planted on an acre, and estimates the yield at R1,440 for six acres. He then wishes the public to believe that my estimated expenditure of R1,400 on six acres will yield only R40 nett profit, or in other words only 2 6-7th per cent. or, say, 3 per cent. He seems to have forgotten that since he has reduced the number of trees on six acres to 1,800 from 18,000, he should also have proportionately reduced the expenditure. In my estimate the cost of watering 18,000 trees is put down at R600. It would not be correct to say that one-tenth the number of trees would cost only one-tenth the sum for watering. While the quantity of water required would be very much less, the area over which the trees are scattered would be the same, still I think one-tenth the number of trees would not cost for watering more than one-third the original sum, *i.e.*, ⅓ of R600=R200. Similarly the cost of watching, superintendence, &c., was put down at R444; but when a large estate is purchased the cost for six acres would be very little; I think, one-fourth of the 444 would be ample, *i.e*, R111. Now, taking the Honorary Secretary's figures as to yield, let us see what the profit is on 6 acres containing only 1,800 trees.

	R.	A
1,800 plants at R5 per 1,000	9	0
Ploughing 6 acres at R3 per acre	18	0
Planting and first watering at 12 As per 1,000	1	6
40 cart loads of manure at 8 As a cart...	20	0
Watering for first year	200	0
Watching &c., ...	111	0
Total...R359	6	
or say R360	0	
INCOME.		
From 6 acres at R240 each .	1,440	0
Deduct Expenditure	360	0
Net profit...1,080	0	

or a return of 300 per cent on the original outlay.

Now, sir, the Hon. Secretary says the outturn is only 3 per cent., and from his own figures I prove it is 300 per cent. May I not fairly ask which is the more exaggerated statement?

I do not wish to take up any more of your valuable space, but it would be unfair to myself were I not to state my authority for saying that 3,600 trees could be planted on an acre, and that the trees would grow well if thus planted. The following is an extract from a paper by the Assistant Superintendent, Government Farms, and is taken from the Report of the Saidapet Farm for the year ending 31st March, 1879. Page 130:—"The casuarinas were planted more closely than in previous years. This was done partly for the sake of the shade the trees will afford each other, and thereby be able to protect themselves better from the sun than when planted far apart, but chiefly to induce the trees to grow straight and upright, it having been observed that, when casuarina trees are planted far apart, instead of developing a straight stem their main stem is sometimes liable to fork, and to produce many side branches, but no proper main stem, which considerably reduces the value of the tree. . . . In giving each tree 12 square feet, 3,630 trees can be planted on an acre of ground." My own opinion at present is that 12 square feet is not sufficient for a tree to grow very well, but that 25 or 30 square feet would be ample. I am borne out in this view by the fact that at Tranquebar there is a plantation of 60,000 trees doing remarkably well, although each tree has only 36 square feet of ground at the most. I am quite sure the Honorary Secretary's motive in exposing (as he thought) the fallacious hopes held out by me, was really to place people of small means on their guard; but I contend that when one in his position attacks me so publicly he ought to be at least accurate. I may add that the Perseverance Casuarina Company (Limited) has been formed with a capital of R20,000, and that it seems to be in fair way of being a success.—*Madras Mail.*

BEE-CULTURE IN INDIA.

Bees' wax and honey form no very insiguifican items in our trade returns. People in India care very little for bee-culture; they are content to know that particular districts of Southern India afford both these items of luxury and medicament; some few may try to be critical about Cuddapah honey, but about the honey-bee of India most of us are as ignorant as those simple rustic folk in England, who, though "bee-masters" themselves, yet are in blissful ignorance of the full value of their interesting charge, their instincts and habits. Among the insects of commerce which India possesses, there is a *hiatus* left in respect of bees which amounts almost to neglect of the gifts of Providence. Not many months ago a project was talked of for utilising the countless tons of bats' manure which the hill-caves of Cuddapah were said to contain; whether it is to come to any head, or is to remain in the category of this *non posse*, remains to be seen. In the meantime, it is interesting to know that Indian bees are beginning to be recognised as very promising producers of wealth, and that a venture is about to be made for utilising the Indian bee to the purpose, if not to the same extent, that it is in France and elsewhere. Possibly, with those peculiar views held by certain classes of Mussulmans of the sacredness of the bee, some little opposition in its being domesticated may ensue, but it is not likely to be long-lived. It is a very remarkable fact that customs and prejudices exist long after the age which gave birth to them. The hill-men of Cuddapah go out after the honey and wax, which they exchange with the low country-folk with instruments of barbaric sound. We wonder if they have heard at any time of Virgil and the directions he gives,—when you see the swarm issue from the hive, watch them attentively and raise tinkling sounds and clash the cymbals of Cybele. Somehow, the prejudice is both an old and deeply-rooted one which ascribes to bees a love for discordant sounds. To return to our muttons: an adventurous gentleman, whom a recent number of the *Tropical Agriculturist* named, is, we learn, about to start bee-culture in India. People have ventured on silk worms, and recorded successful issues, and we see no reason for believing the bees of the country to be more intractable. Bee-culture may have some little difficulties at first to contend with; so has silk-worm rearing, and what patience and unremitting care has compassed in one instance, they may succeed also in compassing in another. Cuddapah honey bears a high commercial value: when pure, it has a bright light yellow hue; it is only after it gets into the hands of the bazaar man that it acquires the mawkish taste and color that it does when it is brought into the market. We venture to predict a promising future for bee-culture in districts whose conditions are favourable

to the industry, and trust, Narbonne may find a formidable rival in Cuddapah and other honey-yielding tracts. It is not likely that the little honey used in hospital practice is always from Europe; and we see in the determination of Government to utilise as far as practicable local supplies an earnest and a guarantee that local efforts will meet with all the support that their real merits entitle them to. To the present day the caves of Salsette and Elephanta are as much frequented by bees as were formerly the clefts of rocks in Palestine, and as now are the fissures and crannies of the Cuddapah hills; no one either in this presidency or at Bombay, or for that matter any part of Asia, has tried to domesticate the bee, and the credit will be all the greater when some one shall be found to dissipate the illusion that the honey-bee of India is an unmanageable creature.—*Madras Times.*

THE SCIENCE OF AGRICULTURE.

Mr. Buckmaster of South Kensington, lately delivered a most interesting lecture on "Agricultural Scientific Education. "It is now proposed in rural parishes to establish classes for teaching the science of agriculture, a subject which was added to our list three or four years ago, but which had not received very much attention. The teachers of these agricultural classes must be qualified either by passing an examination in the subject, or by the diploma of the Highland Society, or they must be graduates of some recognised University. The pupils must receive not less than twenty lessons between the examination of one year and the examination of the succeeding year, and the instruction must be given according to a syllabus prepared by the professional examiner in this subject. The pupils must be instructed in the nature of soils. This is a subject on which we all need more information. It is the raw material in which the farmer has to work, and it should be a part of his business and education to study this raw material, and to know all that he can know about it. The distribution and formation of soils, their classification; substances found in the ashes of plants, the sources from which these substances were obtained; active and dormant matter in the soil; conditions which regulate the conversion of dormant matter into a state available for plant food. Influence of the mechanical condition of the soil on the growth of plants, good and bad management of farmyard manure; artificial manure; phosphates, superphosphates, ammoniacal manures, nitrates, salt, chalk lime, soot—their use and special properties; drainage of land, its influence on temperature and health of stock rotation of crops, good courses of crops, bad courses of crops, chemical composition of the substances used as food, materials necessary for the growth of the body, maintenance of animal heat, formation of fat, muscle and bone, the economical uses of foods, mixed foods, and general rules for the preservation of health. The examination will be within the range of this course of instruction, and every qualified teacher will receive a payment of £1 or £2 for every pupil who passes the examination, and this payment comes out of the annual Parliamentary grant for education. The pupils are encouraged by prizes of books, certificates, and bursaries. Such was a general outline of the scheme for promoting the establishment of classes for teaching the science of agriculture. It may not be all that some think necessary but faithfully carried out, it was capable of accomplishing a useful educational work in a direction not hitherto attempted, for there was nothing in the education of Scotland which had any reference to its industries. The agriculture of the future must every day become more and more thoughtful and scientific. Cheap bread and cheap meat may not be inconsistent with profitable agriculture. No one will pretend to say that he knows all that is to be known on this subject, or that the earth produces all that it is capable of producing. Agriculture, like every other civilised industry, could make but slow progress until those sciences on which the industry depends were more generally cultivated and understood. It is our increased knowledge of geology, chemistry, and physiology, which enables us to understand and explain many things which were regarded by our forefathers as unaccountable mysteries—(applause). The laws which regulate the growth of a blade of grass or the transformation of a turnip-fly or a fluke, are just as fixed as the law of gravity. It should be part of the education of every farmer to study these things, to try and understand them, and turn them to useful purpose in his daily work. All new methods of cultivation, and every new manure, have had one subject—viz., to increase the productive power of the earth, and to make it bring forth more abundantly. We have largely aided our national resources by the importation and manufacture of artificial manures, of which our forefathers knew nothing. We have economised labour in every direction by the introduction of improved machinery. We now stand on the threshold of still greater changes, which are only to be limited by the highest intellectual effect of our nature. It is impossible to make any progress in any industrial art without a knowledge of those laws and principles upon which the art is based. To manage your land in this particular way, to grow this particular crop in succession to some other crop, for no other reason than our forefathers used to do it, and they used to do it because their forefathers did it—(applause)—with a creed of this kind no industry can make progress, and the higher nature of a man, instead of being quickened, must stagnate in his daily work. The progress of agriculture, like that of every other industry, is a constant struggle with natural laws and natural forces. It is only by knowledge that we can subjugate these forces to our use, and make them our willing subjects and slaves. Science discovers law; art applies them. The science of an industry is for the most part a distinct thing from its practice, but the most successful farmer is he who is able to unite in his daily life science with practice. There can be no such thing as two kinds of agriculture—one scientific and the other practical. All practical agriculture to be successful must be scientific, and yet there is no opinion more deeply impressed on the minds of some men than the very common belief that science and practice are opposed to each other.

COCONUT CULTIVATION: SOUTHERN INDIA.

About a month or six weeks ago we made a few remarks on the coconut planting industry and stated that many advantages are likely to be derived by small capitalists giving this subject greater attention than it has lately received. We have been favored by a correspondent with a pamphlet on casuarina and coconut planting published in Madras some 15 years ago, when the planting industry occupied greater attention than it now does, and when small capitalists applied for land in places near Madras for the purpose of planting casuarina which was all the rage at the time We find on a reference to the pamphlet which, by the way we may mention, contains a good deal of valuable information about casuarina planting, that coconut plants may be safely planted with casuarina and after the latter are cut up and sold, the coconut tope will be there and from it the owner may obtain the revenue which is always available from the coconut tree. Coconut plantations are known to have

thriven in the suburbs of Madras and to this day, to the north and south of the city, large plantations may be seen. It appears, however, that at a place known as Edakanaad, situated between Sadras and Pondicherry, coconut plantations are in a thriving condition, but the owners of plantations "are far from being perfect in the art of planting." In the Godavery district, coconut planting is carried on with great success, and those engaged in the industry in Madras may well borrow a leaf from the system adopted in the granary of the Northern Circars in respect to this industry. It is to be regretted that the author of the pamphlet does not give particulars of the system adopted in the Godavery district which may be usefully followed in other places. The great difference in planting coconuts on the Malabar and Coromandel Coasts is this—in the former, the heavy and continuous showers of rain for almost nine months in the year, render the watering of the plants unnecessary after six or eight months. On the Coromandel Coast, the rainfall is very much less, and it is necessary to water the trees till they begin to bear, and even after that, when toddy is drawn, it is necessary that the supply of water should be continuous. Plantations should be situated on land where fresh water is to be had near the surface. The plantations in and about Madras are situated on *clayey* soil which is easily irrigated and the trees can be planted closer than in a plantation of sandy soil. It is, however, not considered advisable to plant the trees too close, for if they are so planted, the yield of coconuts will not be as large as it would be otherwise. The writer of the pamphlet says that the profit from each coconut tree bearing toddy is as small as two rupees per annum—owing to this small revenue, the owners of gardens prefer to obtain the coconuts and sell them. We are not disposed to accept the statements of the pamphleteer that the yield of toddy from a coconut tree results in so small a profit as two rupees per annum. If that is the case, there is not likely to be such a large yield of toddy in Madras and in the suburbs as there is at present where some hundreds of shops —there are fully three hundred shops within the limits of the Municipality—are in existence and there is no question as to the large quantity of toddy sold by their owners. The pamphlet contains many useful hints on coconut cultivation, such as the raising of plants in nurseries, the cost of conveyance by rail, and of the valuable species of coconut grown in Ceylon and in parts of the Nicobar islands between which and the west coast a large trade in dried coconuts is carried on for exportation to Europe and other parts. To those engaged in growth of casuarina some of the suggestions contained in the pamphlet may prove useful. They may be induced to adopt the writer's suggestions to plant coconut trees with casuarina and some of the hints may also be useful in dispelling the wild theories that have lately been promulgated in respect to the profits to be derived from casuarina planting. On this subject, the Secretary of the Agri-Horticultural Society at Madras has lately published some useful statistics which go to show that casuarina planting will yield a fair return, but not to the extent anticipated by the promoters of a newly established company at Madras Nevertheless, we think, that were greater attention given to coconut planting in Madras and in places where plantations are likely to thrive, it will turn out to be a successful and paying undertaking.—*Madras Standard.*

ORANGE CULTURE IN SYRIA.

Some notes on orange culture in a recent consular report from Beyrout, are quoted in the London *Times*, from which we learn that the two districts in which oranges are the most plentiful are those of Jaffa and Sidon. The orange trade began to assume considerable proportions some 40 years ago, and the new Government of Egypt took shape, and it is now one of the most profitable in the two towns above mentioned. Unfortunately the inhabitants, allured by first gains, commenced planting gardens, and expending money beyond their resources, the result of which has been that, in spite of all remunerations for small outlays, their improvidence has placed most of them in the power of money-lenders, who continue to advance at interest of 15 to 20 per cent. However, a Company has lately been formed in Jaffa to negociate loans with orange cultivators, and if its operations be carried on fairly, we may expect an extension of horticulture, with benefit alike to the Company and the borrowers. At the present moment Jaffa possesses some 340 gardens, averaging from 2,000 to 2,500 trees in each. The crop of fruit from these may be put down at about 36,000,000. A garden costs from 40,000f. to 50,000f. and brings in 4,000f. to 5,000f. per annum. For several miles round Jaffa extends a fertile plain, on which water is always to be found at a depth of 40 ft. or 50 ft. With capital and enterprise much of this might be planted, and the orange trade doubled in a short time. The present system of irrigation is that of small wells, from which the water is drawn by mules; but experiments have proved that very little engineering skill would be required in order to turn the streams of the River Andjah, some four miles from the town, over the plain. The land near Jaffa would then be cheapened in proportion as the value of that freshly-watered rose. At present, unplanted land close to Jaffa, able to support 2,000 trees, is worth 2,000f. to 3,000f.; but at two or three hours' distance it will fetch only 5f. to 6f. a deunum. The export is carried on chiefly by sailing boats for Egypt and Constantinople, and by steamers for Russia, Trieste, and Marseilles. Exportation in cases is a comparatively recent introduction, which has given considerable impulse to business with Europe. The orange gardens of Sidon are cultivated on the same principle as those of Jaffa. An acre of land at Sidon is generally valued at from 6,000f. to 7,000f., and is capable of bringing in an income of about 600f. The exportation begins in September, and is at first almost exclusively directed to Russia, till the winter closes the Black Sea ports, when it is continued to Trieste and Egypt. European cargoes are packed in paper and close cases; the rest are sent in open crates. Each case contains some 300 oranges or lemons, and last year's export is reckoned at 20,000 cases, all of which fetched very high prices, especially lemons in Russia. The average prices are for 1,000 lemons 150 to 170 piastres; while for 1,250 oranges, reckoned as a trade 1,000, the cultivator receives 70 to 80 piastres.—*Journal of the Society of Arts.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special letter.*)

PARIS, 10th September.

The French are very extensive spinners and weavers of Australian wool: it forms the basis of the woolen and silken stuffs which they export to that colony. The pure breed of French merinos, such as it exists at Rambouillet, differs on several important points from the Australian merino; the latter is less heavy and smaller; the staple of its fleece is, however, finer, in the sense that its diameter is narrower, but the Australian merino wool is less elastic and its undulations not so regular as that from the perfect Rambouillet sheep. Now Australian wool growers aim at fineness of fleece: hence, why many consider the crossing of native merinos with

the best imported Rambouillets would be an advantage. Perhaps it would also tend to diminish the darker-colored flesh of the Australian sheep. Following M. Bourdil, an ex-Commissioner, Australia had in 1879 66 millions of sheep, and exported in that year 143,000 tons of wool, at an average price of 1/0½d per lb.; in 1877, the mean weight of an unscoured fleece was 4½ lb., and of washed 2½ lb. The most appreciated wools are grown, according to the same authority, in Tasmania and Victoria. New South Wales, in 1878, possessed only 29 sheep; at present she has 29 millions. To Tasmania reverts the honour of having first imported merinos from Saxony.

The *Société Nationale d' Agriculture* has the excellent habit to pass in review the history of the country's agriculture for each year: the *résumé* is ever the product of M. Barral, who, in addition to being an able chemist, is one of the most practical minds in France, and whose long public career has ever been associated with the progress of the age. A few gleanings from that interesting document:—It draws attention to the discoveries of Pasteur, who not only has found a remedy in inoculation against the terrible stock plague *charbon*, but has pointed out that the origin of that malady is due to the burial of diseased animals in lands over which cattle subsequently range, and thus catch the animalcules or plague-germs, as thrown up by worms from the pits where the carcases have been interred. The United States are accused of having introduced the phylloxera into France: whether the charge be accurate or not, the antidote has come from the same source, as the grafting of American vine stocks has been found efficacious in resisting the ravages of the vine bug. Testimony is borne to the happy results attending also the employment of sulphuret of carbon, and, above all, to the adoption of autumnal irrigations and rich spring manurings, known as the Faucon process, and whose author has been recompensed by an *objet d' art*. In what may be designated industrial agriculture, the cultivation of sugar beet ranks high, and its development has received a fresh impulse from the reduction of the inland duty on sugar. Connected with this progress is the now general adoption of the extraction of the juice by the process known as *diffusion*, imported from Austria, instead of the old plan of presses. The pulp resulting from the new system has been found to be more nutritive for feeding purposes. In the northern and central regions of the country, where beet culture prevails, this pulp has next to revolutionized stock farming: agriculturists in the neighbourhood of the factories no longer rear stocks; they purchase the lean kine in other districts and fat them. It is a branch of farming very remunerative, as the demand for fresh meat exceeds the supply, and no danger is apprehended that America will be able to compete in furnishing live stock to the butchers. The distillation of alcohol from beet and maize also has made important progress, and M. Savalle has demonstrated that rectified alcohol is so chemically pure, that it is of no importance from what substance it be obtained. Despite the development in the preparation of the cheese and butter industries in Denmark, England, and Sweden, France continues to hold her own. It is satisfactory to observe that M. Duclaux has obtained a medal for his Benedictine labours on the rôle of animalcules in the manufacture and ripening of cheese. Respecting eggs, France not only exports millions for consumption, but for hatching too, and for the latter supplies incubators. M. Joseph Boussingault, son of the veteran chemist, has also been honored for his researches in Agricultural Chemistry; nor have the national teachers been overlooked for their humble but important services. One schoolmaster aged 75, and after 50 years in harness, has been pensioned; he is happy, as he boasts, "I am going now to commence new experiments." Some local Agricultural Societies award premiums to the schoolmistresses for inculcating general notions of farming, dairy management and house-keeping to their pupils.

This year's harvest will be inferior to last season's; wheat will represent a less yield of 30 millions of bushels; barley is fair; rye, good; oats, bad; maize, passable. On the whole, in point of cereals, France and Russia are the most favored countries in Europe. Forage is next to a failure; beet is suffering from abnormal fluctuations of temperature, but the vintage promises to be excellent in quantity and quality.

The Electricity International Exhibition has, from an agricultural point of view, some attractions. In principle the application of electricity is simply a transmission of force; the secret of the economic utility of that power has been found; the applications will come in due course. Professor Dêhérain exhibits his experiences on the influence of electric light on vegetation; M. Felix, on the application of electricity to ploughing and threshing; M. Albaret, to the lighting of farmyards and agricultural operations, and the examination of eggs by electricity.

In the south of France, where the climate is hot and the country mountainous, rearing sheep for their milk, to produce cheese (Roquefort), is largely extending. The best milking ewes ought to have four or six teats, the udder voluminous, the wool rare, and secreting much grease, ears long, head small and without horns. Sheep with four teats ought to be sought. In the Agricultural College of Montpellier there is a ewe with two lambs, and yielding milk from six teats. So far the experiments have not succeeded of obtaining an animal producing much milk and a good fleece at the same time. Counting milk, lamb, and wool, a ewe produces net about fr. 48 yearly; six quarts of milk yield 1 lb. of cheese. The Chilians, to obtain special skins much sought after, cross the sheep with the goat; experiments are being conducted in the end of a similar crossing, for improving the milking capacities of ewes. Goat farming does not pay: the animal is destructive, its flesh held in little repute, and its offal of no value.

To combat the epidemic of typhoid fever from which horses now suffer, a veterinary urges the use of arsenic as an infallible cure or preventive; he holds back, however, the recipe. The stable ought to be sprinkled with a solution of carbolic acid, two ounces in a quart of water. Arsenic imparts a fresh and sleek look to the coat, and in Vienna is given to make carriage horses foam at the mouth.

Up to the present the mechanical fatting of poultry consisted in storing the birds in a pigeon-holed revolving tower, and making each shelf with its tenants pass before a man with a bucket of prepared liquid food, that he injected in measured quantities through a tube, working by a treadle, into the throat of the bird. In Italy and France the Humane Societies attempted, but without success, to put down this mode of rapidly contributing to our food supplies. An improvement has taken place: instead of the revolving tower, the birds are placed, 6 to 8 in number, under a kind of box or melon frame, and left to enjoy all the liberty they can find therein; the feeding apparatus is maintained, each bird being taken out to be dosed, and then put back to enjoy its confined "constitutional." The frame is heated to a certain temperature, that which aids the putting up of flesh.

M. Guignet draws attention to cases of pigs having been poisoned, by giving in spring cooked potatoes and their germs, or later a wash of green potato stalks; he adds, excepting the tubercle, every other part of the potato contains as deadly a poison as nightshade.

Among the many prizes offered by the National Agronomical Institution of France, is one of much importance the right of two of the most successful candidates of the annual examinations to reside abroad in the centres of the best farming districts for three years, at the expense of the Government, they furnishing reports on the farming of such countries.

ESPARTO OR ALFA.

By C. G. WARNFORD LOCK.

The celebrated German traveller, Dr. Gerhard Rohlfs, devotes a whole chapter of his new book, "Nene Beiträge zur Entdeckung nnd Erforschnng Africa's" to the subject of "Esparto, and its increasing Importance in Enropean Commerce," from which the following notes are condensed :—

A portion of the Sahara, known to the French as *le petit désert*, comes within the influence of moistnre-laded winds, and is clothed with vegetation. One of the most nseful plants, covering almost the whole district, is esparto or alfa (*Macrochloa* or *Stipa tenacissima*). Long known and locally utilised for mat-making, it is only within recent years that the true value of this plant, which needs neither care nor culture, and thrives with a minimum of moisture, has been recognised. It grows in thick branches close together, presenting a subnlate appearance, and reaching a height of six to ten feet. The tenacity of its fibre constitutes its industrial valne, for it is scarcely fitted for consumption as fodder. Indeed, Duveyrier states that it has such a powerful constipative effect, that the shepherds of the desert edge drive their camels and sheep every third or fourth day to drink at mineral springs, in order to counteract the binding action of the esparto diet. Rohlfs himself noticed how soon the camels and sheep grew tired of grazing upon it.

The one word paper explains the whole importance of esparto. The day has long since passed when rags and similar stuff sufficed to supply the world's needs of paper. The moment has arrived when new sources of paper material must constantly be sought. This is easily explained when we reflect that the yearly consumption of paper by the four great cultured nations of the world stands thus :—England, 13¾ lb. *per capitem* of the popnlation ; America. 12 lb.; Germany, 10 lb.; France, 8¾ lb. These figures are always on the increase. And though Russia takes only about 1 lb., and Austria 4½ lb., the amount in both these countries double themselves with every generation.

No plant seems better adapted for paper-making than esparto. It may be regarded as an inexhaustible source of wealth, not only in Algeria, but for all northern Africa. Algeria already owes a portion of her railways to this plant. The section from Arzew to Saida is approaching completion, and others are in progress. Some seven or eight million acres of esparto ground exist in Algeria alone.

Hitherto, the greater part of the esparto grown both in Spain and North Africa has gone to England, though the Americans are beginning to import direct from Africa. Up to the present, German paper-makers have not availed themselves of the use of this plant. England, in 1868, imported 95,828 tons—92,927 being from Spain, and the rest from Algeria. But Algeria rapidly attained greater importance, while Spain fell off. In 1874, England's imports were 119,188 tons—54,942 from Spain, and 37,516 from Algeria. Since 1870 other countries have contributed to the total. Tunis and Tripoli figure in 1871 with 11,579 tons, increased to 18,670 in 1874. Malta provided 3,261 tons in 1871, and 7,185 in 1874, not of its own production, but derived from Cyrenaica, and the so-called Libyan coast plateau.

The influence of other lands, Tunis, Tripoli, Cyrenaica, and perhaps the Libyan coast plateau, upon the Algerian and Spanish trade, has, especially of late years, caused a reduction in price. As, however, in most of these lands, robbery is still rife, Spain and Algeria will long continue to enjoy a practical monopoly. How strongly the rational conservation of this valuable plant is urged in France may be gathered from the following words of the journal, *L'Exploration* (1878, p. 156) :—"As in France laws have been made against the felling and destruction of forests, so must the Colonial Government busy itself with the protection of this great staple of the high plateau, and not only severely punish the before-mentioned crimes (burning by the Arabs, and killing of the plants by careless gathering), but also fortify the esparto region against the constant encroachments of the sand of the Sahara. [Rohlfs characterises the latter as a groundless fear, the sand-dunes being on the whole stationary] It must not be lost sight of that all Europe and Ameriea are dependent upon Algeria and that, should the whole esparto district be carelessly left to greedy robbers, who care little for the public property, finally nothiug will remain but a neglected waste, an unfruitful steppe." It is as well to observe that, firstly, Algeria possesses, at the utmost, not more than one-sixth of the esparto region, and, secondly, the same land will, when desired, grow excellent wine.

On the subject of adulteration and faulty packing, Dr. Rohlfs quotes at length from Noble's circular of 14th January 1875.

The preceding remarks indicate what stress is laid upon the export of this plant to France, Great Britain, and the United States, while Germany remains outside. Yet none will suppose that Germany is blessed with a superabundance of paper material. The Leipzig paper trade alone has of recent years a value of about ten million marks (£500,000). It is therefore a reproach to German merchants that they should have paid so little attention to this material. With this object, it is not at all advisable to go to Algeria, nor to Spain, where German merchants would find it difficult to gain a footing in competition with the old English houses. But is not the whole remainder of North Africa open ? Not to speak of Morocco, where, especially south from Cape Ger, a wide stretch of country still remains unoccupied, on which esparto forms the chief vegetation—the esparto-grown portions of Tuuis, Tripoli, Barca, and the eastward-lying Libyan coast plateau, stretching to Alexandria, are absolutely without any rational commerce ; as the natives tear up the esparto, root and branch, so is it carried to the shipping ports, sorted, and sent into the market. Here is a field for German enterprise. Dr. Rohlfs snggests the possibility of establishing esparto paper factories in convenient localities, and supposes that about half of each plant would be available as fuel.

The remainder of the chapter deals with African trade generally, but the whole tenonr of it is to urge the Germans to no longer remain passive and unmindful of the resources of North Africa : and Dr. Rohlfs is not likely to preach in vain to his countrymen. Now, if these waving acres of esparto offer such great inducements to the astute and cautious German, do they not merit even greater attention from ourselves ? Already our paper makers have cause to tremble for the future, since France has made such strides on Tnnis, and if our merchants allow themselves to be outstripped by German rivals on neutral territory, we shall soon have to import all our paper from the Continent, in spite of all that Mr. Routledgeis doing for us.—*Journal of the Society of Arts.*

GOLD PRODUCTION.—It is reported that the total product of gold in the whole world last year was 118,000,000 dols., nearly half of which was mined on the continent of America. The product of silver is said to be 94,000,000 dols., of which 76,000,000 dols. was produced in that country. The grand total of precious metals was, therefore, 212,000,000 dols., an increase, as compared with the three preceeding years.—*Journal of the Society of Arts.*

PRUNING CONIFERS.

(Field, 10th September 1881.)

There is a prevalent notion that conifers do not like pruning; and in many cases trees that would make good specimens get ruined from want of a little timely attention in this way during their earliest stages of growth. In forests, where trees are planted thickly, there is no chance for them but to run up straight; they get crowded by their neighbours and lose their lower branches by reason of the dense shade in which they are placed; but when planted at wider intervals for ornamental purposes the side branches retain their vigour, and unless checked by timely pruning rob the leader of its proper supply of sap, until, instead of making a handsome pyramidal tree, it becomes merely a scrubby bush. Now, I find that where they have made several leaders, and have become quite stunted in growth, they may be renovated by careful pruning, although, of course, the process is slow, for conifers will not make shoots from old hard wood like a deciduous tree; but by keeping all the lower branches stopped in for a time, a leading side branch will straighten up and become a good leader. In fact, we have many Wellingtonias and other varieties of conifer that have been beheaded by violent gales of wind, snapping the succulent leaders short off; yet by carefully stopping the side growths they have quickly formed a new leader, and the junction of the two is hardly visible. When conifers are grown for either ornament or profit, I would strongly advise the careful use of the knife and saw as an indispensable part of their treatment; for a really ornamental well-proportioned tree means a profitable tree, as none of our older kinds of forest trees form so large a quantity of timber in a given number of years as do some of the newer kinds of conifers. J. G.

A CHEAP FERTILISER.

(Field, 27th August 1881.)

Sir,—Shortly before his decease, I received the following letter from Mr. J. J. Mechi of Tiptree Hall:

Dear Sir,—Very many thanks for your interesting and valuable pamphlet of American agricultural statistics. What a fortunate thing for three-fourths of our population that they will not want bread, which they certainly would do if dependent solely on home supplies. I have no fear of foreign competition, either in corn or meat, provided I am enabled, by capital and skill, to produce maximum crops in ordinary seasons. In such an exceptional one as the last, neither skill nor capital were of avail. I hope America may escape such a disaster. My crops promise well. Come down in July and see them, and take a crust and cheese, perhaps both "American."—Truly yours, J. J. Mechi.

P. S.—The non-improvers will suffer by foreign competition, and will be forced "out of the market." According to my estimate, *at last* £100,000,000 is required in agricultural improvements by land-owners and tenants—I mean in agricultural improvements and investment of capital.

What proportion of the £100,000,000 Mr. Mechi conceived necessary to be expended in fertilisers, in order to put the British farmer in a position to compete with his American rival, cannot now be ascertained. It must, however, have been considerable; and the question may fairly be asked, From what sources are these fertilisers to come?

The estate from which its owners "calculate" upon extracting so much wealth has evidently been the bed of an extinct lake. The area is some 6,000 acres, or nine square miles. Except in one direction, where there is a small opening, it is surrounded with hills. The opening, it is plain to be seen, has been caused by the lake breaking through its bounds, and rushing away to join the sister lake, Seneca. This must have occurred at a remote epoch, as the upper crust or covering of the bed of marl is fully 4ft. thick, and is composed of rich vegetable mould, representing the growth and decay of ages.

Underlying this is the marl or albemarle, as it is termed, though it is not white, but a rich grey. The deposit varies from 60ft. to 6ft. in thickness, and each 100 acres has been estimated to contain 2,000,000 tons of fertiliser, giving for the 6,000 acres some 100,000,000 tons, which, it is claimed, sells here in the States for £2 a ton. On taking a piece in hand it is found to consist of myriads of minute shells, of various forms and sizes, which crumble into powder under the slightest pressure. The analyses of chemists show it to be composed of decayed vegetable and animal matter. About seventeen miles distance is Syracuse, the centre of the great salt industry in the States, and it is averred that salt has been found underlying the fertiliser. The water of the lake was originally salt or brackish—a condition favourable to the rapid growth of these lacustrine shells.

A word on guano, which I see is causing some discussion in England. I have recently returned from an extended tour in Peru and Chilli, where I had occasion to investigate this subject thoroughly. The supply of some 800,000 tons a year may last five or six years longer. The quality will grow inferior year by year, as it has done since the Chinchas were exhausted. In America the farmers and planters are ceasing to use it. The first say it is the source of the foot-and-mouth disease; the second that it has destroyed the fine old-fashioned flavour of the tobacco.

The value of the marl as a fertiliser depends, of course, upon the amount of phosphate of lime that it contains, and some of the analyses estimate this at a very high figure, by reason of its fossiliferous ingredients.

New York, July 20. J. H.

LIQUORICE ROOT.*

There are several districts in Spain, writes United States Consul Morston, from Malaga, to the Department of State, in which liquorice root is obtained, and large exports are made from Spanish seaports to the United States. France also consumes large quantities of this root in the manufacture of liquorice paste, and probably takes nearly as much of the United States.

This root is used in the United States principally for sweetening in the manufacture of plug and other kinds of tobacco; it is also used in the manufacture of drugs and in the preparation of medicines. It grows wild in the lower lands, in marshy-ground, and on the banks of rivers. Probably the best quality obtained in Spain is found in the provinces of Aragon, Murcia, and Toledo. The very best Spanish liquorice root is found near the margin of the Ebro, in Aragon. The next in point of quality is obtained near Cordova. When it once takes root it is almost impossible to eradicate it. It grows in many countries, and varies in quality according to soil. Spanish liquorice differs quite materially in the several provinces, the principal variations being that in some parts the bark is red, brown, or light colour, the inside varying from light yellow to brown; the proportions of saccharine and starch vary also. Many kinds are fibrous, while others are almost as hard as wood. The ground is pulled at intervals of three, four or five years, according to circumstances, by digging trenches, pulling everything visible as long as possible until it breaks. After a year or two it shows above the ground with a little stem; in the spring over this stem there are flowers. From the time this stem appears until the flowers have all fallen this root is not in condition to extract, for the sap does not return to the root until then. Each year, till the second is called, the quantity of roots and tops increase, until the ground is used for cultivation of any kind.

* From the *Oil and Paint Trade*, September 6, 1881.

It is from September till March that the root is gathered, and goes through a process of drying or curing before it is considered marketable,

Liquorice root is also found and gathered in Asiatic Turkey, Greece, Italy and the Sicilies, and in Spain. In Italy and the Sicilies very little, if any, is exported as root, it being used in the manufacture of roll or stick liquorice. There is a small section in England which produces a limited quantity. The United States also have liquorice root in several parts of the country, but the quality is not such as to give it value.

The quality of root produced in the diffcrent countries is as follows:—Asiatic Turkey, decidedly bitter; Greece, bitter, but not so bitter as Asiatic Turkey; Sicily, sweet; but less so than Spanish; Spain, rich and sweet; Italy, richest and sweetest of all.

Malaga has not, up to the present season, been considered an important shipping port for the root, Seville, Alcantc, Barcelona, and Bilbao being nearer the producing districts. It is probable that during the coming year of 1881 there will be some shipments from Malaga.

The value of this root does not admit of its being increased in crop by cultivation, and the quantity gathered depends greatly upon the severity or mildness of the winter. If severe, it lessens the quantity gathered. Again, if other crops are good, labour being scarce, less root is gathered; consequently prices are higher. There are one or two large French establishments in Spain for making paste and stick liquorice, one in Seville and the other in Saragossa, besides a few small Spanish concerns also engaged in the manufacture of liquorice paste.

A YEAR IN FIJI; OR, AN ENQUIRY INTO THE BOTANICAL, AGRICULTURAL, AND ECONOMICAL RESOURCES OF THE COLONY.

By JOHN HORNE, F.L.S., &c. (STANFORD.)

(*Academy*, 17th September 1881.)

Mr. Horne investigated most thoroughly the two large islands of Viti Levu and Vanua Levu, and visited several of the smaller ones, the number of which is reckoned at about 200. Furnished by the Governor with a circular-letter to all the chiefs, he met with attention, civility, and assistance wherever he went. Indeed, his experience reflects the highest credit on the civilising agencies, both lay and spiritual, which have been at work among the Fijians. In each town both a church and school were to be found. In small villages one building served both purposes. The schools were well attended, most of the rising generation being able to read, write, and cipher to some extent. And family worship was conducted in most native homes both night and morning. What difficulties he met with in his journeys arose from the nature of the country, not from any jealousy on the part of the natives, whom he found "extremely kind."

It would be difficult to find any other portion of our globe so well adapted, both from climate and soil, to varied and extended production as Fiji. Yams, bananas, sugar-canes, coconuts, bread-fruit, and *dalo*, or *taro* a tuberous plant, have long been cultivated by the Fijians, of whom Mr. Horne says that their instincts are agricultural, and that they find a use for all the vegetable products of their country, and have a name (sometimes several) for each individual plant; coffee, cotton, tobacco, and arrowroot are grown with success; most of the exotic fruits, spices, and vegetables which have been introduced have succeeded; and the climate is, in the opinion of the author, well adapted to all our vegetables, to potatoes, cinchona, tea, rice, and the rearing of silk-worms. The fruits of the temperate regions do not generally succeed; the grape-vine, though it grows fairly, becomes an evergreen, and bears only occasionally a few bunches of fruit. The climate is not too hot, but the want of success in the production of grapes is due to the vine not getting a season for rest. Cattle, as well as sheep and angora goats, thrive. Maize is grown chiefly for the discharge of taxes, which are paid in kind. The principal staples of the Fijian group are likely to be sugar and coffee, but the production of both requires much labour, and the former machinery in addition. The procuring sufficient and competent labourers is one of the great difficulties the settlers have to face. The Fijians are not to be depended on; and, in the opinion of Mr. Horne, India is the country to be looked to for supplying this pressing want. The Fijians have a passion for the sugar-cane; they are constantly sucking its juices, and the quantity they will consume in an idle hour, or when listening to a story, is astonishing. Though the natives spend some skill and labour in cultivation, yet they allow the land they have been at the pains of clearing, and from which they have taken but one crop, to return to its natural state. So vigorous is vegetation in that favoured climate that land so abandoned is at once overgrown with reeds, wild sugar-cane, tree ferns, and large creepers, and after a few years it is covered with forest trees. Mr. Horne considers the climate of Fiji, though tropical, to be very healthy. Malarial fevers are entirely unknown, even on the edge of mangrove swamps. However, during the months of December, January, and February, a heavy, languid, oppressive feeling is experienced, accompanied by an unwillingness for the least exertion, either mental or physical. The dull, indolent habits of the natives, too, have a depressing effect on those who are in contact with them. To judge from the meteorological tables furnished in the Appendix, the climate is singularly equable: cold is unknown, and the mean temperature of the year only varies by three degrees. The rainfall is excessive, and the damp was very hostile to Mr. Horne's botanical collections. With the exception of some tender ferns, he found it impossible to dry his specimens in paper, and was at last reduced to wither them well in the sun and air before they were pressed at all. The flora of the group is very interesting, and is carefully treated by the author. He added to the plants of Fiji already known 300 species of flowering plants and thirty-five ferns. One observation of his is specially worthy of notice, that, though the mountains attain a height of 3,000 feet, there appears te be no ascending scale of vegetation, great numbers of plants ranging from the tops of the mountains to the sea-level, and many sea-level plants being found at the highest elevations. The forests of Fiji furnish many sorts of valuable timber, but they are diminishing from the constant fires, and Mr. Horne is urgent as to the necessity of replanting. It certainly seems anomalous that in so damp and rainy a climate bush fires should be so frequent.

MANURING FRUIT TREES.

(*Field*, 3rd September 1881.)

In no part of gardening has a greater change been observable between the last few years than in that of fruit culture, more especially as regards the application of rich solid or liquid foods in the shape of top-dressings or abundant applications of manure water; for it is now pretty generally admitted that our old terror of farmyard manure, as being the forerunner of most of the ills that fruit trees are heir to, was entirely without foundation, and that barrenness is oftencr the result of exhaustion than of over-luxuriance. I have lately had the good fortune to see some of the finest examples of fruit culture that I believe are to be found in the United Kingdom. I may mention Barham Court, where what may be called the French system is so well carried out that I question if sunny France or the Channel Islands can show a better example of all-round fruit culture; for not only is every kind of pear and

apple worthy of culture here found in such a position as to insure its perfect development, but plums, peaches, cherries, vines, melons, and, in fact, every edible fruit, is not only large in quantity, but far above the average of excellence as regards quality. But I need only refer in a casual manner to this subject, for in all sorts of seasons the crops have been good here. What I want to impress is how this excellence is attained, for the natural soil is by no means extra fertile; on the contrary, it is rather poor and hungry, and such as would be called unsuitable in many counties. But if this precluded such land being converted into fruit gardens, I fear that Kent would not have much more area under fruit than other counties. The fact is, fruit trees are not so fastidious as regards soil as was at one time imagined, and in this case a moderately fertile soil, well broken up, has been converted into an exceedingly fruitful garden by the application of rich top dressings of best farmyard manure, for between the rows of cordons or espaliers of various forms, the soil that is solely devoted to the trees was ankle-deep in manure; all vinery and forcing fruit house borders were mulched, and pot fruit trees were all plunged in soil covered with manure. The extraordinary vigour of the wood would have made "root pruners" anxious to commence operations; but here, by studying the kind of stock that each sort succeeds best on, and by double grafting in many cases, and, above all, by great care in pinching the young growths at particular stages of growth—the energy of the tree is expended in perfecting fruit and fruit buds for another year, instead of useless spray-like watery shoots. The old plan of cutting the breast wood off within two or three leaves of the spur from which it sprang is entirely discontinued, and the growth is allowed to make six or eight joints before being stopped. By that time the crop is swelling fast, and the trees show but little inclination to make wood growth, or if they do, it is from the tips that will be cut off at the following winter's pruning, while the buds for another season's crop are perfecting at the base of the spur, without danger of being driven into wood growth, as in the case when other outlets for the sap is cut off.

Fruit farms or gardens where the trees or bushes are grown in more natural forms than in the preceding instance are numerous in this neighbourhood, and I may refer to the well-known firm of Messrs. Skinner & Sons as an instance of successful fruit cultivators for market, for on various farms belonging to this firm may be found such fine crops as would scarcely be credited in localities where the manure cart is still dreaded; and I may briefly sum up the grounds for their success, which, although more conspicuous in a good fruit season like the present, when the trees and bushes are borne down by the weight of fruit, has been steadily increasing through all the bad seasons we have had—for good cultivation is the best antidote for "bad seasons." But to return to modes of culture. Here we find the extension system in its widest sense and fullest development, apple trees that bear 40 sieves on a single tree, and other trees in proportion; even the bush fruits such as gooseberries and currants are giants of their kinds, and filberts and cobnuts, which although pruned the severest of any fruit trees, extend to gigantic proportions, and the weight of nuts borne by one bush is hardly credible. But to support this drain upon the land a constant system of high feeding is practised; all kinds of London street refuse and manures are got together during the year, and such dressings applied as would have frightened our forefathers. For growers for market are now fully alive to the fact that a good article always commands the top price in market and a ready sale, and they find it to their interest to grow good reliable sorts in the highest state of perfection in which they can be produced. Cultivated orchards that are planted with standard fruits of various sorts, and bush fruits between, are heavily manured and dug in winter, and any trees, especially heavily cropped, have a top dressing over the roots while the fruit is swelling and abundant applications of liquid manure. And at this time, when one finds hop poles and cross bearers put under the branches to keep them from breaking down with the weight of their fruit, there can be no question that the trees need all the help or stimulus that can be given them to perfect such crops year after year.

In orchards on the grass devoted solely to standard or half-standard trees, where the grass is fed off by sheep, one gets the most conclusive evidence of the value of rich top dressings, for where the grass is cut and carried away the trees quickly fail to be prolific, unless a winter dressing of manure is applied, the same as on cultivated soils. But where sheep are constantly fed and pastured under the trees, they remain vigorous and prolific as long as a limb is left standing. In these orchards any kind of garden refuse or green food from the farm can be usefully applied to supplement the keep of the sheep, as the larger the number the better for the trees; and if every farm had its orchard, we might soon hope to have fruit both abundant and cheap, for this system of combining fruit culture with farming or stock rearing promises to be a source of benefit both to the producer and consumer. J. G.

Maidstone.

VEGETABLES FOR THE TROPICS.

(From *Sutton's Tropical Garden Guide.*)

(Continued from page 379.)

Cabbage (*Brassica capitata*).

There is generally only a short season during which it is possible to cultivate cabbage, so that there is no occasion for the great variety of sorts used in England. Any of the following will be found very useful—Early York, Nonpareil, and Sutton's Imperial. Sowing cabbage before September is attended with great trouble, and generally results in failure. From the beginning of this month seed may be sown for successional crops until the end of the year. The first sowings will need protection from the rains, and may be planted in large gumlahs. Do not sow too thickly, and if the plants come up well and become at all crowded, thin out immediately to prevent damping off. On no account plant out until the rains are over, in the beginning or middle of October. Make the soil very rich on which the plants are put out. Put the plants about 18 inches apart. A plantain leaf makes a very good protection for the young plant for a few days until thoroughly established. Watering and the application of liquid manure is important. After the first cabbage heart has been removed, the stem will throw out an abundance of sprouts and greens for a long time.

Savoy Cabbage (*Brassica bullata major*).

Same cultivation as for cabbage.

Capsicum and Chili (*Capsicum annuum*).

These annuals are very easily grown. Sow at commencement of rains in beds, and transplant when a few inches high, 18 inches apart. Water with liquid manure once a week, and to obtain large specimens pick off some of the first flowers. Avoid too frequent watering, as it causes the roots to rot.

Couve Tronchuda or Portugal Cabbage (*Brassica costata oblonga*).

This is a delicious vegetable. The top forms a fine cabbage of delicate flavour, and the midribs of the largest leaves are excellent when dressed as Sea kale.

Carrot (*Daucus Carota*).

It is of no use to sow before the rains are over. The ground should be well pulverised by repeated diggings, and should not be too heavy. Sow either broadcast or in drills; if the latter, 8 inches apart. When the plants are established, hoe out to 6 inches apart. The soil

should not be heavily manured, but plenty of water should be given. In storing carrots it is a good precaution to cut off the tops a day or two before raising the roots. When taken up and tolerably dry, store in sand or friable dry soil in large earthen vessels.

CELERY (*Apium graveolens*).

This root may be grown to as great perfection in tropical climates as in England. The secret appears to be to keep it in constant growth by a liberal supply of water and liquid manure. Sow as soon as possible after August for earliest crop, and again later for succession. Sow in gumlahs in a light soil, where the plants should remain until they are 3 or 4 inches high. The seed is sometimes six weeks before it germinates. Dig trenches 18 inches apart, 18 inches wide, and the same depth. At the bottom place a liberal supply of cow-dung, well decayed, on the top 4 inches of mellow mould, and in this plant the seedlings 18 inches apart, and water liberally. Do not commence earthing up much before the fourth month from time of sowing. It is generally in best condition for the table when five months old, for, though not full grown, it is of far better flavour than when more advanced. To obtain a very early crop the following season it is possible to sow at the end of January, and keep the plants through the hot and rainy seasons for planting out in September or October following.

CAULIFLOWER (*Brassica Botrytis cauliflora*).

All the directions given for the cultivation of cabbage apply equally to cauliflower. The soil cannot be too rich, nor the application of liquid manure too great. It is well worth while to pot off the young seedlings when very young, and keep them thus until the time for planting out. The cramping and starving the plants materially modify the tendency of cauliflowers to form leaf instead of heads.

CUCUMBER (*Cucumis sativus*).

This is particularly difficult to bring to perfection in India, on account of the ravages committed by a small red beetle, which infests the plants from the commencement. Muslin guards are an efficient protection against the attacks of these insects. Sow the seed at the end of October in good rich leaf mould, friable and well decayed. The plants may be placed in large pots or pans, and made to grow up a palisade or veraudah.

CRESS (*Lepidium sativum*).

This may be sown almost all the year round in small pans, thus keeping up a succession. A few days after sowing it is ready for cutting. The seed should not be covered, but sown broadcast on the surface after the soil is well watered.

WATER CRESS.

During the cold season this is raised without any difficulty. Sow in shallow pans with holes in the bottom. Stand these in a running stream or a pond so that the bottoms only are immersed. It is important that the water should have free access through the holes so as to keep the roots of the cress always wet.

DANDELION (*Leontodon Taraxacum*).

This plant is valuable as a medicinal salad. Its cultivation is very simple: sow as soon as the rain commences, in drills 10 inches apart, on a bed of rich soil not too heavy. Water frequently, and thin out to 8 inches in the rows, and when fairly grown keep the leaves off the ground by means of gravel or dry earth, covering with an inverted flower-pot. In the district of Guneah Khind several acres are grown for the supply of the Indian Medicinal Department.

EGG PLANT (*Solanum ovigerum*).

This is most successful when sown during the rains. Select a seed-bed of well-prepared soil, and when the plants are large enough transplant to 18 inches apart, on well-manured land prepared for irrigation. Water with liquid manure about once a week.

ENDIVE (*Cichorium Endivia*).

Sow about the middle of October, broadcast. As they do not bear transplanting well it is best to thin out the plants to 9 or 12 inches apart. Blanch by tying up the leaves into a cone with plantain leaf fibre.

(To be continued.)

THE NEED OF SPECIAL CULTURE FOR THE FINER GARDEN FLOWERS.

(*Field*, 3rd September 1881.)

In these days, when so many people are wishing to do something for the improvement of their flower garden and the fuller embellishment of their places with hardy flowers, many mistakes are being made every day as regards the selection and placing of the plants. The selection is a serious business, owing to the immense number of things that are offered, and the little knowledge people generally have of them. But, supposing we get over this difficulty, and get the finest collection of plants possible in Europe, much may go wrong if we do not place the plants rightly. The common way is to put almost every choice thing in what is called the mixed border, and placing it there very often means losing it in quick time. No doubt the well-made mixed border is one of the prettiest sights one can see; but the knowledge of plants and the taste requisite to make it are very rarely found. We have not seen three good mixed borders in twenty years. This is caused (1) by the repetition of the same thing, where it happens to be a popular or showy plant, all along the border; (2) by allowing a number of subjects to exist in the border, which speedily overrun it, and exhaust the others; and (3) by the ill-placing of nearly all the plants. The gardener who made a really satisfactory mixed border without much naked earth throughout the spring, summer, and autumn, and without filling up his gaps with weedy bedding plants and annuals, would be deserving of honourable distinction. Besides, the mixed border is not fitted to be brought into the open garden landscape, so to say, when made as it generally is; it is rather suited for the quiet walk or on the kitchen garden borders. However, the point of this article is to show that if we are to succeed with our finer races of hardy flowers, it cannot be in the mixed border. Each important family of flowers is worthy of special culture, and without it no satisfactory result can be obtained. Whether we take to carnations, pinks, pansies, phloxes or lillies, stocks, double wallflowers, cloves, tall scarlet lobelias, or any of the beautiful families of plants now obtainable, in every case they ought to have special culture in fresh soil if we are to have the best result. Even an annual that one fancies, such as the Rhodanthe, or a beautiful ornamental grass like one of the Brizas, it is not easy to succeed with, unless the plant has a fair chance apart from the confusion and weariness of the ordinary border.

Now this special culture is possible in two ways at least—either in the beds of the flower garden or on the lawn, and also in a plot of ground which ought to be set aside for nursery beds of the choicer flowers. Such plants as carnations, cloves, stocks, and pansies last a considerable time in bloom, and, therefore, may be introduced with taste into almost any position—not, perhaps, into a set pattern of carpet beds; but still, by themselves, on a lawn or associated with other things, the tasteful gardener will find a good place for them. It is not that they always want a bed to themselves, but they may often be grouped with other plants. For instance, carnations may go with a thin crop of standard roses, or may be followed by late-blooming gladioli, rising thinly over the carpet of grey leaves. So, again, pansies have admirable uses for mixtures of this kind. But the mixture must be "balanced"—plants put together that help each other, not rob or injure each

other—and in such a way a great deal of good work may be done in the flower garden or on the lawn.

But, apart from these ways, the plan wholly indispensable for an interesting garden is to have a piece of ground in or near the kitchen garden or any other open position sheltered, but not shaded, for the growth of any good plants we are interested in. Such ground should be treated as a good market gardener or kitchen gardener would treat it—well enriched, open, not encumbered with impediments of any kind. It must have a walk round it, within a wide border; but, apart from this, the fewer walks the better. It can be thrown into strips, say, from five to seven yards long, and these in their turn thrown into 4 ft. beds; but in this case the little pathways need not be gravelled or edged, they may be simply marked out with the feet. It is better to see the ground covered with twice the quantity of flowering plants than a great number of edgings and much gravel. If any edging is used in such a place, it should be of thin stone sunk in the earth, as these edgings are never offensive, troublesome, or costly. Flints or half-sunken bricks will do as well, if the thin stones so easily got in the western counties are not obtainable. With the aid of such a division of the garden, the cultivation of many charming plants becomes a pleasure, whether it is a bed of seedling verbenas, of alpine auriculas, of any favoured flower much used for cutting, and the culture is the most certain and pleasurable that one can follow. Well furnished, such a garden is a pleasure to the owner and all his visitors. Granting good cultivation, a dual kind of arrangement may be well carried out here. Thus, for example, hyacinths grown in the open air may be left in the ground for several years, their roots planted deep, and when they die down, or just before they die down, some beautiful annual or other light rooting plant may be put in the same beds to furnish them gracefully, but not in the least rob the roots. This we have seen done frequently, without in the least deteriorating the bloom of the open air hyacinth growing in well-prepared beds. In these little distinct beds, with one or two things combined in each, and fully exposed to the sun, with good preparation at first, we get the best result, and there is very little trouble afterwards. When the things do get tired of the soil, or require a change, having no plan, it is more easy to establish a kind of rotation, making our pink beds of the past few years the annual plant ones for the next, and so on. It would be easy to so change one's favourites from year to year, that richly feeding plants should follow those of a surface-rooting kind, and thus the freshness and novelty of the garden would be kept up. The abolition of all edgings, beyond one or two main lines through the space, would tend to more careful culture, as the whole spot could be so readily dug up and manured, or otherwise attended to.

Such a plot well done would be a paradise for ladies who wish to cut their flowers in quantity, and also a great aid to the gardener in replenishing such other arrangements of similar plants as he desires to establish in other quarters—on the margins of shrubberies, in the flower garden proper, or on the rock garden. It is also a great help to those who wish to exchange with their friends or neighbours in the generous way that all true gardeners like. The space that such an arrangement should occupy will of course depend upon the size and wants of the place in every case; but anywhere where the room could be spared an eighth of an acre of ground might be devoted to the culture in simple beds of favourite flowers, and even the smallest place should have a plot of the same kind.

ORANGE TREES.

TO THE EDITOR OF THE "AUSTRALASIAN."

SIR,—Will you kindly tell me in your next issue the proper mode of pruning orange trees? Ought the lower branches to be cut off, making them into regular trees, or should the branches be allowed to grow close down to the ground? Do you recommend much thinning out?

Eldorado. T. H.

[Experience has shown the desirability of allowing the branches to hang low enough to shade the stem of the tree from the sun. Orange trees are subject to a disease of the bark near the ground, and as this occurs chiefly on the north-west side of the tree, growers have concluded that it is either caused or aggravated by the heat of the sun when its power is greatest—about 3 p.m. The small weak branches should be taken out, the head generally should not be much thinned.—ED.]

A PREVENTIVE OR CURE FOR BLIGHT ON FRUIT TREES.

SIR,—Your correspondent's letter respecting the use of the above recalls to me a remark which fell from Mr. Bosisto confirming the above statement. He said that at his distillery he had a number of apple trees attacked, and the refuse from the still had been employed, and cured them of blight.—Yours, &c., J. H.

Sandhurst, Sept. 6.

FARMERS AND THE MANUFACTURE OF FERTILISERS.

(Field, 10th Sept. 1881.)

SIR,—In your editorial on the Agricultural Lookout in last week's *Field*, you say, "All are agreed that the only chance the British farmer has of competing successfully with the foreign producer rests in the application of capital to the soil for the purpose of maintaining and increasing its fertility, and of improving the modes and appliances of agriculture." You go on to say, "The question is, seeing that sooner or later—and the sooner the better—something must be done, by whom is it to be effected?"

You have here put the difficulty fair and square before your readers, and you have left it to their common sense and their self-interest to supply the practical answer. It is not out of place to suggest a reply to one aspect of the question, *i.e.*, to that important one involving the subject of expense, which will to some extent cover the difficulty.

It is well understood that the supply of guano is running short, and that some of the best houses in the trade are with difficulty able to respond to the orders they receive. However, as demand tends to regulate supply, there is little doubt that the necessary substitute will be available when the time comes. But in these hard times the profit of production is something to think of, and believing that such might be as useful to themselves as to an outsider, why do not the British landowner and the British farmer become their own manufacturers of artificial fertilisers, taking time by the forelock to prevent the manufacturers making them pay fifty per cent over the cost price of an article they must have if they are to continue growing corn as hitherto?

It is possible to produce, for instance, a superphosphate of lime, seventy-five per cent soluble, at a cost of, say, about six pounds a ton to the manufacturer, if he goes the proper way about it; and if such be the fact in his case, there is no reason that it should not be so in that of others.

I do not, of course, suggest the home manufacture of fertilisers; such an idea is out of the question. A combination on the part of landowners and farmers to keep down prices by no longer permitting a monopoly in the artificial manure trade is within their own power to accomplish, and they may possibly find that raw material procurable at home could be worked up with greater profit than that derivable from the applications to their land of American bicarbonate deposit, which

they would hardly be able to put down under five pounds a ton, and which, judging from its selling price in the States, cannot be very rich in soluble phosphate of lime, however rich it may be in total phosphates, the percentage of which, by the bye, your correspondent "J.H." forgot to mention in his interesting letter in *The Field* of Aug. 27. J. E. P.

THE MODE IN WHICH SEED BURIES ITSELF IN THE GROUND.

(*Gardeners' Chronicle*, 17th September 1881.)

Sir John Lubbock, Bart., President, read a paper at the British Association, on "The Mode in which the Seed of Stipa buries itself in the Ground." One of the most interesting parts in botany, he said, was the consideration of the reasons which led to the different forms, colours, and structures of seeds; and it was, he thought, pretty well made out that a large proportion of those might be accounted for either as serving to protect the seed or to assist in its conveyance to a place suitable for its growth. If the seeds of trees fell directly to the ground, it was obvious that very few of them would have a chance of growing. It was an advantage to them, therefore, of which many availed themselves, to throw out wings, in consequence of which the wind wafted them to a greater or less distance. Others, such as the whole tribe of nuts being edible, were carried about by beasts and birds, and though some were sacrificed, others survived. Fruits, again, in consequence of their sweetness, were carried about by animals, which, after partaking of the fleshy portion, dropped the seeds themselves. Many seeds were covered with hooks, and thus adhering to the wool of sheep and other animals, were carried to greater or less distances. Others, like those of our common Dandelion, were provided with fairy parachutes, and were thus borne away by the wind. Others again, like some of the Violets, Geraniums, Vetches, Brooms, Cucumbers, Cardamine, Oxalis, and others, had beautiful and varied contrivances, by which they actually threw the seeds to a distance, in some cases, of more than 20 feet. Others, again, were enabled to penetrate the earth, and thus sow themselves in the ground. In one of our English clovers, Trifolium subterraneum, after the flower had faded, it turned downwards, and buried itself in the ground. The ground-nut of the West Indies, and more than one species of Vetch, had a similar habit. In the Erodiums or Cranebills the fruit is a capsule, which opens elastically, and as in the case of the allied Geraniums, sometimes threw seeds to some little distance. The seeds themselves were in some cases spindle-shaped, hairy, and produced into a twisted awn. The number of turns on the awn depended upon the amount of moisture. If a seed be laid upon the ground, it remained quiet, as long as it was dry, but as soon as it was moistened, the outer side of the awn contracted and the hairs surrounding the seed moved outwards, the result of which was to raise the seed into an upright position. The awn then gradually unrolled, consequently elongating itself upwards, with the result that if it was entangled amongst any of the surrounding herbage the seed was forced into the ground. A still more remarkable case was that of the Stipa pennata. The actual seed was small, with a sharp point, and with stiff short hairs, pointing backwards. The upper end of the seed was continued into a fine twisted rod; then came a plain cylindrical portion attached at an angle to the corkscrew, and ending in a long and beautiful feather—the whole being about 1 foot in length. The end was supposed by Mr. Francis Darwin, to whom they were indebted for a very interesting memoir on the subject, to act very much in the same manner as that of Erodium, already mentioned. He did not doubt that the end would bury itself in the manner described by Mr. Darwin, but he doubted whether it always did so. One fine day, not long ago, he chanced to be looking at a plant of that species, and around it were several seeds more or less firmly buried in the ground. There was a little wind blowing at the time, and it struck him that the long-feathering awn was admirably adapted to catch the wind, while on the other hand it seemed almost too delicate to drive the seed into the ground in the manner described by Darwin. He therefore took a seed and placed it upright on the turf. The day was perfectly fine, and there could therefore be no question of hydroscopic action. Nevertheless, when he returned after a few hours, he found that the seed had buried itself some little distance in the ground. He repeated the observation several times, always with the same result; thus convincing himself that one method, at any rate, by which seeds bury themselves is by taking advantage of the action of the wind, and that the twisted position of the awn, by its corkscrew-like movement, facilitates the entry of the seed into the ground.

TEA-CULTURE IN AUSTRALIA.

The following article will be read with interest by the planters. It is taken from the "Town and Country Journal," a weekly journal published at Sydney, dated 9th July:—

It may prove interesting to furnish a few particulars concerning this, one of the most interesting plants that can be met with in our gardens. We have been induced to refer to the tea-plant on this occasion, chiefly because the honour of first introducing it, and of preparing the herbage for use, has recently, and on previous occasions, been claimed in other colonies, and by persons who have not the shadow of a right to do so. It was cultivated in Sydney before either of the colonies referred to had a name. It was introduced and cultivated by the late Thomas Shepherd, at the Darling Nursery, Sydney, as early as 1830, where the original plant might have been seen up to a few years since, when alterations in the grounds required its removal. From this old plant thousands of young ones were distributed during the many years it stood, producing annually large crops of seed and numerous young plants from layers, throughout this and the neighbouring colonies. It may be that within 20 or 25 years past, plants have been brought to the colonies from China or elsewhere, and as a matter of fact we know such to be the case, but it is quite certain that the originals in all the Australian colonies, were the offspring of this early introduced one. Some of the earliest young tea plants propagated to the Sydney Botanic Gardens, and if we are not mistaken these very plants are still to be seen there.

With regard to preparing tea leaf it may be said that nothing of consequence was attempted until about 1846-7, when two samples of cured leaf were exhibited by Mr. T. W. Shepherd, who had succeeded his father at the nursery, at one of the Horticultural Society's exhibitions. One of the samples consisted of young leaves, just emerged from the buds, and curled in the orthodox manner to represent the tea known as gunpowder. Beside this sample, which consisted of about 2lb one of a Chinese gunpowder, tea, specially brought from China for the exhibitor, was placed for comparison. This was a very high priced tea; we have an idea that it was about 16s per lb. The two teas were much alike both in apperance and taste, indeed some of the visitors were almost inclined to doubt the genuine character of the exhibit. A great deal of pains had been taken in gathering, sweating, and curling the leaves to give them as much the appearance of the Chinese tea as possible. The trial was satisfactory as to quality, but such tea could not be produced at a profit even at 16s per lb without much cheaper labour. The other sample consisted of full grown leaves not curled but merely sweated and dried, and of course did not present the ordinary appearance of tea, nor was it palatable as an infusion. It was merely prepared as a trial for producing a coarse cheap tea that could be grown and prepared by any person without any appreciable cost and which would pay at a few pence per

pound. These leaves were purposely selected as affording the extreme of unsuitableness and for the purpose of showing that ordinary tea quite as good as the coarse hysonskins that at the time formed the bulk of the tea ration tea imported from China. Half grown leaves would make a fair tea, and the curl is not absolutely necessary if the leaves are otherwise properly cured. Gathering the leaves is the main expense, and this precludes all chance of tea culture in Australia as a commercial enterprise until the cost of labour falls to something like a level with that of other countries or the cost in other rises to the Australian standard. At the same time the requirements of cultivating the plant are so simple that there is no reason why it might not be found in every garden, and the leaves gathered and made use of in lieu of the imported and often adulterated costly article. The shrub is as easily grown as a rose or geranium bush, and if as generally cultivated for home use as these are, the colony of New South Wales would be a gainer to the extent of at least £100,000 sterling per annum, while many families would be relieved from a very considerable drain upon their incomes. Practically they could obtain their tea for nothing. Housekeepers in the bush, where tea is so largely consumed, will understand what a considerable saving this would be. Five shillings a week —£13 a year—for tea as a moderate estimate for the cost of tea for even a small family of five or six persons. On an average probably the expenditure would be considerably more, and all this might be saved by adding a few tea plants to those already cultivated for family use. A few years ago we published full particulars relating to tea culture in Australia, and it may be that we will soon have the articles revised and republished. If the culture became naturalised, in the way suggested, there would always be at hand the material for establishing the industry on a scale of magnitude whenever the circumstances of the clony should become so changed as to render it probable that it would prove a commercial success.

AGRICULTURE AT THE BRITISH ASSOCIATION.

(*Field*, 10th Sept. 1881.)

Mr. F. H. Moore read an important paper on "The Depression of Agriculture: its Effects and its Lessons." Three points considered were—(1) Causes; (2) Changes brought about; (3) Remedies.

(3) *Remedies.*—After quoting correspondence from Professor Wrightson and Mr. Gilbert Murray, in which the latter laments the absence of sound technical teaching, Mr. Moore proceeds to sum up what, in his opinion, must be done to enable agriculture to flourish; for that with fair seasons, it can be made to answer, he does not doubt. Charges on the land will have to be reduced, and it is only reasonable that trade and income should bear an equal share. Rents will probably come down, but this is a matter that must regulate itself. Labour must be more economically used, and labour-saving machinery encouraged. We must grow such crops as will make the most money; and the farmer who expects to thrive must be able to take advantage of every appliance that this age of wonderful activity can give him. In other words, he must be properly educated. Mr. Moore, at some length, sketched out the aids of science to the art of agriculture, which too often the ignorance of the farmer prevents his using, and at the same time very properly limited the direct advantage which farmers can expect to derive from scientific teaching. The conclusion of the paper is so much to the point on this head that we venture to introduce it.

Seeing how beneficent an influence the technical application of the sciences of chemistry, biology, physics, and mechanics may exert on the future progress of agriculture, it may not be out of place to inquire how far the well-informed agriculturist should be acquainted with these subjects. Should he endeavour to become deeply versed in these sciences, he would find himself

Nourishing a youth sublime

With the fairy tales of science, and the long result of time, instead of acquiring such a practical knowledge of his art. On the other hand, he may set such high value on practical knowledge as utterly to ignore theory, and to content himself entirely with such rule-of-thumb information as he may acquire by daily work on a farm, so that however correct his knowledge may be, it is none the less empirical. Between these two extremes there is, it seems to us, a *via media* preferable to either. A well-informed agriculturist should have acquired a sufficient knowledge of the principles of science to enable him not only to understand what improvements in agriculture have been effected by science in the past, but also to form an adequate conception as to what information agriculture is likely to receive from science in the near future. The suggestions as to improved agricultural practice have emanated from chemists, mechanicians, and other scientific men, but it is the agriculturists themselves who have given effect to these suggestions, and thereby secured substantial advances. If the agriculturist is sufficiently cultured to be able to determine whether in any doubtful case the solution of the difficulty is most likely to be furnished by himself or by a scientific worker, or if, in other words, his scientific education has been such as will enable him in any doubt or difficulty to see exactly where the shoe pinches, this we apprehend is all that is necessary. Let the suggestions of scientific men fall on good ground in the minds of agriculturists, and nothing but good can result. Our fault is, in looking upon science, that we expect too much, and do not realise that it is, to use the words of Oliver Wendell Holmes, "a first-rate piece of furniture for a man's upper chamber, if he has common sense on the ground floor. But if a man hasn't got plenty of good common sense, the more science he has the worse for his patient." In fact, it can almost be said to be a certainty that, however much help we may get from the applied sciences in our social life, their help to our agriculture will never cause a very revolutionary change. After all that we can do in the shape of manuring the soil by the addition of the best manures of which experimental research and the knowledge of the chemist can point out; after we have tilled it by the most effective implements which engineering skill can produce for the purpose, and which are as different from the rude implements of our forefathers as light is from darkness; after the skill of the botanist has been exercised in the selection of nothing but the best seed and the destruction of weeds; after the application of the knowledge of the entomologist in the destruction of insect pests—after all these things the farmer has naught to do but to trust that the great controlling influence of all—the weather—will be favourable to his work, and enable him to reap a good reward for all his labour and expenditure. We cannot warm the perhaps cold earth with the telegraph wire, nor can we command sunshine by means of the mighty steam engine. We live in an age of wonderful life, but our agriculture, though partaking to a certain extent of this vitality, is still the same slow, anxious profession it was when Virgil wrote his "Georgics," when old Tusser penned his quaint "Rules of Husbandry," or when Arthur Young fought for and taught improved husbandary. That we have made gigantic strides in agricultural practice since those times is undoubtedly true; but after all, it means but little else than that we risk a very great deal more than did our forefathers to the uncertainties of our very uncertain climate. To use a sporting phrase, we lay more heavily and at shorter prices in favour of warmth and sunshine and "the earth yielding forth its increase." Goethe's expression of "Light, more light," may very well be altered to "Sunshine, more sunshine" for our crops in future, and to "Knowledge, more knowledge," on all that appertains to the soil, the animal, and the plant, for our farmers. With these, British agriculture may once again be remunerative, and perhaps even prosperous.

HORÆ HORTULANÆ:—ON SOILS.

(*Gardeners' Chronicle*, 17th September 1881.)

"Ah! if I had but your soil, I should get on," says the unsuccessful gardener, when viewing with envy the products of a successful brother; "it is impossible to grow these things on my land." Indeed, each of us has, I suppose, in turn complained of the disappointing character of the ground in which circumstauces have led us to attempt to cultivate our favourite plants. And yet, when we come to think over it, soil is the one thing which, above all others, is in the gardener's own hands. But each of us has it in his own power so to modify the special soil of the spot where fortune has placed him as to make it suitable—in large measures, at all events, for the plants he loves.

The sea has always seemed to me a great consolation for gardeners; and in this way:—Throughout living Nature there are found two substances, often companions, in nature very similar, and yet, in the work of life, of different, perhaps of antagonistic functions: I mean potash and soda. In every living being, animal or vegetable, you will often find these two; but they are held in different proportions in the different fluids and solids of the body, and appear to play different parts in the labours or the organism. While the animal body may, with comparatively little harm, be almost drenched with that commonest of soda compounds, table salt, a much smaller dose of potash may become a distinct poison. Now the sea is salt by reason of the great mass of the soda-salt contained in it; the quantity of potash is by comparison exceedingly small. Yet one common commercial source of potash is furnished by the ashes of seaweeds. These, living and growing in the sea, reject the abundant soda and pick up the scanty potash. This strange fact is, I say, a consolation to the gardener, for it shows him that what we call soil is not in itself food, but merely a carrier, throughout which the real food need be but thinly distributed. Much the same is seen in the air we breathe; the oxygen on which we live makes up a fifth only of the atmosphere, the other four-fifths are supplied by the useless nitrogen which we take into our lungs, it is true, but send out again unchanged, making no use whatever of it in our bodies. Still less, indeed, does the plant take up into itself, out of the manifold mixture which we call soil. The real food of even the most luxuriant vegetable growth is small in quantity, and, as far as we know, comparatively simple in quality; abundance of material and complexity of composition are necessary for making the soil a fit carrier of the scanty precious real food, but are necessary for this alone.

This I take to be the first principle of the gardener's art, this the chief object of the gardener's pains—to bring and keep the soil in such a condition that the meagre handful of elements which serve as actual food shall be placed in the best circumstances, and prepared in the best possible way for reception by the plant. That the actual food (putting on one side for the present the matter of water) is scanty, every one knows. A tall tree, to take an extreme case, when burnt to ashes, dwindles to a mere handful of salts, to which you may, if you please, add, for the sake of completeness a tiny flask of ammonia to represent the nitrogen which it drew from the ground; the two together seem a trifle compared with the mass of earth through which the tree's roots wandered, and which served it as soil. Still greater is the contrast between the earth-drawn material of one of the luxuriant sunflowers, in which æsthetic visitors to my garden at the present time find so much delight, and the load of earth which circumscribes its roots; burn the gorgeous plant and it vanishes to a pinch of salts and a whiff of hartshorn. These and these alone it took from the soil; all the rest came to it from the air.

The several elements of the actual food, too, are few in number—a little potash, soda, and lime, with a sprinkling of sulphur and phosphorus, and a trace of magnesia, alumina, silica, and iron; these, with some nitrogen and hydrogen, to form ammonia compounds, are the actual food elements of every plant, and of all plants. These, letting alone for the present the debated question as to how far carbon compounds may be absorbed from the soil, are the naked elementary things on which the plant actually lives. These are found in one proportion or another in, I might almost say, every soil. In almost every barrowful of earth taken from where you please, analysis would detect enough to supply, I would venture to say, the ashes of a tree, and we must remember the living root will pick up minute fragments which would escape the chemist; they are found scattered and distributed in a mass, it may be, of alumina, or of silica, or of lime, of which the plant makes no use at all. The difference between bad soil and good soil is not so much whether these elemental things are all present or no (though sometimes, it is true, one or the other may be all but absent), as whether they are present in appropriate arrangements and suitable conditions.

The broad characters of these "arrangements" and "conditions" are very fitly indicated by the well-known gardening phrases of "dead" earth and "live" earth. A little while ago I dug up and brought to the surface the subsoil of some lightly and poorly cultivated land. I added to it ammonia salts and chemical compounds, so that as far as the mere elements of plant life were concerned, it was on a level with the cultivated patch by its side, and I sowed and planted. Joseph shook his head, prophesying that no good things could be hoped for from "that dead soil," and he was right; the seedlings in large measure failed or the seedlings dwindled and went off, and the planted perennials draggled out a stunted, poverty-stricken life, or vanished wholly out of existence. In spite of the presence of the elements of food the "dead" soil was unable to meet the wants of the plants, and to help them in the struggle of growth.

What then is the difference between "dead" earth and "live" earth? The fundamental difference is that told by the plain simple meaning of the words. Good soil, fit for the growth of plants is really and truly alive: the thin crust of the earth which we cultivate is a widespread organism in which forces contend in the same way as they do in a living body, in which atoms are whirled to and fro in molecular and chemical conflict.

A great deal of the work of the animal and indeed of the vegetable organism is done by means of agencies which we call "ferments." The action by which the tiny globule of yeast changes sugar into alcohol and carbonic acid is a type of the multitudinous and as yet mysterious actions going on not only in the digestive canal of the animal, whereby food is dissolved and transmuted, but in nearly all the passages and cells of every herb and beast, whese blood or sap is being made, and where living protoplasm is being built up or broken down; and live soil is alive by virtue of its abounding in similar ferments. You pour some ammonia on to "dead" earth; it remains ammonia, and as ammonia is soon washed away. You pour the same quantity on to good "live" earth; in a short time tiny activities are at work, and the ammonia is soon changed into nitric acid, and this into some nitrate or other. Now, though all living matter, either in the changes attending on life, or in the decay which follows upon death, is, by the action also of ferments, resolved into ammonia, and though the ammonia thus produced is to a large extent the ultimate source of that nitrogen on which plants must feed in order to live, evidence is forthcoming to show that ammonia does not serve as the direct but only as the indirect food of plants; before a plant can

take up the nitrogen present in ammonia, that ammonia must be changed into a nitrate. And all over the globe the ferments in live cultivated soil are busy changing the useless, we may even say the harmful, ammonia into the beneficial nitrate.

This one ferment change going on in live soil has already been fairly worked out; but in all probability it is merely one of a vast number of similar changes going on in the earth, of whose existence we have indications, but concerning which our knowledge is imperfect and inexact. I am treading now on dangerous, untrodden ground, where we sadly need the light of careful experimental research; but I feel confident that future inquiry will justify the view that good rich soil is ever in travail, seething in molecular strife for the benefit of the plant, that the earth is not merely a storehouse whence the herb draws directly the material it needs, but rather serves at once as kitchen and stomach, where food is both cooked and digested, in order that the rootlets may take it already prepared for further use, and the cells for which it is intended be saved many a laborious task. The plant, in fact, is fed by the soil, rather than feeds on the soil; all vegetable organisms are, as it were, parasites on Mother Earth.

Nor is this view refuted by the fact that many plants may be cultivated on pure useless sand, watered with appropriate saline solutions, or even in the solutions themselves apparently free from all the ferments of which I have spoken; for every living organism has almost unbounded powers of adaptation, and will make shift for itself under widely different countries. Plants thus grown may live, but do not flourish. I, however, am speaking, not of what plants can achieve, but of what they are in the habit of doing under ordinary circumstances; and the objection which we are considering will first have force when we see market gardeners preferring to grow their produce in large vats of saline solutions.—Dietes.

(To be continued.)

SUB-TROPICAL GARDENING.

(*Field*, 10th Sept. 1881.)

This kind of gardening was introduced in order to avoid the eternal round of geraniums, calceolarias, and a few other common bedding plants, which, however worthy of culture they may be, can hardly be said to convey any adequate idea of the riches of the plant world capable of cultivation out of doors in our climate. For some years, however, the very name proved sufficient to deter many from giving the system a trial, from the erroneous notion that only tropical vegetation—the inmates of our stoves—was admissible. This arose through Musas, Caladiums, and similar tender plants being recommended in the first instance, together with costly preparations for supplying bottom heat, special soils, &c., all of which were at one time considered necessary. But not only have such unsuitable subjects been generally discarded, but more recent events have proved that even better and more lasting results can be attained by the use of plants of even a much hardier character than soft-wooded bedding plants, the sole representatives of out-door decoration some twenty years ago. Now with the rich store of fine-foliaged plants from temperate climes at command, it is quite possible to have a beautiful garden of hardy plants alone; for such subjects as the Ailantus, Paulownias, and other fine leaved shrubs make beautiful beds if cut down close to the ground every year like herbaceous plants. We have also the hardy palm (Chamærops), noble yuccas, and graceful bamboos, the beauty of which can hardly be excelled by any of the inmates of our stoves; and as regards dwarfer subjects suitable for edgings, we have such hardy plants as Siebold's plantain lily (Funkia), acanthuses, and plants of a similar character; while amongst plants that are annually raised from seeds, and merely require the protection of glass to start them, we have infinite variety between the stately Ricinus or castor-oil plant, and the dwarf Centaurea or Chamæpuce, from which to select colour or form. It is by selection from the various sections that the best results are obtained, and one great advantage of using permanent plants in pots for central objects in groups, or as isolated specimens on the turf, is that, while they add variety to the arrangement during summer, they can be taken up and utilised for in-door decoration as soon as the beauty of the out-door garden begins to fade. In this way a maximum of interest and pleasure may be enjoyed from both the out-door and in-door garden, according to the season. Sub-tropical and other fine-leaved plants, therefore, used properly, become a source of pleasure, affording as they do distinct phases of beauty. One tires of the continual repetition of the same class of plants, however well or tastefully they may be arranged; and by having totally distinct types of vegetation in separate divisions, such as the sub-tropical in one, carpet beds in another, and flowering plants in another, the result will be a well-varied and interesting garden.

Although tender plants in pots are decidedly effective for special occasions, in a general way any plants that are not able to stand out of doors from the first week in June until the last week in September can hardly be called fit for summer bedding. Amongst the most suitable are several kinds of palms, such as Seaforthia elegans; Chamærops excelsa and C. humilis; Aralias of various sorts; Dracæna australis and D. indivisa; Phormium tenax and its variegated form; Yucca aloifolia variegata; Hedychium gardnerianum, a noble-foliaged as well as a beautiful flowering plant; Ficus elastica, or indiarubber plant, a useful plant, either as a large or small specimen; and Eucalyptus globulus, the bluish-grey tint of which is quite unique in its way. Erythrinas make fine autumn beds; being very brilliant in colour, they are useful for lighting up sombre masses of foliage. Bamboos have such beautiful feathery foliage, that, when the winter is too severe to trust them out, they should be utilised as large pot plants for plunging out of doors in summer; they luxuriate on the margins of water, and look particularly well in irregular groups or clumps. Abutilons are particularly well adapted for open-air decoration, either planted or plunged; Abutilon Boule de Neige, Boule d'Or, and Darwini are all good; A. tesselatum and A. Thompsoni are also very effective, the markings of the foliage being rich and varied. The hardiest tree fern, Dicksonia antarctica, looks well plunged in shady dells where a good canopy of over-hanging foliage gives shelter and shade; and several varieties of dwarf ferns, such as the Bird's-nest Fern, are admirably adapted for undergrowth to the above.

Plants raised from seed will, however, form the majority in most places, from the lack of room under glass for sheltering many large plants. Of these the most generally useful are Cannas (called Indian shot, from their very hard seeds, which require soaking before they are sown). If sown in February, in strong heat, they make fine plants for bedding; their foliage is lovely, and the flowers rich in colour. The underground roots are permanent, and increase in size and strength every year. They may be taken up and wintered under glass, or securely protected in the soil by means of external coverings. The splendid masses of cannas one sees in the public parks are generally protected in winter. The tall light-green-foliaged varieties make excellent centres for groups, as they mostly flower freely, and the dwarfer bronzy-foliaged sorts are good for edging. A new variety, called Adrienne Robin, is very good. In addition to seeds, cannas are readily increased by division of the roots. The castor-oil plant is perhaps the noblest we have that can be raised from seeds. The latter should be sown in February in heat, and the young plants shifted on as required. They often grow from 8ft. to 10ft. high, with foliage nearly a yard in width. The

dwarf bronzy-foliaged R. Gibsoni is very effective for margins. It usually produces seeds very freely, and they frequently ripen out of doors in warm summers. Solanums, treated in the same manner, are also very effective. The spiny-leaved S. robustum, the elegant cut-leaved S. laciniatum, and S. Warscewiczi make beautiful single specimens or edgings to groups of taller plants. Wigandias, Ferdinanda eminens, and Melianthus major are likewise all beautiful plants, treated as annuals; and among dwarfer subjects that can be raised with them I may mention Braziliau beet, with its richly tinted leaves and midribs; Acacia lophantha; Amarantus in variety; Cineraria maritima; and Centaureas, with their silvery, elegantly cut leaves. There are, moreover, the dwarf thistle-like Chamæpuce diacantha and Cassabonæ, Echeverias in variety, Stachys lanata, and many other dwarf plants suitable for edgings or carpeting beneath tall-growing subjects.

Of hardy or permanent plants in addition to those already enumerated, I may mention the many beautiful varieties of maples, from the well-known Acer Negundo variragatum to the beautifully cut-leaved A. polymorphum and its varieties. These, treated as dwarf standards, with the ground covered with dwarfer plants for contrast are very beautiful. Bocconias, with their tall spikes of graceful flowers and noble foliage, make effective and permaneut plants for isolated groups. The Pampas grass and Arundo ought also to find a place in every garden, for they are beautiful at all times of the year, and on the margins of water are quite at home. Several varieties of Rhus or Sumach have very beautiful foliage, Rhus glabra laciniata being especially elegant. Aralia japonica is also well adapted for flower garden decoration, as are likewise Retinosporas, Junipers, and Cupressnses among conifers. Of dwarfer plants for edgings or carpeting we have the gold and silver Euouymuses, golden honeysuckle, and a variegated vine. The Tritomas, with their fine rush-like foliage and flame-like spikes of flower, the Funkias, the variegated grasses such as Poa trivialis argentea, the Polemonium cœruleum, the Vincas or periwinkles, Santolina, Stachys, Sedums, Cerastiums—these and many more are all useful plants in the flower garden. In fact, the material to select from is unlimited, even if we confine ourselves to fine-foliaged plants; but there is no reason why beautiful flowering or berry-bearing plants should not be utilised with excelleut effect—as, for instance, ornamental gourds, egg plants, the Cape gooseberry, &c.; while tuberous-rooted begonias, and may equally brilliant plants that do uot fall in with the ordioary bedders, might in some places be associated with the fine-foliaged plants.

As to arrangement, in all cases beds or sets of beds of the simplest design are the best. Shelter from wind is also of the first importance, and for this reason recesses in shrubberies or banks clothed with foliage form the most fitting background for beds or groups to nestle in. Avoid Musas or Caladiums, the leaves of which tear into shreds if winds cannot be entirely shut out; also plants that look unhappy on the occurrence of a cold night or two; and concentrate your efforts on subjects that grow and look luxuriantly under nearly all conditions. If a dell or garden overhung by trees is at command where ordinary flowering plants run all to leaf and refuse to flower, take advantage of it for fiue-foliaged plants. It will form a charming change from brilliant bedding plants or severely geometric carpet beds to come upon a garden where each plant spreads broad its delicate foliage on the grass, even in our variable climate.

J. G.

PARAFFIN.—In the *Colonies and India* it is stated that a thick vein of a peculiar substance, containing half its weight of pure paraffin, has been discovered at Hawke's Bay, New Zealand. It is said to be worth £40 a ton.—*Nature*, August 11, p. 34.

PHASKOMYLIA TEA.—Dr. Xavier Landerer, writing in the *Chemist and Druggist*, says one of the street cries of Athens is "Buy Phaskomylia tu bunn," or the Sage plant of the mountain, the apple-bearing Sage. The herbalists gather it, and tie it in bundles, which they sell in the market for about 10 leptas. A tea made from this herb is drunk in all chills and gripes, as a matter of course, without consulting the doctor; it is sold, too, in the coffee-houses and confectioners' shops. The plant is called apple-bearing, because the puncture of the insect, Cynips salviæ, causes the growth of galls known as Gallæ esculentæ, and like little green Apples. These are collected and eaten after being steeped in water to remove the bitter and styptic constituents. The plant is very common in the mountains of the district of Maina, and the galls are collected and boiled in honey or sugar, the consere thus made being used like other sweetmeats, or mixed with water as a beverage, a teaspoonful to a tumbler. This Sage plant is found in all houses of the poorer sort, and on board ships and on cold days Phaskomylia tea is drunk. The plant is also kept on hand in all the coffee-houses, even as far as Odessa, and its infusion is a favourite beverage. In Odessa a kind of punch is made of it with rum.—*Gardeners' Chronicle.*

WOOD PULP FOR MAKING BARRELS.—The latest novelty in the application of wood pulp comes to us from America, namely, for making barrels for holding both solids and liquids. The following account of this manufacture is given in a recently issued report from America: —"Wood pulp, so conspicuous of late years as a material for the manufacture of paper, has been found to afford one of the best means of making light cheap, and durable barrels, adapted for all purposes for which these useful packages are demanded. The barrel is made in one piece of coarse wood pulp, subjected to a pressure of 400 tons. The heads are made in the same way, giving a degree of compactness of grain that is sufficient for every use. When the barrels are put together they are very light, very strong, and very satisfactory in every way. Two kinds of barrels are made—one for fruit, flour, and other dry substances; the other for oil, lard, beef, pork, and liquids of all kinds. These latter are made impervious to the infiltration of oil and other liquids by a simple process. The flour barrels are so strong, that when filled they can be dropped from a waggou without injury, and fruit packed in them keeps a long while, being excluded from all contact with the air. These packages can be made for half the cost of ordinary barrels."—*Ibid.*

ROOT PRUNING.—Unpruned trees are benefited by root pruning, like other trees; but they do not require it nearly so often, because, being allowed to extend, they run themselves out into fruit. Pruning is one way of lessening the effects of root pruning, and curtailing its usefulness. Keep up the demand for food by encouraging a large breadth of branches and leaves, and reduce the supplies by curtailing the roots, and a decided check is given to over-luxuriance at once. This is the philosophy of root pruning. I may just add that I have for many years tried the effect of tree growth and shoot extension with a minimum amount of pruning, or none at all, upon many other kinds of plants—among which may be named the hawthorn, Cratægus pyracantha, and other hardy shrubs, the Bougainvillea, Clerodendron, Stephanotis, Allamanda, roses, &c.—and always with the same result, that is, of running the plants into flower or fruit abundantly at au early age. The Cratægus pyracantha, it is well known, does not fruit freely when young; but we have a number of quite young plants here, growing in a strong soil, that fruit in the most profuse manner. Let the branches extend, and never shorten them, and each one will produce dense wreaths of berries. It is only when you begin to crop the shoots, as they do pears and apples, that they cease to bear fruit.—J. S. W.—*Field.*

PLANTING IN MANILA.

"There is a local industry, which for some time has become extraordinarily extended in this quarter —that of the manufacture of common hats from Balinag and Pangasinan These hats are in great demand in Europe and America, especially in the latter, from which large orders have been sent to Manila. It is to be remarked that a good business is done in Europe and America after receiving these hats, by altering and adopting them to suit the taste of customers there."—*Diario de Manila*, 3rd Sept.

"*Sugar.*—A well informed person who has been applying himself to studying statistics, and who investigates whatever can contribute to give greater knowledge of the riches of this country, assures us that the production of sugar in the Philippines during the present years may exceed 200,000 tons. These figures place the Philippines in an honourable position. It is certain that in year to come, the production of this valuable article will go on increasing here."—*Comercio*, 3rd Sept.

"*To Coffee growers.*—We have seen a telegram from Spain dated yesterday, announcing a further fall in the prices of coffees from these islands, and great reluctance on the part of consumers to buy Philippine coffee, of which there are new large stocks in the Peninsula. The nominal price was $18 per Castilian quintal. This explains the complete stagnation of business here as to transactions with this article which finds no buyers at $1,353 If holders here do not lower their rates we forsee that the stocks in hand will be increased by the first arrivals of the new crop. We believe that the quantity stored in Manila now amounts to 10,000 piculs. We are informed that in Spain, attention has been drawn to the quickness with which stored Philippine coffee loses the green colour, while that from Porto Rico, Cuba, and Mexico preserves its colour longer. Hence the latter description is more in demand and is quoted at higher rates than that from these islands. Probably this is owing to the faulty mode of collection in this country, perhaps from over haste to pluck the berries from the trees. Hence we draw the attention of planters to it, so that on investigating the origin of this serious defect they may be able to remedy and thus enables Philippine coffee to recover its repute. Notwithstanding that it was believed here to be superior to coffee from other countries, it must have become deteriorated, when it is quoted in the European markets at such low rates." —*Straits Times.*

THE PLANTING ENTERPRISE IN SUMATRA.

Regarding Deli, Langkat, and Serdang, the Samarang *Vaderland* of the 22nd August contains an article in which the origin of planting enterprise there and its results are thus set forth :—

Twenty-five years ago the State of Siak, which now forms the central portion of the Residency of the Eastern Coast of Sumatra, was connected with the Netherlands Indian Government by rather weak ties. The Netherlands had concluded several engagements with the Sultan of that State, but evidently more sympathy was felt there for the British, which is very explicable from the active trade between that territory and Singapore. It was not until one Wilson attempted to establish a second Sarawak at Bukit Barn and Klapa Pati, and the Sultan applied for the aid of the N. I Government against him, that Siak was actually brought under Netherlands authority. This happed in 1858. In the following years, the numerous dependencies of Siak were visited by Mr. Nets her then Resident of Rhio and engagements were entered into successively with the headmen and people, whereby they acknowledged the supremacy of the Netherlands. The Resident also exerted himself to call attention to the fact that the insignificant trade of these petty states was far below the productive power of the country, and also to encourage enterprising Europeans to settle there. He wrote on the subject to a trustworthy inhabitant of Batavia advising him to send a competent person to make inquiries on the spot. The result was that in 1863 Mr. J. S. G. Gramberg, from whose articles in a magazine in Holland, we derive these particulars, undertook a voyage to the east coast of Sumatra. He visited all the coast districts in Malacca Straits, entered into negotiations with the Sultan of Siak, brought with him to Batavia specimens of native produce, and showed that a European settlement in those districts would have every chance of proving a success. The mercantile community of Batavia, remaining faithful to their traditional policy of unwillingness to invest money in enterprizes in little known places Mr. Gramberg met with discouragement and, for a long time, it appeared as if all the pains and trouble he had taken would be in vain. At last, one enterprising person came forward. He asked for information, received the most recent specimen of tabacco Mr. G. had brought, and decided on going to Deli to start a tabacco plantation there. This first pioneer of planting enterprise on the East coast of Sumatra was Mr. Jacobus Nieuhuys, who first set the business on foot on behalf of Mr. Van Arend, and became afterwards tobacco planter on his own account in Deli. The splendid results yielded by the first tobacco crops in Deli are generally known. The excellent quality of this product caused so great a sensation in the European market that, soon, Hollanders, British, Germans, French, and Danes came in great numbers to settle in that fertile district, and several Companies were established with the object of carrying on the planting business on a large scale. The Colony thus growing with such unusual rapidity had, however, to struggle through many difficulties. Trade increased to an extent never before known. The native princes and chiefs profited much meantime. Some of them became wealthy, but they cared little about order and security, and the European authorities stationed at Rhio and represented in Siak by only an Assistant Resident with limited jurisdiction had not sufficient power to ensure the same. It was not until 1873, when the East coast of Sumatra was formed into a separate province and an Assistant Resident stationed at Deli, that this state of things began gradually to improve. That this was necessary becomes apparent when attention is paid to the rapid increase of the foreign portion of the population. Before 1862 there was not a single European in Deli and there were only a few Chinese retail dealers and revenue farmers. In 1864 there were only three European planters near Labuan Deli, the chief town. In 1867 there were already 1,000 Chinese, chiefly coolies and the export of tobacco reached 1,300 piculs.

Further statistics show that in 1874 the estates held by Europeans were 23, being 10 more than in the previous year, planted with 31,295,555 trees yielding 19,642 piculs of tobacco. In 1876 there were 75 estates with 7,600 coolies and the population were 124 Europeans, 9 Arabs, 7,607 Chinese, 774 Foreign Orientals, and 30,204 natives. This increase of population, chiefly in the foreign element, indicates the expansion of trade and industry. In 1877 the estates were 87 in number, of which some were afterwards abandoned and nutmegs and coconuts were also planted, the latter proving however, unremunerative. The Official Colonial report for 1880 gives 70 as the number of estates, legally established in 1879 under contracts sanctioned by the European authorities, namely, 39 in Deli, 22 in Langkat and 9 in Serdang. As to production, the above report states that, on almost all the estates tobacco was cul-

tivated. On 3 of them nutmegs as well; coffee on 1; and coffee and cocoa on another, 3 of the new estates had produced nothing in 1879 and the crops of two others had not been ascertained. The tobacco yield for 1879 amounted to :—

for 32	estates in Deli	5,488,151	Amst. lb.
19	do	Langkat 1,401,516	do
9	do	Serdang 1,321,925	do
		8,211,572	do

Certainly a remarkable result in a country where, fifteen years ago, there was hardly any trade and industry owing to misgovernment, exactions, civil war, and absence of European enterprise.

The revenue in these districts in 1879 amounted to 1,195, 196 guilders, and the expenditure to 693,870. This large revenue is partially derived from excessive taxation, the incidence of which is now becoming more severely felt from a recent fall in the price of tobacco, resulting in several estates proving unremunerative, and in other being even abandoned. The above journal urges a reduction of taxation on the ground that the Opium and Gambling farms revenues there fully meets local expenditure.

Messrs. F. E. and L. C. J. Simonnar have been granted a concession for 75 years by the Netherlands Indian Government to work diamond, gold, platina, and coal mines in the Chumpaka district in the province of the S. and E. Division of Borneo.

A petition signed by 44 mercantile firms in Batavia has been presented to the Governor General of Netherlands India, praying that book-keeping in the Dutch language, or in the Malay language written with Roman characters, be made compulsory on Chinese and Foreign Oriental traders there as a check on fraudulent bankruptcy among them.

Several British and Dutch capitalists have also formed a Steam Navigation Company at Amsterdam with a capital of $250,000 to run a line of six steamers from there to Java, for carrying cargo only at a minimum rate of freight. The first steamer of this line was to leave Amsterdam in the middle of last month.—*Ibid.*

SPECIMENS of a new leech previously unknown in France, the *Hæmopsis sanguisuga*, have recently been exhibited at the Société de Biologie, by Dr. Megnin (*Med. Times and Gaz.*, July 30). They were found adhering to the mucous membrane of the mouths of some artillery horses that had just returned from Tunis. The brooks of North Africa are said to be full of this kind of leech.—*Pharmaceutical Journal.*

GRAFTING.—Professor Budd says that in the Iowa College graft-room they graft not only Apple and Pear, but Plum, Cherry, Apricot, and Peach, successfully on seedling roots—preferring seedlings of the Miner Plum for the stone fruits—using it even for Cherries. They graft quite early in the winter, on roots stored in November, and then immediately plant or store them closely together in a bed of sand in a cellar with humid air, but with floor and sand never more than damp. Only the roots and the lower end of the scions are covered by the sand. For the stone fruits care is taken not to let the wax wraping of the union of graft and stock be in actual contact with the bark. A light coat of moist clay is first applied over the cuts, and over that is closely wrapped a strip of muslin from a roll which has been soaked in a melted mixture of white rosin, linseed-oil, and a small quantity of wheat flour. This is a rather novel recipe, dispensing with the generally-used beeswax. The flour is stirred into the hot mixture to prevent the hardening and drying of the cloth which should hermetically seal the wounds. The planting should be done very early, on the first practicable day, and the grafted roots must be kept entirely dormant, but entirely fresh, until planted.—*Gardeners' Chronicle.*

MUSK RAT.—The tail of the musk rat has already made its appearance in this country. The odour seems to be intermediate between sumbul and musk seed.—*Pharmaceutical Journal.*

OVER-GROWTH.—"Since the subject of vegetable pathology," writes Mr. Berkeley, "has been taken up so successfully by Sir James Paget, attention has lately been very much turned to anomalies as well as to ordinary forms of disease. A very curious one, if not entirely new, has lately occurred, which I lose no time in communicating to the *Gardeners' Chronicle*. I have observed for some time that a plant of Thuya gigantea has appeared in a very unsatisfactory condition, though one close to it is a fine sample of growth. On examination I found a large excrescence like a corn at the base of the tree, which had a diameter of more than 13 inches, while the trunk of the tree had a diameter of 3 inches only. I had a section made with a circular saw, which was impeded when half-way through. At the point where the impediment took place was a little lump of hard iron-stone, which had the curious effect of causing a strange diversion of growth, which was more rapid than it had previously been, but the principal energies of the plant were diverted; a few roots were thrown out on one side, while there was not a trace of roots on the other. The strangest part was that the growth of the stem was more rapid, but the health of the plant completely deranged. It was clearly not a case of exostosis, depending on an imperfect developed bud, but very analogous to a wen in the human frame. The case is so curious that I have sent a drawing which may, I hope, be acceptable. Since the above was written, Dr. Masters has pointed out that a similar production is noticed and figured in 1879, vol. ix., pp. 372, 377, and I have observed somewhat of the same kind at the point where plants have been grafted. I do not think it is analogous to what are called gnarrs, but that it is a kind of hypertrophy."—M. F. B.

COFFEE AND OTHER PRODUCTS IN CEYLON.—I have within the last few days received through the Director of the Royal Botanical Gardens a further report upon the coffee leaf disease by Mr. Ward. This most able and deeply interesting paper will forthwith be laid on the table. In the opinion of Dr. Trimen it exhausts the subject, and completes the work which Mr. Ward undertook, so far as it can be carried ont in Ceylon. Although Mr. Ward has not been able to suggest any mode of treating the disease which shall absolutely eradicate it, he has at least given to the world in the life history of the Hemileia the true data upon which a mode of dealing with the disease may hereafter be founded, and in the meanwhile such remedial measures may be adopted as may enable the coffee to withstand the strain of the disease. Although vast injury has doubtless been done by the disease, the export of coffee from Ceylon will long continue to exceed in value by far all other exports put together. It is, however, very satisfactory to note that other products, both old and new, are fast increasing in quantity and value. The export in 1880 of the produce of the cocoanut in its various forms was valued at six millions of rupees. The quantity of cinchona bark exported has risen from under 15,000 pounds weight in 1876 to 1,061,989 pounds weight in 1880. The export of tea also has doubled. Tobacco is another staple which experience has shown can be profitably grown in Ceylon. The value of the exports of tobacco last year exceeded a million rupees, and, considering the unceasing demand for this article, the cultivation of it on a large scale on suitable soil could hardly fail to be successful. Other products such as India rubber and cocoa are being grown in increasing quantities, and I feel confident that the exports of future years will exhibit a variety of products which may in time equal the value of our coffee crops.—*Speech of Sir Jas. Longden in opening the Legislative Council of Ceylon, Sept. 28th, 1881.*

MACKAY, QUEENSLAND, THE GREAT SUGAR REGION.

(Written for Ceylon Observer.)

MACKAY, Queensland, 4th Sept. 1881.

On Tuesday morning, August 31st (the date, in 1606, of the discovery of Torres Straits for which I am making), we were roused at half past 3 a.m.(!) in order to leave the "Alexandra" steamer and get into the small "Dugong." Our steamer, the big one, went off north and we had to wait not only for the steamer bound south and take the passengers for Mackay, but also, after that, until the tide enabled the "Dugong" to go up the Pioneer river to the wharves at Mackay, a town which sugar has raised from nothing to rapidly increasing importance in ten years. Before breakfast, however, we landed on Flat Top Island, where there is a lighthouse and telegraph station. Hence we telegraphed, had a glorious view of the Pioneer river district, of the semi-circular mountain ranges of sea and river and land, sunshine and clouds, for clouds were gathering which issued in a truly tropical rainfall during the night. It was welcome but transient, and not a drop has fallen since, to our great comfort as knockers-about, but to the regret of the planters who have young cane in the ground. As soon as I stepped on shore on the beautiful little islet (one literally of thousands, through which our course has run and will run) I was face to face with tropical vegetation and much of it common to Ceylon. On the shore was the goat's foot ipomea, and festooning the bushes the very convolvuli common near Colombo. The screw pine was abundant, and in the lighthouse-keeper's garden there was a coco palm, *vinca rosea* (so common in our Cinnamon Gardens), &c. There were forms not familiar to me intermixed, however. Going along the banks of the Pioneer river, I could almost fancy myself on the Kelani or other Ceylon stream. *Hibiscus tiliaceus* most conspicuous, and the same trees as line the road from the Baidge of Boats to Hauwella festooned with the same species of creepers. But mixed with forms which I recognized were others new and interesting. Most conspicuous is what the people here call "the palm," or *palma elegans* or the Alexandra palm, or the cabbage palm. It resembles a thornless katu-kitul, or rather a very luxuriant areka palm, with more of a tendency to bend. These palms are in masses everywhere, beside rivers or lagoons and add much to the beauty of the scenery. The inflorescence and seeds are much like those of the arcka, only the seeds are much smaller, like wild dates, and of a brilliant red as they ripen. This palm would be beautiful and useful in Ceylon, so I got Mr. Charles Mackinnon (brother to the *Argus* proprietor) who drove me out to a grand sugar estate yesterday, which he has just purchased for £95,000, to get me some seeds. Also some of what he called "quadroups" or Queensland plums, and some ripe Queensland raspberries. This indigenous raspberry exactly resembles the cultivated "rasp" in flower and foliage, but the fruit is more like a strawberry, being almost round like a scarlet thread buttou. Very pretty it is, but the flower is not equal to the true thing. If we can grow it from the seed, however, cultivation might improve it.

Mackay (in 21° 10' south) has about the climate of those parts of Bengal where 75 inches of rain fall, with a far less severe hot season, and what grows well here ought, I think, to do well in our hill country. All the way from Sydney hither the bougain villea has been blazing,—pink, magenta, and bright scarlet. So with the bignonia which the Tamil coolies call the tangapu or gold flower. On Sydney bay shores the lantana, chiefly the pink-blossomed, abounds, and on to this place we have seen it. Indeed it threatens to take possession of large portion of Queensland, but the colonists are much more troubled about a jute-like weed, *sidus retusa*, I think. It covers whole plains and prevents the sheep getting at the grass. The once much dreaded thistle (which grows only in good soil and opens it up) is nothing to this "curse of Queensland." Of the blue-blossomed duranta and the "shoe-flower" bibiscus they make fences here, and in gardens I have seen dates, mangoes, cocoauts, *ficus bengalensis*, *ficus religiosa* (the bo-tree), *poinciana regia* and pines growing together. Some of the planters' bungalows are beautiful. At one where we met Mr. and Mrs. Hewitt and Mr. and Mrs. Romilly the verandah opens out on the river (Pioneer) bank, and they told us that although a little low fever and ague occurs occasionally in the district the banks of the rivers are the healthiest parts! The climate, after all, is a semi-tropical one, without frost, and that it is favourable to human health the looks of the people shew. We saw about a couple of hundreds of "fair women and brave men" at a ball given by Mr. and Mrs. Davidson (he a nephew of Davidson of Tulloch), and they all looked robust, although the men were browned by the sun, to which all expose themselves with impunity. I went yesterday to buy a white cotton umbrella, and the shopman told me there was absolutely no demand for men's umbrellas. We saw little children lying out bareheaded in the sun all day, and we were told that cases of sunstroke are unknown. The gentlemen sugar planters, like the ploughmen, go about in trousers and shirts,—coat and waistcoat generally dispensed with in working hours. At Mr. Mackinnou's estate yesterday I saw the hospital for the Kanekas (South Sea Island coolies), and it was empty. Of late years there has been little sickness or mortality amongst these people, and they look well clad, well fed, and well-to-do. Each, when he goes back, is sure to carry away a gun. This ought to strengthen the tribes to which they belong, but the chiefs object to the withdrawal of the young males, and from this cause and the islanders dying out I feel certain that ultimately, if not soon, Hindu cooly labour must be resorted to. There is a sum of £600 per annum on the Queensland estimates for an immigration ageut, and I believe the necessary law has been passed, but the working men and others also are strongly prejudiced against the introduction of immigrants other than whites. If they prevail Mackay will never turn out, as it is capable of doing, 300,000 tons of sugar instead of the 10,000 now produced.

We saw opposite Flat Top Island three schooners just arrived from Solomon Isles with "boys" and a few women. I never felt so inclined to believe the development-from-ape theory as when I saw the Kanekas ranged on deck, although they were well dressed, in "jolly" condition, and many of them smoking pipes. Their bushy heads of hair were generally dyed a bright yellow with lime or ashes, and in that repect they reminded us of the Somalis at Aden. But their features are even more of the negro type, and it seems to me they are the shortest race of human beings I have yet seen. At the suggestion of Mr. Jaffrey, who is very largely interested in sugar, I spoke several sentences in Tamil to the "coolies," but they only grinned at me. When our steamer left they gave us a loud cheer which went off into a yell, such as no doubt they utter when attacking their enemies. They make good cart drivers, but the ploughing on the sugar estates is done by white men, the proportion of an estate force being 20 per cent white men to 80 per cent blacks. It is certain that whites could not do the "trashing," cutting of the canes, &c., or if they could the pursuit would not pay. For while the Kanekas get only £6 per annum, with lodging, rations and medical attend-

ance,* the wages of white men is 20s to 25s per week, with lodging and rations. If the resources of tropical Queensland and Australia generally are to be developed, Indian coolies must be introduced. It was very amusing to see an experienced Kaneka drayman pushing his "new chum" countrymen out of the way with an emphatic "Get out of that, will you?!" As far as I could see the black labourers are treated well and work heartily here. But more labour is wanted, so that instead of the "trash," withered leaves, &c., being removed from the field, it is often set on fire on dewy nights. The agents, one of a French sugar machinery company, the other of an English firm, who are travelling with me, did not approve of this and of other expedients, but good sugar is turned out and it pays. Mr. Davidson, who had experience in the West Indies, told me it was a great thing here to have no prejudices to contend with. He said this pointing to a plough with three horses ploughing earth up to the rows of sugar. He said if he ventured to substitute plough for hoe in the West Indies the negroes would say: "Me have grow him sugar! my father he grow sugar; my grandfather he grow sugar. When *you* larn grow sugar?" The agents for improved sugar machinery, by which it is alleged a large additional percentage of sugar can be obtained, now say that Mr. Davidson himself is likewise prejudiced. But people have to be cautious. They have before them the "dreadful example" of Mr. Tooth (brother of the ritualist clergyman), who ruined himself by buying every new machine he read of. Mr. Van de Velde, the agent of the Lille firm, tells me there is a machine for separating the fibres of sugarcane before it is pressed between the rollers, which ensures a large additional percentage of juice. The difficulty with the cane in its ordinary state is that it has a siliceous skin and knots a good deal like the bamboo (one cane is called the "rose bamboo"), and it has, much of it, to be passed twice under the rollers. Most of the estates, ranging about 5,000 acres each,† have been made from "open forest" land—park-like expanses of rich alluvial land of a rich black colour, deposited by the river but owing its origin to volcanic mountains. Others have been opened or are now opening on what is strangely called "scrub land," really what we would call forest in Ceylon. On such land the cane will yield a first crop and six ratoon crops without renewal. The canes are at first rank and yield juice largely in proportion to sugar. The weight of cane per acre decreases, but the percentage of saccharine matter increases as time goes on. That was the experience of a planter who had taken eight crops off the same land. Manuring is not entirely neglected, but most of the "megass" (exhausted cane) is used for fuel, with coal and wood. The latter is already scarce, and firewood in Mackay is very expensive.‡ The average yield of cane is over a ton an acre, say up to 30 cwts, and 15 tons cane give 1 ton sugar. 1½ ton per acre is a fair average, and the sugar can be sold at Mackay for £22 10s per ton. Many small planters, who cannot afford the very expensive machinery necessary for the manufacture of sugar, sell cane to the mill owners, at 11/ per ton on the field, the purchaser cutting and carting it to his mill. At a large estate called Yengarie, in another district, the small growers crush their cane in common mills, and the juice, which is paid for by strength, goes 5 miles in pipes to the central factory. Mr. Van de Velde tells us that in Belgium beet juice is thus conveyed for a distance of 45 miles! Mr. Jeffray has got a most complete set of machinery for a new estate, The Palms, and amidst this machinery, and no doubt to inaugurate the great mill, the ball was given, to which Mr. Jeffray procured invitations for me and my companions. Nothing could exceed the kindness of the Davidsons. Mr. Davidson, the leader of the sugar planters here, is a fine energetic fellow: I told him that the joke in the Highlands when I was a boy was that Tulloch spent the money which his brother Henry Davidson, the London merchant (father of our host), made. I heard Mr. Jeffray say that from one estate he did not expect a shilling of return until he had spent £40,000; but then he looked for a minimum return of 20 per cent. Mr. Mackinnon asked Mr. Paton yesterday what a set of best machinery to take in 2,000 tons of sugar per annum would be. The answer was £25,000, with 15 per cent added for freight. What with setting-up and all, I suppose the cost would be £30,000 to £35,000, so you will see that only men of capital can set up large mills, and small ones won't pay so well. There is room, however, for men who only *grow* the cane and sell it. At Pioneer estate, where I went yesterday with the purchaser, Mr. Mackinnon, Mr. Brandon, the banker, told me that Mr. Spiller, the pioneer sugar planter of the district, who in consequence of bad health had sold this magnificent estate for £95,000, began with £35, and gradually added to his machinery as he got on. Mr. Jaffrey having introduced me to Mr. Davidson, the latter most kindly made out a map of the district, laid out three days' drives, and gave us letters of introduction, four of us going. On the fourth day (yesterday) Mackinnon drove me to and over his magnificent estate, and up the Pioneer till we came to scenery like that on the Findhorn river. The visit to this district has been a most enjoyable one, and as I telegraphed to Albany the success of sugar is certain and great. But there is only one experiment with coffee about 15 miles off. That I cannot manage to see, but I've had a long talk with Mr. Costello, a candid, sensible Irishman, who said he was not responsible for the over-sanguine statements which appeared in the *Mackay Standard* and were copied into the *Observer*. The result has been one letter to the editor, Mr. Black, whom I have met, and another to Costello, from Ceylon. The latter was from a Ceylon planter who proposed to come at once with his coolies. Costello advised him to come and see first. He tells me he will persevere, but the thing has never yet paid. He is troubled with borer in the stems, and trees are dying from the small fungus, so fatal in Maskeliya, etc. But the terrible expense is in weeding: six times a year at £1 per acre each time. Higher up on the mountains and nearer the equator coffee may yet do well. But if any man brings coolies to the Mackay district and is a wise man he will employ coolies and cash on what is known to pay—sugar. It has had it troubles in the aspect of sugar and coffee estates. Some of the Mackay sugar estates are on low hills, and I was much interested by travelling over a hard wood railway of 3 miles extent on the Cedars estate which cost only £120 per mile. But instead of one expanse of perennial green as in the case of a coffee estate, a sugar plantation is, like a corn farm, in all stages of growth, from a few inches to a dozen feet high, while whole fields are bare and lying fallow or being ploughed. But most of the estates here are on perfectly flat land, and these, no doubt, are the cheapest to work. On one of the estates we saw "the first locomotive in Mackay," one of Fowler's in connection with his portable narrow-gauge railway. Most of the carriage is done in carts and drays, pulled by from one horse to six or eight, while *eight pairs* of bullocks in a dray are quite common. On a large sugar

* Passages both ways also paid.

† But none fully cultivated.

‡ As are most other things, for little besides sugar is grown.

estate about a hundred horses require stabling, feeding and attendance. The animals are fed on the tops of cane passed through a chaff cutter, maize and molasses. It is said the molasses so injure their teeth that the horses do not last more than 6 years. It is obvious therefore that machinery, even to steam ploughs, is likely largely to supersede horse as well as human power on the big estates ranging up to 15,000 acres. I suspect that Mr. Mackinnon will not long delay the experiment of steam ploughing. Horse ploughing, itself, is a great saving on hoe work. The soil is generally so deep as well as so rich, that I suggested to Mr. Mackinnon the probability of a renewal of his soil by means of a steam subsoil plough. Fallowing or expensive manuring would thus be avoided or delayed.

Mackay, with its lack of chimneys, looks much like a town in Northern India, only the houses are all built of wood with galvanized iron roofs. So all over Australia: bark and logs, timber and sheet iron come first, and brick and mortar, stone and ornamental iron work come subsequently, as wealth increases. Selection had been stopped here for a while, but is again allowed under new rules. Allotments are restricted to 1,280 acres (2 square miles), and the prices per acre, to be paid in ten annual instalments, are doubled, 15s. per acre and 20s. according to position. Conditions as to residence (self or bailiff) are laid down, and a certain amount of improvement, by culture, house erection, etc. The conditions are still very easy for *bona-fide* settlers. But there is a good deal of evasion and what is called "dummyism," Mr. Mackinnon shewed me a place yesterday belonging to Mr. Jaffrey, on which a so-called house of sheets of iron was erected and a paddock enclosed. That was all!

COFFEE IN QUEENSLAND.

Monday, Sept. 5th, 1881.

The following is from Mr. Costello regarding his diseased coffee:—

"The Alexandra, Sept. 5th, 1881.

"DEAR SIR,—I send you per favor of Mr. Davidson the specimens you asked me for, viz.—branch of a healthy coffee tree, branch of a diseased tree, also the stem and roots of a tree that has died out. I would take it as a great favor if you give me you opinion of samo—Believe me to be, faithfully yours,

"J. M. COSTELLO."

I wrote him that the leaves had no sign of *hemileia vastatrix*. Neither had a tree which I saw with a good few red berries at Mr. King's. That tree was not pruned, but grew native fashion, and as they have had nearly three years o drought a good many of the berries were shrivelled.

The stem shewed that his tree had died from the minute fungus, generated by damp. I asked him to let us know further about his experiments, but I suspect that farther north (towards the equator) and higher up the mountains will be the place for coffee, if labour can be got.

Off the North Coast of Java, between Surabaya and Batavia, 28th September, 1881.

I wrote you last from Mackay, or Sugaropolis, as it ought to be called, being actually founded on sugar. Our voyage from Mackay was a delightful one over a calm sea, amidst "summer isles of Eden," and sheltered by "the great barrier reef," nature's breakwater, the workmen being the coral insects. "Whitsunday Passage," through which we passed before reaching Port Dennison and Bowen, is supposed by some to be more beautiful even than Sydney Cove. There are literally thousands of islets scattered about the shores of the Pacific along the western coast of Queensland, but unless they contain mineral wealth, which probably they do (for minerals, from coal to gold and opal, seem to be everywhere), they can seldom be utilized. There was a good-sized one in Keppel Bay, on which a squatter resided, and there are others of the larger islands which yield grass for cattle. Then in the north there are mountainous islands—eminently Hinchinbrook Island, on which probably coffee, cinchona and other tropical produce can be successfully cultivated. But generally there is but little good soil on the islands or on the mountain ranges. Granitic porphyry is too common, the trees are generally eucalypti whose leaves do not yield much humus, and the rains, though heavy enough in the north, fall generally in one half of the year, drought distinguishing the other half. The compensation is in fine elastic climate and minerals. There is some fever in the tropical parts, but nothing to compare with that of Java, Ceylon and India. People ought to guard themselves more from exposure to the sun than they do, however.

We landed at Bowen and had a look at this fine town with grass-grown streets. It is one of a class pretty common in Australia—towns which rise rapidly and then suddenly go down again before a rival which attracts trade, or because gold or other minerals give out. Bowen has a fine port, being so superior to other places on the coast, but Townsville is now the great and rising town of Northern Queensland. Bowen may recover importance when connected with the trans-continental railway which is projected to Point Parker on the Gulf of Carpentaria. Landing at Townsville I was struck with the resemblance of the Bay (Cleveland Bay), to that of Naples, Captain Cook's "Magnetic Island" standing for Sorrento. Castle Hill too, on which villas are built, resembles Malabar Hill at Bombay. For its age this is a wonderful place. Like most Queensland towns as yet, the houses are chiefly built of wood and iron, the quantity of galvanized iron used in Australia being enormous. Of course, as wealth is accumulated and time advances, stone and brick take the place of wood.

The Queen's Hotel, at which we stayed, is one of the nicest in Australia. There are long wide verandahs below and in front of the second story, the upper one being filled with bamboo lounging or smoking chairs. Facing the beach and bay, there is a fine breeze and a beautiful view of the Bay, Magnetic Island, &c. It struck me that residence here for a time at the best season might be good for consumptive and other debilitated patients. The climate is a tropical one, but more like that of Northern India in the cold season than anything else—only superior. Cases of fever are not unknown, but they are mild.

While staying at the hotel, preparatory to starting with Mr. Jeffray to the delta of the Burdekin river, destined to be the scene of extensive sugar culture, I met a Mr. Lyall who told me that the Herbert river district was the very queen of Queensland, and all the accounts I have heard and read agree as to its beauty and fertility. But while my fellow-voyager, Mr. Van de Velde, went to the Herbert river, I went in a steamer provided by Mr. Jeffray to the delta of the Burdekin.

On the beach at Townsville, which is hard enough to enable horses and carriages to drive and ride on it, we found the goat-foot ipomea growing, but much more sobrust in the stems than ours in Colombo. A floating substance on the sea, coming from the great barrier reef, formed the subject of discussion in the newspapers when we were there. It was popularly known by the outrageously absurd name of "whale's spawn," but I think a writer was correct who identified it as the same vegetable growth which gives its name to the "Red Sea." The soil in the immediate neighbourhood of Townsville is not rich, but the place is the centre of much mineral and pastoral enterprize, and grand sugar lands are within easy reach. Mr. Jeffray took me in his steamer, as I have indicated, to see the rich delta of the Burdekin, a river which has a

course of 700 miles and carries down fertile matter from volcanic and other formations. To get to our destination we steamed back out of Cleveland Bay, rounded Cape Cleveland, and landed, after a night's steaming, on the banks of a creek between Cape Bowling Green and Cape Upstart. A buggy and horses were waiting for us, and we bowled away over country which in Ceylon would be considered impracticable. From swamp covered with saline grasses (which cattle greedily devour and get fat on) we came to raised terraces of rich black soil, interspersed with creeks and lagoons. Most of the creeks and lagoons were bordered or covered with mangroves, red and white—the red most valuable as fuel for sugar making, as well as other purposes. I had five or six days driving and riding over this wonderful country; of which we got a view from a range of curious sandhills. As we journeyed, through rich grasses, several feet high, or just starting after being burnt by the blacks to enable them to catch their game, we started huudreds of kangaroo and wallaby, which, after standing up and staring at us, bounded away to stand up and stare again.

Of aquatic birds, pelicans, storks, ibises, geese, ducks, laughing jackasses (the great kingfisher of Queensland has splendid plumage), we saw immense numbers. We went on maugrove trees over a creek which I suppose human beings had scarcely ever before visited, for we *could not* frighten some beautiful Burdekin ducks which were on the mud below us. The trees, other than gums and wattles, were many of them familiar to me. Very common on the banks of creeks was the tree named after Leichardt, which also grows in Ceylon. It somewhat resembles what we call "the country almond" in Ceylon, trees of which, by the way, were growing on the beach at Townsville, introduced, I was told. I saw a large lily, the fellow of that which grows on banks of rivers in Ceylon, and the beautiful place of our good friends the Grahams was called Liliesmere, from the abundance of waterlilies, pink, white, but specially blue on the lagoon or rather lake beside which they reside. Here I was delighted to see a splendid orchard of oranges, mangeos, &c., which, although only five years old, is already bearing heavily. The question, ere long, will be what to do with the oranges, mangoes, pineapples, bananas, &c., produced so abundantly in this soil and climate. The long spells of dry weather, it is certain, greatly improve the flavour of the fruit. I never saw mango trees in Ceylon so loaded with fruit at five years old, and as for oranges, few are obtained in Ceylon from trees under five years old. Around Mr. Graham's house were specimens of numerous foreign trees and plants, including the cinnamon of Ceylon and China, the tamarind, sisu, &c. But sugar, sugar, is the absorbing cry here, as much and as exclusively as coffee once was the cry in Ceylon.

Mr. Jeffray, who is the head of the agency firm of Sloane & Co., of Melbourne, Sydney, Brisbane, and Townsville, had come to "the Burdekin" delta to see an estate of about 20,000 acres of fat alluvial, of which 1,000 acres are to be covered with sugar in the very shortest period on record in the annals of the enterprize. To effect this Mr. Macmillan (formerly Government engineer and roadmaker, born in Mull and educated in the Inverness Academy) has got a steam plough, "sulky" ploughs (on which a seat is prepared for the ploughman), and all kinds of improved implements. It was a sight to see the steam plough, drawn successively by two engines, nearly a quarter of a mile apart, tearing the virgin soil and throwing up three furrows. But Mr. Macmillan (who calls his place Ardmillan) was not satisfied. The steam power was sufficient for a six-furrow plough, and that he was intending to get. The only drawback to this grand place is possible prolonged drought, such indeed as existed. But the rich deep black soil was retentive of moisture, there were heavy dews, and there are wonderful facilities for cheap irrigation. By the way, a Frenchman, on hearing of an experiment in this direction, went about exclaiming: "De sugar on de Burdekin vill nevare be, bekase Mr. Macmillan, he do *arrogate*." But what Macmillan "arrogates" he will do. After years of hard work, in the course of which he has made his way (fighting it sometimes) through thousands of miles of trackless forest and scrub, he is as full of strength and energy as ever. And he is a thoroughly scientific man as well as being otherwise qualified to be manager for the company of which he, Graham and Jeffray are members. Mr. Graham is an Irishman, whom I had previously met at a lodging-house in Sydney. There we had a long talk about the labour question, little thinking either of us that we should again meet where the question was so practical and urgent a one.

The sugarcane in Northern Queensland does not grow so much more luxuriantly than in Ceylon, but the proportion of saccharine matter in the juice must be much greater. Eight per cent is a good result, but in an experiment at which I assisted we got from 10 to 11½ per cent. The intrument, (Beaumé's) was exactly on the principle of the lactometer: a glass tube graduated. The more watery the juice (which was pressed from pieces of cane in a vice and received into a jug) the more the instrument sank. Sugarcane has its troubles as well as coffee. In 1875 the estates in the Mackay district were nearly snuffed out by a visitation of a fungus like red rust. But sugarcane can be uprooted and replanted and be ready for cutting in about 15 months, and there are about 100 kinds to select from. The Bourbon which was so liable to the rust has been superseded by the "Rose bamboo" and other kinds: at present there is no pest of consequence. As with the coffee in Ceylon, so, probably, with sugar here, it will be found that vast unbroken areas of one plant present conditions favourable for plagues, insect and fungoid. I think I mentioned in writing from the Mackay district (named after a Scotch sea captain who is said to be still engaged in the Kaneka trade) that the *average* yield of sugar per acre is 1½ ton, and as it takes on an average 15 tons of cane to produce 1 ton of sugar, that means 22½ tons of cane per acre. Much greater weight of cane is produced per acre on new land redeemed from "scrub" (that is forest), but the percentage of sugar is not so high. The percentage has been known to increase up to the 8th year. I think I wrote from the Mackay about the large number of horses required to work a sugar estate. The ploughmen are almost all white men, the proportion on most estates being 20 per cent whites to 80 per cent blacks or "coloured persons." There are large acres of available sugar lands to be had on any terms, and persons who have not capital to set up a mill can cultivate and sell cane to the manufacturers. I cannot now relate all the incidents of this most interesting journey to the grand delta of the Burdekin, some parts of which, I believe, we were the first to explore, seeing as we went fine "pockets" of land. On our journey back, which we made byroad (?) and rail, we struck the banks of the river at several points and admired its broad and in some places rocky bed, lined with casuarinas and with scarlet and white blossomed "bottle-brush" trees. The scarlet blossomed ones gleamed out like ironwood trees when the foliage is young.

The German element will here rapidly merge into the English, although the Germans do associate together and have their own newspapers, concerts, and so on. They are an industrious and thrifty people, and the English workmen complain of them as "living on the smell of an oiled rag." What with cheap German labour and cheaper

Chinese and Kaneka, the case of the British workman and labourer is no doubt often a hard one. But his destiny, if he would but see it, is to direct labour or to perform it by means of such fatigue-saving expedients as "sulky" ploughs &c. In returning, Mr. Graham drove us 56 miles in grand style, over some most difficult country. The last 35 miles to Townsville was on a railway which is being pushed on to the rich gold mines of Charters Towers and to Hughenden. It will ultimately join the transcontinental line to the Gulf of Carpentaria. It is like all the Queensland railways on the 3 feet 6 inches gauge, which answers fairly for this country and its traffic, but ultimately I should think all the Australian Colonies will adopt the English gauge of 4′ 8½″. I noticed that there was scarcely any ballast, and that the sleepers (timber being plentiful) were laid very close together. We had the hill ranges close by us all the way, and we got back to Townsville a week after having it, having seen much of interest. It was very fortunate for me that Mr. Jeffray, so largely interested in the sugar enterprize and so ready to help me to see everything, was my fellow-passenger.

The ranges of mountains we skirted in sailing from Townsville to Cooktown seem to me most likely to be the seenes of coffee, cinchona and other tropical cultivation: the Cardwell district, opposite which is Hinchinbrook Island, the Bellenden Ker ranges &c. We could not land at Cooktown, and so I missed seeing a town where the Chinese largely outnumber the Europeans. That is what is dreaded all over Australia, but I think the dread a needless one. John Chinaman comes where he can get gold on the surface to carry away, but I have seen a notice of only one case where the Celestials have boldly tackled a reef. What with diamond drills, borers and other machinery, my belief is that mining ere long will cease to be a precarious pursuit, becoming steadier and largely profitable. I do not think so poorly of our race as to suppose that it cannot assert and retain its superiority over the olive-skinned Mongolians as well as over the black races of Australia and the Pacific Isles. But the aid of the Hindu coolie is wanted in Northern Queensland at least—where sugar can be cultivated without risk of frost, but with risk of fever (to some extent) for the white man.

Amongst our passengers from Townsville were a Mr. Chester, Police Magistrate of Thursday Island, and a Mr. Elliott who was proceeding to complete surveys of the recently discovered port at Point Parker on the Gulf of Carpentaria. That port promises so well that General Fielding and party are now surveying a line for a trans-continental railway to it, instead of the one originally projected through South Australia to Port Darwin. The merits of this line to Queenslanders are that it will run entirely through their own territory while opening access to the Indian Ocean. The South Australian Government have resolved to construct their line at the rate of £200,000 per annum at the utmost, from revenue or borrowed money. This means ten years delay. The Queensland Government on the other hand, have sanctioned the principle of paying a private company (who have employed General Fielding) by alternate blocks of land on each side of the railway. It will thus be the interest of such a company to introduce population to cultivate their lands. The railway now finished from Brisbane to Roma will be continued to the Gulf of Carpentaria on the one hand and to the junction with the N. S. Wales lines on the other, the lines from Rockhampton, Townsville, &c., being joined on to the main line. The completion of such a comprehensive scheme will give an immense impetus to the prosperity of every enterprize in Queensland. I am only giving the bare outlines of a magnificent scheme. If a good port is settled, the only other objection is the swampy nature of the shore of the Gulf, from the confluence of so many rivers there. On the vast swamps the true rice plant *oryza sativa* is said to be indigenous, and Mr. Armit describes millions of pigeons as feeding on the grain. Mr. Chester told us that these pigeons, or other pigeons, flocks of which we saw off the coast of Australia, came across from New Guinea. From this great island we were only 70 to 90 miles distant when we landed on Thursday I land.

MALTA MELONS.—A correspondent sends us six melon seeds received by him from Malta, and asks us to give them a trial in Colombo. We shall do so and report the result.

GOLD.—The following statement of the approximate export of gold from Australasia, shews how great has been the falling off in the Southern Colonies in the output of the precious metal :—

1865	£9,553,640	1873	£9,369,120
1866	9,618,442	1874	7,662,925
1867	8,783,489	1875	6,949,516
1868	9 351,191	1876	5,793,374
1869	10,382,955	1877	7,295,868
1870	8,237,367	1878	5,567,084
1871	7,605 893	1879	2,405,302
1872	7,597,021		

Last year the export was larger than in 1879, but it fell far short of the £10,382,955 of eleven years previously.—*Madras Mail.*

ENEMY OF LEDGERIANA: THE "KU-UK."—In Mr. Moens's report for 1879 on the Government cinchona enterprize in Java he stated that half a bouw of Ledgeriana at Rioen-Goenoeng had been "entirely destroyed by the koe-oek, the larva of a chafer, which had chosen the fine rootlets in this plantation for its food." We expressed regret in a foot note to this statement that the scientific name of this insect was not given. In Rigg's Sundanese Dictionary we find the following explanation of the word :—"*Ku-uk*, a big full-grown onggrét. Also the beetle which is often found among old horse or buffaloe-dung: in this latter sense it is a geotrupes." "*Onggrét*, the grub of the *Légé*, a cockchafer called *Melolontha vulgaris*. The onggrét lives in the ground, and it is a soft white grub with sharp red jaws. It is one to two inches long and is very destructive to young plants, the bark of the roots of which it feeds upon, and in the humabs, or upland rice plantations, it sometimes nearly destroys the whole crop by eating off the young and tender roots of the paddy."

PAPER PLATES.—The latest application of paper is the adoption of paper plates by some of the great restaurants and *cafés* in Berlin. The innovation was first introduced during the summer of last year by the adventurous landlord of a much frequented open-air restaurant. Every customer who ordered bread and butter, rolls, cakes, buns, or similar articles, had them served to him upon a little paper-plate, made of a light paper-maché, adorned with a pretty border in relief and having at the first glance a great similarity to porcelain. Guests, waiters, and hosts were all pleased with the novelty; it saved the waiters many a deduction from their wages on account of breakages, which the deftest and cleverest can scarcely avoid when he handles hundreds of pieces of crockery during a single afternoon and evening. The paper plates were so cheap that the landlord did not care to assert his ownership over them, and his customers were allowed to carry them away, like the pretty serviettes of thin paper used in so many restaurants in Holland. There was also a considerable saving of the time lost and the chance of accident incurred in the cleansing of earthenware pottery. The success of the experiment has been so marked that the new species of plates is likely to be introduced into a great number of restaurants.—*The Paper World.*

CINCHONA "PUBESCENS": IMPORTANT INFORMATION.

We have been reading the very elaborate and valuable Report, just published, by Colonel Beddome on the Government Nilgiri plantations, in which he enters fully on the question of the disputed "Pubescens," and comes to the conclusion—in agreement more or less with Mr. Cross—that this Cinchona is not a hybrid at all as supposed by Mr. McIvor, not even a variety of Officinalis as surmised by Mr. Howard, but that it is more nearly allied to Succirubra, and will, in reality, most likely turn out to be identical with *C. Magnifolia*. The question will shortly be set at rest, since Colonel Beddome has sent dried specimens of both *magnifolia* and the so-called *Pubescens* to be compared with the typical specimens of the various species in Kew Herbarium. A first trial shipment of "Pubescens" bark has also been made by the Madras Government, the report on which is now due and will be full of interest. "Magnifolia" grown on the Nilgiris has given a favourable analysis, and so has "Pubescens," as shewn by Mr. Howard. Colonel Beddome says of the latter (which he believes to be a slight variation of the "Magnifolia" species) that it is "very strong growing, and will certainly yield far more bark in a given time than any other," and probably prove to be longer lived; it will also grow very high up, flourishing vigorously above 7,000 feet at Dodabetta. This is all good news for "Teja" and others who are cultivating "Pubescens" or "Magnifolia" trees; but Colonel Beddome fears that a good many Ceylon planters got seed off Succirubra trees very like the "Pubescens," when they applied for the latter. There is a great deal of very valuable information in this Report extending over some 30 pages foolscap.

CINCHONA CULTIVATION IN BORNEO.

Mr. Loyalty Peake writes to us from Sarawak:—

"I shall be much obliged, if you will give me the following information:—

Average quantity of dry bark from uprooted succirubra tree		2 years old
,, ,, ,, ,, ,,	3	,, ,,
,, ,, ,, ,, ,,	4	,, ,,
,, ,, ,, ,, ,,	5	,, ,,

also annual quantity likely to be taken of renewed bark dry from 6 years of age till 10 years. I am getting on very well with my nurseries and hope to have something worth showing in 18 months' time."

It is very difficult to answer Mr. Peake's enquiries: planters do not uproot or even coppice or strip succirubra trees before they are 5 or 6 years old, and as to 'average results,' a great deal of experience will yet have to be put together, before we can speak with certainty. We should be inclined to put the average yield per tree for succirubra over a large clearing at from 4 lb. to 5 lb. of dry bark, at five years old. We know of 100 trees 14 years old which, when dug up, gave over 16 lb. dry bark on an average (although they had been coppiced twice before). Then six year old succirubras (choice trees no doubt) have given 12 lb. dry bark each; while in another case 4,000 trees 6 to 7 years old only gave 12,000 lb. dry bark, or 3 lb. each, but these were probably only coppiced. Taking 5 lb. of dry bark as the standard at five years old (including root bark) for succirubra trees, Mr. Peake cannot be far wrong in counting one pound off or on for each year. As regards the crop to be got from stripping the stem between the 6th and 10th year, we should be inclined to put it at an average of ½ lb. per tree per annum, if a considerable area were taken into account. Selected trees would no doubt give much more.

FROM ADAM'S PEAK TO MINNESOTA:

A CEYLON PLANTER'S EXPERIENCE IN THE FAR WEST.

Heron Lake, Jackson County, Minnesota, U.S.A.
August 30th.

DEAR SIR,—I have been intending to let you know how we are getting on in this part of the world, and if you can find room, it may, perhaps, interest your readers to hear of some of their Ceylon friends down here. I left Ceylon in November 1880, thoroughly disgusted, after six years' work, with bad crops, leaf disease and reduced screws, and after staying a few months in England, decided to try my luck in the great North-West, and accordingly sailed by the "Bothnia," Cunard Line, in company with another Ceylon man. After being rolled about for about nine days, we arrived in New York, and after a very short stay proceeded to St. Paul's, the capital of Minnesota, where we were forced to remain about two weeks, on account of the severe rains and the floods caused by the melting of the vast quantities of snow, and the lines being carried away thereby. After nearly committing suicide several times, we at last were able to proceed to Heron Lake, a small town 160 miles distant, where my friend's partner had already purchased land and built a good house. On arriving at Heron Lake, we found we had struck a temperance town, with a good hotel and bar but no liquor. Never shall I forget the feelings I experienced on driving out the four miles, the whole prairie under water, and slush up to the axle-tree, and in very truth I agreed with the man who had told me his first impression of the locality was that "it was the last place commenced just before knocking off work on the evening of the sixth day, and that the Almighty had not thought of finishing it since."

On arriving at the mighty river Des Moines (usually a stream some 8 ft. wide), we found a stretch of water about half a mile broad and had to get our baggage and selves across in a punt by means of a pole. On arriving, we found ourselves well repaid by the splendid accommodation provided us by Mr. K.'s housekeeper, a nice American lady. Next day, we went and called on Mr. P., another Ceylon man who had purchased a nice farm, with some fine heavy timber around his house. His habitation was better than many a S. D.'s bungalow, but as he was living by himself in the house we could hardly congratulate him on its appearance, though he informed us he had been "putting it to rights all the morning." It consisted of two rooms, the outer one being used as a store for Indian corn. The windows of the bedroom were, in some cases, ignorant of the existence of glass, and while conversing with the worthy proprietor a hen flew in and laid an egg in his unmade bed. The colt took a stroll into the other room, and, having been satisfied with a good round feed of corn retired. A wren had built its nest in a pair of trowsers hung behind the door, and was quite happy. In fact, everyone and everything seemed to be on the most friendly footing.

As spring advanced things began to look better, and the dead grass having been burnt off gave place to a rich green for miles round you. Having thoroughly investigated matters, I came to the conclusion that one might with care make money and live happily here. So I invested in a piece

of land conveniently situated with regard to the railway, and have since been joined by a friend, who intends taking a share with me. I can thoroughly recommend the country to young fellows of small capital (say £1,000) and steady habits, and who are not afraid to rough it a bit at first. I have a man to help in the farm work, and his wife runs the house. Society, as might be expected, is in a very primitive state. A dirty ploughboy (knows not the use of a fork and commences his attack on the butter by first cleaning his knife in his mouth), a shoeless and stockingless individual called a woman (who does not possess such an article as a comb), and a species of vermin designated a child, make up the number around the festive board. Dinner in this country is cooked in ten minutes and consumed in three-and-a-half minutes. Another-one-and-half minute may be allowed for cleaning up, after you have finished the meal that has been thrown at you about 12 o'clock. These are, perhaps, disadvantages. On the other hand, there is plenty of sport: duck, geese and prairie chicken abounding in this locality, and a decent shot may always during the season procure his five or six birds of an evening after work. Unbroken prairie land may be procured from the Railroad Company at $5 (£1) ℔ acre, and improved farm land with buildings, a decent house, barn, and granary for about $10 (£2) per acre. We are mostly going in for stock-raising, for this line of farming is more remunerative than grain, which requires more hired labour, which is extremely expensive. a man hired by the month receiving from $20 to $25 per month, and another dollar and a quarter for his team. In harvest time, these figures rise considerably. There are now in this vicinity five Ceylon men, besides two previously in the O. B. C. Bank in Calcutta and Mauritius, and two or three other Englishmen. We are getting along very well, and here one always has a home, with good sport and good health, and can always make a living at the worst of times, which is more than one can say of Ceylon. We hope soon to see many friends from the old island and England, and I hope you will let some of those 400 planters out of billets know that there is such a place as Heron Lake, and that with not less than £1,000, and a little discomfort perhaps, one can be very jolly in this benighted country.

We will let you hear from time to time, and in some future letter I will forward you an estimate of expenditure and returns. Meanwhile, with salaams, yours truly, DOTALA.

CINCHONA CULTIVATION IN CEYLON: GOVERNMENT *VS.* PRIVATE ANALYTICAL CHEMISTS.

THE MADULSIMA COMPANY TO HAVE THEIR OWN CHEMIST.

Kaudy, 1st October 1881.

[The Secretary to the Planters' Association of Ceylon sends us for publication "copy of the correspondence on the subject of the proposed appointment of a Government cinchona bark analyst at Hakgala with a view to carry on experimental cultivation."]

The Hon. the Colonial Secretary, Colombo.

SIR,—I have the honor to invite the attention of Government to the annexed copy of a resolution passed at a recent meeting of the Planters' Association, and trust that it may receive the early and favorable consideration of His Excellency the Governor.—I am, &c.,

(Signed) A. PHILIP, *Secretary.*

Resolution referred to:—"That in view of the large area of land now planted with cinchona, and of the fact that the climate and soil in many parts of Ceylon are well suited to its successful cultivation, Government be requested to appoint a bark analyst at Hakgala, with a view to carry on experimental cultivation."

Colonial Secretary's Office, Colombo, 13th October 1881.

SIR,—With reference to your letter of the 1st instant, I am directed to transmit to you the enclosed copy of an extract from a letter from Mr. Thiselton Dyer.—I am, sir, your obedient servant,

(Signed) GEO. T. M. O'BRIEN, *for Col. Secy.*

A. Philip, Esq., Secretary, Planters' Association.

(*Extract referred to.*)

Dr. Trimen is undoubtedly correct in thinking that no attempt should be made to combine the duties of the assistant director with those of a chemist. There can be no doubt that in the present state of the cinchona industry, the services of a chemist on the spot would be of great advantage to the planters. Mr. Karslake, one of the Directors of the Madulsima Company, has communicated with Kew upon the subject. But it was obviously impossible to give him any encouragement in the idea that this was a matter in which the Ceylon Government could be expected to bear the expense. The Company have therefore intimated their intention of sending out a chemist to receive a salary of £600 a year with a house and free passage, and Mr. Karslake has been put into communication with one of the leading officers of the Chemical Society in order to select a suitable person. I am more particularly to mention this circumstance in order to show the rate at which the market value of scientific services is estimated by private employers.

It is obvious, of course, that only men with large capital can offer terms such as these. The members of the Planters' Association might, however, combine to employ a chemist for their joint assistance; and Sir Joseph Hooker has already suggested that, if this were done, the Government might assist by affording laboratory accommodation in the Colombo Museum.

SALE OF LEDGERIANA SEED IN COLOMBO.

This day (12th Oct.) Mr. Symons had another sale of Java Ledgeriana seed with the following result:—

			R.		R.
5 boxes,	each containing	2 grams at	65	per box	325
1	,,	,,	55	,,	55
5	,,	,,	54	,,	270
5	,,	,,	52	,,	260
3	,,	,,	50	,,	150
3	,,	,,	46	,,	138
5	,,	,,	45	,,	225
3	,,	,,	44	,,	132

4	,,	,,	42	,,	168
3	,,	,,	41	,,	123
5	,,	,,	40	,,	200
53 boxes.					R2,519

There being 480 grains in one oz. troy, and say 16 grains in a gram, *i. e.* 30 grams to an ounce, and at an average of R47·50 per two grams, it would be R712·50 per oz. troy.

After the sale of Ledgeriana seed, the following lots of other cinchona seeds were sold to-day:—3 oz. officinalis at R6 per oz., 1½ succirubra at R31 per oz. from the same Gardens.

THE INDIAN TEA CROP.—The Kurrum correspondent of the *Delhi Gazette* writes:—"The tea crop will, I believe, be within the average, owing to the terrible smashing so many estates got from the hailstorms in May last. One in particular, about which I wrote at the time, standing rather high, has never recovered the mauling it then got. The expected outturn per acre was 2½ maund; the actual outturn will not exceed 1½ maund."

CARDAMOM CUTIVATION

is rapidly extending, and with good reason, in both high and low country districts in Ceylon. Returns of close on 400 lb. per acre of a crop which sells at from 5s to 8s per lb., must leave a margin of profit sufficient to induce a general rush into this most profitable of new products. Cardamoms are among the best-prized of spices in the world—far-famed as "grains of paradise"—and they will always continue to be much valued. But even if the average price fell to 2s per lb., the cultivation will pay well. With care and under favourable circumstances, it is believed a crop up to 600 lb. per acre can be gathered in our planting districts in Ceylon. Hitherto the great cry has been for "bulbs," and high prices have been paid for these with considerable expense for transport, and trouble and uncertainty about the transplanting. But it is now found that propagation can be made quite as readily, indeed, with better results from seed, which are from one-fourth to one-tenth the cost. Bulbs have sold as high as 25 rupees per 1,000; indeed, we have heard of an estate in Rakwana against which, including carriage, the cost of a thousand bulbs run up to nearly ninety rupees! Now, thanks to local enterprise and careful experiments, germinated seed which can be sent per post anywhere in small tin-boxes are available at no more than *three rupees* per 1,000! Here we have another illustration of the success which is likely to attend the cultivation of new products in Ceylon under European skill and enterprise. The Mysore native who had been 'cardamom planting' all his life smiled (in scorn doubtless) over his master's idea that seed could be got to supersede the clumsy and uncertain bulbs; but like so many of his countrymen he now feels he has learned something from "master" which neither he nor his fathers nor grandfathers seem to have known before. In one case the plants grown from seed have succeeded far more satisfactorily and rapidly than those grown from bulbs at ten times the expense. The plan adopted is to place the seed in drills in the nursery bed, the said drills being simply drawn with the finger or scratched with a stick. The young plants will soon be ready for the transplanter, while their removal to the clearing need not take place until they are a good size and sufficiently hardy.

In recently compiling the pamphlet "All about Cardamoms," we overlooked useful information given by one authority with special means of gaining experience, namely, Mr. R. H. Elliot, "the Mysore Planter," who has a long chapter on Cardamom-planting. It is chiefly based, however, on Mr. Ludlow's "Memorandum," from which we ourselves quoted fully, but Mr. Elliot adds some results of practical experience. The following are the rules observed by the natives of Coorg in cardamom planting:—

1.—Select land that is damp, and, if possible, with a stream or two running through it.

2.—In clearing for cardamoms, cut away the underwood and fell a large tree here and there.

3.—Burn the underwood when three parts dry, so that the burning may be as light as possible.

4.—Pits to be dug a foot deep, and a foot and a half wide, and about three feet apart, and these to be carefully filled with top soil.

5.—In cutting the bulb, take sufficient for the spring of three more shoots, and take great care not to hack or injure the bulb in any way.

6.—The part cut off for transplanting is not to be planted deep, nor are the shoots to be cut.

7.—Should the new shoots hang down, they are to be tied together and a support given.

8.—The plants to be regularly weeded.

9.—When the plant comes into bearing, all the racemes should be laid out above the fallen leaves and rabbish.

10.—In clearing wottee swamps (the wottee is a species of bamboo which grows in clumps), a clump of wottees to be left at intervals.

11.—The stem of the cardamom-plant is not to be heaped round with fallen leaves, mould, or rubbish.

12.—After the cardamoms have been picked, the racemes that have borne to be removed, and old shoots to be cut off.

13.—The cardamoms to be planted early in the monsoon.

Mr. Elliot's manager has acted on the above system with a perfectly satisfactory result, but he adds:—

The principal difference between this system and that pursued in Coorg seems to lie in the fact that the underwood with us is burut, while in the Coorg account no mention of burning is made. With us, too, some attempt is made to transplaut, and fill up the land regularly; while no such attempt seems to have been made in Coorg. Then the method of picking seems to differ. The Coorgs seem to make a clean sweep at the outset, and at the same time remove the racemes that have borne crop. We pick the ripest seeds at first, and then go over the clearing a second time, when the remainder of the crop is removed, and the bearing racemes are then taken off.

My manager in India, is decidedly of opinion that young plants are much to be preferred to removing bulbs from those that have been long growing. He is also of opinion that, in removing a portion of the bulb, as much should be removed as to give three or four shoots; so that, in case one should rot, you would have the others to fall back on. Another reason for doing this is that the eyes on the bulb lie so close together that, if you tried to remove only one, it is probable that the coolies would injure several in cutting it out, and you would, therefore, lose the mother-plant, and run every chance of losing the one removed for transplantation.

We have as yet made no attempt at manuring the plants, as what little we have planted have borne little, and do not seem to require it. Nor have I ever heard of an attempt being made to manure this plant otherwise than with the vegetable mould, or top soil of the jungle. There are, besides, considerable difficulties in the way of manuring, on account of the rugged nature of the ground in these jungles, and the consequent difficulty of transporting manure of any sort. Nor does it seem to me that a light seed like the cardamom can remove so much from the soil as to call for any other manure than the vegetable mould which can be so readily procured.

According to Mr. Ludlow (who had gained his experience as Assistant Conservator of Forests in Mysore), the cardamom plant can "be grown from seed, and admits of transplantation, but will not last long except in a thoroughly congenial soil." As regards fruit-bearing, Mr. Ludlow says:—

One rhizome will often have over twenty stems, and, as these die off, (and they seldom last longer than seven or eight years), fresh ones spring up to supply their place. The fruit is occasionally borne on the upper part of the stem, but this is extremely rare, and I may mention that in Munzerabad I have never seen or heard of an instance of this departure

from the ordinary habit of the plant. When from one stem four racemes are thrown out, it is called by the natives the true or full crop; if three only, three-quarter crop; if two, half crop; and if one only, quarter crop. One raceme will have from eight to fourteen branches, and each branch from three to six pedicels. When the plant is grown under the most favourable conditions, these branches are grown close together; when, however, the conditions are unfavourable, the racemes are long and weak, and the branches far apart.

And on this Mr. Elliot remarks :—

It seems to me that one of the first things to be done towards improving cardamom cultivation is to propagate the variety which produces seeds on the upper part of the stem. It is obvious that the yield per acre can never be very great as long as we have to depend on the ordinary way in which the plant bears; but if we can procure plants which will bear above as well as below, the cultivation would at once be placed on a much more satisfactory footing. Another advantage will be that a portion of the seeds would not be so liable to the attacks of rats and vermid as they are at present.

We had lately sent to us by a resident in of Matale a fine specimen of cardamom with the flower on the upper part of the stem.

Although we think it well to make these quotations from Mr. Elliot's book to supplement the information already collated, yet it is evident that in India they are far behind us in respect of the cultivation of cardamoms, since Mr. Ludlow states that only 28 lb. of crop can be regularly got from an acre! No doubt this was from the spontaneous jungle growth, but unless Coorg planters can now multiply this return by nearly twenty, they had better come to Ceylon and see how some hundreds of pounds' weight of cardamoms can be raised per acre.

A very important point to the cultivator of this spice is the extent of the market available. It is but a spice, though an extremely useful one, after all. In India and the East generally, it is universally used in cooking. In Europe the consumption is small, save in Turkey, where it is said an almost unlimited field for consumption prevails. No doubt this refers to all Muhammadan countries from Turkey to India, and it is therefore pretty evident that the cardamom planter in Ceylon need not be afraid of the price falling below his limit of profitable return for a good many years to come, even should cultivation extend to some thousands of acres in Ceylon.

THE PROGRESS OF CINCHONA CULTIVATION IN THE DISTRICTS OF MADULSIMA AND HEWA ELIYA.

(By H. Cottam.)

Rapid progress has been made in these far-off districts of the Central Province in the making of nurseries and the planting out of cinchona of every variety introduced into Ceylon from India and Java, from the famous Ledgerianas of Messrs. Moens and Gammie down to the hardy succirubra self-sown amongst the coffee. No sooner does the visitor to Madulsima arrive in the district than a fine growth of succirubra may be seen above and below the road, filling up the vacancies and checking wash on steep ridges, and ravines and forming quite a new feature in the appearance of Amanadova estate, the grand entrance to Madulsima. Officinalis thrives well here, and Messrs. Cockburn and Bowles successful planting of last season of both varieties are something to be proud of, especially the ten acre clearing of officinalis, without a failure and well-grown for its age. Above this model officinalis clearing, an extension is in course of preparation by Mr. Bowles for the coming season's planting, and large nurseries are ready with hardened plants of the same variety.

We then enter Ahnie Mallie under an avenue of fine grown succirubra trees measuring about two feet in circumference and some of them 15 feet high, a magnificent growth and healthy trees. Passing more nurseries and fields of coffee planted up with both varieties, principally officinalis of last season, and a portion of Vercelle Pattannie also dotted with cinchonas, Galoolla clearing is soon reached, an addition to 13 acres of cinchona succirubra, well spoken of as worth a visit. With the new clearing now being roaded and drained for cinchona, Galoolla will make a good show at some future time.

Battawatte possesses a handsome succirubra clearing of 22 acres and Doomoo fine specimens of trees measuring between 20 and 23 inches of fine growth. Mr. Mason intends planting his already valuable estate with 100,000 cinchonas, and Battawatte a similar number amongst coffee. Coodatova has made giant strides and was early in the field with several good varieties. Of course, the whole of this estate will be planted, and the Company may be congratulated on possessing the services of an energetic, painstaking superintendent in Mr. Walter Stewart.

A belt of jungle divides the above estate from Uvakelle, and here may be seen a fine field of succirubra; some of the oldest trees in the district, full grown and scattering seed broadcast. Some months ago, when I passed through this field, millions of seedlings were springing up under the trees, clearly proving the suitability of both climate and soil for cinchona On Uvakelle a small clearing is being lined and drained for the coming season. This estate will probably be entirely planted, judging from the supply of plants in the nurseries and under the trees, though I have not seen the nurseries lately. Mahadova and Auckland contribute largely to the enterprize, both being included in the Cinchona Company, whose operations will presently be noticed, and full justice done. Auckland is well worth a visit—prettily situated as the estate is, with its park-like patana lands and clumps of jungle, fine climate, elevation, and beautiful views. The cinchona here is a great success and does Mr. H. C. Plumridge considerable credit, considering that the estate was not then part of the Company's property, and cinchona culture in the district was in its infancy. Shawlands can show some of the best varieties doing well and planted in separate clearings: Ledgers, Emelina Calisaya, officinalis, pubescens, and fine-grown succirubra trees in the old clearing, extensive nurseries of all varieties, and virgin soil to start their growth. Doonheendekellie should grow good samples, the soil and climate being well suited to the rapid growth of many varieties of cinchona. Forest Hill grows succirubra well, and there is a clearing being got ready for the coming season. Yaphami or Yapome estate has extensive nurseries, and fine old trees bearing seed of good quality. The whole of this estate will be eventually planted up, as also the other properties of the same proprietor in this district, Dorapotha and Quedgeley. So far, we have reviewed all the estates in upper Madulsima, all of which, without one exception, are pushing forward the cinchona enterprize, Banchory and Devenick included.

Before we dive into statistics and figures, from thousands to millions (!), we will take a stroll through Hewa Eliya district. Passing the neat little hospital under the inspection of Dr. Chellappah (who administers the precious bark to fever-stricken patients, though they are comparatively

few in so healthy a district), we emerge from a belt of jungle dividing the districts into Wewebedde or Tavalampalassi, being near the outlet to Lunugala, where a cart road was traced, once upon a time. Cinchona cultivation is progressing on this estate; 100,000, including some valuable Emelinas, being put out and ready for planting during the coming season.

Dunedin, another of the Company's estates is to be fully planted. Hitherto the variety planted here was succirubra, and roughly estimated at 275,000; there are other kinds including a few Ledgers.

Ascending to a considerable height, we then reach the far-famed Cocogalla, and the crack Ledger field, so often referred to in the columns of the *Observer*, closely planted, and well covering the ground. The Ledger field can be distinctly seen a great distance off, being of a brighter green foliage than the officinalis above it. This valuable and handsome clearing contains forty thousand Ledgers, and, including the officinalis, 50 acres at 5,000 plants per acre, gives us 250,000 of fine specimens of well-grown and best variety of valuable cinchona. When passing through this unequalled field, I could only see three plants dead in the quarter of a million! The new clearings are now being drained and roaded for the reception of some 60,000 more Ledgerianas, making one hundred thousand in all raised from Java and Indian seed, the old Ledgers being those of Mr. Moens, and those in the nursery raised from Mr. Gammie's seed. There seems little difference in appearance. In fact the able manager of this division of the Company's estates has succeeded in raising fine beds of Ledgers from cuttings! In addition to the possession of a compact cinchona plantation, the whole of Cocogalla estate will be planted with cinchona. At present, there are about half-a-million cinchonas in the lines of coffee doing remarkably well.

New Forest contains some 500,000, or half-a-million, trees. Say Cocogalla and New Forest between them contain over 1,200 000, many of which are already 24 inches in circumference, and officinalis raised from Abbotsford seed, fine, straight, symmetrical, smooth-barked, handsome trees added to this some 750,000 (three-quarter of a million) plants in the nursery of valuable kinds making a sum total of about 2,275,000 cinchona trees of varieties on Cocogalla, New Forest, and Dunedin. Much may be learned by a visit to these clearings and nurseries. The *modus operandi* is simply perfection; well-made beds, shaded from the sun, by substantial sheds; the pricking out beds covered by ferns, and coolies employed repicking over, and referning, watering, and every care taken to make the enterprize a success.

Now, allowing that the Cinchona Company alone possesses 4,000,000 of plants of all kinds by Christmas well advanced, and plant out another two millions, making six millions; surely the rest of the district, which now possesses over two millions, can put out from their extensive nurseries another two millions, making up the round ten millions for the districts of Madulsima and Hewa Eliya, including the Lunugala estates. Before leaving Hewa Eliya, we must have a peep over the ridge, passing through Hewa Eliya, Elemane, and Rathkele estates. These properties contain half-a-million cinchonas scattered about: 35,000, 300,000, and 172,000 respectively, or a total of 507,000, including 8 acres under shade, 4,000 Ledgers, and 160,000 in coffee on Rathkele estate, where extensive fencing has been carried out to keep cattle from intruding.

Through another belt of jungle, the bridle path, obscured from the sun's rays by gigantic keena trees, brings us out on to the vast undulating patana lands adjoining Roseberry estate, where one might almost fancy one's self on a sheep run in New South Wales.

Roseberry estate grows very fair succirubra, and a great quantity is put down already with nurseries in reserve. Crossing another range, we enter the Uva estate, a fine promising property both for its coffee (almost free from disease) and cinchona succirubra.

At some future time, we can speak of the suitability of the land below this estate in the neighbourhood of Bintenni tank, for the production of new products, but will confine this article to cinchona only.

The first cinchona estate proper, that is, the first land devoted entirely to the cultivation of the bark, was The Park near Lunugala opened by Messrs. Pulteney and Flanshaw. Another entire cinchona estate called Seafield is situated near Yapame, and the famous Kehelwatte possesses one of the finest nurseries of all kinds, including pubescens, and planted 10 acres succirubra, four acres officinalis and a considerable quantity scattered amongst the coffee. Yaphame estate we mentioned before as producing good seed, there are also nine acres of succirubra planted here. Kosgahadowa and Mausa and Lunuvissa estates I did not visit, but they all contain a proportion of cinchona and nurseries. Clifton and Melrose and other new estates down the Batticaloa road near Lunugala: Medampitiya, Galbode, and Tillycairn near Passara. Hanipha estate has made progress and a clearing is in course of preparation for this season. St. Mary's estate might be called in Madulsima. All have cinchona growing more or less.

Now to come to statistics. The following estates are opening up clearings for Christmas planting:—

Galoolla	50	acres	of officinalis.
Cocogalla	21	,,	Ledgers & officinalis.
Wevabedde	5	,,	Calisayas.
Forest Hill	12	,,	officinalis.
Seafield	60	,,	succirubra.
Kehelwatte	46	,,	pubescens and succ.
Hanipha	25	,,	Condaminea.
Shawlands	35	,,	Calisayas &c.
	254	acres	(E. & O. E.)

There may be a few more clearings including a small one at Uvakelle and another at Amanadova, making over three hundred acres. Planted say 5,000 to the acre, equal to one and a half million, a considerable help to the rough estimate of ten millions for Madulsima and Hewa Eliya. Now supposing ten thousand acres are brought into cultivation, in round numbers, @ 1,000 cinchona plants per acre, we arrive at ten millions. Therefore, considering that 5,000 per acre is the usual thing, the surplus 4,000 per acre over a large area make up for coffee not planted with cinchona. The next thing to consider is the price or value per average tree, according to age and soil and variety of bark cultivated. We hear of 7 year old trees realizing the enormous sum of R40 or £4 sterling. According to such a calculation, *forty millions sterling* would be raised, enough to make one's hair stand on end to contemplate!

The question is what would be a fair average price. Let us say R5 or ten shillings per tree, and we realize five millions of pounds sterling. Then descend to five shillings per average tree, and we get two millions, five hundred thousand pounds sterling; equivalent to two shillings and sixpence per tree, one million, two hundred and fifty pounds sterling. We must draw the line at R1·25 or *half-a-crown* for *crown* bark, and then we get £125 per acre or R1,250—twice as good a prospect for planters as coffee cultivation without leaf disease.

Two hundred thousand acres of cinchona in the Central Province of Ceylon, containing at the rate of ten millions to every ten thousand acres or two hundred millions of cinchona trees, valuing, say, only one rupee per tree or two hundred millions of rupees, or £20,000,000 sterling, four times the value of one million cwt. of

coffee at 100 *shillings* per cwt. !! Will our Government stand still with such a prospect and say no railway for the present? Are the planters to wear themselves out first and spend all their money to prove to the Government that cinchona will pay, and that coffee will be improved by the rooting up of the cinchona, and tonic manure from falling leaves? If the Chinese give up opium for cinchona, there will be little fear of glutting the market with a population of 400,000,000 of Chinese. One thing they may do, and that is, set to work and cultivate cinchona themselves, as the Yankees are trying tea in Georgius. Whatever price quinine stands at, *it will always be a drug* in the market! I have no personal interest in bringing to public notice the great progress making in the cultivation of cinchona, beyond wishing to cheer up desponding brother-planters in these hard days of leaf disease and low prices of coffee, and an obstructive policy displayed on the part of the Ceylon Government in delaying railway extension.

Passara, 30th September, 1881.

H. H. THE MAHARAJAH OF JOHORE'S TEA AND COFFEE GARDENS.

We would recommend all who take an interest in planting to drive over to Tanjong Putri, Johore, and make an inspection of the tea and coffee plantation of H. H. the Maharajah of Johore. It will show those interested what can be done in these two products, and enable them to form some estimate of what the ordinary soil of the country in low lands is capable of producing. The plantation in question may be termed an experimental one. It is within two or three miles of the town, and there are about two acres of tea, and the same amount of coffee planted. The coffee is Liberian, and the trees are about two years old. The plants are six or eight feet high, and the branches cover a circle of about ten feet in diameter. They are one and all loaded with berries in different stages of ripeness. So covered with berries are they that it will probably be necessary to thin them, and it is somewhat surprising to learn that, although the ground has been used by gambier and pepper growers, no manure has been required for the coffee. The tea has been planted quite recently, and a portion of the plants have been cut about one month and show a wonderful growth of young leaves which, as is pretty generally known, produce the finest quality of tea. Various kinds of tea plants have been planted together, but the bulk of the seeds came from the Indian tea countries, though all of the plants seem equally healthy and strong. On the ground there is a shed for cooking and preparing the tea leaves. The kiln dried tea is very similar to Assam, and the same leaves sun-dried give a decoction similar to the tea used by the Chinese. In both cases the flavour is an agreeable one, and should take well in the local and home markets. The undoubted success of both tea and coffee so near our own door is truly remarkable, and leads one to anticipate a possible prosperous future for the waste lands of our island as well as Johore. Close to the plantation we have described, H. H. the Maharajah has taken in hand to clear a large patch of primæval jungle of its undergrowth, leaving undisturbed the high forest trees. This is intended for cocoa which has been tried to a considerable extent in the open country, but it is thought that it may do better in the shade, as there the tree itself, as well as the subsoil, will be protected from the rays of the sun. It is interesting to see the Yakoons of the jungle working away heartily —felling the smaller trees, and they seem to be well suited for the work—being muscular and active in their movements. Either residents or strangers have the opportunity of spending an agreeable day at Johore in visiting the plantations we have described, and H. H. the Maharajah, who is an enthusiastic planter, has always been kind enough to give those who take an interest in such matters all the information and assistance in his power.—*Straits Times.*

SALE OF CINCHONA BARK IN COLOMBO.

Messrs. Robinson & Dunlop put up for public sale at their offices to-day (Oct. 20th) the undermentioned lots of cinchona bark :—

	lb.			R.	c.
T. C. A.—	1,232	lb.	mixed officinalis and succirubra twigs and pieces. From full-grown trees in Dikoya district. Analysis by Mr. Dixon shews 1·04 yield of sulphate of quinine...	0	27
Diagama—	1,886	succirubra	twigs ...	0	27
	88	,,	quills ...	0	35
	366	,,	broken quills ...	0	49
	158	,,	chips ...	0	33
	103	,,	dust ...	0	7
	252	officinalis	dust ...		
	421	,,	twigs ...	0	21

From three year old trees, grown at an elevation of 5,000 feet in the Agrapatana.

	lb.			R.	c.
Kabragalla—	112	succirubra	twigs and chips.	0	22
	78	,,	root ...	0	56
	22	,,	quills ...	0	84
Avoca—	232	,,	twigs ...	0	15
	40	,,	quills ...	0	25
	298	officinalis	twigs ...	0	20
Gonavy—	132	,,	twigs ...	0	10
Valladolid—	3,727	,,	stem pieces ...	0	54
	332	,,	root ...	0	57
	201	,,	twigs ...	0	21

From 3½ year old trees, Maskeliya. Analysis by Mr. Symons gives yield sulphate of quinine 1·16.

	lb.			R.	c.
Errol—	260	succirubra	twigs ...	0	16
	500	,,	root bark	0	81
	284	,,	stem pieces ..	0	64
	204	,,	bark ...	0	58

The above from three to four year old trees, Dikoya district.

	lb.			R.	c.
Agrakande—	557	succirubra	bold twigs ..		
	184	,,	quill and quill pieces ...	0	29
	56	,,	pieces and shavings (from 4 to six year old trees) ...	0	85
	170	,,	pieces (from 9 year old trees) ...	1	5
	267	,,	(mossed) stem shavings from 4 to 6 year old trees...	1	40
	370	,,	(mossed stem chips from 9 year old trees ..	1	30

The attendance was not so good as on previous occasions, and, owing to the recent fall in Europe prices obtained were lower than at last sales. Buildings were fairly spirited.

TREE PLANTING is going on briskly in the Cape Colony. Mr. W. Rogers, of the Bontebok, has obtained about thirty thousand young trees from the Botanic Gardens, Grahamstown, for planting on his farm.—*Cape Paper.*

CULTIVATION OF "LEDGERIANA" CINCHONA IN CEYLON.

FOUR YEAR OLD TREES ON YARROW ESTATE, PUSSELLAWA, YIELDING 9·06 PER CENT OF PURE QUININE.*

We have already on two separate occasions referred to the successful cultivation of the precious Ledgeriana on Yarrow estate, Pussellawa. Mr. Thos. Christie informed us how these trees were the result of a pinch of seed received from Mr. McIvor, during his visit to Ceylon, he (Mr. McIvor) at the same time expressing doubt as to the successful growth of the species which had comparatively failed under his care on the high and cold hillsides around Ootacamund. That our Ceylon hills on the contrary are admirably adapted at a medium elevation, and in select spots up to 4,500 feet or so, for the culture of Ledgerianas has now been satisfactorily demonstrated by the result of experiments not only on Yarrow, but on St. Andrew's, Maskeliya, and under Mr. W. Smith's care in Lindula. The great success of the Yarrow trees was shewn by the analysis of bark giving 8·4 per cent of quinine, valued up to 17s per lb. Since then the price of sulphate of quinine has fallen, and therefore although the highest valuation in the accompanying analyses is 16s 1d, it must be noted that the percentage of quinine 9·06 is very nearly the highest yet attained not only in Ceylon, but, considering the age of the trees, we may say it is equal to anything realized by Mr. Moens in Java. The detailed analyses given by Mr. Symons are as follows :—

Analysis of "Yarrow" Calisaya Ledgeriana bark taken from 3½ year old trees, growing at an elevation of 2,500 feet :—

Sample.	Pure Quinine.	Crystallized Sulphate of Quinine	Approximate Value in London per lb. in Sterling.

Those marked "*" contain but a trace of other Alkaloids.

* In the table as it originally reached us, and as we mentioned in a paragraph yesterday, the maximum given was 10·56 per cent., but this is a mistake as Mr. Symons explains :—"I am very sorry to see my clerk has made a mistake in copying out one of the analyses. R* should be pure Q. 9·06 in place of 10·56. You will see that this is correct, as 9·06 + 3·02 = 12·08, the proportion of sulphate of quinine. 10·56 would give 14·08 % of quinine which is rather stiff, even for Yarrow."

Analysis of "Yarrow" Calisaya Ledgeriana bark taken from four year old trees, growing at an elevation of 3,000 feet :—

Sample.	Pure Quinine.	Crystallized Sulphate of Quinine.	Approximate Value in London per lb. in Sterling.

Those marked "x" contain but a trace of other alkaloids.

C. H. H. SYMONS.

COLOMBO, 18th OCT. 1881.

Remark of Mr. Symons referring to R* :—"It is really a splendid bark. The five marked "x" are all fine types."

Yarrow estate is situated in the district of Nilambe and lies at the back of Pooprassie, adjoining Galloway-Knowe and Hanagalla estates, distant about 12 miles from Gampola. In elevation the cultivated area ranges from 2,500 feet to 3,400 feet. A well-known visiting agent has reported upon the estate as follows :—"The feature of the estate (Yarrow) is now its Ledgeriana trees, and the analyses of bark which has been the talk of everyone for the last few days. There are 140 trees altogether, some first-class, but all very good. I consider that for cinchona the estate is especially well adapted." We learn further that the trees are growing most vigorously (of quite as rapid growth as the succirubras it is said and have a thicker and heavier bark! and average from 15 to 20 feet in height. The superintendent has about 10,000 seedlings of Ledgeriana coming on promisingly, and the majority of the trees are now heavily laden with seed crop. We do not regard the fact of the trees being laden with seed at so early an age as a good sign : we should have preferred that they had fully matured with at least six or seven years' growth, but still no doubt the seed, when compared with that of the less valuable species, will be very valuable.* At the same time, careful selection will have to be made to secure the best, for it is very striking to note the great variation in the bark of different trees grown from the same "pinch of seed." For instance the seed gathered from the splendid tree marked "R*x," with 9·06 of pure quinine, ought to be nearly three times the value of that taken from "R," the bark of which only gives 3·455 of quinine. By careful selection guided by analysis, the proprietors of Yarrow ought in a few years, to be able to shew trees grown from the seed of "R*x" yielding a considerably increased percentage of quinine at the same age, until Mr. Moens' maximum of 13 per cent is beaten. (Mr. Wm. Smith's maximum the other day for trees 5½ years old was 9·6 per cent) Calisaya "Ledgeriana" is undoubtedly the species for a large number of planters in Ceylon to turn their attention to; but it may be asked if its cultivation becomes general and fairly successful, what will become of the market. With the millions of trees—a considerable number being 'Ledgers'—about which Mr. Cottam writes from Madulsima, all flourishing exceedingly; with propagation by seed, suckers, and grafts engaging attention in so many quarters, where is

* Seed of the Ledgers is too precious, we fear, for the proprietors of Yarrow to try an experiment recommended by Colonel Beddome, of cutting off the panicles of flowers from trees flowering prematurely. It should be tried though on two or three trees to note the effect on the growth of the trees and on the virtue of the bark.—ED.

it all to end? It is of course difficult to say how the demand may respond, but one thing is certain: that it will be a long time before the fortunate possessers of "Ledgeriana" trees can have any occasion to complain of the cultivation of cinchona not being remunerative.

THE GOVERNMENT OF CEYLON AND CINCHONA CULTIVATION.

What is wanted is that the gentleman who is coming out to take charge of the Hakgala Gardens should qualify himself before leaving England to analyse bark, so as to be able to carry out experiments *pro bono publico*, and to turn the Government Cinchona Garden to some practical account. We shall be told, that such time as Mr. Nock could give to analyses in London, if Government granted a delay, would not suffice to enable him to qualify himself for the work. Here is the Maduksima Company getting out a special Chemist on £600 a year, and there are the doubts which "scientists" have for some time been inclined to cast on the local analyses made by gentlemen who, a short time ago, were in complete ignorance of the process. But we have pointed out that the work of local "amateurs" (so-called) have been substantiated more than once by the analyses of the Messrs. Howard, and we may ask what great mystery can there be in the matter, when Mr. Gammie, a gentleman with precisely the same training as Mr. Nock, has not only qualified himself as Bark Analyst, but is doing good work as a Manufacturing Chemist. Mr. Nock, it will be remembered, is specially recommended by Mr. Morris for his experience in cinchona culture; but what possible service can this gentleman render to the Government (unless they mean to go in for growing bark to sell) or to the planters except he is able to set a whole series of experiments agoing with different species, different modes of culture and of harvesting, for which, at almost every turn, analyses will be indispensable? It is, we fear, too late now to telegraph to Mr. Nock to spend a few months in London, in order to qualify as a Bark Analyst. If this cannot be done, we would suggest that the Government utilize the services of their Science Master, Mr. A. C. Dixon, to co-operate with Mr. Nock in his cinchona experiments. Mr. Dixon has a special laboratory at his command, and would, we have no doubt, take a personal interest in aiding Hakgala experiments with such analyses as Mr. Nock and Dr. Trimen might require. If, in addition, Mr. Nock were allowed to visit the different districts and take a note of the results of planting experiments and experience, we have no doubt that his work in cinchona alone would be of great value, even at this late hour, to the Ceylon planters.

UDAGAMA (SOUTHERN PROVINCE, CEYLON), Oct. 8th. Good planting weather. Showers every day with now and then a heavy burst for a short time. Liberian coffee, pepper, cardamoms and nutmegs on young estate making a good start. Ceara rubber sown the first week in April now between nine and ten feet high and steady with all. Ponderosa do not trouble much and the small mouse deer let us off easily. Cinchona (Calisaya) six to eight inches high sown April 7th.

AUSTRALIAN FRUIT FOR ENGLAND.

(*Journal of the Society of Arts.*)

I note with interest the information in the *Journal* of 9th inst., page 773, that we may expect fruits of various kinds from Australia. No doubt apples, pears, and oranges can and will be shipped to advantage thence to this country, because all these fruits ripen after being plucked; but I think the writer in the *Colonies and India* is over sanguine as to first-class grapes being able to stand the voyage, and to arrive in such good condition as to compete with home-grown hot-house productions. Be that as it may, my experience of thirty years as a grape grower teaches me that grapes never ripen in the slightest degree after being gathered, but merely whither and shrivel, &c. I think all grape growers are agreed on this point. If I am wrong, I shall be glad to be corrected.

JAMES FILDES.

44, Spring-gardens, Manchester, 10th September, 1881.

DR. GILBERT and Mr. Lawes have received, by the decree of the German Emperor, the gold medal of merit for agriculture, in recognition of their services for the development of scientific agriculture.—*Athenæum.*

LAND OUT OF CULTIVATION.—As an example of land permanently thrown out of cultivation we may cite an instance of a large estate on the confines of Hants and Wilts, and consisting of over 1,000 acres, which, after being let to a tenant for a number of years for £300 a year, was at last abandoned by him, and has for some time been without an occupier. The owner, determined to put it to some use, has now resolved to make a huge rabbit-warren of it, and for this purpose has turned out 1,200 rabbits to populate it. Considering that of all animals, rabbits are among the most prolific, and that they sell for about 1s apiece, the experiment will probably be a successful one, though whether the owner's neighbours will not before long consider they have just cause of complaint against him in the too frequent visits of these industrious borrowers remains to be seen.—*Land.*

FIBRES.—A Dikoya planter writes:—"I think, if you refer to my letter, you will find I said that the fibre I sent you grew very freely in the *poorest* soil and not *present* soil, as you have in the *Observer*. I am sorry that it is valued at such a low figure, as it grows very freely and is everlasting. The more it is cut the better and thicker it will grow: a crop might be secured every year, but I have no doubt the fibre would be better for being kept longer. I think it better in every way than the aloe fibre and much stronger. I have prepared the aloe fibre years ago—I mean the common green that we used to grow by the side of ditches to keep buffaloes out of coffee, not the Mexican slow-growing blue variety. This fibre can be grown in lengths of ten or twelve feet, and I have no doubt I can send you some that length. Perhaps I have made some mistake in the preparation. Certainly the fibre pulled off the living tree is twice as strong as the fibre that I have prepared by cutting the sticks, and burying them in mud by the side of a stream for twelve days and then washing. I consider this fibre far superior either to the best jute, or American green aloe, both of which I have repeatedly tried and prepared. The yield of fibre is much larger in proportion also to any other fibre producing plant. In the Rhea* is the same plant as the Dutch call 'Rhami' it will never do in Ceylon, for I have tried it repeatedly, but the Rhami I have tried is not a grass."

* The Rhea or Chinese grass-cloth plant, is *Boehmeria nivea*, a small shrubby plant about three or four feet high.—ED.

Correspondence.

To the Editor of the Ceylon Observer.

ALUM A CURE FOR WHITEANTS ATTACKING COCO PALMS AND CACAO PLANTS.

Matale, 13th October.

DEAR SIR,—I have been trying to grow coconuts for a long time, but have found that the greatest enemy I had to contend with was whiteants. To prevent these destructive insects from attacking the young plants, I only knew of the sawdust of five different kinds of woods, namely jak, sapu, del, wavarenne or javarenne and lunumadilla, but as the sawyers asked me 50 cents a bushel for the sawdust, I found it too expensive, and so had to look about for something else. Seeing in your Directory that alum is a preventative of several noxious insects, I thought I would try it for whiteants. Nearly two months ago I put down about a dozen young plants, and underneath and all round them I sprinkled powdered alum (about one tablespoonful to a plant), since which time I have not seen a whiteaut near them, although in one or two places where I planted them I had previously lost several—this over a period of more than 5 years. I therefore conclude that alum is a decided success. It is quite possible that powdered alum may also turn out to be a preventative of grub. I mentioned my experiment to Mr. E. Grigson, and he said he would give it a trial for grub. I have no doubt that if he does do so and finds it succeed, he will let the public know through your columns.

I may mention that I found the whiteants had attacked a cacao plant. I therefore sprinkled a little powdered alum round it, and, as it was dry weather, I watered it once, immediately after applying the alum, and I am happy to say that the whiteants have left it, and it is now flourishing. I give you this in the hope that it may turn out of use to any who have been pestered, as I have been, with whiteants. I fancy for grub about 2 lb. per acre would be enough, and, as it is procurable in the bazars at from 19 to 25 cents per lb. (if a success) it would be cheaper than collecting the beetles as at present.—Yours faithfully,

L. F. K.

P.S.—Mr. Ward may, perhaps, find that alum may be useful in the cure of leaf disease.

PLANTING OPERATIONS IN THE PANWILA DISTRICT.

Maria, 14th October 1881.

DEAR SIR,—Will you allow me to thank those gentlemen who visited this estate since my cballenge made last July: all have expressed themselves satisfied.

I would feel obliged for a visit from those gentlemen who visited this estate between July and November 1880, when I showed them some fields which were then bearing about 15 cwt per acre. Some then thought the trees would not be able to bear any crop this year; they (no doubt remembering the field) will be agreeably surprized even this year to find a crop of from 10 to 12 cwt. per acre and trees looking more fit for another crop next year than they looked last year.

The weather for the last three months being very dry, our trees are somewhat feeling the want of rain; some crop is lost at the end of branches and the beans of our first picking was rather small. But the coffee we are now gathering will be of larger size and as soon as rain sets in the crop will ripen: that is from February blossom. But our crop from April blossom will not be ready to pick till the end of November or middle of December. Whereas the Planters' Association gave a prize for an essay on opening a new Arabian coffee estate (now not wanted, so some say); then for elaborate buildings which so some say was not required; and then spent so much money on a sulphur and lime cure book before it was proved a success—I think that the planters ought to reward me as the champion of Arabian coffee who have proved beyond a doubt that Arabian coffee even with leaf disease can and will pay handsome profits (if properly worked); at least with a small outlay. Cocoa is doing first rate and I trust next year to show both cocoa and coffee side by side (cocoa planted in 40 acres between coffee) giving good crops. This year the cocoa is giving the first (maiden) crop; there are only some 200 trees in full bearing this year, which are full of crop.—Yours truly,

J. HOLLOWAY.

CINCHONA CULTIVATION:

WHAT IS C. PUBESCENS *(INDIAN VAR.)*?

DEAR SIRS,—What are we in Ceylon cultivating under the name of C. pubescens?

Mr. Cross, in his late report of the Indian Government's Nilgiri Cinchona Plantations, after shewing what are Condamineas, goes on to say:—"But that known as Pubescens, and specially claimed as a hybrids is a narrow leaved variety of red bark from Soute America." The South American bark collectors called it "Pata de Galliuazo" in contradistinction to the large leaved or "Teja" bark. So far well; the Nilgir, pubescens, can be a red bark and yet be very value able, but here comes an anomaly. Howard in his "Quinology de Pavon" gives tbis variety called "Pata de Gallinazo" and calls it "Nitide C. Peruviana" and says its bark is comparatively useless in commerce. Both Mr. Howard and Mr. Cross are authorities on cinchona. The latter doubtless saw this variety growing when collecting with Markham and would not be likely to make a mistake in identity. The question therefore remains, are we in Ceylon cultivating a comparatively useless bark or not? Any information tending to clear up the above, will, I am sure, be gladly received by proprietors of C. pubescens and all cinchona planters. The best and most reassuring would be the results of a sale of bark, if any Ceylon grown has reached the London market yet?—Yours faithfully,

TEJA.

["Teja" cannot have the "Cinchona Planters' Manual" by him—indispensable, it may be said to be, to all who wish to have the answers to such questions as the above. On page 43, he will read:—

"*C. pubescens*, generally considered a cross between *officinalis* and *succirubra*, has a bark very rich in alkaloids. It has a stem free from lichens, grows very luxuriantly, and renews its bark rapidly. Mr. McIvor says of it:—'Up to the present time *C. succirubra* has produced in the same period of growth more than twice as much stem bark as any other species we have in cultivation, and *C. pubescens Howard** will produce nearly twice as much stem bark in the same period of growth as *C. succirubra*.' It is very unlikely that such extremely sanguine hopes will be realized, but its robustness of growth seems undoubted. De Vrij got from a specimen of the bark of this hybrid 9·47 per cent of alkaloids, of which 5·728 was pure quinine, sulpbate of quiuine being 7·637. From another sample analysed by Howard, the return was 12·90 per cent of alkaloids, of which 6·94 was sulphate of quinine. A tree yielding such quantities of splendid bark is simply invaluable, but being a hybrid, plants raised from its seed are but little to be depended ou as being true to type; indeed in some cases its bark is said to bave been found altogether devoid of alkaloid. The preceding analyses are undoubtedly

* Mr. Howard does not wish his name to be connected with "Pubescens."—ED.

exceptional ones, and no reliance should be placed in them as fair indications of the value of *pubescens* bark. The ordinary yield of quinine that may be confidently expected is from 2·50 to 3·50 per cent. Renewal of the bark is effected with great facility, the resulting yield of quinine being from 3·10 to 4·90 per cent. In this, and in the large yield of thick bark, lies the advantage of cultivating this trees which is greatly increased by a careful selection of stock trees. I have found the seed of this hybrid very hardy and easy of germination, the young plants growing with the greatest rapidity and should most strongly recommend its further cultivation, by cuttings, if possible. The elevation at which *pubescens* grows is about the same as that for *succirubra*, and probably extends higher."

Mr. Melvor may have been wrong in regarding his Pubescens as a hybrid, indeed we are likely to have the term discarded—but Howard's analyses cannot be wrong. There is another C. pubescens, Vahl. (Arica bark) less well-known.—ED.]

SILK-GROWING IN CEYLON.

Parate, Moratuwa, 15th Oct. 1881.

SIR,—With reference to your remarks on "Silk Growing in Ceylon" in your impression of the 7th, Dr. Vanderstraaten seems to have misunderstood what I told him about the domesticatiou of the tussur silkworm. I said that I had not succeeded in rearing the tussur silkworm on growing trees in the open air, because the caterpillars were always devoured by birds, lizards, or ants; but I did not say that the tussur silkworm could not be domesticated. The nature of this insect renders it unsuitable for feeding on plucked leaves like the mulberry and castoreil tree silk-worms, but it can be kept on cut branches with their ends inserted in water to prevent the withering of the leaves, and I now have about three hundred tussur silkworms and about as many of the atlas kind which I am keeping in that way for the purpose of sending the live chrysalides to London for trial in England by Mr. Alfred Wailly *(Membre de la Société d' Acclimatation de France)*. The eggs of both species hatch too soon for transmission from this to England. I believe that any effectual method of protecting the silkworms from the numerous enemies to which they would in this country be exposed, if they were on growing trees in the open air, would be more troublesome and expensive than the culture of the mulberry tree and domestic management of the true silkworm. But by my plan of keeping the silkworms on cut branches or suckers inserted in water-pipes, it would be quite practicable to produce cocoons in sufficient quantity for manufacturing purposes, and I shall be glad to show it to anybody taking an interest in the matter, By coppicing the trees, a constant supply of suckers could be obtained, and the only thing I am in doubt about is the most suitable tree to cultivate for the purpose. But that could be easily ascertained by enquiry in the districts in which tussur cocoons are collected for manufacture.

Though a species of bombyx may be polyphagous in a state of nature, yet it does not follow that it has not got its own proper food plant on which it is more at home than on any other. The atlas, for instance, is very polyphagous, and yet I know of no tree except the *Milnea Roxburghiana*, on which the cocoons or larvæ are to be found in large numbers, nor have I successfully domesticated the atlas moth on any other tree for more than one generation, though I have tried several other trees. There does not seem to be in this country any tree on which tussur cocoons or larvæ are to be found in greater numbers than twos and threes, but in the north of India there must be trees of one or more species on which the insect is to be found in much greater abundance, because the cocoons could not otherwise be collected in sufficient quantity for manufacturing purposes. The tussur silkworm has not hitherto been artificially reared, all the tussur silk in use being obtained from wild cocoons gathered in the jungles; and before attempting the domestication of this kind of silkworm as a commercial speculation, the species of tree on which it is found in the greatest abundance in a state of nature should be ascertained.

The subject seems to be, commercially speaking, better worth investigating than some of the "new products" that we read of; but it must not be supposed that tussur silkworm can be used as a substitute for true silk which is the produce of the *Bombyx mori* or *Sericaria mori* as it is now named, and in a country where mulberry leaves can be obtained at all seasons, it would, in the absence of epidemic disease affecting the true silkworm, be of no practical use to cultivate plants for feeding the tussur species, unless it were for the purpose of utilizing soil too sterile for the growth of the mulberry tree. I am using a common patana weed, and it answers better than any other plant that I have tried for feeding the tussur.

There is no doubt about the suitableness of this country for the *Sericaria mori* or true silkworm, if the business be managed in a rational way; but no success is to be expected from attempts to feed the silkworm on the leaves of the lettuce tree or anything else but the mulberry leaf. Very many attempts have been made to find substitutes for the mulberry tree for feeding the silkworm, and success has from time to time been reported, but the only useful result of all such experiments has been to confirm practical sericulturists in the belief that no substitute for the mulberry tree can ever be found. In countries where silk production is an established business it is not necessary that the sericulturist should be a mulberry planter, because mulberry leaves can be bought in any quantity required, but here it is of no use to begin with silkworms without first making a mulberry plantation. It is also useless to send all the way to China and Japan for silkworm eggs, at the risk of being cheated with bad ones, when eggs of warranted good quality can be had by application to Rev. Father Palla of Galle.

Three species of mulberry have already been naturalized in this country—the common sort (*Morus indica*), the white mulberry (*M. alba*), and the large-leafed Philippine Island species (*M. multicaulis*). I find the last-mentioned the best for this climate, but, perhaps, the white might be the best kind for the colder parts of the country. The common mulberry does very well if it is constantly pruned so as to make it produce tender shoots, but the leaves become rusty and unfit for use if they are not plucked from the tree soon after their appearance.—Yours faithfully,

ALEX. T. GEDDES.

A CURE FOR GRUB.

16th October 1881.

DEAR SIR,—Will your correspondent, whose opinion you gave as a footnote to "Moles"'s letter in your issue of the 11th, kindly give us his reasons for adopting the Government principle of *quieta non movere*? Though I have not collected so many as two million cockchafers, I have seen enough of the ravages of grub to convince me that planters muzzled will be unable to apply a remedy, and until the grub pest is overcome the disastrous effects of leaf-disease will be more and more apparent in the table of exports.—Yours faithfully,

AUSPEX.

CINCHONA PUBESCENS IN CEYLON AND INDIA.

Walaha Valley, Oct. 20.

DEAR SIR,—Enclosed is a copy of analysis of some pubescens cinchona bark, sent from an estate in this valley, from about a dozen different trees, five years old. Do you think it good?—Yours truly, M. M.

Colombo, Oct. 7th, 1881.

Analysis of ——— cinchona bark.
Crystallized sulphate of quinine 4·90 per cent.
Gross value in the London market 6/3 per lb.,
with Howard's sulphate of quinine at 10s. per oz.

[This result, equal to 3·68 per cent of quinine, for five year old trees, is very favourable indeed. We see that a bale of natural pubescens bark from Dodabetta sold in May last for 7s 1d per lb., against 4s 6d to 5s 9d, the price realized at the same time for natural officinalis bark. The Dodabetta trees must have been 12 years old, but those from which the bark was taken, were growing on poor soil and under unfavourable circumstances. No analysis of the bark is given in the papers before us.—ED.]

CINCHONA PLANTING ON THE "KANNAN-DEVAN" MOUNTAINS, S. INDIA.

Oct. 1881.

SIR,—In your reprint of my article in the *Field*, at page 282 of the *Tropical Agriculturist*, you preface the extract by a remark concerning the planting advice therein given, which leaves me in doubt whether you consider my information reliable or not.

I should consider it a kindness if you would point out where, in your opinion, exception may be taken.

The figures are taken from actuals so far as the estimated cost of opening goes, and the price of land is also a known fact. The price of opened land—*i. e.* just planted up—is, I think, fairly estimated; and as to the results, I had no less an authority than that of Mr. Crosse.

Please always remember that I wrote of coudaminea bark grown from Dodabetta seed, and that I reckoned the prices to remain what they now are.

No better counsel can be added than that given by you; viz., to go to Kodakanel; take a cottage there for six months; and march across to Devikolum, and look well into matters before investing.

STAPLEGROVE.

[We certainly regarded the letter in the *Field* as presenting a too flattering account of the probable experience of a planter in the region referred to. Little was said of the difficulties of pioneering; nothing of the immense liability to failures in new clearings of cinchona. Does our correspondent know that cinchona clearings in Ceylon have been almost completely replanted three times over? Our advice was that any one thinking of an investment should spend, not six months, but a *year* at least, on the spot, gathering experience.—ED.]

SILK IN CEYLON.

21st October 1881.

DEAR SIR,—Mr. A. T. Geddes is quite right in his remarks as to the mulberry being the most suitable food for *Bombyx mori*: the plant is very easily grown, and its leaves keep fresh for a longer time than those of any other shrub. The sole aim of every sericulturist at present should be to obtain a breed of worms of a far healthier standard than those now in the island. Even the eggs, so much recommended by your correspondent, seem to have been of small practical value: either the stock from which they were procured was greatly debilitated, or no care whatever was taken of the moths when laying, for, in some cases at any rate, the eggs have been hatching out at odd times during the last three months. This, as another correspondent pointed out, is very objectionable, and leads to endless confusion.

Mr. Geddes appears to think that the whole of the island is suited to the cultivation of *Bombyx mori*, but I think he is wrong. I do not know the average temperature of the hill ranges of China, whence the insect originally came, but I should suppose it to be much less than in our lowcountry. Father Palla's success (?) seems to show that the climate near Galle is too forcing, for his single-brooded moths have, in the first year, produced two broods. Next year may produce three, with still further decreased vitality.

If the cultivation of the mulberry worm in this country is to be successful, it will not be with the single-brooded variety, but with multivoltine species.

More attention might with advantage be paid to the indigenous races, the tussar, &c., some of which produce four or five broods in a year. The natural food of these seems to be the common oak, found generally on the patanas. I first met with *A. Paphia* on this tree, but it feeds also on the wild sapota and on the Avocado pear. This is at an elevation of between 3,000 and 4,000 feet. Of course, at lower elevations the food-plants will be different.

Mr. Geddes seems to infer, from his finding the worms only in twos and threes, that the trees they were feeding on were not the most suitable, but it frequently happens that bad weather, birds, lizards, and other plagues will reduce a batch of 800 to a dozen or less.

For indoor cultivation, the oak is objectionable: its stems are stringy and not easily cut, and the leaves soon become crisp.

The coppicing of the trees on which the worms are fed is not to be recommended. The mulberry worm, when young, prefers tender, succulent leaves, but the tussar, atlas, and other worms of allied species, refuse to eat immature leaves, so that suckers would be of no use, even were the coppicing system practicable on the trees the worms prefer.—Yours faithfully, B.

COTTON CULTIVATION AND MANUFACTURE.

Deyenewatte Estate, Passara, 18th October 1881.

DEAR SIR,—In your issue of the 14th inst. you again urge capitalists in Colombo to start a cotton mill.

Ceylon is certainly behind the age, when Calcutta, Madras, and Bombay are manufacturing their own cloth from Indian (and Egyptian) cotton liut.

Why should old King Cotton be left out of your list of new products? It grows like a weed and bears well in hot, dry, weather, when coffee, cacao, and tea would be suffering from drought. Every cotton planter must make up his mind to lose lint during wet weather, though the seed would be still valuable as food for cattle or the engine. I wonder if the Ceylon Government, would give a bonus for the *first ton* of cotton passed through the *first Colombo mill?*

The seed arrived from Watson & Co. of Bombay and from the manager of the Tuticorin mills. The former was distributed by the undersigned to natives in the Dumbara Valley, and the latter case of seed rotted in the Batticaloa customhouse.

Meanwhile, we find Bombay working 43 mill, driving 1,184,136 stinnies, and 12,586 looms, and paying 20 to 25 per cent on their paid-up capital.

Now, Mr. Editor, that your breakwater is nearly ready for the reception of large vessels, there will be no fear of wetting your bales of cotton, if the mill is not ready in time and lowcountry planters are obliged to export to Bombay or Liverpool.

The Chairman of the Liverpool Chamber of Commerce valued my cotton grown in Dumbara at one shilling and nine pence per pound; Mr. Blood had it valued by the brokers. I have about two cwt or 224 lb. in store, gathered from Deyencwatte bushes of the same quality, and strong in staple, at your disposal. —Yours faithfully, HENRY COTTAM.

PLANTING IN THE PANWILA DISTRICT.

Maria, 20th Oct. 1881.

DEAR SIR,—Glorious weather for ripening crop: all hands picking. Parchment now is a fine sample, a good, full, and large bean. It is a pleasure to go round the estate and see the trees with the ripe cherry and coolies bringing in their boxes.

Kotmale is desponding. Coffee on this and Eriagastenna is bearing as well now as ever it did, in spite of leaf disease. During the dry season we applied proper manure carefully and in proper time. Estates are giving an average of from 4 to 6 cwt. per acre, on an expenditure every year of from R80 to R100 per acre. This pays, and although old king coffee may hang down his head on account of leaf disease and a disagreeable atmosphere, there is proof he still smiles on those who treat him according to his present requirements; and beforelong he will shake himself clear of the yellow fever, and be as sound again as ever, except where the fever has been allowed to have its way without the necessary stimulant and disinfectant, and, in fact, been fed by improper application of artificial manures.—Yours truly, J. HOLLOWAY.

BEES AND COFFEE BLOSSOMS:—CAN IT BE?

DEAR SIR,—Sir John Lubbock has recently made some very interesting statements with regard to "bees," and probably we shall all now be more inclined to believe that these industrious little creatures exercise no inconsiderable influence in our flower and fruit gardens. Can it be that, during late years, they have vastly decreased in numbers in the hillcountry of Ceylon, and that this is one reason why our coffee blossoms nowadays fail, in a great measure, to fructify? If there is anything in this latter idea (which has emanated quite recently from a discerning son of Mars), why not attempt to utilize bees in our long and dreary up-hill battle with short crops? The planting community is now in as well-nigh as disparing a state as was the monarch of the forest in the well-known fable, and who knows but that, if we invoke their aid, our friends, the bees, will do us just as important and timely a service in freeing us from our net work of troubles, as did the wee bit of a mouse for his friend the lion?

During the past twenty years, what thousands and thousands of acres of coffee have not taken the place of an equal area of luxuriant forest and jungle redolent, of perennial wild flowers? Now, as every one knows fields of coffee burst into blossom only very occasionally, and at such a time the question to be answered to-day is: "Where are the bees on such occasions?" If absent, why not make a provision for them the whole year round, by planting up one per cent of the coffee with perennial flowering shrubs? In due time, introduce your army of bees (just as you now do a herd of cattle in stalls for manuring purposes); carefully house them and so ensure their not being disturbed by beast, bird, reptile or *cooly*. A million or so of bees on an estate, in blossoming time, may yet be found to be worth their weight in gold! By-and-bye, we would, perhaps, see a new industry started—kanganies rearing swarms of bees, or bringing them over from India, to be let out for hire for a season, just as they now do gangs of coolies. If the experiment worked well, they would probably hunt in couples, for the more bees on our estates would mean all the more boxes of palam for the coolies to pick, and all the more rupees to carry back to India. Then would we all remember the well-known lines, and sing:

"HOW DOTH THE LITTLE BUSY BEE," &c.

[We must ask Mr. Benton's opinion on the matter. —ED.]

HOW TO CHECK COFFEE LEAF-DISEASE: SUPPORT THE TREES UNDER CROP, AND MAKE PLANTATIONS (NOT WORN OR WASHED OUT) TO PAY.

Lindula, 20th Oct. 1881.

DEAR SIR,—Nearly three years ago, in addressing you on the subject of leaf-disease, I stated my belief that no economical or practical antidote would be discovered in our time. So far, dire experience has proved I was not wrong. I deprecated then, as I do now, the idea of trusting to scientists entirely to help us.

Agricultural chemists, from whom aid was expected, have not yet attained sufficient knowledge of their science to enable them to prescribe antidotes for plant-pests. Surely the failure of Liebig and other eminent chemists to find a remedy for the potato and turnip diseases bears me out here? Such a discovery would have been of far more importance than any for "leaf-disease."

The dearly-bought experience of the practical agriculturist has more frequently been the means by which a cure has been effected; the "special letter" from your French correspondent in your issue of Friday last, notwithstanding. In the letter to which I refer, he alludes to the happy results attending the employment of sulphurate of carbon for phylloxera on the grape vine. It may be so, but it is not the first time we have heard of the discovery of a cure for this disease, which, on extensive trial, has proved to be "no cure at all." I place more confidence in the system mentioned by him of "autumnal irrigation and rich spring manurings," which it would appear, is designated the Faucon system. Your correspondent might have given us some details. It is undoubtedly, however, a more frequent application of manure in smaller doses for the purpose of affording a continuous supply of *available* food to a plant, which is drawing its sustenance from the soil nearly all the year round.

For some time back I have been experimenting in this direction, hoping to, at least, mitigate the ravages of leaf-disease, and so far, with great success. The experiments will necessarily be incomplete until a year, at all events, has elapsed; but, I must say, judging from present appearances, I am looking forward with some confidence to the result. Most of those interested have been, and doubtless still are, experimenting for the combatting of our common enemy, but I am encouraged to lay mine before you at this early stage recommended, as some such system is, by that eminent authority, Monsieur Pasteur. My own notion is that, if manure is applied in small doses, so that the stimulant ingredient, which it ought to contain would be asserting itself simultaneously with the expected attack, it will carry the trees safely through. Should it be found that this would entail a triple application per annum, a heavier outlay need not be incurred than by manuring once a year with the ordinary dose, if the soil is in that condition by which it can be laid on broadcast and raked in. Some years ago, farmers thought it sufficient and economical, in manuring for green crops, to apply it in large doses, under the impression that it would enrich the soil for several years, and the succeeding crops require no application. Recent experience has, however, proved it more beneficial for *each* crop to be manured, and in some instances even two manurings in one season, where the growing

crop is found to be backward. There are several reasons why frequent applications of manure are more effectual in producing good crops, the chief being, that the noxious ingredients, which all soils contain, have the power of rendering unavailable as plant food that which may have been applied in the most *available* form, thus depriving the plant of the full benefit of the application. It is well-known that all Ceylon soils are rich in a low compound of iron which has this peculiar power, more especially over phosphates, which are so essential to the well-being of our coffee trees. Knowing this then, it follows that better results must accrue from more frequent manuring. If it were possible to apply quicklime in large quantities, to neutralize the pernicious effect of the alumina and iron so abundant in our soil, there would be less necessity for such frequent manuring. I therefore feel convinced that, if an improved method of cultivation is adopted, the ravages of leaf-disease can be mitigated. It may be said, and with force too, that this is a matter of £. S. D. which, in these days, it is no easy matter to command!

If I am not occupying too much of your space, I want to have my say on a state of matters which, if not soon altered, must speedily bring ruin to the coffee enterprise of Ceylon, and it is one which you, with your wonted foresight, have been continually drawing attention to, viz. the comparative cessation of manuring operations. It cannot be denied that the wherewithal for this purpose is but too frequently at the disposal of people who are not resident in the island, ignorant too of the first principles of good husbandry, and who are only too pleased to act on the advice of the professional visiting agents, which has all tended in one directiou recently. In the present depressed state of the bean, and the debit balances fast accumulating to huge dimensions, it may be more pleasant for a mortgagee to hear, through the professional visiting agent he has employed, that estate expenditure can be cut down to half that of former years. It may tend to raise the V. A. in the estimation of his principal, and so make future employment in like cases sure, but I doubt if it is sound advice, either for borrower or lender. I hold *it is not.* Let economy be the order of the day; but nothing could be a greater fallacy than to stop cultivation, with the hope that one day leaf-disease will disappear, and manuring operations again be undertaken with a prospect of good returns.

Say what we may, this was one of the most favourable blossoming seasons we could have wished for; and what is the result? No improvement on the previous season, which was one of the worst. Given suitable soil, climate, aspect, and elevation, it is an axiom that, if it be remunerative to cultivate *without* manure, then *with* manure it will be more so; and again, if land will not pay to cultivate with manure, then it most assuredly will *not* without it.

With the exception of grub and bad seasons, I consider the professional V. A. and restive mortgagees are doing more to foster leaf-disease than anything else. Let those of our professional Visiting Agents who have give themselves up to insensately indiscriminate declamation in tendering advice, speak out boldly that which must be no longer concealed viz., that mortgagees, where it is in their power, must make a liberal allowance for manure as the *only* chance they will have of recovering that already invested. Let the *Observer* peg away at railway extension, so that ready and cheap transport may be had, and coffee will yet be emperor.—I am, dear sir, faithfully yours,

JAMES SINCLAIR.

P. S.—Your issuc of Tuesday has just reached me, in which a letter appears signed "Post Tenebras Lux," and lest it may be taken for granted that I advocate the cultivation of worn-out estates, that is estates with surface soil all washed away, I may say that, in respect of such, I agree with him, coffee will never again be king. Bravo "Old Rag" for your notice of your Kotmale correspondent's letter!—J. S.

LIBERIAN COFFEE NOT RIPENING.—We have received a sample of Liberian coffee cherries (dry and half-ripe) picked from some 8 trees in front of Eriagastenna bungalow, Panwila district. The plants were got out from Kew exactly five years ago. Hitherto the crop has all ripened, but this season, although the trees look healthy, Mr. Holloway fears not more than five per cent will ripen. He adds:—"The trees have been manured with cattle dung, pulp and lime, and stand under a fair amount of shade. Arabian coffee trees close by look well, and are likely to ripen all their crop." Perhaps the elevatiou (1,800 feet?) is against the Liberian coffee?

COFFEE STILL KING IN CEYLON.—Who says coffee in Ceylon is rapidly going downhill, past recovery? Wherever coffee has been properly cultivated and taken care of on suitable land, is it not still bearing paying crops? We are told of fields in Dolosbage which are doing better this year than during any one of the past ten seasons. Again, we learn of coffee which was considered useless and abandoned, being resuscitated and through cultivation brought to bear 5 to 6 cwts. steadily for several years. We admit the area in these cases is not large; but is it not one of the mistake of the past, putting too great an area on each plantation under one product. On the other hand, is it not a fact that coffee has had far less done for it all over the country during the last three years than at almost any previous period? Not simply has there been less manuring, but the attention usually given to ordinary or extra cultivation has been concentrated on new products,—perhaps wisely, seeing they offer on the whole greater promise, in the face of leaf disease, but at the same time, it is not fair to neglect and yet simultaneously cry down "coffee." Our chief staple is not dead or dying, and will be found still to respond to cultivation and liberal treatment.

TEA CULTIVATION is rapidly extending, we are glad to learn, in what is the Tea region of Ceylon *par excellence*,—Dolosbage, Ambegamuwa, Yakdessa and Yatiyantota, as well as on the Western face of Adam's Peak. Locally-produced seed is becoming available: that from the Horagalla trees being very fine. On Windsor Forest, a set of Jackson's improved patent machinery is in course of erection. The Tea-roller —an admirably simple and suitable machine—is already working, the result being that 2 or 3 coolies suffice where 40 able-bodied men were formely required. Mr. Hay never saw the equal of this new and improved machine, in India. Jackson's dying machine is now being erected, and when the Windsor Forest Tea house is complete, it will probably serve for the produce of well nigh 1,000 acres of tea on plantations within a reasonable disiance. The largest "break" of tea—some 23,400 lb.—as yet prepared for one shipment from Ceylon has just been sent to Colombo by Mr. Hay from Windsor Forest, and will have early despatch to the home market. There is no abatement of the sanguine anticipations formed by practical Indian planters of the success of our enterprise: good seed of the right sort (Assam hybrid as a rule being best) to begin with and a fair start in cultivation, under experienced guidance especially for pruning, gathering and preparing: and then all should be clear to a careful intelligent planter. Another warning both to planters and consumers is that tea should not be drunk under from 3 to 6 months after preparation. Is it not at present issued, sold and drunk much within this period?

JAVA LEDGERIANA SEED IN CEYLON.—We are reminded that "Mr. W. Smith of Mattakelly had his Ledgeriana seed from Mr. A. M. Ferguson in Sept. 1876, at the same time as Mr. Leechman and Capt. Bayley had theirs, and that they were the only persons in Ceylon who had Ledgeriana seed at that time and they were also the first to receive it. This will be seen by Mr. Moens's Report for 1876."

TEA IN NATAL.—Another rival to India as a tea growing country has sprung up in Natal, where the plant has been introduced, and is said to thrive better than it does in this country, while the cost of cultivation is much less. The flavour of the manufactured leaf is said to be superior to China tea, and does not possess the pungency that is peculiar to most Indian teas.—*Englishman.*

CROSS FERTILISATION OF WHEAT.—Some successful experiments have been lately made in America in the cross fertilisation of wheat, a feat which has probably never before been accomplished, and which, owing to the peculiar structure of the flower, presents great difficulties. Ripe seeds have been obtained from the plants operated on, but it remains to be seen whether the new plants will combine the characteristics of the two parent varities.—*Ibid.*

COFFEE AND NEW PRODUCTS.—Mr. J. Holloway writes (too late to attend to his wish) :—"On second consideration, please leave out of my letter from 'whence the planters'; &c., up to 'cocoa is doing first rate.' It was meant in chaff, but may not be taken so, and I wish for no P. A. prize. My whole desire is to make Coffea Arabica pay, as I am firmly convinced it will, in the end, hold its own among all new products. I have, by careful watching and proper treatment, proved beyond a doubt that, in spite of leaf disease and other evils, it does yet pay where properly cultivated. I plant all new products, but will not neglect "the goose that lays the golden eggs."

"TEA-PLANTING IN CEYLON."—An India tea-planter, now in Ceylon, notices the pamphlet on tea cultivation and manufacture published at this office, as follows :—"The essay seems complete enough in a general way, but might have been more concise in dealing with the different stages of manufacture. I am not in a position as yet to offer an opinion on the 'selection of land,' 'planting out' &c., as I 've been only a few months in the island, but my idea was an arrangement of "notes on manufacture' principally, beginning with 'pruning,' and dealing with the different stages as they come in order. If the Ceylon teas are to take a prominent position in the London market, much more attention must be given to the 'withering,' 'fermenting,' and 'sorting' stages, as the general complaint is that they want strength, although the flavor is all that could be desired."

HAPUTALE.—A correspondent referring to this district writes :—"You gave me some Liberian coffee seeds some months ago. I lost no time in sending them to ——. Enclosed letter will shew the result. The estate is 4,000 to 5,000 feet elevation." The extract from the manager's letter is as follows :—"The Liberian coffee seed has altogether failed, notwithstanding all the care bestowed on the nursery. Only about ¼ of the seeds germinated and these only one or two at a time, but these would die before throwing out the first pair of leaves and so on right through the nursery. The last plant died yesterday. I do not think it possible to raise a plant at this elevation. Heavy rain fell here yesterday; though today has been fine: the monsoon is not far off, and I expect to be able to plant out cinchona at the beginning of next week. The estate is looking well, and the crop is beginning to show up. I think I may safely say I never saw less leaf-disease on the estate than now."

LIME is not a general remedy for grub, and digging is too expensive for many estates to indulge in. But are we for these reasons to do *nothing*? The very least the Government could do would be to offer a large reward to any one who may discover a cheap and effectual poison that at the same time would not be injurious to the vegetation. But of this I have small hopes.—*Cor.*

COFFEE AND CHICORY.—In a long paper on "The Skin and Complexion" contributed to the *Daily News*, by John L. Milton, Senior Surgeon of St. John's Hospital for the Skin, London, we find the following paragraph, one part of which ought to be printed in letters of gold and a copy sent to every English household, at the expense of the Colombo Chamber of Commerce :—The diet for any one who suffers at all from the skin must be good; above all, the reader should start with a substantial breakfast. Coffee, made from the freshly-roasted berry—ground at the time of using, without any chicory (which is only to be regarded as a poison) is one of the first necessaries. No cumbrous machines are wanted—such things only get foul; coffee is best made by simply pouring boiling water upon the ground berry, and putting the pot upon the fire to boil for a few minutes. If tea be preferred, it should be made with some variety of the pure old China black, like the Lapsang Souchong. Hill tea will not do for skin disease, especially when coupled with dispepsia; some specimens are so loaded with starch that when boiling water is poured upon the leaves and allowed to stand for a few minutes it becomes like thin arrowroot. But even the best tea should never be allowed to draw; from one to two minutes is quite enough to extract all that is refreshing.

INDIA-RUBBER GATHERING IN COLUMBIA.—An interesting account is given of this process in a report just issued by the United States Consul at Carthagena. When the hunter has found a rubber-tree he first clears away a space from the roots, and then moves on in search of others, returning to commence operations as soon as he has marked all the trees in the vicinity. He first of all digs a hole in the ground hard by, and then cuts in the tree a V-shaped incision with a machete, as high as he can reach. The milk is caught as it exudes and flows into the hole. As soon as the flow from the cuts has ceased the tree is chopped down, and the trunk raised from the ground by means of an improvised trestle. After placing large leaves to catch the sap, gashes are cut throughout the entire length, and the milk carefully collected. When it first exudes the sap is of the whiteness and consistence of cream, but it turns black on exposure to the air. When the hole is filled with rubber it is coagulated by adding hard soap or the root of the mechvacan, which have a most rapid action, and prevent the escape of the water that is always present in the fresh sap. When coagulated sufficiently the rubber is carried on the backs of the hunters by bark thongs to the banks of the river and floated down on rafts. The annual destruction of rubber-trees in Columbia is very great, and the industry must soon disappear altogether, unless the Government puts in force a law that already exists, which compels the hunters to tap the trees without cutting them down. If this law were strictly carried out there would be a good opening for commercial enterprise, for rubber-trees will grow from 8 to 10 inches in diameter in three or four years from seed. The trees require but little attention, and begin to yield returns sooner than any other. Those that yield the greatest amount of rubber flourish on the banks of the Sinu and Aslato rivers. The value of the crude india-rubber imported into the States annually is about $10,000,000.—*London Times.*

CINCHONA CULTURE IN MADRAS.—Colonel Beddome's Report is the most elaborate and carefully complied, yet drawn up on the Madras Government Cinchona Gardens. He has since, as our readers know, visited Ceylon at the request of his Government, in order to note the condition and progress of our local Cinchona enterprise and any improved methods of culture introduced. We fear Colonel Beddome was not greatly impressed by what he saw in Ceylon. We now learn that, before going on leave to England, Colonel Beddome has been ordered to complete his visits of inspection by going to Darjeeling. We shall look with interest for his reports on the Ceylon and Sikhim plantations.

JALAP.—Not long ago samples of jalap, grown on the Nilgiris by Mr. Jamieson of the Government gardens there, were sent to some of the hospitals in Madras for trial, and the reports show that the jalap is likely to be largely used in the hospitals in this presidency, but that a little more care is necessary in the cultivation of the plant. Dr. Thompson, of the 1st district, says that the jalap administered to patients in his hospital had a pretty good effect upon them; Dr. Roberts of the 2nd district says that the jalap is in every way an active and efficient purgative. The Surgeon of the 4th district says that the jalap was found to be efficient. The medical officers of the General Hospital and of the Penitentiary have not fully reported on the effects of the jalap, but there is no doubt that forthcoming reports will be as favorable as those sent in by the other officers. The Surgeon-General, with the Government of Madras, is of opinion that, if jalap can be grown on the Nilgiris at five or six annas per lb., it will be an economical measure for supplies to be sent to all the medical stores in India—the cost of jalap powder supplied from England is 1s 6d per lb. If jalap can be grown on the Nilgiris at 8 annas per lb. we see no reason why it should not be used in preference to English which, with exchange and other charges, ought to cost 14 annas per lb.—*Madras Standard.*

QUEENSLAND PINE.—From a very interesting pamphlet by Mr. Walter Hill on the Queensland timber, we extract the subjoined note concerning *Araucaria Bidwillii*, the Bunya Bunya Pine:—"A noble tree inhabiting the scrubs in the district between Brisbane and the Burnett rivers. In the 20th parallel it grows thickly over a portion of country in extent about thirty miles long and by twelve broad. The wood is not only very strong and good, but it is full of beautiful veins, and capable of being polished and worked with the greatest facility. The cones produced on the extreme upper branches, with their apex downwards, are large, measuring 9 to 12 inches in length, and 10 inches in diameter. On coming to maturity they readily shed their seeds, which are 2 to 2½ inches long by 1 inch broad, sweet before being perfectly ripe, and after that resemble roasted chestnuts in taste. In accordance with regulations issued by the government, the tree is not allowed to be cut down by those who are licensed to fell timber on the Crown lands, the fruits being used as food by the aborigines. The trees produce some cones every year, but the principal harvest happens only every three years, when the blacks assemble from all quarters to feast on it. The food seems to have a fattening effect upon them, and they eat large quantities of it after roasting it at a fire. Contrary to their usual habits they sometimes store up the Bunya nuts, hiding them in a water hole for a month or two. Here they germinate, and become offensive in taste to a white man's palate, but are considered by the blacks to have then acquired an improved flavour. The taste of the Bunya, when fresh, has been described as something between a chestnut and a raw potato."—*Indian Forester.*

TEA EXPORT TO AUSTRALIA FROM INDIA AND CEYLON:—From the 1st to the 8th of the current month, Messrs. Watson and Co.'s Tea Report tells us that the quantity of tea, exported from Calcutta to Australia and New Zealand was 54,900lb., which, added to the 378,491lb. exported from the 1st of May to the 30th September, gives a total of 433,391 lb. for this season. From the beginning of the year to the 27th September, Ceylon has sent 103,962lb. to the Colonies, a much larger proportion relative to the amount of tea produced than was sent from India.—*Englishman.*

THE CEDARS OF LEBANON.—The Vienna *Politische Correspondenz* says:—"The once famous cedar forest of Lebanon, formerly so extensive, has dwindled down to the dimensions of a mere thicket, numbering about 400 trees. To save it from complete destruction and preserve it at least in its present extent, Rustem Pasha, the Governor-General of the Lebanon, has issued a special ordinance, containing a series of stringent regulations calculated to check, if not quite to put a stop to, the vandalism and carelessness of most travellers. It is expressly forbidden to put up tents or other kinds of shelter within the district of the trees, or to light fires or to cook any provisions in their vicinity. No one is allowed to break off a bough or even a twig from the trees. It is forbidden to bring any beasts of burden, be they horses, mules, asses, or any kind of animal, within the district. Should oxen, sheep, goat, or other pasturage cattle be found within the prescribed limits, they will be irredeemably confiscated."—*Colonies and India.*

TEA PLANTING IN AMERICA.—While our Indian Tea Planters are combining to force the products of their plantations into the American market, an individual planter "who has had fifteen years' experience in India," is trying to persuade the Americans that they can grow their own tea. Her Majesty's Secretary of Legation reports from Washington that the local Commissioner of Agriculture has, under the advice of a Mr. Jackson, the enterprising planter in question, selected a tract of land in Georgia for an experimental farm, on which the raising of tea on an extended scale will be carefully and thoroughly tried. Samples of the teas already produced by Mr. Jackson have been sent to Thompson, Brothers, tea merchants, in Mincing Lane, London, to be examined; and the reply received is that "they represented teas of a high type, the flavour, though not strong, being remarkably fragrant. In appearance they resemble Indian tea, but the flavour is more like that of the finest Chinese black tea, or of the hill teas of India." The importation of Virginian tobacco planters to Bengal is thus avenged. "Can we afford to pay our labourers four times as much as they do in the Eastern countries?" is the pertinent question which Mr. Jackson puts to himself and his Americans. "Yes," replies the writer; but it is doubtful whether his readers in India can agree with him. It is true that one coloured man or negro is said to do the work of two average coolies; but even then labour is twice as expensive in Georgia as in Assam. Although, too, in some of the operations connected with tea planting, such as hoeing and weeding, manual labour is said to be cheapened by the use of the plough (at which negroes are skilful)—a circumstance of which Indian planters might learn to take advantage—yet picking, which after all absorbs the greater part of the hand labour required in the various processes of tea production, cannot be completed by a fewer number of hands in the one country than the other, for it is a process at which muscular strength does not tell. On the contrary, clever manipulation, which is the point of the Indian coolies, is what is wanted far more.—*Pioneer.*

JOHORE AND ITS PLANTING ENTERPRISE.

Some time ago we acknowledged the receipt from Mr. Garland of a plan of one of the planting divisions of the Johore territory—Gunong Pulai Johore—from which we compiled a list of estates blocked out, the area cleared, and the names of proprietors. We are now greatly indebted to the courtesy of Mr. E. A. Watson (the energetic planting pioneer of Johore, as he may well be designated) for a series of finely executed surveys and plans of the remaining divisions of the Johore hill-country :—Gunong Panti Johore; Gunong Batu Bahat Johore and Chapal Enas Bedira districts. These plans enable us to form a very good idea of the country in which, in the course of a dozen years or so, there may be found between 30,000 and 40,000 acres under cultivation with coffee, cinchona and tea. As most people know, the little island of Singapore (27 × 14 miles) is situated at the Southern extremity of the Malayan Peninsula, from which it is separated by a strait from three-fourths to a mile wide. The territory of the Maharajah of Johore occupies the Southern portion of this peninsula, and the town of Johore itself is not more than a dozen miles from Singapore, there being the ferry and a drive across the little island between the two. The extent of territory belonging to the Maharajah is not very well defined, boundary disputes between himself and his next neighbour on the peninsula (the Rajahs of Muar and Pahang, who will have no white settlers) having still to be settled, but, as we have said, it is not likely that the area available for planting purposes will be found to exceed 50,000 acres. Further north on the western side of the peninsula we come to the other British divisions of the Straits territory, Malacca and Province Wellesley and the island of Penang, and besides these we have the Settlements under British protection with representative Residents, namely, Perak, Selangor, and Sungei Ujong. There are several Ceylon colonists (including Mr. Downall) interested in this portion of the peninsula; but we have yet to see plans of the land blocked out and apportioned, in order to form some idea of its future prospects as a planting territory. Mr. Low, the British Resident in charge of Perak, is evidently an official of the right stamp, determined to do all in his power to encourage tropical planting enterprise.

Meantime, we have to call attention to Johore itself with its great capabilities and many advantages in situation, means of transport and climate for a planting settlement. In proportion to the land available for occupation, it is evident that the expenditure which will be required on roads to give requisite means of transport will be very limited in Johore. With more than one tidal river opening up the country to the base of the hills on which ply large boats owned and worked by Chinese, transport of food for labourers up, and of crop down when it begins to come, will not be an occasion of much anxiety to the planter. As regards climate, while the pioneers must inevitably encounter some of the risks always attendant on the opening up of a new country, we do not think there is any reason to suppose that fever will be prevalent after the clearings are planted on the hill-sides. The really dangerous portion—the terai—of the country, at the foot of the hills, has been already occupied by the Chinese with their gambier plantations, and it is a curious fact that, as in Ceylon, so in Johore, where the native cultivator has ended, there the European colonist begins. Gambier borders with coffee and tea in Johore, just as the Kandyans' terraced paddy-fields run below the coffee-clearings in the hill-country of Ceylon. For situation, Johore has splendid advantages in its proximity to the free port of Singapore with its great trade and capital; for, although hitherto the large mercantile houses of the Straits have taken little or no part in the planting enterprise, there can be no doubt that when they see the produce coming in from the plantations, the merchants will manifest a good deal of interest in the work so pluckily begun by Ceylon planters. Capital will then not be wanting to develop the territory, at an accelerated rate. Labour has been one of the uncertain elements, but so far as contract and heavy work is concerned, we think Johore is well off with its Chinese, while arrangements are now being made for obtaining Indian cooly labour, which is more suited for picking crops and perhaps for weeding and pruning. Nothing can be more enlightened and encouraging than the attitude of the Maharajah towards the planters. The land has not only been granted on exceptionally easy terms, but reversing the traditional policy of his Government (which is to tax the land occupied at once) he is prepared to accept a small export duty on the produce shipped, so making it very easy for the coffee, tea and cinchona planter without much capital, who will only feel the burden of Government when he begins himself to derive a substantial return from his investment,

Referring to the several districts of Johore, so far occupied, we find that 'Gunong Pulai' is the one next to Johore town on the North-west, the foot of the hills being twenty miles or so from the town. The range runs up to close on 2,000 feet, the forest-land being divided into some thirty blocks aggregating 14,144 acres, of which about 11,000 acres have been taken up by European proprietors. In this district about 1,200 acres are now under cultivation, while preparations are being made to clear a large additional area. A list of the estates and proprietors in this division was given by us in the *Observer* of 2nd July last.

The next or "Panti" division lies farther North and East. The total area blocked is 10,758 acres, of which it will be seen by far the greater part has been taken up, the list being as follows :—

NOTE.—The Muntahat Range adjoins the west side of Panti, and is now blocked out. Kotta Tinggi is a village on the Johore River, 7 miles along the cart road from Gunong Panti and 50 miles by river from Johore town or Singapore. It has a resthouse.

There are only two clearings here so far, but a good deal of forest is coming down this season. Most peculiar is the flat table-land, covering 1,200 acres, 1,600 feet above the sea, and surrounded by precipices 200 feet high, which occupies the centre of this district. Mr. Watson tells us that ingress is only obtained easily at one point, and that the plateau is well watered and covered with grass. The Maharajah reserves this probably as the site of a future Sanatarium, the climate being as cool here as at points more than double the height above sea-level in Ceylon, apparently.

The Muntahat district next to Panti has yet to be occupied; but farther North, we have the Batu Pahat divisions which are highly favoured in the Batu river as a means of transport. On the side of this river, 6 miles from the mouth, there is a store and wharf at a point only 2½ miles from the eatates! It is no wonder therefore, that out of 10,000 acres blocked out, there are already clearings aggregating 1,500 acres in this specially favoured division. The lists are as follows :—

NOTE.—These estates are situated about 30 miles from mouth of river. The relative positions of hills and river are only approximately shown in plan.

The Maharajah of Johore is to be congratulated on securing as settlers or proprietory taxpayers, so many men of enterprise, skill and capital. Ceylon's time of misfortune has proved a grand opportunity for the Malayan Settlements, and we cannot grudge the good men they have taken from us, much as we should like to have seen their enterprise and money, under the auspices of a fostering Government, devoted to the further development of Ceylon. We have still extensive reserves in this island calling for occupation; but the present Administration are apparently bent on doing nothing save to cut down expenditure in the directions where it can least be spared. Meantime, however, we are not so churlish as not to wish all success to Johore, which we must regard not so much as a rival to, as an offshoot from, our Ceylon Planting Eeterprise.

THE GOVERNMENT MANUFACTURE OF CINCHONA ALKALOIDS IN INDIA.

This mail has brought us the following communication from the veteran Quinologist, Mr. John Eliot Howard, F. R. S. :—

Lord's Meade, 30th September 1881.

DEAR MR. FERGUSON,—The enclosed answer to a request that I would criticize the last *Blue-book* issued, was sent to the Indian Government some months ago. It will probably appear in the next *Blue-book*, whenever that may come out. In the meantime it may be of interest to some of your readers.

If you reprint it, it would be well to do so *verbatim*. This is the only copy I have, and, if not used, should be returned to me.—Yours very truly,

JOHN ELIOT HOWARD.

Lord's Meade, Tottenham, June 21st, 1881.

MY LORD,—In reply to your letter of the 13th instant, I beg to transmit the following remarks on the collection of papers sent me for perusal:—

1.—I observe that 190,798 lb. of dry bark of the species *C. succirubra* were made over to the Government Quinologist, by whom 3,750 lb. of febrifuge were manufactured from it. This is under 2 per cent of the alkaloid contents, and falls very far short of what is to be expected, if the bark were thoroughly exhausted. It may, perhaps, be as much as can be looked for from the rough process employed. In Mr. Moens' report for the year 1879, I read thus:—"In the analytical laboratory of the medical department, by De Vrij's method (so called) out of 3,000 kilograms of dry bark, 56 kilograms of quinetum were prepared, less than 50 per cent of the alkaloid that was present in the bark."

2.—The result is that from bark valued at nearly 6d per lb., the febrifuge is estimated to cost R16-3-1⅝ per lb.

Contrasted with this the cost to the Government of the following pure preparations supplied from Europe is given (at page 21) as per lb.

	R.	A.	P.
Cinchonidiæ sulphas	17	8	0
Cinchoniæ sulphas	5	0	0

3.—At page 56, I learned that the average quantity of drug given in each case is

Sulph. of cinchonine ...	78·91 [grains]
Sulph. of cinchonidine ...	68·863 ,,
Quinetum	107·135 ,,

the "Quinetum" meaning "the Sikkim febrifuge," as is evident from the next sentence:—"This drug [the above febrifuge] required a large quantity to be given before the patient was cured."

4.—So that one lb. of sulph. cinchonine would cure eighty-five cases at an expense of R5, whilst one lb. of the febrifuge might cure sixty-five cases at an expense of R16. Or with sulph. cinchonidine one hundred and one cases would be cured at an expense of less than R17.

5.—So much for the supposed *cheapness* of the febrifuge at the time referred to in these calculations. But it must be remembered that, owing to the increased supplies of cinchona bark from every quarter, the price of Quinine is diminishing, whilst the price of the febrifuge must remain much the same and contrast still more unfavourably with the diminishing price of other alkaloids.

6.—I assume in these observations that the cost of the febrifuge cannot be much lessened. I rest this on the necessarily wasteful character of the process employed—although the best, perhaps, that could be employed on the spot.

7.—I presume that it would be an advantage to the medical profession, if the objectionable portion of the produce of the red bark were thoroughly investigated. The present papers confirm the opinion I expressed in my last letter of its decidedly emetic properties.

8.—Whilst retaining these properties, I cannot consider that the Sikkim febrifuge fulfils the benevolent intentions of Her Majesty's Government. It seems generally admitted in these papers to be a nauseous medicine detrimental in a greater or less degree alike to Europeans and to natives. It is well remarked at page 13 that "the miseries caused by Indian residence and illness are depressing enough in themselves, without being intensified by nauseating agencies quite foreign to the therapeutic effect required."

9.—Apart from these effects the efficacy of the remedy seems to be universally admitted, being apparently that of the cinchonidine and cinchonine of which it is chiefly composed.

10.—I find in Mr. Moens's report on the Government Cinchona Enterprise in Java for 1879 the following analyses of the different kinds of quinetum, from which it will be seen how small a percentage of the whole requires to be sacrificed in order to remove the obnoxious amorphous alkaloids:—

PREPARATION OF FEBRIFUGE ALKALOID.

In the analytical laboratory of the medical department Weltevreden, by de Vrij's method so-called, out of [illegible] kilograms of dry bark 56 kilograms of quinetum were prepared—less than 50 per cent of the alkaloid that was present in the bark. With this quinetum, trials will be made in the different military hospitals. Analyses were made of different kinds of quinetum, the result of which is given below. Of these analyses the second was performed by Mr. J. Hekmeijer, principal of the analytical laboratory at Weltevreden.

COMPOSITION.	1	2	3	4
Insoluble in dilute hydrochloric acid ...	0·52	1·02	9·00	6·22
Water	4·30	0·80	6·00	3·80
Ash	3·00	[illegible]	2·20	9·10
Quinine	6·74	1·60	6·94	13·42
Cinchonidine	25·13	59·20	[illegible]	40·56
Cinchonine and quinidine ...	[illegible]	[illegible]	[illegible]	27·30
Amorphous alkaloid ...	7·12	0·12	9·22	4·81
Colouring matter and residuum	1·08	1·08	5·36	1·00

Quinetum No. 1 is that prepared in British India and sold by the Government there at 20 rupees per English pound. It is of a fine white colour, and has a peculiar sweet smell. It is packed in tin boxes holding ½ an English pound, which are provided with directions for use in English and Hindustani. No. 2 was prepared at Weltevreden. It has the same appearance and smell as the Bengal, but is a little darker colored. No. 3 is a sample of the first quinetum prepared by Broughton in Madras and called by him amorphous quinine. It is a yellow stuff, sticky like resin, and looking like rhubarb powder,—on the whole a very impure preparation. Equally with the samples 1 and 4, I owe this also to the kindness of Dr. King, superintendent of the Bengal cinchona gardens. No. 4 is quinetum of the manufacturer Whiffen in London. This had a gray-brown tint, smell of methyl-alcohol, and left a sandy residuum on solution in dilute hydrochloric acid.

11.—I have confidence in the chemical skill of Mr. Moens, and therefore present these detailed analyses as fully reliable.

12.—I do not know whether the Indian Government have any serious intention of improving the alkaloid; but if this be the case, I should be happy, if desired, to supply further suggestions.

13.—In the meantime, I append some remarks on another preparation analysed by the same chemist:—

Beside these samples of quinetum, another preparation was analyzed, produced by the same maker, under the name of quinetum sulphate. It has been tried in British India, and consists of

23·26	per cent sulphate of	quinine,	
51·40	,,	,,	cinchonidine,
24·30	,,	,,	cinchonine.

This has a very good appearance and greatly resembles the quinine sulphate of commerce, but with the microscope the larger crystals of cinchona sulphate can be detected. This preparation is apparently combined mechanically by the mixture of ½ cinchonidine sulphate with ¼ quinine sulphate, and an equal quantity of cinchonine sulphate. The quinetum of different preparations was also of very different composition. As the loss is so excessively great in the preparation by extraction with dilute hydrochloric or sulphuric acid (de Vrij's method) that about half of the alkaloids are as good as lost in the process, another method of preparation is to be adopted in Bengal, and at the same time a large proportion of the quinetum will be made into sulphate compounds, with a view to remove the amorphous alkaloids, which sometimes form ½ of the whole, and to which disagreeable results are ascribed.

14.—In reference to the above, I must say that I cannot find that any advantage has been shewn to result from the administration of mixed alkaloids. The alternate use of these is attended with better results, as I have found that, when the constitution has become intolerant of quinine from long use, the change to sulph. cinchonidine has been decidedly advantageous.

15.—The cheapest preparation, and the one which is best adapted for prescription, is the muriate (not sulphate) of cinchonine, and this in ordinary cases I have found in this country entirely successful. I do not, however, recommend this preparation, which is, by all accounts, inferior, as a medicine, to the sulphate of cinchonidine.—I am, &c.,

JOHN ELIOT HOWARD, F.R.S.

To the Under-Secretary of State for India.

Mr. Howard's calculations and advice are deserving of serious consideration at the hands of the authorities in India. At the same time we must point out that the argument in reference to the nauseous effect of the locally-manufactured febrifuge is not borne out by medical men all around. A good many hospital surgeons speak in high terms of the Sikkim febrifuge and use it freely for native patients; and the hope of the planting and mercantile community was, that through using their own preparation, the Government would be able to extend the consumption very largely among the millions of India who stand in need every year of such treatment. But if the Sikkim febrifuge is more expensive than the preparations offered in the open market, the sooner the Indian Government abandoned cinchona cultivation to private enterprise, and buy all their stores of quinine and the inferior alkaloids, the better we should say.

THE GOVERNMENT OF JAMAICA AND CINCHONA CULTIVATION.

We learn that the Government of Jamaica having proved experimentally, the feasibility of growing cinchona to good profit in the island, is now offering grants of public lands to private individuals who will embark in the enterprise. The spot chosen is on the Blue Mountains, some 50 miles from Kingston, in a delightful climate, free from extremes. The Government not only offers land, but supplies plants and seeds at a reasonable rate An ounce of seed, costing a guinea, will produce 20,000 seedlings, enough to plant 5 acres. Directions for raising and cultivating cinchonas have already been published and circulated by the Director of Plantations, Mr. D. Morris. The following are the conditions on which the Government will for the present make such grants:—

"1. The grantee shall pay to the Government before he enters into possession of the land as purchase-money for the concession to be made to him the sum of £ , being his bid at public auction at the upset rate of 2s an acre on the estimated acreage.

"2. The Government, while not requiring that a certain fixed amount of land be planted year by year, will look for immediate steps being taken to establish the cultivation of Cinchona upon the land after the purchase-money has been paid. The grantee must, however, undertake that at the end of five years from the date of payment, he shall have cleared and planted with Cinchona a total extent of not less than one-sixth of the quantity of land actually granted to him.

"3. No timber shall be felled except on land about to be brought into cultivation. A certain quantity of timber may, however, be cut down on other portions of the land, provided it is used solely in the erection of necessary buildings on the land itself.

"4. The Government reserves the right to make public roads through the land to be granted without paying any compensation except for the value of Cinchona or other valuable trees actually destroyed in the course of the work.

"5. No land shall be cleared of forest within a distance of two chains from any spring or from the source or feeder of any stream, nor shall any land be cleared of forest within three chains of the centre of any prominent ridge or dividing line of watersbed without written permission from the Director of the Public Gardens and Plantations.

"6. The land will be held by the grantee for the first five years on lease at a peppercorn rent If any of the conditions herein mentioned be broken the Government may resume possession of the land without compensation of any kind, and the purchase money will be forfeited. If the conditions be complied with a patent of the land will be given to the grantee at the end of five years free of further cost, and the land will become his in fee simple, subject only to the reservation above mentioned in the matter of roads.

"7. Questions that may arise as to the efficiency of the cultivation established at any period, and as to the value of trees that might be destroyed in the construction of roads, and as to the extent of land necessarily cleared, shall be decided by the Director of Public Gardens and Plantations.

"8. A diagram of the lot to be granted will be furnished from the office of the Surveyor-General, but any expenses that may be incurred for surveying or running the lines at the request of the grantee will be borne by the grantee. If the lines be run by the grantee a copy of the plan of the same should be sent to the office of Director of Roads and Surveyor-General for examination

"9. Intending applicants for the grant of land on these conditions should address themselves to the Director of Roads, by whom all requisite informations will be afforded."—*Gardeners' Chronicle.*

COIR FIBRE.—At the Horrekelly Company's sale of coir fibre this afternoon the price realized was only R4 per cwt.

TEA.—It is reported in China that the Russian trade in brick and fine tea in Central Asia, is now seriously interfered with by the Indian teas, which are preferred to China teas on account of their greater strength and flavour. The same may be said of the estimation in which Indian and China teas are held in England. The man or woman who has once taken to Indian tea will not return to the use of China tea, so long as Indian tea is to be had for love or money.—*Madras Mail.*

TEA PLANTERS will be sceptical of the reason given by a *Times* correspondent for the excellence of the Kiakhta or Caravan tea, imported into Russia from the north of China. The tea comes overland, and its exquisite delicacy of flavour is attributed to its exposure to the air during the twelve months journey in loose and clumsy paper packets and sheepskin bundles, which rids it of tannin and other gross substances, a process of purification which cannot take place in the hermetically closed boxes in which the tea ordinarily reaches Europe by the sea route. This of course is only an opinion: we have heard and improving the flavour of tea by keeping. A chest of Indian tea that had accidentally got among the lumber was lost sight of for ten years. Those who quaffed the beverage brewed from this tea declared it exquisite. Indian tea planters, we fear, cannot afford to wait for ten years to improve their teas, and this advice to keep their produce, is not likely to be accepted.—*South of India Observer.*

INDIAN LABOUR FOR FIJI.—Once more the Government of Fiji have decided upon importing Indian coolie labour for the planters. But this time there is this important distinction, that the Indian coolies are not to be, so to say, forced upon the planters, as they were originally, but are requisitioned for by the planters themselves. All the same, whilst asking for coolies the planters are angry and dissatisfied at the necessity which makes them engage a class of labour, which they have good reason to dislike. But it is a case of coolie-labour or none at all for many of the plantations. As numerous requisitions have been sent in by the planters, there would seem to be every chance of our despatching a few hundreds of our surplus millions of half-starved agricultural labourers to a land, which will be, for them, flowing with milk and honey. It is to be hoped that on this occasion care will be taken to send none but men who are really agriculturists; and where there is so large a field to select from, it should not be difficult to get coolies of comparatively good physique. It is satisfactory to learn that the coffee plantations, which at one time seemed doomed owing to the leaf disease, are in a very flourishing condition, and bid fair to increase largely in extent, and to prove amply remunerative. Recent experiences seem to show that the disease has not there the same disastrous effect it has in Ceylon; and notwithstanding that some estates were attacked, the quantity exported last year was fifteen times as much as the quantity exported in 1879. The quantity of the berry is, morever, very well spoken of. On the whole it would appear that in a few years' time coffee-planting in Fiji will prove, perhaps, more remunerative than in Ceylon, and that planters, forgetting the scurvy way in which they were treated by a former Government, will be attracted to islands which contain large areas of incomparably fine coffee land—out of the influence of the trade winds—that can be had on very moderate terms, whilst there is in the neighbouring colonies a large and yearly increasing market for the berry. When Mr. Horne, the Director of the Mauritius botanical gardens and forests, visited Fiji, in 1878, he estimated that the export value of coffee from the islands would before long attain to a million and a half, or to two millions sterling.—*Pioneer.*

COFFEE LEAF DISEASE: MR. MARSHALL WARD'S REPORT.

Mr. Marshall Ward's final and (so far as it goes) exhaustive Report has at length seen the light. Dr. Trimen, it will be observed, is very severe on "blind, empirical, haphazard experiments (so called)." He would reject all notions of "cures" or "specifics" and would adopt rather the old adage "Prevention is better than cure," but, unfortunately, neither he nor the Cryptogamist throws much, if any, new light on the means of applying preventive checks. This motto is, indeed, one that came up very early in the discussion on Coffee Leaf Disease, the veteran Mr. R. B. Tytler using it, if we mistake not, some half-dozen years ago, to enforce exactly the same lesson of "careful cultivation and judicious manuring," which the Director of the Botanic Garden now seeks to apply, and which, indeed, has been repeated at intervals ever since Leaf Disease first troubled the coffee in 1869. It is because cultivation and manuring, as then practised, appeared to have no permanent effect in checking the fungus that the aid of science was first called in, and now, so far as practical results are concerned, the great benefit planters will derive from the thorough investigation which has just been completed is to learn that scientists are not able to do anything for them:—that they must just help themselves according to sound rules of cultivation, bearing in mind what is said about burying diseased leaves, the planting of other trees among or alongside the coffee, well-directed and well-timed pruning, more frequent applications of manures in lighter quantities (according to Mr. Sinclair's sound recommendation), and the judicious use of caustic lime. Strangely enough the only curative ingredients that Mr. Ward speaks of with approval are our old friends "sulphur and lime" which Mr. D. Morris at the outset recommended for the destruction of bis "filaments."

Among the most important paragraphs in the Report are those in which Mr. Ward discusses the bearing of well-timed "Manuring" and "Pruning" in counteracting the effects of leaf disease on crop. We are rather surprised to find Mr. Ward giving special attention to the origin of Leaf Disease in order to dispel so-called popular and erroneous notions. We were not aware that Dr. Thwaites' explanation under this head at the very outset had ever been seriously questioned, and one reason for assurance that the fungus had not begun to feed on cultivated coffee previous to 1869, was that it had never come under the notice of the late Director, while, when *hemileia* did appear, the rapidity with which it spread wherever a coffee brush grew afforded conclusive proof that it could not have troubled the coffee previously without being observed. Dr. Thwaites wrote so far back as June 1872, that he had discovered the fungus on the native wild coffee plant, and the fact that it must have in the first instance passed from a jungle plant (probably in the Madulsima forest) to the cultivated coffee, has since then been generally recognised. "Cultivate highly and manure judiciously" was the burden of Dr. Thwaites' recommendation in his first report on the subject, and the lapse of a decade has not much improved on his remedy. Nevertheless, there can be no doubt of the great value of the information now given by Mr. Ward. As Dr. Trimen says, the many questions connected with the pest, which have been the subject of so much and varied discussion during past years, are now narrowed down to a very limited compass; the life history is completely worked out, and science has given the practical agriculturist all the aid and information that can probably be expected from it.

LETTER FROM THE DIRECTOR OF THE ROYAL BOTANIC GARDENS, FORWARDING A THIRD REPORT BY Mr. MARSHALL WARD, CRYPTOGAMIST.

No. 29. Royal Botanic Gardens,
Peradeniya, 19th September 1881.

Sir,—I have the honour to forward to you a Third Report on Coffee Leaf Disease by Mr. Marshall Ward. In this he sums up the whole results of his investigations, which has extended over more than twenty months.

1. Continuing in the steady course of direct experiment and observation, and avoiding everything in the way of conjecture or theory, the Cryptogamist has now established the main facts of the true nature of this parasitic disease beyond dispute. Briefly, they are these. Leaf disease itself is purely local and in no sense constitutional; it is caused solely by the *Hemileia* runs a short and definite course, and is so formidable from the cumulative effect of constant repetition. The whole *direct* damage done by the fungus to coffee is loss of leaves; other serious evils, however, and especially diminished crops, follow on from this. Cleared of many erroneous observations and inferences, the ordinary life-history of *Hemileia* is now shown to be of extreme simplicity, and the necessary conditions for, and exact duration of, each stage from spore to spore again have been demonstrated with unfailing and convincing frequency. It is not too much to say that as regards the structure, circumstances and habits of *Hemileia* on the coffee-leaf we are now completely informed; and probably no fungus-pest has ever before received so prolonged and continuous an examination.

2. This being so, I apprehend the stage to be now arrived at when remedial measures may be intelligently considered, and blind, empirical and hap-hazard experimcuts (so-called) to be no longer justifiable. We know that there is one sufficient cause of leaf-disease —the uredospore of *Hemileia vastatrix*, that this is produced only by a previous one, is carried freely by the wind, may retain its vitality for several weeks or months, and can germinate only in moisture. This then is a *vera causa*, and, in accordance with the well-known medical aphorism, to remove this would be the true practice. Difficult and perhaps impossible as this may be under present circumstances, Mr. Ward here urges several preventive measures acting in this way, and it is, in my opinion, the one which promises the best results to the practical and inventive capacity of coffee-planters. Valuable guides, also in the same direction, are found in the close relations here clearly formulated between attacks of disease and weather. The portion of the report devoted to this subject deserves careful study for its obvious practical bearings, especially as to the question of the possibility of having the coffee-tree in the most suitable condition for resisting the effects of the growth of the parasite at the seasons of its chief invasions.

3. Next to removing the cause come curative measures. Mr. Ward has done well to insist strongly that to find an agent that will kill *Hemileia* is not the most important or indeed a difficult thing to do. But he has narrowed down the practically available chemical substances of this kind to a very few, and his experiments with them do not, in my opinion, lead

one to expect that it is in this direction that the principal relief is likely to be found. We may surely now well reject all notions of "cures" and specifics. "Prevention is better than cure" is an old adage, and with our new vantage ground of knowledge of the extremely short period during which it is possible to get at the parasite at all, the short life of each individual *Hemileia*-plant, and the frequency and want of periodicity (in the almanac sense) in the attacks of the disease, it may well be doubted whether so much benefit is to be obtained by never-ending attempts to check each attack, as by a general combination to destroy spores and hinder their dispersion. I would particularly call attention to the experiments with lime and sulphur made by Mr. Anton at Harrow—in their careful accurary models worthy of imitation of the mode in which such should be conducted—as illustrative of the temporary nature of the benefit obtained at so large an expense.

4. The only other course is by careful cultivation, judicious manuring, and attention to the individual trees, so to improve the coffee as to enable it to endure the disease, produce fresh leaves, and bear a larger crop; but Mr. Ward properly points out that the benefit so obtained is not due to lessening in any degree leaf-disease; the parasite indeed is likely to be increased rather than diminished.

5. On the whole, I am convinced that the possession of this clear and counected history of the disease of the coffee-leaf in Ceylon is a great gain, and has given us a largely increased chance of dealing with its ravages.

6. As I have been requested by you to offer my opinion as to the desirability or otherwise of the Cryptogamist's appointment being continued over a third year, I have, in concert with Mr. Ward himself, considered carefully the present position of the enquiry from all points of view. I may say at once that Mr. Ward looks upon the present report as final in its character, and does not anticipate that any discovery of practical value would result from further work at *Hemileia*. Indeed the only point of any importance remaining unsolved is the history of the second kind of spore to which attention was called in the last report. To that nothing can yet be added. From the purely scientific aspect of the enquiry, further information on this matter would doubtless be of considerable interest, but any practical bearing of the discovery af a second host-plant for the fungus is rendered unimportant, since the ordinary mode of its direct dissemination by the yellow uredospores has been so completely demonstrated. The Cryptogamist does not consider that another year's sojourn in Ceylon would be profitably spent either to the Colony or to himself in this search, which would be possibly futile (since the discovery of such a plant, if it exist here, is greatly a matter of chance), or, if successful, offers so slight a probability of contributing to the main purpose of the enquiry. In this opinion I fully concur. I may add, however, that though Mr. Ward may be no longer in Ceylon next year, we may perhaps have yet the benefit of some researches on the nutrition of plant-cells, commenced here in connection with coffee, but requiring for their completion work in the well-equipped laboratories of Europe and facility of reference to living authorities and published memoirs. This work, though not strictly any part of the leaf-disease enquiry, bids fair to be of special value to the growers of our staple product.—I am, &c.,

HENRY TRIMEN,
Director, Royal Botanic Gardens.

FROM MR. MARSHALL WARD'S REPORT.

From H. Marshall Ward, Esq., to the Hon. the Colonial Secretary.

Sir,—I have the honour to present you with a further report on the progress of the investigation into the life-history of *Hemileia vastatrix*, which I have conducted during my stay in Ceylon.

You will see that the nature of the fungus, and its causal relations with "leaf-disease" on the coffee in the island are satisfactorily determined, and that the knowledge now to hand, together with what has been put forward in my previous reports, leaves no doubts as to the bearing of the several points established upon the general questions which have been raised.

So far as coffee is concerned, the life history and anatomy of *Hemileia vastatrix* may be considered complete. The important periods occupied by the several phases of its life history have also been ascertained, and a considerable number of developmental periods on the part of the coffee have been resolved and brought into correlation therewith.

I have, moreover, to call your attention to the real connection between climate and leaf disease, which is no longer to be looked upon as a vague expression; but which I have shown to be of exactly the same nature as the relations existing between any other organism and its physical environment, and comparable to the equally important dependence of coffee or any other plant upon climatic conditions.

I have attempted to place the essential details of the history of this fungus, and its true relations to the coffee, &c., in the clearest form; and have omitted no fact which throws light on the difficulties experienced in understanding so intricate a subject. Having shown that the individual fungus plant is derived from without, and injures the coffee by robbing it of food—on the manufacture of which a large expenditure of energy had been employed—by occupying valuable space on the leaves, and by producing profound disturbances in the functions of the plant, I further proceed to the examination of the obvious consequences of such damage on a large scale —the falling of leaves, blossom, and crop.

The distribution of the fungus has also occupied much of my attention, and the fact that it is conveyed from place to place by wind is now established by irrefutable evidence. Other important means of distribution are fully examined below, and the facts collected remove all difficulties in understanding the wide and rapid spread of the parasite by the quickly germinating spores. I further proceed to show what occurs on large masses of coffee, as cultivated over vast open areas in Ceylon; and you will notice that the application of the preceding knowledge to the more complex problems there presented enables one to explain facts, or rather collections of facts, at first apparently difficult of explanation. One important point I would especially direct your attention towards: what is known to the planters as an attack of leaf-disease, followed by the fall of leaf, is not a simple matter, but the combined or successive effects of several generations of the fungus.

Much of my time has been devoted to experimental research into the efficacy of certain substances in destroying the fungus, and the advantages and disadvantages possessed by such of these as can be employed will be indicated below. It will be seen, however, that the problem of combating this disease is not a mere matter of quantity of chemicals and their efficacy in killing the fungus; in any scheme for mitigating the ravages of the pest, provision must be made for removing sources of re-infection, and at the same time keeping up the strength of the coffee tree. Moreover, whatever the application to the diseased leaves, it is clear that its continued action can only be counted upon for a short time after each renewal.

I have pointed out the importance of manuring and pruning, from the point of view suggested by the above, and it seems necessary to call particular attention to the value of whatever break-winds, or tracts of forest, or patana, &c., may separate estates from

diseased areas. That the planting of other trees on estates, and among the coffee, is an important aid to the same effect will, of course, be apparent. "Leaf-disease" appears to affect different estates in different degrees on account of variations in soil, climate, and other physical peculiarities; but I would draw attention to the explanation of this. Careful cultivation and natural advantages of soil, climate, &c., enable certain estates to stand forth prominently, as though "leaf-disease" did not affect them, or only to a slight extent; while poor nutrition, the ravages of insects, &c., have in other cases their effect as well as "leaf-disease."

These attendant conditions, though they may complicate the problem before the individual planter, have, of course, however no connection with the origin of the parasite which causes "leaf disease." Manure, again, can in no way be looked upon as either a cause of the disease or a cure for it: its proper action is that of a food.

The question whence the fungus originated admits of no direct answer. I have, however, placed before you a strong array of facts tending to prove that *Hemileia* existed in Ceylon long before it was discovered on the cultivated coffee; if, indeed, *Hemileia vastatrix* proves identical with *Hemileia Canthii*, there can be little room for doubt that the former passed to the coffee from jungle, as I have long suspected to be the truth.

A review of events during the past year shows that the expectations held by planters during the earlier months of the season have not been fulfilled; and it must be recorded with regret that the general and magnificent blossom which appeared so promising in March last have, with few exceptions, given results far below what was expected from them. Notwithstanding the favourable weather, and the rarity of the fungus at the time, a very small proportion of the flowers came to the stage of young fruit; and it is to be feared that a much smaller fraction will become ripe crop. As an illustration of this, I may quote the following from the remarks of a correspondent in one of the daily papers early in the year:—

"The prospects of a really good year could not have been more perfectly fulfilled from the succession of fine blossoms that came out; and, apparently, we had wheather to set them beautifully. Hope against hope has been disappointed; the greater number of these blossoms came to nothing; and then at most only gave the crop that is now showing, and that, I fear, will prove deceptive, although many estates have estimated from 25 per cent. to 50 per cent. over last year. The failure of the blossom is a mystery, for, on examining the clusters that have set, and are maturing on one side of an eye on a branch, on the other side of the same eye you find blossoms have entirely failed—in fact, when fresh blossoms came out of the same eye where the clusters were, they also failed, while later blossoms on the same branch set all right. This cannot be laid down to leaf disease, or want of manure."

It is important to notice, however, that some estates hold forth promise of even large crops, and that the general aspect is decidedly better than it was last year at a corresponding period.

That this improvement is largely due to the more favourable season of the current year, and the condition of the trees after the rest of last year, there can be no doubt; but to this must be added the equally true statement that careful cultivation and attention have had marked effects in enabling trees to set and ripen crop to a larger extent than they would otherwise have done, as is shown by comparing more neglected coffee.

SEC. I.—THE LIFE-HISTORY OF HEMILEIA VASTATRIX ON COFFEE.

§ 1. The outcome of numerous observations in addition to and in continuation of those referred to in former reports, shows that the history of the fungus which causes coffee leaf disease may be fairly stated thus.

An orange-coloured papillate spore, or granule of "rust," taken from a patch on a diseased leaf and sown in a drop of water on the lower surface of a healthy coffee leaf, soon germinates—*i. e.*, it absorbs water and oxygen, swells up slightly, and protrudes a delicate, thin-walled tube from one or more points of its surface. This tube is a *direct continuation of the spore itself*, and the granular orange-coloured contents of the latter pass along the cavity of the tube as it extends on the surface of the leaf.

On arriving at the orifice of a *stoma* or "breathing pore," this germinal tube commences to block it up, and soon sends a prolongation through the orifice into the passages between the loosely arranged cells of the interior of the leaf. Once safe inside the leaf, the short tube begins to branch in two or three directions, each branch absorbing the fluid bathing the leaf cells with which it is in contact.

As these first-formed branches gather strength and material, they put forth several other branches which rapidly extend into the spaces between the tissues around, and in this manner is formed a spreading meshwork or *mycelium* of short, stumpy, fungal tubes. As growth proceeds from the primary tube in all directions around the point of entry, the increasing *mycelium* soon requires more food than can be obtained by simply absorbing the nutritive fluids bathing the leaf-cells with which the branches are closely in contact; this increased demand for food is effectually supplied after a time by the sucking organs, or *haustoria* which become formed by the older branches. Each bores through the wall of the cell with which it is in contact, and by means of the perforated passage obtains as food the contents of the leaf-cell.

As growth proceeds in all directions from the point of entrance of the germinal tube—*i.e.*, a *stoma*—the leaf-cells first attacked and injured are evidently those nearest this central point, and the destruction of tissue proceeds in a centrifugal manner, *pari passu*, with the spread of the destroying *mycelium*.

The injured cells become paler in colour as their contents become altered and destroyed, and thus shine through the outer layers of the leaf with a paler hue than the remainder of the tissue: the yellowish circular spot thus produced is the first indication to the naked eye of the damage done to the leaf—it is the so-called "pin-spot." As the destroying mycelium extends itself further into the tissues, its course is marked by dying cells, and a circular spreading of the pale disease patch is obvious to the outward observer. From the same cause the discolouration appears at a later date on the upper surface of the leaf, as the branches extend there.

When a vigorous, centrifugally spreading mycelium has thus been formed, the older portions at the centre commence to form *spores*: these are produced in compact groups from the substance of certain processes which are formed by aggregations of branches of the mycelium forced through the stomata. The first formed spore-groups appear at those stomata which lie close around the point of origin of the mycelium, and they are followed by others successively protruding through stomata further and further away from this point: thus, the production of spore-bearing heads also takes place in a centrifugal manner, and successive circles of them become arranged around those first formed. Each spore-bearing head is capable of producing large numbers of spores, successively budding forth during the period of activity.

After a stock of spores has commenced to accumulate, falling off as they become ripe, and adhering to the leaf as the yellow or orange-coloured "rust powder," the completely exhausted leaf-cells, which have been destroyed by the mycelium, turn brown and decay, and in place of active, translucent, living cells, we find a mass of empty, shrivelled, useless, and discoloured vesicles. From what has been said above, it is evident that the resulting brown dead patch, seen from without, necessarily commences in the centre and spreads in a circular manner as before. Under certain circumstances, the second form of spore is produced later by the old spore-bearing heads, and shortly afterwards the growth ceases. In most cases, however, the attacked leaf falls before this, especially when many "disease spots" have become established in its tissues.

The above is a short account of the succession of phenomena presented by the fungus on the coffee, from the germination of the papillate spore to the production of many similar spores from the adult mycelium; and it must be noted that each one of these spores is capable of reproducing the same cycle of phenomena, provided it meets with proper conditions of development. In this way the germination, growth, and reproduction of *Hemileia* are repeated again and again on the coffee on estates.

I will now proceed to state the results of observations and experiments made to determine the following points:—

(*a*) What period is required; and
(*b*) What conditions are necessary, for the complete germination of the spore?
(*c*) What length of time is occupied in forming a vigorous mycelium?
(*d*) How soon after the germination of the spore may the mycelium produce spores again? and
(*e*) How long may the "disease spot" luxuriate at the expense of the leaf?

§ 2. (*a*) How long a period is required, and (*b*) what conditions are necessary for the germination of the papillate spore?

I find that a spore of *Hemileia* is capable of germination immediately after its complete formation on the diseased spot, and that in 12 to 24 hours after its removal from the "rust" patch to a healthy leaf, it may throw out its germinal tube: the conditions necessary for this are the presence of water oxygen, and a sufficiently high temperature. If the mature spores be gathered dry and kept dry and cool for some time, no change occurs during that time; nevetheless, spores thus kept for six weeks in a closely-stopped dry tube, germinated. In close covered cells, again, where the parts were sealed with wax, I have sometimes found germination delayed, or even altogether prevented. Finally, in cases where coffee on flats has become chilled or "frosted" by excessive radiation, the spores of *Hemileia* may be found destroyed in large numbers.

The sum total of observations indicates that germination occurs most rapidly in a warm, damp, steamy atmosphere on the surface of vigorous young leaves. Under these favourable circumstances, germination is commonly completed and the tubes have begun to enter the stomata within 48 hours from the moment of sowing.

Germination—*i.e.*, the swelling of the spore, and protrusion of one or more germinal tubes—may apparently take place anywhere and on any surface, provided the necessary conditions of moisture, &c., are fulfilled; and it is a fact that myriads of the spores germinate on substances other than a coffee leaf, only to shrivel up and die at the completion of the process.* Experiments already quoted in previous reports show that this is true for glass slips, and I have demonstrated the same for cloth, soil, and rocks on estates, &c.

* There is, however, an exception to this statement, as I shall describe shortly, in the leaf of one other plant, *Canthium campanulatium*.

Where germination occurs on a living coffee-leaf, however, the tube does not thus die, but enters a stoma, and forms the mycelium as described above; and this suggests the next question.

§ 3 (*c*) What length of time is necessary for the formation of a vigorous mycelium?

On the third or fourth day after a successful sowing of the spores, I almost invariably find a small branched mycelium within the leaf; vertical sections of the infected part of the leaf show that the tube has penetrated through the stoma, and begun to branch in the intercellular spaces connected with it, while horizontal sections of that portion of the leaf show that the branches (usually about three) at first spread in a direction parallel to the plane of the leaf. At first there are no haustoria, and the contents of the tubular, stumpy branches are pale and finely granular at the growing ends.

Within a week from the date of entrance through the stoma, the mycelium has become a tolerably vigorous structure, rapidly spreading in a centrifugal manner as described, but still living on the fluids bathing the cells, the contents of which are still, to all appearance, healthy. During the second week the minute parasite increases rapidly in size and vigour, and the leaf cells first attacked have by this time haustoria piercing their walls in all directions, and, as a rule, sucking out their contents. It is usually about the end of the second week, therefore, before the pale discolouration (caused by the shining through of the damaged cells) first become observable.

It will be seen further on how remarkably constant are the phenomena described; nevertheless, it is not to be wondered at that some differences occur. It is of importance to note that no other conditions than those given appear to be necessary for the development of the mycelium. A succulent young leaf, with thin cell walls sometimes developes a spot more rapidly, probably because the cells are more easily emptied by the mycelium than are those of an adult, leathery leaf, under the same circumstances; but no evidence of a "necessary predisposition to disease" on the part of the coffee plant is forthcoming, and it cannot now be doubted that any leaf of any variety of coffee will allow of the entry of the tubes, and their development into mycelia. So far as any general statement can be made on the subject, a vigorous and perfectly healthy leaf of West Indian coffee is quite as easily infected with the disease as an Eastern variety, or, if anything, more rapidly.

No doubt the quantity and quality of food present in the leaf cells, the vigour of the sap-flow, the thickness of the cell walls to be broken into, and the number, &c., of cells to be attacked, have their due effect on the rapidity of development of the fungus; and we already know that the degree of moisture, warmth, &c. as well as characters of soil, affect the coffee tree—and through it, of course, the parasitic fungus, is evident from the co-relations of both. It may be fairly stated, however, that under ordinary circumstances the pale, yellowish "pin-spot," heralding the outbreak of "rust," is observed about fourteen or fifteen days after germination of the spore, and this is sufficiently constant (of course I speak from experience at Peradeniya) to enable one to predict the date of appearance of the disease spot, after making a sowing of the spores, with considerable certainty.

To give an instance. On July 24th of this year a few yellow spores were sown on the under-side of a vigorous young leaf of a variety of *Coffea arabica*, and the sowing enclosed in a cell clipped on to the living leaf and kept moist as in previous experiments. From other experiments with the same variety of coffee during June and July, I was led to expect that the first indication of the yellow patch to the naked eye should appear in 15 days from the sowing of the spores, and

accordingly made a note to the effect that the "pin-spot" should be visible on August 8th, following. The plant was put into a closed wardian case, and remained quiet as in other experiments.

On August 7th, the first indication of a barely visible yellowish discolouration was detected; this increased during the 8th, and on the morning of the 9th was quite distinct as a "pin-spot" visible to the unaided eye. This remarkable experiment is illustrative of a series extending over many months and more or less successful in an equal degree; and I would call your attention to the following facts regarding them, as placing still further beyond cavil the nature of the parasite.

The fungus mycelium arises *in the tissues immediately covered by the area whereon the sowing is made*, and no matter how "virulent" the produced spot may be, *the early discolouration affects no other region of the leaf or plant.* I have now (September) five plants in a case, each of which was infected in January last. In each example the "disease spot" appeared at the region of infection *and nowhere else.* Up to date *no other spot has appeared, either on the infected leaf or elsewhere on the plant.* Here, again, I am quoting a few examples out of a much larger number illustrating the same thing. We may now pass on to the next question.

§ 4. (*d*) How soon after the germination of the spores may the mycelium produce spores again?

Here, again, my statements depend upon experiments of the same nature as those above quoted, and the outcome of these indicates that a few spores generally appear in the centre of the yellow patch a day or two after it is visible to the unaided eye—*i.e.*, during the third week of its life the mycelium commences to bear the spores in the manner described above. There appears to be more variation in the time required for the production of spores, however, than in that required for the formation of the mycelium. In very hot weather after rain the rapidity of their formation is marvellous, and the yellow patch is quickly covered with the orange-coloured dust. They, moreover, are produced more rapidly and in greater quantity on a vigorously active young leaf than on an old matured one under the same conditions. That the nutrition of the leaf-cells, by affecting that of the mycelium, influences the amount and rate of development of spores, there can be no doubt; and cases are not uncommon where the mycelium produces no spores at all, or very few, and these very slowly. On the other hand, in very succulent, quickly-grown leaves with thin-walled tissues, and full of fluid, I have known the spores to appear in 10 days from the sowing of the original spores, and I am informed by Captain Bayley of Galle that he has found a sucker which was not 14 days old, with the spores fully developed upon the leaf. This would also appear to be a case in point. Nevertheless, in the majority of experiments the spores appear during the third week—a result which, as already stated, admits of prediction being founded upon it with considerable accuracy.

As to the number of spores produced, and the time during which the mycelium produces them, no general statement can be made. As already said, no spores at all appear in some cases, while on well-nourished mycelia their numbers are enormous. In some of my experiments, where only one patch of mycelium is fed by the plant, I have noticed long, pendent clusters of spores hanging down from each stoma into the perfectly quiet atmosphere of the wardian case. Supposing each of those clusters to be 1-25th of an inch long, and that 100 of the clusters depend from the whole patch, it may be deduced, from certain known particulars as to the size, &c., of the individual spore, that in the example given *there were probably a hundred and fifty thousand spores visible at the same time.* This was on one rust patch, and I have counted as many as 127 disease spots on a single pair of leaves.

Of course, such pendent clusters never form in the open, since the slightest movement of the leaf by currents of air would scatter the loosely-attached spores in all directions: nevertheless, equal numbers must be formed on estates, only the wind detaches them as fast as they are matured. A simple proof of the successive appearance of the spores is afforded by the following experiment. On lightly rubbing the end of the finger or a brush over a rust patch, vigorously active in fine weather, all the spores may be removed from the spore heads except very rudimentary ones: on re-examining the smooth patch some 24 to 48 hours after, the powdery spores have again covered the patch. This may even occur on the ground, so long as the leaf still retains its green colour—a fact of no small importance in considering the possibility of removing fallen leaves.

§ 5 *(e)*.—As to the time during which the above spore-production goes on, I have established the following facts. In experiments where only one disease spot is allowed to flourish on a single leaf of the plant, the spores may be formed continuously during eight to ten weeks or longer if the plant is in a vigorous state and kept undisturbed: even in the open, I have watched disease-spots on which spores continuously appeared for five or six weeks in fine growing weather.

But, as a rule, the leaf falls before the mycelium has attained the possible limits of its development, either from being torn off by wind, or because numerous "disease spots" have formed, and the leaf soon succumbs to the multitudinous drains on its resources. It is certainly a remarkable fact that a leaf will support one or two "disease spots" for a long time without apparent injury; but this is easily explained if one bears in mind that the limits of the mycelium closely correspond with those of the discoloured-patch. Excepting that a tax is put upon the cells in more distant parts of the leaf—since the local action of the mycelium is very powerful—it must be remembered that all the green parts of the leaf are still practically healthy, and can do work for the plant. In proof of this I may cite an experiment made on a healthy plant of Jamaica coffee. The leaves were all removed but two, besides the terminal bud; a sowing was made on one of the two dark green, full-sized, and very fine leaves. On January the 28th the first spores arose from the yellow "disease spot," increased in numbers, and were produced in abundance during the following two months. The activity of spore production then slowly diminished as the destroyed tissues turned black, but up to May 25th, (*i. e.* nearly four months later) there was still a feeble production of spores around the edges of the slowly spreading spot; the rest of the leaf remained dark green, and, to all appearance, perfectly healthy; and so it has remained up to this date (October 5th)—half the leaf black and shrivelled from the action of the fungus, the other half healthy and green. Not only are both leaves still firmly attached, but several new ones have been formed by the plant. In cases where several "disease spots" are permitted to drain the leaf, however, the latter soon falls, and this is of course what occurs on estates generally.

The Life-history of a pair of Coffee leaves, before and after being attacked by Hemileia.

I will now trace the history of a pair of leaves, as actually observed on coffee in the open, as a simple example of what occurs where the conditions cannot be controlled as in the above experiments.

§ 6. The bud, a terminal one, became exposed about the 1st of March, 1881, as the then end pair of young leaves diverged from one another; it remained as a minute green point, shining and hard from the resinous coating excreted over it, up to March 14th. Soon after, about March 21st, a gradual swelling of the bud was observed, and by March 29th, the two new leaves were seen as dark green, somewhat ovate bodies, tightly appressed face to face, and about a quarter of an inch long.

If we now examine the kind of weather which, generally speaking, prevailed during this period, a natural correspondence is traced between it and the development of the bud. During the first three weeks of March, a continuance

of dry, hot days caused all quick growth to cease, but the opening of the bud commenced at once after the showers which set in towards the end of March, and continued for the most part throughout April.

On April the 2nd, in fact, after a week of showery growing weather, the swollen bud had burst, and presented two leaves each $\frac{3}{4}$ inch long, and by April 25th these were fully formed, handsome, bright green structures, about $4\frac{1}{2}$ inches long by $2\frac{1}{8}$ inches broad in the middle:—on or about this date the leaves ceased to enlarge, and may be considered adult, and in full working order.

During the last week in April and the first week in May, much rain fell in heavy showers; but from May 8 to May 25 a hot period intervened, the mornings being frequently close and steamy, however. At this time a few spots of "leaf disease" were observable here and there on surrounding coffee trees.

Now, from April 25th, the period at which we may consider the leaves adult, to June 1st, no trace of *Hemileia* was discovered on either of the leaves; but on June 1st a distinct, though small "pin-spot" was seen on one of the leaves, which I shall call the left-hand leaf, and on June 3rd a few spores were seen proceeding from this. On the latter date, also, I found a minute yellow "pin-spot" on the right hand leaf of the pair.

The question is, what connection had the weather, the presence of spores, and other circumstances with this definite appearance of two "leaf disease spots," on leaves which had been to all appearance perfectly healthy from April 25th to June 1st—*i.e.*, during some five weeks? It may first be stated that the weather from May 25th commenced to indicate the wet usually associated with the incoming of the south-west monsoon, and wind and rain prevailed more or less up to the end of June, June 20th to 26th being, however, fine.

The disease was first noticed on June 1st: if the "pin-spot" arose from the germination of a spore as described above (§ 2), this spore probably commenced its action within three weeks or so previously. On comparing the notes made about the requisite period, two points are clear; 1st, there were spores being shaken and blown about at that time; 2nd, it rained heavily up to May 8th, and a series of hot, close, steamy mornings occurred thereabouts, and it also rained during the week preceding the discovery of the spot. It is evident, in fact, that an odd spore of *Hemileia* germinated (probably in the dew) on each leaf on or about the 16th—18th of May, and sent its tube into the leaf to form the mycelium of which the presence was discovered on June 1st—3rd.

On June 15th, the spot on the left hand leaf was large, and producing abundance of orange spores which were being widely distributed by the high winds (from June 3rd to 15th), as well on surrounding trees and leaves as on other portions of the same leaf surface.

On June 29th, many more disease spots were apparent for the first time: these rapidly came to produce spores, and on July 1st numbered 35 new patches, each pouring forth hundreds of spores to be distributed as usual. The spores which produced these probably germinated about June 15th in the showers so prevalent during the month. By this time, also, the disease was bad all over the tree. I think it highly probable that the 35 new spots arose from spores detached from the one spot of June 3rd.

By July 6th, the leaf was badly diseased: the one older spot (of July 3rd) beginning to turn brown in centre, but still active in spores; the others which might be termed the second generation, shining through above with an orange hue.

On July 15th, there appeared about 12 new spots, evidently from spores which germinated during the last week preceding July 1st. Each series of spots on the left hand leaf could now be distinguished as follows:—One large and old spot, with a black patch in the centre, and few spores—that of June 3rd. A number (35) of very active spots which are just commencing to become brown in the centre—those of June 29th. A smaller number (12) of new active spots and only just tinged yellow above—those of July 15th.

On July 23, the leaf was evidently becoming destroyed by the numerous (48) virulent spots draining it, and curious green rings around the spots of June 29th alone represented the normal colour of the leaf; by July 26th, these had faded, and the leaf was quite yellow and exhausted, and it fell during the night of that date.

As to the right hand leaf, its history is very similar. On June 15th there were 2 *Hemileia* spots on it, a new one having appeared in addition to that of June 3rd; on the 29th June appeared 57 new ones, which spread rapidly, and covered the greater part of the leaf by the 6th July; on July 15th were 13 still newer spots: the three generations were quite evident on July 27th, when the leaf was yellow. Before the last day of July this leaf also had fallen.

It is clear from the foregoing that what the planters term an "attack" of leaf disease, *i.e.*, a sudden outburst of the "rust," results from the coming to maturity or at about the same time of a series of mycelia which have been formed from the successful sowing of a certain number of spores, and since all were exposed to similar conditions we must look for the origin of the rust to the conditions previously present. It is clear, however, that we cannot say exactly when a given disease spot commenced to form; we can only argue from the known data. I do not think that any mycelium takes less than one week, or more than three weeks to form, as a rule, however, and hence the above argument may be widely applied.

But the serious matter to face is the evident cumulative power of the fungus; in the examples cited, the few isolated spots produced (no doubt by the germination of spores from fallen leaves, &c.), during May, in their turn sowed spores which came to a head in June: these became sown and were successful before July, and so on. The effect on the tree cannot be wondered at, where the above recorded history of a pair of leaves may be approximately put as follows:—

One month to form the pair (March 25th—April 25th); one and a quarter month in the enjoyment of normal functions, &c. (April 25th—June 3rd); three-quarters of a month with one or two disease spots (June 3rd—29th); one month of continual struggle with increasing spots (June 29th—July 27th); finally resulting in the destruction of the leaves.

On the connection between Climate and "Leaf Disease," &c.

§ 7. An early observation in the present investigation was that the more carefully coffee plants were sheltered, the less "leaf-disease" did they appear to incur. As I progressed, the following truths became apparent also. In the S. W. monsoon, coffee plants placed in a verandah in the teeth of the wind suffer more from the disease than similar plants in the N. E. verandah, and therefore sheltered, while the reverse holds good, generally speaking, for the alternate monsoon. In the gardens at Peradeniya, moreover, the disease hardly affects plants which are sheltered, at a time when the S. W. monsoon is blowing through exposed trees with hardly a leaf left on them. One patch of trees is very instructive in this respect. There is one tree at the end through which the S. W. wind blows before reaching the others; and it is dark green and bushy, long after the other trees are badly diseased and nearly leafless. The explanation seems simple: all the spores formed on this tree are blown away to the other trees—any spores to reach this tree must first travel about a quarter of a mile, a public road, bamboos, and the river intervening. When the wind changes, however, this tree becomes very bad, being in its turn the possible recipient of every spore formed on the trees now to windward. With this change of wind, also, the trees at the other end of the patch recover more rapidly than those more to leeward.

An extension of these observations to estates and larger masses of coffee, demonstrates the fact that the

sudden appearance of the "disease" is closely connected with *wind*, and this connection is of exactly the same nature as we should expect if the wind blows spores about. That the wind does carry spores of *Hemileia* as well as other fungi, is now proved. How far a single spore may be borne on a high wind is partly answered by my experiments in July, &c. Here were clearly spores caught in transit under such circumstances that we may safely conclude they would have travelled at least twice as far if they had not been caught by the obstruction —that is to say, the spores would travel 50 feet in one journey. But it must be remembered that the very light dry spore torn by the wind from a leaf on a hill or other elevation might be carried much further.

But even if the spore only moves *per saltum*, it may be borne some distance on a dry, gusty day over such open country as the coffee districts, and there can be no doubt that, once it has reached an area of coffee, the fungus has every chance of distributing its spores rapidly over the trees to leeward; the progeny having equally good chances, on the whole, of travelling back again when the wind blows in the opposite direction. It is in accordance with these facts that wind-blown areas of coffee become so badly diseased.

But another series of events suggested an equally important connection with atmospheric *moisture*. Of two series of plants in the same exposed verandah, I found that those placed on the edges of the verandah, and kept wetter on the whole (from drip, driving rain, &c.), appear to become worse "diseased" than more sheltered ones. Experiments then proved that plants strewn with spores and placed in wardian cases became diseased in a fortnight to three weeks, if the interior of the cases was kept wet and the atmosphere surcharged with moisture; whereas in very dry cases no such infection took place. These and other experiments now before you led to the establishment of the connection between rain, dew, &c., and the outbreak of disease, and is in agreement with the known facts that *Hemileia* flourishes especially in damp, steamy districts, and breaks out suddenly and badly in close, hot weather after rain.

The suggestions that electrical disturbances, &c., have any influence in producing or diminishing attacks of "leaf disease" have not been corroborated by investigation. I find nothing to warrant any direct connection between the phenomena of disease and thunderstorms.

But the admitted fact, that the great outbursts of *Hemileia* occur during the S. W. monsoon, and about the break of the N. E. monsoon, is also in accordance with the foregoing. It is in June and July especially that the winds and saturating rains first occur near Kandy, for instance, and it is in July and August that the "disease" is at its height: clearly this occurs because the wind distributes spores which the rain then causes to germinate. So, also, during the other periods of wind and rain. It is difficult to say of any two seasons that the outbreaks of *Hemileia* are more or less virulent, because no standard of comparison is given. In continuously wet weather the spores are less readily distributed by wind currents through the air, but each one stands a better chance of germinating on a neighbouring leaf: this I believe to be the reason why the "disease" comes and goes in virulent and sudden attacks in a dry year such as this; but "hangs about," to use a popular expression, during a wet season like that of 1880. The same, of course, applies to damp and sheltered portions of an estate, or whole estates, or even districts, and a little reflection will convince any one with the competent knowledge that such is the case.

But there are other conditions to be taken into account in comparing the "attacks of leaf disease" in different districts, or on two estates, or even in different years. It is plain that since *Hemileia* only attacks the leaves, there can be none of these extensive outbursts of disease on denuded coffee, and hence, from circumstances of soil, treatment, climate, &c., it may occur that two areas of coffee differing in this respect—*i.e.*, in the proportion of foliage on the trees—may differ in the amount of "rust" and in the apparent "virulence of the disease." It is because a large surface of food material is offered to the fungus that it is so successful, and it is because a large area of leaf surface is offered to the spores, that they affect their inroads on the coffee with such facility.

Speaking of the coffee near Peradeniya for illustration, then, (each valley, and many estates differing in various ways as regards climate), the chief reasons that there was so little "leaf disease" noticeable during February, March, and April of this year (1881) may be thus summed up:—(1) There were at that time but few leaves formed on the trees, and therefore but little surface on which the wind could sow spores; (2) there was but little wind to carry spores, and hence few flying spores to be sown; and (3) the rain was chiefly in showers with long dry intervals, and so the under surface of the leaf would rarely be wet for more than a few hours at a time.

But with the April rains came the conditions required for the germination of the comparatively few spores which had been successfully placed in the interval, and these gave rise to the still (comparatively) few "rust-patches" of May-June. Then came the heavy winds and scattered the "rust" produced by these patches on to the now numerous leaves; rains, moist air, and dews accompanying or following the wind; the consequence and climax being a widespread attack in July. On July 15th the weather cleared up, and it was hot until the end of the month, and, although a number of spores would germinate in the dews here and there, there was a lull in the disease as the already-destroyed leaves fell to the ground. Much distribution of spores occurred in this dry interval however, and the rains in August enabled them to form mycelia, and so on.

It is therefore evident that no general statement can be made as to the time of year an "attack of leaf-disease" may be expected, beyond saying that, since it is at the burst of the south-west monsoon (or north-east as the case may be) that the estate is in full leaf, the winds carrying spores about and shaking the trees, and the rains are affording moisture for the germination of the spores, so it is some time within three weeks to a month afterwards that the outbreak of rust may be expected.

That pruning, manuring, shelter and other such processes of cultivation should be directed in accordance with these principles, will be obvious, but as this is important, I shall refer to it in more detail shortly.

"*Attacks of Leaf Disease.*"

§ 8. Since illustrations from the estates themselves are in some respects more intelligible, I propose to give one or two examples further showing the truth of the above remarks.

On an estate in Dimbula the experiences as regards the outbreaks of leaf disease this year were as follows:—The disease commenced to show in May, increasing during June, and becoming very severe about July 1st, when the attack was at its height; before or about the 15th of July an immense quantity of leaves were falling, and the disease was "passing away." Very little more occurred, except in damp corners of the estate until August, when a milder attack was noticed towards the end. On examining the weather and state of the coffee from February, it is clear that this illustration confirms what has been already said.

During the April rains the spores (which had been slowly accumulating as the leaves formed) germinated, and produced a large stock of spores in time for the monsoon winds and rains of May and June. The latter month being very wet, we cannot doubt that immense numbers of spores germinated, their tubes entered the leaves, and the resulting mycelia would be rampant in

July, as was the case. During July less germination went on in the dry weather, but a stock of spores was ready for the wet August, and the resulting mycelia should (according to experience) produce their spores about the end of the month. Such was the case, but the "attack was a milder one," partly because there were at that time fewer leaves left on the trees, partly because the winds had been less active in the interval.

A second illustration is afforded by an estate in the neighbourhood of Badulla. On the 1st January, 1881, the coffee was luxuriant in wood and leaf, but during the last week in January "a most virulent attack of leaf disease" appeared, and a bad fall of leaf succeeded it. By the end of February it had "passed away," and the coffee set to work to produce new leaves. By March 30th the "estate had recovered." The improvement went on through April and May up to June. A little *Hemileia* then showed itself, and during July and August a "mild attack" made itself evident.

The last ten days in December, 1880, were "especially wet," with mists and rain all day. January opened with fine weather for most of the first fortnight, and then the wet weather returned for sixteen days. February and March were fine, hot, and marked by thunder-showers every now and again. The "virulent attack" which came on during the last week in January would naturally result from the success of spores germinated during December, and the fact of its "passing away" in February is in agreement with what I have established earlier—that the spores accumulated could not germinate in the dry weather.

Another example may be taken from the extreme east of Uva, where the worst "attack of disease" came on in October and November.

In August, 1880, the place was looking fresh and green, and a little rain fell. September was very dry, and a "very mild attack of leaf disease" was experienced. October and November were wet, with a fine interval of about a week late in October. During November "a very bad attack of leaf disease was experienced, and a larger fall of leaf than had been witnessed for years." At this period, too, much crop fell from the trees. This state of affairs continued into December, which was a very wet month. During January, 1881, (the weather still wet) the dropping of crop continued from the trees still poor in foliage, but a diminution of disease was noticed. In February the weather became very dry, the remaining bad leaves dropped, and new ones commenced to form. This continued through the dry March, the new leaves being produced in weather when those spores which did get on to them could not germinate. In April the coffee had recovered and was quite green and luxuriant. But the large masses of foliage had now been exposed to occasional access of spores for three months or so, and the first spell of wet weather would be expected to cause their germination. This happened in May, the first 15 days of which were wet, and the consequence was an outbreak of the rust in June. These illustrations, read in the light of experiments and previous knowledge, show clearly enough the nature of the disease and the manner of its dependence on climate, &c.

We are now in a position to inquire further into the matter of leaf disease, as it occurs on large areas of coffee such as are found on estates and in open districts.

SEC. II.—LEAF DISEASE ON LARGE MASSES OF COFFEE.

§ 9. Perhaps the simplest example of what occurs on estates generally is afforded by what happened this year to a somewhat oblong patch of coffee trees, standing in a slightly isolated position at Peradeniya, and on which I have kept close watch for the past 14 months. The wind of the S. W. monsoon blows through these trees along the longer axis of the group, and in such a way that one tree at the end receives the wind before the others.

During January last many of the leaves had fallen, and the trees looked thin after the "attack of leaf disease" which occurred towards the end of the year 1880; on February 1st, 1881, there was in fact, but one pair of leaves at the end of each twig in many cases, and no twig had more than two pairs and a terminal bud. During the hot February, this end bud slowly developed, and before the end of March a second end bud had formed and opened; the average number of completed leaves at this time was, therefore, three pairs to each twig.

During the hot weather which prevailed in March, these leaves were all dark green, and healthy, and scarcely a trace of *Hemileia* was to be found in the gardens; the consequence was that each tree appeared fairly clothed with leaves, and though still somewhat thin, a dark green colour had come over the mass of coffee.

During April and May the formation of buds and leaves increased more rapidly in the growing weather; for although still very hot, a series of showery and steamy periods alternated, and the trees formed foliage with corresponding activity. Up to this period—the end of May—no leaf could be said to be "diseased" to any extent, and, indeed, it was not common to meet with a disease-spot at all.

It may be fairly stated, therefore, that during the period between January 1st and May 31st, the trees, after a short period of rest or exhaustion resulting from the late "attack of leaf disease," set to work vigorously to produce leaves, and that during the interval, at first slowly and then more rapidly, they succeeded so far as to produce five or six pairs of clean, healthy leaves along each free twig. From January 1st to May 1st, these trees would certainly have been pronounced "free from disease" in any estate report.

But, unfortunately, the very weather which promoted the growth of leaves during April, *i. e.*, alternations of showery and hot periods, dewy mornings, &c., also enabled a few straggling spores* of *Hemileia* to germinate here and there on the leaves. Consequently, before the end of May a corresponding number of "disease-spots" had burst forth from the infected leaves, and the spores produced by these were being shaken off, and more or less shed on surrounding leaves. During the first week in June a good many more spots, still isolated, had made their appearance, and what would probably be termed a "mild attack of leaf disease" was noticeable.

Before following the course of events further, I would, at the risk of repetition, call attention to the conditions which are found to rule the propagation of the fungus, and compare the facts with what occurred here. During the hot dry weather of February and March, apart from the fact that very few leaves existed for the fungus to attack, the want of moisture was of course inimical to the development of any spores accidentally conveyed to the living leaves from the leaves lying on the ground, and the few odd spores left from the last attack on the end leaves no doubt remained dormant. In April, however, a single showery night and dewy morning, probably followed by a steamy close day, might be sufficient to enable the spores near the stomata to send their tubes into the leaf; once inside, as we know, they are safe, and from what is taught by experiments, we should expect to see the "disease spots" fully developed within about three weeks. That this actually occurred is evident from the gradual increase of spots during May; each spot produced would then shed its spores around as the breeze shook the trees, and each spore washed to the underside of the leaf is capable of at once germinating, &c., as before. In this manner it is

* These spores may have been blown on to the leaves from the leaves on the ground, or they may have persisted through the hot dry weather.

easy to explain the gradual accumulation of disease-spots and spores during May and the first week in June. That such is the explanation seems placed beyond doubt by the following facts:—

(1.) During the first fortnight in May, observation showed that the shaking of the branches had caused many spores to fall on the leaves, &c., round about; that some of these remained adherent cannot be doubted.

(2.) During the April and May showers it was easy to see that rain falling on the upper side of a leaf runs down to the point of the leaf, or along natural furrows to the edges, and that the drops of water there formed often contain spores of *Hemileia*. It is evidently in this manner that rains wash the spores to the edges and lower surface of the leaf; once there, germination is successful if the atmosphere remains moist for a sufficiently long time.

(3.) Examination of the leaves in May showed that spores *were* present on the lower surfaces. Since the winds were not high, these probably reached their destination in the manner described.

(4.) I have shown that moisture, a proper temperature, and oxygen are alone necessary for germination, and that if this occurs on the lower surface of the leaf the tubes enter and form mycelia in the intercellular spaces inside the leaf. An examination of the weather shows that just such conditions existed about the given periods as were required.

As I have shown, spores were present in some quantity on the leaves before the end of May, and before the 15th of June the trees were becoming badly diseased. The last week in May was a wet one (after a fortnight or more of *dry windy* weather), and the atmosphere damp for some days; then again followed a short period of warm, steamy, cloudy weather with brighter intervals. That numerous spores were distributed in May, and germinated in the interval between May 25th and June 1st, there can be no doubt, and I have shown that if such was the case, the resulting disease patches should begin to appear some 15 days or so later. And this actually occurred; for on June 15th my notes run:—"All trees except the one at south-west end badly diseased with "pin-spots," especially the lower branches. These lower branches are sheltered and moist."

It will thus be seen that the very close connection which exists between the parasite and its conditions of existence, &c., can be traced here, and it will also be seen that this connection is no more mysterious than that between the life of any organism and its natural environment: sow the spores of *Hemileia* on a proper nidus, and give them air, water, and warmth, and they germinate and flourish as do the seeds of coffee or any similar plant in damp, warm, aërated soil.

The stock of spores formed on the trees was already large, but after June 15th—20th, an enormous increase occurred, and it is necessary to see the effect produced shortly afterwards. The weather on and about the 20th was hot and close, and every "disease patch" was now covering thousands of spores, the mycelia being abundantly fed by the now well filled leaves; windy periods had also occurred, and, partly by shaking the "rust" on to the same or lower leaves, partly by rubbing leaves together, and partly by carrying the spores bodily through the air, the wind had caused a very effectual dissemination of these spores. June 26th to 29th were wet days, and these success fully-located spores which had not germinated already, no doubt did so now; at intervals, up to July 5th, we had also wet weather. All above were short periods of driving high winds alternating with steady south-west breezes.

It is clear that the stock of spores accumulated from the disease spots which commenced action on or about June 15th had everything in their favour during the following three weeks, and it follows that during some three weeks later a corresponding amount of mycelium should be formed, and "leaf disease" be proportionally bad. The weather cleared up after July 5th and remained fine and hot for a fortnight or so, and during that period a most disastrous outbreak of the orange-coloured rust occurred, especially during the second week in July. These facts are again closely in accordance with what should be expected from the experiments; the disease spots which came out on July 14th, for instance, would be from spores which germinated about June 30th or a day or two before; those which appeared on July 7th, from germinal tubes of June 21st or later, and so on.

But still stronger evidence of these truths is afforded by what followed. On or about July 12th the air had become quite dry again, and up to July 30th no rain fell; from the 15th to the 30th, in fact, the air was so dry, and the winds (at intervals) so fresh, that probably no germination of spores could occur. Here, then, was a chance to test the accuracy of the preceding work, and I may mention that it was just such a dry interval that had before given me the clue to the facts.

During these 15 days or so myriads of spores were formed and distributed by the wind. The rains came on again on August 1st, but the air did not become very moist, and fine weather with hot winds ensued during the first week. The number of spores which would germinate successfully during this week would probably be few, because the air was probably at no time nearly saturated for 24 consecutive hours, and the leaves were never wet for anything like so long a period; those spores which did germinate, however, should produce visible disease-spots on or about August 15th to 20th. I happen to have a curious and conclusive proof that such was the case.

A perfectly clean and healthy plant of *Coffea Arabica*, which had been sent to me in a wardian case with three others from Samarang, Java, had been planted out direct from the case on August 1st amongst the badly diseased coffee; it had been packed so that no injury accrued to it, and was altogether a satisfactory subject for experiment. I planted it in the evening of the day on which it was unpacked, shook a few spores from a neighbouring diseased plant on to one leaf, and moistened them with water; rain fell during the night, and the next day was wet up to the evening, hence the sowing was moist for about 24 hours at least. On August 18th there were one or two developing "disease-spots" quite visible to the naked eye, and on the 20th they were in full bearing. On August 7th, the rain commenced in earnest, and was of a character exactly suited for the germination of the spores—warm, steady, drizzling, continuing for hours, and saturating the air with moisture. This sort of weather continued to the 12th, and two fine and still days followed; then another wet period for a fortnight or so. The germination of the spores would be mainly effected between the 7th and 12th, however, and according to my previous results, a "bad attack of leaf disease" should be apparent about August 30th to September 6th. It is just manifest, as I write this (September 2nd) there are pin-spots commencing to show on nearly every leaf."

§ 10. From the sequence of events thus occurring on a small mass of coffee, more or less under control, it is not difficult to infer what takes place on large areas such as estates, or groups of estates; but before examining this it is necessary to consider and destroy a number of complicating circumstances.

Certain portions of most estates are subject to conditions of a more extreme nature than I have yet considered. The ravines and hollows are in some cases never quite dry, and it becomes a serious question whether

On September 9th, these and numerous other disease-spots were sporulating all over, and before September 30th almost every leaf on the above plant was badly diseased. The three other plants, however, were not then placed in the N. E. verandah of my house, about *an inch of Hemileia* up to October 7th. (the date on which I add this note).

ther the germination of spores is ever prevented in these places; continual evaporation from the water below keeps the foliage of the coffee moist, and, as such places generally possess very luxuriant and leafy trees, there is no lack of food for the fungus. The slightest shaking of the branches and leaves sheds spores around, and such hollows become quiet centres of disease, whence the wind periodically bursting in, further disseminates the spores. A similar argument applies in different degrees to flats where moisture is abundant from excessive dews, &c.

High and exposed ridges and faces are commonly badly diseased. This is partly because the wind conveys spores very readily to such places, and partly on account of the damp mists commonly enveloping them, and affording the moisture necessary to germination. The fact that such regions are usually much washed, and therefore afford poor soil for the roots of the tree, has no more direct bearing on the subject of leaf-disease than has the converse fact that the soil in flats and hollows is usually good.

Other things being equal, there can be no doubt that a gently sloping sheltered estate, or portion of an estate, suffers less than an exposed one, and if a dry climate is added to these advantages, the difference is even more obvious. On the other hand, an estate through which the wind blows freely, and the rainfall and general moisture of which is high, suffers more. The understanding of these points is easy in the light of the other facts.

§ 11. And now, bearing in mind what are the conditions which rule an "attack of leaf-disease," I will shortly examine one or two further illustrations, taken from both sides of the coffee country.

My attention was drawn some months ago to a remarkable case of outbreak of *Hemileia* rust on a fine field of coffee situated in the following manner:—The whole estate lies in an incomplete basin, open to the east, and sheltered by high forest-clad hills on the west, south, and north sides. A steep ascent through jungle enables one to arrive at the top of the estate from the south-west side, and from this eminence one looks suddenly over the coffee on to the lowcountry beyond. The position of affairs was as follows: the coffee to the extreme east of the estate alone suffered from "leaf-disease," and all the rest of the basin nestling under the forest-clad sheltering heights, had been free from "rust" until this year (this was in 1880). Could I explain the remarkable and sudden outburst of *Hemileia* on the south-west sheltered slopes?

During 1879 and 1880 much of the jungle had been cleared on the other side of the ridge, and on riding up to the estate one felt the force of the wind severely. I have little doubt that the destruction of this sheltering jungle, which had hitherto prevented the carrying of spores (acting so to speak as a filter to the beating wind), now enabled free passage of them, and the consequence was an outbreak of "rust" soon afterwards. Other instances of the same thing are not rare, and indeed we must look upon the opening up of such large unbroken areas of more or less well prepared food to the fungus as one of the chief causes of its lamentable abundance.

On an estate in quite another part of the country, I found the natural features and their effects illustrated in another manner; the main fields of coffee lie on slopes chiefly facing the east and north-east, and widely open in those directions to the low-country. Stretching upwards, and much broken in character, lay coffee estates for several miles in a westerly direction; the S. W. monsoon sweeps all these estates before arriving at a broad plateau, or slight hollow which is situated at the top of the slopes referred to, and then, passing over the edge, falls down these slopes to the low-country. Now this plateau, notwithstanding that it possesses fine coffee, serves as a kind of reservoir of fungus spores, and for the following reasons; the spores carried into it by the wind are very successful in obtaining a footing, since at that height there is usually sufficient moisture clinging about the coffee to enable them to germinate. Not only so, but every puff of wind sends spores produced hereon over the ledge to the slopes above referred to; these slopes are continually becoming infected, therefore, from above, and I have little doubt that were the plateau in forest instead of in coffee, these effects would cease to a corresponding extent.

These examples may suffice to show how natural peculiarities of an estate affect its supply of disease-producing spores; but I would refer to other physical features, the action of which largely affect the question—in some cases masking, in others intensifying the ravages of the pest.

The "lie of the land," as planters term it, is closely connected with this, since so many other things are implied by it; but it matters not how an estate is situated, so far as *Hemileia* is concerned, provided the spores obtain access to the coffee and moisture to germinate. An eastern aspect is often drier, less affected by wind, and, from these and other causes, possesses more luxuriant coffee than an estate facing the west; though in other cases the reverse holds good. But on going more closely into the matter, it occurs that a drier climate may mean less wash, and therefore better soil, which, of course, *cæteris paribus*, implies more luxuriant coffee; again, absence of wind entails obvious advantages when one looks on the damage done to coffee torn by cold, boisterous blasts, while beating rains are well known to wash soil bodily away.

Under such circumstances then, the natural advantages are all on the side of the coffee. Less *Hemileia* is blown into the place, and there is less continued moisture to favour its propagation, and therefore less chance of its spreading when once there; while on the other hand, soluble and valuable constituents of the soil are more abundant, and the coffee is consequently more luxuriant, and shows the ravages of what disease there is less evidently.

And this brings me to another and very important point. It is commonly stated that strong, thick, luxuriant coffee suffers less than poor, thin trees with few leaves, and it is asserted that this is because the weaker coffee is more "susceptible to the disease" than the luxuriant trees—that the latter possess some mysterious power of "throwing off the disease." Facts, however, are against any such view.

A densely clothed tree, from the fact that it is not so easily penetrated by the wind, especially when supported by a number of others, may not become so much "diseased" in a given time as a thinner one, every leaf of which is reached by the wind-blown spores. Again, the dense leathery texture of a strong leaf depends on its tougher cell walls, and repletion with food, sap, &c., hence the mycelium may not make such apparent havoc with the tissues of its leaves in a given time as it does in the thinner, softer leaf of the more unfortunate tree; but there can be no doubt that the chief cause of the prevailing belief about luxuriant trees is that their ability to produce foliage more rapidly and abundantly, partially masks the effects of the fungus by maintaining a general dark hue.

The characters of the soil, again, are continually quoted as having a direct effect on the fungus; but it will be seen from the above that, however much it may affect the coffee, good or bad soil only indirectly affects the fungus. It must be remembered that the mycelium of *Hemileia* requires *living material*, already manufactured by the plant, for its chief food. Of course, in so far as rich or poor soil enables the coffee tree to make this food, the mycelium present in the leaf is affected, and flourishes well or ill. So with other peculiarities of soil, &c. A damp, ill-drained piece of land may afford an advantageous position for the fungus spores, inasmuch as they there germinate readily; but it is less so for the mycelium when once established, because the

nutrition of the coffee is affected by the sour sub-soil and other causes.

In this connection also come other complications. It is common to find "grub," "black bug," and other pests affecting coffee in dumps, hollows, or any clay sub-soils, and I sometimes hear such remarks as that *Hemileia* is worse where "grub" is, and *vice versa*. Careful comparisons prove, however, that no connection other than an accidental one exists; the fungus may spread rapidly it is true on a field of coffee affected by "grub," because the foliage being thin and easily stirred by the wind, every facility for distribution and germination (such places being usually wet) occurs. But it is worthy of remark that a less vigorous mycelium is often found on such coffee, and that if a type of the fungus were to be selected, it were best got from a tree unaffected by any other pest.

§ 12. I have now shortly examined the natural peculiarities of soil, climate, &c., so far as they need be considered in this connection, and it is of course clear that numerous combinations of all degrees of these may occur. The same is true of that part of the work on a coffee estate which is under control.

Manuring is clearly effectual to a large extent in masking the effects of "leaf-disease," but *it is in no way a cure for it*, in the sense of diminishing the ravages of the fungus. Of every basket of proper manure now placed at the roots of the coffee tree, a certain proportion must be looked upon as serving the mycelium of *Hemileia* for food, after undergoing the necessary transformations in the plant; nevertheless, as experience shows, it is necessary to apply manure to enable the tree to produce and bear crop, and it therefore becomes the more imperative to understand the conditions of its action. Manure is usually applied either early in the season—I speak particularly of the districts to the south-west of Nuwara Eliya, &c.,—to produce and support blossom, or later, to "carry the tree through crop," as it is termed. That both methods have their advantages is undeniable, and where possible both might be employed, were it not for the expense. Indeed, what practically comes to this has occurred on a few estates, where the early manuring has been followed up by applications of lime when the young crop is on the trees.

Now, from what has been said of *Hemileia*, and its relations to the coffee, it is evident that one desirable object in the cultivation of the tree is to produce mature leaves *as soon as possible*, and to keep them on the branches *as long as possible*. The difficulties to be contended against are as follows: if leaves are produced in April and May, they become attacked by the fungus while still young, and in August and September the ripening crop is too often left bare on the branches. On the other hand, those leaves which were in bud in December are matured and well hardened when the fungus spores are blowing about, and have already enjoyed a much longer lease of life than the others.

But, unfortunately, it is in April and May that the growing season is usually at its height in these districts, and it is doubtful how far leaves could be put on the trees at an earlier date, unless the weather were very wet as in 1880, when the additional leaf was largely at the expense of blossom. Nevertheless, I would urge those planters who have the necessary climate to arrange matters so as to produce their leaves as far as possible either earlier or later than at present. The reasons why those districts suffered from such a "bad attack of leaf-disease" in July this year have already been detailed, and it will be noticed that when the winds commenced, large surface of young and succulent leaves were ready to receive the spores of *Hemileia*; then followed the rain, germination of spores, and finally the fall of leaves as the fungus destroyed them.

Pruning should of course be arranged with the same object in view—to produce matured leaves during those months when least wind and damp may be expected. That some such object is kept in view by many planters would appear from the various kinds of pruning I have witnessed. A practical question of this kind must be decided by each superintendent on each different estate. The following hints may help to guide some, however.

The chief cause of the "failure of blossom" and the "dropping of crop" in all stages is the loss of the leaves, suddenly, and at critical stages: *i. e.*, at periods when the blossom or crop most requires the food manufactured by the leaves.

The leaves fall so suddenly, and in such large quantities, because the rapidly developing fungus is quickly spread over a large area of succulent foliage by the winds, at the time of the monsoon rains.

In so far as this large surface of young leaves can be produced at a period earlier or later than that during which the spores are being distributed by wind in such vast quantities, the trees will reap the benefit, since the disease cannot spread so rapidly, and the leaves will enjoy better health, and consequently do more work for the trees.

I fear this can only be effected by pruning and applying the manure at times when they will act less rapidly than at present. It is clear that leaves are formed more slowly from January to March than from Apr to June, for instance (in the districts referred to); but the advantage gained by either having fewer leaves on the trees in May and June, or many hardened ones would probably be a decided one.

I am, of course, also aware, that great difficulties stand in the way of a modified system of cultivation; not only difficulties with labour and estate routine, but also with the seasons. But in so far as the above ends could be attained, I believe advantage would accrue, and the manure would at least stand less chance of being wasted as food for the fungus.

Another point, already referred to in part, is shelter. There can be no question that coffee under artificial shade is spared a large infliction of wind-blown spores, and although such sheltered trees often tend to form foliage in excess of crop unless the season be hot and dry, it becomes an important question how far the visitations of *Hemileia* could be checked by belts of trees or other shelter. It is matter for regret that such immense, unbroken areas of coffee exist without break of any kind, and one can trace the swaying backwards and forwards of the spore-laden winds in consequence. A subject of some importance in this connection is the planting of other trees among the coffee; this is of course done to some extent in the case of Ceara rubber and Cinchonas, and although the success of the experiment is not yet established in these cases, I would call attention to its general importance from the above point of view.

The value of a broad acreage of patana or chena land to the windward side of an estate is another illustration of the importance of any break in the onward career of windblown spores. Many planters have recognised the fact that they do not get leaf disease from the low-country patanas to windward, a fact worthy of remark in this connection.

This being so, it should be the aim of all to see how far the leaves can be kept on the trees by manure, artificial treatment, and cultivation, on the one hand; and how far the sources of infection can be lessened by the destruction of fallen leaves, and the prevention of spore invasions carried by wind from without. To those acquainted with the immense areas of open coffee under cultivation, and the difficulties of working steep and broken land, the practical application of hints to this end are admittedly very difficult; nevertheless, in face of the following facts, it must be insisted upon that any

of the most important steps in combatting the inroads of *Hemileia* is the destruction of fallen diseased leaves as speedily as possible.

1. A mature spore is capable of germination within 24 hours of its removal from the parent mycelium.

2. A leaf which falls while still green in parts may continue to shed spores for some hours after reaching the ground.

3. Ripe, dry spores retain their vitality for several weeks or even months.

4. Any of these spores blown from the ground on to the new flushes of leaves which become formed after the "general attack," &c., may become a new centre of disease in two or three weeks after germination.

I now pass on to the subject of the amount and kind of damage done by leaf disease to coffee—a subject already treated of at some length in former communications.

The Fall of Leaves, Flowers, and Crop.

§ 13. As I have already shown in a preceding report, and as is generally held proved, the most obvious damage done to coffee by *Hemileia vastatrix* is the periodical destruction and premature fall of leaves which it causes; if the leaves can only be kept on the trees for longer periods, the chief problem is solved.

Without insisting more in detail here upon the facts before published and the additional proofs of the damage done now laid before you, I propose to examine a series of phenomena which at first appear extraordinary, but which a little reflection shows to be naturally consequent for the most part on the foregoing. The blossom of the coffee tree appears chiefly during the early months of the year in the districts south-west of Nuwara Eliya,* and this year an exceedingly promising series of blossoms was produced on most of the estates. Part of this blossom never came to anything beyond the stage of buds; another portion produced young fruit, but soon dropped off; while a small fraction furnished the crop now ripening up to a greater or less extent.

The following remarks apply more particularly to the districts above indicated; but the facts apply equally to other parts of the country as well, making proper allowances for differences in climate, seasons, &c.

The trees, which were recovering from the late "attacks of leaf-disease" in December and January, had commenced to clothe themselves with foliage in February and March, but were not generally luxuriant before April; by force of habit, so to speak, the flower buds became formed in the hot weather, and expanded as more or less luxuriant blossoms on shoots which were still struggling to produce leaves to replace those which had been lately lost.† That many of these early flowers buds and flowers were poorly nourished on the still incompletely clothed shoots, is not surprising, and, in contrast with this, it appears that the March blossoms (which were generally better also), coming out on shoots already fairly well supplied with leaves, and rapidly forming new ones, were usually the successful ones. That this should be the case follows naturally from the fact that the latter blossoms and resulting young fruit had more material to draw nourishment from, more leaves being present at the time, and more time having been given for the storage of those food-materials which the young berries required.

I found also that the later blossom consisted mainly of finer flowers, better nourished and more vigorously developed as a rule. Not only so, but on a given estate there was more crop "set" on recently manured fields than on the fields which had received less liberal treatment; while comparisons over large areas convinced me that the same held true for trees on good deep soil, as opposed (other things being equal) to trees grown under poorer conditions.

But the statement that without leaves the tree cannot produce blossom and crop admits of more direct proof. In December, 1880, I stripped all the leaves from a tree on an estate in Hantane, and left it to recover as it could; the trees around proceeded to bear blossoms as usual in January, February, and March, but this particular tree was unable to produce a flower, all its energies apparantly having been required to replace the leaves.* Here we see that the loss of leaves by the ordinary trees (caused by the November attack of leaf disease) being made up in time to enable the trees to produce blossom, only reacted to the extent described above; but the second loss, following on the first, in the example given, not only prevented the setting of crop, but even prevented the tree from blossoming at all. And so with other examples.

It thus becomes clear that, in the cases referred to, the blossoms produced at a time when the number and conditions of the leaves did not afford adequate nutrition, only partially succeeded in producing the required fruit; while those blossoms which appeared later, and were better nourished, yielded more promising results in proportion as they *were* better supplied with food, &c.

I have devoted much time to the examination of the extraordinary phenomena termed by the planters "failure of blossom," and the following summarises the results arrived at. A certain proportion of incipient flower-buds did not come to anything at all, but formed at most yellow, sickly-looking protuberances which snapped off at a touch; in other cases the young buds opened slightly, and then "rotted off," passing through shades of yellow and brown to black. These buds and young flowers were peculiarly brittle, and their cells were full of brilliant, waxy-looking, dense protoplasm; the consequence was they would break or snap at a touch, and were in no way limp or shrivelled. In some cases the flower was more or less deformed, the style protruded, and the corolla imperfect, and such flowers often rot away at the centre.

A large proportion of the flowers, however apparently in all respects normal, became fertilized, lost the useless appendages, and in the ovary remained to produce fruit; nevertheless the fructified ovary did not swell beyond an initial stage, but turned yellow and dropped off while little bigger than a pin's head; or, in other examples, it remained stationary for three or four weeks, and then either dropped or proceeded to swell up.

Another series of events may follow the normal fertilization and swelling of the ovaries of successful flowers, and render it by no means certain that the fruit will be matured. Many young berries turn yellow and sickly when little larger than a pea, and are detached with a mere touch; others acquire the normal size, and begin to turn orange and then shrivel up to a rotten or "light" brown mass. It thus appears that any estimates of the crops, founded on the amount of blossom, &c., were this year likely to prove fallacious; and that such has been the cause is well known.

* In some parts of Uva and a few other places, the coffee blossoms nearly all the year round, a fact of great importance in several respects; the picking is more expensive, but the trees are less exhausted by the distribution in time of their arduous task. One Uva planter tells me he has had 13 blossoms within 12 months.

† A correspondent to a daily paper wrote in June from Kotmale to the effect that splendid blossoms were general, but a large quantity of the February blossoms were destroyed, and similarly in March. Then two small blossoms in January and one in April should have given crop. His experience is also to the effect that manured coffee did best.

* Similarly with 20 trees stripped in December, 1880, and 40 stripped early in January, 1881: on flowers were borne by any of them though magnificent blossoms formed on all surrounding trees.

But it should be noticed that the falling of crop, when once it has begun to swell, depends on exactly the same kind of poor nutrition that was referred to before; for it is essential to note that just at the season when the crop is commencing to swell rapidly before ripening, another series of *Hemileia* attacks come on—*i.e.*, at a time when all that the plant can supply in the way of elaborated food is required for the crop on its branches, the fungus come at myriads of centres to rob it of this very material. Not only so, but by occupying space on the leaves, destroying their tissues, and shortening their period of activity, it prevents them from doing anything more for the tree; moreover, the profound disturbance of physiological relations which results affects the whole plant.

I have given details in an appendix note of the observations chosen to illustrate the above remarks; these may be compared with a sort of standard based on comparative examinations. I estimate that an average "cluster" of flowers (counting all the flowers produced during the year on both sides of the branch) contains 15 to 20 individuals, and that a good sample of "spike" or flowering twig supports 10 to 12 such clusters. We may assume, therefore, that a fair spike has 200 flowers on it in the season.

I gather from planters that 100 cherries per tree will give approximately one cwt. per acre, supposing the trees equal and at a common distance apart. I also learn that less than 15,000 cherries fill a bushel measure.*

Supposing the average coffee tree of 8-15 years old to bear ten primaries, each of which supports five secondaries, and that each of these fifty secondaries produced only five such spikes as have been described above; then we have each tree bearing 250 spikes of blossom. The startling conclusion is arrived at that each such tree has about 50,000 individual flowers on its branches in the season! It appears to have been a common event at one time for large fields of coffee to yield at the rate of 10 cwt. per acre, and such occurs in places now. If the above data are correct, the trees would give 10 cwt. per acre if only 1-50th part of the blossom came to maturity—*i.e.*, if each tree ripened 1,000 cherries. Hence we are driven to conclude that less than 100th part of the blossom becomes ripe crop, as a rule.

I am convinced that in some cases where not more than three cwt. per acre will be picked, the trees produced blossoms as large as the above.

It is of course true that no one could expect so large a number of flowers each to produce ripe fruit; but the present state of affairs is not due to a mere crowding out of flowers or young fruit by successful competitors in a fair struggle for existence. The tree as a whole is poorly nourished from want of leaves, and no sooner does it make arrangements to replace this want than it is again denuded: that the visible effects of the damage should appear in the flowers and fruit is in accord with experience elsewhere.

There is a concensus of opinion among planters that the "tree is weakened," and that manuring enables it to "set more crop." In the sense I have insisted upon, the tree may be considered "weakened," that is to say, it is capable of supporting less crop; but it still puts forth immense energies periodically to replace the lost leaves by new ones. That more blossom was successfully "set" this year on manured coffee than on trees poorer in food material, is therefore not to be wondered at; just as little surprising is it, also, that coffee in deep good soil in a drier climate, and which had been less harassed by *Hemileia*, should produce good crops.

* I had a quarter of a bushel of cherries counted, and found 3,747; this would be nearly 15,000 to the bushel. In the Ceylon Directory, however, the number is given as 14,000, and this may be a better average. A planter who counted the cherries in ½ bushel, found 1,828: this gives a little over 14,600 to the bushel.

Sec. III.—REMEDIAL MEASURES.

§ 14. In considering the question of remedial measures it is necessary to apprehend clearly the nature of the problem to be dealt with, and this is by no means a simple matter. It has become a popular error to suppose that the discovery of some chemical which will destroy the fungus is the chief aim of investigation; this is, however, the simplest of all the questions to answer, and indeed no such chemical could be of any use so long as the following points remained undecided:—(1) When should the fungus be assailed? and (2) How often would it be necessary to apply any external remedy? But however cheap and easy the application of any reagent may be, and however efficacious the chemicals used, it is clear that care must be exercised in treating such an organ as the leaf of a permanent plant like coffee so as at the same time to produce in contact with it a continuous and readily diffused body strong enough to kill the fungus without hurting the leaf or tree.

Much of my time during the earlier portion of this year was employed in watching the effects of certain chemicals on coffee and on the fungus, and numerous experiments with all kinds of reagents have convinced me of the following facts. In devising any direct mode of attacking the fungus, some rapidly-produced, fairly soluble material must be employed, so as to be already on the leaves at a time when the spores are germinating.

At this period the delicate tubes are easily destroyed and offer hardly any resistance to weak caustic or poisonous solutions; but they are formed so rapidly and enter the stomata so quickly, that any application must be already on the spores when they emerge. No attempts to attack the internal mycelium have succeeded in the slightest degree, and statements to the effect that the mycelium was prevented from producing spores by the absorption of reagents through the stem are not supported by the evidence. Unless the germinating spore is destroyed before the tube enters the leaf, nothing short of injury to the leaf need prevent the mycelium from producing spores again as described.

A suggestion to bring about lateral absorption of carbolic acid through the cambium of the tree, and in some supposed manner to attack the fungus from within, was met at the time with the necessary proofs of its erroneous nature. It was, however, attempted on several patches of coffee trees, with the results predicted—injury to the trees and no diminution of the disease spots.

The greatest difficulty of all in this connection is presented in the fact that the fungus spends nearly the whole of its active life in the tissues of the leaf. In common with other such parasites, its life is apparently so arranged that *as short a time as possible shall intervene between the well-protected spore-condition and the safely ensconced mycelium.* It is clearly a condition of success, therefore, that the reagent be on the spore at germination.

A second essential is that the whole of the spores be destroyed, since I have shown how rapidly a single spore may reinfect a leaf, and its progeny spread on to neighbouring trees. This important condition demands two properties on the part of the reagent used, (1) that the chemical employed shall rapidly diffuse and reach every corner of the plant, &c., and (2) that it shall be continuously evolved or persistent in its action. The first of these conditions absolutely precludes the use of any liquid, in the opinion of most planters, since the distribution of such cannot be carried out thoroughly without greater expenditure of labour and money than are forthcoming for the purpose. As to the second condition, the difficulties are very great, since few substances or compounds can be suggested which will at the same time readily diffuse and yet persistently carry on the work required. Nevertheless, no substance is of any use that will not act persistently, for we have

seen that the rapidly-germinating spores are continually being brought by the wind, and the tubes produced as continually entering the stomata of the leaf during the rains, &c.

And here a fresh difficulty arises. To meet the requirements of the case, the reagent must be soluble, and yet the time when it is most required to be active is *when the rains are continuously dissolving it, and running off with it in solution to the ground.* This being so, one must also be doubly careful in selecting nothing which (or products of which) may do harm to the tree on being washed into the soil around the roots.

All the mineral or metallic poisons, such as salts of copper, zinc, antimony, &c., are therefore useless for the purpose, though fatal to the fungus. Either on account of their prime cost, or danger and difficulty of application, &c., the following chemicals, though readily killing the fungoid tubes, must also be placed out of account; acetic acid, osmic, chromic, and other metallic acids; bromine and iodine and compounds, hydrocyanic and other organic acids of like nature.* This rapidly brings the list of available reagents down to a limit, and it appears clear that the possible chemical must be selected from among the following: sulphuric acid and compounds of sulphur, nitric acid, hydrochloric acid and compounds of chlorine and carbolic acid. Ammonic potassic, and sodic hydrates also kill the tubes effectually, as do strong solutions of common salt and other similar compounds.

Nevertheless, very few of the above are available, since most of them would have to be applied in a liquid form, or are in other ways unsuited. Some compound which will continuously evolve an easily diffused, readily soluble gas, forming with the water on the leaves a solution sufficiently strong to do the maximum of injury to the germinating spores, and the minimum of harm to the coffee leaf—the after-products of which are not injurious to the tree when washed to the roots—such is the desideratum.

Carbolic acid is not sufficiently soluble and diffusible for the purposes required, and its highly caustic and irritant characters make it a very dangerous reagent to put on living coffee trees. Nevertheless, I shall refer to experiments where it has been largely used in a certain form. Its great cheapness of course commends it.

Chlorine compounds are not available. The caustic nature of "chloride of lime" brings about the destruction of the leaf tissues, while the passage of gaseous chlorine, hydrochloric acid, and other allied compounds into the stomata, is fatal to the tree.

Considering all the facts, I find sulphurous and allied acids the best and most available reagents yet suggested for the destruction of the fungus on the coffee; and of all the methods for procuring the destructive gases, there are none to equal that proposed some time ago—the interactions of sulphur and freshly-burnt lime on the moist leaf—and for the following reasons:—

(1.) The mixture is slowly continuous in action for long time.

(2.) The slowly-evolved gases distribute themselves rapidly by diffusion.

(3.) The chief gases are very readily dissolved in water.

(4.) The solution formed is strong enough to kill the germinal tubes, but too weak to injure the leaf.

(5.) The acid solution does not concentrate to a dangerous strength, since it is continually being absorbed by portions of the lime, and the compounds become further oxydized to neutral or nearly neutral salts.

(6.) Not only are the final products harmless to the tree, but the chief one (sulphate of lime) is a valuable manure.

(7.) The mixture is simply and readily applied by coolies' hands.

* I omit here all mention of many other expensive bodies.

It is therefore evident that sulphur and lime, evolving sulphurous gases on the surface of the leaf, &c., comply with most of the requirements above commented upon. Having decided upon the best reagent, and the time to apply it, it remains to examine another very important point, viz., what is to be used as a measure of success in the experiments?

In more or less preliminary trials with lime, or sulphur and lime, I was much impressed with the fact that every one relied on the general impressions created by simply viewing the coffee from time to time. This admits of too much chance of fallacious conclusions where a small difference may be of importance, and I accordingly tried to get rid of subjective sources of error by the following scheme.

Since the reagent, by destroying germinating spores, should give the leaves on which they were germinating a longer lease of life, so to speak, if the trees are equal in other respects, the treated specimens should possess more leaves than those not treated: this being so, we can decide whether any resulting darker shade is due to an increase in the number of leaves or to some other change produced. If the leaves, however, remain longer on the tree, that tree should drop less crop; and hence the second test. Other checks to the work will be noticed below.

A number of preliminary experiments with lime, sulphur and lime, carbolic acid, &c., may be passed over as not yielding sufficiently definite results, or not having been performed at the proper time. Of my own numerous preliminary trials, I shall only quote those which throw direct light on the matter; but I here take the opportunity of thanking several gentlemen for the aid afforded me, either by the practical application of my suggestions, or in giving me valuable hints derived from their former experiences.

The first experiment on Harrow Estate.

§ 15. Mr. Anton, of Pundaluoya, has been good enough to give me the following account of an experiment carried out by him on Harrow estate in 1879-80, and which from the results obtained, he felt encouraged to repeat during 1880-81.

Sulphur and lime were applied on an area of coffee of a certain acreage from July 20th to August 12th, 1879, and the results compared with what happened on another area of similar coffee. Both the treated and non-treated fields were considered equal as regards soil, exposure, altitude, &c., and both had been well manured in May, 1878. At the time of application both areas were badly rusted with *Hemileia*, and presented a good crop, which it was feared would not all be picked on account of the known tendency shown by diseased trees to drop crop.

During October, 1879, to January, 1880, the crop was picked, and it was found that the sulphured coffee bore about 6 cwt. per acre, proportionally little light, while the non-treated area only gave 4 cwt. per acre and twice as much light. Mr. Anton suggested that the difference was due to more leaves having been kept on the trees by the treatment, and it will be seen that such was no doubt the case: the explanation of this may be deferred until the second experiment on Harrow has been described.

The second experiment on Harrow Estate.

§ 16. After the results obtained in 1879-80 it appeared desirable to repeat the experiment of applying sulphur and lime to the coffee at a time when the rust had already made its appearance. I undertook the task, therefore, of watching a second attempt, and of examining the results as it proceeded.

A series of fields of coffee, covering 32 acres, and forming an irregular oblong block, were selected for the experiment: on 24 acres were applied sulphur and lime in the proportion of 1 to 3. The mixture was thrown in by hand at the rate of about 4 oz. per tree. The other eight acres remained untouched. This field of

eight acres lies below the bungalow, and slopes chiefly to the north-west; the sulphured fields lie south and east of the bungalow, and are somewhat broken by ravines and roads.

All the coffee was about 24 years old, and bore but little crop last year. The soil is somewhat loam-like, though not heavy, and numerous boulders and rocks—not calcareous—are interspersed among the trees. The higher parts are washed, and therefore possess rather poorer soil than the lower. The untreated coffee was, on the whole, slightly better in point of position and soil than the bulk of that sulphured.

The climate is described as wet in the S. W. monsoon, but, considering the elevation (3,500 to 4,000 ft.) hot, and especially so among the rocks. The weather during the early part of 1880 was exceptionally wet, and much blossom was lost. June, 1880, was tolerably fine, but July decidedly wet.

The treatment of the coffee had been liberal, the manuring commencing in December, 1878, and being completed in March, 1879. The application of the manure was made from below upwards, cattle manure, &c. (two baskets per tree) and castor cake and bones (1½ lb. per tree) being the ingredients used. On this account, the lower (unsulphured) portion "had a better early blossom set" from being manured at an earlier date, and consequently carried a little more crop at the time of the commencement of the experiment than the higher parts of the sulphured area. When the experiment was arranged (August, 1880) the position of affairs stood thus:—Crop advancing. Still some six or eight weeks of S. W. wind to be expected (blowing over the *unsulphured* coffee before reaching the treated fields) and occasional rains of course.

The objects of the experiment were: (1) to save leaves, by preventing the entrance of germinal tubes, &c.; (2) to see what proportion of leaf and crop existed after a certain period; (3) to see if the quality and quantity of the "cherry" or "parchment" differed on the two areas.

The sulphuring was commenced on August 9th, but had to be suspended on account of wet weather; leaves sent to me on August 14th demonstrated the destructive effects at the time of this partial application. On August 18th the sulphuring was recommenced early in the morning in my presence, and I spent two days examining the effects on leaves with which sulphur and lime had been in contact for a period varying from five to forty hours. A strong and irritating odour proved the presence of the sulphurous gases, and there was no room for doubt as to the destructive effects of the reagent on the various fungal filaments and on the spores and germinal tubes of *Hemileia*.

The interval from August 20th to August 30th was fine, and the penetrating gases made havoc with the fungus on all sides. Then came the rain, and from September 1st to September 12th very wet weather prevailed. There can be no doubt that the chief destructive effects of the sulphur were made evident before this, and that very little, if any, results in this direction occurred later.

On September 12th Mr. Anton wrote to me to the effect that the "disease" was reappearing on spots here and there: this must have arisen from spores which germinated at the end of August; whether from odd spots which had been missed, or which had been blown on since, it is impossible to say.

On September 27th I again visited the coffee, and could detect little difference; everywhere was a fairly filling crop, and picking proceeded rapidly. Microscopic observation demonstrated the presence of new fungal filaments and spores of *Hemileia*, &c., on the leaves, and it was plain that the coffee was "re-infected."

On November 19th the sulphured area looked darker than the other, and fewer trees could be detected which were evidently suffering from crop. Little disease appeared anywhere. On November 25th, however, another outbreak of disease was apparent, though it did not become bad.

On December 20th my notes run to this effect: "I am convinced that the sulphured patch looks darker."

Before proceeding to give the details of the tests used to decide what had occurred, I propose to examine the results of preliminary experiments, which help to throw light on the matter.

A number of coffee plants were sulphured in the nurseries in July, 1880, before planting out. These were about one year old and had no primaries, and had been pricked out from among the coffee in July, 1879.

Another series of plants, put out in June, 1880, had not been sulphured before planting out. These were nearly two years old, and had three pairs of primaries each: they had also been carried a short distance before planting, but had been placed in the field a month earlier than the preceding.

In August, 1880, Mr. Anton drew my attention to the fact that although the two-year-old stronger plants had been three months in the open, they possessed fewer leaves than the others, which were only one year old and had been planted out only two months, and he attributed the difference to the effects of the sulphur, believing that the treatment had kept a larger number of leaves on the plants.

On counting 500 of the *unsulphured* plants, we found the total number of leaves which they possessed was 2,544—*i. e.*, an average of about five leaves each. An equal number of sulphured plants gave 3,165, or an average of about six leaves each.

From observations on carefully-sheltered plants grown from seed, and put out as above, I find that a healthy one-year-old plant should have about 60 leaves, and a two-year-old probably more than 250. This being so, the difference between the above plants is much larger than appears at first sight, the sulphured plants possessing six leaves out of a possible 60, or 10 per cent; and the others only five in 250, or 2 per cent.

From the known properties of lime and sulphate of lime, from analyses of coffee and coffee soils, and from the experience of several planters who have used slaked and caustic lime alone on coffee lands, it is clear that lime in general is a valuable soil ingredient to Ceylon coffee, and it becomes a question of some importance, how far the success of the Harrow experiment may have been due to the various actions of lime with respect to coffee and coffee soils.

Experiments demonstrate that the foliage of coffee becomes darker after caustic or partially slaked lime is added to the soil and forked in, and it is on record that decided benefit has resulted from using sulphur and lime amongst the manure applied to the roots of the tree.

I now proceed to examine the Harrow experiment on its merits, as an attempt to cope with leaf disease and obtain more crop.

The crop picked from the 24 acres (sulphured) on the one hand, and that from the eight acres on the other, were kept separate, and a return made showing: (1) the actual quantity of ripe "cherry" (fruit) obtained from each; (2) the amount of "parchment" (pulped beans) which this gave; and (3) the proportion of "light" or bad beans yielded.

The 24 acres (sulphured) gave 1,168 bushels of ripe "cherry," or at the rate of 48¾ bushels per acre; the fruit from the eight acres (unsulphured) measured 291 bushels—*i. e.*, at the rate of 36¾ bushels per acre. Hence very nearly 12 bushels per acre more were obtained from the sulphured area than from the other. The "outturn" from the 1,168 bushels of sulphured coffee was 548, or nearly 17 per cent, that of the 291 bushels was 184, or nearly 63¾ per cent.; thus, the unsulphured coffee gave a better outturn. But the difference in

"light" coffee is most remarkable. The 1,168 bushels of sulphured coffee yielded 12½ of "light," or nearly 2·235 per cent; whereas the 291 bushels gave 9—*i. e.*, 4·891 per cent. In other words, the light coffee from the unsulphured area was more than twice as much per cent as that from the treated coffee.

The unsulphured coffee, therefore, (which started with no disadvantage, but rather the reverse, considering that it was below the bungalow, on better soil, and manured two months earlier) ripened less crop and produced much more light coffee, though the outturn was superior in the proportion 63 : 47 per cent.

A sample of each coffee was sent to Colombo, and cured separately; each sample measured 9½ bushels, and it will be seen that a slight difference obtains still in favour of the sulphured coffee :—

As I cannot do better than make use of the accompanying remarks on the above, Mr. Bois's letters are published with his permission :—

Colombo, 1st March 1881.

MY DEAR MR. WARD,—I have this morning had a long talk with Mr. Anton with regard to the experiment upon the Harrow Estate, and he mentioned that you were somewhat puzzled with the outturn of the coffee in Colombo, and Mr. Symons' report thereupon. Now, I do not think that they are in any way unfavourable to the coffee (marked E) which had been treated with sulphur and lime. It is true that the F unsulphured sample had a smaller proportion of small size; but, on the other hand, the bean of E might have been of closer texture (and therefore of better quality) seeing that the outturn of clean coffee from the parchment was 4·27 in the case of E, and only 4·39 in F. If the bean had been smaller and the outturn worse, I should give my opinion against the sulphur and lime, but in the present instance I am not disposed to do so. You will notice also that in the sample F there is a larger proportion of Peaberry, and although this quality is prized, it is, I believe, the result of impaired growth. As regards the colour, there was certainly a difference, but so slight as to be almost inappreciable. Mr. Symons was a little doubtful about it at first, and it was not until we had both carefully examined it in the same light that we came to the conclusion that there was a difference. I should not like to say that the E mark was inferior, or that the slight difference in colour was sufficient to influence the price; in fact, I do not think it would do so. You must take my remarks for what they are worth, but so far as I can judge the experiment on Harrow is by no means discouraging.—Yours faithfully,

FRED. WM. BOIS.

Colombo, 3rd March 1881.

MY DEAR MR. WARD,—I have no objection whatever to your using my letter if you find it desirable.

I attach considerable importance to the difference of 6 lb. in 240 lb. parchment, as it is equal to 2½ per cent. I also attach importance to the difference between 2½ per cent and 5 per cent of light coffee.—Yours truly,

FRED. WM. BOIS.

Besides the above reports on the samples, I sent marked packages of each to several firms in Colombo, and must take this opportunity of thanking those gentlemen who took so much trouble with my samples. I was anxious to see if experts could detect any important differences in the parchment, and the samples sent were simply marked with letters. Examples of the opinions given are selected as follows :—*

(1) "I am of opinion that the F† is slightly superior in colour and brightness to E : it is of a brighter, clearer, bluish-green than E, which has a decided brownish tinge; but both are extremely fine samples. The F is a larger coffee, but contains more triage than E, and the outturn is consequently worse, but equal quantities of the bulk size were in the following proportions :—134·8 F to 131·3 E, or 2·4 per cent in favour of F, which I pronounce decidedly superior, as far as the good coffee is concerned, to E, E being one per cent better than F as regards triage."

(2) "A‡ is about one per cent heavier than B, and the beans were better in colour and fuller in size when peeled as compared with the parchment."

(3) "The coffees look *very* similar, but the A has a larger proportion of "0" size, "1" size, and Peaberry, the most valuable qualities, while B has a much larger proportion of No. 2, the smallest size. On the other hand, A has a slightly larger proportion of blacks and browns, but we could not tell whether this would be the same in a larger sample, although we may mention that the A showed a good many poor pickings of this description than the B in the two samples of parchment sent down before."

(4) "500 cubic centimetres of A weighed *nett* 227·35; 500 cubic centimetres of B weighed 224·35."

(5) "Both the samples are of exceptionally good quality, far superior to the bulk of this season's crop, and the coffee appears to be almost free from diseased beans, which are now so prevalent. * * * The only difference we can discover in the two samples is that A is rather a deeper colour than B, but both coffees would obtain the very hightest prices of the day."

(6) "The slight difference in the colour of the two

---

* Each of the numbered paragraphs gives the opinion of an independent expert.

† F = Unsulphured coffee; E = sulphured.

‡ A always = Unsulphured coffee; B = sulphured.

samples of coffee you sent would not affect the selling value."

(7) "Sometimes I think A a shade better than B, but cannot make up my mind about it."

(8) "They are both fine samples of coffee in parchment, and would probably give a very good outturn; they peel a long, well-shaped, close bean, such as is much sought after by buyers. Of the two, perhaps B contains beans slightly larger than A, and smaller too, being scarcely so regular as A. In colour the samples appear alike—both fine."

After the completion of the experimont on Harrow it was not an easy task to determine exactly the effect that had been produced on the trees. It was urged that the darker colour of the sulphured area might have been due to the manure, in conjunction with sulphate of lime, &c., having benefited the trees more than the manure alone; or it might be due to the immediate action of caustic lime on the manured soil having rendered certain useful ingredients rapidly available; or, finally, it was probably due to the fact that more leaves had been kept on the trees by the destruction of the fungus in August. On December 20th, therefore, I tried to decide this question by stripping the leaves from ten trees on each area, and ascertaining the average number of leaves per tree. The following tables give the results:—

A.—UNSULPHURED COFFEE.

State of Tree as regards Crop, &c.	Number of primary Branches.	Number of full-sized Leaves.
Heavy crop, thin tree..	18	518
Do. ..	8	218
Fair crop and tree in fair condition ..	4	974
A fine tree ..	8	1,300
Do. ..	10	1,300
Fair crop and in good condition ..	9	966
Small crop, tree in good condition ..	13	1,800
Heavy crop and badly diseased all over ..	13	370
Small crop, fine condition ..	12	2,295
Heavy crop, fair ..	10	858
	105	10,599

B.—SULPHURED COFFEE.

State of Tree, Crop, &c.	Number of Primaries.	Number of full-sized Leaves.
Small crop, tree diseased	10	1,010
Fair crop, good condition	10	1,400
Do. ..	10	650
Small crop, fine tree ..	14	1,900
Heavy crop, tree "shuck"	21	438
Heavy crop, fair tree ..	9	475
Do. ..	9	337
Fair crop, good condition	11	676
Do. ..	14	998
Heavy crop ..	13	778
	121	8,662

On comparing these tables it will be seen that the trees not sulphured had more leaves in the proportion of 10,599 : 8,662. On considering the matter further, and comparing the trees selected, it occurred, however, that had we selected trees less irregular in point of size, condition, number of primaries, and other respects; and, moreover, had we counted *all* the leaves, instead of selecting only those which were considered full-sized (a difficult thing to determine properly) the results might be different.

Since I was very anxious to get at the truth of the matter, a number of preliminary attempts were made to select some fair standard of comparison. It was decided to select trees each of which possessed 10 uninjured primaries, to count all leaves more than two inches in length, and to *weigh* the leaves as well as count them.

On December 21st the trees were selected and stripped, the leaves put into baskets, and weighed and counted while fresh. The results were:—

A.—UNSULPHURED COFFEE. Number of Leaves over 2 inches long.	Weight of the Leaves.	B.—SULPHURED COFFEE. Number of Leaves over 2 inches long.	Weight of the Leaves.
2,868 ..	4½ lb. ..	3,396 ..	4¼ lb.
2,590 ..	3½ ..	2,734 ..	4
1,548 ..	2½ ..	1,330 ..	3
724 ..	1 ..	836 ..	1
658 ..	1 ..	1,318 ..	3¼
852 ..	1¾ ..	940 ..	1½
672 ..	1 ..	690 ..	1
638 ..	1 ..	454 ..	0½
570 ..	1 ..	1,028 ..	1½
2,302 ..	4 ..	2,596 ..	5½
13,422	21¼ lb.	15,322	25¾ lb.

On comparing these we find the unsulphured coffee averaged 1342·2 leaves per tree; the sulphured 1532·2. The weight indicates about 631 unsulphured leaves to the pound, but only 599 of those sulphured.

On January 20th, 1881, these observations were repeated with the same precautions, and the following were the results:—

A.—UNSULPHURED COFFEE. No. of Leaves over two inches long.	B.—SULPHURED COFFEE. No. of Leaves over two inches long.
1,892 ..	2,266
1,186 ..	1,700
1,469 ..	1,066
1,032 ..	1,318
896 ..	792
1,398 ..	2,715
1,036 ..	1,118
1,836 ..	1,268
2,332 ..	1,980
1,762 ..	1,100
14,839	15,323
Total weight—15 lb.	Total weight—8¼ lb.

Comparing again, it appears decided that the darker colour of the sulphured coffee was (in part, at any rate) due to the presence of more leaves in the proportion of about 1,532 leaves per tree, against about 1,484, and that there was more matter in the sulphured leaves, which only took about 839 to the pound, against 989. The chief reason why both sets of leaves weighed less than in December was on account of the drier weather prevailing at the time of the January experiment.

Before discussing this matter further, I will conclude the account of the Harrow experiment. The cost, I am informed, was R20·47 per acre; sulphur at R190, and lime at R25·25 per ton in Colombo. It was found that seven men, carrying about half a mile, could apply the powder to one acre per diem.

It appears from the foregoing that sulphur and lime applied at the critical period, when the germinating spores of *Hemileia* are threatening to denude the trees laden with crop, prevent the fall of leaf to a certain extent, and for a short time by destroying spores and germinal tubes, and that no harm accrues to the coffee from the after products; but it must also be pointed out that either from the action of the lime alone, or from salts of sulphur and lime as well, a distinct benefit to the trees is obtained as the results of the absorption by the roots of the compounds dissolved in the water in the soil.

The Peradeniya Experiment.

§ 17. In order to have a second experiment performed of the same nature as that on Harrow, a piece of coffee was selected on Peradeniya estate in June 1881, and half the piece treated as before.

The coffee chosen covers a narrow, oblong tract of 16 acres. It is described as good coffee, and at the time the experiment began had a fair crop on the trees. A great deal of trouble was spent in obtaining equal areas for experiment, as the ground is somewhat broken by hollows, ridges, and patches of grass or stones.

A line was marked by driving stakes into the ground, dividing the 16 acres longitudinally; the half which was treated lies generally to the north of the other half.

The sulphur and lime were applied on July 6th, 7th, and 8th, and the experiment was completed on the 16th, rain having come on and interfered with the application.

The whole area is fairly sheltered, but the S. W. blows across the lower end as if from S. to N., therefore blowing across the unsulphured patch first.

The soil is stony and light as a whole, and somewhat shallow in places; and the coffee is somewhat old. Leaf disease was becoming very bad when the experiment began, and much "rust" was present on the leaves.

The area was manured with bulk (cattle and poonac) in January 1880, and gave little crop last season.

On July 15th no change was discernible; the field was yellow with rust, and the sulphur and lime first put on were washed largely to the soil by the rain. Examination of given leaves demonstrated the activity of the reagent.

On July 26th I again saw the coffee. Many leaves were falling in the hot, dry weather, and although *Hemileia* was still abundant, the manager (Mr. Huxley) thought the strip was looking better.

During the first week in August, the bad leaves had fallen for the most part, and the new leaves were already making the coffee look darker; but at the end of the month a decided though slight difference in colour could be detected on either side of the line of stakes: this was most evident on one of the later treated parts.

About the middle of August, however, a fresh "attack of leaf disease" had broken out all over the field, and it became clear that the benefit, so far as external application was concerned, would be partial and temporary.

This follows, also, from the other facts. In applying sulphur and lime on July 8—16, those spores and tubes were destroyed which would have produced spots about August 1st and later. The rain, however, broke into the experiment (and it is clear that no application could be made then), while spores did not cease to arrive and break forth from mycelia already inside the leaf, and the consequence was a new outbreak about the middle of August. Of course the good done made itself visible—germination was, at least, to some extent, delayed, and the cleaner leaves showed forth and darkened the colour.

It remains to be seen how much benefit will be derived from the experiment in the end. The crop from each field is being kept separate, and it will be pulped, &c., separately. This cannot be decided before the end of the year. I am strongly of opinion that the darker colour, which is now increasing, is due to the action of the lime on the soil, and the absorption of lime and sulphur salts, &c., by the roots.*

Experiment on Belgravia Estate.

§ 18. Acting on suggestions derived from preceding experiments, the following plan was adopted, and Mr. Elphinstone kindly undertook to have it carried out on Belgravia estate, Lindula.

A square of coffee was selected in April consisting of trees as equal as possible and situated on a flat surrounded by sheltering hills. About 100 trees were enclosed in a square of canvas arranged as follows: stout posts driven into the earth at intervals of a few feet supported two lengths of canvas or ceiling cloth three feet wide, carefully nailed on and joined. Hence the enclosing wall was six feet high.

The wind of the S. W. monsoon comes in at one corner, and blows diagonally across the square. The soil is fair, but somewhat moist at this spot. All the leaves and prunings were carefully removed from the enclosure, and leaves were buried in the soil.

The enclosure was completed in May, and a considerable number of "rust-patches" were already on the leaves all over the enclosed and surrounding coffee. On May 18th the whole inside of the enclosure was treated with sulphur and lime, thrown by hand into every tree, and on the logs, ground, and canvas. Microscopic examination demonstrated the destruction of the germinating spores as before.

At the end of June the enclosure showed no marked difference to the unaided eye, and it became clear that the disease was very little reduced inside the square.

On August 13th I again visited the enclosure. Looked down on from above, the colour of the coffee was darker under the lee of the corner where the wind caught the square, and became paler towards the opposite corner. Careful examination showed that the trees in the more sheltered corner had less rust on the leaves than those in the opposite corner; at the same time no one could undertake to say that the most diseased corner was more free from the rust than the coffee immediately outside and partially sheltered by the whole square.

It was perfectly evident, in fact, that whatever good had been done by the application of sulphur and lime on May 18th, it was only a transitory benefit; the coffee had become re-infected, and was nearly as bad as ever. In short, one application of the reagent was clearly shown to be insufficient.

On reflection, and as the facts already detailed in this report became known, the explanation of this disappointing fact revealed itself to the following effect:—

1st.—It is clear that those germinal tubes which were already in the leaf when the application was made were safe from the effects of the reagent, and would produce spores (according to the knowledge now to hand) some fortnight to three weeks later. Hence there would be the means of re-infection already inside the enclosure, unless the sulphur and lime acted long enough to catch the new spores also. This it did not do at that season, being largely washed off during the monsoon rains.

2nd.—These newly-produced spores would germinate in the rains and their tubes enter the leaves forthwith, and within another three weeks—*i.e.*, six weeks after the original experiment—produce a second stock of spores. It must be remembered that the six-feet wall of canvas could not prevent some motion of the trees by wind and a consequent shaking of the spores on to surrounding leaves.

3rd.—From the fact that the corner of the square furthest removed from the point where the S. W. wind first touched the whole, was most diseased on August 13th, two conclusions might be drawn; either the greater shaking of these trees by the wind enabled the spores they produced to fall more freely around, and therefore to infect more leaves than was possible among the trees in the sheltered corner; or, the greater amount of infection was due to the advent of spores derived from without, the wind passing over the sheltered trees having dropped spores into the more exposed corner, and provided for more disease spots in proportion.

Examination of the canvas demonstrated that the last explanation holds good. I took pieces from both the upper and lower portions, and found numerous spores of *Hemileia embedded in its meshes*, and in all stages of germination and decay, as well as quite recently blown and fresh specimens.

The Belgravia experiment, therefore, may be held to prove, (1) that one application of the reagent can have

* The results will be watched and reported upon, if necessary, at the end of the season.

no effect lasting more than two or three weeks;* (2) that re-infection takes place from surrounding coffee in a very short space of time, by spores carried bodily through the air or shaken off from the leaves immediately around.

The Experiment on Wallaha Estate.

§ 19. The experience derived from the observations on Harrow (and also on Kataboola, Mount Vernon, and other estates) made me anxious to apply the same methods to coffee where unslaked lime *alone* had been used; and this I have been enabled to do through the kindness of Mr. Talbot, who has undertaken to carry out an experiment arranged as follows:—

A field of known area has been divided into two equal longitudinal halves, and in August, the crop coming on rapidly, freshly-burnt lime was strewn all over one-half for the double purpose of killing all spores with which it comes in contact, and to serve as a top-dressing which will rapidly make its way to the roots. The crop will be picked and pulped separately from the two areas, and it will then be possible to determine how far the success in the Harrow experiment depended upon the lime used.

The experiment now proceeding on Peradeniya will serve as a further check, since the mishap of rapid and continuous rain turned the application, practically, into a top-dressing of sulphur and lime salts for the most part. I contemplate reporting on both experiments when concluded, if results of sufficient importance are obtained.

Experiments with Carbolic Acid.

§ 20. I had already satisfied myself that, taking into account its slow diffusibility and the danger of using it on a living plant, carbolic acid is not available for the purposes of the planters, when, in January last, I was invited to be present at an experiment of a novel nature. Wrappers were loosely tied around the stem of the tree enclosing a mixture of carbolic acid, water, and mud between the wrapper and the bark of the tree. Under the erroneous supposition that the cork-clad bark and the cambium could absorb the liquid with benefit to the diseased tree, the object of the inventor was declared to be to "deal with the disease after it has entered the leaves." I pointed out the reasons why this could not succeed, and also took occasion to insist on the dangerous properties of carbolic acid in connection with living coffee.

Some months afterwards the ill-effects of the treatment were still visible on trees at Pallekelle, Roseneath, and Peradeniya estates. The caustic liquid having destroyed a more or less complete ring of bark, cambium, &c., had injured each tree to a corresponding extent. Examination on the spot at intervals after the experiment convinced me also that no temporary benefits were secured. Another series of experiments, based on sounder principles, have been made as follows:—An intimate mixture of fine clay powder containing 12 to 15 per cent of carbolic acid is mixed with lime, also in fine powder, and the mixture thrown by coolies' hands on to the diseased leaves in the same manner as with sulphur and lime.

The object of using lime here is, however, different from that aimed at where sulphur is used. Carbolic acid is very slowly volatile, and with difficulty soluble in water, and where drops of the acid touch a leaf, &c., destruction of the tissues ensues. Carbolic acid has, moreover, a powerful odour, and it appears to be assumed in the experiments that the odour is a measure of so much vapour passing off from the mixture to be dissolved in the water on the leaf. I do not find, however, that the destruction of *Hemileia* spores in the neighbourhood of the mixture is commensurate with the alleged results. It is true that where water is in contact with the powder a solution is obtained sufficiently strong to kill germinal tubes, but the diffusion of this over the leaf is a very slow process. Under any circumstances the results of experiments with carbolic acid powder are not as yet encouraging, though I am of opinion that more might be done with some modification of it,* if it were not for the fact that *the accumulated powder and solution are a source of danger at the roots.*

I will pass on to the description of a few illustrative experiments before reporting further on the larger ones. A sturdy coffee plant, of which two leaves were diseased with "rust patches," was placed in a small wardian case, the whole of the inside of which was painted with a saturated solution of carbolic acid in water. In the overpowering atmosphere produced the plant was tightly enclosed. After 24 hours I opened the case and removed the plant: the odour of carbolic acid was so strong, that one could with difficulty hold the head in the enclosure. Nevertheless, spores taken from one of the patches germinated nominally in 24 hours. It is thus clear that in using carbolic acid (as with other reagents) the germinal tubes will have to be attacked with a solution of the acid.

Another experiment throws light on this subject. A thin layer of the mixture of carbolic acid powder and lime was sprinkled on the surface of the mould around two coffee plants, and at once watered. The watering was continued at intervals for three weeks, when one of the plants had but one yellow leaf left, and the leaves of the other were pale and drooping. The effects of even a dilute solution of carbolic acid at the roots are disastrous, though in the case of a large strong tree they may be to a certain extent masked by other changes.

But observations on whole estates prove the same, and I have failed to discover the good effects said to have been produced on estates by the treatment. That the germinal tubes are killed wherever a solution of carbolic acid comes in contact with them is true; but such a solution is not produced in the way described in the experiments on Peradeniya, Gleneagles, Pallakelle, &c.

If carbolic acid powder could be used with safety, it would be more efficacious without the lime, which could be used with benefit as a manure; but in face of the fact that whatever external application were used, it would have to be repeated at least every three weeks or so, it would be highly injurious to permit such an increase of carbolic acid in the soil as would be the case here.

SEC. IV.—ON THE "ORIGIN OF LEAF DISEASE."

§ 21. The story of the discovery of the fungus *Hemileia vastatrix* by a well-known planter in Madulsima in 1869 need not be repeated in detail here; but since a general impression exists that the year of its discovery has connection with the date of its introduction into Ceylon, that because it was first seen in Uva, it necessarily originated there, I would call attention to facts which throw the gravest doubts on such a view, if they do not invalidate it altogether.

I am told that when *Hemileia* was first seen on the coffee it was already common on the estate, and, indeed, on a neighbouring estate as well, and it is doubtful whether it had not already been observed in other parts of Ceylon. An examination of the weather reports in 1869 on the estate where the discovery took place shows the following:—

March, 1869, was very dry, and April the same up to the 12th, when the wet set in for a fortnight or so. During May were showers at intervals, but cloudy, hot weather prevailed. Now, it was about June 1st, 1869, that *Hemileia* was first observed, and the spores which produced the spots that noticed no doubt germinated in April; for in the first place, *the spots were advanced and numerous*, and in the second, *the leaves were already falling*. In September, 1870, the disease was found in Nilambe and Hantane, and was there also in some

* I doubt whether the effect lasted more than one week.

* As, for instance, using the weak powder alone on the leaves, and the caustic lime separately as a top-dressing to the soil.

quantity when discovered. Without, of course, making any positive assertion on what cannot be proved, it is very probable that *Hemileia* was already widely spread on the coffee in 1869-70, a conclusion rendered the more likely if we reflect how difficult it is to notice new discolourations on the leaves.

Apart from the extreme probability, however, that *Hemileia* slowly accumulated on *Coffea arabica* by passage from some jungle plant, I proceed to give strong objective evidence that such a view is most likely. I find, as indeed was already known, that *Hemileia* occurs on a native wild coffee *(Coffea travancorensis)*, found in the jungles, and have experimented with the spores of the fungus on this plant with the following results: they form germinal tubes, block up the stomata, send branches into the leaf, and form the mycelium in *Coffea arabica*, as well as in *C. travancorensis*; and, conversely, *C. travancorensis* can be infected by spores from *Hemileia* on *C. arabica*.

The anatomy of the fungus on *C. travancorensis*, moreover, offers nothing different in any important respect from that of the common *Hemileia;* the mycelium, it is true, is usually less highly developed and produces fewer spores and less virulent spots in consequence, bnt this depends on vigour and not on specific differences of any kind. It is at least probable, therefore, that *Hemileia vastatrix* lurked in the jungle long ere *Coffea arabica* was widely planted on estates in Ceylon.

About a year ago, however, my attention was directed towards another possible holdfast for "leaf disease" by finding a *Hemileia* which had already been collected by Dr. Thwaites in 1868, and named *Hemileia canthii* from the shrub on which it occurs *(Canthium campanulatum)*. This *Hemileia*, on closer examination, did not appear to me to present sufficient differences to warrant its being constituted a separate species. In size, colour, shape, and marking, the spores resemble those of the *Hemileia vastatrix*; the structure of the spore-bearing head which protrudes through the *stoma* and the mode of origin of the spores are just as before. Unfortunately, I was unable to obtain a stock of fresh material at the time of these observations, and that in the herbarium at Peradeniya was 12 years old, consequently no sowings could be made, and the evidence was incomplete.

During my journeys among the estates, however, I lost no opportunity of searching for *Canthium campanulatum* and its *Hemileia*, and found the shrub in Dumbara, Pussellawa, Haputale, Balangoda, Badulla, &c., at various times. It appears to be a widely-spread plant, therefore, but very few specimens as a rule occur together. During all this period I only met with the fungus in fruit once, though the yellowish spots and mycelium occurred oftener.

In January last I commenced experimental sowings with spores of *Hemileia vastatrix* from coffee on the leaves of *Canthium* plants placed in pots, &c. The result was what I suspected—the germinal tubes blocked up the stomata, sent their branches into the leaf, and commenced to form a normal mycelium in the intercellular passages of the leaf, as in coffee.

In August last, during a journey from Madulsima, I had the startling fortune to meet with a fair-sized shrub of *Canthium* badly diseased, and of which the leaves were in some cases covered with rust.* The plant was on the roadside a few miles out of Badulla, in the direction of Passara. Carefully collecting specimens, I proceeded to clear up what details I could on the fresh mycelium, &c. The mycelium and spore-bearing head are quite similar to that in coffee, the chief differences being due to the denser structure, &c., of the leaf in *Canthium*. The passages between the very small dense cells, with thick walls and closely-packed contents, and the small total mass of loose tissue in the leaf are among the chief peculiarities here. The stomata are also small.

The mycelium is therefore much less highly developed, and it is difficult to detect the thick stumpy branches among the crowded leaf cells. In proceeding to form the spore-bearing head, the branches meet in the chamber below the stoma and fuse into a cellular body, as in *Hemileia vastatrix*; but instead of many branches so meeting the sparse mycelium here sends but two, the fusion of which strongly resembles a definite process. The spores are produced in smaller numbers, but essentially as on coffee, and the sparse mycelium and spores recall what is seen in *Coffea travancorensis*.

The germination of the spore occurs readily, and resembles that of *H. vastatrix*. I have not succeeded in finding *teleutospores* of *Hemileia canthii*.

Of course, on obtaining the above specimens, I at once instituted experiments to show whether the germinal tubes enter the coffee leaf. These experiments have not as yet been successful so far as to produce disease spots and fruit, since so many foreign spores were intermingled with all my specimens that their more rapidly-developed mycelium sadly interferes with germination. I hope, however, to conclude successfully before long.

It may be mentioned here that another possible source of the original spores on coffee may be some other host plant altogether; though it by no means follows as a necessity that the *conidia* produced by the *teleutospores* of *Hemileia* ever germinate successfully in Ceylon. This, however, is hardly a matter for discussion here.

* It is worth remarking that a *pyrenomycetous* fungus occurring as a black crust on many of the leaves is very similar to one common on coffee, and interferes sadly with experimental sowings.

SEC. V.—SUMMARY AND CONCLUSION.

§ 22. I have now placed before you the details of what has been ascertained regarding *Hemileia* and its relation to coffee leaf disease, and may sum up the main points of importance as follows:—

1.—*Hemileia vastatrix* is a parasitic fungus, the spores of which are capable of rapid germination on the moist surface of a coffee leaf. The short tubes thus produced enter the breathing pores of the leaf, and in less than a week, in favourable circumstances, begin to form a mycelium which, at the end of another week or so, have done sufficient damage to the leaf to produce yellow spots. During the third week the spores are usually produced, each to act as before, if sown, &c.

2.—A leaf of the coffee attacked at numerous points by such germinatiog spores rapidly succumbs to the ravages of the mycelium, and falls long before it would normally have done so; not only by directly robbing the tree of food prepared by the labours of the leaf, but, further, by occupying space and shortening the period of usefulness of the leaf, is the tree injured.

3.—The loss of matter and functional disturbance brought about by these continued and periodical ravages have for effect a diminished power to mature crop on the part of the coffee; and flower-buds, flowers, and berries fall because the nutritive relations between the shoots, leaves, and flowers have become overthrown. More crop is borne, as a rule, however, where the trees contain more food material to support it.

4.—The spores of *Hemeleia* are carried by wind. Whether a spore travels a long distance in one journey, or whether it is swept along in successive leaps, it may be carried from one estate or district to another. The shaking of the trees also disseminates spores, and they are driven from fallen leaves to the trees. These spores, scattered on the foliage, become washed down to the lower surface and germinate as before, provided the atmosphere, &c., be sufficiently moist.

5.—No special predisposition on the part of the coffee is required for its infection, and no other conditions are necessary to the spore than moisture and the presence of air, &c., as with any germinating seed.

6.—The spores are in such countless numbers, germinate so rapidly, and some of them so easily

escape the action of even the most efficacious remedies, that no good and lasting results can be obtained from external applications unless the sources of reinfection be removed. No attempts to combat the disease by passing ingredients into the tree have shown any trace of success: the mycelium cannot be attacked after it has entered the leaf.

7.—Diseased leaves should be collected and destroyed, and every means possible employed to prevent the ingress of winds. Cultivation should be directed to these ends, and the pruning and manuring, as far as possible, arranged so that large masses of young foliage are as seldom as possible exposed as a surface of food material for the spores at those times when they are most blown about, as at the bursts of the monsoons. In cases where the disease is threatening to denude the trees of leaves at the critical period when crop is ripening up, there can be little question of the use of lime, unless weightier considerations, based on the results of experience with that particular soil, forbid it.

8.—Manure can in no sense be properly looked upon as a cure for the disease. In so far as it enables a tree to clothe itself with dense foliage, the tree may be able to afford the sacrifice of a number of its leaves to the fungus; but the well-fed mycelium will in such cases produce more spores in proportion, and these may be the more readily distributed, and germinate on other leaves, and so the stock of fungus be actually increased. Nevertheless, careful manuring is necessary for the production of crop without damage to the tree.

9.—The burning of fallen leaves, &c., is almost universally condemned by planters as too dangerous. In cases where this cannot be done, it is better to bury the leaves and prunings than to leave them tossing about. In doing this, the layers of leaves and prunings (which may be mixed with weeds) should be carefully covered with caustic lime and earth and not disturbed for several months. The suggestion that the leaves might be placed under pigs and cattle affords a less safe alternative; but even this plan is much better than leaving them to be blown about the estates. The sooner the leaves are gathered after falling, the more spores are destroyed with them.

10.—The origin of leaf-disease cannot be traced with certainty; but the evidence is so strong in favour of its having arisen from an invasion of spores out of the jungle, that this view may be considered highly probable. Once on the coffee, its spread would be very rapid, where such large unbroken areas extend. No trace of valid evidence exists for the views that the disease has been "induced by artificial manuring," or "caused by alterations in the sap of the tree;" it is, beyond all doubt, the results of the action of a fungus derived from without, the spores of which were either imported into Ceylon (an improbable event) or came from the native jungles.

In conclusion, I beg to call your attention to certain important details in the following appendix. I remain, &c., H. MARSHALL WARD, B.A., Camb., Peradeniya, September 1881. Cryptogamist.

APPENDIX.

A.

The following table summarizes shortly a number of experiments, selected from a large series, made to determine (1) the time occupied in the germination of a spore, (2) how soon afterwards the "disease spot" appears on the leaf, (3) how long the mycelium may continue to produce spores. In each case a vigorous young plant was selected, which had been grown for some months in a sheltered situation, and was clean and healthy. On a recently-formed leaf a sowing of spores was made, kept moist for 24 to 48 hours, and then (the damp cell having been removed) placed in a carefully cleaned Wardian case, well lighted, sheltered, and kept at an average temperature of about 78° Far. In all cases the spores were found to germinate in 24 hours, and the tubes had commenced to block up the stomata within 48 hours. For all examples, also, the following holds good: the "disease-spots" appeared on the leaf on which the sowing was made, and within the area of sowing, *and nowhere else on the plant.* Moreover, no more "disease" appeared on the same plant, even after keeping it for several (six or eight) months, unless a fresh sowing was made and kept moist for 24 to 48 hours as before.

These facts prove (1) that the "disease-spots" and "rust" result from the tubes and mycelium traced by the microscope from the spore, (2) that the fungus corresponds in area with the disease spot, (3) that, even if spores be present on the leaf, no "disease" results, unless the conditions (moisture, &c.) for germination be also present. Finally, taken in conjunction with the results of microscopic analysis, they prove that the disease-spot is due to the action of an organism derived from without, which passes through definite changes, and has a limited term of life:—

Variety of Coffee.	Date on which spores were sown.	Date on which spot appeared.	Date on which spores were first seen.	Approximate date of greatest vigour.	Approximate date on which spot turned black in centre.	Approximate date on which spores ceased to form.	Time occupied in forming "disease spot."	Time during which spores were continuously produced.
A.—Jamaica	Jan. 27	Feb. 4	Feb. 6	Feb. 12	—	—	8 days	—
B.— do	Jan. 30	Feb. 13	Feb. 15	Mar. 1	April 25	May 1	14 days	10 weeks
C.—Nakamaal	Jan. 11	Jan. 25	Jan. 28	Feb. 6	Mar. 14	April 1	14 days	8 weeks
D.— do.	Jan. 23	Feb. 4	Feb. 6	Feb. 13	Mar. 10	Mar. 31	12 days	7 weeks
E.— do.	Jan. 22	Feb. 3	Feb. 6	Feb. 14	Mar. 12	April 1	12 days	7 weeks
F.—Java	Jan. 18	Feb. 6	Feb. 9	Feb. 20	April 2	May 1	19 days	11 weeks
G.— do.	Jan. 22	Feb. 4	Feb. 6	Mar. 1	Mar. 30	April 20	13 days	10 weeks
H.—Indian	Jan. 11	Jan. 26	Jan. 30	—	—	—	15 days	—
I.—Ceylon	Jan. 21	Aug. 7	Aug. 10	Aug. 0	—	—	14 days	—
K.—Java	July 24	Aug. 17	Aug. 20	—	—	—	16 days	—
L.—Ceylon	Aug. 1	Feb. 3	Feb. 5	—	—	—	13 days	—
M.— do	Jan. 21	Feb. 3	Feb. 6	—	Mar. 20	—	14 days	—

N.B.—In addition to the above, several other experiments of the same nature made during the year gave similar results. In all cases the spots appeared on the 12th to the 15th day and the spores on the 15th to 20th day, after germination. The average of the 8th column (164/12) gives nearly (13·7) as the period between the date of sowing and that of the first appearance of the "pin-spot."

B.

The following table summarizes in a similar way the results of the observations made to determine (1) how long a time is occupied by the coffee plant in forming a complete pair of leaves, (2) at what period they become attacked by the fungus, and (3) how long they survive the ravages of the pest. In all the specimens selected, there were several of the disease spots on each leaf; but, of course, no absolute standard of the damage done is given, and it must be remembered that a young leaf badly spotted falls sooner than one affected in a less virulent degree.

The following example will illustrate the mode of reading the columns. Taking the specimen F, the minute terminal bud evident so early as September 6th, 1880, remained quiescent during forty days—till October 16th—and then commenced to swell and unfold its pair of leaves. In about a month's time (November 15th) the leaves were completely formed and in full activity, and apparently clean and healthy. November 13th was the last date on which no trace of disease was visible to the naked eye; but it is evident, from what is known of the periods in the life-history of *Hemileia*, that the germinal tubes had already entered the stomata, and formed mycelia, for on November 23rd the yellow spots ("pin-spots") were apparent, and had developed spores before December 5th. The formation of spores continued, and the leaf was badly diseased with "rust patches" before December 22nd, when the spots were already old and turned brown. On January 1st, 1881, the leaf had fallen, and an examination of the last two columns shows that, out of 2½ months' term of life, the leaf was obviously pestered with the fungus half the time. Moreover, we must recollect that nearly a month (October 16th to November 15th) was occupied in bringing this leaf in full activity, and probably a fortnight must be added to the last column, during which time the mycelium was forming. How little of the total life and powers of such a leaf benefited the tree will be evident on comparing these results.

The method adopted in arriving at these conclusions was to mark a given vigorous twig, and note the progress of the bud, fungus, &c, at intervals of a few days. No other conclusions than those for which the tables are designed are intended to be drawn: *e.g.*, in the example given, the date December 5th (in the 6th column) does not mean that *the first spore formed on that day*; but that, taking notes of the progress of events on December 5th, I found *spores were already formed by the spots in some quantity*, whereas they were not present when notes were taken some days earlier.

To take another example (K), we find a very different series of events when no mycelium or only an odd spot appears: here the bud of January 30th began to unfold in February, and reached its full development as a pair of leaves about March 10th. Up to June 26th no signs of disease had appeared, and we notice that the traces of spots noted on July 6th never came to anything, as signified by "0" in the column: the leaf fell on August 10th, after a total life of 21 weeks or so. In such a case, we may safely assume that its work was chiefly devoted to the benefit of the tree:—

	Date on which the bud was first noticed.	Date on which unfolding of leaves had begun.	Date on which leaves may be considered adult.	Last date on which leaves appeared quite clean.	Date on which the "pin-spots" were first noticed.	Date on which the spores were first noticed.	Date on which the leaf was badly "rusted."	Date on which the spots were brown.	Date on which the leaf fell.	Total life of unfolded leaf (approximate).	Time during which the "disease" was visible (approximate).
										Weeks.	Weeks.

N.B.—In the example marked (*) the leaf never became badly diseased, but at most one or two "pin-spots" appeared and produced no spores at all, and it is doubtful if the mycelium of the fungus was ever present to any large extent. In all the other cases about 10 to 15 "disease-spots" appeared on each leaf, and produced spores as described.

C.

An instructive series of observations were made to obtain an answer to the question: how long will the leaf remain on the tree when not attacked by *Hemileia*, or when only one or two small and barren disease spots appear? The methods adopted were the same as before.

To take an example (C) we find that, on December 20th, the tree was adult, and in full working order. It retained its green, bright colour until April 2nd, when a few faint yellowish cloudy patches were observable. (These are the signs of approaching dissolution.)

On April 25th the leaf had become yellow, like

an autumnal leaf in Europe, and fell soon after, about May 3rd, having done its work for the tree, but having escaped the ravages of the mycelium *Hemileia* :—

Date on which leaf may be considered fully formed.	Date about which leaf began to turn yellow.	Date on which leaf was quite yellow.	Date on or about which the leaf fell.	*Hemileia* spots, absent or present.	Length of time the leaf remained (approximate).

F.—Jan. 2	April 25	May 1	May 8	None.	18 ,,

* One minute spot on February 22.

† 4 small dull spots in November.

N B.—These examples should be compared with examples G, I, and K, in the last table. It is to be noted that none of the small spots taken into account here were either very vigorous or present for a long time before the leaf fell. It is also worth remark that 20—21 weeks is the longest period I have yet found a coffee leaf to persist on the trees in the open.

D.

To determine, as far as possible, the rate of growth and other changes in leaf, buds, and leaves at Péradeniya, certain trees were selected in August 1880, and watched during the following twelve months, notes being made at short intervals as to the conditions of the buds and leaves on twigs around which coloured ribbons had been loosely tied.

The shortest time in which a pair of leaves was developed in my experiments was about four weeks, when the bud first exposed, on April 10th, became an adult pair of leaves by May 8th; and the longest period occupied by the same process was, excluding a very abnormal example where 17½ weeks were occupied in the process, 13 weeks, where a bud which first appeared free on October 29, did not begin to open until the following January, and its leaves were not fully formed before February 27th.

During the very dry weather experienced in Péradeniya from December to March, there is on the whole much less activity displayed in the formation of leaf-buds and leaves than during the period from April to August, and this is in accordance with the general experience of planters on the Kandy side of Nuwara Eliya. Of course there are differences in the rate of development of leaves, dependent on circumstances other than the weather, since the time at which pruning, manuring, &c., are done affect these and other phenomena; moreover, since the buds are slower in development where winds or a general low temperature prevails than where the air is quiet and warm, it will be evident that elevation affects this as other processes of growth. The trees on which my observations were made suffer much from leaf-disease, and bear little crop, circumstances which must also be taken into account:—

Branch A. (Tree not Pruned.)

Date on which leaf may be considered fully formed.	Date about which leaf began to open.	Date when the leaves separated.	Date on which the leaves were full sized, &c.	Time occupied in opening (approximate).	Whole period of development (approximate).
Aug. 26	Sept. 26	Sept. 6	Oct. 16	7 weeks.	101 weeks.
Sept. 6	Oct. 10	Oct. 20	Nov. 15	4 ,,	12 ,,
Oct. 29	Dec. 10	Feb. 1	Feb. 25	7 ,,	13 ,,
,,	,, 10	Feb. 1	Feb. 24	March 20	8 ,,
March 7	March 30	April 7	April 25	4 ,,	7 ,,
April 26	May 25	May 25	June 15	3½ ,,	8 ,,
May 25	June 15	June 25	July 14	4 ,,	7 ,,
June 26	July 6	July 18	Aug. 1	3½ ,,	5 ,,

On this branch, therefore, eight pairs of leaves were completely formed during the 12 months (August 1, 1880, to August 1, 1881), the period of slowest growth being September to February; that of quickest growth, April to August. The pair of leaves which developed most rapidly was formed in June—July; that which developed most slowly, in January—February:—

Branch B. (Not Pruned).

E.

The fact that the spores of *Hemileia* are conveyed from place to place by wind has been abundantly proved. I select the following as illustrations of experiments equally successful in Badulla, Dimbula, and other districts besides those named.

Clean slips of glass measuring 3 in. by 1 in., and therefore approximating the area of a coffee leaf of small size, were smeared evenly on one side with a thin layer of pure glycerine, and exposed in various positions for various lengths of time, in such a manner that spores borne by the wind to the viscid surface would be retained, and afterwards detected by microscopic examination.

The examples chosen for the following table illustrate more or less the following conclusions: that (1) the spores are borne by wind in all parts of country, (2) the more "rust" present, the larger the number of spores in the air.

To illustrate further, No. 5 may be selected as remarkable. In Péradeniya, on July 8th, 1881, the trees were much diseased and "rust-patches" showing up badly all over, the wind was very high, and blowing from the S.W. in heavy gusts. One of the slips of glass was placed vertically on end in a cleft bamboo and arranged so that the viscid surface faced the nearest coffee at a distance of 18 feet. The length of the bamboo was a little over 5 feet. After 12 hours' exposure the slip was examined, *and* 117 *spores of Hemileia found imbedded in the glycerine*, together with small insects, insects' eggs, spores of various fungi, algæ, and lichens, and pieces of sand, &c., blown in the same manner on to the trap set.

Another proof of the same fact is afforded by my finding numerous spores of *Hemileia* entrapped in the meshes of some canvas exposed amongst the coffee for several months: there were spores in all stages of

germination, as well as fresh and recently-blown specimens :—

District.	Month.	State of the Disease.	Wind.	Distance of glass slip from coffee.	Distance of glass slip from ground.	Method of exposure of the slip.	Length of exposure. hrs.	No. of *H. V.* spores found.

F.

The following may serve to convey some idea of the enormous masses of fallen leaves which are often left to blow about estates :—

(1) On a patch of 100 coffee trees, in the neighbouring of the Ramboda district, swept clean on January 1st, 1881, the quantity of leaves which fell from the trees during January and February was as follows :—They weighed 18 lb. (very dry). Since 2,092 went to the pound, the experimenter estimated nearly 38,000 leaves in all. On the same patch, from March 1st to April 31st, the weight was 19 lb., 1,290 leaves to the pound. The March and April showers cause flushes of new leaves which are larger and heavier ; at the same time fewer leaves fall in those months.

(2) In Madulsima, on a swept patch of 100 trees as above, there fell from 20th December, 1880, to 20th January, 1881, 22 bushels of air-dried leaves fairly heaped.

(3) In Pundalu-oya the following observations were carefully carried out. All the leaves and prunings, which had fallen during the past ten or twelve months, on an oblong field of 6 acres, were collected and heaped, and the cubic contents measured. It was estimated that more than 1,200 cubic feet of leaves and prunings had been collected.

On a swept, square area, measuring about one-tenth of an acre (160 trees) and enclosed with cadjans, the leaves were allowed to fall for two months (February and March), and 20 bushels of leaves were collected ; during April and May there fell 11 bushels on the same area.

G.

I have obtained, among others, the following estimates as the cost of sweeping up fallen leaves, &c., in answer to inquiries, and as the result of experiments actually tried. Each of the following paragraphs is quoted from the letter of an independent observer :—

1. *Kotmalé.*—"I have done 80 acres, which gives me a fair idea of what the cost should be, as in some cases the branches, &c., had to be carried as much as 200 yards. ..... Thoroughly sweeping the ground and carrying branches and leaves to ravines or other suitable places for burning has, I find, cost me 10 coolies per acre, which would be equal to R3·50 per acre."

2. *Uda Pussellāwa.*—"The cost [of sweeping up leaves and burying them] is rather heavier than I anticipated, as each man on an average did but 100 to 200 trees a day, the field being widely planted ; this would take 7 men to the acre = R2·50 per acre. But I only employed lads to do it, rated at 25 or 29 cents each. They certainly can do the sweeping more nimbly than men, but for the holing, lining and filling up, bigger men would have done quicker work ; and in this case I am certain R2 per acre would be ample. Then, again, if this field had not been in contract, I would have made the sweeping work act for a weeding, and so saved R1·50 per acre for this month."

3. *Madulsima.*—"The cost of removing the leaves prunings, &c., was as nearly as I can make out, R6 per acre. You will have noticed that they were removed only to a short distance—on to the grass fields adjacent."

4. *Mātalé.*—"My official estimate for weeding and sweeping combined for 12 months = about R1·25 per acre. I have done it 12 times a year for 8 years..... It cost me more at first by from 50 to 75 cents an acre by contract. I do it now by estate labour..... People who do not manure so much as we do might weed and sweep more cheaply."

H

The following illustrations give some idea of the proportion between the numbers of successful and unsuccessful flowers in the clusters up to May this year.* They were obtained by counting the flowers and young berries in the various clusters, and are all taken from "spikes" which appeared capable of producing much more than they actually bore : I estimate about 200 flowers to each "spike" during the season.

The tables are not intended to prove *by how much* a tree is benefited by manure, but to illustrate (1) that a very large percentage of flowers become fertilized but do not ripen as crop, and (2) that more fertilized flowers on the whole arrive at the stage of green crop when the tree has been manured. It must be remembered further that the 5th column does not refer to *ripe crop:* the trees had to pass through a second attack of leaf-disease ere that stage, and it need only be said that a much larger proportion ripens on manured than on neglected trees, other things being equal. This proportion I have computed.

In reading the results, the example No. 4, Table II., may be instanced :—A flowering shoot on a fine tree possessed nine double clusters of flowers ; of the 200 or so of flowers which are typically produced, we find that 131 were apparently fertilized, and commenced to swell as berries. Of these, however, 39 never came to anything beyond the size of a large pinhead ; the remaining 92, however, had swollen and (in April—May) become green crop about the size of a large pea. The question, how many of these 92 will ripen up as mature crop, depends on the condition of the tree as regards leaves, and therefore, on the degree of damage done to it by the forthcoming attacks of *Hemileia.* From comparisons with other trees of the same age and condition, I have estimated that 60 of the cherries may ripen. This is certainly not *below* the number.

Both the tables were compiled in April—May, and represent what occurred largely at that time in 1881:† leaf-disease appeared in June, and became bad in July and August, denuding most shoots of the majority of their leaves. This causes a further reduction by the dropping of the half ripe crop, or by its turning yellow and shrivelling up to "light" brown and black masses. As far as I can ascertain,

* The crop begins to ripen about August ; picking concludes about December.

† The seventh and last columns were compiled in September, after examining many trees.

this will reduce the number given by from 75 to 25 per cent. according to the state of the coffee, &c :—

I.—*Not Manured.*

General type of tree selected.	Number of clusters (double) on spike.	Number of flowers fertilized.	Number of berries which fell early.	Number of berries swollen.	Per cent of successful flowers in May.	Probable number of ripe berries picked (calculated).	Probable per cent of all failures (supposing 200 flowers per spike).
Very thin ...	10	46	38	8	17 ℘ cent.	4	98 ℘ cent.
Very thin ...	8	—	—	2	—	—	99 ,,
Poor & thin	9	—	—	10	—	5	97 ,,
Fair ...	9	89	42	47	53 ℘ cent.	24	88 ,,
Rather thin	10	92	50	42	45 ,,	20	90 ,,
Thin ...	9	82	71	11	13 ,,	8	96 ,,
Very poor...	10	46	43	3	7 ,,	2	99 ,,

N.B.—The numbers in the 7th column are least reliable, having been calculated before all crop is ripe; nevertheless, they are not too low for these and many other unmanured trees of 15 to 20 years in ordinary soil. At the same time, it will be noted that even four cherries per shoot would mean 1,000 per tree, if regular on trees with 250 shoots. This over the whole acreage would mean 10 cwt. per acre, if the regularity were kept up. What must be the irregularity where 2 cwt. or so result! As already pointed out, however, these tables are only for illustration; no exact calculations can be based on the numbers without many more data.

II.—*Manured Coffee.*

General type of tree.	No. of clusters (double) on spike.	No. of flowers fertilized.	No. of berries which fell early.	No. of berries swollen.	Per cent of successful flowers in May.	Probable No. of ripe berries picked (calculated).	Probable per cent of all failures (supposing 200 flowers per spike).
Very large & fine: no crop last year	13	264	162	102	39 ℘ cent.	70	74 ℘ cent.*

Luxuriant ...	14	184	119	65	35 ,,	50	75 ,,
Fine tree ...	10	118	82	36	30 ,,	20	90 ,,

A few further illustrations of the damage done are afforded by following figures. A gentleman in the Kandy district counted the flowers which had set on two branches, and found as follows on March 29th, 1881 :—

Branch.	No. of double clusters.	No. of flowers fertilized.	Approximate percentage if 200 flowers per spike.
A ...	11 ...	108 ...	54
B ...	11 ...	106 ...	53

On counting the same clusters on June 14 following, the following were the numbers :—A had dropped all but 38, and B all but 52 of the berries, which promised to mature. This was, of course, before the July attack of leaf-disease, and a large reduction always occurs then from leafless branches being unable to mature the nearly ripe cherries.

On September 13th, the branches were again examined, and the following report made :—One of the branches has lost all its leaves, and is blackening at the tip. In a week or so more, I expect to see the 'dying back' reach the crop, which in its turn will also die and drop off. The other branch is not so bad as the one mentioned, though it is fast following suit."

I quote the following from a letter which I received from one of the oldest and most experienced men in Ceylon, in answer to my enquiries :—

"I used to consider 10 to 12 berries from one eye good—say 20 to 24 in the double cluster, but I have seen a great many more. 12 berries—or 6 berries on each side of the branch—would now be very good. It is thus we lose our crop now: a pretty regular blossom comes out, and every one says: 'Now we shall get a crop;' but instead of having 6 to 12 berries in an eye* we have one, two and three..... I used to calculate that one measure of ripe cherries from a tree would give fully 5 cwt. per acre, after allowing 'for ordinary vacancies.'"

I.

EXPERIMENTS have been made to answer several questions put forth from time to time by planters and other gentlemen on the following points :—

1. *Can the germinal tubes enter the leaf from above?*

No attempts to infect a leaf from above have succeeded, and I never find the mycelium originating from tubes of the upper surface; that this is because the dense epidermis of the upper surface protects the leaf, as is proved by the following experiments. Spores sown on a patch of the upper surface whence the epidermis was carefully removed with a sharp razor not only germinated, but commenced to enter the leaf at once. Again, spores sown on the viseid surface of the stigma of the flower readily germinate, and the tubes commence to enter the tissues which are unprotected by epidermis. These tubes soon die, however, and never arrive far down the style.

2. *How do the spores reach the under surface of the leaf?*

If a coffee tree be watched when blown by a steady high wind, a large portion of the leaves are seen to be turned half round on the axis of the leaf stalk, and in a such a manner that the lower side of the leaf is beaten obliquely by the wind; if such a leaf be compared with the glass slip in my experiments of July 8th and 9th, it will be evident that many spores may strike it, some of which will stick to the epidermis, which is probably never quite dry. If one watches a tree in still, rainy weather, when the fine rain falls straight down on to the quiet leaves, the rain-water is seen to be shed from the glossy upper surface of the leaf in small streams; still more careful examination demonstrates that some of the water flows to the tip of the leaf down the inclined mid-rib, while the rest flows to the edges along the depressed channels formed by the sinuous curving of the lateral parts. These small streamlets carry spores (which had been blown on to the upper surface) to the edges of the leaf; on arriving there, many of them stick just under the edge by capillary attraction while the water drips away. This may be proved by supporting perfectly clean slips of glass in fine rainy weather in the position of a coffee leaf, and shaking a few spores on its upper surface. It also explains why so many of the disease spots appear first at the tips and edges of the leaves.

Various combinations of these circumstances of

* Since 264 flowers were here actually fertilized, the percentage must be based on that number instead of 200 as with others. Here again, if the trees were regular, these numbers would represent *enormous* crops. But they are not; hence the impossibility of estimating crops as is said to have been done formerly. However, the numbers fairly illustrate how the decrease occurs, as also that more cherries per cent ripen on manured coffee than on trees which have not been manured.

* *I.e.* in the single cluster on *one side* of the twig; 2 eyes the "double cluster" referred to before.

wind and rain account largely for the distribution of spores on the lower surface of the leaf; but there are other ways in which the spores obtain a proper area for mischief. In Wardian cases, where the plant is kept damp, and the lower surfaces of the leaves become wet, I find the spores formed on a given spot simply wander by physical means on the film of water spread over the same leaf, and germinate on another part of the same surface. So, too, one may often observe that a vigorous "rust spot" has distributed many of its spores immediately around itself, as well as on other leaves and plants rubbing against it.

3. *Does Hemileia occur in the seed, or stem, or root, &c.?*

No. I find no trace of the mycelium in any other part of the plant than the leaf, and the comparison of seeds and plants of West Indian as well as Javan and Indian coffees has convinced me that no traces of *Hemileia* mycelium do occur elsewhere. The yellow streaks and marks on what is called "diseased" or "bad" wood are evidences of poor nutrition, but there is no mycelium in the tissues.

4. *Is a tree already diseased, more or less liable to infection than a healthy tree; and are selected trees able to resist the disease?*

I find that the germinal tubes enter the green parts of a leaf already spotted with disease as they do any other leaf; such leaves are neither more nor less liable to infection. Not only do I find no support to the view that certain trees resist disease; but, after trying infection experiments with all kinds of coffee, it seems that Ceylon varieties are no more liable to disease in this sense than Indian or Javan and Jamaican.

5 *Why do the lower leaves on the branch usually become worse diseased at first?*

The lower leaves are the older, and have been longer exposed to serve as a resting-place for any chance spores, blown through the air, or shaken from a higher part. In many cases, also, and especially in nurseries, &c., they are nearer the ground, more shaded, and hence moist for longer periods than upper ones. The fact of their being older in many cases explains also why they fall before the others; having already done much work, they cannot long support the fungus mycelium, if the latter is in any large quantity.

FORESTRY.

(*Gardeners' Chronicle*, 24th September 1881.)

My residence at Weybridge abuts on the beautiful property of Admiral Egerton, St. George's Hill. Through his kindness I have been in possession of about 2 acres of woodland for the last twelve years. This bit of forest was formerly one mass of Spanish Chestnut stumps, grown for coopers' hoops, and interspersed with Scotch Fir, Birch, Beech, and Oak. The soil was sand or gravel, with about 6 inches of peaty mould on the surface, and the interspaces were covered with Heath, Calluna vulgaris, and Erica Tetralix. I cleared the soil of nearly all the stumps, planting specimen Conifers, and leaving some of the trees, all small, sowing Heather seed in the vacancies made by the extraction of the roots. Wishing to allow the eye to range over my shrubbery into the adjoining forest, and not wishing to cut down the trees I had left, I met the difficulty by cutting off all the branches 15 feet from the ground, a proceeding which raised the most terrible opposition in my family circle. I was accused of destroying the trees, of turning them into mops or broomsticks. Such, I must confess, appeared to be the result of my foresting for several years, but results have followed, in the course of time, to which I wish to draw attention.

Firstly, the mutilation of the trees was carried out in the spring, on my return from winter exile. In every instance the wounds made healed readily during the summer period of active growth. Now the trees operated on—Firs, Chestnuts, Birch, Sycamore—have columnar shafts, like marble pillars, with scarcely any perceptible scar left. This I have not found to be the case with trees operated on in the autumn, when growth is all but suspended. But the fact which has principally struck me is, that these trees, thus deprived of their lower branches for 15 feet from the ground, have all shot up perpendicularly. No large branches have formed, only a mass of small branches, and the trees have all grown rapidly in height. It would seem as if all the branches that are destined to make timber branches come naturally from the lower part of the tree, and that once they are removed only small branches appear, the vitality of the tree centres in its trunk, and the tree grows upwards. Thus there are many Scotch Firs, exposed nearly all round to the air and sun, that have gone up perpendicularly like an arrow, just as they do when planted closely together in a forest. The artificial removal of the lower branches for 15 feet appears to have produced the same effect as the absence of light and air produces in crowded forests—to have run them up perpendicularly; above the amputated region small branches have grown, and are gradually forming handsome trees. The Scotch Firs are becoming fine, tall, elegant trees 50 or 60 feet high. The Birches and Beeches are assuming the same form, a vertical one. The Spanish Chestnuts are ascending, and appear likely to become handsome trees, although still rather too globular. The Oaks alone seem rebellious; true to their nature, they will spread.

The practical fact that the elimination of the lower branches entirely modifies the growth of Conifers and other trees, running them up vertically even when fully exposed to sun and light, is probably well known to foresters; but it is new to me, and probably will be new to many of my readers. It is a valuable fact in landscape gardening, as it renders it possible to preserve many trees, destined to become handsome majestic denizens of the shrubbery or park, which otherwise would have to be sacrificed for the sake of the view.

I may add that I have been clipping for some years Cedars, Deodars, and Wellingtonias peripherically, in open situations, where they are fully exposed to light, for want of space, with the same result. They have not made any large inferior branches, but have run up, forming handsome pyramidal columns.

As the light and sun penetrated everywhere in my shrubbery, the Heather has clothed the ground; I have had it clipped with the shears every autumn for the last five years, and now it entirely covers the soil with a swarth of Heather. Recently, when in flower, the ground was one sheet of bloom, and the effect was very good—the Heather with the tall trees rising out of it. —Henry Bennet, M.D., The Ferns, Weybridge.

NOTES ON NEW ZEALAND TREES.

(*Field*, 8th October 1881.)

There are several trees which are not mentioned; but probably they do not grow in the Auckland district. About the chief of these is the koi-koi, which I think is one of the most beautiful of the native trees; it grows to a large size; the trunks are often 6ft. in diameter; it usually grows to the height of about 50ft. Its leaves are of a beautiful dark shining green, and are something similar in shape to a walnut leaf, but somewhat larger; it bears large clusters of berries, somewhat like bunches of grapes, but they are not so thick, and are about as large as the seed of a horse chesnut; when ripe they turn yellow, and have the appearance of small lemons. The seed is inside a sort of pod, very similar to that of the sweetbriar, and of a bright red colour. The pod, as I have already men-

tional, is of a bright yellow; they are, however, as bitter as gall, and quite unfit for eating; should a stranger taste one, it is a long time before he can get rid of the flavour. The wood is of a deep red colour, somewhat like cedar; it splits very readily, and is chiefly used for fencing; it does not grow south of Cape Egmont. Another tree of equal importance is the matai, a tree very similar to the white pine, or kahitea. The wood, however, is more valuable; it is, like the koi-koi, of a deep red, and lasts a great number of years. It is chiefly used in the construction of bridges for beams; but it is seldom used for anything else, except posts, as it is much too brittle. The tawa (generally pronounced like tower) is common, I believe, through all the North and a great portion of the South Island. There are two varieties of it—the white and the black; it is only used as firewood, as it very soon decays, although it attains a large size. It has a leaf about 2in. in length, of a light-green colour, somewhat like an almond in shape; it bears a purple berry, something like a plum, but more oval, with each end pointed like a lady's shuttle; inside is a sort of kernel, inclosed in a shell like the koraka. The berry is often eaten, particularly by the juvenile portion of the community; it is very sweet, though sickly in taste.

The puketea, a large tree which grows in swampy places, is also very common. The foliage is of a light-green, and the leaf almost circular, and the edges are gagged like the teeth of a saw; it is a curious sort of tree, which sends out large flanks or buttresses, and the roots run along the surface of the ground for a considerable distance, and, unless the traveller is exceedingly careful, he is apt to receive an ugly fall, and perhaps bark his shins, through tripping over them. The wood is of a dark green or brown colour, but is not much used; it rather inclined to be spongy, and sucks in any moisture very readily, which causes it to rot; it is very often hollow, and affords a refuge for wild bees, which frequent the woods in large numbers, and often as much as 1cwt. of honey is got from a single tree, though I have heard of quite double that quantity being got at times; they also inhabit the rata. I have heard it said that there was a tree growing in Devonshire that for years baffled the botanists; but it was at last recognised, by a gentleman who had visited New Zealand, as the puketea. The miro is another tree that is common in some parts of the forest; it is also a species of pine, much resembling the matai, but the foliage is of a very dark green. It bears a bright scarlet berry, not unlike a cherry; it is greedily devoured by the wild pigeons, but is not fit for human consumption; the wood is of a right red colour, and is very stringy, but is not used much except for firewood. The honeysuckle is also very common, and is one of the finest of the New Zealand forest trees. It often reaches the height of 100ft.; it grows somewhat like a poplar, but the leaves bear no resemblance to the former. The bark is about half an inch in thickness, but is not used for any purpose, as it decays very rapidly. The wood is much used by cabinet makers; it is very handsome, with dark-red spots, so different to any other sort of wood I have ever seen; the leaves are about six inches in length by about one in width; it is of a dark rusty green. It bears a flower like the French honeysuckle, but smaller, I believe, it derives its name, (I have been unable to obtain the native name), but it is entirely useless. It bears seed inclosed in pods, like a small bean—when the seeds are ripe they split open, and the seed fall to the ground. The ngaio (nio) is another which is also common, but I believe it is almost universally to be a very handsome tree, with large light-green leaves, with small light-coloured spots. On the upper side the veins run very evenly, and one would almost suppose that it had undergone the operation of being pressed; it bears a small berry of a pale purple colour, with a stone inside, it is a little larger than a pea. One of the most remarkable is a kowini, or wild fuchsia; it is perhaps one of the most common: it has a much darker green than any other I have seen. The under side of the leaf is a silvery white, the flower is much smaller and less beautiful than those grown in gardens: it bears a luscious fruit, which grows in large quantities; the berries are just about the colour of a blackheart cherry, and it leaves your lips and hands stained with the dye; soap and water, however, will quickly remove all traces. It rarely exceeds 30 ft. in height; the trunk is often 3 ft. in thickness; the bark is similar in colour to all other fuchsias, and the light-red trunks catch the eye of the traveller at once.

There are a few more trees worthy of mention, such as the whitewood (or mahoe), a tree about the size of the fuchsia, with light-green leaves and clusters of purple berries. Why it was called whitewood I can never understand; it is decidedly bright yellow. There is also a birch, or, as the natives call it, "waiwoki"; it only grows in swampy ground, and, I should say, belongs to the myrtle family; it bears bright scarlet berries very much like the holly. They are much sought for by the juveniles; the wood is white, and is chiefly used for fencing. The titoki, or tapitap, is frequently to be met with; its leaf somewhat resembles that of the elder, but is of a darker green; it seldom grows more than 3 ft. in diameter; it bears a curious red berry, the stone being on the outside; the wood is light-coloured and intensely tough and stringy, and is much used for shafts for carts and handles, for all sorts of implements. The mairi is rather a rare tree; the wood lasts for very many years; it is mostly used for house blocks, and not unfrequently for burning; it is intensely hard, and the wood is of a light-red colour; its leaves are much like those of the willow in shape, but of a much darker green, its branches spread out on all sides like an ash tree, which give it a very stately look. The last of the list is a cypress, which grows only on the sides of the mountain ranges in great quantities, and is, of course, just as sombre-looking as most trees of the cypress family are. I believe that as yet it has not been used for any particular purpose. It splits very readily, and, should, therefore, be easily worked. Strange to say, the foliage seems only to grow on one side of the tree. Most of the New Zealand trees are medicinal. The sap of the rata creeper will effectually stop the flow of blood from a wound. A small piece of puketea bark will cure toothache; while the leaf of a shrub called korimiko will prove a good antidote for slackness of the bowels. Only two of the shrubs are known to be poisonous, and those are the tulu already mentioned, and the waranga or kangiora, of which there are two species. The shrub only reaches the height of from 12 ft. to 14 ft.; it has large, heart-shaped leaves, the under-side being quite white, and in the summer it bears large bunches of small bell-shaped flowers, of a light buff colour, which have a peculiar, though not unpleasant, smell. The leaf is exceedingly poisonous to either cattle or horses—it has an intoxicating effect on the latter.

I think I have mentioned all the New Zealand trees, with the exception of a few varieties of birch, and a tree they call lacewood; they can scarcely be called trees. The lacewood is so called on account of the stringiness of the bark, which comes off in small strips, and is remarkably strong; the tree bears clusters of snow-white blossoms, not unlike the orange, but they have no perfume like the former. The best timber next to the kauri is called kiaki, or red pine; it grows very plentifully in the province of Taranaki, and in the neighbourhood of Pelorus Sound in the northern part of the South Island; it grows to a very large size, and what grows on the latter forest is not so good as the former, by reason of its rapid growth, and this is accounted for owing to the deep nature of what it grows, where, sheltered from all the prevailing winds, and to lack of exposure, it springs up very quickly, and consequently there is not much substance in the wood. Millions of feet of this valuable timber are being wasted annually

in the first-named place, owing to the difficulty of shipping it. The kia-kia, or tawhera, which has already been alluded to in your first report, there are two varieties of. There is little difference between them. One has white fingers, and the other dark brown or black. The former is considered the best, but when the season is over the fingers decay; while on the dark-coloured species they continue to grow thicker and thicker till mid-winter, when they ripen, and the rough horny substance peels off, and a rich sort of pulp remains; it is very sweet, and many prefer it to the other fruit. They are generally called pineapples in this form, though in reality the kia-kia and it are one and the same, only the other comes at a different season.

INDIAN HOME-MADE QUININE.

(*Pharmaceutical Journal*, 10th September 1881.)

The Indian Government has lately published a further series of papers containing information respecting the preparation obtained from the bark of cinchona trees grown in India. This preparation, known by the name of "Cinchona febrifuge," consists of a mixture of the alkaloids of cinchona bark together with some colouring matter and other impurities. The object of introducing it into use was to provide a cheap substitute for the quinine sulphate manufactured in Europe, and it was considered that if a process of preparation were adopted by which the alkaloids associated with quinine in cinchona bark were extracted together with the quinine, instead of being separated from this alkaloid as in the ordinary manufacture, the object in view would be promoted, inasmuch as the alkaloids associated with quinine would be made available as medicinal agents with advantage, and the cost of transporting raw material and manufactured product to and from Europe might be saved.

In the case of the produce of Indian-grown *Cinchona succirubra*, the plan above mentioned seemed especially desirable, because that bark contained but a small amount of quinine, and it was associated with such a large proportion of other alkaloids as to be unsuitable for the purposes of the European quinine manufacturers, while the available quantity of this red bark was in excess of the demand for other purposes.

For these several reasons the Government of India has directed special attention to the utilization of the succirubra bark by the production of the article known as "Cinchona febrifuge." At the hospitals throughout India and the various military stations, this preparation has been used in the treatment of fever under conditions that provided for obtaining knowledge of its effects and for ascertaining how far it could be accepted as a trustworthy substitute for quinine.

In the first series of reports upon this subject, issued in 1878, the views expressed were very conflicting, and the influence of prejudice for and against the use of the "febrifuge" was often to be recognized not only in the unfavourable reports, but also in those which favoured its use. One point, however, that was opposed to the introduction of the "febrifuge" seemed to be very generally established, namely the nauseous character of the preparation, manifested by its rejection by the stomach in numerous instances. In some cases this effect was referrible to faulty administration, in others it may have been due to idiosyncrasy of the patients, but the more likely explanation was the presence of the amorphous alkaloids commonly associated with quinine, and perhaps some other impurities of like origin.

Since that time improvements have been effected in the preparation of "Cinchona febrifuge" as it is carried out in India, and a superior preparation of the same kind, manufactured in England, has been introduced under the name of "Quinetum." It is therefore intelligible that in the series of reports now published, the general tendency of the opinions expressed is somewhat more favourable.

The efficacy of the febrifuge as a remedy appears to be very generally admitted by those who have tried it, and it can readily be understood that in the treatment of fever it would be efficacious as a medicine in proportion to the cinchonidine and cinchonine of which it is chiefly composed.

In regard to the other characters of the febrifuge, the papers now published confirm the opinion expressed by Mr. Howard some time ago that it has a decidedly emetic property. It may, however, be assumed that it would be an advantage if the objectionable portion of the mixture could be separated from the useful alkaloids. In any case it is desirable from a medical point of view that this portion of the product obtained from Indian red bark should be thoroughly investigated, for so long as the Sikkim febrifuge retains the objectionable emetic properties it cannot be regarded as fulfilling the benevolent intentions of the Government. In the papers which are published in continuation of the series issued in 1878, there seems to be a general admission that the febrifuge is nauseous, and generally, in some degree, detrimental alike to Europeans and to native Indians.

Dr. T. E. Charles remarks in his report that "the "miseries caused by Indian residence and illness are "depressing enough in themselves, without being intensi-"fied by nauseating agencies quite foreign to the thera-"peutic effect required."

In Mr. Moens' report for 1879, on the Government Cinchona Enterprise in India, there is a table of analyses of different samples of febrifuge, from which it appears that the proportion of the obnoxious amorphous alkaloids does not amount to ten per cent, and that therefore little material would be lost by the removal of them.

The applicability of the febrifuge as a substitute for quinine appears therefore to be in a great degree dependent upon the possibility of effecting this separation. There is also the further question whether this can be carried out at a sufficiently moderate cost.

The relative cheapness of "Cinchona febrifuge" being one of the chief advantages attending its use, it is important to consider such facts as we are in possession of for elucidating this point.

In the first place, it appears that for the purpose of carrying out the manufacture of the "Cinchona febrifuge," a quantity of dry succirubra bark, amounting to 190,798 pounds, was made over to the Government Quinologist, and that the product obtained from that quantity of bark amounted to 3,750 pounds. This is less than two per cent of the material operated upon, and so much less than what might be expected from the data available for judging as to the amount of alkaloids in the Indian-grown red bark, that we must conclude the extraction of the bark was very imperfect.

In Mr. Moens' report for the year 1879, this defective character of the manufacturing process is still more forcibly pointed out by the statement, that in the analytical laboratory of the medical department the yield of alkaloid obtained in that way was less than one-half what the bark contained.

The bark used in making the febrifuge was valued at sixpence per pound, and upon that basis the product obtained was estimated to cost rather more than thirty-three shillings per pound. For the sake of comparison it may be useful to refer here to the cost of the pure sulphates of cinchonidine and of cinchonine supplied to the Indian Government, and for this purpose we take the data furnished by Dr. Smith, Surgeon-General to the Acting Chief Secretary to the Government of Madras, showing that cinchonidine sulphate cost about thirty-four shillings per pound, and cinchonine sulphate about ten shillings per pound.

Another point to be taken into account in judging of the relative cost of the preparations used in the treatment of fever is the quantity of material required in each case. The data given by Surgeon-General Cornish

to the Madras Government show that the average quantity of drug given in each case was for—

Cinchonine sulphate	.. ..	78·960 grains.
Cinchonidine	,, ...	68·863 ,,
Quinetum (Sikkim febrifuge)	..	107·135 ,,

According to these figures a pound of cinchonine sulphate would cure eighty-five cases at a cost of ten shillings, whilst a pound of the febrifuge would cure only sixty-five cases at a cost of thirty-two shillings, and a pound of cinchonidine sulphate would cure a hundred and one cases at a cost of less than thirty-four shillings.

As regards relative cost, even at the time above referred to, it appears, therefore, that the advantage was not in favour of the Indian-made febrifuge. Beyond that it must also be remembered that owing to the increased supplies of cinchona bark from every quarter the price of quinine is diminishing, while that of the febrifuge remains much the same and will present a still more unfavourable relation to the cost of other alkaloids.

We have nothing to indicate that there is any probability of the cost of the Indian-made febrifuge being reduced, for though the full amount of alkaloid is not obtained by the process adopted, it is perhaps the best that could be employed on the spot, and its wastefulness is an inevitable characteristic.

Mr. Howard's opinion is unfavourable to the use of mixed alkaloids, and he is unable to perceive any advantage that has arisen from their administration in that way. On the contrary he thinks the alternate use of the different alkaloids separately is attended with better results, since he has observed that when the constitution has become intolerant of quinine from long use, the change to sulphate of cinchonidine has been decidedly advantageous.

PROFITS OF GRAPE CULTURE IN CALIFORNIA.

The grape interest is expanding in every direction. It is not only in one section of the state that viticulture is receiving such marked attention, but everywhere, both north and south. Thousands of acres are set out with grape cuttings, and in three years' time returns can be had. Even at the present time, offers have been made in Fresno county to harvest the next grape crop, taking all the chances of possible failure or material deterioration into consideration, for the net guaranteed sum of $150 per acre, the entire expense to be assumed by the contractor, without takers in a single instance. The net profits of careful cultivation have been, in some instances, over $300 per acre. The wine, brandy, and raisin interest, centre on this one branch of industry, which is at present in its infancy, and has just emerged from that heavy cloud that has been weighing it down for years.—*Rio News.*

BANANA CULTIVATION IN COLOMBIA.

With reference to the profits of some branches of tropical agriculture Consul W. W. Randall—formerly vice-consul general at this port—writes as follows from Barranquilla, Colombia:

"The banana is planted at a cost of 15c. each, including the cost of and labor in clearing the land. It develops in eight months, and yields a bunch of bananas worth in your markets from $1 to $2. They can be sold here at the ship's side for 25c. per bunch. After the first crop the cost per year is trifling and the returns sure. Fortunes have been and still can be gathered on this simple product. Another important plant which yields an immense profit and appears to be but little known is the cocoa or chocolate plant. This plant attains maturity in this country in three years; the crop on the fourth year returns the original investment. After this each plant can be counted on to yield the owner at least $1·50 profit per annum. Being planted closely, the result per acre is about $500 profit. With a hundred acres carefully cultivated a man can have his income of $50,000 without fear of frosts, freshets, drouth, or any of the uncertainties attending a northern climate."—*Rio News.*

GUATEMALA INDIGO.

The catalogue of objects exhibited by the republic of San Salvador at the Paris exhibition contained the following contribution to the history of the cultivation and preparation of indigo in that country: This species of indigo is known to American and European commerce as "Guatemala indigo." In Salvador it is called by the native name of "liquilite," and is considered the most important agricultural crop of the entire republic. The plant grows wild, but is cultivated in properly prepared ground. Both the crops and the produce vary according to the geological composition of the soil. Thus at the base of the volcano of San Salvador the yield of dye is sometimes about half a pound per load of leaves, while at some distance from the sea, thirteen or fourteen ounces are obtained. Indigo is grown over nearly the whole of Salvador, forming extensive fields and furnishing one of the most valuable products to its agricultural industry. The localities in which the plants are grown are called "manchones."

The workmen, who are styled "sacateros," cut the plants with a small sickle, and make them up into sheaves of from fifty to sixty pounds weight. The plants, after being cut, are thrown into vats filled with water; they are here allowed to soak for a period of from twelve to seventeen hours, the time varying according to the temperature and quality of the water. When the liquid is in a state of fermentation the coloring matter is drawn off into another vat, where it is beaten or kept in motion by means of wooden wheels, and then the dye is precipitated by the sap contained in the bark of the "tihui late" of the "platanillo," or of the "cuaja tinto." The first named bark is referred to as a species of *Ionidium*, the second to *Canna indica*, while of the third no clew is given as to the scientific name of the plant. All these plants have an acid reaction. When once the dye is precipitated it is allowed to remain during the night, and the next day it is boiled, filtered, pressed, and dried in the sun. Each bale, or "surou," contains 150 pounds, and the different qualities or grades of the indigo are specified by numbers—from four to six, ordinary quality, or "cortes," from seven to nine, fine or superior, or "sobresalientes."

The usual annual produce of indigo in Salvador amounts to about 2,400,000 pounds, the annual exports being between 14,000 to 15,000 "surous," of 150 pounds each, representing an approximate value of 1,721,378 piastres or dollars. The superior quality indigo is sold at the country fairs at about 8 reals per pound. In the American and European markets the prices vary of course, according to the supply from other countries.—*Scientific American.*

HORTICULTURE IN ALGERIA.

(*Journal of the Society of Arts*, 7th October 1881.)

Mons. V. Ch. Joly has communicated a paper on this subject to the Société d' Horticulture of Paris, of which the following is an abstract:—

The more we advance towards the north, the more we find the taste for horticulture developed, just in the same proportion as were nature does least, necessity will always render man active and industrious. Before speaking of the production of fruits, flowers, and trees, I ought to mention the great question which preoccupies Algeria, namely the water question; without water, no vegetables, no animals, no colonisation is

possible. As there is no stream with a regular course, water is a question of life and death; mere watering is of no use, it must be constant and through irrigation. Rain falls only during four months consequently it is dry for the rest of the year, and this dryness prevents the cultivation of quinine, coffee, indigo and tea.

The destruction of the forests has done here, as elsewhere, incalculable mischief, and the planting of trees is an urgent necessity. The *Eucalyptus* would render great service. In poor soil the family of the acacias offers species which, besides furnishing firewood, would give an industrial product of great value; by judicious planting in from ten to fifteen years, the climate, now very variable, would be rendered more equable, the springs would be increased, immense pasturages would be restored, and the native population now necessarily nomadic would become settled, and the European element would be more constant. The ruins so frequently met with show that the country was at one time populous, but the destruction of forests led to the destruction of animal and vegetable life. The principal trees met with in the public gardens are the date, Bourbon palm, the *Sabal*, the *Chamarops*, the *Caryota*, the *Areca sapida*, the bamboo, the banana, the *Dracœna draco*, the yucca, the aloc, the *Agave*, besides the *Eucalyptus*, and the plane tree. These last two play a great part in the plantations of new villages, where the engineers form broad boulevards, as they there form an enclosure which rapidly protects the inhabitants against a torrid sun. The *Eucalyptus* especially is the tree of health for low and damp grounds, on account of its great power of evaporation, as well as for its resinous juices; it grows from six to ten feet in height in one year. The temperature and moisture should always be considered as from non-attention to these important factors great waste often occurs, thus the fruit trees of the temperate zone perish quickly in Algeria, while the trees of the South of France, the almond, the jujube, pomegranate, fig, and medlar, ripen two months earlier than in France, and are of the first quality.

Until now the principal centre of horticultural production has been Algiers and its suburbs. Everywhere irrigation is applied, the water being raised by rough homely instruments which labourers like, as they can make and mend them themselves. Near Algiers are the gardens of Madame Rossier, about 10 acres of which are devoted to cultivation of flowers for the local market. At Boufarik, Madame Rossier has also about 18 acres of nurseries of fruit and fruit trees. At the same place are the beautiful nurseries of Mons. Herran, whose orangeries are models of cultivation; the trees are planted in lines at a distance of from 16 to 20 feet apart. Irrigation takes place twice a month after the roots of the trees have been bared. Broad trenches are cut, and at a suitable time they are smoked and then recovered after the irrigation. The cuttings are arranged so as to allow a broad space for the air and the sun. Besides these orangeries, there are about 35 acres of vineyards, which produced in 1881, wine to the value of £1,000. Not far off, at Blidah, are the superb orangeries of Mons. François, jun., who sent this year to France four million oranges. There are at Blidah nearly 1,000 acres planted as orangeries, and producing about £30 the acre, while the expense of cultivation is only a seventh of that amount.

Little has been done to assist nature in the cultivation of flowers in Algeria by man. Although the winters are mild, hothouses are necessary for propagating and for protecting certain plants from the heavy winter rains, or from the summer dust. At Algeria, in the flower market, there were to be seen some cut flowers, but few or none in pots. The flowers to be seen in April were our common ones, roses, geraniums, violets, heliotropes, lilies, heartsease, and pinks. If flowers are little cultivated in Algeria for private houses, they form a considerable industry for perfumery. Thirty years ago, Mons. Simonnet, at Algiers, and Mons. Mercurin, at Chéregas, introduced into the country the planting and distillation of odoriferous plants, since which time this industry has prospered so much, that the geranium alone covers more than 1,300 acres, and furnishes more than 6,000 kilogrammes of essence. The olive, suitably grafted and cultivated, will constitute an immense fortune for the country if it is worked according to its nature: it is thought that the region suitable for it could easily furnish 700 to 800 millions of square feet, producing annually more than 300 millions of francs.

In conclusion, a few words may be mentioned about the most precious plant for Algeria, the vine, which alone is destined to renew the face of the colony. It is planted everywhere from Kabylie (which produces an abundance of table grapes) to Morocco. And this is easily explained when we remember that at the end of five years the cost of the ground, the planting and expenses of cultivation is repaid, in addition to a revenue of £20 to £30 the acre. The vines are planted in lines from 5 to 6½ feet apart, to facilitate labour, and a road for carts is left around the plantations. Fortunately, no phylloxera has yet appeared, but the curse of the vine in Algeria is the blue fly, which has to be knocked off the vines, and burnt with lime or petroleum. The expense of carriage is the great drawback to the prosperity of Algeria, and if this were lessened, it might become one of the richest colonies in the world.

THE COFFEE AND SUGAR PRODUCING COUNTRIES.

CENTRAL AMERICA.

(*American Grocer*, July 9th 1881.)

Nowhere has such an impulse been given to coffee planting since the great rise in October, 1871, as has been the case in Central America, especially in Costa Rica and Guatemala.

Costa Rica has for its president General Thomas Guardia, a mum of great energy and a good statesman, who rules the country as a sort of dictator. Guatemala is similarly governed by Lieutenant General Rusino Barrois, whose presidental office was last year prolonged for another six years. Honduras' president is Mr. A. Soto; Mr. Joacquin Zavala is the chief magistrate of Nicaragua, while that of San Salvador is Mr. B. Zaldivar y Lazo. Although there are at times bickerings between the five republics, peace is upheld between them, and internally there is less revolution than in most other Spanish-American republics.

SIZE AND POPULATION.

	square miles.	*population.*
Guatemala	30,836	1,190.754
San Salvador	4,765	482,422
Nicaragua	34,058	300,000
Honduras	30,668	351,700
Costa Rica	13,174	185,000
	113,501	2,509,876

The respective capitals are:—Guatemala, 45,000 inhabitants; San Salvador, 16,000; Managua, 10,000; Tegucigalpa, 12,000, and San José, 12,000.

Central America is volcanic and mountainous, with a most fertile soil, especially on the rich table lands, a deep black loam being highly favourable to coffee cultivation. Geographically their position between the two oceans could hardly be better; the climate is generally healthy, labour is abundant and cheap without the necessity of procuring either negroes or coolies. A large portion of the natives consists of pure Indians and half breeds, quite amenable to field labour. The consequence of this happy state of affairs is that Central America progresses rapidly, both mentally and materially, and that it has a great future, provided i

keeps out of revolution, the usual bane of the countries originally settled by Spaniards.

Costa Rica's finances are flourishing; the income in 1880 was $2,802,279, the expenditure $3,460,597, but this included $1,255,961 paid for building the inter-oceanic railway, $138,892 for other public works, and $173,585 paid Peru in settlement of a debt. This year the income will square the outlay; the foreign debt is $5,463,285, and the state owes some money at home, but its assets are about twice its liabilities. The import last year was $2,669,861. The export through Punta Arenas, $3,524,810, and through Lima, $211,142. The export included 23,267,065 pounds of coffee, the balance being India rubber and skins.

MARITIME MOVEMENT.

	steamers.	*sailing vessels.*	*tonnage.*
Entered at Punta Arenas..	96	63	196,007
Sailed from ,, ..	95	59	188,163
Entered at Lima	41	130	103,867
Sailed from ,, ...	40	123	106,659

Railways so far in operation, only about seventy-five miles, but already of great value to the coffee planters. Telegraphs, 395 miles.

Guatemala's income in 1877 was $4,503,523, and its expenditure $4,428,298. The public debt in 1879 amounted to $5,369,529. The import in 1878 was $3,238,000, and the export $3,919,000; the latter included $3,449,740 worth of coffee, the balance being sugar, skins, cochineal and indigo. The arrivals at San José in 1876 were 26 sailing vessels, while from three to four steamers touch monthly at the Pacific ports.

Honduras is financially less favorably situated than the preceding republics, for it owes in England and France together with some £8,000,000 while the income in 1877-78 was only $533,469, against in expenditure of $1,189,546. The liquor tax is, however, producing larger amounts since 1877. The export amounted in 1880 to $1,305,000, the bulk being indigo, cattle, dyewoods and hides. The Atlantic ports are Truxillo and Omoa, and tho Pacific port is Amapala. There is a railroad of 37 miles from Puerto Cortez to San Pedro. Telegraphs there are 150 miles.

Nicaragua.—The revenue of the country was $1,750,000 in 1877, against $211,405 in 1858, showing a remarkable increase; the expenditure in 1877 was $2,235,000, and the foreign debt amounted in 1878 to $2,234,607.

FOREIGN TRADE MOVEMENT IN 1878.

	import.	*export.*
Greytown.....	$616,000	$595,000
Corinto.....	347,000	575,000
San Juan del Sur	33,000	138,000
Chinandega	9,000	27,000
	$1,005,000	$1,335,000

The bulk of export consisted in India rubber, coffee, skins and fustic. There entered Corinto in 1876, 35 vessels, and steamers touch at the various ports two to three times per month.

San Salvador.—The income of the republic has from $798,000 in 1869 gradually risen to $2,686,000 in 1878, the liquor monopoly yielding $719,000 alone. The public debt increased from $1,830,000 in 1877 to $2,294,000 in 1878.

	import.	*export.*
1878.....	$2,500,000	$3,626,000
1877.....	2,586,000	3,956,000

Indigo and coffee were the two heaviest articles of export, the latter $1,800,000 worth; then came sugar and tobacco. The entries in 1878 were 22 sailing vessels and 82 steamers, with a joint tonnage of 163,232.

Central America at present produces 33,000 tons of coffee, against 10,000 in 1868 and 3,000 tons in 1836. This coffee, Costa Rica in particular, is very popular, both on account of its looks and its flavour. London and S. Francisco in particular have known how to appreciate Costa Rica coffee since they became familiar with it; hence it brings comparatively more there than elsewhere. New York, we are sorry to say, has not yet learned to fully appreciate this excellent coffee, which is absolutely unsurpassed by any other sort. The sorts coming nearest to it in point of outward appearance and delicacy of flavour are Orizaba and Cordova, from the famous Mexican volcanic region. All these coffees have a great future before them. While Java and Arabian coffees grow so well on the slopes of mountains, Costa Rica flourishes most in the incomparable black soil of the mountain plateaux of that country, mid-way between the Pacific and the Atlantic.

Railroad building is proceeding most actively in Central America, cheapening the transportation of the precious bean and infusing life everywhere.

SUGAR: CONCRETE CONVERSION IN NATAL.

For the first time in the history of the colony—for the first time we believe in South Africa, a successful attempt has been made in Natal to convert concrete into a serviceable marketable sugar. Such an event requires more than a passing notice at our hands. The Albergeni Sugar Works—situated as most of our planter readers know on a convenient site near the mouth of the Umgeni, on the north bank of the river—were taken over at the beginning of the year by Mr. Rudolph Wilhelm, for the purpose we have indicated, to convert grey and low sugars as well as concrete into a very fair saleable sugar. The Albergeni Sugar Works were originally used as a crushing mill, but much of the machinery has been retained for the process used in the conversion, while considerable new and expensive plant has been added. The buildings are lofty and roomy, and, as the supply of water is inexhaustible, they are in every way suited for the carrying out of what is emphatically a new industry. We propose to give some description of how this interesting work is now being done at our own doors. It must be premised that the labour of the converter here is more arduous, and calls for more skill than is required of the operator in any of the great centres at home, where the sugar is deprived to a large extent of the molasses. Here, in the concrete, the manager of the Albergeni Sugar Works has to contend against molasses, syrups, and such vegetable matter as may happen to have found its way into the ugly stuff he has to make sugar out of. To proceed—the concrete, being received into the mill from the establishments of the local planters who manufacture it, it is at once put into what is technically called the blow-up. These vessels on an average are at home prepared to liquify about four tons of sugar at each charge. They are fitted with a perforated false bottom placed above twelve inches from the true one, and each charge of concrete is melted to the consistency of 20 to 29 degrees Baume. Steam is then freely admitted by a pipe 2½ inches in diameter between the two bottoms, and the sugar is melted to a heat of about 150 degrees Fah. The concrete, now reduced to a dirty black stream, is run off in about half an hour to what are called the bag filters. The arrangement is a purely mechanical one, and consists in passing the solution into the top of a square cistern, and thence into twille l cotton bags eighteen inches in diameter and six or eight feet long. There are from 70 to 100 of these cloth cases, and they depend from the shallow tank into which we have seen the liquid flow. They are surrounded by the sides of an iron box, so that the juice may be kept hot, and also that steam may be introduced to keep up the temperature and clean out the bags. It should have been stated that each bag is also enclosed in a coarse sheath. The object of running the liquid into these filter bags is to remove all inherent insoluble matter, and the step

is an important onee preparatory to passing the sugars through the charcoal filters. To watch this process we have to perform certain gymnastic feats which require extraordinary care, unless the acrobat wishes a bath in boiling water. The liquor, still of a dark hue, is run to another cistern, whence it is pumped into large cast metal receivers, which in turn feed the charcoal filters. The passage of the sugar through these is the part of the system which has most interest and novelty to the untravelled colonist. The charcoal filters are huge tanks of cylindrical form, and are composed of cast iron plates. They are about seventeen feet decp and over five feet in diameter, and they are furnished with a perforated false bottom placed about three inches above the real one, its removal permitting of thorough cleansing. The true base is of a conical shape, which allows all the liquor passing through the charcoal to be collected at one point in the centre, and so be drawn off to the very dregs. The cistern is permanently closed on the top, although there is at the bottom a man-hole door to permit the charcoal being withdrawn. The filters contain about five tons of the charcoal through which the melted sugar passes in precisely the same way as water is sometimes filtered through sand. The bone charcoal, in order to its coutinuous use, of course requires great nicety and cleanliness of treatment. In the meantime the charcoal is imported, but we expect to see it manufactured on the spot soon. It must be washed thoroughly, otherwise it would get impregnated with oxide of iron, carbonate of lime and other substances which would, of course, have a deleterious effect on the sugar, making it lose both its colour and weight. The material—which, to the superficial observer, has the appearance of fine coal "dross"—is therefore removed from the filter, washed with hot water for some hours, after which it gets a sousing for four hours in cold water. The charcoal on being taken out of the filter is run up by an ingenious hoist to the top of the kiln, where it goes through the process of being reburned and revivified. This kiln is composed of thirty pipes equally divided on each side of the fire, and these pipes are kept constantly at a good heat. The charcoal passes through them, and is received into coolers without coming into contact with the air. These coolers are divided into two parts, and from the under part a charge of charcoal is drawn every twenty minutes, thereby allowing only the same quantity to be put into the pipes at the top. It will be seen, therefore, that the kiln is so regulated that the operator, who is generally not a skilled man, cannot draw off more than a certain quantity of charcoal at a time. Having watched how the charcoal is dealt with and made fit for its valuable purpose, let us return to where we saw the sugar pumped from the cast metal receivers to go through the filters. It is led by pipes from the bottom to a small square box, where the liquid is divided and run into receivers, whence it is drawn to the vacuum pan as the operator requires. To sum up then:—The concrete is melted and passed through the bag-filter to extract extraneous matter—a merely mechanical process. It then passes through the charcoal—a chemical process—to decolorise. The concrete is now liquified, and its turn has come to be made into respectable sugar. It is therefore taken back to the vacuum pan, to have the water which we have seen put into it taken out, and thus to have it crystallised. From the vacuum pan it goes straight to the centrifugals, the syrup being sent back to go through the process we have described, as very little syrup is put out at the Abergeni Sugar Works. We have now seen the huge lumps of dirty concrete, with all its impurities, sent through the mill and returning to bags waiting for it as perfectly clean, wholesome sugar. It only remains to be said that the boiling department is under the competeut charge of Mr. Heims, and that the manager of the mill is Mr. T. H. Wilson, who has had sixteen years' experience of his business on the Clyde. So far the results obtained at the works have been highly satisfactory; and when a new kiln, now on the way out, is erected, the output will probably double itself. We wish Mr. Wilheim every success in his praiseworthy enterprise.—*Natal Mercury.*

CINCHONA:—RED BARKS.

(*Pharmaceutical Journal*, 3rd September, 1881.)

In a paper on "Red Bark," read before the British Pharmaceutical Conference, Mr. John Eliot Howard adopted the distinction made by Professor Karsten between the genera *Cinchona* and *Cinciuchona*, namely that in the former the capsules are dehiscent from the apex and in the latter from the base, and described what was to be understood by the term "red bark." *Cinchona succirubra*, the true species of the red bark, was so named by Pavon to denote the peculiarities of the juice. Like other species, it exists under somewhat different forms (illustrated by specimens that were exhibited) and the differences, though apparently trivial, are important to the cultivator for reasons that have been explained in the 'Nueva Quinologia,' and on account of the relative preponderance of quinine or cinchonine and cinchonidine. Specimens of genuine red bark and of the more resinous sort which used to be imported from South America and sold at a high price, though useless to the quinine manufacturer, were exhibited to illustrate the state of degeneration to which Mr. Howard predicts that the truest red bark in India will arrive by age, and towards which Mr. Broughton believed some advance was made during the continuance of his observations. Since that time Mr. Howard has had the opportunity of examining specimens of much more mature bark carefully collected by Mr. Cross at Ootacamund, and exhibiting the true characteristics of genuine red bark. These samples contained respectively 0·86 and 0·91 per cent. of quinine, with 1·5 to 2·0 per ceut. of cinchonidine, and 3·5 to 4·0 per cent. of cinchonine. In reporting upon these barks to the Marquis of Hartington, Mr. Howard pointed out that they are most characteristic specimens, well illustrating the mistake of the excessive cultivation of *C. succirubra*, and that it is only by renewing that the bark of such trees can be made serviceable. Another sample described as red bark is not from *C. succirubra*, but is the produce of a tree yielding juice that becomes only golden coloured, and identified by Cross as "Pata de Gallinazo." That it is a much better sort for cultivation than the *C. succirubra*, with which it has been confounded, is shown by its containing 2·25 per cent. of quinine. The full information upon both these barks, which was published by Mr. Howard and sent out by the Government in 1862, has apparently beeu without result, as these two species are still confounded under the name *C. succirubra*. There is also a third species confounded under this head, the "cucharia," or "pig skin," a sort of red bark, little valued formerly by reason of its poor appearance; but in regard to contents in alkaloid more valuable than the true red bark, as it contains from 1·37 to 2·14 per cent. of quinine. The propagation of so many millions of trees of what is called *C. succirubra* in India, in spite of the warnings and of the information gathered from the Spanish botanists, strongly impresses Mr. Howard with the question whether the information he is now giving or may be able to render hereafter, will be turned to any account, otherwise than amongst those private cultivators who gladly avail themselves of such assistance, and who will find eventually that they have done well to attend to the careful discrimination of species and forms of species by cultivating only those most adapted to their purpose.

A paper by Mr. Holmes, raising the question which kinds of cinchona bark should be used in pharmacy, pointed out that the kinds of barks now cultivated in Java, India, Ceylon and Jamaica, have been former years a regular article of commerce, but are not recognized in the pharmacopœias, and cannot therefore be used for

pharmaceutical purposes, although the officinal bark of South American origin is often comparatively worthless, and very rarely of good quality. Mr. Holmes suggested that cultivated cinchona bark should replace the barks now officinal, partly because the latter are often mixed with false barks, and the bark of hybrid species is not unfrequently mixed with that of good quality, as it is not to be distinguished by external characters except by experts. Mr. Holmes pointed out that one variety of cinchona bark, that of *C. succirubra*, is easily obtainable in almost unlimited quantity, and of very good quality, owing to the circumstances that the tree grows at a lower elevation, is very hardy, easily propagated, and cultivated over a much greater area than other kinds. Owing to the relatively small proportion of quinine that it contains, as compared with the other alkaloids, it is not adapted for the requirements of quinine makers. For these reasons, Mr. Holmes is of opinion that, as already suggested by Professor Fluckiger, the bark of *C. succirubra* seems to be the most suitable for use in medicine and pharmacy. Mr. Holmes also suggested that purchasers should require from wholesale dealers a statement of the percentage of alkaloids in the barks supplied to them, in order that pharmaceutical preparations, when made from bark thus guaranteed, should be of satisfactory quality. As regards the strength of the fluid extract, if made from the red bark according to the British Pharmacopœia, it would in all probability deposit some of its active constituents, and it might be desirable to adopt the strength of the United States Pharmacopœia, which is one-fourth that of the British. Mr. Holmes considers that neither the decoction nor the infusion of cinchona bark possesses any advantage over the fluid extract and that it would be a boon both to the patient and the dispenser if these preparations could be superseded by it. As regards the simple tincture, which differs in strength according to the British, United States, French and German pharmacopœias, an equalization, or at least an approach to uniformity, is desirable, and as regards the compound tincture, which contains, according to the British formula, saffron and cochineal, according to the German and five others, cinnamon and gentian, it is desirable to consider whether these ingredients should be retained or not.

Mr. W. de Neufville, in a paper upon the same subject, took exception to the statement of Professor Fluckiger that flat calisaya, or the yellow bark of the British Pharmacopœia, is more scantily and less regularly imported than hitherto. On the contrary, he asserts that during the last few years the supply of this bark has so considerably increased that the drug trade has not been capable of absorbing it. As regards the regularity of importation, even during the late Peruvian war the shipments of calisaya bark have been, contrary to the assumption of Professor Fluckiger, more constant than those of barks from the northern districts of South America, the supply from which has sometimes failed altogether, owing to the frequent drought of the Magdalena and other rivers. As opposed to the recommendation to supersede South American by Indian-grown barks, Mr. de Neufville pointed out that the planting and cultivation of cinchonas has already been commenced in Bolivia and Peru and that the results have been very satisfactory, the produce of these plantations having been sold for high prices in the London market during the last two years. Mr. de Neufville also urged that if the flat calisaya of American origin is to be abandoned, because it does not contain sufficient quinine, there is no reason why the American calisaya quill bark should not take its place, since it is rich in quinine, contains a good proportion of other alkaloids, and is easy to work.

In the discussion that followed the reading of these three papers Mr. Wellcome suggested that, in view of the difficulty attending the separation of the cinchona alkaloids, the percentage of total alkaloids should be taken as an index of the value of a bark. Mr. Brady said the thanks of the Conference were due to Mr. Howard for having brought this subject forward by the contribution of his paper and the interesting illustrations by which it was accompanied. Dr. Paul, being called upon by the President to offer some remarks upon the subject, said no doubt it was a very general opinion that there was need of making some alteration as to the kind of bark that should be officinal in the Pharmacopœia. The only question seemed to be what kind or kinds of bark should be chosen for pharmaceutical purposes. He did not agree with the suggestion that American bark should be entirely superseded by that of Indian growth, although the excellent qualities of Indian "crown" and red barks rendered their introduction desirable. The Indian red bark was already coming largely into use on the Continent, and it, together with American quill calisaya, would satisfy all requirements.

CAT-PROOF GARDEN FENCE.

TO THE EDITOR OF THE "AUSTRALASIAN."

Sir,—In answer to "Florist," who, in your issue of 27th ult., wishes to know how cats may be kept from climbing over his paling fence into his garden, a simple way is to nail on the outside of the fence, near the top, a continuous strip of tin or iron about 9 in. wide, to extend the whole length of the fence, and he will find that this will effectually keep out cats, opossums, *et id genus omne*. Bushman.

Rockhampton, Sept. 6.

FUNGUS HUNTING.

The town of Leeds has, within the last few days, been the gathering point of a large number of distinguished mycologists, who met there for the purpose of carrying out a "fungus foray" and obtaining a better knowledge of the fungi of Yorkshire. The arrangements for this meeting were made by the Yorkshire Naturalists' Union, and as the result of excursions to Harrogate and Ripon, a collection of specimens was obtained, which, together with contributions from other parts of the country, furnished material for an exhibition at the Mechanics' Institute in Leeds that was both interesting and instructive to those who visited it.

In the afternoon of Saturday a lecture on Fungi was given by Mr. Plowright, of Lynn, in which he described their structure and the mode of reproduction of spores. The application of fungi as articles of food was also illustrated at the dinner in the evening, the soup being made from fungus, and the lamb cutlets served with mushroom sauce, while at a later stage the members had an opportunity of experimenting on the digestive properties of *Fistulina hepatica*, *Helvella crispa* and *Hydnum repandum*, which had been prepared according to the recipes in a monastic cookery-book three hundred years old.

In the course of the evening, Mr. J. Horsfall referred to one branch of mycology as having special interest for the medical profession, since it is highly probable that the woolsorters' disease, scarlet fever and other diseases are of fungoid origin.—*Pharmaceutical Journal.*

THE COFFEE AND SUGAR PRODUCING COUNTRIES.

CEYLON.

From the *American Grocer*.)

Besides coffee the chief products of the island are coconut oil and pearls, the latter are fished around Manaar Island, and are in beauty and value only surpassed by those of the Persian Gulf, the annual product of these pearls being about £260,000. The island for-

inerly also furnished to the world's trade a good deal of ivory, but elephants are gradually becoming extinct in the southwestern forests.

Coffee is and remains the chief product, and its yield has increased as follows:—

	Export.—*tons.*
1836	3,015
1846	8,695
1851	16,987
1856	22,310
1861	29,695
1865	43,805
1867	41,862
1878	31,600

If since 1865-67 there have been years of less abundant yield, this has been due to a disease of the tree which attacks the leaves and affects the productiveness of the plant. But for this drawback production would probably have gone on expanding all along, for none of the elements for its doing so are wanting: climate, soil, labor, capital, and an unrivalled geographical position, especially since the Suez Canal is at the disposal of Ceylonese trade, and the large steamers from the extreme East on their way to Europe or America touch there.

Barring the disturbing influence of occasional short crop from some cause or another connected with the plant itself, coffee cultivation in Ceylon has therefore a brilliant and secure future before it, there being no apprehensions of interruptions of a political or servile nature, as they may happen elsewhere in the future in coffee growing countries.

Ceylon's production is important enough to require being taken into consideration in making estimates of the world's annual coffee supply.

COFFEE PROPAGANDA IN BRAZIL.

(*Diario de Santos*, 7th August 1881.)

The propaganda in favor of augmenting the actual zones and of obtaining new ones for the consumption of Brazilian coffee, continues in the city of Rio de Janeiro. The government, the society "*Centro da Lavoura e do Commercio*," and the Commercial Association, each according to the extent of their powers, are endeavouring to assist this movement, it having already been resolved to open an exposition in the beginning of November next. As we have said before, we have but little confidence in the practical result of an exposition without the express condition that the exhibitor of any sample must declare the quantity he can supply and the time within which he can do so, binding himself to make a contract of sale if there should be a buyer and at a price to be determined between the parties. Without this we shall always have pompous and luxurious samples without any practical value. This exposition measure being once resolved, the government should at least take the greatest possible advantage of it, installing a jury or congress in which the elements of agriculture and commerce predominate; in short, an assembly of practical men who, without much pompous phraseology and application of theories, should give their opinion on important questions of economy which at present occupy the attention of all, such as: the question of the substitution of agricultural labor, the amplification of the rural credit system, the question of export duties, and transportation tariffs. There is no doubt that our province will take a conspicuous place in this exposition, and it is highly desirable that her representation in the jury be in harmony with her importance, for though all the coffee will be Brazilian, yet it is certain that in various points the position of our coffee production diverges from that of Rio. Whereas the good qualties of Rio are perfectly known as such, and even preferred in the United States, ours have up to this time not met with great approbation there; but it happens that in Europe where, with the exception of washed, very little "superior" and "good Rio" goes, the discredit of Brazilian coffee is in a great measure owing to that source. It is well known to all who are versed in the coffee trade that the higher class of consumers in a large part of Europe much appreciate our brands of "superiors" and "good" on account of their good taste, so much so that a great portion passes as Java, Laguayra, Haiti, etc., whose agriculture, of much older existence, knew how to establish a reputation for the fine products which it brings to market. If we persisted only during a few years in improving and perfecting our coffee, we would in our turn obtain the same renown, and the new producing countries would certainly in their turn be obliged to make use of our name for the sale of their products. The quality of our coffees diverges in general form that of Rio, so much so that old Rio merchants, perfect judges of the qualities there, do not understand the judicious classification of a Santos lot, and, as their customers are different from our, they generally ignore the exigences of the consumers of our qualities. It would, therefore, be desirable that in due time the necessary steps should be taken that the judging of coffees from the province of São Paulo be done by competent persons. It should be a conjunction of planters, dealers and exporters from our province.

BRAZIL COFFEE EXPOSITION.

(*Rio News*, 15th August 1881.)

The continued agitation of the coffee exposition project leaves no doubt as to its realization at no distant day; but it resolves none of the doubts as to the practical results to be obtained through such an enterprise. The early appeals for aid in this industry, and all that is written and said in its favor now, are devoted chiefly to the imaginary necessity of enlarging present consuming markets and opening up new ones. Among the latter have been mentioned the vast empires of Russia and China. If this desire to extend and enlarge consuming markets be the chief object of these expositions—and we have heard none other mentioned—then why is it that they are to be held down here in Rio de Janeiro? Is it to be supposed that a coffee exposition at the Typographia Nacional, in this city, will make the Russian acquainted with the good properties of this beverage, or that it will make John Chinaman discard his tea for Brazilian coffee? Does any one think that a display of São Paulo and Rio de Janeiro coffee in this city will prove to Englishmen, Frenchmen, or Americans, that it is equal to Java, Mocha, or Laguayra? Is it anticipated that the coffee buyers and coffee drinkers of the world are coming down here to look at some parcels of samples? And if no one believes these things, then what is it all for? No one urges the necessity of improving the quality of the product and lowering the cost of production; every one seems to be possessed with the desire to find new consumers. The increase of consumption must therefore be the main object! Now how is this to be effected by an exposition in Rio de Janeiro? And how is it to be effected any where by the mere display of samples? What assurance is offered that the crop will correspond accurately to the samples? And if it does not, with whom rests the responsibility? Besides, who can estimate the supply corresponding to any particular sample, and who can determine prices, as compared with other coffees, for any future time? And still further, will these samples, if sent abroad, represent general grades, or the product of certain planters? To be plain, the whole scheme is visionary and impracticable in the highest degree. If the object were to improve the product and lessen its cost, then there would be the best of reasons for holding annual competitive expositions. Or, if it were proposed to hold an international exposi-

tion at London or Paris, in which Brazilian coffee would enter into competition with the coffees of other countries, then there would be other good and sufficient reasons for giving it all support. But these purposes do not appear. The samples of the Brazilian product are to exhibited in a Brazilian city where no other coffee is used, and to Brazilian brokers and exporters who already know all about it. And then, when the exposition is closed, the Brazilian people will go on drinking Brazilian coffee, and the Brazilian exporter will continue to export Brazilian coffee, just as before. On the other side of the water, the foreign consumer will read in the *Times* a four-line account of this exposition of coffee in Rio de Janeiro, and will continue sipping his fragrant Mocha without the slightest idea of what it is all about. Some neatly labelled samples will be sent abroad to be exhibited to a curious world by Brazilian consuls, but as no one ever goes to a consulate when he can help it, they will probably serve no other good purpose than to reduce the consul's household expenses. Unsatisfactory and disappointing as these results will be, they are just what may logically be expected from this present crude and visionary scheme. In the main, the desire to attain some beneficial result for the coffee producer from an exposition is praiseworthy in the highest degree, and if rightly located and conducted these benefits will surely follow. In our opinion there are but two bases upon which successful coffee expositions can be held—both international, and both competitive. The one should be held in this city so that the Brazilian planter may see the foreign product, test it, and learn the methods of its cultivation and preparation for market. By this means he will learn just how his product compares with those of other countries, and just where he must improve his product in order to enhance its marketable properties. The other base is an international exposition in some great commercial centre, as London or Paris, where the consumer may see all these products, and test them. Both the producer and consumer must be educated, but that cannot be done by an exposition of Brazilian coffee in a Brazilian city. A coffee-house for the free supply of the Brazilian beverage in London or Paris will do more to increase the sale of this product, than all the domestic expositions that can be held.

THE CHINESE QUESTION IN BRAZIL.

(*Rio News*, 15th August 1881.)

In a country where slavery exists, and all social and industrial life is impregnated through and through with the pernicious influences of that institution, the introduction of a semi-servile race cannot be otherwise than dangerous. Salvery is an institution which not only works great injustice to the enslaved, but it also degrades and debases the enslaver. No people who have been trained to the employment of slave labor have ever been able to easily take up the system of free labor, and to employ it with justice to the laborer and profit to themselves. The nearest approximation to such a transformation was in the southern section of the United States, but the result there was obtained under economic and political conditions which undoubtedly exist in no other part of the world. It is through these pernicious influences of slavery that the free and slave laborer have never been able to work side by side. The freeman has a natural antipathy to companionship with the slave, and the master does not know how to draw just distinctions between them. For this reason, primarily, the introduction of Chinese laborers at this time under any system of contracts, should not be permitted.

With regard to the present systems of agriculture and the relative value of the two systems known as the *grande lavoura* and *pequena lavoura*, there is a vast field for research which the Brazilian agriculturists should explore at once. It is clear that the country has made very little progress under the system now in operation, from which it can be logically deduced that there is something wrong with it. If no progress can be made under it—if in reality there has been an actual decline in certain localities and industries, is it not best that some other system should be tried, even were there no proofs in existence as to its superiority? Can there be any real progress in that unreasoning conservatism which clings to antiquated methods and systems, and refuses to give a place to anything new? Is this the enterprise and emulation which are to aronse the jealousy of Americans?

The statements of our colleague regarding the system of *grande lavoura* in the United States, are wholly mistaken. That system, as such, is unknown there. The nearest approach to it was in the Southern States during the existence of slavery, where large properties were held and cultivated by methods not greatly dissimilar to those employed here. The abolition of slavery, however, broke down that rotten, old system, and now it is not uncommon to find freedmen owning and tilling little plots of ground which once formed parts of the great estates upon which they labored as slaves. In the West—throughout the whole country in fact, the system employed is essentially that of small farming. Here and there are large estates which have been acquired through the industry and good management of a few individuals, but their proportion to the small farms is about as one to five hundred. To small farming is due the agricultural prosperity of the United States from which it may be inferred that it would result beneficially here, that unjust laws have kept back the stream of European emigration to Brazil through which this system of small farming could best be established, and that the immediate policy of the country should be the employment of its present laboring element rather than its substitution, and consequent exclusion, by the introduction of Chinese under contract. Were we to discuss this question still further we should undertake to prove that the needs of agriculture do not lie in the acquisition of cheap, servile laborers, but rather in the acquisition of a higher grade of agriculturists, of better methods of cultivation, of the use of machinery, of raising the standard of intelligence among the laborers, of the breaking up of the great estates, of the abolition of export taxes, and the reduction of transportation charges, and of a general and radical change in the legislation of the country through which small farming is discouraged and European emigration is driven away. The question is a broader and deeper one than this demand for labor would signify; it involves changes in the whole industrial and fiscal legislation of the country.

FRUIT-GROWING: DISBUDDING AND THINNING.

(*Australasian*, 17th September 1881.)

In the interests of the grower any excess of blossoms over the number required to produce the due amount of crop is undesirable. The effect of blooming is, to a certain extent, a tax upon the strength of the tree, and when "sheets" of bloom are produced, the powers of the tree are oftentimes so severely tried as to prevent any appreciable crop being carried; fruits are formed, but they are seedless, and thus, when the process of stoning or pip-forming, as the case may be, should take place, the imperfect embryo fruit falls off, leaving the grower too frequently without a crop. In ordinary seasons, when the blooms are not so excessively abundant, the process of reducing the crop to proper dimensions may without injury be left until it has well set, so that the grower can see what he has to deal with. But when as in the present instance, the flowering is likely to exhaust the tree and preclude its yielding a fair crop, an extensive and severe pruning of the fruit spurs should

be resorted to in the case of cherries, apples, pears, and such other fruits as bear upon spurs, whilst peaches should not only be closely pruned, but should have their blossoms thinned by hand. The pruning of fruit spurs is a practice to which amateur pomologists are, not unnaturally, inclined to object. The desire to have heavy crops is, perhaps, not confined to growers of that class, but the more experienced growers for market have learned to aim at the production of fine fruit, and, to that intent, to avoid heavy yields of small samples; this they do partly by spur-pruning and partly by early-thinning after the crop is set. The powers of the tree are not so severely taxed in producing the fleshy portion of the fruit as in forming the seed. The fleshy envelope of the peach, for example, is a mere mass of water; if the tree be well supplied with moisture, the weight of crop may be doubled or even trebled without injury to the tree, as the number of seeds would be no greater than before; the flesh only would be increased in weight. It is, therefore, expedient to thin off most of the surplus peaches before stoning takes place, leaving only a small margin for the final thinning.

The work of disbudding is undertaken with the object (1) of conserving the growing powers of the tree, and (2) of giving such a direction those powers as will improve the constitutional vigour of the branches that are intended to form part of its permanent structure. When the young shoots, or the more forward ones, are pushing for wood, a selection should be made by the grower, who should rub off with his finger and thumb the more forward of the shoots that will not be required. A week or ten days later a second disbudding may take place, and at a like interval the final touch may be given. By adopting this plan many wounds that would otherwise be made at the winter pruning will be saved, and the liability to gumming be lessened. There should be few shoots requiring entire removal in the winter, but the remainder will need the proper shortening. The wood not having been crowded, as it is when disbudding is not practised, is well ripened and healthy; the foliage is large, strong, and well developed; the fruit, too, if the crop be not too heavy, is fine, highly-coloured, and well-flavoured. Thus, both thinning and disbudding may be regarded as essential to the successful cultivation of the peach and the nectarine in this country.

Disbudding is even more essential in the case of vines. Whatever system of pruning and training is adopted, a number of young shoots, whose presence would be injurious, are sure to appear on both the old wood and on the new. In disbudding vines there can be no difficulty, nor need the work be partially done, as we have recommended in the case of peaches. Every shoot that is not required either to form part of the vine or to carry a bunch of fruit during the current season may be rubbed off at once. Under those two heads may be ranked every shoot that springs. A weak one may sometimes be left as the source of a stronger one the next year, or to fill a vacancy on a trellis; such a shoot would be a wood shoot proper. Vine shoots should not be crowded, but each branch should have abundance of space to develope its leaves; then the wood will be strong, well ripened, and if the soil be right, the vine will retain health. Mildew will, however, be liable to occur under certain conditions of soil and weather, against which provision cannot always be made. As in the case of rust in wheat, the visitation cannot always be guarded against; indeed, the development of mildew on vines may be said to depend chiefly upon atmospheric conditions.

VEGETABLES FOR THE TROPICS.

(From *Sutton's Tropical Garden Guide.*)

(Continued from page 471.)

GOURD OR PUMPKIN (*Cucurbita gourgera* and *C. Pepo*).

The cultivation of the Gourd is not only interesting but profitable. Sow about the middle of the rains on a heap of well-rotted manure, previously covered with good soil. Pick off the first flowers to allow the plant to gain strength. Water plentifully, and place dry litter under the fruit; and shade the plants carefully.

HERBS.

These form an important item in domestic economy, and can be easily cultivated in good ordinary garden soil kept moderately moist. The cultivation is the same as for Parsley.

KNOL KOHL (*Brassica Caulo-rapa*).

This is a very valuable vegetable, and requires but little attention. Cultivate as for Cabbage. The roots should be ready six weeks or two months from the time of sowing.

LEEK (*Allium Porrum*).

Leek should be sown earlier than Onion, as it is rather longer coming to maturity, and, as it should always be transplanted, it is well to give as long a time for growth as possible. When ready for transplanting, well water the soil, so as to allow the removal of the plants without the loss of the fibrous roots. Plant out in rows 1 foot apart by 6 inches in the rows from plant to plant. Earth up from time to time to blanch the root, and water liberally.

LETTUCE (*Latuca sativa*).

Of Lettuces there are two classes, Cos and Cabbage, and both are equally useful. The seed grows but slowly, and is so subject to the depredations of ants, that it is well to sow in pans and isolate them by placing them upon an empty flower-pot standing in another larger pan full of water. The soil should be very light and friable. Plant out the seedlings, as soon as they have made their second pair of leaves, in light, rich soil. Succession crops may be grown almost all the year round.

MELON (*Cucumis Melo*).

No fruit better deserves cultivation in tropical climates than the Melon. Sow middle of March in the spot where it is to remain, as it cannot bear transplanting. Dig a trench 14 to 16 inches deep, and 2 feet wide, and see that the soil is good and rich. Sow a double row of seeds in each trench. When the plants are a foot high, train along the top of the trench, and let the roots only come into close contact with water.

MUSTARD (*Sinapis alba* and *S. nigra*).

This requires so little cultivation, that directions are scarcely necessary. Sow at intervals, for salad, the whole of the cold season. The seed germinates in two days.

MAIZE.—INDIAN CORN (*Zea*).

The unripe heads of Indian Corn, when cooked, are very delicious: boil in milk, afterwards roast and eat with pepper, salt, and butter. Sow the beginning of rains in rows 1 foot apart, and the seed 8 inches apart in the rows.

ONION (*Allium Cepa*).

There are two principal classes of Onion. First, the English varieties, which grow to a small size only, but are excellent for their keeping qualities; and secondly, the Italian varieties, to be used especially for early crops, and which grow usually to a very great size. Of the English varieties we recommend Improved Reading, James's Keeping, and Bedfordshire Champion. Of the Italian Onions the best are Giant Rocca, White Giant Tripoli, The Queen, &c. The middle of October is the best time for sowing, and this may be done either in drills or by sowing broadcast. In either case the young plants should be thinned out when well established, leaving them about 6 inches apart. A still better plan is to sow in seed pans and transplant, as then the seed is protected to a great extent from the ravages of ants and other insects. During early growth water freely, but just before the commencement of the hot season

it is well not only to cease watering, but to hasten ripening off by breaking down the tops.

PARSLEY (*Petroselinum sativum*).

Sow any time after middle of September in gumhahs protected from the heavy rain. The seed takes 10 days to germinate. Transplant when the seedlings are 4 inches high, about 1 foot apart, in the shade, and keep them well watered.

PEAS (*Pisum sativum*).

The round varieties of Peas will generally be found most suitable for cultivation in the tropics. There is no occasion to manure the land heavily for Peas, but it is important that it should be well dug, and that the Peas are not sown until the soil is well pulverised and tolerably dry after the rains. In England it is important to get as much sun as possible. Of course in hot countries this is not so, and therefore it is well to plant the rows much nearer together, say 30 inches from row to row, instead of 4 or 5 feet as in England. When Peas are sown late in the year for succession, the ground will require watering twelve hours previous to sowing. If they do not show above ground a week after sowing, the earth should be gently removed, and if the Peas are found in a dirty, wet condition, unsprouted, another sowing should be made at once. Sometimes the outside shell of the Pea becomes so hard that it is necessary to soak the seed in water for some hours previous to sowing. When about 6 inches high it is desirable to stick the rows, after earthing up on each side. It is of little use to sow later than December.

POTATO SEED (*Solanum robustum*).

The expense incurred in the transport is so great, and the chance of failure so considerable, that it cannot be worth while to order out a large quantity of Potato tubers from England, but it is far better to obtain seed which has been raised from good sorts in England. Potato seed is cheap, will travel safely by post, and a packet is sufficient to sow a large piece of ground.

RADISH (*Raphanus sativus*).

For Radishes, a shady spot should be selected. The land should be light, and not recently manured. Do not think of sowing before October, and if rains are not over it will be better to postpone it until the middle of the month. Sow either broadcast or in drills a foot apart. In the latter case the seed should be covered with about a quarter of an inch of mould, and the plants thinned out to 3 or 4 inches from row to row. Make successional sowings every fortnight, and do not stint the supply of water. If the ground becomes caked and hard it should be loosened with a rake.

SPINACH (*Spinacia oleracea*).

Sparrows are so fond of the seed and young plants that unless the protection of a net is given the crop will probably be lost. Sow in drills, as soon as the rains are over, in good rich soil in a shady place. The drills should be 1 foot apart, and the plants in the drills 4 inches apart.

(To be continued.)

CINCHONA CULTIVATION IN JAMAICA.

The following appeared in the Kingston (Jamaica) "Gleaner" and "Tri-weekly Gleaner" of the 27th August 1881:—

We publish to-day (see page 501 of the *Tropical Agriculturist*) the terms upon which the Government of this Island, being desirous of encouraging the cultivation of Cinchona, offers to make grants of public lands to persons who will embark in the enterprise. The situation of the land is not mentioned, but we presume the extensive unopened tracts of forest on the higher Blue Mountain slopes are referred to. The Government has already encouraged, under favourable concessions, the cultivation of cinchona by private enterprise thereabouts, and is now, we are glad to believe, seeking to establish the industry systematically. The land we speak of lies at elevations of from 4,000 to 6,500 feet; is without roads, but of fine quality: is distant from Kingston two score miles, but possesses a climate delightful alike to those who dread the cold of a northern winter and those who dread the heat of tropical high noon.

To anyone who thinks seriously of investing his capital in cinchona cultivation in Jamaica, but fears to venture, we would point out that he will not be alone in the undertaking. We could name at this moment several gentlemen, including His Excellency the Governor, who have devoted land and capital to it. In his last Report, Mr. D. Morris stated that large numbers of plants had been put out at Whitfield Hall, Radnor, and Clydesdale. To this list, the names of many well-known high plantations between St. Catherine's Peak on the west, and Blue Mountains on the east, might be added, while the cultivation of cinchona adapted to lower elevations is being prosecuted with vigour in Manchester. The demand for seeds and plants increases daily, and can hardly be met. This new industry brings into productiveness regions which in many cases were unsuited for coffee or provisions, and which were a burden on the owner. We regard this departure as creditable not only to the Government, but to the planters who have been so often, so foolishly, and so freely accused of indifference to their own best interests and to opportunities of unfamiliar profit.

Estimating the gain which may accrue from new enterprises is always a delicate affair. In the present case we will give the statements of authorities on the subject in preference to opinions of our own, merely pointing out that many of our shrewd and experienced planters have satisfied themselves as to the profit derivable from cinchona, and have given evidence of the faith that is in them. In his valuable report, to which we have already referred, Mr. Morris describes how he found a patch of *cinchona officinalis* which had long been deserted on Whitfield Hall Estate, and which was found hardy and thriving. He says:—

"As indicating the value of cinchona planting in the Blue Mountains—taking these 379 trees which occupied an area of less than 120 square yards—it was estimated that if they yielded on the average one pound of dry bark per tree (young trees at the Government Plantations yielded 1½ pounds per tree), each tree would be worth at least 5s.; this would give £94 15s. as the value of 379 trees on an area of 120 square yards, one-fortieth of an acre. Under ordinary conditions it would not, however, be advisable to plant the trees so closely as this, but the value of an acre of land planted with trees even at one-half the above rate would amount to more than £1,890. Large as this sum may seem, it appears that with the precious Ledgeriana bark, grown by the Dutch in Java (a few plants of which have just been introduced to Jamaica), the yield per acre, as quoted by Mr. J. E. Howard, F.R.S., is estimated, from actual sales, at £2,000 per acre."

We will take in addition to the above, the statement made by Mr. Clements Markham, in his interesting and important monograph on "Peruvian Bark." In his chapter on "Financial Results," he says:—

"The result of the sales of bark from the Government Cinchona Plantations on the Nilgiri Hills, in India, is that a sum of £173,046 has been realized. The total cost of the whole enterprise from the commencement, including interest, was £129,628 in 1876. By the year 1879, allowing for charges during intervening years, the sum to be debited against the enterprise was only £38,942. In 1880 the whole capital account had been paid off with interest, and the plantations began to yield a clear annual profit. It is therefore true of the Cinchona enterprise that as a mere commercial

speculation, it has paid off the whole outlay, including introduction of the plants, cultivation, and interest; and has become a complete financial success."

Mr. Markham also gives figures to show how private enterprise in India and Ceylon is reaping the same reward. For his remarks on this point, we must refer our readers to his work. It is shown that while the Government of India will in future have as much demand as it can meet, in supplying cinchona febrifuge for the millions of India, the planters of Ceylon and India, as well as of Java, find a ready and profitable demand for their bark in Europe. At the same time a vast market for the bark is being found in China, where until now opium has been the cheapest drug as a cure and preventive of fever, and where from 30 to 40 per cent of the population use it, to their own ruin and to England's disgrace.

The prices obtained for Jamaica bark should stimulate to activity in planting cinchona. Mr. Markham, in his sketch of Cinchona Cultivation in Jamaica, says that *C. officinalis* does not thrive so well in this island, but he speaks favourably of *C. succirubra* and *C. calisaya*. But the latest results furnished by sales of Jamaica "grey" barks, are proofs that *officinalis* grown here commands better prices than that of Ceylon: and last week we had an opportunity of seeing how, as Mr. Morris describes, the *officinalis* spreads in self-sown forest patches at the highest elevations, thus exhibiting great fitness for the soil and situation. The island has now, therefore, at least three kinds of cinchona well established: *officinalis*, *succirubra*, and a good variety called *calisaya*, but supposed to be a hybrid between the other two. Moreover, the *ledgeriana*, a variety of *calisaya*, introduced by Mr. Morris, is now growing well as a plant, and seed of it has already been imported. Of this *ledgeriana*, which Morris says fetches 17s. per lb. at Amsterdam, Mr. Markham writes:—"These plants yield an extraordinarily large quantity of quinine, as much as 9·97 per cent. In this respect they are unequalled." With regard to the species known as *succirubra* and yielding the "red" bark of commerce, a variety which Mr. Morris recommends as being peculiarly suited to so much of our land from 2,000 feet upwards, Mr. Markham writes that it yields a larger percentage of febrifuge alkaloid than any other. As time rolls by, other varieties again may be found to naturalise themselves easily, "the Blue Mountains of Jamaica * * * being about the same distance from the equator on the North side (18° N) as the calisaya forests are to the south."

As the Government now offers land for cinchona, it is also ready to supply the seeds and plants. Seeds of the *officinalis*, for cultivation at elevations above 4,000 feet are supplied at 5s. an ounce; of *succirubra*, at elevations between 2,500 and 4,000 at 3s. An ounce is sufficient to produce 20,000 seedlings, which will plant five acres. Boxes of seedlings may be had at a guineâ per box, and plants are obtainable at from 40s. to 60s. per 1,000.

We hope to witness an early extension of cinchona cultivation by men who have capital and can await the first yield in the fourth or fifth year. The opportunity now offered is excellent. It is possible that a market for the Jamaica bark will be found some day in the U. S. A., which consumes vast quantities of quinine, but for the present England takes all that can be shipped, and at remunerative prices. The time cannot be far off when the masses of Jamaica will be provided by Government with a cheap, effective febrifuge, now so greatly needed. And leaving out of question the commercial and social advantages resulting from cinchona, it may be fairly claimed that this tree, which once inspired the prose of Madame de Genlis and the verse of La Fontaine will, with its graceful stem, shining leaves, and clustering flowers, be an additional ornament to the far-famed but neglected mountains of Jamaica.

THE SUGAR AND TOBACCO INDUSTRIES OF 1881 IN JAVA.

(*Field*, 15th October 1881.)

After three consecutive very bad years, it is satisfactory to be able to report a most splendid sugar harvest for the season 1881. In all probability, the production of this year will surpass that of any season known, in proof of which we have the most remarkable fact that the planters themselves confess they are contented; an admission that would scarcely be made under any other conditions than those of unexpected success. At the very lowest computation, the actual production of 25 per cent more than was calculated upon in April last. One great reason for this satisfactory result is the glorious weather that has reigned almost uninterruptedly throughout the grinding. In May and early in June, a few days of rain made many anxious, but the wet monsoon, that has during the past three years taken to usurping the place of the dry one, finally took itself off, and in many districts not a drop of rain had fallen for nearly two months. In Batavia, where they never see a pound of raw sugar from one year's end to the other, they are crying out for rain; but it is better for them to frizzle for a month or two, than that the sugar industry should receive a blow. Had the present season been as bad as its predecessor, the consequences would have been most serious. The population, both European and native, of the eastern half of Java, from Cheribon to Bezuki (*i.e.*, Java proper, as distinguished from Sunda), is so dependent on the sugar culture, that its success of failure affects it most intimately. So heavy had been the losses of the preceding seasons that many factories dared not risk the buying of new machinery, however sorely they required it. The production of sugar during the past four years has been as follows:—1877 (a tremendously hot year), 4,091,570 pikuls; 1878, 3,786,404 pikuls; 1879, 3,851,692 pikuls: 1880, 3,639,757 pikuls. The difference between 1880 and 1877 is thus 451,813 pikuls, representing a value of more than half a million sterling, and this in the face of wonderful improvements in machinery. However, this year will compensate for everything which will be good for everybody, for sugar planters are the most liberal class in Java, and have no idea of excluding others from the benefits of a good time.

A feature this year is the almost exclusive employment of steamers in place of sailing vessels for conveying the produce to Europe. The fact becoming known that the best sugar harvest would be late, some speculative ones thought to be the first in the market, and chartered steamers. But the impartiality of the telegraph soon equalised matters, and now every sugar port has a quantity of steamers loading in it. Thus few, if any will reap the advantage of priority.

The tobacco harvest is unfortunately very easily disposed of in three words, viz., there is none. The suddenness and completeness with which the tobacco industry has vanished from the land, so far as Europeans are concerned, is simply appalling. Bismarckian tariff tactics have had a good deal to do with it—some will have it everything—but there is always a good market for good leaf, and this is just what Java does not produce in any quantity. For this the planters have to thank their pernicious system of allowing the native to do all the planting, and simply buying the produce at a fixed rate, in consideration of having made an advance. There are several tobacco planters in Java who make money, but these are all men who take the thing in their own hands. Things may improve, but that they will ever wear the aspect they wore only a few years since, when the term tobacco planter was synonymous with that of Cræsus, is extremely doubtful.

A COFFEE MILL took fire on the 30th ult. at Casa Branca, San Paulo, and was destroyed, with about 5,000 arrobas of coffee. The loss is estimated at 40,000$. The mill belonged to the estate of the late Luciano Ribeiro da Silva.—*Rio News.*

PROGRESS OF THE TEA ENTERPRIZE IN MADRAS PRESIDENCY.—A return just published in Madras shows that tea is grown in three districts of the presidency, namely in Madura, Malabar, and the Nilgiris. In the two first named districts there are only five plantations, but on the Nilgiris there are 79. The total average of land under tea is returned at 2,573 acres against 9,123 acres of land taken up; the acreage of land with immature plants is returned at 1,705. The approximate yield of tea of all the estates is returned at 649,460 lb., the cost of cultivation varying from Rs. 50 to 200 per acre.—*Englishman.*

HOW TO EXTERMINATE COCKROACHES.—I would recommend "G. H." to get a pint of beer, and to heat it in a saucepan, dissolving as much sugar in it as will sweeten it nicely. Then procure two or three common 1-lb. jelly cans, fill them half full with the beer and sugar and stand them where the cockroaches are likely to run. Put them down in the evening, and in the morning he will have from six to a dozen of the pests in each jar. The same mixture will do for two nights, when if desired the dose should be repeated. As the jars are smooth outside, it is desirable to tie some rough material round about them such as a bit of netting or shading material. I found this plan more effectual than any poison I could procure.—THOS. FRASER, The Gardens, Gordon House, Isleworth.—*Gardeners' Chronicle.*

ORANGE TREES IN POTS.—As the fruit is approaching the ripening stage, it is necessary not only to withhold manure water, but water of any kind must be given carefully, else the rapid swelling of the fruit bursts the skin and spoils it. If there are trees with ripe fruit, they may be removed into a late vinery where Grapes are hanging. It is one of the good fruits of the Orange tree that it may be removed from a warm to a cool house, or *vice versa*, without any probability of constitutional derangement. The fruit may hang on the trees until it is wanted, and when cutting it a few leaves should also be cut with it. When the trees with ripe fruit can be moved in this way, it allows of the right kind of treatment being given to those that may be bearing fruit not fully developed. The temperature should be kept up to 65° or 70° at night, if the fruit is green.—F. DOUGLAS, 'Loxford.—*Gardeners' Chronicle.*

JALAP.—A note was read by Mr. T. Greenish, on "Some Samples of Jamaica-grown Jalap," sent to the Curator of the Museum of the Pharmaceutical Society by Mr. D. Morris, Director of the Botanical Gardens of Jamaica. One sample consisted of small tubers and another of slices of larger ones. The slices of the tubers had been dried by artificial heat, and they bore evidence of having been heated while still moist. The tubers lost 17·3 per cent. of water between 220° and 225° F., the slices 14·1 per cent. The tubers contained 8·27 per cent. of resin insoluble in ether (Mayer's "convolvulin") and 0·86 of resin soluble in ether. The sliced tubers contained 8·68 of insoluble resin and 1·21 of soluble resin, these amounts being in each case calculated on the dry substance, showing that Jamaica-grown jalap yields less resin than the average of good Mexican jalap, and that it approaches more nearly to that grown by Mr. Smith in the Botanical Gardens of Trinity College, Dublin (*Pharm. Journ.*, 2, vol. x., p. 529). Professor Tichborne said he considered the growth of large tubers of jalap to be a mistake, as he had always found them to be deficient in resin. Mr. Young, however, said that a Calcutta firm, in ordering jalap, had desired to be supplied with the largest obtainable tubers. It may be remarked that the tubers examined were the result of Mr. Hanbury's introduction of jalap into Jamaica in 1862.—*Pharmaceutical Journal.*

TEA AT NIJNI NOVGOROD.—Of all the articles of trade which come to court public favour in Nijni, the most important and valuable is tea, and, although the Moscow merchants, by the excellence of their seafaring tea, chiefly imported from Odessa, have almost entirely driven from the market the Kiakhta, or caravan tea, still one-tenth of the enormous quantity of tea sold here is grown in the north of China, and comes overland. I was curious to compare the taste of some of the very best of both qualities, and was brought to the conclusion, confirmed by the opinion of gentlemen interested in the sale of seafaring tea, that, although some of their own is more high-flavoured and stronger, there is in the Kiakhta tea an exquisite delicacy arising from its exposure to the air during its 12 months' journey in its loose and chimsy paper and sheepskin bundles, which rids it of tannin and other gross substances, a process of purification which cannot be effected in the hermetically closed boxes it reaches Europe by the sea route; so that if seafaring tea, like portwine, easily commends itself to the taste, and nerves of a strong, hardworking man, a dainty refined lady would give preference to a cup of Kiakhta tea, as she would to a glass of Chateau Yquem.—*Times of India.*

TIMBER IN BRITISH COLUMBIA.—Though the agricultural capabilities of British Columbia may not be so great as other parts of Canada, its mines are doubtless very rich, and from a recent report of Professor Dawson, of the Dominion Geological Survey, its forests are of great importance. Many first-class mills have been established in various parts of the country, and the total annual product is stated to be about 200,000,000 feet, of which 25,000,000 feet is exported to other countries, 25,000,000 feet used at home, and 150,000,000 feet sent to California. Professor Dawson estimates that 110,000,000 acres (or two-thirds of the whole province) are covered with timber. The Douglas Fir, or Oregon Pine, is the most valuable commercial tree. It frequently exceeds 8 feet in diameter above the ground, and rises to a height of from 200 to 300 feet, forming large and dark forests. The Western Hemlock and Red Cedar are the other important trees of the province, both of which, the latter especially, grow to a great size. When the great plains of Canada become populous, the mines and forests of British Columbia should be of great importance, and their produce ought to provide a large and profitable traffic for the Canadian Pacific Railway.—*Times.*

COFFEE LEAF DISEASE IN JAVA.—The coffee leaf disease during the past year has not only continued to spread in the plantations at the westward end of the Island of Java, but has also appeared in several gardens in the central region. As the subject in question is unfortunately of interest to some of our colonies, the notes furnished by her Majesty's Consul in regard to it may prove to be of some value. A commission was appointed by the Government of Netherlands India to investigate the origin of the disease, and their report tends to show that it is mostly met with on poor or worked-out ground, and that the succession of wet seasons has greatly spread the contagion; it is, however, hoped that a recurrence of normally dry years will cause a marked decrease in the percentage of trees attacked. The presence of the disease is in Java detected in two ways, viz.: either by the appearance of light green spots on the upper side of the leaf, or by the presence underneath of an orange-coloured kind of dust. In plants severely attacked, the leaves turn black or brown, and rapidly fall off. The chief Government inspector in Java recommends the adoption of the following simple measures for the suppression of the disease. —1. The hoeing up of the ground surrounding the trees beyond the spread of the branches to the depth of abot six inches, leaving the clods turned up intact. 2. The construction of ditches, or holes about eighteen inches deep between every intermediate row of plants, disturbing the earth dug out proportionately over the garden. 3. In regular gardens or wherever the con-

struction of ditches is impossible, the formation of holes about eighteen inches in diameter at an interval of every four trees, dispersing the turned-up earth amongst the plants. 4. The careful manuring of the ground at the distance of about a foot from the stem of each tree, and covering the manure with earth.—*Colonies and India.*

OLIVES.—From the *Colonies and India* comes the news that at the Botanic Gardens of Cape Town a bushel of olives has been gathered, and in consequence of this proof that this fruit can be grown at the Cape the Stellenbosch farmers have seriously resolved to undertake olive-planting as a new branch of agricultural industry. It may be hoped, therefore, that this colony may soon be able to supply olive oil as good or better than that produced in Europe. Indeed there is little reason why our extensive colonies should not supply all the drugs for which at present we are dependent on other countries.

IPECAC.—During the present month there have been offered at the drug sales in London, 5 bales of false ipecacuanha (*Ionidium Ipecacuanha*), false star anise (*Illicium religiosum*), and a large quantity of Indian dill seed (291 bags). The last is easily distinguished from English dill seed by being more elongated and narrower, more convex, of a paler colour, and slightly different odour. *Ionidium* can scarcely be confounded with ipecacuanha, ou account of its dirty white colour, branched habit and freedom from transverse annular ridges. Marking nuts (*Semecarpus Anacardium*) and the bitter seeded cardamom, chiefly without the husk, were also offered.—*Pharmaceutical Journal.*

CUPREA BARK.—In Messrs. Gehe's report for September some startling statistics are published respecting the "cuprea" bark that has recently acquired such importance as a source of quinine, which may well raise doubts as to the uniform character of the product that will soon appear in the market under this name. A correspondent, to whom this firm applied for information, states that the district in the province of Santander, Colombia, in which this bark was originally found, is now being worked by two companies, employing between them seventeen hundred men. As each man is estimated to be able to collect 20 lb. of bark daily, or equal to 8½ lb. of dry bark, this number of men would be able to collect in thirty days upwards of 400,000 lb. of dry bark, and enormous as this quantity may appear, the consignments being sent in by the collectors appeared to indicate that it would be exceeded. The original "cuprea" bark yielded about 2 per cent of quinine sulphate, and if this harvest were of equal quality it would represent more than 8,000 lb. of quinine sulphate. In confirmation of these statements it may be mentioned that during the past week 8,000 serons of "cuprea" bark were imported into London. The effect of these enormous consignments upon the price of quinine is already felt. Messrs. Gehe also mention having received from the Argentine Republic specimens of the bark, leaves, fruit, etc., of a number of plants used in that country as popular remedies. Some of these possibly may become objects of inquiry, so they may be briefly mentioned here. "Durazuillo" (*Cestrum pseudoquina*, Mart.: Solanaceæ): leaves and root bark much used in fevers and bowel complaints. "Chucu" (*Nierembergia hippomanica*, Miers: Solanaceæ): produces cold fever in animals eating it; and *Zanthoxylum Coco* (Rutaceæ) used as a remedy for the effects of "chucu." "Chanar" (*Gourliea decorticans*, Gill.: Leguminosæ): fruit used in disorders of chest and lungs; the bark used by midwives. *Zizyphus Mistol*, Griseb.: fruit a powerful diuretic. "Piquillin" (*Coudalia lineata*, Griseb.: Rhamnaceæ): used as a laxative, especially for children. *Celtis Tala*, Gill. (Urticaceæ): infusion of leaves used in affections of the chest. *Martynia montevidiensis*, Cham. (Gesneraceæ): seeds used in affections of the eye. *Prosopis Tintitaco* (Leguminosæ): fruit diuretic. "Topas Aire" (Comoositæ): used in affections of the eye.—*Pharmaceutical Journal.*

AMERICAN MAIZE IN INDIA.—Some very successful experiments in the cultivation of a few of the best species of American maize have been conducted this year in the Kulu district, by the Rev. Mr. M. Carleton, who, for some years past, has been living there. Some splendid specimens of stalks and cobs of the different descriptions of maize, and large quantity of seed, have been sent to the Punjab Government and district officers, and the Lieutenant-Governor, as a mark of his appreciation of the services of Rev. Mr. Carleton, and to encourage him in his efforts to improve and increase the food-supply of the Province, has given him a grant of R500. The following particulars regarding the experiments will interest many of our readers. Mammoth Dent corn, a new variety, said to yield in America, under high cultivation, up to 130 bushels per acres. In Kulu under fairly good cultivation, a crop of nearly 100 bushels per acre has been grown, and the Rev. Mr. Carleton considers that this description surpasses all that he has ever introduced. Blunt's Field corn: this variety was introduced last year; it bears from four to six cobs per stalk, and promises well. Western white corn: the Rev. Mr. Carleton introduced this variety four years ago, and it has done remarkably well seemingly in this country. Longfellow's Field corn: this variety comes from the extreme Northern States, especially New England, and is regarded as one of the most prolific of all the northern varieties. It ripens very early, taking only about seventy days to grow. The crop of this class was unfortunately almost entirely destroyed by monkeys. We wish the reverend gentleman every success in his experiments, which hitherto have been conducted entirely at his own expense. The sample cobs of corn grown by him would rather surprise some of our Indian agriculturists.—*Civil and Military Gazette.*

SCIENCE AND INSECT AND FUNGUS PESTS.—In 1842, Steenstrup published his celebrated work on the 'Alternation of Generations,' in which he showed that many species are represented by two perfectly distinct types or broods, differing in form, structure, and habit; that in one of them males are entirely wanting, and that the reproduction is effected by fission, or by buds, which, however, are in some cases structurally indistinguishable from eggs. Steenstrup's illustrations were mainly taken from marine or parasitic species, of very great interest, but not generally familiar, excepting to naturalists. It has since been shown that the common Bynips or Gallfly is also a case in point. It had long been known that in some genera belonging to this group, males are entirely wanting, and it has now been shown by Bassett, and more thoroughly by Adler, that some of these species are double-brooded; the two broods having been considered as distinct genera. Thus an insect known as Neuroterus lenticularis, of which females only occur, produces the familiar oakspangles so common on the under sides of oak leaves, from which emerge, not Neuroterus lenticularis, but an insect hitherto considered as a distinct species, belonging even to a different genus, Spathegaster baccarum. In Spathegaster both sexes occur; they produce the currant-like galls found on oaks, and from these galls Neuroterus is again developed. So also the King Charles oak-apples produce a species known as Tetras terminalis, which descends to the ground, and makes small galls on the roots of the oak. From these emerge an insect known as Biorhiza aptera, which again gives rise to the common oak-apple. It might seem that such inquiries as these could hardly have any practical bearing. Yet it is not improbable that they may lead to very important results. For instance, it would appear that the fluke which produces the rot in sheep, passes one phase of its existence in the black slug and we are not without hopes that the researches, in which our lamented friend Professor Rolleston was engaged at the time of his death, which we all so much deplore, will lead, if not to the extirpation, at any rate to the diminution, of a pest from which our farmers have so grieviously suffered.—*Pharmaceutical Journal.*

COFFEE LEAF FUNGUS:

MR. MARSHALL WARD'S REPORT AND MR. SCHROTTKY'S EXPERIMENTS WITH CARBOLIC ACID.

The following correspondence has been sent to us for publication :—

From Eugene C. Schrottky, to the Hon. the Colonial Secretary, Colombo.

Sir,—In paragraph 20 of the Cryptogamist's third report on Coffee Leaf Disease, lately published as a Sessional Paper, refereuce is made to experiments with carbolic acid.

1. As the short account there deals chiefly with experiments that have been carried ou for the last year under my direction and by my advice, and as it is in a great measure incorrect not only in its detailed statements but also in its general conclusions, I have been asked to furnish you with an authoritative accouut of these experiments, so that it may be placed ou record supplementary to paragraph 20 of the said Report. I have now the honour to do so, in justice to myself and in the interests of your government and the colony. My professional work as an agricultural chemist having before this come to the notice of your government with some appreciation (vide Colonial Secretary's letter to me of the 4th November 1876), I trust I shall be considered justified iu thus officially addressing you.

2. In the résumé of my work, addressed to the Planters' Association, I brought my experiments under two distinctive heads, the 1st being attempts to render the condition of the sap of the coffee tree, to some greater or less extent, unsuitable for the support and development of the fungus, the 2nd being experiments with topically destructive applications of suitable chemicals.

3. In his remarks ou the 1st set of experiments, the Cryptogamist has persisted in giving the same peculiar exposition of the principles on which I worked and of the object I had in view, as he had done previously in public print, and which on that occasiou was corrected both by the press and by professional men, who styled this said exposition as unfair.

When I commenced these experiments, I contended that as there were on nearly every estate a certain number of *individual* trees which, year after year, are known, practically speaking, not to suffer from leaf disease, while the surrounding ones are heavily affected (all external conditions being apparently similar), and as ou the other hand there are other individual trees on which the disease exists in a chronic state, which are scarcely ever free from it, though all the rest of the estate may be unaffected by it, these facts, I argued, furnish indirect evidence that there are certain unknown conditions of the coffee tree which are either particularly favourable or unfavourable to the development of the disease.

4. The Cryptogamist has given us uo explauatiou of these *established* facts well known to every planter (he conveniently ignores their existence), and the above arguments must, therefore, be accepted as sound and compatible with our present knowledge of the life history of the fungus. His statement that he has failed to obtain any evidence of a special predisposition of the tree to the disease cannot, of course, be taken to do away with the fact that such predisposition exists on the part of individual trees.

5. Such direct evidence as the Cryptogamist seems to require to confirm facts of practical observation will, in my opinion, never be forthcoming with our present chemical and microscopical means of research, no more so than any direct evidence could be produced why vaccination diminishes the natural liability to infection from smallpox.

The cause is too subtle—the fact remains.

6. Holding these views I proceeded to ascertain how far the presence or prevalence of certain chemicals in the sap of the coffee tree could produce conditions either favourable or unfavourable to the establishment of the fungus in the stoma of the leaf or to its development. To avoid any error in mistaking the cause of any observed effect, I did not choose to let these chemicals be absorbed by the roots but caused their direct absorption into the sap of the tree laterally, through the cambium cells of the stem. This novel idea, in correctness of principle fully accepted by local experts in vegetable chemistry, was, I regret to say, greatly made use of by the Cryptogamist to throw doubt upon the *bona fides* of my experiments. My proceedings were said to be opposed to all kuown laws of vegetable physiology, presumably because "No one has succeeded in proving that either stem or leaf can absorb water through their corky or cuticular coverings to an appreciable extent"; (so the Cryptogamist states in his letter to Mr. Talbot, 28th January 1881).

It became a question as to who was more competent to authoritatively decide this point. It was definitely settled by my experiments at "Holbrook" proving that such absorption in the case of the stem can take place to an extent that I myself would have thought almost impossible.

7. Details of the inoculation experiments, their results and the general conclusions they led to, you will find in enclosure.

As the planting public have been fully informed by me that even the most promising of these experiments, ou account of the evanescent character of the effects and the danger to the tree, held out no hope to me that I might find practical means to mitigate the ravages of the disease by influencing the condition of the tree, it is difficult to understand why the Cryptogamist thought it necessary to refer to it in his report.

8. You will observe from enclosure that on seven different estates careful observation had established that the main effect of inoculation with carbolic acid consisted in rendering the majority of pin-spots barreu. As every pin-spot appears capable under favourable circumstances of producing 150,000 spores, I think I was justified in considering the effect of the treatment in the light of a beneficial result and as an important step in the right direction.

The Cryptogamist's statement that "examiuation on the spot convinced him that no temporary benefits were secured," *entirely unsupported as it is*, is almost puerile in face of the large testimony of both practical and scientific observers to the coutrary.

It was of course quite within the Cryptogamist's proviuce to show that we were wrong in our deductions as regards these experiments, but in order to make a statement like the above justifiable, he ought to have supported it by overwhelming proof, showing :—

1st. Why the non-fruiting of the majority of pin-spots on the treated areas, considering that in adjoining untreated areas this fruiting had freely taken place during the same period of observatiou, could not be considered "a temporary benefit." Or

2nd. To what other cause or causes this non-fruiting of the fungus on treated areas could be attributed.

9. It is with some reluctance that I go into these lengthy details regarding experiments that have led to no practical results in my hands, but my object in thus shewing that nothing worthy of the name of proof has been advanced by the Cryptogamist against the principles and arguments which guided me in these said experiments is—to leave the way open for some more successful experiments in this direction.

Any one therefore, professing to have discovered a method or means by which the condition of the sap of the coffee tree can be rendered more or less unsuitable to the development of the fungus, should not be considered *prima facie* undeserving of encouragement and of a careful trial of his method.

10. The Cryptogamist then passes on to refer to the second set of my experiments based on what he is pleased to term "sounder" principles. As a matter of fact there are no principles at all involved in these experiments. The fungus is external to a large extent, easily accessible, and it was merely a question of empiric trial to decide what substance or combination of substances would destroy it without affecting injuriously the coffee tree.

Here, it may not be out of place to mention that the cryptogamist's *prima facie* rejection of metallic poisons as likely to be injurious to the roots of the trees is not justified, as the soil has a peculiar power of decomposing the same and thus rendering them insoluble and innocuous. I have only to point out that metallic poisons are constantly used for similar purposes with no ill effect to vegetation, singling out the successful battle with the Colorado beetle as an illustrative example.

For the destruction of Hemileia I have selected on the basis of comparative trials with a great number of suitable substances, (among which sulphur and lime,) carbolic acid as most suitable and efficient.

The properties of carbolic acid, it seems necessary to reiterate, are two-fold. In its concentrated and uncombined form it is highly caustic and destroys organic compounds by breaking up their tissue; but in certain combined forms or in a highly diluted state its causticity ceases and then its second property, that of a most powerful antiseptic even in most attenuated dilutions, comes alone into play. In its presence no fungoid forms of certain types can develop without more or less immediate collapse, and to this is due its great efficacy as a disinfectant which has deservedly raised it in the estimation of the public, above other disinfectants, such as sulphurous acid, permanganate of potash, sulphate of iron, chloride of lime, etc. In employing it against coffee leaf-disease I have relied entirely on this second property; by using it in a combined form, I have greatly reduced its causticity, and by binding it in the form of a dry powder have enabled the planter to further dilute it with anything suitable and to apply it in the form of dust to the trees.

The powder is much lighter and can be applied in more perfect manner than the sulphur and lime mixture.

11. At an early stage of my experiments I had published a description of the main composition of this powder. The Cryptogamist kindly corrects me and states: "an intimate mixture of fine clay powder containing 12 to 15 per cent. of carbolic acid is mixed with lime."

I beg to hand you the following:—

Colombo, 12th November 1881.

E. C. Schrottky, Esq., Colombo.

DEAR SIR,—In reply to your enquiries we beg to state that we have prepared the carbolized powder sent for use in your experiments against coffee leaf-disease on 'Peradeniya,' 'Pallekelle,' 'Gleneagles,' 'Gangapitiya,' and other estates strictly in accordance with your instructions, and that the same would be wrongly described as a mixture of clay and carbolic acid,—no substances of the nature of clay entering into its preparation.—We are dear sirs, yours faithfully, LEWIS BROWN & Co.

It makes of course some difference whether mere mechanical mixture of clay and carbolic acid or a chemical compound of the same is employed.

12. You will find in enclosure my statements to the effect that the powder, as used by me, parts slowly with its carbolic acid in the form of vapour, that this said vapour is distinctly noticeable under ordinary circumstances for about 8 to 10 days after each application, that further, the powder touching by nature of its distribution the different external forms of the fungus either on the leaves or scattered elsewhere about the area, as well as the vapour given off by it, it will have a maximum effect when there are heavy dews or slight showers after the application to supply the moisture necessary for (absolute) contact, and that I advised not less than two applications following at an interval of ten days.

The spores and other forms of the fungus would therefore be kept, by this said treatment, in an atmosphere tainted with carbolic acid for a minimum of twenty days; they would be subjected to the influence of condensed moisture, such as dew, or of showers of rain, thus enabling the powder to establish contact where it touches the spores etc. and likewise dissolving the vaporized carbolic acid and making it effectual where the powder does not actually touch the fungus.

13. Being fully aware of these statements on my part, the Cryptogamist now describes in the paragraph under comment, an experiment setting forth that spores subjected to the action of an atmosphere containing vaporized carbolic acid for 24 hours had germinated and that therefore as with other reagents the germinal tubes will have to be attacked with a solution of the acid. This experiment has been wrongly quoted by the Cryptogamist and supplies no data bearing in any way on the merits of the carbolic acid vaporization process, as recommended by me.

The Cryptogamist omits to use the powder which I or others would have gladly supplied him with, he keeps the spores only for 24 hours in contact with a carbolized atmosphere, and he fails to supply the *condensed* moisture necessary for contact.

14. I fail to reconcile some of the Cryptogamist's further statements regarding the action of the powder on the fungus. He says: "It is true that where water is in contact with the powder a solution is obtained sufficiently strong to kill germinal tubes, but the diffusion of this over the leaf is a very slow process" and then further on—"but such a solution is not produced in the way described in the experiments at Gleneagles, Pallekelly, etc."

It ought surely not be necessary for me to point out that nature is not sufficiently prejudiced to withhold dew and rain, which the Cryptogamist considers affords sufficient moisture to form a solution in the case of the sulphur and lime treatment, so prominently brought forward by him.

15. There remains now only for me to deal with the Cryptogamist's opinion "that more might be done with some modification of the powder, if it were not for the fact that *the accumulated powder and solution are a source of danger at the roots.*" This is illustrated by an experiment, shewing that a mixture of carbolic acid powder and lime was sprinkled round the trees, then watered for three weeks and that the results were disastrous to the trees. There are, however, no details given as to whether the ordinary carbolic acid powder (which *is* a mixture of clay and acid) or the special prepared powder as used by me has been employed; the age and condition of the trees are not given, nor the quantity of powder used per tree, nor the amount of water per square foot which has been consumed in watering these said trees for three weeks. In the absence of these details I cannot further comment upon this experiment.

Suffice it to say that my experiments either on small or large areas have yielded sufficient evidence to enable me to state that there is neither now nor has there been at any previous stage the slightest reason to think that the carbolized powder in the way and manner in which its use has been recommended by me, has affected or is likely to affect the trees injuriously through its being washed down to the roots.

The nature of carbolic acid, an essential organic compound, makes an accumulation thereof in the soil, impossible.

16. In connection with this subject the Cryptogamist says or is made to say by the printer: "The effects of even a diluted solution of carbolic acid at the roots are disastrous, though in the case of a large strong tree they be to a certain extent masked by other changes. But observations on whole estates prove the same." There is some error in this last statement. *No such observations have been made.*

17. I have, of course, not entered upon these experiments without fully considering the possible effect of the treatment in all its bearings and our present chemical knowledge of the properties of carbolic acid in combined and uncombined forms justifies my saying that used as recommended by me, the danger to the trees of accumulation of the said powder in the soil apprehended by the Cryptogamist, is groundless.

18. As practically of more value than the above remarks I have the honor to append to this the result so far of the carbolized powder treatment on two estates. I have selected these two estates from among four on which my advice not to operate on less than 100 acres has been taken, as sufficiently representative to illustrate what success and what failure has resulted so far, if we take as a measure the extent to which the treatment has succeeded in keeping the area practically free from leaf-disease.

You will observe that even in the case of what I style a failure, important beneficial results have been obtained and must be attributed to the mitigation of the disease by the treatment; but these are collateral benefits apart from the main question and may for the present be left out of count.

I stated nearly six months ago in my *résumé* that the degree of success will depend on *how* and *when* the applications are given. Experience has enabled me now to emphasize this statement. Full details will be given by me in due time, when the planting public will rouse itself to action. In the meanwhile I may say that I can only direct and advise: the success of the treatment, if success there is to be, rests with the planter; and if therefore estates that have passed successfully through the periodical south-west monsoon attack of the disease get equally well through the north-east monsoon attack, the planting community will owe a debt of gratitude to those of its members who, other circumstances as time of application etc., being most favourable, have successfully battled the disease by possessing to an eminent degree the two qualities, essentially necessary for a work of this kind viz:—PATIENCE and PERSEVERANCE.

The subject matter of this communication being of considerable general interest, I have taken the liberty of sending copies thereof to the Chamber of Commerce, the Planters' Association and the Press, for their information.—I have the honor to be, sir, your most obedient servant,

EUGENE C. SCHROTTKY,
Technical and Agricultural Chemist, etc.

Colombo, 16th November 1881.

APPENDIX A.

Failure of the Carbolized Powder Treatment at Gleneagles Estate, Agrapatana.

1st application in May. Management changed end of May. Present manager writes to Messrs. Whittall & Co., June 20th, 1881:—"To the *naked eye* Mr. Schrottky's treatment has had a very marked effect on the fungus...I calculate that from 70 to 75 % of the fungus has been destroyed; and though discoloured in places, the leaves still appear to perform their functions and do not fall when the tree is shaken, as in the case of diseased leaves." It was observed that the fall of leaf had been less at that period than on surrounding estates and a careful investigation was made. Leaving out details the manager writes:—"The foregoing figures on analysis show that Gleneagles had lost per tree 11 leaves from disease and from 16 to 17 leaves due to other causes; while —— an adjoining estate[—*E. C. S.*] had lost per tree 82 leaves from disease, and 10 leaves from other causes. The above figures I purpose verifying some 3 weeks or one month after the next application, but they are in the present instance as correct as any can be, and we have satisfied ourselves that nowhere on other portions of the estate was there a greater fall of leaf than on the fields selected for investigation. I think, therefore, there can be little doubt that if the vaporisation has not entirely eradicated leaf disease it has prevented to a very great extent a heavy fall of leaf."

II.

A neighbouring planter having seen Gleneagles before the treatment and having taken part in the inspection writes to Messrs. Whittall & Co. 24th June 1881:—"I have been in the habit of seeing the coffee in the field above the road to Gleneagles bungalow from time to time during the last year and I have often observed that this particular field was one of the parts most subject to leaf disease on Gleneagles or on the adjoining estates. Six weeks ago it was suffering from a very bad attack and when I went up with Mr. Schrottky on the day of treatment, I called his attention to the fact that here leaf disease was to be found in its most acute form. I can now say that this field at least seems to have been cured by the vaporization, for I have never seen it for the last 12 months more free from leaf disease than it is at present. Regarding the comparative fall of leaf on —— estate and on Gleneagles I can only add my sorrowful testimony that I was a witness to the investigation. The fact is patent that more leaves and those mostly diseased have fallen on the untreated area than on parts treated by Mr. Schrottky's method."

III.

Mr. J. Whittall writes to Mr. Schrottky, 20th September 1881:—"I was over Gleneagles estate last week and it certainly compares favourably in appearance with ——, ——, and other properties around; at the same time there is no doubt it has also suffered badly from leaf disease."

IV.

Mr. Schrottky's report to Messrs. Whittall & Co., after the south-west monsoon attack of the disease had passed away—20th October 1881:—"I find, generally speaking, but little leaf disease present in a vigorous, *growing* condition. There are sufficient remains, however, to show that in parts of the estate the S. W. monsoon attack must have been a pretty severe one, though even now sufficient data are available to prove, on comparison, that it has not been as severe as on neighbouring estates.

"Broadly speaking, I cannot say that the treatment here has kept the disease in bounds as much as it has done, so far, on other estates, and though the weakness of the trees, where grub is prevalent, had no doubt a great deal to do with the severity of the attack in some parts, I cannot, considering the nature and habit of the fungus, attribute the but partial success here of the treatment to the *presence of grub*. I am of opinion that even with grub we can stamp leaf disease out, if only the treatment is systematically carried out. Unfortunately the change of managership and the continuous rain after the new manager had taken charge has stood in the way of my instructions being strictly carried out here. These were originally to give three applications at about ten days' interval; so

that whatever disease may linger on through the first application would die out during the following two applications, before it had time to regain vigour, fruit and re-infect the estate.

"The three applications were given here on the 13th May, 23rd June and 30th July respectively, that is at about five weeks' interval, this being sufficient time for whatever percentage of the fungus had escaped one application, to regain vigour, fruit and spread a thousand-fold, before the other application followed. This experience, of course, enables me now to say the treatment must be carried out at a certain time and with a certain system and at *no other* time and in *no other* manner. This much as regards the actual prevalence of the disease past and present.—The next question we had to consider was, what has been the effect of the treatment on the trees generally? It is with regard to this question that we have come to a conclusion which, under the circumstances, must be considered a most important and satisfactory one. On my very first round through the estate the manager drew my attention to the blackening and dying back of the branches of the trees (due, as has been proved now, almost exclusively to the effect of leaf disease), and he stated that this had taken place at Gleneagles to nothing like the extent it had done in surrounding estates, and that a neighbouring planter observed first this difference and pointed it out to him, the manager. We have verified this important fact, not only by general observation and comparison, but also in detail by counting the dead branches on the different descriptions of trees 'in the *worst* bit of that part of Gleneagles which has suffered *most* from grub and leaf-disease combined' and compared result by counting the dead branches on trees in similar, untreated fields. We counted on treated fields on Gleneagles on average *bad* trees 35 primaries and secoudaries that had died back. On average fair trees, an average of 9 dead branches only. At one untreated field we counted on average *bad* trees 69 dead branches, on average fair trees, 60 dead branches, at another untreated field on average *bad* trees, we counted 117 dead branches, on average *fair* trees 78 dead branches; as the average fair trees constitute quite 75 per cent of the trees in the fields we compared, Gleneagles stands with regard to the dead branches on these trees as 9 to 60 at one field and as 9 to 78 at the other field."

The manager, in forwarding this report, adds in a letter to the firm—21st Oct. 1881:—"The figures as regards the dying back of the branches are correct and nowhere here have we the same extent of bare-looking coffee as there is on the estates named by Mr. Schrottky."

The field on Gleneagles above referred to had been manured six weeks before this examination, and the question came to be considered whether this non-dying back of the branches might not have to be ascribed to the effect of the manure. But as this dying back is the work of some months, there is no room for doubt left that the benefit must be ascribed to the carbolized powder treatment.—E. C. S.

Main results:—A mitigation of the attack; leaf disease worse in adjoining estates; collateral benefits, such as, comparatively speaking, diminished fall of leaves and corresponding reduction in the dying back of branches, but failure of the main object to keep leaf disease practically out of a given area.

Success so far of the Carbolized Powder Treatment at Gangapitiya Estate, Dumbara Valley.

The history of the estate: Rather old coffee, generally regarded as a nest of leaf disease, reporting very bad attacks twice a year, in October and January.

I.

Extract from the visiting agent's report to Messrs. Whittall & Co., 2th April 1881:—"The coffee is not looking well, most of the wood has been spoilt with leaf disease."

II.

First application of the carbolized powder on 21st April.

About ten days after application: "I examined some of the leaves that had a bad attack on them (before treatment) and it appeared, as if the lime and carbolic was killing or eating up the fungus, and left the diseased patch with the same appearance, as if the leaf disease insect had been feeding and sucking out the spores. But some seem still to have escaped." Extract from estate report to Messrs. Whittall & Co by 30th April 1881. L. B. VON DONOP.

III.

"I met Mr. Schrottky this morning at Gungapitiya and we examined together the results of the treatment here. He considers them most satisfactory, and *so far* as the experiment has gone, I most certainly agree with him.

"In exposed places such as along roads and ridges trees were found very badly affected, but this it appears is caused by the powder [or rather its vapour,—E. C. S.] being blown away from there, as inside for every twelve leaves affected, only on one could a living fungus be found. The rest of the leaves had a black spot, where the fungus had been established. On those where the disease had only commenced, a dried up pale yellow mark was observable but in both cases (which I consider most important), the leaves appeared healthy and performing their functions." Extract from a letter to Messrs. Whittall & Co., by L. B. VON DONOP. 31st May 1881.

IV.

"The estate may be said to be free of leaf disease, but occasionally two or three trees are found to be diseased; these trees and also those surrounding them are at once well powdered with the preparation, so as to try and prevent it going any further.' Extract from manager's letter to Messrs. Whittall & Co., 11th September.

V.

Extract from the Visiting Agent's Report, 28th September 1881.

"Since I was last here the coffee has improved very much in appearance, most of it is now looking luxuriant and vigorous.....We scarcely saw a sign of leaf disease."

VI.

"Mr. Schrottky arrived here this morning and we had a look round the estate. As I pointed out to Messrs. Whittall and Young on the 28th ultimo, there is a little disease on the flat that adjoins the river and also on two or three small patches where there is heavy crop. It does not seem to have spread, and the rest of the coffee may be said to be free from leaf disease. In looking back at old reports I find that leaf disease has usually been very bad during the month of October and at the present time I know that there is a great deal of disease in the district." The Manager's letter to Messrs. Whittall & Co., 10th October 1881.

VII.

"The trees are again beginning to throw out new wood and the estate may be said to be *practically* free from disease." Extract from manager's letter to Mr. Schrottky, 3rd November 1881.

A CURE FOR HEMILEIA VASTATRIX? MR. SCHROTTKY'S EXPERIMENTS WITH CARBOLIC ACID.*

"There are more things in heaven and earth than are dreamt of in our philosophy," and amongst the apparently insoluble mysteries seems destined to remain the sudden development and rapid spread of the coffee leaf fungus in 1869. It was known that the climate of Ceylon, combining almost constant moisture with tropic heat, was specially favourable to the growth of those low forms of vegetation known to naturalists as fungi, but amongst some sixteen hundred species described by Thwaites, Berkeley and other cryptogamists, not a trace of that ultimately named *Hemileia vastatrix* had been discovered, until it suddenly appeared and rapidly overspread the whole expanse of cultivated coffee about twelve years ago. The new fungus was equally a surprise to cryptogamists and coffee planters, and Berkeley's instincts guided him aright when he added to the name of this fungoid pest the same qualifying term which had previously been applied to the insect destroyer of the grape vine: *vastatrix*. Each in its way shews how powerful for destruction very minute and apparently contemptible natural agencies may be. The fungus which has inflicted such terrible injury on a great enterprise in Ceylon and Southern India, which has appeared in Sumatra and Java, and even in that far isle of the Pacific, Fiji, seems to confine itself to coffee. Mr. Ward has mentioned another plant on which the fungus has been found, but we believe that plant is closely allied to the coffees. As the doctrine of spontaneous generation is out of court, we seem confined to the conclusion (originally arrived at by Dr. Thwaites), that up to 1869 the fungus existed on the indigenous coffees in our jungles, but in a low and latent form. What cause or combination of causes, in the shape of atmospheric or other influences, gave the fungus such virulent activity in 1869, is, as we have said, still a mystery unsolved. But all the evil effects which Mr. Ward attributes to wind (the worst of the triad of planters' foes: "wind, wash, and weeds") may justify the guess that the opening up of large expanses for coffee culture favoured the rush of wind into such spaces, the moving air first passing over forest containing trees infected with the fungus and carrying the spores on its wings. This is what the wind does now in careering over fields and plantations of coffee, and perhaps the most important lesson to be derived from the elaborate reports of Mr. Marshall Ward is the necessity of providing for our coffee fields that *shelter* of which it was a mistake ever wholly to deprive them. We are familiar enough with the difficulties, objections, and reasons which led orthodox planters to leave nothing on their plantations but coffee. Of course the extensive cultivation of cinchonas on coffee estates has to some extent remedied the mistake which was made. But cinchonas themselves require shelter, and vast numbers either die out or are cut down or rooted up year by year. The time, therefore, seems to have arrived for lining off plantations into moderately sized squares by means of the rapidly growing eucalypti and acacias of Australia, trees which combine rapidity of growth with a good quality of timber at a comparatively easy stage of growth. Those who believe in the doctrine of cycles will not forget that leaf disease has now been ravaging our coffee for over eleven years. A decrease in the virulence of the pest, therefore, may be now confidently expected. And even those who doubt the cycle theory must admit that pests of a like nature, the coffee bug for instance, have abated into comparative innocuousness with "effluxion of time." But, while looking for relief to "time the healer," judicious cultivators will not neglect any one of the lessons which their own experience and the observations of scientists have taught. We can understand some feeling of despairing impatience, when planters are told that manure they must, although with the knowledge that much of the manure they apply will go to feed the parasite instead of the plant. Culture, pruning, and application of remedies, too, must be so attended to as to induce the tree to put on and *mature* its foliage in advance of the period when the winds of the monsoons blow the spores on to the leaves, while the moisture of the monsoons favours the rapid germination of such spores. The better grown the leaves on a tree are, the better able they will be to resist the insidious fungus. It will be gratifying to Mr. D. Morris and his friends to be assured that the effect of Mr. Marshall Ward's extended experiments and careful research is to confirm the value of a combination of caustic lime and sulphur, resulting in the production of sulphurous acid gas, as a remedy for the fungus. It would be "a perfect cure," if we could only apply it to every existing spore, for certain it is that every spore which sulphurous acid gas reaches, it destroys. The limit to total destruction is the physical impossibility of the universal application; while even such partial applications as are known to be beneficial to such areas as can be reached are limited by considerations of finance. The idea that trees treated with lime and sulphur, and so cleared of leaf disease, become in their last state worse than in their first seems due to the fact that a tree freed from the debilitating fungus is enabled to put on a large crop of foliage, and if that foliage is not itself protected by the application of the remedy, the appearance of the tree when re-infected is bad in proportion to the number of leaves it carries. To be effectual in keeping fields of coffee or whole plantations free from fungus and its debilitating effects, the envelope of sulphurous acid gas must be kept up by *frequent applications of lime and sulphur, at shortly succeeding intervals*. The effect of "the interactions of sulphur and freshly burnt lime on the moist leaf" are thus enumerated in Mr. Marshall Ward's latest—we are sorry to believe his *last*—Report:—

(1) The mixture is slowly continuous in action for a long time.

(2) The slowly-evolved gases distribute themselves rapidly by diffusion.

(3) The chief gases are very readily dissolved in water.

(4) The solution formed is strong enough to kill the germinal tubes, but too weak to injure the leaf.

(5) The acid solution does not concentrate to a dangerous strength, since it is continually being absorbed by portions of the lime, and the compounds become further oxydized to neutral or nearly neutral salts.

(6) Not only are the final products harmless to the tree, but the chief one (sulphate of lime) is a valuable manure.

(7) The mixture is simply and readily applied by coolies' hands.

The merits of sulphur and lime being thus so great, it is unfortunate that the cost of purchase carriage and

* See Mr. Schrottky's letter on page 515.

application of these substances should be so great as to be practically prohibitory, not only as regards frequently repeated treatment, but even with respect to one application in a year. The cost of experiments ably conducted by the late Mr. Anton on Harrow estate ranged from R20 to R47 per acre, an average of R33·50, or say £3. One thorough application of lime and sulphur, costing £3, destroys, according to Mr. Schrottky, only 40 per cent of the fungus existing on the trees. To be fully effectual the application should be repeated twice again at short intervals, so that the cost would be raised to £9 an acre. Now what Mr. Schrottky professes to prove, in the correspondence which appears in today's issue, is, that carbolic acid, in the form in which he applies it, while not open to the objections stated by Mr. Ward, either as regards destruction of tissue or injury to soil, is effectual in destroying, by one thorough application, 70 per cent of the fungus at a cost of only R5 to R7 per acre, say an average of R6, or less than one-sixth the cost of lime and sulphur. Three applications of carbolic acid powder would cost only R18, and Mr. Schrottky, as we understand him, insists on three applications at intervals of ten days to ensure perfect success, the area operated on not being less than 100 acres. We have gone over the whole question in conversation with Mr. Schrottky, and he seems confident of his position. Injection of the acid into the cambium of the plant, he admits to have been in his hands a failure, while he does not abandon the principle involved. But for applications of his powder, repeated as indicated, he claims perfect success. And we understand him to claim for his application an effect which Mr. Ward has denounced as impossible. The Government Cryptogamist insists that nothing (short of the destruction of the leaf, of course) can destroy the fungus once it is lodged in the intercellular tissue. Mr. Schrottky contends that his remedy prevents fructification in such cases: the importance of which fact may be estimated from this other, that out of one stoma may come 150,000 spores. As we understand Mr. Schrottky, the effect of his remedy on the affected leaf is that not one of the possible 150,000 spores lives to emerge. All this he says his experiments have proved, and, if he is correct in his facts and deductions, we need not dwell on the importance of the issue. In the course of a long conversation, in which our enquiries were very searching, Mr. Schrottky revealed to us the composition of his powder. He did not enjoin secrecy, but we do not feel at liberty without his permission to publish the constituents of the powder, almost impalpably fine, which he employs. It is prepared expressly for him by Calvert's firm, and we may say that the absorbing substance is not clay, while the proportion of acid is far less than that contained in the common preparation which Messrs. Lewis Brown & Co., Calvert's agents, advertise as "15 per cent powder." This means that 15 per cent of carbolic acid, which is in the nature of an alcohol, is in this case mixed with clay. When the acid goes off in the form of gas, which it gradually will when exposed, the inert clay will remain, and, obviously, its effect on coffee soil would be almost *nil*. In the case of Mr. Schrottky's powder, the acid is not only far less in proportion to the solid matter than 15 per cent (so that while fatal to the fungus it does not destroy leaf tissues) but the residuum, instead of being merely inert like clay, or injurious to the soil, as Mr. Ward mistakenly imagined, is positively beneficial to the soil as a fertilizer.

Steering clear of the controversy between the scientists —one eminent as a mycologist while the other has the no small advantage of being an experienced chemist— we have thus endeavoured fairly to represent the main results of experiments conducted by Messrs. Marshall Ward and Schrottky. Gratitude is due to each for valuable additions to our stock of knowledge in regard to a painfully interesting question. Mr. Schrottky, however, claims for his carbolic acid powder superior qualities of cheapness and effectiveness, which, we submit, demand attention not only from planters, who are so deeply interested, but from the Government to which Mr. Schrottky's paper is directly addressed. Before Mr. Marshall Ward leaves the island, we trust that he, in conjunction with Drs. Trimen and Thwaites, and perhaps some other naturalists or men of science, may be requested to aid a committee appointed by the Planters' Association, in thoroughly testing by a complete set of experiments the correctness or otherwise of the effects which Mr. Schrottky claims for carbolic acid powder as prepared for him. The preparation being very different to that which Mr. Marshall Ward, under a natural enough misapprehension, condemned, there can be nothing inconsistent in his taking part in the proposed enquiry.

But, if all that Mr. Storck of Fiji alleges can be substantiated, then a perfect cure for *Hemileia vastatrix* has been already discovered in that island of the south to which we sent the coffee fungus with the coffee seed. We in Ceylon are not too proud to receive good in return for evil, and we shall look with very deep interest for the advent of Mr. Storck, who thus writes to the *Fiji Times*:—

SIR,—In continuation of former publications on the subject of coffee leaf-disease, I wish to communicate another short paper with a view of dispelling certain incorrect impressions held by the general public, and which are even shared by experienced planters, who might have been expected to know better. The most widely disseminated and at the same time most discouraging belief with coffee planters, consists in the erroneous notions on the term of life enjoyed by the units of the fungus, which is in reality very short. Leaving on one side all microscopical and physiological speculations, we may consider the red rust appearing on the under side of a diseased coffee leaf as a mass of seeds, which practically speaking, partake more or less of the nature of any other seedling.

It is a fact sufficiently well established by scientific men, and other close observers of nature, that Hemileia Vastatrix lives and preys upon no others but the coffee plant, just as Botrytis Infestans confines itself to the potato, and Oidium Tuckerii to the grape vine. Of the numberless spores of the coffee fungus, thousands of millions alight upon uncongenial bodies, whether organic or inorganic, there germinate and perish for want of congenial food and shelter. Comparatively few only reach the under side of a coffee leaf, and finally succeed in finding their way through by means of their germs into the cuticle of the leaf and there establishing a new root-stalk or mycelium. Were the natural propagation of the fungus not so precarious, no coffee plant could live where it is once habilitated. The spores are said by scientists to germinate within from one (?) to seventeen days, and this space practically determines the extreme age of a spore under natural conditions. A great deal has been made of the circumstance of spores of the fungus having been kept and their vitality preserved in letters, that means between dry paper, for two years, and which is quite likely. The spores of ferns, especially similar to those of

fungi and other crytogamous plants, have been known to germinate when kept under similar conditions between the sheets of an herbarium after more than twenty years; but the same spore under natural conditions, within the influence of the moisture and temperature of their native soil and atmosphere, must within a certain time germinate and take root or else perish.

When, some eighteen months ago, a certain area of coffee plantation was destroyed, there were a number of stumps left in the ground. They were stumps of old coffee trees mostly, sluggish in vegetation, and slow to produce new growth; they all made a start after a while and grew up free of disease, and continue so to this day. This plainly shows that before the new vegetation had formed sufficiently to afford a home for the disease, the fungus had actually died out for want of food.

Based upon the above mentioned facts and my own observations, I started my several experiments, and I claim to be the first to have reduced the treatment of Hemileia Vastatrix to a rational system, the pursuit of which has so well rewarded me with unqualified success. I would rather now deal with the coffee fungus than with a bad weed.

An attack of leaf-disease lasts from seven to ten weeks, nor would the treatment of it last longer, provided there was no chance of re-infection from outside of the area treated.

But unless the treatment becomes general and simultaneous throughout the country, both in the plantations of white proprietors and the nurseries and patches planted by the natives, it will have of necessity to be permanent, for which my method is eminently adapted. Should however the Colonial Government adopt my treatment with a view to making its application general, I would undertake to stamp the disease out in this country as completely as if it had never been here. Kill all the spores as fast they form and what must be the result? Once more let me assure your readers that size and numbers of areas to be treated makes not the least difference to me. I undertake to cure, and keep clean for ever after, any or all of them, at moderate cost.—I am, etc.,

JACOB P. STORCK.

Upper Rewa, Sept. 9th, 1881.

It will be seen that Mr. Storck is ready to extirpate the disease from the island. If the larger design is not encouraged, then he says he can "undertake to *cure, and keep clean forever after*, any or all [areas of whatever size], *at moderate cost*." If any man—whether his name is Schrottky or Storck—can fulfil the promise so expressed, he will go down to posterity as the greatest benefactor of the coffee enterprise and of coffee planters in the Oriental and Austral portions of the world; for the effects of the coffee pests have to be gauged not merely by ruined fortunes but by blighted lives and broken hearts.

CHINA GRASS DRESSING MACHINES.

By C. G. WARNFORD LOCK.

(*Journal of the Society of Arts*, 21st October 1881.)

I have just received from the Agricultural Department of the Indian Government a report on the trials of the China grass machines,* which was intended for incorporation in the article on "Fibrous Substances" in Spons' "Encyclopædia." It has arrived too late for this purpose, but will probably interest readers of the *Journal*.

The seven competing processes may be thus briefly described:—

1. J. P. Vander Ploeg's appliances consisted of a crushing and a scutching machine; he cleaned the fibre finally by boiling it in a prepared liquor.

2. J. Nagoua used a combined crushing and scutching machine, adaptable to both operations.

3. R. H. Collyer boiled the stems first in water with a very little soda, then passed them through a machine which broke them up, and again through the same to clean them. He had also a smaller manual machine costing only £60, but unsuitable for a regular factory.

4. Laberie and Berthet's machine crushed the stems, which were kept constantly wetted; the fibre was then steeped in a bleaching liquor and an alkaline liquor.

5. J. Cameron abandoned the machines described in his specification, and brought a hand implement.

6. C. F. Amery broke the stems in a crushing machine, boiled them in an alkaline solution, and again passed them through the breaking machine.

7. C. E. Blechynden steamed the stems, peeled them by hand, and then beat them by hand with mallets.

The reports of the experts upon all the samples turned out by the competitors concur in placing them far below the fibre imported into England from China, which is valued at £50 a ton. The most favourably received samples were Nagoua's, described as containing "some good fibre, and fairly marketable," and valued at £26 a ton; and three lots from Cameron priced at £15, £18, and £11 a ton respectively. One of Cameron's samples was approved of as being the best as far as freedom from bark was concerned; but the fibre was broken and tangled, would never give so large a yield of silver as Nagoua's, and the silver would not be so long. The brokers say that none of the samples are nearly up to the requirements. Nagoua's is the only one which could be used for China grass purposes, and this would only sell freely in a market bare of the regular article. Accordingly, the prizes originally offered will not be awarded, but certain of the competitors are recommended for smaller grants. The lesser value placed upon Vander Ploeg's fibre is attributed to the fact that he aimed at producing it in a finished state fit for the spinner, and not to the inability of his machines to compete with Nagoua's and Cameron's. It is also remarked that Cameron's process is but an improvement upon native methods current in India, and such as is applied in many of the Indian gaols for extracting aloe fibre; it can be employed upon green or dry, short or long stems, but would hardly be applicable on a plantation where many acres had to be cleared quickly. Therefore the recommendations are 5,000 rupees each to Nagoua and Vander Ploeg, and 1,000 to Cameron.

The committee conclude that, from the low valuation put upon the samples produced at the competition, it does not seem probable that the Indian product will yet be able to compete with the Chinese. But if the plant can be grown in the moist climate and rich soil of parts of Burma, Upper Assam, and eastern and northern Bengal, with only the ordinary care required for a rather superior crop, it may possibly succeed commercially. Until this has been satisfactorily proved, and a real need has arisen for effective modes of treatment, the Government has no intention of renewing the offer of prizes; and will content itself with maintaining some acres of the plant under cultivation, for supplying roots to intending growers.

Thus, even after much experience has been gained in the matter, and with every incentive to success, the machinists of Europe are compelled to confess their complete inability to match the manual work of the Chinese. It may be incidentally remarked that out of the seven competitors, no less than four dropped from their proposed plans, these four including all the English. This fact seems to indicate an imperfect previous acquaintance with the material to [illegible], and amounts to an acknowledgment at the eleventh hour that they had been working in the wrong direction. This may probably help to account for their awkwardness. On the other hand, of the remaining three, two (the Frenchmen) have presumably not confined to experiment upon the plant which is under cultivation in the south of France, and they are in fact already well known among Continental textile [illegible]. The moral of this is the necessity for further experiment on the part of English machinists.

LEAF DISEASE IN LOWER MATALE.

Lower Matale, 20th Nov. 1881.

DEAR SIR,—During December and January last, the coffee hereabout suffered very much from a severe and prolonged attack of leaf disease. The ground became thickly covered with fallen leaf, the denuded branches blackened and died off, while a very fine blossom, which had previously seemed to have set well in the most favourable weather, also blackened and died off. In fact, on my return after a few days' absence, the coffee looked as if a fire had passed over it. In this forcing climate, however, the coffee with a good pruning quickly recovered, and though the crop is moderate and late, yet till the other day I have never since seen any appreciable leaf disease, while the trees have been better and more largely clothed with leaf and wood than I have known them to be for many years back. A few days ago, however, I noticed leaf disease rather bad here and there in all stages, while in parts there had been a rather heavy fall of leaf, particularly on trees that had cropped well. I may mention that the latter part of the S.W. and the early part of the N.E. monsoons have been very showery, but that the coffee is very little exposed to the wind of either monsoon: of the latter monsoon there has as yet been hardly a breath. The soil is good, the coffee well cultivated, and is quite an average for lowcountry, the elevation being from 1,200 to 1,500 feet.

Returning home yesterday morning, I thought I would pass through an estate in the neighbourhood which I knew had been systematically "schrottkied," just to compare notes. This estate is in all respects very similar to this, though perhaps not so well cultivated as regards weeding and pruning, but *under* Mr. Schrottky's directions, the whole of its coffee was treated with his powder. Later on I understand this was done a second time, and that, besides, any trees showing signs of disease had one or two other applications. Mr. Ward may perhaps be interested in hearing that early in the year the fallen coffee leaves were carefully collected and burned *all* over the estate. I would just further add that this property, like my own, is well surrounded with chenas and paddy-fields, with the exception maybe of a few small coffee gardens.

As I approached the estate, I perceived a very fine coral plant clearing, but, on passing through it, I discovered this was merely shade and shelter for chocolate and Liberian of all ages, from three years downwards. I was sorry to notice a little leaf disease both in the pin-spot and germinating stages on several of the Liberian plants, and some rather bad on a few younger specimens. As I reached the store, I observed a large pile of empty barrels, which I concluded had brought up *the mixture*. Round about I saw a good deal of very vigorous looking coffee, which, after careful examination, seemed to be practically free from disease. As, however, I have such patches on my own unschrottkied place, I determined to advance, and I very quickly came upon coffee with the fell disease in all its glory, in all its stages, quite as bad as anything I have. And yet this coffee had been several times treated with Mr. Schrottky's mixture, the last as late as last month or early in this, and the foliage was even yet largely covered with the mixture. The pest seemed chiefly in the fruiting stage, and the spores appeared to be remarkably healthy and well-coloured. One little collection of spores had several particles of the mixture right on the top of them, so that apparently the filament had grown right out of a stoma and fruited, quite unaffected by the little pile of mixture over or near. The pin-spots generally looked healthy, and I do not think more had gone bad than the usual percentage resulting from natural causes. Near the bungalow I was shown a few trees of vigorous coffee, which I was told had been treated six times with the mixture during the last ten months. On these I found abundant healthy leaf disease. On the other hand, I found one redeeming promising point. There seemed to be no fresh fall of the leaf, and, considering the comparative less vigour of the trees, one would have expected to find a very considerable fall. Still, it does not follow, that this absence of fall is a result of the Schrottky treatment. The time for the fall then may not have yet come, or it may be retarded by some unknown natural cause, or it may have taken place some time ago. Nevertheless, there is the fact, and Mr. Schrottky is entitled to make the most of it. If at a small cost we can only manage to prolong the attachment of the leaf, the benefit would be enormous, and would give promise of hope for something further. But, so far as the warding off of the disease, his system, I fear, is practically a failure.

I think it was this gentleman who reminded us that one fact was better than a dozen theories. Let him then come up and study these facts, instead of wasting his time theorizing on paper to Government. I wish him every success, partly for my own interests, and partly because he has worked away at the practical part, and mainly at his own expense. Whereas, at the country's expense, Mr. Ward has laboured diligently for the scientific world. Any practical suggestions made by him have been little more than a re-warming of the recommendations of others. Shortly after his arrival he told me, that, if he found he could do the planters no good, he would pack up and be gone. 'T is a pity that he only found out this sorry result, just as his term of engagement was about to expire. As he is if anything more confident and dogmatic than Mr. Morris was, it is to be hoped that his "life history," when he is gone, will not also be found wanting; but when one thinks of host plants and the imperfectly followed up class of spore, one feels not merely practically unbenefited, but also scientifically doubtful.—Yours truly,

A. G. K. BORRON.

JAMAICA.—The *Gleaner* complains that the export of walking-sticks threatens the extinction of the pimento, from which such canes are cut, the negroes stealing them from the pimento walks. The island still escapes the yellow fever now raging in other West Indian Colonies. Sir Anthony Musgrave has contradicted a report that he would be immediately succeeded in the Governorship by Sir Henry Irving. The port of Havana (Cuba) has been declared infected.—*Colonies and India.*

TEA FARM.—The *American Grocer* speaks as follows of an experimental tea farm started by the United States Government:—"The Commissioner of Agriculture, Hon. W. G. LeDuc, has recently leased for twenty years two hundred acres of land to be used as an experimental tea farm It is situated at Summerville, S. C., twenty-two miles north-west of Charleston on the line of railway running from Charleston to Augusta. Lands were first examined in Florida in the vicinity of Jacksonville and along the St. John's River as far as Palatka. Tea plants that had been furnished by the Department were found growing in a thrifty manner. The farm in South Carolina is to be placed in charge of an expert whose experience was acquired in tea cultivation in India. The Commissioner is firm in the belief that tea culture can be made a profitable industry in the United States. There would be a better chance for success were the enterprise not dependent upon the whims of Congress."—*Produce Markets Review.*

To the Editor of the Ceylon Observer.

SALT FROM THE NIPA PALM.

Colombo, 21st Oct. 1881.

DEAR SIR,—In recent numbers of the *Tropical Agriculturist*, Messrs. W. Ferguson and M. Cochran gave interesting descriptions of the production of lime from the kumbuk tree. The following extracts regarding the manufacture of salt from the nipa palm may also, perhaps, be deemed worthy of insertion.—Yours, KÁROLY FÜRDÖ.

"On the left bank (of the R. Abai Borneo), there are two small branches, Gading and Paka Paka, inhabited, the Data (chief) said, by some villager of Ida'an. There appear to be but few people living on this river, or rather salt-water creek. Three very small hamlets, containing altogether about thirty houses, were all I saw. There are numerous sheds for making salt, which appears to be the principal industry of the Bajus. The manufacture is conducted as follows:—Great heaps of the root of the nipa palm, that always grows in salt or brackish water, are collected and burnt; the residue is swept up and thrown into half-filled pans, where the ashes and small particles of wood are separated and the water boiled; a coarse bitter salt is the result. It is not disagreeable after a little use, and I much prefer it to the common article brought from Siam, and generally sold in these countries. The natives of the north seldom use the imported salt, except for preserving fish, whereas towards Sarawak, the Siamese is rapidly taking the place of that procured from the nipa palms."

"The nipa palm is indeed a blessing to the natives; as we have seen they make a salt from the ashes of the root; they extract a coarse sugar from the stem: they cover in their houses with the leaf: from the last also they manufacture the mat called kejang, with which they form the walls of their houses, and the best awning in the world for boats, perfectly water-tight, and well-adapted to keep out the rays of the sun. The cigars are rolled up in the fine inner leaf, and a native could doubtless tell of a dozen other uses to which it is put. In ascending rivers, there is nearly always deep water near the nipa, but shallow near the mangrove."

"The banks of the Kabataan, except near the entrance, were entirely of mangrove swamp, until we arrived within a short distance of the scattered village of Menggatal, but from our boat we could see the sloping hills that rose almost immediately behind the belt of mangrove. The first buildings we saw were those in which the natives were making salt. I have already described the process pursued in the Abai, but here it was somewhat different, as they burnt the roots of the mangrove with those of the nipa palm, as well as wood collected on the seabeach, and therefore impregnated with salt. In one place, I noticed a heap, perhaps fifteen feet in height, sheltered by a rough covering of palm-leaves, and several men were about checking all attempts of the flames to burst through by throwing salt-water over the pile. This, doubtless, renders the process much more productive. In one very large shed, they had a kind of rough furnace, where they burnt the wood: and suspended around were many baskets in which the rough remains of the fire are placed, and the whole soaked in water, and stirred about till the salt is supposed to have been extracted from the charcoal and ashes. The liquid is then boiled, as at Abai, in large iron pans purchased from the Chinese."—*Life in the Forests of the Far East*, by Spencer St. John, F.R.G.S. F.E.S., vol. I. pp. 233, 287. (1862.)

WHAT IS GOOD PARCHMENT COFFEE?

October 26th, 1881.

DEAR SIR,—I have often noticed that coffee dealers, as well as some merchants, prefer the white parchment coffee to the reddish parchment. Old experienced hands will not be guided by that as a test for good parchment. The cherry, when half ripe, will give the whitest parchment; but the bean is not heavy, and very often not full, whereas the reddish parchment is a sign that the cherry was very ripe on the tree before being plucked: the bean is full, heavy and good in colour. There is, however, a discoloured parchment, more of a greyish colour, which has been too long allowed in fermenting cisterns, or in heaps, and has a musty smell. It is difficult to say how it may turn out.—Yours truly, PARCHMENT.

ENEMIES OF CEARÁ RUBBER SEED.

Allagalla, Kadugannawa.

DEAR SIR,—I can add another enemy to the Ceará rubber seed. I have my Ceará seed, which have been previously dipped in kerosine oil, planted in bamboo pots in my store. One morning, I noticed two or three seeds had been removed. On that evening I examined the pots again, and saw that every pot contained its seed. The next morning, on examination I found 21 seeds had disappeared. On a closer examination, I found in one or two pots the foot print of a rat, and, a short distance from where the pots were, the husks of eight or ten seeds broken into small pieces. I think that there can be no doubt that the rats carried away the seeds.—Yours faithfully, WM A. F. MURRAY.

P.S.—If a lighted lantern is hung over the pots all night, the rats will keep at a distance.

BEES AND COFFEE BLOSSOMS.

SIR,—It is to be hoped that any of your upcountry readers, who may have experienced visits of swarms of bees to their coffee estates during blossoming time, will not hesitate to attempt to throw some light upon the question mooted by one of your correspondents, who seems to attribute our successive short crops to the yearly decreasing swarms of bees, brought about by the denudation of forests, and the introduction of wide expanses of coffee plantations, which burst into flower only very occasionally.

In addition to the suggested planting up of one per cent of never-ceasing flowering shrubs (intended as a playground, in turn, for the different hives of bees, until the bursting of the big coffee blossoms, when the whole army would simultaneously be set free and sent to the front), I consider it would be necessary to plant up, say, five per cent of the acreage with Coorg, Mysore, Neilgherry, Liberian, Jamaica, or even Brazilian coffee trees. These would, no doubt, blossom at the same time as the originally planted trees, which, from their interminable *in-and-in* treatment, have arrived at their present almost *unfruitful* stage. The bees would assist quickly to distribute the new and invigorating pollen, and help to bring us back once again nearer to the much-wished-for

ROUND MILLION.

[One scientific authority says:—"Bees certainly help to fertilize coffee blossom, but there are other agencies at work to bring about the same thing, if the flower is healthy." But an old Kelebokka planter remarks:—"Bees are all nonsense for coffee estates, as each coffee blossom contains all the organs of fructification within itself. It is quite possible that a bee might carry the pollen of a healthy tree to a weakly one and so improve the seed, but it is just as likely that the order of things might be reversed."—ED.]

COFFEE CULTIVATION AND MANURING.

No. I.

Kotmale, 28th Oct. 1881.

DEAR SIR,—The figures you append in your foot-note to my letter of the 6th only convince me of the absolute inutility of *promiscuous* manuring, and show at a glance that coffee was not kept up by manures to any appreciable extent; contrariwise rather. I note that 224,000 cwt. manures came upcountry in 1874, and that the crop of the following season, that ending 30th Sept., 1875, was the largest ever gathered, that in fact which most nearly approached the round million, viz., 968,694 cwt. In the years under notice the young districts were mostly just being planted, and thousands of acres of coffee there contributed to the crop of 1877-78, which, notwithstanding that estates had all the advantages derivable from 548,000 cwt. manures sent up from Colombo only reached a total of 620,292 cwt. I hope I may be disappointed of my fears. Certainly just now everything is *couleur de rose*. Even *here* it is possible to get a whole bushel picking now and again. Should this promising state of affairs continue, and the crop of 1881-82 equal or exceed that of last season, then, sir, we must conclude that all the treatment coffee requires is to be let alone, or, at least, to be not so hacked about and cut up with knife, mamoty and fork, as in past years. That planters, as a body, do not anticipate such luck as non-decreasing crops, their general thick-planting of cinchonas in the coffee adequately proves; and your papers of next year will, in such happy event as suggested, bristle with letters on the question of which to stick to, which to abandon. Perhaps that old judgment of Solomon may settle the matter.

Mr. Holloway's experiments are of great interest. Perhaps his soil is somewhat better (more soil-y) and his climate less unsuitable, where such good results are obtained. Would Mr. Holloway guarantee such good returns as Maria and Eriagastenne give him from *any* young estate, say in Dimbula or Dikoya, given that he had the charge of such estate, and full discretion allowed him in that position?

As for Mr. Sinclair's perpetual petty-manuring scheme, as he says, the cost is enough to prevent its general adoption on trial. The first proposition of the axiom he adduces (in the last paragraph but one of his letter) is a most fallacious one for promiscuous manurers as it stands. I would amend it thus: "if it be remunerative to cultivate (*i.e.* to grow coffee) *without* manure, then *with* manure," containing those coffee plant foods in which the soil is more or less deficient, "it will be more so."—"Manure" is a vague term.—Your statistical croaker,

POST TENEBRAS LUX.

[We need only remark: there are not a few old coffee estates in the country which have uniformly year by year, with scarcely an exception, even to the present time, given a paying return, and this is attributed simply to judicious systematic 'manuring.' It is an 'axiom' with not a few agents and proprietors now, "no manure; no crop"—(that is, crop to cover expenditure). That manuring of recent years does not give the same results as in olden times, and also that a great deal of money is often wasted in manure, may be very true, but that does not affect the general question of the value, nay, the necessity for liberal cultivation in the present day.—ED.]

No. II.

Langdale, Lindula, 27th Oct. 1881.

DEAR SIR,—While fully agreeing with Mr. Sinclair, that coffee can, as a rule, only be made to pay now-a-days by means of manure, and that those interested have much risk of ruining their properties, if they do not apply it, I must join issue with him on his statement that "this was one of the most favourable blossoming seasons we could have wished for." I take it for granted that, like myself, he is referring mainly to Dimbula. If so, facts are stubborn things. I challenge him to deny any of those I now beg to lay before you.

As a rule, the blossom bursts in Dimbula and Kotmale some two days earlier than in Lindula and the Agras. On one of our early blossoms, Dimbula and Kotmale had a good show all round, and a little later the rain came just when it was wanted to set the blossom. In Lindula and the Agras, it fell the day the blossom burst, and ruined the bulk of it. Another blossom set well on Carlabeck, but not on Langdale, nor lower down the valley, simply because Carlabeck, being nearer the ridge dividing us from Uva, got rain just in the nick of time, while it did not fall on Langdale, nor lower down. Another blossom set well on Langdale and Carlabeck, but not much lower down, as rain fell on the upper places where needed, and did not fall much lower down.

These facts are inexplicable on the theory that the season was good, and the fault lies only in the want of manure. In the first case, many unmanured places, but otherwise in good heart, set the blossom better than on manured places farther up. In the second, the better manured estates of the two named did not set its blossoms as well as the other which got the rain. In the third case, with much the same rainfall, on all healthy coffee the blossom set much the same on both places, but I have no doubt the manured coffee will stand its crop best.—Yours faithfully,

E. HEELIS.

28th October 1881.

DEAR SIR,—There is nothing like muck, and were our soil in that much-to-be desired condition where a heavier outlay need not be incurred by frequent applications of infinitesimal doses than by manuring once a year with the ordinary dose, one would be prepared to admit there was something to be done. Coffee estates were, however, unfortunately cast in a different mould to flower gardens, and the excessive cost would therefore alone be sufficient to condemn the whole theory, even if labor were so abundantly plentiful as to enable one to manure the whole of an estate once a fortnight. Experiments on the bungalow field or some such favored spot are most unreliable. I neither believe in nor advocate the present low diet our seedy friend is being subjected to, as if to test how little he can pull through on, but one must cut his coat according to his cloth. Where manuring can be indulged in, let it be done rationally and as economically as possible, and all such clever, expensive experiments left to those who can afford them. We have got so accustomed to bad seasons that we can listen quite resignedly to a thunderstorm on the top of our best blossom, and before crop is over even forget all about it! What is a worn-out estate? "One with surface soil all washed away."—Q. E. D.! This is also something new, but don't you believe it, for there are many estates in some of the older districts with as fertile subsoil a couple of feet below the surface as many estates higher up ever had on it.—Yours truly,

SCEPTIC.

COFFEE LEAF-DISEASE.

DEAR SIR,—May I, through the medium of your columns, ask Mr. Marshall Ward if he has ever succeeded in producing *Hemileia vastatrix* by the contact of a diseased leaf with a perfectly healthy plant? Also, if the disease *was* so propagated, if the healthy

plant was wholly affected by the disease or only locally affected, that is only when the healthy plant had been brought in contact with the diseased leaf? A gentleman told me recently in Dikoya that he had fastened a leaf rich with the so-called spores back to back with a leaf of a tree free from disease without the latter being in any way affected. Can it be that the gentleman in India is after all correct, that the orange dust is the excreta, and that the disease is to be looked for in the filaments of the mycelium only? The filaments would, I should think, be conveyed by the wind from place to place as readily, if not more easily, than the spore dust.

INQUIRER.

P. S.—It may be asked: what is the object of this inquiry? Well, simply this, that, if the red dust is innocent, any hope for remedy must be the destruction of the mycelium, and not merely that of the affected leaves. Mr. Morris, I think, found the ground under diseased trees, as also the stems and branches of the trees, covered with mycelium.

P. P. S.—Inquiries have adduced the fact that far fewer bees have been seen of late years about the estates than formerly, due probably to the destruction of forests.

[Mr. Marshall Ward affords an answer, in his Report to our correspondent's enquiry, as follows:—

"How long a period is required, and what conditions are necessary for the germination of the papillate spore?

"I find that a spore of *Hemileia* is capable of germination immediately after its complete formation on the disease spot, and that in 12 to 24 hours after its removal from the 'rust' patch to a healthy leaf it may throw out its germinal tube: the conditions necessary for this are the presence of water, oxygen, and a sufficiently high temperature. If the mature spores be gathered dry and kept dry and cool for some time, no change occurs during that time; nevertheless, spores thus kept for six weeks in a closely-stopped dry tube germinated. In close covered cells, again, where the parts were sealed with wax, I have sometimes found germination delayed, or even altogether prevented. Finally, in cases where coffee on flats has become chilled or 'frosted' by excessive radiation, the spores of *Hemileia* may be found destroyed in large numbers.

"The sum total of observations indicates that germination occurs most rapidly in a warm, damp, steamy atmosphere on the surface of vigorous young leaves. Under these favourable circumstances, germination is commonly completed and the tubes have begun to enter the stomata within 48 hours from the moment of sowing.

"Germination—*i.e.*, the swelling of the spore, and protrusion of one or more germinal tubes—may apparently take place anywhere and on any surface, provided the necessary conditions of moisture, &c., are fulfilled; and it is a fact that myriads of the spores germinate on substances other than a coffee leaf, only to shrivel up and die at the completion of the process. Experiments already quoted in previous reports show that this is true for glass slips, and I have demonstrated the same for cloth, soil, and rocks on estates, &c.

"Where germination occurs on a living coffee-leaf, however, the tube does not thus die, but enters a stoma, and forms the mycelium as described above."
—ED.

GOVERNMENT GARDENS IN CEYLON.

WHY NOT ISSUE LIBERIAN COFFEE, COCOA, AND CINCHONA PLANTS FREE TO THE VILLAGERS WHO SHOW THEIR EAGERNESS TO CULTIVATE BY STEALING PLANTS? THE CULTIVATION OF LIBERIAN COFFEE

29th October 1881.

DEAR SIR,—I visited the Henaratgoda Gardens a short time back. They are worth seeing, and are kept very neatly by Mr. Zoyza who has charge. My object in writing is not to describe the gardens, but to draw attention to the fact that from 150 to 200 thousand Liberian coffee plants are likely to be wasted. There are this number, I believe, in the nursery beds, and the price per 1,000 is put down in the list at R30! Private individuals are advertizing Liberian coffee plants at from R12·50 to R15 per 1,000, and yet, in gardens opened for the purpose of introducing and distributing new products, the price is simply prohibitory to the natives. I do not know what steps, if any, have been taken by the Government Agents of the Western, North-Western, Central, and Southern Provinces (Eastern, North-Central, and Northern, I consider too dry) to introduce the cultivation of this plant amongst the villagers. Like all Easterns, the Ceylonese are very conservative, and slow in adopting any new thing. It is therefore incumbent upon the authorities to use a *little* effort in *endeavouring* to shew the people the advantages they will derive from growing Liberian coffee to replace the Arabian, which has died out altogether in the villages of many districts.

Coffee was the stay of the villager. From it he purchased clothes, saltfish and other commodities that he needed, and had a few rupees to put by. Now numbers of them can hardly get one meal per day to eat. Some years ago, it was a difficult thing to get Sinhalese to do any work but by contract. Now, let it only be known that labor is wanted, and you are inundated with men and boys at from 25 to 33 cents per day; and, in some districts, gangs of women go regularly to weed and do other works on estates: shewing plainly the poverty of the people. No doubt bad seasons for paddy and dry grain have had a good deal to do with this state of matters, but it is greatly aggravated by their having nothing to fall back upon. To return from this digression. A large number of the Liberian coffee plants in the Henaratgoda gardens are almost too large for transplanting with success, and very shortly will simply be of no use: it seems a great pity that this should be. The gist of this letter is to suggest that Government, through the different agencies, should (imitating the example of that enterprizing native gentleman, Mr. J. P. William) distribute gratis *all* the Liberian coffee plants they have, as, even if they reduce the price, I do not think they will get purchasers,—at any rate, for any appreciable number, as there seems very little demand for them just now. No time should be lost, as there is only about one month more of this monsoon in which it will be safe to plant. If my suggestion is adopted, the natives to whom they may be given should be *strongly* impressed with the *necessity* of planting in the open, and shading well till thoroughly rooted. When once established, the plants cannot have too much sun. If planted amongst jak, kekuna, coconuts &c., as was the custom to do with Arabian coffee, their labor will be in vain, as they will grow up like areka palms, and hardly fruit at all.

But, perhaps, Dr. Trimen may have an idea that, if there is no sale just now for the plants, there may be by-and-bye for stumps. The sooner this idea is got rid of the better. *Liberian coffee stumps will not grow.* I had heard this before but did not believe it, and so risked 3,000 very fine large plants to test it. The plants were pulled and stumped one evening, and planted out next day in most favorable weather—such weather as Arabian coffee stumps would have leveled in—and the result has made me a wiser man. In three months more than half had died, and the rest simply existed, with here and there one or two that seemed likely to do well. At Kalutara I was shewn portions of a field two years old, that had been planted with *suckers*, and a small straggling bush that had grown from a *primary*. In the face of these facts,

it seems rash to say that stumps will not grow; but if the evidence on this head were collected I am sure it would bear me out in my assertion. It would at least be risky for any one to try them on a large scale.

If conservatism is inherent in the East, it certainly seems capable of infecting Governments and individuals naturalized in it; and for illustrations of this we need not travel from home. I will say nothing of our island Government: its tendencies are only too noticeable. And what of our planting community? Are we not saturated with it, moving in the same old grooves till dire necessity compelled us to step out? We are quick to see apathy in natives. How was it with ourselves where cinchona was brought to our notice? Those who emancipated themselves from old ideas are now reaping that reward, whilst others have now repented, amended their ways, and live in hopes that they may not be too late. Nor is it any better with Liberian coffee and cocoa. How slowly their cultivation extends. It surely cannot be for want of money, as we were assured a short time ago that, for sound investments, there was plenty in the country. Now, few will assert that cocoa is not a paying product, and there is plenty of land suited for its growth, if people would only look for it. There was a rush, a few years ago, to plant Liberian coffee, but since then its cultivation has not appreciably extended. Why is this? Is it want of confidence, and, if if so, what has caused it? Some of these causes are I think, very plain: the pioneers of this coffee knew very little about it, and hence, to their cost, made some mistakes. To begin with the trees: they were planted 10 feet square, giving about 400 trees to an acre; some few even planting wider. To cover the expenditure, these 400 trees would have had to give very large crops indeed, and possibly they *may* yet do this and leave a fair profit.

Experience has since shown that about 800 trees per acre can be grown without crowding, thus doubling the crops without much increasing the expenditure. Perhaps it is not generally known that 1,000 cherries, at 800 trees to the acre, yield 8 cwt; and, as trees topped at 5 to 6 feet, giving from 2,000 to 5,000 cherries, are not uncommon, surely the calculation of a yield of 1,000 cherries per tree is very moderate; and I am confident this can be considerably exceeded by a proper application of manure. Another cause no doubt is the fact that land has been opened and planted with Liberian coffee that would have been better left in jungle. This is a mistake that has been made by others as well as growers of low-country produce, as it was common enough for men of sense in other respects to attend sales and bid for land that they knew no more about than the babe unborn. This "buying a pig in a poke" has caused grief to many, and will still, I fear, in times to come. This, however, should not be laid at the door of the coffee, for it will no more grow on bad soil than will its elder brother Arabian, though Liberian will force its roots through soil, and obtain nourishment from it where its more tender brother would starve, An advantage that the grower of Liberian coffee has is that he can, in all the sheltered portions of his estate, grow cocoa, without at all injuring his coffee. The difficulty of pulping is almost got over, and no doubt Messrs. Walker & Co. will soon perfect what they have already advanced so far. As regards a market for this coffee, I am not competent to speak; yet there can scarcely be a doubt that for many years to come America will take all we can produce, and by them other markets are sure to open up. My advice to intending low-country planters is this: do not buy your land hap-hazard but ascertain for yourselves that the land is really worth planting, and if you cannot do this for yourselves pay some competent and reliable person to do it for you. Far better to throw away £10 than £1,000. Then the rainfall should be *at least* 70 inches a year and pretty evenly distributed; places with protracted drought, or that only get one monsoon, should be avoided. The distances apart should be 8 feet by 7 feet, and in poor soils even $7\frac{1}{2} \times 6\frac{1}{2}$; closer than this I would not recommend. All other matters are pretty much the same as in the planting of Arabian coffee. With decent soil, a fair rainfall, and proper altitude, Liberian coffee *cannot* be a failure. The crop certainly does take a long time to ripen (13 to 14 months as far as has been ascertained), but it may ripen within the year, when it settles into our seasons and loses its native habits. Has it been certainly ascertained how many months the berries take to ripen in Liberia?—Yours, &c., W. J.

COFFEE LEAF DISEASE: THE CARBOLIZED POWDER TREATMENT AND MR. WARD'S REPORT.

Agrapatana, 30th October 1881.

DEAR SIR,—Averse though I am to a discussion, at this stage, of mere opinions as to the merit of the carbolic acid treatment recommended by me (in face of actual practical results), there are a few remarks on that subject, in Mr. Ward's final report, which have attracted my attention and which deserve some notice at my hands. Mr. Ward, though admitting carbolic acid among the available reagents or chemicals which might be used for the destruction of generating spores, is of opinion that this acid is scarcely sufficiently soluble and diffusible for that purpose.

Now, considering that carbolic acid is readily soluble in about 60 parts of water, and that a solution of *less* than one per cent strength suffices to destroy the spores whether germinating or not; considering that the method I have devised of its application admits of its being diffused to a perfection unapproachable by the sulphur and lime mixture; and lastly considering that the vapour of carbolic acid given out by the powder is perceptible for nearly a fortnight after each application, I submit that Mr. Ward's opinion, as above quoted, is not based on sufficient evidence to carry weight.

The carbolized powder, as used by me, comes strictly within the "compounds which" (to quote from Mr. Ward's report) "will continuously evolve and easily diffuse a readily soluble gas, forming with the water on the leaves a solution sufficiently strong to do the maximum of injury to the germinating spores, and the minimum of harm to the coffee leaf—the after-products of which are not injurious to the tree when washed to the roots." Mr. Ward, though admitting that a certain benefit may be derived from the carbolic acid treatment (if done at the proper time), has expressed himself privately to the effect that the acreage treated under my advice would probable suffer after the first rain, from the carbolic acid being washed into the ground. This opinion results have proved completely unfounded. The areas, on the contrary, have considerably improved after every rainfall, and our experience extends to 11 months. I am completely at variance with Mr. Ward regarding his statements that "the mycelium cannot be attacked after it has entered the leaf."

I have seen proof to the contrary, which not only satisfied me and the planters who worked with me, but also one of our oldest and most respected authorities on the subject.

One of the results of the carbolic acid treatment to which I attached great importance was that it prevented the mycelium of the *majority* of pinspots, on leaves marked for observation, from fructifying, and caused them to die and dry up—so far as the brown-

ing of a pinspot without fructification may be termed so. In adjoining untreated fields, the pinspots on the marked area were found to have fruited freely during the same period of observation. In several cases, the marked leaves were kept under observation for more than six weeks.

There is no special knowledge of Mycology required to distinguish when spores are thrown out by the fungus and when not. I am open to correction.

I am, again, at variance with Mr. Ward regarding his statement that no predisposition is required to infect a coffee tree. How does he account for individual trees being comparatively free from it, though surrounded by thousands of badly diseased trees), and I differ with him in considering manure only so much additional nourishment for the fungus. I have never seen a well manured tree so badly diseased as an unmanured one. The fungus, though perhaps it germinates and establishes itself as freely, does not spread or fructify as much on manured as on unmanured coffee, one or two kinds of manure excepted. This is well-known to every experienced planter.

I am afraid, however, I shall transgress on your space, were I to write more, and you will perhaps say, *cui bonum?* I close therefore and remain, yours faithfully. EUGENE C. SCHROTTKY.

COFFEE-LEAF DISEASE: MR. WARD'S REPORT.

1st November 1881

DEAR SIR,—Dr. Trimen's introductory letter to Mr. Marshall Ward's last report is remarkable in more than one respect, and invites criticism. Surely the worthy Director, when saying that "probably no fungus-pest has ever received so prolonged and continuous an examination," inadvertently omitted to say that the thoroughness and completeness of the information stands scarcely in proportion to it. For, beyond correcting Mr. Morris in his filament theory, the present report adds little to the researches of the Rev. R. Abbay and Dr. Thwaites, as far as the life-history of the fungus, pure and simple, is concerned.

The Colony had a right to expect the *whole* life-history from a cryptogamist specially employed and selected for the work. Other mycologists have had no difficulty in describing the life-history of other members of the same family and have discovered the respective second host plants. Dr. Trimen assumes a great responsibility in saying that the discovery of the second host plant of *Hemileia vastatrix* is unimportant. To say that, in his opinion, it really did not matter whether anything was known about the history of the second kind of spore, or not, is an ill-chosen apology for Mr. Marshall Ward having failed to follow it up.

The proportion of teleuto-spores to uredo-spores, produced by each disease spot, is formidable enough to make the discovery of the second host plant one of the greatest importance to the coffee industry of Ceylon. It will probably make little difference to estates which are chronically suffering from this pest and are never free from it. There the uredo-spores play no doubt the most important part in originating each successive attack; but as regards estates that suffer periodically, say once a year, there is every reason to believe that the attack is chiefly, if not entirely, *originated* by the products of the second kind of spore. There is no evidence produced by Mr. Ward to show that the uredo-spores can lie dormant through heat and dew and rain for, say, nine months, nor does our knowledge of the life-history of other members of the same family justify *in any way* the assumption that the discovery of the second host plant would be unimportant to the coffee industry.

Mr. Marshall Ward's report is interesting, but it fails to give us that complete information on the life-history of the fungus, which the Colony had some right to expect. A CRITIC.

COFFEE LEAF-DISEASE AND MR. WARD'S INVESTIGATION.

2nd Nov. 1881.

DEAR SIR,—In your issue of the 31st ult., you drew attention to Mr. Ward's statement that "the disease is quite compatible with and indeed prefers healthy and luxuriant trees." This statement is opposed to facts. The disease prefers sickly trees, and on these it luxuriates and spreads in a manner which shows that on or in such trees it finds its true home and conditions *most favourable* to its development.

You also bring prominently to notice that, according to Mr. Ward's observations, 24 hours' soaking rain is required to give the fungus a fair start, and that it rules supreme during moist, rainy weather. If this is the case, how are the attacks of the disease to be accounted for that occur, in some districts, during dry weather, and which (the attacks), according to the observation of experienced planters, are apparently originated by and accompany the advent of high dry winds?

Mr. Ward's conclusions as to the atmospheric circumstances which favour the development of the fungus are, I think, perfectly correct, as far as the uredo-spore is concerned. How important, therefore, to find out what form of the fungus originates the disease attacks during dry weather; how important, therefore to find out what becomes of the products of the second kind of spore—a subject to which I endeavoured to draw your attention in my letter of yesterday

A CRITIC.

HOW TO CULTIVATE COFFEE AND FIGHT "LEAF DISEASE"

DEAR SIR,—I am glad to see, from your issue of 25th inst., that Mr. James Sinclair is experimenting in Liudula to mitigate leaf disease and get trees to give crops. I can assure him he is on the right track: manuring in small doses where necessary is one point. The kind of manure required is, however, the greatest point, and we cannot depend on the analysis of soil to guide us. If our soil is deficient in potash, it will not do to put pure potash to the tree, but we must put the material out of which potash is made, and let the roots do the rest. In all cases, mix woodash with your bones and lime with your poonac before applying. Apply no patent manure without some cattle or good compost being thoroughly mixed with it. In high and wet districts, lay your roots bare in the *hot* weather; apply your manure, cover over the soil, then stamp the soil so that it gets hard and does not allow too much moisture to get to the roots. In the lowcountry, cut holes in the wet weather, apply your manure, cover with soil the hole half full, and put leaves, mana, or rubbish on top, or fork in: both districts in what manure you give above the tree. You cannot use too much woodash and lime while leaf-disease hangs about. Since the late rains, my disinfectants have again driven leaf disease out of my coffee where affected. This time it settled close to on a native man's tree garden where del, jak, and a lot of other trees had lost their leaves and the branches dying off as well as some of the trees are dying. The planter must trust to his eye to detect when, where, how and what manure or disinfectant to apply, by the appearance of the coffee. In some cases it is necessary to make holes below the trees (get from Walker & Co., one like Holloway's Earth Auger) to let the earth damp escape and then throw a little gas lime into the hole or sulphur and lime and leave the hole open. Knife-prune early and

hand-prune twice besides. Wherever you see leaf disease coming mix 1 of woodash and 1 of country unslacked lime and throw freely both over and under the tree. In all cases, the fight must be fought by the superintendent who is on the spot. One practical man in each district can do more than all the visiting agents, who, no doubt, are all good men, but are *not* on the spot. J. H.

A HORTICULTURIST'S ENQUIRY.

Down South.

DEAR SIR,—I shall feel thankful to your subscribers who have flower gardens for their experience as to the most successful way of propagating rose-trees by planting their slips or cuttings. I have tried several methods to gain my end, but they have invariably resulted in failure—so much so that I am unable to replace the tea-roses I have at present (by fresh ones), which are dying out, being old.

I am aware that in the Central Province and Morawak Korale they are grown without much care or effort, but this is due to the mild climate of those places, which gardeners down south cannot unhappily boast of.—Yours faithfully, TEA-ROSE.

COFFEE CULTIVATION AND MANURING.

DEAR SIR,—Mr. Jas. Sinclair's letter, in your issue of the 25th, is interesting, as showing the feeling which is working among us for a more scientific system of agriculture than has hitherto been practised. There are some points in his letter which I should like to take notice of, in the hope that discussion may create additional interest in the subject, and that, out of it, a more generally sound system of manuring may be deduced.

The idea of using more than one application of manure in a year is one which occurred to me some years ago, after having studied the work of Messrs. Lawes and Gilbert at Rothamstead. I gave it up, however, after a few small trials, as practically inapplicable to coffee, and for the last two years I have been working in a direction which I think more likely to be productive of result, viz., to the production of a manure which will act continuously upon the coffee throughout the entire twelve months. I must join issue with Mr. Sinclair, when he says that it is well-known that Ceylon soils are rich in a low compound of iron which has the power of rendering *unavailable* the food which may be given to the plant in the most *available* form. I did not know that such was the case, nor do I think that it is so. Peroxide of iron, in which form most of the iron in our soils is, I believe, to be found, is beneficial rather than the reverse, being a fixer of the more valuable constituents of manure, and thus preventing their waste. If sufficient iron in a noxious form were present in our soils, the coffee would be found not to grow on such soils, whereas the higher percentage of iron is generally to be found associated with superior coffee. If I am correct, the necessity for the frequent application of quicklime to our Ceylon soils would not be so evident. I would wish to caution planters against the indiscriminate use of lime, which I have before urged in the *Tropical Agriculturist*. Lime, applied without very careful consideration of the results which are desired to be attained, is apt to be injurious, though the ill effects may take time to show themselves, and at best it should always be looked upon as the preparation for subsequent manuring. Is not Mr. Sinclair somewhat hard upon the visiting agents? It may be the case that some among them, instead of being ahead of the times, as they ever should be, are living upon a past reputation, but surely such is not the case with all or even the greater number. For my own part, I would rather have my estate unmanured than manured haphazard and without any judgment; for unscientific manuring has, I believe, done as much as anything to put coffee into such a condition that it succumbs to leaf-disease, and the Colombo agents are naturally distrustful when they find that certain applications of manure are attended with negative, or, perhaps, positive evil results.

Mr. Marshall Ward's report is calculated to be of great practical benefit to those who will study it carefully and follow his suggestions, and I may add that his deductions seem to be borne out by and to explain the results of my own experiments, and probably those to many others, who will, I hope, give us the benefit of their experience.—Yours faithfully, CULTIVATOR.

[We certainly do not sympathize with any indiscriminate attack on Visiting Agents. But does not our correspondent's argument seem to tell against the present system by which a planter who has gained his experience, perhaps in one or two adjacent districts, is made Visitor of Estates and adviser of proprietors whose interests are scattered over the whole hill-country from Matale to Badulla? If it were possible, we would prefer to see the experience and ability of Visiting Agents utilized more particularly in those districts with which they are best acquainted. Of course, sensible men make their visits to plantations worked by careful and experienced planters, a matter of form, but in other cases has not the judgment of the estate manager been overruled to the detriment of the property?—ED.]

MANITOBA AND CEYLON PLANTERS.

1st Nov. 1881.

DEAR SIR,—I have received a letter from a Ceylon planter who went to try his luck in the Far West, and it may be interesting to some of your readers to know a little of what he says about farming in Manitoba.

He writes:—"Since arriving here, I have been looking about for some land, and have now fixed on a lot of 330 acres. Of that, I get a free grant of 160 acres from Government, and 160 I get at 10s an acre, and am allowed ten years to pay it by instalments. In Winnipeg I met two Morayshire men, and we all started off together for up-country. We bought a tent and provision, and when night came on camped out. We were a fortnight on the road; so you may suppose I have seen a good deal of the country. Both these men have taken land beside mine, 320 acres each. My land is a mile from the railway, which is to be opened next year. Several farmers, who have seen the land, say I am very lucky in getting such a good bit. I am well supplied with water, having a stream running through my land, and can get plenty of duck and snipe shooting, and prairie fowls in any number. There are very few farms opened out so far west as I am, but next spring I expect the land round about will be bought up fast. What I have seen of the country I like very much indeed, and the land I have seen crops on is splendid. I hope, in a year or two, to be independent, and be able to take a run home to Scotland. The work will be a little rough at first, until I get a house built, and some crop in, but nothing but what *any one* could stand.

"There is always plenty of work to be had here, and the lowest pay one gets just now is two dollars a day; so that a man can soon save a little money. I think any one who is steady and willing to work, could be independent in a few years, although he had not a penny to start with. You can tell all those who are out of billets in Ceylon that they will get plenty employment here, if they are willing to work, and would soon be able to have farms of their own, and be independent."—Yours truly, PLANTER.

COFFEE IN THE PHILIPPINES.

Maskeliya, 2nd Nov. 1881.

DEAR SIR,—Having read your article headed "Coffee planting in the Philippines," I would refer your correspondent from "Pakhoi," China, to a book called "Tropical Agriculture" by P. L. Simmonds, where he will find a detailed account of coffee cultivation in those islands. Among other observations, Mr. Simmonds says:—"Coffee in the Philippines:—"The export of coffee from Manila was in 1864, 37,845 piculs of 1¼ cwt, and in 1874, 45,842 piculs. The value of coffee exported in 1872 was stated at $369,000,000, and in 1873 at $1,126,000,000. This coffee is quite equal to that of Java. The beans are medium sized and of a pale colour. The plant thrives wonderfully in the Philippines, and its berry has so strongly marked a flavour that the *worst* Manila coffee commands as high a price as the best Java. Not till European capital calls large plantations into existence in the most suitable localities will the Philippines obtain their proper rank in the coffee-producing districts of the world."—Yours faithfully,

H. D. DEANE.

COFFEE SOILS.

DEAR SIR,—I now send you copy of an analysis of soil. You will no doubt agree with me that few would have ventured, after such a report, to invest capital and cultivate land of that description. But I knew what could be done with the soil, and so did not hesitate to lay out money and with fair results. From four to six cwt. per acre in these times is not bad. This is my reason for not putting much faith in analyses of soil.—Yours truly.

PLANTER.

I now pass on to No. 2 soil in small bags. This is a most extraordinary sample. It consists almost entirely of nodules of ironstone, partially decomposed gneiss and quartz, with only a minute quantity of *lime, potash, phosphoric acid* and *nitrogen*, &c. The proportion of organic matter and combined matter is higher than in No. 1 soil, but this is due rather to the combined water which is present in consequence of the larger amount of iron and alumina. I am surprised how coffee can grow at all upon such a soil. Its retentive properties seem so small that I would not advise any serious expenditure in the way of manure. I should prefer to let it go into grass which, if guinea, must be of use to you in making manure for No. 1 soil which is worth some expense. When you look at the two analyses, you might, perhaps, think that the difference between the two soils is not so much, but decimal one (100) per cent of a constituent means one ton per acre for six inches of soil. You will, therefore, see also how important it is that the greatest care and delicacy should be taken in the analysis, in order to correctly estimate the small quantities of the important constituents.

"INSECTS" AND COFFEE BLOSSOM FERTILIZATION; WOOD-PULP AND TEA CHESTS.

Kotmale, 3rd November 1881.

DEAR SIR,—In this interesting discussion on coffee blossom fertilization in Ceylon, let us substitute "insects" for "bees," and we shall have material to work on. I cannot recall, in my experience of apiary visits to coffee estates, a single instance in which those visits were more than *flying* ones. You hear the hum, 'the murmuring of innumerable bees,' to the north, and by the time you could look up, behold! they had passed to the south.

Now and then a swarm may be seen on jungle trees near the coffee, or on fruit trees at bungalow, but their stay appears to be in no way connected with the coffee.

But when we turn to the more comprehensive "insects," we can all recall the flitting of humming-birdhawk-moths from tree to tree, and the impassive manner in which those little rose beetles established themselves on our blossoms.

What Sir John Lubbock said about the "little busy bee" at York was:—"At the close of the last century, Sprengel published a most suggestive work on flowers, in which he pointed out the curious relation existing between these and insects, and showed that the latter carried the pollen from flower to flower. Darwin further investigated the subject in 1862, and others had followed in his steps. The general result was that to insects, and especially to bees, we owed the beauty of our gardens, and the sweetness of our fields. To their beneficent, though unconscious action, flowers owe their scent and colour, their honey, nay, in many cases, even their form. Their present shape and varied arrangements, their brilliant colours, their honey, and their sweet scent, are all due the selection exercised by insects." We should remember that Sir John was speaking in England to an assemblage mostly English and presumably entirely European.

You have two extracts from the *Field* in your issue of the 1st. Both are interesting. One refers to the use of wood pulp for making barrels. Had we only an enterprizing Yankee or two here, this material would be utilized at once in the manufacture of tea chests to out-Chinese the Chinese cases for lightness and durability. It is a shame to this intelligent age that packages of Ceylon and Indian teas should be so clumsy as they are. The second extract brings us back to coffee cultivation, and is a delightfully epigrammatic sermon on the follies of unscientific pruning and manuring, this latter work being itself always, to a greater or less degree, a root-pruning. Surely it were better to leave the roots alone entirely, even allowing weeds to protect them from the ill-effects of sun and heavy rain, than, after encouraging the demand for food by branch pruning, to prevent, by perpetual disturbance of the root, your poor coffee from having the food you so cupboard-lovingly, but ignorantly intend for him. Poor old coffee! Don't blame the planters because, in their nescience, they treat you worse than Tantalus? Remember we are but men; his tormentors were gods.

POST TENEBRAS LUX.

GIRTH OF CINCHONA TREES.

Haldummulla, 3rd Nov. 1881.

DEAR SIR,—A question having arisen regarding the girth of the older cinchona trees (succirubra) on Kelburne estate, the proprietor, Mr. Campbell, undertook to measure the trees, and he sends the following measurements, which will be a matter of interest to you and your readers:—

	Girth. ft. in.
No. 1.	
At 12 in. from the ground on lower side	
„ 15 „ „ „ ...	4 8
„ 6 „ „ on upper side ...	3 11
„ 6 ft. „ on lower side ...	3 2
Height, 40 ft. (measured).	
No. 2.	
At 12 in. from the ground on lower side ...	6 0
„ 15 „ „ „ ...	5 1½
No. 3.	
At 12 in. from the ground on lower side ...	5 7
„ 15 „ „ „ ...	4 7½

—I am, yours truly,

HENRY WALKER.

SARAWAK.—The future prosperity of the country must depend in a large degree on the fostering of its agricultural capabilities particularly in the Gambier and Pepper branches, as it is principally to them, and the impulse given to trade caused by their development, that we owe the large increase to our revenue that we may may count upon next year. *Sarawak Gazette.*

BARBADOS.—The shipment of crop was nearly closed, the total being 50,574 hogsheads sugar and 31,937 puncheons molasses—about an average crop. A fair proportion of this had gone to the United States and Canada. Growing crops promised well under the influence of refreshing rains. Cargoes of American produce still continued to arrive. A good trade exists with Demerara in the export of coral lime. The House of Assembly was still in recess, and would continue so till Octoher 10th. Mr. C. Masservy had been gazetted Superintendent of Public Works for the Colony. Mr. C. Masservy would not arrive till towards the close of September.—*Colonies and India.*

THE SALE OF JAVA CALISAYA LEDGER SEED at Mr. Symons' coffice resulted as follows :—

1 box	...	@ R 33	R 33

33 ,,			R891

Average 27 rupees per box of 2 grammes or 31 grains: about half the price obtained at the former sale, no doubt, owing to the full analysis being given.

CINCHONA ON THE SHEVAROYS:—Dr. Shortt writes to the Madras Horticultural Society from Yercaud:—"Cinchona hitherto on these hills has been simply as an experiment: one or more trees only were to be seen on a few estates. Of the different varieties, the *cinchona succirubra* thrive well here, and this variety is best suited to these hills. Efforts are now being made by a few planters to extend cinchona cultivation, and on my estate self-sown seeds of this variety were found growing in the vicinity of the parent plants, and the trees are so extremely prolific in their seed productions that I have been able to collect and distribute the seeds freely. The difficulty of getting the seeds to germinate is rather trying, as the process requires much care and attention, more especially without the aid of a propagating house. Of the cinchona trees on my estate one seems a hybrid, and on sending specimens of the flowers and leaves to Mr. Jamieson, the Superintendent of the Government Gardens, Ootacamund, that gentleman recognized itas one which, he says, has been named *Cinchona Lanosa.* This plant also seeds very freely and largely."—*Madras Standard.*

LIBERIAN COFFEE PULPER.—Supply is generally soon ready for demand, and Messrs. J. Walker & Co. are generally well to the fore in supplying the planter with any appliance necessary for the cultivation of new products, whether it be transplanters, bark shavers, or a Liberian coffee pulper. For some time past the latter has been exercising the inventive faculties of Messrs. Walker's staff, the result being a machine which Messrs. Walker guarantee will do its work to the satisfaction of the Liberian coffee planter. Yesterday we had the privilege of watching atrial of it in pulping some 'Liberian' from Kalutara. The coffee was put into a machine with a grooved cylinder and circular sieve working underneath. Here it was crushed between the cylinder and breast and the skins separated from the beans in the sieve. The skins were then put into another machine, which threw them out at the back, and any beans which had not been separated in the first machine were thrown out in front. There was no damage done to the coffee. It is intended to have the two machines combined as one. We congratulate the makers ou their success.

JAMAICA.—The local papers advertize large importations of Canadian-built carriages. They also publish statements which seem to imply that each West Indian colony is practising quarantine against its fellow-islands under a wholly wrong impression that yellow fever exists there. Thus, at Fortune Island, the Atlas steamer "Alveus" was not allowed to call on arrival from Jamaica, because yellow fever and smallpox were believed to be raging there. The Bahamas have also quarantined against Jamaica, under the same dread; whereas the *Gleaner* asserts that, in spite of the intense heat, the public health of the Colony is "very good."—*Colonies and India.*
