Mr. Leechman, besides the care, intelligence and industry which he brought to his task, was specially fortunate in his first planting season. We are in a position to make use of the details of an experiment which, although it now promises to be a success, was commenced and for a couple of years carried on in the face of conditions of meteorology, insects and *reptile* life (for there can be no doubt that the small lizards, instead of destroying the mole crickets, aid and abet them and other insects in cutting down the young plants,) most trying and disheartening. The scene of this experiment is on good soil in the Siyane Korale, seven miles to the right of Henaratgoda railway station; the sanitary conditions being better, we should say than at Udapolla. For luxuriant growth of weeds and abundance of insect life, however, we should say that the scene of *our* experiment is equal to any site in Ceylon. Except that a rock, like porphyritic granite, is more abundant, standing up in fantastic shapes, we should say that in undulating features, elevation, exposure to wind, etc., the Siyane Korale estate closely resembled that in the North-western Province. From nigher contiguity to the Peak ranges, there ought we should think, to be more rainfall. The gentleman who has mainly conducted this experiment was recently asked for its history from the commencement. Extracts from his candid and interesting statement, may be of use to some of our readers, as warnings as well as encouragements. Both here and on Udapolla the discovery had to be made that Liberian coffee plants, stumped before being put into the field, *will not grow*. Once rooted, the case is different. But here are the details:—

"On reviewing the whole subject of this estate, I suppose I am expected to begin at the beginning, and, however much against the grain, assume my share of blame for the early failure and loss, that took place on first opening; but, in taking my share of blame, I must assign you yours, though in both cases censure should be mitigated by the consideration that we were both in ignorance of how to deal with the new plant we took in hand, and, like all new beginners, especially those who think they know a thing or two, we made mistakes, and suffered for our mistakes.

"Eighteen months before you had land to put them in you purchased 1,000 plants then of the proper size, for putting out in the field. The seller engaged to keep them for twelve months, as they then were in bamboos. Within six months, a large number of them perished, from various causes, and they were then planted out in prepared ground, two feet apart, where they remained for fifteen months, before the place was ready for them here, and they were then from three to five feet high, and many of them in flower. They had therefore to be stumped, and I did not then know that Liberian coffee would not patiently bear being stumped; that only a small percentage will grow at all; and a still smaller become good trees under the most favourable circumstances: and the circumstances were not favourable. The plants had to be brought 25 miles; but they were carefully taken up, in a wet afternoon; were conveyed, during the night, and were all planted and shaded before noon next day. The rains continued heavy for three days after planting, when they suddenly ceased, and we had no more for three months. At the end of twelve months, there were still one-fourth of the 1,000 alive, but by far the greater part of those were plants taken from a younger nursery to make up the tale. Some few of the larger stumps that had been long given up, began to grow, after being thirteen months in the ground, and have since become tolerable plants.

"For upwards of twelve months, before the purchase of the land, you had been collecting plants from various sources, at your house in Kolluppitiya, where they were put into soil, composed of a greater or less depth of road wash over seasand, and they began to perish as soon as the roots reached the sand. Many had died before they could be taken, and many more had got their death before removal, however favourable the season, or however skilful their subsequent treatment might have been. I was not aware of that fact, two-and-a-half years ago, but it has painfully impressed itself on my mind since, and determined me never again to plant in the field any but healthy Liberian coffee plants, and, if it subsequently looks unpromising, to pull it up, and replace it with a better one, if I have it.

"When I took charge in April, the land had been felled and burned; the fire had been a very bad one; and there remained a very heavy job of clearing up, before lining and holing could be proceeded with. If I could have got the people of the neighbourhood to go on with the work, on the same terms as they had done the felling, time would have been saved, and some of the planting have been done in the only safe time for planting, that the whole season afforded, but, as soon as I took over charge, the villagers made a demand of 20 per cent increase on the wages for which they had been working. Had I given in to this, I would have laid up a load of trouble that might have lasted for years. I therefore obtained a contractor from a distant village, who promised to bring his own people. As soon as I found that he did not bring his own people, but employed the very neighbours, who had struck for higher wages, on their own terms, I dismissed him, and gave the work to another. The mistake of which I had to gather the fruit at the very beginning, was not giving out a felling and clearing contract but commencing the work with Sinhalese labour by the day.

"From the first I had been doing my best to secure Tamil coolies, but six weeks passed before I was able to establish the nucleus of a labour force on the estate. As soon as my neighbours saw that I could do without them, they were ready enough to come to work on my terms, and the labour difficulty was finally over; but, as things turned out, the season was lost. The monsoon rains began on the 17th May, before a hole was cut, and ended on the 6th of June. Again the weather became showery on the 15th and continued so till the 23rd. It was during this time, that I removed 4,000 of the larger plants from Kollupitiya. I did the best I could for them; none of them were twenty-four hours out of the ground, and they were all carefully shaded with jungle leaves almost as soon as planted, but the rains stopped the next day, and we had not another drop for upwards of a month. In over twenty years' experience of other parts of the Western Province, I concluded that June was generally a safe planting month, but, at least in this district, the season of 1879 was abnormally dry, but I could not know that it would be so, and balancing chances, I believed then that the best course was to venture planting out. The choice I had to make was between the possibility of an unusually dry season here, of which there was then no special indication, and the certainty that if the plants were left *in situ*, for six months, a large proportion of them would die, and all be more or less deteriorated. In reviewing the affairs at this lapse of time, I see no refuge under the circumstances, but to do exactly as I did then.

"It remains to treat of the small plants that remained at Kollupitiya, after the more advanced ones had been removed. I did not see them from the middle of June till the beginning of September, during which time I found that thirty per cent of them had perished. Here was another difficulty: if left where they were, few or none would survive till the next planting season. On the other side I had prepared soil of the best quality; I could regulate shade and water at will; I had baskets to plant them in, filled with highly-manured surface soil, and, though the weather was extremely dry, I thought that, by dipping the roots as soon as taken up, in diluted cowdung, and then wrapping them in wet gunnies, they could be saved, and I would have been perfectly successful, but for an enemy with whom I had no previous acquaintance. This land was the chosen home of the mole cricket, and September is the month in which its armies are most numerous and most active. I had been so confident in my resources for saving those seedlings, that I brought away above three thousand of those that had already dropped all their leaves, but the very first night that they were in the ground the crickets cut five per cent, and they continued to increase their depredations nightly, till within a month not five per cent remained uncut, and, in very fact, before the middle of November, when they stopped, there were not 300 out of the four thousand, that might have been fairly expected to survive, that the cricket had not destroyed. I believed at first, that they were only in the rooted and trenched nursery ground, and tried to exterminate them by digging them out. I thus destroyed many thousands, but produced no effect, and I soon found that they were everywhere. My two years' experience has not resulted in any plan of absolute protection for plants under eight or nine inches in height, but, though many are cut in the germinating sheds, they are very much safer there than outside. Again the baskets are not a certain protection, but the percentage of destruction is much less than outside. The bad months are March and April, September and October, but there is no time that more or less of them are not in the ground. The conclusions I have arrived at are, that germinated in sheds and transplanted thence into baskets, we may calculate on a loss of 20% before the planting out; but, if they are kept in the baskets till well hardened, and eight inches high, and planted out at the end of the cricket seasons, in May and November, very little loss will take place in the field. I may be asked, why, when seedlings are in such danger, on this place, I do not get strong, well-hardened plants, from elsewhere. My answer is that, except when very young, the Liberian coffee stands transplanting badly, and, if it encounters a serious check in the operation, it never regains its original vigor, even when it survives the occasion, and our climate is so uncertain, that the finest planting weather may be suddenly succeeded by a period of dry sunshine, very trying to any recently-transplanted member of the vegetable kingdom. For those causes I germinate the seed in sheds. I transfer the seedlings to baskets, and can avail myself of a few showers at any time, without fear of any serious check to the growth of the plant, and it is by this treatment that I have plants with seven pairs of branches, and a fair sprinkling of flower at eighteen months from seeds.

"Of the first year's planting, the least disastrous was the produce of the seed you imported, and which only gave about 800 plants. These I planted during the November rains, which came late that year, and stopped early; so that they had to encounter a trying drought, before they were fairly settled; besides, the crickets having lingered long that season, about 200 of the smallest were cut. With all those drawbacks, about a third of that lot survived, and are now many of them fine trees, with a sprinkling of crop, and a large promise for *next year*.

"As nearly every one who had imported or bought imported seed had burned their fingers more or less severely, there was no more question of resorting to Liberia for seed, and locally-grown seed continued very scarce and very dear, and none was obtained till the following June, when 20,000 were purchased for R300 from ———. This seed could not have been good, for little more than 30 per cent germinated in the sheds. I was at first inclined to ascribe some of this loss to neglect of watering during ten days of compelled absence on my part, but continued experiments with fresh seed proved that there had been no loss from this cause. Liberian coffee seed held its high price till the end of 1880, when so many trees came into bearing that the supply very nearly came up to the demand, and it has regularly fallen in price ever since till now. I can supply it from my own place at a nominal price, say, one rupee per thousand. From my last nursery I planted up all the land formerly opened, supplied the thousands destroyed by crickets, and a new clearing of three acres. I have now about 8,000 ready for removal from the germinating sheds, and as soon as they are clear, I propose putting down 30,000 seeds to produce plants for November planting. Those I now have will be ready for May, but they will not suffice for all the interplanting contemplated for the coming year, besides the demands of the old field. I propose planting what still remains in jungle of the 40 acre block. The following is my estimate for the new clearing per acre:—

Felling contract	R10
Lining and holing	8
Rooting batali	8
Plants	9
Planting and shading... ...	8
	R43

The [illegible] cost of the 3¼ [illegible] lot was R100 for cooly labour, and I can get the [illegible] by contract, R1·50 [illegible] than they cost by my own people.

"[illegible] is [illegible] that I [illegible] was no doubt due to my own [illegible] of the [illegible] much more to white ants and other insects. I did everything that my judgment could suggest for [illegible] welfare,

but in upwards of 50 acres planted, three and some of it four times, I have not 3,000 plants living. Some of them are now doing well, but many of the weaker plants in exposed situations will evidently fail still. I think I know enough of the plant now, to secure greater success, if I ever have to deal with it again, but I will not willingly undertake it. One special tree one of a batch of 500 odd, planted in July 1879, of which very few remain, has reached a height of ten feet, and has branches of five: it has flowered in great abundance, for twelve months, but shows no symptom of fruiting, and all the larger trees seem to follow suit.

"I have planted over 1,000 teak trees along the boundary, and in lines across the front field: they have got on superbly, wherever the soil suited them. I have arranged to get a bag of seed from Kotudeniyawa to extend its cultivation.

"For boundary fences, where the soil is good, and for shelter belts, I know nothing to compare with the Indian bambu. Its quick growth, of nearly 20 feet in a year; its density and intricacy, will let no wind, much less any more solid substance, through, and I see no serious difficulty in keeping it within assigned bounds. I find some difficulty however in propagating it, otherwise than from seed. I have tried many plans without complete success in any, but I do not despair of overcoming it. In the boundary fences, I have tried layering, which so far seems to succeed, but I cannot apply that plan to fresh lines of shelter. I have tried putting down whole lengths, in trenches, with all the branches attached, but cannot assert that it will succeed.

"I have no doubt that but for *Hemileia* Liberian coffee is the most profitable of our low-country products, but with the active presence of this pest we have an element that defies all our culculations. On this land I have no doubt that the crops would be from 6 to 10 cwt. per acre after the third year, which, with cheaper labour, and lighter public burdens, would place us in advantageous comparison with our upcountry brethren, but with the same enemy to contend with, and the same ignorance of how it is to be successfully attacked, I fear we cannot congratulate ourselves on our better position. The cryptogamist has finished his task, and left us exactly where he found us, as regards a practical remedy. We have no right to complain that science has done no more for us than it could, but it need not have accompanied its failure, with advice equally impracticable and useless. *Hemileia* cometh where it listeth, but we know not whence, nor need we enquire where it goeth, would it only go. As for the various plans of treatment proposed on more or less sound principles, I, for my own part, am sceptical of success, I would indeed try them, and do them full justice, though with the minimum of hope as it is better to be doing something than standing still in the confession of utter helplessness. On all hands it is admitted, that lime is an antifungoid, and I am now applying lime, by dusting it on the trees, whenever the leaves are sufficiently moist to retain it. So far, I do not see that it has had any direct effect on the *Hemileia*, but I believe it will be otherwise beneficial. If it do not benefit the tree already affected, by even partially checking the pest, it will probably render those now free, less liable to an attack, and at the last, and the worst, the soil will be so far improved as a hundredweight per acre can improve it. I think I see a gleam of hope, in the case of Liberian coffee, in the fact that different varieties are differently affected. One variety it strips of every leaf in a few months; another gets more or less of the pinspots on every leaf, but drops none, and ripens any crop it may form; a third gets spots, but the *Hemileia* never fructifies; and a fourth absolutely refuses to admit it, though exposed to infection from neighbouring plants for twelve months. Should this on further observation, be confirmed, we will only have to propagate from the varieties that have the best powers of resistance. So far as my observation enables me to judge, *Hemileia*, having once found a home, on a Liberian coffee plant, never leaves it again, but goes on affecting each leaf as it is developed. I have stumped great numbers of young plants, from one to four feet: for the greater part, the stump did not even make an attempt, to throw a sucker, and when it did, the pest appeared again on the first leaf opened. I may mention here, that I obtained some of the seed recommended as the produce of the oldest trees in Ceylon. The plants grown from this are the only lot that got *Hemileia* in the nursery, that indeed showed it on the seed leaves, when they had no other. I could not at first admit that the yellowing of the seed leaves, indicated the presence of the disease, but that point was subsequently placed beyond dispute. There is no time in the life of a coffee plant when it is in such vigor as in its third year; it has enjoyed the fresh energy of the soil; its sprinkling of crop, makes no exhausting demands on its resources; and the consequence is that the maiden crop is the most perfect seeds it ever yields. I would, therefore, in the cause of obtaining the most perfect plants, use the selected seeds of selected trees, bearing their maiden crop. I have here such a variety of Liberian coffee plants; leading varieties and sub-varieties that I feel myself quite unequal to their classification. They differ in the height of the stem at which they branch; in the size, form, and colour of the leaf, in the angles that the branches make with the stem, in the closeness of the foliage, and above all in their susceptibility to disease. So far as I am able to judge, in the present state of my experience, there are two varieties that absolutely refuse accommodation to the intruder, and there is a third that gets the pinspots, a few here and there, but they do not seem to fructify, and it hardly seems to suffer. This latter is that which needs most room, in its third year. The branches reach a length of four feet, and stand out at right angles with the stem, being well furnished with secondaries, and the foliage very full and close, of a very light green. It is a late and a light bearer, so far as I have yet seen, certainly not to be propagated as the Liberian coffee of the future. The first favourite is a handsome tree; foliage very dense dark green, and glossy, and an early and heavy bearer; the joints are very close; it produces from twenty to thirty-five flowers, at each joint flowers out to last pair of leaves, and averages twenty fruit at each joint, and so far seems proof to *Hemileia*. The next in order branches nearer the ground, in some cases within a foot, it has long narrow leaves, width one-third of length with great density of texture, and a tough leathery look. It is a tolerable bearer but not equal to number one and it is not absolutely impervious to *Hemileia*, but seems to have considerable power of resistence. One plant, that has been spotted for twelve months, has not dropped a leaf from this cause while several of its near neigbours are leafless. I am watching to ascertain the varieties that are most susceptible to the pest, but though I have marked down several to be avoided, in further propagation, my observations are not complete, and I will reserve what I may have to say till better informed.

"The money spent by me, since I took charge, two years and nine months ago, up to the end of 1881, is:—

1879...	...	R3,946·64
1880...	...	3,602·41
1881...	...	3,229·64
		R10,778·69

From this sum, deduct receipts for estate's produce R742·98, leaves balance to debit of R10,025·71. As I was not furnished with account of money spent on felling, before I took charge, I could not include it, and the previous expenditure for plants was something considerable, but it has not come into my accounts. With those items added, and the large sums subsequently paid for coffee and cocoa seed, the portion now planted, say 70 acres, will be heavily handicapped, but the sooner the whole property can be planted up, the lighter it will be all round. Plants can now be reared for a comparative trifle, and I can now work at a much lower rate than in the earlier days of organizing and fighting against the extravagant demands of everyone with whom I had to deal. If I had to begin anew, in this neighbourhood, I would have no hesitatiou in undertaking to bring 100 acres of Liberian coffee into bearing with everything but the permanent buildings complete for R15,000, and such a property should then be worth R50,000 if we only calculate five cwt. per acre at 60s, and a local annual cost of 40s. When the contemplated filling-up is completed, I would value the 70 acres open now at R21,760, and the remaining jungle at R3,240, making for the whole property R25,000, and my estimate would

have been less modest, but for the presence of *Hemileia*, for I have seen clearings bearing over three times the crop I have chosen to stand on.

"The trees continue to grow as they have been doing for the last nine months, but Ceylon must bo its diminished head before the fertility of Java, where they are represented to have made 4½ *to* 5 *meters* in 1½ *years*. I have none of that age over four feet, and those, the longest legged varieties, and I have seen them six years old, on our best soil, but none that reached 5 *meters* anywhere.

"The Pimento has been a dead failure, and I have no great success to record of the Rubber. Only 10 or 12 per cent of the Cardamoms have failed.

"The felling of the remaining portion of the 40-acre lot will be finished before the end of next week and the holing of the inter-planting is well advanced."

The above carried the history of this sorely-tried but at last fairly successful experiment up to the end of 1881. Since then, the progress of the place has been encouraging, and we have now no doubt of its ultimate success, *malgré* leaf-disease, crickets," lizards, and all the other "ENEMIES OF THE COFFEE TREE.

PLANTERS' ASSOCIATION OF CEYLON.

The following are extracts from the 28th annual report for 1881-2 of the Ceylon Planters' Association read at the annual meeting on 17th February 1882:—

GOVERNMENT SALES OF CINCHONA BARK—Through the good offices of Mr. Wm. Martin Leake, this important matter to all interested in cinchona cultivation was brought under the notice of Parliament by Captain Price, member for Devonport, who asked the Secretary of State for India whether it was the fact that the Indian Government were exporting large quantities of cinchona bark for sale in London, and whether, in introducing the cinchona plant into India, the Government did so with the object of encouraging private enterprise or of competing with it in the market. In reply the Marquis of Hartington said that the object of the Government in introducing the cinchona plant into India was to provide an abundant supply of a cheap febrifuge for that country, that almost all the bark produced in the Bengal plantations is manufactured in India for use there, but difficulty had been found in treating the produce of Madras plantations in the same way, and hence most of it had been sent to England. It is believed that the sale of this bark has established the reputation of Indian grown bark to the advantage of private growers, but an experiment is now being made on a large scale with the view to the manufacture of this bark in England, on Government account, and, if this proves successful, it is likely that Government sales will be discontinued. Your Committee further placed itself in communication with the various Associations and representative bodies in India, with the object of obtaining suggestions and co-operation in endeavouring to prevent a continuance of Government competition with private enterprize in the markets for Cinchona bark, and it is satisfactory to note that the Nilgiri Planters' Association recently promptly acted on your advice, and brought the subject prominently under the notice of His Excellency the Governor of Madras, whose reply, if not altogether satisfactory, was both sensible, and statesmanlike.

A GOVERNMENT CINCHONA BARK ANALYST AT HAKGALA.—At a recent general meeting, the following resolution was passed:—"That, in view of the large area of land now planted with cinchona, and of the fact that the climate and soil in many parts of Ceylon are well suited to its successful cultivation, Government be requested to appoint a bark Analyst at Hakgala with a view to carrying on experimental cultivation." In reply the Government forwarded an extract from a letter from Mr Thiselton Dyer, which, though bearing upon the subject, could not be viewed as an answer to your representation, and it must be felt by all that a matter of such importance, namely the fostering of a rising and important industry, deserves greater consideration. In the letter referred to Mr Dyer states his opinion that, in the present stage of cinchona cultivation, the services of a chemist on the spot would be of much advantage to the planters, and, though the establishment of several local bark analysts has to a considerable extent met a want long felt by growers of cinchona yet, your Committee feels that, without in any way interfering with private enterprize, there is need for Government to take steps to specially prosecute experimental cultivation with a view to the development of the more valuable varieties of cinchona. Your Committee recommends that Government be again addressed on the subject.

LEAF-DISEASE.—There has been no general mitigation in the severity or prevalence of the disease during the past year. The final report of Mr. Marshall Ward, before leaving the island, though interesting and valuable in many respects, unfortunately indicates no cure, and indeed holds out but little prospect of an effectual remedy being discovered. Mr. Schrottky with laudable perseverance, continues to devote a considerable expenditure of time and money to the prosecution of experiments in the treatment of the disease, and it would be premature in your Committee to express an opinion on the results hitherto attained. By the unanimous resolution of a general meeting of the Association, the Government has again been urged to offer a reward for the discovery of a cheap and effectual remedy for the disease, and it is confidently hoped that a handsome reward so offered may encourage fresh efforts, and induce many who are not personally interested in coffee cultivation to undertake experiments which must be attended with more or less expense. The duty of Government to assist and encourage private enterprize in this direction, by every means in its power, considering the vast importance of the subject to the general interests of the island, is so obvious, that your Committee trusts no time will be lost by His Excellency the Governor in giving effect to the recommendation of the Association.

RAVAGES OF GRUB AND THE SERVICES OF A NATURALIST.—In April last your Committee invited the attention of Government to the very serious ravages of grub in several of the coffee districts, and requested that the services of a naturalist might be directed to remedial measures because the Association is of opinion that the aid of science is required to lead the enquiry to a successful issue. Your Committee regrets very much to report that so far the Government has taken no steps to meet your wishes, as, it has transpired, that the letter forwarding your representation has miscarried in transmission from one Government department to another. A copy of the letter referred to has now been furnished, and your Committee trusts that Government may see its way to early practical action in the matter.

ADMIXTURE AND ADULTERATION OF COFFEE.—Your late chairman, Mr. Wall, interested himself greatly in connection with a memorial to the Secretary of State on the subject of the admixture and adulteration of coffee, but owing to a divergence of opinion with the Chamber of Commerce, the united action and co-operation in the matter, which is so desirable between the two bodies, could not be maintained, and has resulted, your Committee regrets, in the abandonment of the memorial for the present.

"THE TROPICAL AGRICULTURIST."—Your Committee was glad to note the commencement during the past year of this local periodical of information on tropical agriculture. It recognizes its great usefulness as supplying an important want and has no doubt that its development will prove of much value to planters.

COFFEE LEAF DISEASE.

The following letter was then read by the SECRETARY, which was considered very satisfactory by the meeting, and it was resolved that the Government be thanked for the same. The letter was as follows:—

Colonial Secretary's Office, Colombo, 11th Feb. 1882.

SIR,—With reference to your letter of the 11th ult., I am directed to acquaint you, for the information of the Planters' Association that, in accordance with the assurance given in the Legislative Council, the resolution of the Planters' Association enclosed in your letters of 7th March 1881 and 14th January 1882 will be at once laid before the Secretary of State [illegible] with [illegible] a reward will be [illegible] as may be [illegible] properly [illegible] the [illegible] an [illegible] remedy [illegible]. I am, Sir, your obedient servant,

GEO. T. M. O'BRIEN,
for Colonial Secretary.

Correspondence having then been read from Mr. Eugene C. Schrottky, with regard to the treatment of leaf disease,

The Chairman enquired whether the members thought anything more could be done.

Mr. Gibbon said: I have one remark to make. I do not quite see what advantage we could gain from the form of experiments proposed. I do not see how it is possible for any man to get any prize, unless there were some means placed at his disposal by Government to carry out his experiments. Mr. Schrottky has spent much time and money and deserves the warmest thanks at our hands. We may differ from him, and some of us do differ from him, but there can be no doubt that Mr. Schrottky has spent twelve months of his time among us in experiments. We had a Government man with a fixed salary, who has given us the life-history of leaf disease, but, with all deference to Mr. Ward, I must say that Mr. Schrottky has tried to give us the death-history of leaf disease. It would be well to point out to Government that many of the native gardens are being made utterly worthless by leaf disease, and that it is not fair to expect planters to pay entirely for experiments from which the natives would largely benefit, if they are successful. It would be well if the different Government Agents appointed gardens for carrying out experiments. Messrs. Whittall & Co., have put up their estates under experiment, and I do not see why Government should not be called upon to take their share in the business, and to do their bounded duty in the interests of the natives, by actually putting their hands into their pockets and contributing towards the carrying out of the experiments. The sweeping up of leaves, as recommended by Mr. Ward, for instance, might be carried on in the native gardens selected by Government, which, for all they are worth at present, would be readily given by the natives for their purchase. It would not cost government much, and the cost would be nothing compared to the increase of revenue if native coffee were again to come to the front.

Mr. Wright enquired if Government would not fix a certain amount for the reward.

The Chairman said that Government could not be got to fix a reward.

One of the members asked for more information with regard to Mr. Schrottky's treatment, whereupon

The Chairman remarked that he saw the estate on which the experiment of carbolic powder was tried. The place looked to a certain extent free from disease, but he thought the attack was only put off for a time, and that it would come on again with great virulence.

Mr. Gibbon said that no harm could be done by the application of carbolic powder. Experiments were tried on Pallakeily, and he questioned whether the lime or carbolic powder was doing good. At Pallakelly they were trying lime alone now.

LEAF-DISEASE REMEDIES.

The following are the letters of Mr. Schrottky regarding his remedy for leaf-disease read at the recent meeting of the Planters' Association:—

Colombo, 6th February 1882.

A. Philip, Esq.,
Secretary, Ceylon Planters' Association, Kandy.

Dear Sir,—In continuation of my letter of 16th November, and 31st May 1881, I have now the honor to forward you herewith, for the information of the Committee and members of the Association, my concluding notes on the results of my experiments in connection with coffee leaf disease. In addition, I desire to point out that these notes are based, not only on the reports accompanying but to a very great extent also on the evidence that has been collected by me and made public from time to time as to the effect of the carbolized powder on the fungus at various times of the year.

I have carefully considered not only the absolute results of the treatment, but also all the surrounding circumstances, which could possibly tend to lead me to a wrong conclusion. More particularly has this been done with regard to the results at Gangapitiya estate, and I trust that some weight will be attached to my statement that there is no evidence existing that could qualify, to however small an extent, the results there obtained viz., the successful stamping out of disease in April and May, and the immunity from it as long as carbolized powder lasted (for the subsequent 7 months), during all which time the disease was prevalent in every *surrounding* estate; viz., Rajewelle, Gangawatte, Ambacotta, Mahaberiatenne and Mary Mount. The treatment was discontinued at Gangapitiya at the end of December for want of carbolized powder, and leaf-disease has been making some progress since, but, considering the enormous mass of spores of the fungus that were supplied by the surrounding affected estates, this was reasonably to be expected, for we have every evidence now that to ensure *absolute* continued immunity from disease, the treatment must be continuous, except, perhaps, on completely isolated estates.

The experience gathered during the last 18 months has been important, disclosing the period of the year when the fungus may be dealt with most successfully, and as I see my way clearly to modify the treatment, and, the form of application of the carbolic acid, so as to render its action more continuous and effective during rainy weather, and thus more successfully to guard against reinfection, I feel fully justified in having closed the results at the end of December, especially as I have already laid proof before the public that the growth of the fungus can be successfully arrested during January and subsequent months.

I have to regret that the readiness with which the results obtained at Gangapitiya have been attributed to anything rather than the treatment has greatly operated against my endeavours to arrange, before my departure for India, for a continuation of these experiments on a sufficiently large scale to establish thoroughly at the end of another 12 months the usefulness of the remedy. It has been argued that the immunity of Gangapitiya from leaf-disease during all the time the treatment was continued (9 months) was due to exceptional dryness of weather during the south-west-monsoon. But after careful enquiry I find that there has been no difference in rainfall between Gangapitiya and the bulk of the estates with which it is compared viz. Gangawatte, Ambacotta, lower Rajawelle and Rajawelle No. I and No. II. Upper Rajawelle and Pallekelly had a little more rain during the south-west monsoon, but so far from this having caused a greater development of the disease in the latter than in the former estates, the manager of Pallekelly and myself on a visit through these estates in October last came to the conclusion, from what we saw, that there was, on the contrary, less disease at Pallekelly than at Gangapitiya, Ambacotta and Rajawelle No. I and No. II.

It has further been argued that belief in the efficacy of the treatment is considerably shaken by the absence of disease in December on Victoria and Henegahawelle estates. These two estates are exceptionally situated; they are at the very end of the Dumbara district; are separated from Gangapitiya by a range of wooded hills of nearly two miles breadth; they have been more liberally treated (the greater part of Henegahawelle was manured with bulk only lately); and their history as regards time and severity of disease attacks (as appears from estate reports for the past years) differs essentially from that of Gangapitiya and the bulk of estates in the Dumbara valley.

Seeing now how readily successful results are questioned on insufficient grounds, the Association will understand why I can scarcely be expected to continue the further direction of these experiments, not having been able to obtain a sufficient acreage to operate upon during next season. If only one or two estates are operated upon, the results, however successful, would always be open to be questioned on some ground or other, and I would have thus devoted another year of my time to this work without being able to claim that recompense and recognition of services to which a universally acknowledged success would entitle me.

To place results quite beyond cavil, the experiments should be carried on at say five different estates in different districts (Dumbara, Dikoya, Dimbula, Dolosbage, and Matale).

There is a feeling gaining ground that, as considerable sums have already been spent by individual proprietors, the planting community ought, now that such promise of ultimate success is held out, to bear some share of the cost of systematically continuing these experiments.

More especially, as, for a great deal of past expenditure, we have gained nothing except experience of how best to deal with the disease. If the leading members of the planting community will make the endeavour to collect subscriptions from their brother-planters to the extent of R3 to 4,000, I think I will have no difficulty with some more personal exertion in arranging for the rest. The most discouraging feature is the great want of interest generally displayed.

I have delayed this communication so as to hear and answer what could be advanced by practical men against the general correctness of my conclusions.—I am, dear sir, yours faithfully, Eugene C. Schrottky.

Colombo, 13th February 1882.

A. Philip, Esq.,
Secretary, Ceylon Planters' Association, Kandy.

Dear Sir,—With reference to my last letter on the subject of my experiments, and with more special reference to my statements therein, that, during the last south-west monsoon, there was no difference of rainfall between Gangapitiya and immediately surrounding estates, it may, perhaps, not be unnecessary for me to hand you detailed figures in support thereof.

Summary of daily weather reports:—

Gangapitiya Estate.	*Ambacotte and Dangawelle Estates*
	June 1881.
9 days showery ...	9 days drizzle and showery.
1 day r in	1 „ rain.
20 „ fine	20 „ fine.
	July.
5 days showory...	5 days drizzle.
22 „ fine	6 „ fine.
	August.
10 days showory ...	6 days light drizzle.
21 „ fine	5 „ showery.
	20 „ fine.
	September.
6 days showery ..	5 days drizzle and showery.
24 „ fine 25	„ fine.
	October.
13 days rain & wet	6 days showery.
18 „ fine	7 „ rain.
	18 „ fine.

I may further mention that besides what I have already stated regarding the exceptional situation, difference of past history &c., of Henegahawollo and Victoria estates, a comparison of the daily weather reports of the former estate by Messrs. Whittall & Co. has shown that, whereas Gangapitiya from the beginning of June to beginning of October of last year reports rainfall on 30 days, Henegahawelle reports rainfall on only 15 days during the same period.

The difficulty I, and those working with me, have encountered, of keeping leaf-disease out of comparatively small areas, surrounded by affected coffee, and the impossibility of such areas remaining free from it after the treatment is discontinued, will, in the present light of our knowledge, I trust, be fully understood.

Mr. Ward has shown to what great extent the atmosphere is laden with the spores of this fungus in all parts of the country, especially during the periods of severe attacks. This extent is far greater than I had any reason to believe at the outset of my experiments, and this is what necessitates such modification of the treatment with carbolic acid as will render its action more permanent.—I am, dear sir, yours faithfully,

Eugene C. Schrottky.

GREAT SALE OF INDIAN TEAS IN MELBOURNE.

We have received a catalogue of 4,639 chests of tea to be sold on 9th Feb. Appended is the following report:—

Industrial and Technological Museum, Laboratory, 25th January, 1882. Report on Samples of Indian teas received from Messrs. James Henty & Co. The following results week obtained upon analysis:—

Name.	Per Centage of Mineral Ash.	Per Centage of Extract.	Per Centage of Soluble Salts.
Assam Pekoes ...	5·52	46·20	3·42
Assam Pekoes Souchoug ...	5·40	44·60	3·00
Cachar Pekoes ...	5·40	47·52	3·30
Cachar Pekoes Souchoug ...	5·20	44·28	3·00
Darjeeling Teas ...	5·31	42·68	3·12
Dehra Doon Teas ...	5·80	41·60	2·78
Indian Pekoes ...	5·36	42·02	2·96
Indian Pekoe Souchong ...	5·26	43·18	3·06

We have carefully examined the above teas, the leads of which were cut under our supervision, the samples also being taken by us from the bulk. We guarantee these teas to be pure and free from any adulteration.

J. Cosmo Newbery.
Frederic Dunn.

Particular attention is called to the high analysis of the Cachar Pekoes.

The Cachar pekoes, to which attention is attracted, gave over 47½ per cent of extract, but this is still considerably below the result obtained by Mr. Dunn from a specimen of Lool Condera tea: it actually yielded 52 per cent, a proportion entirely unprecedented. It will be observed that the Assam pekoes, although a little lower in total extract, exceeded the Cachar pekoes in soluble salts—giving so high a percentage as 3·42. The Dehra Doon teas, grown at 2,000 feet elevation in 31° north, while they gave rather too high a proportion of mineral ash, gave the lowest results in the valuable properties of extract and soluble salts.

Your obedient servants,
LEWIS & PEAT,
BROKERS.

6, Mincing Lane, London,
27th January 1882.

THE COFFEE GRUB AND MASKELIYA COCKCHAFER.

SPECIMENS WANTED FOR THE BRITISH MUSEUM.

We give prominence to the following letter (with its enclosures) from Mr. Haldane, the writer of the Essay on "Coffee Grub" published at this office:—

Care of Messrs. Anderson, Anderson & Co.,
5, Fenchurch Avenue, London, E.C.,
5th January 1882

Messrs. A. M. & J. Ferguson, Colombo.

DEAR SIRS,—I have to thank you for the copies of my pamphlet on "Grub." On receipt of them I distributed them among people likely to give the subject some attention. One copy I gave to the *Field* editor, and I call your attention to the notice taken from the issue of December 31st.

I made enquiries as to the leading Entomological Societies, and will furnish them with copies.

I was introduced to Mr. Waterhouse, Entomological Curator, British Museum, and gave him some dry specimens of the different cockchafers. I regret I could not find a bottle with specimens preserved in spirits, which would have enabled a more careful examination to have been made by dissection.

I enclose a copy of Mr. Waterhouse's letter on the subject, from which you will notice that the beetle I called the "Maskeliya cockchafer" is, in all probability, a new variety not previously described. Mr. Waterhouse, in subsequent conversation, pointed out the importance of furnishing the Museum with specimens in spirits. These, I have no doubt, you will procure for him.

The "Brouze Beetle" requires further identification, though it evidently belongs to the Buprestidæ.

The same remarks (about identification) apply to the "small cockchafer."

Mr. Waterhouse will be obliged by having specimens of the Ceylon beetles, especially the cockchafers (about which there is still much to learn) and Ceylon moths, sent to the Museum. Beetles should be in spirits and addressed

The Principal Librarian,
British Museum, London.

For the Zoological Department.

I was introduced to Dr. Günther, the head of the Department. He shewed great interest in the subject, and hoped that specimens of Ceylon insects would be sent, as the Museum is not very rich in them. Perhaps you will agree to receive specimens from correspondents in the hills, and lowcountry, and have them sent to the Museum. In this way much will be learned about your insect pests.

The alkaline dressings, alluded to in the *Field* articles are, I fancy, repeated applications of lime—a course I have long advised planters to follow. The advice given that planters must study the subject *ab ovo* is undoubtedly sound. No advice will be of the slightest use until planters can furnish entomologists with the life-history of the insects.

In most copies of the pamphlet I wrote a note requesting any one who could give information on the question to communicate with your paper.—I am, dear sirs, yours truly,

R. C. HALDANE.

(Copy.)

British Museum,
3rd January 1882.

DEAR SIR,—I have named the Ceylonese beetles so far as I am at present able.

Fig. 1 is a species not in the Museum, and at present I do not know to what genus to refer it? I think it must be placed in Leucopholis for the present.

Fig. 4. Family Rutelidæ; Mimela Xauthorhina of Hope.

Fig. 5. No specimen; I know nothing like it.

Fig. 6. Melolonthidæ, Lachnosterna, very near L. costatus, Walker.

Fig. 13. Lachnosterna pinguis, Walker. (Does not quite agree with type, but I think it is the same species.)

Fig. 15 Cetoniidæ Clinteria chloronota, Blanchard.

Fig. 23-24. Leucopholis pinguis, of Burmeister.

The brown one (23) was described by Wa ker under the name Melolontha rubiginosa; but Burmeister's name must stand, supposing 23 and 24 to be the same species, as I believe. So far as I have seen, 23 are all males and 24 all females.

Fig. 28. (Rutelidæ) Anomala elata of Fabricius.

There are a great many more Melolonthidæ found in Ceylon, but for practical purposes I expect you have mentioned all that are necessary.—Believe me, yours very truly, (Signed) CHAS. O. WATERHOUSE.

COCKCHAFERS VERSUS COFFEE.

(*Field*, 31st December 1881.)

"All about Grub: including a Paper on the Grub Pest in Ceylon. Being the result of observations on the Cockchafers and their Larvæ in connection with Coffee Planting." By R. C. Haldane. Colombo: A. M. & J. Ferguson, 1881, 8vo., plates.

The author of the little pamphlet with the above, at first sight, somewhat whimsical title (for which he is probably not answerable), deserves every credit for his attempt to investigate a somewhat difficult subject, a correct knowledge of which is of the highest importance to coffee planters. Evidently an entomologist, but writing as a practical man for others like himself, he has put together notes derived from actual experience, referring to the habits and earlier stages of the Lamellicorn beetles belonging to the families Melolonthidæ and Cetoniidæ, of which the larvæ commit vast ravages in Ceylonese coffee plantations. He is quite aware of the imperfect nature of his observations, and adds a MS. note begging for additional information on the life-history of the insects to which he refers, to be sent to Messrs. Ferguson for publication in the well-known *Ceylon Observer*. We fear that it is out of the power of anyone but a resident to aid in this good work—at all events, until more precise particulars are obtained. There is no attempt at scientific identification of the beetles referred to, and the rough figures given scarcely admit of the formation of a sound opinion as to their specific status, considering the numerous South Indian representatives of Ancylonycha and its allies. They are, however, probably quite accurate enough for re-

cognition as foes by the unfortunate planter; and the best counsel we can give is to urge on the sufferers the necessity for an accurate biological study, continuing Mr. Haldane's praiseworthy beginning. The very excellent work in the Reports of Riley and other American economic entomologists may be taken as a standard.

So far as they go, Mr. Haldane's observations are eminently intelligible and appeal to the common sense of his readers. The system of planting has developed an abundance of food more suitable for the larvæ of the beetles than their natural pabulum, and the excessive rainfall of the last four years has mechanically aided their increase by loosening the soil, facilitating its penetration both by the grub and perfect insects. Rich soil, especially where there is decaying timber, seems to be most affected.

Mr. Haldane has instinctively tried all the methods which have sufficed for keeping down the injuries occasionally inflicted by our European cockchafer; but the luxuriance of tropical life is far too great for such superficial safeguards as hand-picking, collecting on sheets, &c. We may note that French agriculturists have found alkaline dressings the most certain, speedy, and economical mode of destroying the larvæ. It is during the earlier stages, when these are accurately known, that the real work must be done: and it surely is not too much to expect that at least the most destructive kinds should be readily and thoroughly investigated, *ab ovo*. At present there seems some discrepancy of opinion as to the larvæ of some of them, though, from the figures given, we should think the "grey grub" most probably that of one of the Cetoniidæ. It is stated (p. 19) that larvæ of this kind, which presented no distinguishing characteristics, "turned into two distinct varieties of beetles, a proof of how impossible it is to distinguish variety in the immature insect." The author's note shows that he recognizes the inaccuracy of these remarks; there would, of course, be little difficulty to an entomologist in discriminating between the larvæ of a Cetonia and of a Melolontha (amongst other things the head is not as broad as the body in the former, though it is in the latter), and there must have been some confusion in the experiment. In detecting the sexes also, the antennæ will generally be found of use, as the foliated club is (sometimes conspicuously and usually appreciably) larger in the male.

One of the Buprestidæ is represented, with the remark that it probably does no harm. But the larvæ of species of this family are all internal vegetable feeders, and are occasionally very destructive to plant life; so Mr. Haldane's first idea in figuring it among the enemies was most likely correct.

The natural enemies of the "grub" are referred to, and an instance of attack by a carnivorous beetle is recorded at p. 13. This, in all probability one of the great family Carabidæ, is imagined (p. 31) to be a dung-beetle by another observer, whose notes are reproduced. Among them is an expression of belief that the plague has taken so firm a hold on a large part of the coffee districts, that individual efforts can have no effect in reducing it, and that the aid of Government must be invoked. The home authority is here intended, as "it appears to be useless to expect much activity or assistance from the local Government."

GEM-DIGGING IN BAMBARABOTUWA, CEYLON.

(*From an Old Colonist*)

About the beginning of last year gem-digging was commenced on a large scale in Bambarabotuwa. The first spot that seems to have attracted attention was Kekunagahadola, on the lower end of the Petigalkanda range, as it joins the Bambarabotuwa hills, about 12 miles west of Balangoda. There is a hardly practicable foot-path to the spot from Pelmadulla. Early in 1881 several large "catseyes" were found here, and during the middle of the year there were, it is said, over a thousand men hard at work in the gem-pits, about Kekunagahadola and Lilwalahena, about half a mile to the south. About this time a large number of diggers established themselves on the private property in the forests of Hapugastenna and Kundragalla, where they found rubies and sapphires. The pits they sank are about 12 feet deep and 15 square. To the depth of about 4 feet the usual reddish yellow soil is found, discolored towards the surface by vegetable matter; below this there is a stratum of from a foot to eighteen inches thick, of gravel, sand and well-rolled pebbles, in all respects similar to the bed of a stream.

It is in this stratum that the gems are found. In some of the pits, tunnels have been formed for many yards, which must be very dangerous, as no attempts are made to shore up the earth. Some months ago the Assistant Government Agent of Ratnapura brought a certain number of diggers before the District Court, and it is said that the District Judge fined them R10 each. They appealed to the Supreme Court, and the judgment of the District Court was quashed, the fines being refunded to the diggers, who immediately renewed their operations on the Crown lands in the forests about Kekunagahadola, where there are at present several hundreds at work.

The Massana estate is at the upper end of the forest to the east of Kekunagahadola and Lilwalahena, and a small piece of land on the property has been rented to the diggers at the rate of R50 a month. Here also catseyes would appear to be the principal gems found. When poor Crüwell was in charge of this estate, the late Dr. Rudolf Gygax went with him and some other friends in search of precious stones, and though they found nothing of much value poor Gygax considered that a properly organized search on scientific principles would be likely to prove highly remunerative, but we were all so sure of making fortunes then with coffee, that no one liked the idea of allowing anything to take his attention off the one absorbing pursuit. Amongst the rumours in Boltumbe and Bambarabotuwa, it is said, that a Moorman with two Kandians from Balangoda went into the Wellawa forest, up the bed of the Welawe stream, and in two days returned with a catseye, for which they were offered R1,000 in Balangoda. The roads opened over thirty years ago in Bambarabotuwa and Boltumbe, are in many places almost obliterated. They were traced by Government, and sections were made of them, and they were formed into very superior bridle-paths by the planters. Such portions of them as are used by the villagers are still almost fit for cart traffic; in some places they have been blocked up for chena cultivation, and the approaches to the chenas cut through, so that the trace is difficult to find. The Road Committees seem to ignore the line altogether, although few parts of the island are in such great need of being opened up by roads.

If there were any well-defined law on the subject of gem-digging, it is more than probable that capital would be forthcoming for the due prosecution of the search for precious stones, and that an important business would spring up, and bring wealth and civilization into what is now the wildest and most savage part of Ceylon. But in the present uncertainty as to the claims of the Government, and the apparent absence of all law on the subject, no one who has anything to lose can engage in such a speculation. The consequence is that the persons now occupied in gem-digging are more like banditti than laborers, and lead a very lawless and reckless sort of existence.

There certainly can be no reason for leaving the precious stones hidden in the bowels of the earth, where they have been for countless ages, but the present state of all matters connected therewith cannot be considered creditable to a community under European control.

It is not in this way that the Europeans at the head of affairs in Borneo manage the gold washing, at Sambos, Pontianak and Banjirmassing; and unless the Bambarabotuwa gem-diggers are looked after, we may look out for something startling one of thsee fine mornings.

[In a private note to a friend, the writer adds:—"We had to clear our way along our old bridle-path from Boltumbe and in doing this came on several snakes. I send you one whole, which the natives, as usual, say is deadly[1]; it certainly looks a dangerous beast to me, and the head of a big reptile that could not be got into the bottle[2]. The snake the head belonged to was basking in the sunshine on a rock in the middle of the path. I have made drawings of the gem-diggers, huts, and of the hills where hundreds of gem-diggers are now in active operation. Could you put me in the way of sending them to one of the illustrated papers? I think they are the kind of things that such papers would reproduce. I send with this a short account of what I saw and heard during my trip. We did not find any people at work on our land, but we put up in a very good hut they had built, and saw plenty more huts and no end of gem-pits." We shall be glad to forward the sketches and the above description to the editor of the *Graphic*, who, we doubt not, will be very ready to make use of them.—Ed.

SHEEP-FARMING IN QUEENSLAND.

A correspondent sends us a description of a visit to a sheep-farm in Queensland by a friend who is making a tour of the world. We extract the following:—

Queeuslaud, in the island continent of Australia, though only last year it attained its majority as a distinct and separate colonies, is not the least among the Australian colonies, ranking rather as the third in size, with an area equal to twenty-three per cent of the whole area of that island, antipodeal to Britain, and which, though tight, can hardly be learned little. * * *

Plenty of elbow-room there is within its boundaries, for, on an area of 669,520 square miles, there are only in this, the census year of 1881, 218,000 persons; or, on the average, each person, whether man, woman, or child, may look over a space of 2,000 acres, as, in a sense, being personal property.

That the personal interest, in districts known to, or occupied by, the squatter, is a large one, the principal export, wool, by which the colony is perhaps more particularly known, declares. Other growths, other products, are now rapidly making their way in its export lists, but "*revenons à nos moutons*"!

---

1 This is one of the pit vipers, the kunakatuwa and polon-telissa of the Sinhalese, the *Hypnale nepa*, an oily-looking, flat-headed, marbled snake, very common from the coast up to 6,000 feet elevation. It has been erroneously figured in Davy's History of Ceylon as the "karawala," which is the *Bungarus Ceylonensis*.

2 The head indicates its close affinity to *Aspidura Copii*, so rare in 1864, when Günther's work on the Reptiles of British India was published, that only one specimen was known, and this was conjectured to be from Ceylon. It has since been found in Dikoya, and one specimen exists in the Colombo Museum. The head sent proves that it is an aberrant form or new species of Aspidura. Could our friend try and secure an entire specimen of this snake?—W. F.

In the *Queenslander*, a weekly newspaper published in Brisbane, which, I believe, goes generally through the town or country parts of the colony, several firms of stock and station agents have, weekly, announcements of stock and stations for sale which may may afford an idea of the belongings of squatters, which name still is used in reference to the representatives of the pastoral interest. One firm may advertize fifty stations, in one issue of the paper, for sale, varying in size from 50 to 2,000 square miles, and perhaps, as in one case was counted, averaging 550 square miles.

A few are reported as unstocked—several are stocked with cattle and sheep—a number with sheep counted by tens and scores of thousands, and the majority with cattle, also numbering thousands in teens and even scores. One station, offered for sale in the month of November, was stated to consist of about 190 square miles and to be held at an annual rental of a sum equivalent to 1s 4d per acre!

Of the fifteen districts into which Queensland, politically, is divided, that of the Darling Downs, discovered by Allan Cunningham, the botanical explorer, and called by him after Goveruor Darling, is perhaps well-known in the temple of pastoral fame. To its devotees, at least, it bears a charmed name,

Roughly, from its extremities, which have almost the form of a square, it extends over 3° of latitude and longitude, and more exactly covers an area of 25,300 square miles. Four and one half of such districts would equal the United Kingdom in area nearly. Accordingly to the *Queensland Gazetteer* which is, and should be, an authoritative publication, Darling Downs "is the richest pastoral district in the colony, and also comprises a vast extent of fine agricultural land." Sheep grow to a good size, and their wool is of good quality. Away west, on the plains watered by the rivers Barcoo, Thomson and Upper Flinders, sheep thrive well, but they are not so easily reached by a tourist as those of the Darling Downs which lie immediately to the west of Moreton district, in which Brisbane, the capital of Queensland, is situated. A Government railway, starting from Brisbane, now runs west through the northern part of the Darling Downs district with a present terminus at Roma, in Maranoa, the district to the west of Darling Downs. The railway has, by degrees, been constructed within the last decade of years. Having the opportunity to visit a station, where the squatter's harvest, or shearing was in full swing, not far away from the line of railway, as it passes through Darling Downs, first thought and second thought we equally ready to jump at the offer, as a chance of seeing a representative Queensland station while the bustle of its busiest season could be mixed with.

"But surely," thought the tourist, after alighting from the railway train, mounting a buggy by the side of the manager of the station, being driveu a distauce of a couple of miles or so, and being told that a large shed fifty yards off to the right was the wool shed where shearing was going on—"there must be some mistake. There is no appearance of bustle there. Where are the sheep, shorn or unshorn. There is not even a 'baa' to be heard. They don't do this thing so in the old country. Is it a 'new chum' he's thinking of playing upon?" But a "new chum"'s five months experience in Australia directs him to wait for the *dénouement* patiently after returning from the house where at first he was set down. The house is a comfortable one-storied building, with, at the time, a beautiful scarlet-coloured, fuchsia-like flowering creeper meandering over the sides and along the verandah, which opens out on a pleasantly tree-shaded garden kept in good order by an industrious pigtailed oriental. A creek, with permanent water with ample swimming space for open-air bathers, is close at hand. For domestic and bathing purposes in the house, and for watering the plants in the garden, water, by horse-power, is pumped from the creek to reservoir tanks from which it can, by gravitation, flow down to its destination.

There is a slight inaccuracy in the foregoing sentence, because the bath-house is a little building in the garden a few steps off from the main building. If one can't be accurate, one should be as accurate as one can.

The kitchen &c., with servants' quarters, is also a little way off, but connected with it by a covered and creeper-

grown passage. Near the house there are several houses for various station hands, stables for saddle and working horses; a store with all sorts of miscellaneous articles necessary for food, drink, clothing, medicine and general outdoor requirements and operations, in charge of a storekeeper; workshops for carpenter and smith; a small wooden church where service is held once a month by a Presbyterian clergyman from a town fully a score of miles off to the westward; a hut with underground cellar where beef or mutton is kept when fresh and salted for ration requirements; and a butcher's yard where the animals are run in, slaughtered, and dressed. Stables have just been mentioned. In Queensland, particularly, not so much in the southern Australian colonies, it may be noticed that horses are treated as if they really were understood to be "sociable" animals. * * *

From a hill near the house there lies before the onlooker a flat and widely stretching plain, in this year of drought too dry and parched along its surface to gladden eyes devoted to a pastoral occupation. Here and there rise ridges with closely-growing belts and trees, and stones—not found on the plain—cropping thickly to the surface. At one or two points on the horizon hills, more or less elevated, mark the boundary of the prospect there more thoroughly defined than at other point where the plain itself, unbrokenly, is lost to sight in hazy dimness as the sun from an unclouded sky beats hotly down. Solid human flesh exposed in open air is then anything but "easy"!

During shearing time on a station visitors must be very much *de trop*. How much therefore had such an one to be thankful for when not only the shearing operations could be seen but when also those fellows in charge of the out-door arrangements went out of their way, in their busiest time, to show a "new chum" as much as possible of their department! Riding round part of the station, as opportunities were made or arose, gave the stranger an idea of its size. It occupies the *greater* part of 200,000 acres; more exactly it is about 273 square miles in extent and if in one square block would have sides 16 miles in, length. It is of a somewhat irregular shape, as it happens, however. It is fenced and divided into paddocks, some of which are thousands of acres broad. As was mentioned previously, this year and the former one also have been very dry, and the downs do not appear to advantage. Where at present the grass is only inches high, it would be numbered by feet in an ordinary season, as authorities tell, and as the rich-looking soil would also declare. The country is all volcanic, thereabout, and the soil sometimes black, sometimes red, has been formed, according to geologic lore, of the now decomposed lava, which had spread all over the plain in its molten state. No stones are to be seen there on the plain, the soil is pure and unmixed. How for the best soil goes down is generally a matter of conjecture. Its depth is in many places counted in hundreds of feet. I have seen the statement made in print, in reference to some coloured photographs of such country on view in the Brisbane Museum, that "the *ne plus ultra* of a 'run,' climate apart, is volcanic soil for the open country, with salt-bush ridges running through it." The salt-bush ridges are liked on account of the saline plants which find nourishment there from the salt known to be present in soil decomposed from carboniferous rocks. So goes the theoretical explanation, and, where nature fails in supplying the amount of saline plants necessary to the health of thousands of sheep—which, perhaps, she had not calculated on—art steps in and supplies the salt in the form by which it is known in commerce. It is carted out and spread on the plains, and the sheep take it greedily.

Queensland, on the whole, is, naturally, unsatisfactorily supplied with water. Here again art steps in. Dams are constructed or windmill and other power is taken advantage of to get a required supply.

Large dams are made on the plain to store up the rain-water when it comes. At one place on the station a dam had been made at the corners of four large paddocks where they united, in order to water all four. Even in the extremity of the dry season, there was a good supply stored up, though only a proportion of what could be stored. That the sheep appreciated the place was easily evident by the bare ground all round its borders and by the number, standing, drinking in the water, or reposing about, having drunk. My "guide, philosopher and friend" estimated the gathering as something approaching to 10,000 head. Windmills, on American principles, are often used. At one place the water is to be stored in a 10,000 gallon tank, from which, regulated by ball-cocks, it can flow along wooden troughs, lined with corrugated iron, laid out on the plain in two opposite directions for the sheep to drink from at will. A new tank was being erected at that particular place. A small dam had been excavated first, but it was found that the water evaporated very quickly. Our peregrination that day lauded us at that place where the workmen engaged had knocked off for their midday meal, of which we also partook. A sheet was rigged up under the windmill, and all hands gathered round. (It is very hot on the plain at noon.) Boiled salt beef was handed round in a tin dish, and each "hand" suited himself by means of his pocket knife. "Damper," flour baked in the ashes of a fire, when well-made is very good bread, and is also cut up by each diner. Tea, boiled over a wood fire in a "billy," or flagon, was served to each person in small "pints," or tin mugs.

Hungry men can fall to with a relish to such food. The tea has a peculiar "bush" flavour, which, however, is not by any means objectionable. (Generally tin plates, knives and forks are used, but as the men working at the tank were only there *pro tem.* such *impedimenta* were dispensed with. They slept under canvas with low stretchers on which to lay their "swag," or blanket.) The water from underground is generally brackish. The wells may be 100 to 200 feet deep, partly attained to by excavation, wooden planks being fixed at the side and partly by boring machinery. As showing the result of the drought on the plain, skeletons of sheep were numerously lying about. In one paddock, there were more than an average number noticeable: there, several hundreds had been burned to death during a fire. In such a case sheep stand helplessly, and make no effort to save themselves.

Then follows a detailed description of sheep-shearing, accompanied by a plan of the shearing-house.

A DESTROYER OF WHITE ANTS.

We have had, in the course of our career, many inquiries as to how to get rid of white ants, but we have always looked upon these pests as one of the ills which flesh is heir to in this country. But, at the last meeting of the Agri-Horticultural Society, we see that a supposed antidote to white ants has been invented, for Dr. R. F. Thompson submitted a specimen of his antidote with the following letter:—"I read a letter from Messrs. Octavius Steel & Co., in the proceedings of the Society some months back (November 1880) with advertence to white ants causing some of the managers of their tea estates much annoyance and uneasiness. I have given the matter much attention, and now beg to submit a sample of a specific prepared *entirely* from vegetable matter, which, I trust, will meet with success. The lower portion of the plant should be painted with it or smeared periodically; it will gradually dissolve and run down, destroy or remove these pests, and tend to nourish the plants or trees. I should like it tried on trees in the immediate vicinity of white ants. The Secretary mentioned that he had transferred a portion of this material to Messrs. Octavius Steel & Co., who had forwarded it to one of their gardens, where the pest is very rife, and had promised to communicate the result." We shall look forward with some anxiety to see whether it is successful or not. —*Asian.*

COMMERCE BETWEEN AUSTRALIA AND THE EASTERN WORLD

is thus noticed in the *Sydney Morning Herald* of January 18th:—

Although there has now been for many years a regular steam service between India and Australia, the direct trade between the two countries was not been much developed. At one time India took considerable quantities of our gold for the purpose of coinage,

but that trade has now ceased. The recent development of the tea industry in India gives, however, some indication of the beginnings of a new trade. At both the International Exhibitions in Australia, India was represented, though far better in Melbourne than in Sydney; and the Indian tea was brought more directly under the notice both of the trade and of consumers. But the steam communication is not quite direct enough to give to this trade all its requisite facilities. Calcutta, rather than Bombay, is the place of export for such commodities as are most likely to find a market in Australia. Yet the latter port is the main rendezvous of the steam fleet, and is the more convenient for that purpose. Produce coming down from Calcutta and intended for Australia has to be transhipped at Galle, which is little better than an open roadstead; and during the monsoon months, the steam company naturally objects to become responsible for valuable cargo. There is not trade enough at present for a direct line of steamers from Calcutta. We seldom send sailing ships from Australian ports there except with horses and coal, and though such vessels might bring back direct return cargoes, there is an increasing disinclination now to put valuable cargoes in sailing vessels. Time means money, and moreover there is risk of such commodities as tea getting spoilt on a long passage. What is wanted therefore is some form of direct steam communication between Calcutta and the principal Australian ports. We have it with China, we have it occasionally with Bombay, but Calcutta has been out of the running. Perhaps the best chance of establishing such communication lies in our export of coal. Now that compound engines have so reduced the consumption of coal, especially at low speed, steam-colliers are coming into use not only for carrying coal short distances, but even for long voyages; and it may soon become remunerative to send coal in this way to Calcutta and bring back produce. We do send coal to China in steamers and bring back produce. We may thus gradually find a market in India for other commodities besides coal. Our tinned meat, tinned fruits and jams are quite suitable for the Anglo-Indian market. Grapes and apples have already been sent to Calcutta and Ceylon, and landed in good order. Railway timber is in demand in India, and satisfactory experiments have been made with copper ore and tin. There is also some demand for coarse wools. What we could get from Calcutta in return would be such articles as tea, jute goods, fancy goods spices, oils, oilcakes, grain, and some delicate fabrics. A trade of this kind takes its time to grow, but will grow where the interchange is natural, and where facilities are provided. Some of the richest and most productive part of India has its natural outlet at the mouth of the great river which drains Bengal. But though English dominion began there, and though a great centre of commerce must always exist there, Australia has not hitherto had such direct connection with it, as it has with other parts of the world. As a claimant for our trade, Calcutta has hitherto been at a disadvantage. The leader of commerce there, however, are aware of the growing importance of Australia, are increasingly anxious to see direct communication established, and are prepared to give it every encouragement.

In a recent number of the *Ceylon Observer*, the editor observes :—

"A planter writes :—'The bread supplied to us here is oftentimes mixed with rice-flour, and is very dear. How is it we do not get cheap wheaten flour from Australia now, say in kegs of 14½lb.; as also butter and cheese at cheap rates; also good solid biscuits? Planters would purchase such provisions regularly, if sold cheap. We cannot any longer look to England for *cheap* diary produce. Australia must now supply us,' Finer wheat and finer flour than Australia produces, the world cannot show. But, to stand our damp hot climate, the flour must come in tin cases from Australia or it must, immediately after arrival, be put into tins or large earthenware jars. Biscuits and cheese, too, ought to be obtained from the Australian colonies at rates cheaper than England can afford; while, with care in preparation, packing and carriage, butter should be included. Both butter and cheese of good quality and in good condition have reached Ceylon from Melbourne. There are periods of the year, however, when butter becomes scarce and dear in many parts of Australia. The great wants are frequent intercourse, cheap freights, and special arrangements for carrying butter, fresh meat, fruit, &c. Those wants will yet be supplied, we feel certain, and a mutually profitable trade established, between the eastern and the southern colonies of Britain."

CURE FOR CRICKETS.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—Your correspondent "Distracted" complains, in your issue of the 11th instant, of "a plague of crickets." If he will try the Oodbuttee in fumigating his rooms, or sprinkling freely over the places, a solution of carbolic acid, he will at once get rid of his "plagues?"—Yours, &c., John Shortt.

Yercaud, 14th Feb.

COFFEE DYING OUT FROM DISEASE IN BRAZIL.

Through the medium of the ably and honestly conducted *Rio News*, we shall soon know the truth and the whole truth about Brazil. In the paper of 24th December there is a scathing denunciation of the policy of so aiding private enterprize by Government grants of guarantees to private "usines" as really to strangle independent action. The writer shews the deleterious effect of the bolstering up policy on sugar and other industries as well as coffee, and we should wish to copy the whole article. But considerations of available space compel us to confine our extracts to what is said about coffee. It will be seen that not only is disease prevalent amongst coffee in Brazil, but disease of so fatal a nature that in fourteen years once productive coffee orchards had become a thing of the past in a district whence the infection was rapidly spreading. What the specific disease is, we are not informed, but it is evidently as deadly as our fungus. It may be the affection of which we have heard: the trees perishing from the attacks of myriad insects on their roots. Anyhow, we now know that, if Brazil possesses much young and productive coffee, the older plantations are perishing from disease. Over-production will be checked by this fact as well as by its own direct effect of low prices. We quote as follows :—

One of the great obstacles in the way of a permanent industrial development in this country—and we propose to speak plainly—is the lack of individual independence and enterprize. This serious defect is one which has grown out of a long series of administrative errors, and is to day gaining so strong a hold upon the country that it promises to defeat not only the development desired, but to strangle the development already secured. That this statement is perfectly just let us take up any industry that our Brazilian friends may choose to name.

First and foremost among all the industries of the country is that of coffee production. This great industry is so well adapted to the soil and climate of

Brazil that it has attained a magnitude far beyond that of any other country in the world. Year after year it has steadily grown in area, and the reputation of its product has gone out through the world in almost as great a proportion. Apparently it lacks no single element which can contribute to the successful development of a great industry; but is this really the case? Some months since we visited the municipality of S. Fidelis, in the valley of the Parahyba, where the late minister of agriculture found coffee production dying out through the ravages of some mysterious disease. We had derived an impression from the accounts given of this coffee plant disease that it was a new one, and that efforts were to be made to prevent its spreading into other municipalities. The real facts of the case were, however, that this disease had existed in S. Fidelis for some twelve or fourteen years, and that no efforts whatever had been made to suppress it. From small beginnings in the municipality the disease had been gradually spreading in all directions—southerly into the fertile municipality of Santa Maria Magdalena, northerly into that of S. Antonio de Padua, westerley into the famous coffee-producing district of Cantagallo. In response to our inquiries we were told that it was the business of the government to study and check the disease, because the public treasury derived a large revenue from it. We could not find two persons who agreed as to the peculiarities of the disease, nor could we hear of one single person who had made an effort to destroy it. The simple remedies used by fruit-growers to protect their trees, such as lime, salt, tobacco, or carbolic acid washes, had never been thought of, nor was any one disposed to employ them. Everyone was waiting for the government to do something: either to study and destroy the disease, or to substitute a sugar usine, with guarantee of interest for the dying coffee industry. And in the meantime the once highly productive coffee orchards of S. Fidelis have become a thing of the past, and the planters are patiently waiting for the government to set them up in some other kind of business.

This illustration—and it is but one among the many—proves the fatal lack of individual enterprize even in the most flourishing industry of the country. Who knows but what it would have been possible to have stamped out this disease twelve years ago by the simple application of an inexpensive wash? And yet, no one seems even to have thought of such a thing. A few simple experiments might have saved this industry to the municipality, and added incalculably to its wealth. As it is, the fatal policy of waiting upon Government aid has destroyed the industry, and impoverished the planters; and still further, it has even prevented the substitution of another industry.

In another sense, this same mistaken policy is bringing a crisis upon the coffee industry which promises to end in serious loss and disaster. What planter knows that there is nearly three-quarters of a million bags of coffee accumulated at Havre, that there is an aggregate of 1,873,000 bags in the principal ports of Europe, and that the consuming markets of the world are actually glutted? And yet the area of production is being steadily increased, the cost of production tends upward, and there is no improvement in quality. Notwithstanding an increased export the planters find themselves with an enormous stock on hand; and so they come to the government for assistance in introducing their product to new consuming markets. In the face of over-production and glutted markets they are personally helpless, and like children seek for paternal aid and counsel.

We do not speak of these things with any spirit of unfriendliness. The evil—and it is a serious one—is the legitimate outgrowth of that policy which centres so much power in the ministerial departments of the Government. The powers which should be left to the municipalities and parishes are all centered here in Rio de Janeiro. No one can come or go without seeing and feeling the influence and power of the imperial government. And so the people have been compelled to come to the government for everything, and have very naturally been led to expect corresponding assistance and protection in all their needs. Instead of studying the plant diseases and insect plagues, which afflict his industry, the planter turns to the minister for help, and actually sees himself impoverished and ruined in the waiting. When over-production occurs, instead of turning his attention to other products, or improving the quality and decreasing the cost of his product, he helplessly turns to the government for succor. It is needless to argue that all this is radically and dangerously wrong.

SYNTHESIS (POSSIBLE?) OF CINCHONA ALKALOIDS.

We all know what analysis of the alkaloids means, or, at any rate, of the bark which contains the alkaloids. Analysis is just the separation of a compound into its constituents, while chemical synthesis is the union of elements so as to form a compound. Analysis must first, however, reveal all the elements of a compound, before a successful attempt can be made at construction or re-construction. But all the constituents of the cinchona barks have not yet revealed themselves to scientific tests however searching. A new alkaloid has just been discovered, and scientific men themselves feel that more remains to be discovered before nature can be imitated in the "antidote" she has provided for the "bane" of paludal and malarious fevers. Indeed the popular belief is, and we suppose it is correct, that chemists already know all that can be known of the elements of beef; and yet, in the production of beef, Liebig, were he living, would have to confess himself surpassed by the most stupid ox that ever grazed the mead and "ruminated" without a thought of science. The chemist when he had done his best to produce a steak or sirloin, would have to sing in the words of the old song "There 's something wanting." But of the cinchona alkaloids science, as yet, knows even less than she does of beef: less of man's most valuable medicine than she does of his best meat. For ourselves we doubt if ever the alkaloids of naturally grown barks can be perfectly imitated by chemical processes, however elaborate and skilful. *Something* will be wanting. Dr. Hugo Muller, as quoted in the latest report of the Kew Gardens published, that for 1880, not only admits the chemical difficulty, but he very shrewdly points out that, if bark from which as much as 10 per cent of alkaloids are sometimes extracted can be cheaply produced, the pecuniary temptation for science to exert herself in the direction indicated will not exist. Dr. Thistelton Dyer writes, in his preface to Dr. Muller's opinion, as if perfect substitutes had been discovered for vanilla and indigo. Our impression is a very opposite one. Science has extracted the most exquisite colours and the sweetest odours from tar, no doubt; but we have yet to learn that vanilla as a flavour, or indigo as a dye has been superseded. Indigo planters and the cultivators of the vanilla pods, have certainly not considered their occupation gone. Our

own belief is that the discovery of substitutes for the cinchona alkaloids may be relegated to the Greek Kalends, while, if bark becomes very plentiful and very cheap, new uses may be found for it by the brewer, the tanner, the dyer and others.

Mean time, fresh discoveries seem to have been made as to the philosophy of the beneficial action of quinine and the allied alkaloids in disease. In the first place, we are astounded to learn that the main ingredient in tonic mixtures or draughts is not really a tonic! If it restores tone to a debilitated system, tonic it surely must be. But science probably, has invented another term for the process leading to restored appetite and increased strength by the use of infusion of bark We have for some time known that the grand use of quinine, when exhibited in cases of fever, is its power of rapidly and greatly lowering the temperature of the body. It is the sustained, irritating, wasting, weakening heat which kills, and against this unnatural heat, quinine, properly and copiously administered, is almost a specific. Where it fails, more or less, complications of liver inflamed, or in a state of abcess, or of enlarged spleen are generally present. But how is the unnatural heat produced and how does quinine effect such great and rapid reduction of temperature? The answer involves the not very pleasant reflection, that, when we eat, drink, or breathe, we take into our systems the germs of minute organisms, which seem to give more or less trouble according to their number and the health of the individual into whose system they enter. The modern theory of fevers, we are informed, is that they are due to the presence and enormous multiplication of organisms in the blood, the presence of which causes the rise in temperature, waste of tissues, and destruction of the strength. Now quinine is a deadly poison to fever organisms (in most cases), but is not a poison to the human subject. The effect of the administration of quinine is to destroy the organisms and to effect a lowering of the temperature, which is the great aim of modern fever treatment. The natural conclusions our readers will see, are that the use of quinine and the other cinchona alkaloids in modern medicine will be an ever-increasing one, and that, for a period so remote as to be practically indefinite, the cultivation of the fever bark trees cannot be over-done.

As to the possibility of a synthetical substitute, we leave our readers to judge for themselves, with this qualification, that, although alizarin seems really to have largely superseded madder, it has yet to be proved that vanillin is other than a curiosity, or that artificial indigo, equal in quality and as moderate in cost as the product of the plant, has been or ever will be manufactured in the chemist's laboratory. The following is the quotation from the Kew Report:—

"*Possible synthesis of cinchona alkaloids.*—The great extension which has been given to cinchona cultivation as a Government undertaking in Sikkim, the Nilgiris, and Jamaica, and by private enterprise in Ceylon and Southern India has made it a matter of great importance to planters to ascertain what possibility exists of the same success attending the attempts of chemists to effect the artificial manufacture of the cinchona alkaloids, especially quinine, as in the case of alizarian, vanillin, and indigo. As enquries have been addressed to Kew on the subject, it was thought that it might be useful to Kew correspondents to obtain some authoritative information and Dr. Hugo Muller, F.R.S., Foreign Secretary of the Chemical Society, has kindly prepared the following memorandum:—

"The synthesis of the cinchona alkaloids will probably be effected sooner or later. It must, however, be borne in mind that, up to the present at all events, there is, as far as can be judged from what is known about this class of bodies, no indication that this feat will be accomplished in the immediate future.

"The chemical history of the substances [mentioned above] which are now artificially produced, teaches us that, before the synthesis of a body can be prognosticated, its chemical constitution must be thoroughly made out, and this can only be attained by extended investigation of its products of decomposition in a variety of ways. Without going into detail, it may be safely stated, that although some advance in this respect has been made with regard to the study of the cinchona alkaloids, we are still far from having obtained a clear insight into their molecular structure, which, so far as we can judge at present, seems to be of a much more complicated nature than, for instance, that of any of the abovenamed substances. The more complicated the chemical structure of a body, the more difficult in all probability will be its synthesis, and even after this has been accomplished, there still remains the task of finding out means and ways to make the processes involved in it practicable for artificial production. If it should be found that there are no special difficulties in growing bark which like that of *Cinchona Ledgeriana* contains 10 per cent. of quinine, it seems almost doubtful whether we ever may expect to find a synthetic process capable of competing with the natural production.

"It appears, therefore, premature to anticipate already what may require many years to elaborate, and however sanguine we may be in our expectation of the achievements of chemical research in this direction, it seems more than probable that we shall be dependent for some time to come on the cinchona plantations for our supply of this valuable commodity."

COFFEE LEAF-DISEASE.

We have already mentioned that experiments will be conducted on estates in districts so far apart as Dimbula and Rakwana during the present dry season, and we are glad to hear that there is now some prospect of Mr. Schrottky personally superintending the further experiments during the next season. The number and variety of the scenes of applying this remedy will afford better means of arriving at definite conclusions. We understand that Mr. Schrottky has been asked how he intends to vary his treatment so as to make success as sure as it can be made, and he has embodied in the following rough memorandum the outlines of what he intends to do. It would be well to remember, in reference to these experiments, that carbolic acid has been acknowledged by Mr. Ward to be a *remedy* against leaf-disease. Mr. Ward stated that there is no doubt that it kills the germinating spores of the fungus and that more might be done with it, "were it not for the fact that *the accumulated powder and solution are a source of danger at the roots.*" That no such danger exists has been amply proved by the results of past experiments: even with young plants there is no danger, for, Mr.

Schrottky's carbolized powder, mixed ready for application, *i. e.*, in a 3 per cent strength, has been used for now nearly a year with great success down at Kalutara in Liberian coffee nurseries, to keep down leaf-disease. A moderat edusting with the powder every fortnight or so seems sufficient. The following are the outlines of Mr. Schrottky's intended operations :—

1.—Leaf-disease can only be practically got under, in a given area, by the carbolized powder treatment, that is to say, the majority of accumulated spores and actually growing fungus more or less prevalent at *all* times of the year can only be killed, if operations are commenced during March and April, when the fungus is least vigorous and reproduction most slow. This it is intended to effect by a couple of general applications of an impalpable fine powder containing 3 to 4 per cent of carbolic acid, the powder being thrown through the foliage of the coffee trees, and by reason of its fine extreme fineness penetrating everywhere. These applications to be given at a fortnight's interval, with a third additional dose to particularly badly affected places.

2. To prevent re-infection by the spores and other forms of this fungus, which are being constantly supplied by neighbouring places and conveyed by wind to any part of the island, the atmosphere of an estate must be *constantly* and *continually* tainted by carbolic acid vapour. This taint, however faint it may be, is a powerful enough agent to cause the collapse of the microscopically fine and delicate germinating tubes of the spores of *Hemileia*, before they can enter the stomata of the leaf, though it is not strong enough to kill the fungus when once established in the tissue of the leaf. The success of this part of the treatment depends therefore upon the *uninterrupted* presence of carbolic acid vapour in the atmospheric air, so that no germinating spore can escape it.

This it is intended to ensure by exposing at stated intervals throughout the estate, in vessels of a cheap description, a 25 per cent carbolic acid powder ; the powder in these vessels to be changed every fortnight throughout the year.

The cost of all these operations including labour, etc., is estimated not to exceed R30 per acre during the first year, and R15 or R20 during the second year.

The cost during the first year will therefore be not more than that of a *single* application of sulphur and lime

'On a beautiful summer day, the leaves on a tree whispered softly to the zephyrs, and, as their shadow fell upon the valley, thus did they speak, vaunting their luxuriant verdure· 'Is it not true that we are the pride of the whole valley? Is it not by us that this tree is rendered so bushy and wide-spreading, so stately and majestic? What would it be without us? Yes, indeed : we may praise ourselves without committing a sin ! Do not we, by our cool shade, protect the shepherd and the traveller from the heat? Do not we, by our beauty, attract the shepherdess to dance here? From among us in the morning and the evening twilight, the nightingale sings ; and as to you zephyrs, you scarcely ever desert us.' 'You might add a word of thanks even to us, answered a feeble voice from underground.' 'Who is it that dares thus audaciously to call us to account? Who are you who are talking thus?' The leaves began to lisp noisily, tossing on the tree. 'We are they,' was the reply from down below, 'who, burrowing in darkness here, provide you with nourishment. Is it possible that you do not recognize us? We are the roots of the tree on which you flourish ; go on rejoicing in your beauty ; only remember there is this difference between us, that, with the new spring's new foliage is born ; but, if the roots perish, neither you nor the tree can survive.'"

COFFEE AND CHICORY.

Following up the local agitation and the letters of Mr. Thomas Dickson, we have now received (through a Colombo merchant) a copy of a printed circular by Mr. H. Pasteur of Messrs. Parry & Pasteur, which affords the strongest support yet given to the cause of the producer. After reading Mr. Pasteur's figures and remarks, the Ceylon merchants and planters who, last year, opposed a memorial on the subject ought to feel ashamed of themselves; and we may well express the thanks of the planting community to the London Broker who has put the case for relief for Coffee in the United Kingdom, and protection against "adulteration," so clearly :—

Consumption of Coffee in the United Kingdom, from 1842 to 1881.

Table shewing the quantity of Coffee (in lb.) upon which duty was paid for home consumption in each year from 1842 *to* 1881 ; *also shewing the price of Native Ceylon Coffee on the* 1*st January,* 1*st May, and* 1*st September in each year, the amount of duty charged upon Coffee, the duty charged on Chicory, &c., &c.*

a An agitation commenced in 1848 against the sale and

use of chicory and other deleterious substances mixed with coffee.

b November 3, 1852, a Treasury order prohibited the sale of loose chicory or mixed coffee and chicory.

c February 28, 1853, another Treasury order issued allowing mixed coffee and chicory to be sold, if labelled "mixture of chicory and coffee." April, 1853, the duty £20 per ton taken off Foreign chicory.

d February 11, 1860, duty of 6s per cwt. imposed on chicory.

e February, 1861, duty increased to 12s. per cwt. upon chicory.

f April 16, 1863, duty again increased to 26s. 6d. per cwt. on chicory. May 1, 1863, the Treasury order of February 23, 1853, rescinded, and permission given to sell coffee and chicory mixed without labelling.

g 1st May, 1872, the duty on coffee reduced to 14s per cwt., and on chicory to 13s. 3d. per cwt.

Those, who trade in this article, will not be surprized at the extraordinary figures published above, but to any one unaware of the obstacles thrown in the way of the consumers of coffee by British legislation, it will appear almost incredible to find that, whilst in 1854, with a duty of 3d per lb. 37,472,000 lb. were consumed in this country, in 1871, with the same duty and with a population which had increased by some 5 or 6 millions, the consumption fell to 31,000,000 lb. whilst in 1881, with a duty reduced by one-half, *i.e.*, to 14s per cwt. and a population greater than in 1871, by 3,400,000, the consumption was not more than 31,943,000 lb.

This decrease in the use of one of the best and most wholesome of beverages, the consumption of which, in every other country of Europe and in the United States has increased enormously and goes on increasing year by year, is the direct result of a system of fraud and adultcration which has been carried on, and is growing steadily, as it were, under the tender care and solicitude of the British Government, who from time to time revise the regulations relating to the sale of coffee and the various cheap mixtures with which it is adulterated, so that the ingenious importer or manufacturer of ground and roasted acorns, or carrots or any other nasty compounds, may have full scope for the exercise of his industry. (I do not name chicory, which seems to have become an almost too respectable substitute, judging by the fact that even the consumption of chicory has been less in 1881 than in 1880). I do not think any one will call the above statement either exaggerated or highly colored, who will take the trouble to glance at the Treasury Orders, issued from time to time on the subject and which are enumerated as notes to the tabular statement.

In this case it almost looks as if the Treasury and the Excise had taken pains to find means to check and prevent the sale of coffee for consumption in this country without a thought to the loss of revenue. The interests of the chicory growers of France, Belgium and the Channel Islands, and those of the class who live by the making or selling of spurious compounds, which are to be palmed off as "good coffee with a mixture of chicory" appear to be deserving of much more consideration, on the part of Government, than the interests of the millions in this country, who would like to drink either pure coffee or coffee mixed with a moderate proportion of chicory, but who cannot procure such an article in many of the small towns and villages of England; or the interests of the thousands of British subjects, who have invested millions of money in the growth of coffee in the East Indies, in Ceylon, in Jamaica and other British Colonies; or the still more numerous class of importers, dealers and grocers in this country, who see an important branch of their business gradually diminishing, owing to the increasing dislike of the public for the stuff which is sold now under the name of coffee.

It is well known that Ceylon and British India produce the finest coffee, and at one time the bulk of the consumption of this country was of those fine qualities; but now an inferior article is found to do as well for mixing with the various compounds, and the fine Plantation coffees from Ceylon find their way more and more to the Continent direct, where they are better appreciated. London is thus losing gradually a portion of its trade, and will probably go on losing it for there is but little inducement for the importer to bring his goods to a market where there is less and less competition, owing to diminished requirements.

Is there any good reason why the same regulations, which are considered fair and necessary to protect the revenue from the tea duty, should not be applicable also to coffee? Why should tea be protected by legislation against adulteration and not coffee also? Is it too late to bring the subject again under the consideration of Government? Surely the coffee growing British Colonies or Possessions are as deeply interested in this question as the traders in this country; their representatives and the Planters' Associations, should not rest until they have succeeded in obtaining common justice and fair play for one of their most valuable and important productions.

20th January, 1882.

Since the above was in print, a treasury minute, dated 20th January, 1882, has been issued, directing H. M. Board of Customs to permit the importation, under a duty of 2d per lb. of *coffee, chicory, or any other vegetable matter applicable to the uses of coffee or chicory, roasted and ground, mixed, without reference to the proportion of the mixture.*

Thus any roots, turnips, carrots, cabbage stalks, or any other rubbish which our clever and enterprising continental neighbours choose to roast and grind, and mix with an infinitesimal quantity of coffee or chicory will henceforth under government sanction, be pressed upon the British public, under the high sounding name of *French* or *Belgian* or *Jersey coffee*, or whatever other attractive name the ingenuity of these manufacturers may invent.

This stuff, which the public will find scarcely drinkable, will not cost more than 4d per lb. with the duty, and the clever adulterator and his agents who will sell it in the shops for 8d or 10d, or 1s per lb., will realize a profit of 100 per cent, or more; whilst the honest trader, who can make a fair profit by selling pure coffee at 10d per lb., will have but a poor chance against the unscrupulous trader who makes 100 per cent. on the sale of his mixture.

To state these facts is sufficient to ensure the condemnation of the system by any right-minded man, and I cannot but entertain the hope that, when proper representations are made on the subject, they will receive such consideration as will procure redress by Government.

H. Pasteur, 38, Mincing Lane, London, 30*th January*, 1882.

Mr. Geo. Wall—who arrived by the "Vega" on the 26th Feb, and whom we are glad to welcome back in good health and with much of his old vigour—has busied himself as far as he possibly could with this matter while in England. He urged the great evil of the present system on merchants and brokers, and he has brought back with him a variety of samples of the "mixture" supplied as "coffee" to the working classes in England. We trust there will be now no hesitation in forwarding a strong memorial on the subject from Ceylon at as early a date as possible.

THE COFFEE EXPORTS OF RIO AND SANTOS.

We have now received the exact figures, through the medium of Messrs. Kern, Hayn & Co.'s circulars, of the exports of coffee from Rio for the past four calendar years, thus :—

1878 ...	...	...	167,240 tons.
1879 ...	...	...	206,327 ,,
1880 ...	...	...	202,124 ,,
1881 ...	...	...	258,313 ,,

So that, from Rio alone, over a third more coffee was exported in 1881 than was sent away in 1878. The *increase* in exact figures was 91,073 tons, or 1,821,460 cwt. : that is, an increase equal to three times a fair Ceylon crop ! The total export from Rio last year was represented in cwt. by the figures 5,166,260. The Santos circular, although dated 1st January, does not give the shipments for the years, but for last half of each year. For the period between 1st July and 31st December of the past four years, the shipments were :—

1878 ..	...	...	32,654 tons.
1879 ...	...	...	31,733 ,,
1880 ...	..	...	34,160 ,,
1881 ..	...	...	44,157 ,,

It will be observed that the last half of 1881 shewed an increase of 10,000 tons on the corresponding period of last year, while the increase on the last half of 1878 was no less than 11,493 tons. As our readers are already aware, the exports in 1881 of Rio and Santos, with some additions from minor ports, made up a total export from Brazil of as nearly as possible 7,000,000 cwt., besides the quantity (very large) in stock, and the proportion consumed locally. The export of 1882, from Santos certainly, and from Rio probably, will exceed that of 1881. Then the check of low prices may be expected to operate in 1883. Messrs. Kern. Hayn & Co. say, in regard to Rio :—

Coffee.—During the month under review receipts from the interior showed a further decrease, which fact, although we are accustomed to see it repeat itself almost regularly at this time of the year, was sufficient to prevent a decline of some importance in our currency prices.

Regarding Santos, the coffee from which port competes to a greater degree with Ceylon plantation, we have fuller and more interesting details :—

In our report of 1st January 1881, we pointed out that the production of coffee in our province (Sao Paulo) was rapidly increasing and expressed the hope that the railway traffic would assume the quick pace, which large crops render necessary, and we are glad to be able to state that our hopes have been realized.

In the same report we alluded to the eventual inferior outturn of the quality, considering the larger crops we have henceforward to expect and the limited number of black labourers of which the planters can dispose.

This was however—we are happy to say—only to a smaller extent the case than we anticipated, because, though we have to deal with the largest crop known in our province, it is generally agreed that the quality of the coffee received during the last six months, though it is not equal to that of the preceding crop, turned out much better than it was expected.

This may be attributed to the fact that machinery has to a large extent been introduced and now does, of course, the work of many hands; there are hardly any of the the larger planters who have not set one or two steam-engines at work. Whether this system may be a proper substitute for an eventual further decrease of hands during the next years remains to be seen. With regard to the question as to the introduction of Chinese labourers, stirred up some time ago, people here are so far as much in the dark as before, and the arrival of 1,000 coolies, contracted by some enterprizing planters, has not yet taken place.

Coffee :—The month of December witnessed on the whole a very active market, slight fluctuations in currency prices and a strong decline in Exchange during the latter half of the month.

The dull tone reigning in our market at the close of the preceding month continued to prevail during the beginning of December and caused dealers to submit to slight concessions, say of 1 per cent to 2 per cent. Simultaneous large receipts and flat reports from consuming markets, however, caused exporters, to operate with caution and during the earlier part of the month transactions were restricted to small lots.

The number of buyers remained limited until towards middle of the month, when large sales for Havre account were reported, and soon afterwards a heavy decline in exchange called forward a general demand, followed by numerous and large transactions. The market remained very active up to the latter part of the month, when on account of the holidays and of very discouraging reports from consuming countries buyers retired from the market, which closes very quiet.

In our report of 1st July 1881 we estimated the probable export during during 1881-82 at about 1,600,000 to 1,700,000 bags. Efforts have been made to reduce these figures by stating that the present crop had suffered by drought etc., in reply to which accounts we can but state that according to the official railway-statistics 944,519 bags of coffee have been received in Santos during the last six months from which quantity, according to the statistics annexed, about 747,000 bags (equal to about 44,157 tons) have been shipped from our port during the same period, and even those who had an interest to put down the result of the present crop to a smaller figure must now confess that that there is still a large quantity of coffee in the interior. Our opinion therefore is, that we, here in Santos, shall have to deal with much larger export figures than hitherto known, and this not only during this campaign but very likely also during the next one's.

With regard to the 1882-83 crop we consider it still to early, to give even an approximate estimate, but if we were asked to state any figures, we should name 1,700,000 to 1,800,000 bags as the probable yield of the coming crop as far as our personal impression is concerned.

A crop of 1,800,000 bags, at 17 bags to a ton, would be over 111,800 tons, or 2,236,000 cwt., or not far short of four times our Ceylon crop ! These Brazil figures are really overwhelming; but we all know that low prices prevail, and, although the brokers do not mention coffee disease, we are aware that in some parts it has appeared with deadly effect. The labour difficulty, too, cannot long be staved off even by means of machinery and railway facilities.

COFFEE EXPORTS FROM BRAZIL.

Our readers will have observed that Messrs. Wilson, Smithett & Co. gave 250,420 tons as the export of coffee from Rio in 1881. Messrs. Kern, Hayn & Co., writing in Rio on 1st January, stated 258 313 to have been the quantity. Even if the lower figures are the more correct, and the figures for Santos are equally reliable, there is no room to doubt that in 1881 Brazil must have grown over eight millions of cwt. of coffee of which seven millions were exported and one million locally consumed. (The usual estimate for local consumption has been 60,000 tons or 1,200,000 cwt.) Taking Messrs Wilson, Smithett & Co.'s figures, we get

for Rio,	...	...	5,008,400 cwt.
,, Santos	...	...	1,621,880 ,,
Together	...	...	6,630,280 cwt.

Exports from minor ports must have made up the total quantity to 7 millions, and, as the stocks of coffee in Brazil at the close of 1881 were exceedingly heavy, it really seems as if, after making allowance for stocks at end of 1880, the coffee gathered from the trees in Brazil in 1881 could not have been less than 8½ millions of cwt. Whether this is to be the culminating crop, remains to be seen. The check of low prices cannot operate instantly on production; it can immediately affect only exports. But, if low prices continue, not only will exports be restricted and coffee kept on estates, to its damage: the further results may follow of coffee lost from inability to gather it and of production lessened by neglect of ordinary upkeep. The article we quoted from the *Rio News*, too, shews that disease in the coffee trees may prove an important factor in the future of the greatest coffee country of the world. It is tantaliziug that we should be without information as to the nature of the disease. Had *Hemileia vastatrix* really reached the western hemispbere, its characteristics are too marked not to have beeu noticed and recorded. But whether disease affects the foliage, or is coufined to the roots in the shape of myriads of microscopical insects, the account given shews that it is really formidable in its effects and that it bas the power of rapidly extending. From the editor of the *Rio News* or some other trustworthy source, we hope to obtain further information regarding an affection which may possibly, as the years advance, render the competition between Brazil and her competitors in the eastern world a more equal one than it has been since 1869, when the fatal fungus developed in force.

Some thirty years ago, we know, disease on the coffee trees in Brazil was serious enougb to demand the appointment of an Imperial Commission, which reported on the subject, but that report we have never seen. Messrs. Crüwell and Blacklaw reported disease as prevalent; but Mr. Crüwell failed to prove what Mr. Blacklaw absolutely denied—the presence of *Hemileia vastatrix*. The article on Brazil in the new edition of the "Encyclopædia Britannica," although it states that in recent years a disease of the sugarcane has affected seriously that cultivatiou, says not a word about disease in coffee. The meagre article on Coffee is equally silent on disease in Brazil, although it prominently notices the leaf disease of Ceylon and the black rot of Southern India.

NEW PRODUCTS IN CEYLON: OUR SILVER LINING.

At a time when Ceylon shares witb the rest of the world a common heritage of trouble and depression, when many are doubtful of the future, whilst some are confident of better times, it is well to look around us and see if there be not some set-off against low prices and short crops, some grounds for encouragement. We think it may be found to a great extent that, as it has ever been with our cinnamon, and as it is still with our high grown coffee, our produce takes generally a high position as regards value in the markets of the world.

In Java, Cochin China, and some other parts of the world, competitors in the cultivation of cinnamon have found to their cost that it is impossible to compete in quality with the spice of Ceylon, and gradually their plantations have relapsed into jungle. Ceylon plantation coffee has long been recognized as the choicest, next to the produce of Mocha, and even now though rivals in quality have met us in the open market, our finest growths of high grown continue to be sought for at extreme rates for special consumers. La Guayra, Costa Rica, and even some kinds of Rio coffee have supplanted our middling qualities, but we are not aware that they have succeeded in rivalling our finest growths.

Although Ceylon cacao has not yet been shipped to any extent, the parcels that have been placed upon the London market the produce of the Pallikelle estate, have been highly reported upon as regards quality, an opinion supported by the result of sales which have topped the ordinary market quotations, and yielded results which show a wide margin of profit on the cultivation. It of course remains to be seen whether tbe quality of Ceylon cacao grown in other districts equals that of the Pallikelle variety introduced by that veteran planter, Mr. R. B. Tytler, with so much success, but barring accidents this should be the case, as most of the treet in the islaud have been grown from Pallikelle seed.

Another of our new products, cinchona, has in like manner already made a name for itself amongst tbe principal quinine manufacturers of Europe, by whom it is infinitely preferred to most of the Soutb American kinds; the new variety of Cuprea bark we are assured, cannot be profitably employed by quinine makers without the addition of Ceylon cinchona, hence it is that our produce is much sought for and there is very little doubt that this will be still more so when shavings from renewed trees are placed on the market, as they will offer the greatest facilities to the manufacture of quinine. We may rest assured that whatever be the state of the cinchona market our bark will always command attention even though the shipments from South American ports continue as large in the future as in the past, which is scarcely probable.

Our tea although not yet sowell-known and appreciated as it deserves to be, is rapidly rising in favor amongst British consumers, and is already far in advance in general estimation of tbe ordinary China article. It only needs that our tea be well-known and have fair play.

We have no data as to the value of Ceylon grown Liberian coffee compared with that from the African colony, but so long as any figure approaching sixty shillings can be obtained for it in the American market, our planters may be well content.

In all these facts there is certainly some ground for reassuring the hard working enterprizing planters of tbis island admist much that would otherwise led them to dispondency.—"C. Times."

Tea.—The number of Gardens under tea cultivation in Bengal during the past year was 274 against 257 in 1879. The area under plant was 38,805 acres, against 38,668 in the previous year.—*Friend of India*

Betel Nut as a Febrifuge.—After reading your remark about the food of Navvies, it occurred to me that M. Colin might now very advantageously try what the effect the betel nut would have in warding off the malarias, &c., contracted in marshy grounds. I thiuk Johnson, in his "Chemistry of Common Life," informs us that the betel chewer, whether native or stranger, has an invaluable treasure in tbe use of this narcotic, whicb is a perfect safeguard against fevers, agues, and all otber maladies incidental to marsh life. If this is the case, is it not worth a trial during the extensive canalisation soon to be done in France? M. Colin, should he try it, would be able to see if the effect of betel by itself is tbe same as when chewed with the betel pepper leaf, and quicklime.—F. S. C. in *Knowledge*.

Correspondence.

To the Editor of the Ceylon Observer.

THE ADULTERATION OF COFFEE: WANTED THE IMMEDIATE CO-OPERATION OF THE PLANTERS' ASSOCIATION OF CEYLON.

The Scottish Trust & Loan Company of Ceylon, Ld.,
123, Bishopsgate Street Within,
London, January 20th, 1882.

Dear Sir,—I enclose copies of correspondence regarding coffee adulteration, and, unless you stir up Ceylon, and the planters and merchants respond to my endeavours, we shall never obtain redress.

I can make sure of several members of Parliament.
—Yours faithfully, THOMAS DICKSON.

P. S.—Messrs. Patry & Pasteur are preparing a still stronger remonstrance.

Copies of Letters on Coffee Adulteration.

To the Right Hon. the Earl Cairns.

My Lord,—As your name is associated with many philanthropic undertakings having for their object the elevation of the poor in this land, and especially in the erection of Coffee Taverns, where the working classes can obtain a wholesome and nutritious beverage, instead of the alcoholic drinks which ruin their souls and bodies, you will know by inquiry and by the numerous letters which appear in the public journals, how little success has followed the endeavours of your lordship and your many colleagues, entirely arising from the infamous decoction which the purveyors falsely call "coffee."

I therefore address you not only in your quality as a philanthropist, whose purpose has failed, but also as a great statesman whose name stands high on the roll of Fame, as a great exponent of justice, and I appeal to you, in the name of every struggling coffee planter, and especially those of our own possessions in India and Ceylon, to help our cause and to assist us in the petition which the Chambers of Commerce and Planters' Associations of India and Ceylon will forward to Parliament, for the justice, that coffee shall mean coffee. In every country out of England, consumption of coffee increases with population, in England only is it stationary. In every country other than England a good cup of coffee can everywhere be obtained, even amongst the remote and rude inhabitants of Scandanavia and the wilds of Continental Europe. The cause is not far to seek, for it is found in the vile adulterations obtained in this country. Dates, beans, acorns, peas, chicory, carrots and endless abominations have rendered coffee vile to the taste and stomach of all but the wealthy, and this, not through the high price of the genuine article, for as a fact the deliveries of coffee have in no way increased, although the price, is only one-half what it was a few years ago, and this to the great distress of the struggling coffee planter who has seen his crops decimated during the same time by the fearful pest *Hemilia Vastatrix*, and will have to face the decline of this enterprise, unless your lordship and the Legislature of this country affords him justice. Our appeals hitherto have been fruitless against the law which admits of coffee being sold as a mixture.

To your lordship's legal mind I read not demonstrate how this is abused. The failure of the Coffee Tavern movement as a whole points that moral, and the utter inability of a fitful excise supervision to do anything to check it is pressing hard upon the coffee planter, who, in addition, ahs to face the overwhelming competition of the slave grown coffee of Brazil. This latter we can face, seeing that *free* trade (which in this case is not *free* labour) promises no remedy, but we appeal to your lordship to aid us from your high place, in our humble petition to Her Majesty to rescind the order in Council by which chicory and other ingredients are allowed to be mixed together and sold as coffee,—I have the honour to be, your lordship's humble servant,

Thomas Dickson,
Managing Director, Scottish Trust & Loan Company.

123 Bishopsgate Street Within, London, 17th January 1882.

Charles Magnaic, Esq., M. P.

Sir,—As your interest and connection with mercantile affairs is well known and has been frequently exerted for their benefit from your place in Parliament, may I solicit your able services in assisting a struggling enterprize to obtain what they consider justice?

The state of the coffee trade is very unsatisfactory, principally arising from the vile adulteration of the genuine article, actually leading to a falling-off in the clearances of coffee for home consumption, despite a fall of 40 per cent in value and an increase of population.

As bearing upon this, I have addressed the Earl Cairns in hopes he may assist us in the Upper House, and I enclose copy of letter for your guidance.

Our chief hopes however, rest in what you can do for us in the House of Commons, and I shall address the Chambers of Commerce and the Planters' Association of India and Ceylon, and stir up Jamaica, and our other coffee colonies to place their petitions in your hands.

Brazil, Central America, Venezeula, and other coffee producing countries being equally interested, I have addressed the Ministers accredited to this country (copy of letter enclosed) in hopes of their co-operation, and I will be happy to forward you their replies and follow out any suggestion, you may be good enough to make.

In conclusion, I would draw your attention to the remarks upon this subject in Messrs. Patry & Pasteur's annual coffee circular.—I am, sir, your faithful servant.

Thomas Dickson.
Managing Director,
Scottish Trust & Loan Co. of Ceylon, Limited.

His Excellency the Baron de Penedo, Envoy Extraordinary and Minister Plenipotentiary to the Empire of Brazil,

Excellency,—I have the honour to draw your attention to the printed correspondence herewith regarding the adulteration of coffee in this country, and to solicit Your Excellency's co-operation in pressing for some relief from Her Majesty's Government.

The country Your Excellency has the honor to represent is a large exporter of coffee to England and is deeply interested in seeing the produce of its soil fairly treated in consuming countries, and I trust the Government here may listen to our appeal, if backed up by a deputation from those interested and by petitions from the various Chambers of Commerce and Agricultural Associations I have named.

Trusting to receive Your Excellency's co-operation, I have the honor to be, your obliged servant.

Thomas Dickson,
Managing Director,
Scottish Trust & Loan Co. of Ceylon, Limited.
123 Bishopsgate Street Within, London, January 18th, 1882.

Letters to the same purport sent to:—The Minister for Central America, The Ministor for Venezuela, The Charges d'Affaires for Hayti, The Jamaica Agricultural Superintendent, The Chambors of Commerce of Madras, Bombay, and Colombo, The Planters' Association of Ceylon.

TRAVANCORE COFFEE.

6th Feb. 1882.

Dear Sir,—I connot give the exact figures of the exports of coffee from the various ports, but I send you a copy of the Administration Report for 1879 80, the last published. A reference to page 26 and to pages 19 to 25 of the appendix will give all the information that is wanted, for a comparison of crop with acreage.

Details of what has been shipped from the various ports are not necessary to correct the incorrect comparison made in a former issue of your paper.
—Yours faithfully, TRAVANCORE.

[The Report will be duly noticed.—Ed.]

SCARCITY OF INDIARUBBER.

Matale, 15th Feb. 1882.

Dear Sir,—I enclose a cutting (forwarded to me by a Ceylon planter now in England) with reference to indiarubber:—

The scarcity of Indiarubber:—Unless some means are

speedily taken to prevent the reckless destruction of the rubber trees, this important and now world-wide manufacture will be greatly retarded, owing to the scarcity of the raw material. The great and growing demand for rubber has stimulated the rubber hunters of Central and South America to supply the same, but the result is, in their eagerness to meet the extra demands, they destroy the greater portions of the trees. In many places where the rubber trees were seemingly exhaustless a few years ago, the forests have been decimated. The result is that the rubber gatherers have to go farther and farther into the interior and to the mountains for the present supply. Unless the Government of Columbia and South American States do something for the protection and propagation of this valuable tree, the export of raw rubber from these countries will cease in a few years.

It will, I think, be of interest to cultivators of this product, and should stimulate owners of old estates to give rubber a fair trial. My own experience is that rubber seeds should be planted at stake when they are germinated and the root about ¼ of an inch long. No holes need be cut, and planting through old coffee, say 12 12, a cooly will plant an acre per diem, so that, at present prices, R5 per acre should be sufficient for all expenses. The experiment therefore need not be an expensive one. Very little rain is necessary to start the plants. I planted a few acres at the end of last month, and the result is very satisfactory.

The following figures have been submitted to me. I give them for what they are worth and invite criticism :—8 ft. 8 ft. = 680 trees per acre ; 4 oz. per tree = 1½ cwt.; about £10 per cwt. = £15 per acre. Is 8 ft. 8 ft. too close?—Yours truly, Q. R. M.

NORWOOD CINCHONA BARK.

Norwood, Dikoya, 18th Feb. 1882.

DEAR SIR,—In a report of cinchona bark sales, which was published in your paper some days ago, "Norwood Hybrid" appears as selling at 2s. 9d. per pound.

As considerable disappointment has been expressed at the result of this sale, I think it would be as well to let the public know that the parcel of bark in question consisted of hybrid and succirubra MIXED, in the proportion of 1 to 3, as far as I have been able to ascertain.

Keeping this fact in view, I do not think the price realized can be considered unsatisfactory.—Yours truly,

FRED. J. HORSFALL.

MANITOBA AS A FIELD FOR ENTERPRIZE.

Grand Oriental Hotel, Colombo, Feb. 21st, 1881.

SIR,—Observing this morning some questions relating to Manitoba as a field for emigration, and having, during the last year, spent some time in Winnipeg and neighbourhood, I may be able to say something on the subject. The answers to the first questions are substantially correct. The Allan line from Liverpool to Quebec is the most direct, and, I think, also the cheapest line. Second-class £7, first-class £11 to £16. From Quebec by lake steamer to Duluth, the fare is under 20 shillings (exclusive of board); Duluth to Winnipeg about eight shillings.

When I was at the last-named place in October good masons and joiners were getting $7½ a day, or in English money £1 11s 3d!!! As Lord Lorne in the admirable speech delivered at the dinner given him by the Manitoba Club truly said: "*A skilled workman* was *getting as much* as an English *Colonel on* full pay"!! Labouring men were getting from two to three dollars a day.

Land and house property is rising every day. Farms near Winnipeg that last year could have been bought for $8 per acre are now worth $10 per acre.

A great rush is expected during the present spring, on account of the depression in England; so that it is scarcely necessary to advise settlers to be there as soon as possible, as the best locations are being fast selected. To sum up my remarks, I consider that there is a great future for the North-west of Canada. Even the United States papers admit that, and many are accordingly very jealous. When the Pacific Railway is opened throughout next year, there will be an uninterrupted communication between Liverpool and British Columbia through the Rocky Mountains. Winnipeg will be nearer Liverpool by 1,000 miles than Chicago, and be able to undersell the Americans in the wheat trade by more than 10s per quarter. Since the first settlement in Australia, there has not been such an opening for young and enterprizing men as there is now in Manitoba. Everything in the shape of necessaries is very cheap; house rent excepted. But for occupying too much of your space, I could enlarge on this subject, and give my reasons for advising early emigration to the grand North-west.

I shall be happy to give any further information.—Yours truly, CHARLES REA.

P.S.—No one need want who is willing to work.—C.R.

TEA BOXES.

Colombo, 21st February 1882.

DEAR SIRS,—We have pleasure in handing you the Indian *Tea Gazette* of 2nd ultimo, and we have taken the liberty of marking a number of articles which, taken together, form a very interesting discussion on the merits of Messrs. Harvey Brothers, & Tyler's tea boxes. No doubt many Ceylon tea planters will be glad to have the opportunity of reading these articles, either in the columns of your daily paper, or the *Tropical Agriculturist*.—We are, dear sirs, yours faithfully, JOHN WALKER & CO.

The editor of the *Indian Tea Gazette* says :—

In our issue of November 7th, 1881, we inserted a short editorial note questioning, on the authority of certain correspondents, the advisability of using tin tea boxes for the packing of tea, at the same time asking our readers to favour us with their opinions on the subject, in case we were misinformed. Our invitation has met with a response from several quarters, and the correspondence we have received leads us to alter the opinion we formerly held on the subject. A gentleman largely interested in tea, but in no way connected with the manufacturers of the Patent Tin Boxes, writes to us from England :—

"I made enquiries as to the condition in which tea packed in Messrs. Harvey Bros. and Tyler's lacquered tin boxes is turned out in London. I found that the tea was not at all injured by this method of packing, but that its condition is quite as good as that of tea packed in chests. Messrs. W. J. & H. Thompson assured me that you were entirely mistaken in your remarks as to the contamination, but they thought that an objection to the packing in the lacquered tin boxes was the labour of putting up in these boxes. Catalogues were shown me in which I saw that the teas in the lacquered tin boxes fetched higher rates than the same teas packed in chests, the difference being in one case 3d. per lb."

This is certainly a most favourable testimony, and, coming, as it does, from a disinterested party, who writes simply in defence of what he considers the right, we cannot but accept of his statement in its entirety.

Another correspondent gives the results of public sales, which show that teas from the same heap in India fetched from ½d. to 3d. per lb. more when packed in these tins than when packed in chests. Messrs. Harvey Brothers & Tyler write to the *Tea Gazette* :—

Our attention has been drawn to a short article in your issue of 7th November last under the above heading, and we feel sure that you cannot have been aware that tea boxes manufactured by us are entirely free from any of the bad qualities you attribute to tin when used for packing tea.

This is amply proved by the *superior* condition in which tea has been delivered here, as can be ascertained on reference to any of the leading London brokers, who have sold teas so packed, both privately and at public auction, where the prices obtained are a completo answer to any imputation as to any deleterious effect on tea packed in our boxes.

We trust therefore you will give us your assurance that you wrote inadvertently and in ignorance of the merits of our boxes as compared with the ordinary tin sometimes used in making up boxes for tea.

A writer in the *Home and Colonial Mail* says with regard to the adverse remarks of the editor of the *Indian Tea Gazette* :—

He appears to think that tin gives to tea packed in it "a metalic flavour," and that tho tea, if at all damp, is "bound to corrode the tin eventually." He further remarks that "it is a matter of question, whether, even if tea be *thoroughly* dry when packed, the chemical constituents contained in it will not in some way combine (chemically) with the tin, and the tea imbibe thereby some kind of taint," and concludes with the suggestion—although he somewhat doubts its valne—that the tin boxes might be lined with thin paper. It surely needs not to be said that all these fears are chimerical. Tin is one of the purest metals, and is on that very account largely used in the manufacture of vessels for containing or preparing food. Tin canisters, too, as receptacles for tea have been in use for many years, and, indeed, are in daily use by many thousands. The suggestion that the "chemical constituents" of the tea may combine "chemically" with the tin and thus acquire "some kind of taint" is too vaguo for serious notice. Of thin paper it may be said briefly that a worse material for enclosing tea could hardly be discovered, and for the simple reason that, so far from being a repellont of damp, it very readily attracts and absorbs it. That tin boxes made of impure metal, or tinned boxes improperly manufactured, would injure tea—or, for the matter of that, anything else—is no doubt true, but of this there appears to be no fear in the boxes which we saw in the offices of Messrs. Harvey Brothers and Tyler.

He then describes the boxes, and sets forth their advantages as compared with wooden chests. Wo need not repeat these, as they have already been given in our columns. The writer concludes by saying :—

On the whole, then, there should seem to be no room for doubt that the tin boxes of which we have spoken, so far from being undesirable packages for tea, are a distinct boon to Indian planters. They aro handsome, and would thus promoto the sale of the tea, and at the same time command better prices for it; they are convenient; they would tend to ensure purity of the tea; and they would, above all, by giving uniformity of tare, effect a considerable saving in the usual loss at the Custom House, with the authorities of which, we may remark incidentally, they already found great favour. The manufacturers are of opinion that the inherent merits and attendant advantages of theso tin boxes aro as real and apparent as the fears expressed by the writer in the *Indian Tea Gazette* on the use of tin are groundless and vague. Candidly, we quite agree with them.

In the face of such testimony the editor of the *Indian Tea Gazette* confesses that he was wrongly informed regarding these tin boxes. Ceylon tea planters may therefore feel assured that by using Messrs. Harvey Brothers & Tyler's boxes they will not run the risk of their teas being deteriorated, but on the contrary that the value will be enhanced.—Ed.

MANIHOT UTILISSIMA, Pohl.

Tapioca, Manioc, or Cassava Plant, when and by whom Introduced to Ceylon.

Colombo, 22nd Febrnary 1882.

Dear Sirs,—In your article headed "Tropical Agriculture in Ceylon: Lowcountry Products," in your issue of the 20th, occurs the following passage:—"and strictly we cannot include the manioc or cassava plant, with which experiments have been tried since the days of Bennett, if not from an earlier period," which reminded me of the following addition made by me under the 4th line of page 17 of the "*Table of Events*" in your Handbook for Ceylon for 1880-1:—"1786 7. The Manihot or Cassava plant introduced to Ceylon from Mauritius, by Governor Van der Graaf"; which information will be found in the "Materia Medica of Hindoostan" &c., by Whitelaw Ainslie, Madras, 1813, in a footnote to an article on "Tapioca, Jatropha Manihot Lin.," p. 47, as follows :—"Whither [to Ceylon] it was brought from the Isle of France in 1786 or 1787, by Governor Van de Graaf. See Asiatic Annual Register for 1805, vol. 7th, p. 87." As far as I know I do not believe that anlibrary in Colombo has got a copy of the latter work.—In Ainslie's article he says that he attempted to make tapioca from the roots of the manihot in 1813-14, and perfectly succeeded, and he believed that this was the first that was made in our Indian dominions. In Ainslie's "Materia Indica," 1826, which is a second edition of the older work he has a longer notice of the tapioca, which I consider worth publication in your *Tropical Agriculturist*. Moon's catalogue having been published in 1824, Dr., afterwards Sir W. Ainslie was able to add :—"Three species [of Jatropha]) grow in Ceylon, where our article is called *manggokka* (Cyng.)." About the introduction to India of the Cashew-nut, which is a native of tropical America, the following tantalizing bit of intormation is given in a book on Indian botany :—"Native of Brazil, now common in Goa and Warree country, also in Suthern Concan and Salsette, is now naturalized, and affords rather a valuable resource as food. According to Garcias ab Orta, it was first planted at Santa Cruz (?) in Malabar, where only three trees existed in his time." Some chapters of a work by Garcias ab Orta are quoted and commented on in a work by Clusius, dated 1605, but I see no date given for the work quoted. I think it not improbable that the Portuguese introduced the cashew-nut tree to India about a hundred years before Clusius wrote in 1605, but this is conjecture. It is most likely there are authentic records of its introduction in the earlier Portuguese works.

The Pineapple must have also been introduced to India at an early period of the Portuguese rule. "It's not being a native of India is supported by its vernacular names, evidently derived from *ananas*, as well as there being no Sanscrit name for so remarkable a plant. A thing which could scarcely have happened if it had been a native of the East Indies."—Rox. Fl. Ind., 1, 116.—Yours, W. F.

NEW PRODUCTS IN OLD KURUNEGALA DISTRICT.

Madawalatenna, 23rd Feb. 1882.

Dear Sir,—The next time the Matale planter, who has only recently paid a visit to the Polgahawela district, is desirous of seeing most of the lowcountry products in a flourishing condition, he might drive from Kandy to Kurunegala, and on the route he will be amply paid for his trouble by seeing fine plantations of cocoa (second to none in the island for its age), Liberian coffee (that in bearing loaded with crop), cardamoms and rubber. Kurunegala will yet be able to hold its own with the aid of these "new products," which are being planted on all the old estates. The new plantations, Delgolla, Dunveor, Dikoya and Dunira, are well worth seeing. I hear that both on Udapolla and Liberia estates good crops are expected, and now that Arabian coffee is not as flourishing as we could wish, more attention will no doubt be paid to the planting of old estates, and, where the locality is not suited to cocoa, with Liberian coffee, for 4 cwt. an acre from 4 year old trees is not to be despised nowadays. C. H. W.

P. S.—Most extraordinary weather for February. Been raining for the last two hours, and likely to continue throughout the night. Last year's rainfall was about 19 inches over the average, which is about 80 inches. If rain is to continue like this throughout the year, very few coolies will be required to pick the crop of Arabian coffee.

NEW PRODUCTS: THE SUNFLOWER.

DEAR SIR,—Is there any market for this in Ceylon, or any nearer than London? I think of taking a crop off some land lately planted in Liberian coffee, planting between the rows to cover the ground, but should first like to know if there would be any difficulty in disposing of the seed. Simmonds gives a lot of valuable information about the plant in his book, but omits one or two useful items. The ash of stems and leaves, if returned to the soil, should almost make up for what the plants has taken out of it.—Faithfully yours, CHILLY.

The following is from the *Australasian*:—

UTILISATION OF SUNFLOWER PLANT.

SIR,—Can you inform me if any part of the sunflower plant, other than the flower itself, can be utilised? I have a patch growing most luxuriantly, some stems being two or three inches diameter, and nearly 6 ft. high. A. B.

Coleraine, Jan. 9.

[The fibre of the stem has sometimes been extracted, but this plan of turning the plant to account cannot be profitable, as it is now never spoken of. The seed, you are of course aware, is used in feeding poultry. A light oil is also extracted from it.—ED.]

Sir,—A correspondent, "A. B.," in last week's *Australasian* asks if any part of the sunflower plant other than the flower itself can be utilised. I beg to mention, in addition to what you say in your foot-note, that horses are very fond of sunflowers, and will eat them down to within a few inches of the ground. But the principal use to which sunflowers may be applied in this warm climate is the manufacture of pith hats. In the stems there is a fine, strong, light pith. The outside fibrous and woody part is very easily stripped off. If the pith of the sunflower is compared with that used in the manufacture of Indian pith hats, it will be seen that they are identical. If the raw material can be supplied, the manufacture of pith hats ought to follow as a matter of course, and no other kind of hat affords such protection to the head and neck from the sun's rays.—W. L. M.

DATE COFFEE.—This article has been a speculation for some time, and we see another company just announced called the "Belgium Date Coffee Company, Limited," with a capital of £100,000, to be raised, of course, in London, and a list of no less than eight directors, some with high-sounding names. We have no experience of "Date" coffee, but £100,000 is a large sum to raise for the purpose specified. If Belgians are so enamoured of date coffee, why not raise money on the spot instead of applying to London for it? That it will materially affect the consumption of coffee we do not believe, but it is worth while for coffee-growing countries to look a little more closely into the matter than they appear yet to have done. Chicory has had its day, and a mixture of this with coffee is easily understood, but the date process appears likely to supersede it.—*South American Journal.* [To put chicory out of *date*, in truth.—ED.]

THE AGRICULTURISTS OF MALTA are in a state of alarm, owing to the drought, which has continued five months, not more than half-an-inch depth of rain having fallen during that time.

SIR CHARLES HARVEY, Bart., we learn, is to arrive by the S.S. "Quetta" for a sojourn of some time in Ceylon. Such is the agricultural depression in England—land only yielding two per cent—that Sir Charles, although possessed of two thousand broad acres in Norfolk, is coming out to Ceylon to find a more profitable investment for his personal property in as many hundred (200) acres of cinchona property, which he hopes may yield him hereafter a better return.

QUININE TONIC.—The following is a formula largely used in the Department of Public Charities and Corrections of New York City as a means of administering quinine: Sulphate of quinine, thirty grains; dilute sulphuric acid, sufficient; tincture of perchloride of iron, half an ounce; spirits of chloroform, six drachms; water, two ounces; glycerine enough to make four ounces of this mixture. The dose of the mixture is a teaspoonful.—*Oil and Drug News.*

COFFEE.—The Brazilian supplies say Messrs. Wilson, Smithett & Co. (January 20th), have more than counterbalanced the short crops in the East, and stocks have accumulated in spite of the consumption of France, America, and Holland last year showing considerable extension. The surplus of production over consumption appears to have been chiefly directed to Havre where the importations for the twelve months ended 31st December are upwards of 34,000 tons more than in 1880; or an incrof 40 per ease cent.

TEA.—We call the attention of our planters to the encouraging, and, at the same time, admonitory remarks of our Commercial Correspondent, based on the opinion of experienced and sympathetic London brokers. If only capital were made judiciously available, 100,000 acres would very speedily be placed under this product in our planting districts, the crop from which ought to reach 4 to 5 million lb. within a few years. Money to buy seed, to pay for planting, and to buy machinery, is the desideratum of many would-be Ceylon tea-planters at this moment.

CEYLON TEA.—There have been no sales during the week, and former quotations are consequently unchanged. Forty odd packages will be sold next week respecting which I shall send you particulars. Conversing with Messrs. Rucker recently, I was told that some of the Pekoes recently sent from Ceylon were of remarkably fine quality, and that these young growths afforded the trade most conclusive and satisfactory evidence of the suitability of the soil and climate of Ceylon to the tea plant and for the production of the very finest quantities. Considerable care had been taken in the preparation of the samples referred to, which is much needed in all cases, to prevent the irregularity so much complained of by the trade.

COLA NUT.—The introduction of the cola nut into India might be a means of conferring a considerable benefit on the country. The cola nut is the seed of the tree *cola acuminata*, whose habitat appears to be the west coast of Africa. The properties of the nut are said to be twofold. In the first place, like olives, it enhances to many palates the flavour of food eaten afterwards; secondly, it possesses the more important function of staying the cravings of hunger and enabling those indulging in it to endure prolonged labour without fatigue. It is not, however, a stimulant. The taste is bitter. The natives of the West Coast of Africa, particularly in Sierra Leone, are described as being very partial to the nut, both as a luxury and for its other and more valuable quality. In fact it appears, in that part of the world, to satisfy the general craving of mankind for a stimulant. The trade, a consular report from Gambia says, is extending into Central Africa and northward to the African shores of the Mediterranean, indicating an increased demand. The nut has been introduced successfully into the West Indies.—*Englishman.*

An "excellent substitute" for coffee is claimed to have been discovered by Colonel Sladen, Commissioner of Arakan, who has written officially to the Chief Commissioner of British Burmah, recommending him to try it. It is described as a decoction of the seed of the *Cassia tora* or "fætid Cassia," known to the Burmese under the name of "Dangweh.' Colonel Sladen, at the suggestion of Mr. R. Meleod, Extra Assistant Commissioner, roasted the seed and tried its effects, and he believes that "the substitute is likely to prove a most valuable product which in time will revolutionize the coffee trade." Samples have been forwarded to Messrs. Short, Short & Co., London, and to the Bengal Chamber of Commerce. The "Dangweh" is a weed found in every part of Burmah, and no deficiency of supply is likely, should a demand arise.—*Madras Times.*

Agricultural Scholarships for Indian Students at the Royal Agricultural College, Cirencester.—A resolution was passed in 1879 by the Government of Bengal for the establishment of agricultural scholarships for the benefit of natives, graduates of the University of Calcutta, at the Royal Agricultural College, Cirencester. The first two scholars entered this College in January, 1880, and are now making there a very successful career. These were Babu Ambika Charen Sen, M.A., and Syed Sakhawat Hosein, B.A. The *Indian Daily News* states that the two new students appointed by the Bengal Government to enter at Cirencester in January next are Baboos Brojobullub Dutt, M.A., and Greesh Chunder Bose, M.A. The former is the headmaster of the Sreedhur Bungsheedhur School at Nawabgunge, and is the gold medallist of 1880 in physical science; and the latter is a lecturer on chemistry at the Cuttack College. An allowance of 200*l.* a year, tenable for two and a half years, will be granted to each of these candidates, and an outfit allowance of 1,000 rupees has also been sanctioned to each of them.—*Colonies and India.*

The Papaw Tree.—The fruit of the papaw tree, says the *Englishman*, is well known to our Indian cooks as possessing the active property of rendering the beef tender. A slight incision in the rinds of the unripe fruit causes a milky juice to issue, which, rubbed over a beef steak or the toughless meat, will make it quite tender. This powerful action of the papaw plant being observed by a French gentleman, led him to the conclusion that it might be utilized for medicinal purposes and we read in the "Practitioner" for October, that the idea has been put to the test of actual experiment. The French gentleman referred to planted out a large extent of land with papaw trees, the juice of which he is collecting in the same way as opium. Incisions are made on the outside of the half-ripe fruit, and the juice that exudes is allowed to dry and is then scraped off. The granulated product thus obtained resembles coarsely pounded gum arabic It is sticky when wet, and readily dissolves in water. The digestive power of this solution, to which the name of papayine is given, has been tested, and found to be very active. It has been compared with the ordinary pepsine and the liquor pancreaticus of the shops and found to surpass both in the power of digesting either cooked or hard boiled white of egg. The digestive action from it is described as both rapid and easy. It is confidently believed that "we have in this substance a digestive agent of very great potency, and one which is likely to come into very general use in medicine."—The papaw is the common mamiapple of Fiji – *Fiji Argus.* [The ripe fruit is prized for dessert in Australia, although neglected in Ceylon, while in Java, it is mashed up with lime juice and sugar. In this form on Mr. Moens' hospitable board we found it excellent. Dr. King also admired it in Java, and in his house Mr. Moens partook of the fruit, still further improved by being not only mixed with lime-juice and sugar but also stewed.—Ed.]

Manitoba for Emigrants.—A correspondent sends us some questions and asks us to append the answers. We give them below:—I. The best and cheapest route to take from England and cost of passage to America. [London to New York, by Anchor line, £11 to £16 for first class berth.]—II. Cost of train fare or steamer fare to Manitoba. [Rail from New York to Toronto about £3. We do not know the fare thence to Manitoba, but probably about as much again.]—III. What capital is necessary to start with on a very small way? [From £80 to £200.]—IV. What prospect has a man who has no capital at all to start with? [Very good prospects, if he does not mind hard work.]—V. Can a man do any good with £100 to start with? [Yes.]—VI. Can a man with no capital earn enough to keep a wife who has never been accustomed to work? [We should imagine so.]—On pages 558 and 585 of the *Tropical Agriculturist* will be found some information which may be of use to our correspondent.

Coffee Leaf-Disease Manure.—We have received from Messrs. W. H. Davies & Co. a pamphlet relating to the chemical manures of Messrs. Arnott Bros. & Co. This pamphlet describes the various manures which are applicable to different products—sugarcane, coffee, tea, &c. On the subject of coffee we quote the following:—"Some years ago, owing to the fearful ravages of leaf-disease in the coffee plantations of Ceylon and elsewhere, our attention was drawn to the production of a manure which should assist the trees to resist its attacks, by a well known practical Ceylon planter, who for many years had been trying in every way to overcome this scourage. In conjunction with him we have succeeded in bringing out a fertilizer, which, after a lengthened trial, has proved itself of undoubted efficacy in modifying and overcoming the ravages of this disease, and we most confidently solicit a trial of the Anti-Vastatrix Fertilizer, new leaf disease manure, of which we are the sole manufacturers. It is the only Fertilizer, so far, that has really proved or any effect in subduing this disease, and it is fully protected under our registered trade mark. This Manure should be applied at the rate of about four cwt. per acre, and as a large proportion of its components are readily soluble in water, it should be well mulched, which will keep it at the rootlets of the trees, encourage its absorption, and not allow it to be so easily washed away in heavy rain." A number of testimonials from planters in Ceylon, Java, &c., are given from which we quote the following, by a planter in Matale East, writing in 1880:—"The manures I received from you I consider good producers: Anti-Vastatrix, the Ammonio Phospho Coffee Manure, the best. I do not believe any manure can affect 'Hemileia Vastatrix,' being entirely of opinion that it has been caused by the enormous acreage of coffee planted in Ceylon without forest left standing in any large quantity near at hand, and without any other products being planted. Coffee, coffee, all was coffee, and the results might have been foretold by anyone with a really wide experience and comprehensive mind. I believe leaf disease has, and will always exist, but its virulence is entirely owing to what you may call the system upon which it has been cultivated. We shall hear less and less of it as the new products, now being planted, grow up; those lands that should have been planted as coffee will remain as coffee; those that should never have been planted as coffee will be abandoned, or planted with other trees than coffee; of land that was not suitable there has been planted a large quantity there is no doubt. The crops from the estates on which the manures obtained from you were used more than favorably compare with estates equally good, or even better estates, upon which other manures were applied. To vigorous young coffee the manures were particularly adapted."

The Calcutta Tea Syndicate have received a satisfactory report from their delegate, Mr. Sibthorpe, regarding the American and Canadian tea markets and the opening they present for Indian teas. The general conclusion drawn in Calcutta from a perusal of the report is that at no very remote date these countries will be, next to the United Kingdom, the largest customers, while it is not improbable that sooner or later, they will surpass even the United Kingdom itself in this respect.—*Times of India.*

Beche-de-Mer.—Batticaloa, Arali North, 13th Feb. —The rent of the Arali ferry is usually purchased by sea-faring men. Although Government have supplied the renters with two very neat gili boats for the comfortable conveyance of passengers, the renters keep them in a most despicable and stinking state. On enquiry I found that these boats are either taken by these renters for fishing during the night, or let out to others of their own trade for the purpose. By so doing, the renters not only misappropriate and damage the public property, but create unnecessary discomforts and nuisance to passengers. The renters also do not keep a proper number of boatmen for the safe conveyance of passengers to and fro, but keep only one for the purpose: hence hours of delay in crossing the ferry. It is a great pity that Government do not see the necessity of throwing a causeway across the backwater. It would, at least, be a great paliation, if a ferry boat to convey across carriages, horses, carts and bullocks were provided. Before we reach the village of Valani, we have to cross an open level plain, a distance of about three miles along a mud road. The extent of this open land is about 2,500 acres, all of which are left uncultivated, and admirably adapted for paddy cultivation and for opening coconut and palmyratopes. Should the Government but lay out a small sum in spanning the Valani backwater with a causeway, it will not only improve ignorant islanders, in causing an easy intercourse with those living in the peninsula, but will also be a source of increasing the public revenue, encourage and give an impetus to agricultural industry, and enhance the price of landed property. The paddy crop both in the islands and in Valigam West is not all that can be desired. The corn is in the blade, and for want of rain it is all dying, and if there be no rain within a week most of the plantations will have to be abandoned. However, with all these drawbacks, the farmers owning lands by the side of tanks or wells are busily engaged, day and night, in irrigating their lands. On the south-eastern side of this island, near the seashore, the table delicacy of the Chinese, bêche-de-mer, is extensively collected and cured. There are I understand 35 boats, and 100 fishermen, solely engaged daily in collecting this sea slug and chanks, and the capitalists pay at the rate of R15 for every 1,000 of the former, and keep up a regular establishment, trained first under a Chinese, for curing these seaslugs. The curing and manipulation of these, before exportation, is conducted as follows:—As soon as they are taken from the divers, they are boiled in large copper caldrons. Then they are buried in the seashore for 12 hours, and then removed, and, after having a thorough washing in sea-water, they again undergo a similar process of boiling. They are subsequently dried in the sun, and lastly smoked and dried in fire in a closed shed. They are then made ready for the market. There are, I understand, some 150 candies of this annually collected, and cured, and exported to Singapore and China; besides, 5 times as much is collected in the backwaters up the Mannar. It seems this trade was first introduced and monopolized by a Chinese, but he is now being replaced by Nattukotta chetties. Do you or any of your readers know anything, as to the average price ranging in the Singapore or Chinese markets for this commodity?—*Cor.*

Samarang, 23rd Jan.—Van Maanen's method of artificially drying coffee will, we are informed be shortly adopted throughout the whole of Java, for Mr. Van Maanen has entered into contracts with more than fifty planters for that purpose, while the managers of several coffee estates are only awaiting the sanction of their principals in order likewise to join.—*Indische Vaderland.*

How to Push the Sale of Tea.—A discussion has been taking place in the *Friend of India* on the subject of how to push the sale of Indian tea at home, a correspondent suggesting a system of regular auction sales of small packets of tea throughout the country. This scheme is suggested by Col. Mouey as well as by the editor of the *Friend,* but is opposed by the *Indian Tea Gazette* on the ground of its expense.

A Company to be styled the "Timor Guano Company," with a capital amounting to one hundred thousand guilders, is about to be established at Sourabaya. The object of the company is to procure guano from deposits on Baars island in the Residency of Timor, prepare it for sale, and thus enable planters in Java to become independent of costly imports of manure from Europe. The selling price will be fixed at 9 guilders per picul, being 6 guilders cheaper than guano imported from Europe.—*Handelsblad.*

Coffee Adulteration.—Mr. Thomas Dickson, the Managing Director of the Scottish Trust and Loan Company Limited, is doing a good work on behalf of his own and his brother-planters' interests in Ceylon, and we trust the members of the Planters' Association will be roused once more to the duty incumbent on them in this matter. Nothing less than an annual Memorial to the House of Commons from the Coffee-planting Interest of Ceylon, until the grievance is removed, will meet the necessities of the case.

Oranges and Insects.—Old Knox mentioned the fact that, in Ceylon, oranges, if left on the trees until they turn yellow, become infested with insects. What was and is true of this fruit in Ceylon seems true of it in Fiji, as witness the following paragraph from a review of Miss Gordon Cumming's book, "At Home in Fiji":—"We lay under the orange trees in the garden and ate ripe golden fruit." It is a delusion, then, sarcastically remarks the reviewer, to suppose that oranges must be plucked in Fiji before they arrive at the golden stage to prevent the insects destroying them.

The Vines in Victoria.—It is expected that the destruction of all vines in the Geelong district will be accomplished within the next month. The Moorabool, Waurn and Winchelsea divisions of the district are the only ones remaining to be operated upon. About £10,000 compensation has already been paid by Government for the vines destroyed and it is estimated that the total expenditure upon the district will be about £25,000. The act providing for the eradication of vines in the diseased district of Geelong prohibits the planting of fresh vines for a period of four years.—Melbourne *Age.* [All in vain, we fear. —Ed.]

Agricultural Productiveness of America.—Mr. Porter observes that careful estimates show that the United States is capable of maintaining an area of 200,000,000 acres of corn land, which, with the average yield of the past ten years, would yield upwards of 2,250,000,000 bushels of corn. Turning from corn and wheat to cotton, it appears that the whole cotton crop of the world could be raised on a section of Texes, less than one-twelfth of its area; or could be divided between any two of the other principal cotton States without exhausting one-half of their good land. The agricultural productiveness of America is practically illimitable; and when the full importance of the agricultural interest is realized and profited by, it must exercise an important influence over England and the European continent.—London *Times.*

INDIGO (INDIGOFERA TINCTORIA), Nat. Ord., *Leguminosæ.*

It is remarkably strange that this plant, which grows wild in H. H. the Nizam's dominions, is not utilized for its pigment, which is of great importance commercially; besides, it would give employment to the many "ragamuffins" now loafing about in the Hyderabad territory. If my memory serves me right, I think an acre of ground of these plants will produce about ten pounds of the dye. Of course, much depends on the soil, care, *et hoc genus omne. En passants* a short narrative will, I trust, be not out of place. As many of your readers are aware, this dye was introduced into England about the middle of the 16th century, when Queen Elizabeth prohibited its sale, and named it the "Devil's Dye," and "food for the devil!" Thank goodness, we are now living in an enlightened age, (not in Hyderabad though). The Greeks and Romans first utilized the Indigo as a paint, after great opposition by "wood growers," powerful in that age, who introduced several European Governments "to prohibit the use of Indigo as a dye." It was only for a time that this commotion prevailed in Europe. The American Indigo plant is known by botanists as the *Indigofera Anil* growing about three feet high. The Egyptian Indigo plant is named the *I. argentea*, and grows about two feet high. In the Madras Presidency Indigo factories are to be seen in almost every place in which the shrub germinates. There is no reason why grist to the mill should not be obtained from the same plant, which grows freely in the Telinga districts in the Nizam's Dominions.

Deccan, 24th November 1881. FAIRY ROSE.
—*Asian.*

A BIRD-CATCHING SEDGE.

As another example of the wonderful adaptation of seeds for the purpose of distribution, I may mention those of Uncinia jamaicensis, Pers. (Carex humata, Sw.), Grisebach, *Flora British West Indian Islands*, 1864, p. 581. This is a plentifully distributed Sedge, growing in damp hollows and shaded woods on the Blue Mountains, Jamaica. The plant is about a foot or 18 inches high, with narrow pointed grass-like leaves. The flower-head is a slender spike about 3 inches long, of a dark brown shining colour. Its most remarkable feature, however, consists in the spikelets. These are furnished with a smooth long-exserted awn of a peculiar hamate character, resembling a shepherd's crook, but with the hook pressing so closely against its base that it will hold the finest hair. By means of this delicate but wonderfully constructed awn the seeds of the Uncinia attach themselves with great tenacity to the coats of dogs, the legs of pedestrians, or, indeed, to anything that comes within their reach, and when once attached they are removed with the utmost difficulty. In fact, as showing their finely-adjusted powers, and their tenacity, it may be mentioned that if a spike is drawn along the back of the hand the hooks will clasp, and easily pull out single hairs by the roots.

On two occasions lately I have found small birds (grass quits), about the size of an English tom-tit, securely caught by a couple of spikes of this sedge. The spikes were attached along the underside of the body of the bird, with the hooked awns buried among the feathers. Of course, in these instances, the birds were released, but from the secure manner in which they were caught I have no doubt that many birds not large enough to drag out the spikes, or draw the spikelets from their receptacles, must die in this manner from exhaustion, or fall a prey to rats and other vermin.

D. MORRIS, Jamaica, Nov. 14.—*Gardeners' Chronicle.*

TROPICAL FRUITS FOR EUROPE.

SIR, I see by the last two issues of your paper that some readers desire to see fruits of a tender nature brought from India and other distant places. It is very doubtful if such could be profitably accomplished, because of the length and heat of the journey. It would not do to actually freeze the fruit, as proposed by E. T. S., as this would cause both a chemical and mechanical change in its structure, and, even if it could be eaten, the flavour would be changed. If an apple or pear be frozen, and again thawed out, as a rule it will be found altered in flavour, and generally spongy or soft owing to the bursting of the cells. It is true that if excluded from air little change occurs, and this can easily be proved by placing some hard-frozen potatoes in a bucket of cold water, and keeping them underneath till thawed. It would be worth a trial to place some mangosteens in airtight cases, and freeze them hard, letting them gradually thaw on arrival before opening the cases; but it would, of course, be only a doubtful trial at first, and should not be largely entered on. The mostly likely plan to secure success would be to pack single layers of fruit in thin boxes, filling all spaces with cork dust to prevent bruising, and to bring them over in a temperature of about 30 deg. Fahr., if such could be managed. This would check ripening and decomposition, and not greatly affect the flavour if the temperature was raised gradually to 45 deg. on arrival. It would not do to use any liquid to preserve fruit, as it would be absorbed, and possibly change the flavour as well as prevent ripening. It may not perhaps be foreign to the subject to mention that some ten or twelve years back I opened a "pie" of apples in February, at Warlaby, near Northallerton; and, although the heap of fruit had only been protected with about four inches of straw and the same amount of earth, they were in capital condition, although they must have been frozen hard, but they were kept airtight. No doubt a profitable trade could be done in tropical fruits of good quality if they could be imported in a fresh state, and a few trials (which need not be very costly) would probably end in success. WALTER J. MAY.
—*Field.*

CAPSICUMS.

Much has recently been written concerning a kind of capsicum known as "sweet capsicum," but it does not seem to be generally known that a sweet variety of capsicum has long been used in the United States. In Spain, from whence this variety is obtained, two kinds of capsicum are recognised, viz., *pimiento dulce*, or sweet capsicum, and *pimiento picante*, the "biting" or hot capsicum. The latter has the usual tapering apex, whilst the sweet variety is about four inches long, almost as broad as long, the apex being indented or doubled in, and has a bright red colour. This sweet variety may occasionally be purchased in Covent Garden Market in a fresh state, and by the doubled-in apex can easily be distinguished from the hot kind. For curries, the sweet kind is generally first roasted before the fire in order to remove the outer skin, which is the hottest portion of the fruit. The fruit also makes an excellent pickle, either alone or mixed with other substances, and imparts a very agreeable flavour. In the Malayan Archipelago there are to be found both sweet and hot varieties of capsicums, and without one or both, no dish, be it fowl, cold meat, curry and rice, or salad, is considered complete, and the quantity of capsicums consumed by Europeans as well as by natives is perfectly astonishing. A very large number of species and varieties of capsicums are grown and used as condiments in all tropical countries, where there appears to be a greater necessity for pungent seasonings. The generic botanical name of capsicum is derived from "kapto," to bite, on account of the hot, pungent qualities of the pericarp. There are always a few of these shrubby plants grown about the dwellings in the tropics to supply the daily wants of the table, as they are generally gathered and eaten just before fully ripe.

Among the principal species grown may be named the following:—The cherry pepper or round chilli *(Capsicum cerasiforme*, Willd.), the bonnet pepper (*C. tetragonum*, Mill.), the bell pepper (*C. grossum*, Linn.), the spice or goat pepper (*C. frutescens*, Linn.), and the bird pepper (*C. baccatum*, Linn.). The last-named two are more acrimonious than the others. The fruits of these several species are of various forms—round, oblong, cordate, or horned, and in colour either scarlet or yellow; in some varieties they are so little pungent as to be used sliced in salad, in others they are intolerably biting, till the mouth becomes accustomed to them by habit. The cayenne pepper of commerce is obtained chiefly from the pulverised chillies or fruit pods of *Capsicum annum*, Linn., and *C. fastigiatum*, Blume.—*Journal of Applied Science.*

THE BANANA TRADE.

The *Boston Herald*, a leading New England paper, has lately devoted a large space to information about bananas and the banana trade, giving details as to the manner in which bananas are procured for the American market from Central America, Cuba and Jamaica.

It appears that, independently of New York, Boston is building up a banana trade of its own. This year the fruit received in Boston has been unusually fine, and has been in such favour that "the public has bought it in unstinted quantities." It is stated that the value of bananas imported into Boston during the season of 1881 cannot be less than 500,000 dols. Of the fruit received at that port much is sent from Port Antonio, Jamaica, by a well-known house. So firm and enduring is the popularity of the bananas that, the dealers say, peaches are the only fruit which interfere with their sale in the Boston market, where large quantities could be disposed of the year round. On the arrival of the Aspinwall steamers at New York, a regular train, called the "banana train" is despatched at once for Boston with the fruit.

With regard to the manner of disposing of the fruit, the following remarks are made:—

"Very great improvements have been made in handling and protecting this fruit during the past three or four years. Since it all has to be shipped green, owing to its softness and perishable nature when ripe, a good deal of skill is required in caring for it after its arrival. It is all bundled upon hay to prevent bruising, and in the cold months it is kept hanging up in rooms fitted for the purpose, when the temperature can be kept about 60°—too high for injury from cold, and too low for fast ripening. When the fruit is wanted, it is hung in another room where the temperature is up to 80°, and it ripens in a couple of days. Parties who began a few years ago with a dozen bunches shipped to them by each Aspinwall steamer, now sometimes take 1,000 bunches. These steamers now reach New York once in five days, and bring in 10,000 to 20,000 bunches. Beside the Aspinwalls received here, there are the West Indian bananas to be handled, which come in schooners fitted for the purpose. The parties handling this fruit sometimes sell cargoes of from 5,000 to 7,000 bunches in a single day, and, so well arranged are their plans of distributing, that scarcely anything unusual would be noticed, except a number of waggons with apparently small loads of hay; but under this hay are the bunches of green bananas."

The writer says that the "silver skins," so called from the light colour of the rind, are the most popular, and he classes the Jamaica fruit next to that from Colon and Baracoa, the "Aspinwalls" being "the largest and finest bananas received in the eastern market."

An increasing fruit trade is growing up from the Bay of Honduras to the United States. From the Bay Islands and Belize, there are regular lines of steamers started by American houses, which go to New Orleans, Philadelphia, and New York. There is no quarter from which the first-named port can better and with equal certainty receive tropical fruits than the coast of British Honduras.—*Journal of Applied Science.*

BOTANIC GARDENS, TRINIDAD.

We have received a copy of the report on the condition of the Botanic Garden for 1880. It is a lengthy document of nearly sixty folio pages, with twenty-four additional pages forming an appendix. Naturally the bulk of the report is occupied with matters of local interest, but there are several points of interest to home cultivators. It is noted, for instance, that Vanda trees does not flower if subjected to the least shade, but "when placed on an exposed tree or stump every branch produces its two or more spikes of lovely mauve, orange, and white flowers." "Hybrid Moka" Coffee promises to be the most suitable variety for low elevations, vieing with Liberian Coffee in vigour and fruitfulness, with seeds smaller than those of C. Arabica, but much more profusely produced. It is suggested that a good cross might be made between it and the Liberian variety, which is deficient in some of the characteristics of high-class Coffee. Incidentally the probability of the existence in Eastern Tropical Africa of a species of Coffee identical with or closely allied to Liberian Coffee is mentioned. The Saman or Rain tree does not in Trinidad exhibit that phenomenon of exuding moisture from its leaves whiah has given it the name. It is excellent as a shade tree, however, and its fruits furnish good fodder for cattle. The wood of old trees, moreover, is useful wherever toughness, durability, and freedom from liability to warp are desirable.

The Mahogany flourishes well at Trinidad, and its timber is of excellent quality. The Candle-tree (Parmentiera cerifera) also thrives, and its highly nutritious fruits are recommended as food for stock in the dry seasons when there is a scarcity of fodder. The fruit of Musa vittata, originally introduced from Fernando Po, and cultivated for ornamental purposes only, turns out to have very delicately flavoured fruit, which is striped like the leaves. The Bamboo timber (B. arundinaces) is extolled for its durability; but, in order to secure this result, it must be soaked when green, and, when dry, painted with thin paint. Of the Peach Palm (Guilielmia speciosa), which produces edible fruit, it is noted that it bears two crops a year, the remarkable circumstance being that at one season the fruits produced are destitute of seed, but very pulpy, while at another season seeds are produced, and the pulp is proportionately less. These few illustrations will serve to show the valuable nature of this report.

The facts contained in this and similar publications not generally accessible, render it very desirable that some means should be taken to secure a periodical abstract of the facts registered in the several colonial botanic gardens. Such a publication would be of great service to practical cultivators as well as to botanists and naturalists generally. We do not overlook the circumstance that much information of this character is now given in the annual reports of the Royal Gardens, Kew; but these, again, are not very readily accessible to the general public.

Reverting to the report before us we must not conclude our notice without mention of the valuable meteorological records from 1862 to June 1880, given in the appendix. From these we learn that the highest temperature recorded in eighteen years was 95°·5, the lowest 60°.1, the mean monthly temperatures ranging from 76° in January to 79°.4 in May. As to cloudiness, for which elaborate tables are also given for the same period, the minima occurred in December, January, February, and March, corresponding with a low average rainfall (1·88 inch in March), while the greatest amount of cloudiness appeared in August, June, and July, the periods of greatest rainfall (11·28 inches on the average in August). The average annual rainfall is not more than 66·39 inches. —*Gardeners' Chronicle.*

WILD SILKS.

(Handbook of the collection illustrative of the Wild Silks of India in the Indian section of the South Kensington Museum, by Thomas Wardle, London: Her Majesty's Stationery Office.)

The author of the work before us is well known as an eminent silk dyer and painter, and has been engaged for years in the study of the so-called "wild silks" of India with a view to their utilisation. The term wild silks is commonly applied to all kinds of silk other than that produced by *Bombyx mori*. Hitherto these silks have not been cultivated. The small and uncertain supplies which have found their way into commerce are derived from cocoons collected at hazard in the forests, but no organised and systematic attempts have been made to form plantations of the various food trees and to rear the insects in a state of domestication. There can be no doubt that to do so, to attend to the proper collection of the cocoons, and to make use of improved machinery for reeling the silk, and for carding and spinning that from imperfect cocoons, would prove a remunerative undertaking, and, like the introduction of the cinchona and the tea culture into India, would add to the resources of that country and of the Empire at large. To give encouragement to so desirable an undertaking ought to be the task of the Indian Government. Mr. Wardle meantime has greatly improved and developed the methods of dyeing and printing these silks. From trials which he has had made in Italy it has been found possible to convert the Tussur raw silk into tram and organzine of very great fineness. It appears that this silk, the product of *Antheræa mylitta* or *paphia* and some allied species, differs from common silk in its behaviour with reagents. A neutral solution of zinc chloride, gently heated, dissolves common silk instantly, but only acts slowly upon the Tussur. In a cold solution common silk dissolves in three days, whilst immersion for a fortnight produces no effect upon the Tussur. With ammoniacal solution of copper oxide a similar difference of action is observed. Hence we may well infer, as is actually the case, that the wild silk must be the more difficult to dye. The great difficulty as far as Tussur silk is concerned lies in the bleaching process. Being naturally of a darker colour than common silk, and incapable of bleaching by means of sulphurous acid —a deoxidising agent—oxidisers were tried. M. Tessié du Motay proposed potassium permanganate, which certainly removed the brown colour, but unfortunately injured the texture of the silk. With barium peroxide he was perfectly successful. This reagent is, however, as yet too costly for very general use. The author refers to a method not yet fully developed, of presenting nascent oxygen to the silk from a liquid instead of from a solid. He mentions also that Major Coussmaker has succeeded in obtaining perfectly white Tussur silk by modifying the conditions under which the worm spins its cocoon. If his method is practicable upon a commercial scale, the necessity for bleaching would be superseded. As the colours most adapted for dyeing Tussur silk, the author mentions lac, safflower, indigo, the leaves of *Phyllanthus emblica*, the calyces of *Thespesia populnea*, and the flowers of *Butea frondosa* of Hursinghur, and of *Cedrela toona*. Eria silk has less affinity for dye wares than has common silk, and takes up a greater quantity of tinctorial matter. The author, however, has succeeded in producing on it a variety of shades which leaves nothing to be desired.

The work is enriched with illustrations of several of the most important silk-yielding insects in their different stages of growth, of their food plants, and of the machinery for reeling cocoons. Mr. Wardle has deserved well of British commerce and industry for his prolonged investigations.—*Chemical News.*

"THE NEW CEYLON":—NORTH BORNEO.

The new Ceylon: being a sketch of British Borneo, or Sabah. From official and other exclusive sources of information. Written and compiled by Joseph Hatton. London: Chapman & Hall Limited. 1881. Crown 8vo. Maps.

The territorial area of Sabah, or British North Borneo, is comprised in the extreme northern apex of that island, from a point in the centre of Kimanis Bay above Labuan on the west coast to the mouth of the Sibuco on the east, and following the northern and eastern boundaries of Brunei to Gara Peak, the line thence to the mouth of the Sibuco being as yet undetermined. This gives a greatest length, roughly speaking, of 240 miles, (which, curiously enough, is also the greatest breadth of the territory), and an irregular seaboard of over 500 miles. The entire island is some 289,000 square miles in extent—a space nearly equal to that occupied by Great Britain and France together. Briefly summing up its present divisions, it may be noted that Brunei, the small residuum of Borneo proper left to its Sultan, follows on the west coast south of Sabah (having the little British island possession of Labuan near its northern limit), and is itself followed by the much larger native kingdom of Sarawak (not British, as is often imagined, because it is ruled over by an Englishman, which reaches to Datu Head, nearly the most western point of the island. The extension inland of these two kingdoms is bounded by the longitudinal range of mountains; and all the rest is claimed by the Dutch—at least, as far north on the east coast as the mouth of the Attas, just above 3° North lat. This leaves a debatable slip—Tidong—between the Dutch territory and British North Borneo, presumably belonging to the Sultan of Sulu, but with possible claims on the part of the Sultan of Brunei, and which will probably be appropriated by the Dutch.

If it were important that so insignificant a place as Labuan should be in our hands as a coaling station, in spite of its very limited anchorage, there can be no two opinions as to the value of this new territory, with its numerous and fine harbours, situated as it is on the fair way to so many British colonies. Of five of these—in Ambong and Gaya bays, and at Sandákan and Kudat—maps with soundings are given in Mr. Hatton's book, which has also (amongst other illustrations) a good general map of Borneo, by Stanford, scale fifty statute miles to the inch. The new British territory will soon be the best-explored portion of the island, as, in addition to the results of the journeys of Mr. Pryer and Capt. Witti above mentioned, there will be those of a skilled naval officer, now on the way to triangulate the country on a proper base line.

The details given in the diaries we have printed sufficiently indicate the existence of various sources of wealth in Sabah; we believe, indeed, it is already the opinion in Sarawak that the new Association has the most promising part of the island. The fabulous diamonds and gold of the interior will probably not be found, any more than the absurd "tailed men" in whom a lingering belief still exists with some enthusiasts; but gutta percha, indiarubber, and other products of tropical forests, sago, rice, spices, sugar, cotton, &c., to say nothing of pearl fisheries, afford ample scope for the increase of capital; and these are existing now. In the development of the rich natural resources of the country many openings will doubtless occur for the surplus wealth and energy of our countrymen; and we may congratulate ourselves on the acquisition of such a fresh field. Mr. Hatton quotes and indorses Mr. Wallace's commendation of colonial management in Java, and suggests the importation of Chinese labour. On the former point, we believe, there is much to be said *per contra* by those who have looked beneath the surface; and we regret that the Association seems driven to introduce what Mr. Hatton terms "a Chinese colony," as we observe that Sir Walter Medhurst, formerly Her Majesty's

Consul-General at Shanghai, has been deputed by the Association to proceed to Borneo and China, with the view of organising the Chinese Labour Department for Emigration to Borneo. The very term "colony" is an anomaly. No Chinese ever colonise, in the proper sense of that word; they bring labour, and nothing more, abstracting all they can from any country to which they are taken, never spending their earnings in it, and going home with their gains, alive or dead.—*Field.*

ARBORICULTURE IN THE NORTH-WEST PROVINCES AND OF INDIA.

We have now before us the report on the agricultural operations in the North-West Provinces and Oudh for last year, and this enables us to form an estimate of what has been and is being done. Planting trees along the sides of roads has been steadily carried on, though we are not by any means sure that this is beneficial for the roads themselves, however pleasant it may be for the travellers along the roads. With the general operations we do not propose to deal, but only with the subjects specially noticed in the report. And first as to nurseries:—"When Mr. Buck first took charge of the arboricultural operations, he found that a large number of nurseries was kept up at a greater cost than the grant could properly afford. The difficulties in the way of an efficient supervision were insuperable, and it was almost impossible to procure *malis* with adequate knowledge of the work. He therefore recommended that their number should be reduced as far as possible. Mr. Howe, the Collector of Etawah, writes this year: 'I am decidedly of the opinion that the nurseries at the tahsils are a mistake. They are far from supervision, unless the tahsildar happens to have a special interest in the work, which is seldom the case. The past history of the nurseries shows them to be almost entire failures. I think it would be better to have one central nursery at the public gardens, under the management of the officer in charge. Similarly Mr. Twigg of Hamirpore found all the plant in his nurseries either overgrown or non-existent.' There are, however, objections to concentrating the nursery operations at the Sudder station. The Deputy Commissioner of Lalitpur writes: 'A glance at the map of the district will show, as I found before we had well taken the matter in hand, that a central nursery at Mahroni will be useless, as young trees will not bear carrying from Mahroni to Talbehat, a distance of 50 miles. I therefore established branch nurseries at Talbehat, Bansi, and Birdha, which are kept up at a very small cost, and have proved a success.' Cost of carriage is such a heavy charge that, as a matter of fact, local nurseries are far more economical than nurseries at headquarters, if only they are properly managed; but this constitutes the real difficulty. The whole question of nurseries seems at present to be in much haze, which can only be dispelled by practical experience. It is a subject which deserves the careful attention of district officers.

Different means of solving the difficulty have been suggested. Mr. Reid, the Collector of Bareilly, writes: 'It has been found a cheap and easily worked plan to let the tahsildars, whose roads are beyond the reach of the head-quarters nursery, procure, by purchase or otherwise, such trees as they require. They seem to have no difficulty in procuring suitable plants. Mr. Wyer at Azamgarh has adopted a slightly different plan with apparent success. 'Twenty-five roadside-nurseries,' he writes, 'have been established, and are maintained free of expense by zemindars and others interested in arboriculture. As all those who have established nurseries will make use of many of the seedlings for planting out on their own land, they have most willingly undertaken the work and appear to take great interest in it.' The suggestion to buy young trees from private growers appears to be a very valuable one so long as attention is paid to the selection of strong and healthy plants. They can be grown at infinitely less cost by cultivators, who supply their own supervision and have an interest in the success of the plantation, than by any Government officer. It is believed that native zakiras, where young mangoes and other useful trees are grown, can be found in most places. The Ramgarh nursery, under the charge of Mr. Campbell of the Forest Department, seems to have answered the purpose of supplying the district roads of Gorakpur. Mr. Campbell says that it was found possible entirely to eradicate kans grass by planting out pine-apple seedlings. Graft mangoes were imported from Lucknow and Saharanpur, and are doing well. A large number of jack seedlings (20,000) were reared, but were almost all destroyed. Hopes are entertained of better success from rearing them in hollow bamboos instead of in the ordinary way. It may, however, be remarked, as a common result of native experience, that jacks stand transplanting worse than almost any other trees, and that it is usually cheaper and safer to sow them *in situ*, where they are wanted, putting in a sufficient number of seeds to admit of selection and subsequent thinning out. *Inga dulcis* though it thrives generally in the district, altogether failed in the nursery."

The Lieutenant-Governor remarks that the "co-operation of residents along the roads is to be desired above all things, inasmuch as while the expenses of planting and maintenance are thereby saved or reduced, the personal interest taken by the planter of the tree in its welfare is likely to produce better results than is possible from the superintendence of overworked officials."

And this is the real system at all attempts at reforestation in this country.—*Asian.*

ELECTRO-HORTICULTURE.

At the recent meeting of the British Association, Dr. Siemens read an address on Electric Energy:—

On the 1st of March, 1880, I communicated to the Royal Society a paper "On the Influence of Electric Light upon Vegetation, &c.," in which I arrived at the conclusion that electric light was capable of producing upon plants effects comparable to those of solar radiation; that chlorophyl was produced by it, and that bloom and fruit rich in aroma and colour could be developed by its aid. My experiments also went to prove that plants do not, as a rule, require a period of rest during the 24 hours of the day, but make increased and vigorous progress if subjected in winter time to solar light during the day and to electric light during the night. During the whole of last winter I continued my experiments on an enlarged scale, and it is my present purpose to give a short account of these experiments and of some further applications of electric energy to farming operations (including the pumping of water, the sawing of timber, and chaff and root cutting) at various distances not exceeding half a mile from the source of power, giving useful employment during the day-time to the powder-producting machinery, and thus reducing indirectly the cost of the light during the night-time. The arrangement consists of a high-pressure steam-engine of 6-horse power nominal, supplied by Messrs. Tangye Brothers, which gives motion to two dynamo machines (Siemens D.) connected separately to two electric lamps, each capable of emitting a light of about 4,000 candle power. One of these lamps was placed inside a glasshouse of 2,318 cubic feet capacity, and the other was suspended at a height of 12 to 14 feet over some sunk greenhouses. The waste steam of the engine was condensed in a heater, whence the greenhouses take their circulating supply of hot water, thus saving the fuel that would otherwise be required to heat the stoves. The experiments were commenced on the 23rd of October, 1880, and were continued till the 7th of May, 1881. The general plan of operation consisted in lighting the electric lights at

first at 6 o'clock and during the short days at 5 o'clock, every evening except Sunday, continuing their action until dawn. The outside light was protected by a clear glass lantern, while the light inside the house was left naked in the earlier experiments, one of my objects being to ascertain the relative effect of the light under these two conditions. The inside light was placed at one side over the entrance into the house, in front of metallic reflector to save the rays that would otherwise be lost to the plants inside the house. The house was planted in the first place with peas, French beans, wheat, barley, and oats, as well as with cauliflowers, strawberries, raspberries, peaches, tomatoes, vines, and a variety of flowering plants, including roses, rhododendrons, and azaleas. All these plants being of a comparatively hardy character, the temperature in this house was maintained as nearly as possible at 60 deg. Fahr. The early effects observed were anything but satisfactory. While under the influence of the light suspended in the open air over the sunk houses the beneficial effect due to the electric light observed during the previous winter repeated themselves, but the plants in the house with the naked electric light soon manifested a withered appearance. Was this result the effect of the naked light, or was it the effect of the chemical products—nitrogenous compounds and carbonic acid—which are produced in the electric arc? Proceeding on the first-named assumption, and with a view of softening the ray of the electric arc, small jets of steam were introduced into the house through tubes drawing in atmospheric air with the steam, and producing the effects of clouds interposing themselves in an irregular fashion between the light and the plants. This treatment was decidedly beneficial to the plants. Having in consequence of preliminary inquiries determined to surround the electric arc with a clear glass lantern, more satisfactory results were soon observable. Thus peas which had been sown at the end of October produced a harvest of ripe fruit on the 16th of February, under the influence, with the exception of Sunday nights, of continuous light. Raspberry stalks put into the house on the 16th of December produced ripe fruit on the 1st of March, and strawberry plants put in about the same time produced ripe fruit of excellent flavour and colour on the 14th of February. Vines which broke on the 26th of December produced ripe grapes of stronger flavour than usual on the 10th of March. Wheat, barley, and oats shot up with extraordinary rapidity under the influence of continuous light, but did not arrive at maturity; their growth having been too rapid for their strength caused them to fall to the ground after having attained the height of about 12 inches. Seeds of wheat, barley, and oats planted in the open air and grown under the influence of the external electric light produced, however, more satisfactory results; having been sown in rows on the 6th of January, they germinated with difficulty on account of frost and snow on the ground, but developed rapidly when milder weather set in, and showed ripe grain by the end of June, having been aided in their growth by the electric light until the beginning of May. Doubts have been expressed by some botanists whether plants grown and brought to maturity under the influence of continuous light would produce fruit capable of reproduction; and in order to test this question, the peas gathered on the 16th of February from the plants which had been grown under almost continuous light action were on the 18th of February. They vegetated in a few days, showing every appearance of healthy growth. Further evidence on the same question will be obtained by Dr. Gilbert, F.R.S., who has undertaken to experiment upon the wheat, barley, and oats grown as above stated, but still more evidence will probably be required before all doubt on the subject can be allayed. I am aware that the great weight of the opinion of Mr. Darwin goes in favour of the view that many plants, if not all of them, require diurnal rest for their normal development, and it is with great diffidence, and without wishing to generalize, that I feel bound to state as the result of all my experiments, extending now over two winters, that although periodic darkness evidently favours growth in the sense of elongating the stalks of plants, the continuous stimulus of light appears favourable for healthy development at a greatly accelerated pace through all the stages of the annual life of the plant, from the early leaf to the ripened fruit. The latter is superior in size, in aroma, and in colour to that produced by a alternating light, and the resulting seeds are not, at any rate, devoid of regerminating power. Further experiments are necessary, I am aware, before it would be safe to generalize, nor does this question of diurnal rest in any way bear upon that of annual or winter rest, which probably most plants, that are not so-called annuals, do require. The beneficial influence of the electric light has been very manifest upon a banana palm, which at two periods of its existence—*viz.*, during its early growth and at the time of the fruit development, was placed (in February and March of 1880 and 1881) under the night action of one of the electric lights, set behind glass at a distance not exceeding two yards from the plant. The result was a bunch of fruit weighing 75 lb., each banana being of usual size, and pronounced by competent judges to be unsurpassed in flavour. Melons also remarkable for size and aromatic flavour have been produced under the influence of continuous light in the early spring of 1880 and 1881, and I am confident that still better results may be realized when the best conditions of temperature and of proximity to the electric light have been thoroughly investigated. My object hitherto has rather been to ascertain the general conditions necessary to promote growth by the aid of electric light than the production of quantitative results; but I am disposed to think that the time is not far distant when the electric light will be found a valuable adjunct to the means at the disposal of the horticulturist in making him really independent of climate and season, and furnishing him with a power of producing new varieties. Before electro-horticulture can be entertained as a practical process, it would be necessary, however, to prove its cost, and my experiments of last winter have been in part directed towards that object. Where water-power is available the electric light can be produced at an extremely moderate cost, comprising carbon electrodes, and wear and tear of, and interest upon, apparatus and machinery employed, which experience elsewhere has already shown to amount to 3d. per hour for a light of 5,000 candles. The personal current attention requisite in that case consists simply in replacing the carbon electrodes every six or eight hours, which can be done without appreciable expense by the under-gardener in charge of the fires of the greenhouses. In my case no natural source of power was available, and a steam-engine had to be resorted to. The engine, of six nominal horse-power, which I employ to work the two electric lights of 5,000 candle-power, each consumes 56 lb. of coal per hour (the engine being of the ordinary high-pressure type), which, taken at 20s. a ton, would amount to 6d, or to 3d. per light of 5,000 candles. But against this expenditure has to be placed the saving of fuel effected in suppressing the stoves for heating the greenhouses, the amount of which I have not been able to ascertain accurately, but it may safely be taken at two-thirds of the cost of coal for the engine, thus reducing the cost of the fuel per light to 1d. per hour; the total cost per light of 5,000 candles will thus amount to 6d. *plus* 1d., equal to 7d. per hour. This calculation would hold good if the electric light and engine-power were required during, say, 12 hours per diem, inasmuch as the light is not required during the daytime, and the firing of the boiler has nevertheless to be kept up in order to supply heat to the greenhouses, it appears that during the daytime

an amount of motive power is lost equal to that employed during the night. In order to utilize this power I have devised means of working the dynamo-machine also during the daytime and of transmitting the electric energy thus produced by means of wires to different points of the farm where such operations as chaff-cutting, swede-slicing, timber-sawing, and water-pumping have to be performed. These objects are accomplished by means of small dynamo-machines, placed at the points where power is required for these various purposes, and which are in metallic connection with the current-generating dynamo-machine near the engine. The connecting wires employed consists each of a naked strand of copper wire, supported on wooden poles, or on trees, without the use of insulators, while the return circuit is effected through the park railing or wire fencing of the place, which is connected with both transmitting and working machines, by means of short pieces of connecting wire. In order to insure the metallic continuity of the wire fencing, care has to be taken wherever there are gates to solder a piece of wire buried below the gate to the wire fencing on either side. As regards pumping the water, a three-horse-power steam-engine was originally used, working two force-pumps, of 3½-inch diameter, making 36 double strokes per minute. The same pumps are still employed, now being worked by a dynamo-machine weighing 4 cwt. When the cisterns at the house, the gardens, and the farm require filling, the pumps are started by simply turning the commutator at the engine station, and in like manner the mechanical operations of the farm already referred to are accomplished by one and the same prime mover. It would be difficult in this instance to state accurately the percentage of power actually received at the distant station, but in trying the same machines under similar circumstances of resistance with the aid of dynamometers as much as 60 per cent has been realized. In conclusion, I have pleasure to state that the working of the electric light and transmission of power for the various operations just named are entirely under the charge of my head gardener, Mr. Buchanan, assisted by the ordinary staff of under-gardeners and field labourers, who probably never before heard of the power of electricity. Electric transmission of power may eventually be applied also to thrashing, reaping, and ploughing. These objects are at the present time accomplished to a large extent by means of portable steam engines, a class of engine which has attained a high degree of perfection, but the electric moter presents the great advantage of lightness, its weight per horse-power being only 2 cwt., while the weight of a portable engine with its boiler filled with water may be taken at 15 cwt. per horse-power. Moreover, the portable engine requires a continuous supply of water and fuel, and involves skilled labour in the field, while the electrical engine receives its food through the wire (for a light rail upon which it may be made to move about) from the central station, where power can be produced at a cheaper rate of expenditure for fuel and labour than in the field. The use of secondary batteries may also be resorted to with advantage to store electrical energy when it cannot be utilized. In thus accomplishing the work of a farm from a central power station, considerable savings of plant and labour may be effected, the engine power will be chiefly required for day work, and its night work, for the purposes of electro-horticulture, will be a secondary utilization of the establishment involving little extra expense. At the same time the means are provided of lighting the hall and shrubberies in the most perfect manner, and of producing effects in landscape gardening that are strikingly beautiful.

Cultivation of Hops.—M. Müntz.—The author concludes that hop manures should be especially rich in nitrogen.—*Chemical News.*

Manurial Experiments with Saltpetre on Wheat, Barley, and Oats.—Horatio Chancellor.—Saltpetre is most beneficial in dry seasons, and should be applied in successive doses.—*Chemical News.*

Manurial Action of Gypsum on Lucerne.—V. Nanquette, Prof. Medicus, and M. Schell.—Gypsum has proved useful in the cultivation of lucerne, even on decidedly calcareous soils. (This agrees with the view of Prof. Ville.)—*Ibid.*

Comparative Manurial Experiments.—C. Nerger.—In the experiments tried, a manuring, containing otherwise all the constituents of the crop (barley), but deficient in silica, gave the poorest results, being on a level with a plot totally unmanured.—*Ibid.*

Manurial Garden Experiments.—W. Lauche and Prof. A. Orth.—The highest results were obtained with farmyard mauure plus ammonium and potassium sulphates and superphosphate. The crop was the sugar-beet.—*Ibid.*

Influence of Atmospheric Electricity on Growth of the Vine.—Dr. J. Macagno.—The vines experimented on yielded grapes richer in grape-sugar and poorer in acid than those growing under natural conditions.—*Ibid.*

Researches on the Heat of the Ground.—Dr. von Liebeuberg.—All air-dry soils at equal temperatures radiate heat equally. The author insists strongly on the injurious effect of any agency that lowers the temperature of the ground in spring, as reducing both the quautity and quality of the crop.—*Ibid.*

New Researches on the Passage of Rain-waters through Arable Soils.—A. Audoynaud and B. Chauzit.—The chief loss of nitrogen is in the form of nitrates. Sulphuric acid is removed in considerable quantity; phosphoric acid only in traces. The loss of potash and sodium chloride is great.—*Ibid.*

Manurial Experiments on Fruit Trees.—Dr. P. Sorauer.—If liquid manures are too much diluted, the trees are injured by being compelled in seeking nourishment to take up more water than they need. On the other hand, too concentrated solutions occasion a decay of the roots.—*Biedermann's Centralblatt.*

Experiments on Manuring Beets.—M.M. Champonnois and Pellet.—The authors have tried two manures, one based on Ville's manure and the other on the residue of the refuse from refining beet-sugar on Porion's process. The latter was richer in potash, and of course in organic matter, and gave heavier crops.—*Chemical News.*

Changes in Farm-yard Manure on Prolonged Keeping.—Prof. Birner and Dr. Brimmer.—The loss of nitrogen is considerable, but almost disappears if the manure is protected against moisture. On the addition of 1 per cent kainite and 1 per cent magnesium sulphate, the nitrogen is increased by absorption from the atmosphere.—*Ibid.*

A New Method of Determining the Absorptive Power of the Soil.—R. Zalomanoff.—The author recommends the filtration method. He concludes that the results obtained by agitation in a flask are conclusive; that Liebig's opinion on the identity of drainage-water and ground-water is erroneous, and that compounds existing in solution and separated on passing through pulverised bodies or through capillary tubes assume another molecular condition.—*Ibid.*

The Value of Different Forms of Reverted Phosphoric Acid compared with the Soluble Phosphoric Acid of Superphosphates.—Prof. M. Maercker.—In general, precipitated phosphate of lime appears of equal value with superphosphates with an equal quantity of soluble phosphoric acid. Root crops form an exception, as in them soluble phosphoric acid gives a somewhat better return. In light soils the precipitated phosphate was found much superior. Precipitated aluminium phosphate is as the same value as the calcium phosphate.—*Ibid.*

Influence of Superficial Desiccation of the Soil upon its Hygroscopic and Thermometric Relations.—Prof. E. Wollny.—The evaporation of water and the escape of heat are reduced by superficial drying.—*Chemical News.*

Utilisation of Certain Articles of Food in Human Digestion.—Max Rübner.—The proportion of matter assimilated from different kinds of food varies greatly. Of the nitrogenous matter in fresh meat and eggs only 2·5 to 2·7 per cent is rejected; in milk 7 to 12 per cent; in peas, beans, &c., 10·5 per cent. The author maintains that a healthy body can scarcely be formed and upheld with vegetable matter alone.—*Ibid.*

Quantity of Plant-food in the Refuse of Different Towns.—Dr. M. Fleischer.—The Groningen compost contains on the average :—Nitrogen 0 6, potash 0·24, and phosphoric acid 0·5 per cent. The Bremen compost (pail-system) :—Nitrogen 0·52, potash 0·26, phosphoric acid 0·51. The author taking the value of nitrogen at £60 per ton, that of potash at £11, and that of phosphoric acid at £15, values the excrementitious matter of Groningen at £240 per 1,000 inhabitants, and that of Bremen at £150.—*Ibid.*

State of Combination of Phospheric Acid in the Agricultural Soil.—P. P. Deherain and Kayser.—The authors mention that phosphoric acid introduced into the soil in the state of animal charcoal soon passed into combination with alumina and ferric oxide. In cases where the addition of superphosphate was found unremunerative, a considerable part of the total phosphoric acid was found as calcium phosphate. The mud of the Nile was found to contain 2·30 grms. phosphoric acid per kilo. If as much as 0·4 per cent of phosphoric acid is present in the soil, phosphatic manures are useless.—*Ibid.*

Fruits.—The consumption of lumber by legitimate enterprise is something enormous, and from published statistics we gather the following :—To make shoe-pegs enough for American use consumes annually, 100,000 feet of the best pine are required every year. Last and boot-trees take 500,000 cords of birch, beech or maple, and the handles of tools, 500,000 more. The baking of our brick consumes 2,000,000 cords of wood, or what would cover with forest about 50,000 acres of land. Telegraph poles already up represent 800,000 trees, and their annual repair consumes about 300,000 more. The ties of our railroads consume annually thirty years' growth of 75,000 acres. Our packing boxes cost 12,000,000 dols., while the timber used each year in making waggons and agricultural implements is valued at more than 100,000,000 dols.—*South American Journal.*

Manurial Experiments with Phosphoric Acid in Different Forms of Combination.—Dr. Fittbogen, Prof. Dietrich, F. Oldeuburg, Dr. Birner.—The authors have compared the manurial action of superphosphates made from Mejillones Guano and from Lahn phosphorite with precipitated "Kladno-phosphate" (an aluminium phosphate) and with iron phosphate. The proportionate results for grain were :—Mejillones superphosphate 32, Lahn do. 12, precipitated phosphate 8, Kladno-phosphate 9, iron phosphate 10, whilst a check experiment without phosphoric acid gave 9. On doubling the doses, the yield was approximately doubled in case of the Mejillones and the Lahn superphosphate, whilst with precipitated calcium phosphate, with kladno and iron phosphate, there was little difference. The authors conclude that in sandy soils, such as were used in their experiments, only that part of the phosphoric acid which is soluble in water utilized. Plants cannot, by the mere action of their roots, and without the cooperation of ground waters containing carbolic acid, extract any phosphoric acid from the insoluble phosphates.—*Chemical News.*

Lands to be Granted in South Africa.—In 1880 the total area of lands granted by the Crown in Cape Colony was 340,850 acres, while 2,635,588 acres were sold. The total are of the Colony is about 131,711,600 acres, of which 56,900,930 acres still remain unalienated.—*Colonies and India.*

Manitoba.—Mr. Staveley Hill, M.P., is on a visit to Winnipeg, and contemplates a tour through Manitoba and the North-West, with the view of laying the result of his observations before his constituency in West Staffordshire on his return. Two Cabinet Ministers, Messrs. Atkins and Bowell, were also visiting the capital. A large number of permanent settlers were arriving.—*Ibid.*

New Zealand.—Another very valuable industry is likely soon to be established amongst us—the growth and manufacture of tobacco. It is proposed to reduce the duty on the locally-grown article from 3s. 6d. to 1s. per lb., and with such a stimulus the lands in the Colony known to be suitable to the growth of this plant will probably soon be abundantly productive.—*Ibid.*

New Fruits from Canada.—The *Liverpool Journal of Commerce* states that a very interesting consignment of fresh fruit—tomatoes, cantaloups, and other kinds of melons—has just been landed from the Allan Royal Mail steamer *Parisian*, consigned to Messrs. Woodall & Co., fruit merchants, North John Street, Liverpool. These were shipped under a process newly planted by Mr. G. A. Cochrane, of Montreal. The results are stated by the trade to be in every way satisfactory, and shipments of peaches and other perishable fruits are to follow. Mr. Cochrane's patent can be applied to a number of other commodities, and it is believed to be possible that the trade carried on on in preserved and canned fruits may be completely revolutionised.—*Ibid.*

The desire for Colonial Possessions is a growing feeling among Continental nations. The German papers describe the movement in favour of acquiring Colonies for Germany as furnishing a prominent electioneering cry. An organisation has been formed in that country, calling itself the "Society of Commercial Geography," and is engaged in actively circulating papers advising voters to withhold their support from any candidates who are not disposed to support measures for securing to the German Empire suitable Colonial possessions. It is difficult to see what measures are to be taken for this purpose; but it is to be hoped that they will be of a more commendable character than those adopted by France, and that the Germans may be more successful in their Colonial undertakings than their neighbours have been.—*Ibid.*

Plants for Paper-making.—Earnest efforts are made, too, to introduce from South America, *le maté*. It it made of the leaves of the *ilex paraguayensis*, which are singed over a fire made with several sorts of aromatic wood, next dried by a flame (which has no smoke) of other spices of aromatic wood, then these leaves are pounded, afterwards sifted, next pounded, then sifted and re-sifted until a very fine powder is obtained, which is *le maté*. When used, it is boiled in water for two minutes, may be boiled seven or eight times (if care be taken never to let the leaves cool between each of these boilings), and the last decoction will be the best. This decoction is a darkish liquid, less fragrant than good tea, less bitter than coffee, containing the same principles as coffee, and may be used instead of coffee. It produces neither sleeplessness nor palpitations of the heart, enables the drinker to do without food, costs 1d. a pound, and each pound easily furnishes twenty quarts of good strong *maté*; it does not require sugar.—*Stationery Trades Journal.*

Trade in Fungus.—Auckland, August 16.—A steadily increasing trade in fungus is being carried on between the northern part of New Zealand and China, and last year 165 tons, valued at rather more than £6,000 were exported. During the nine yeas from 1872 to 1880 inclusive, no less than 1,132 tons, valued at £47,651, were exported. Very little attention has been paid to this branch of industry until recently. The New Zealand fungus is found upon various kinds of decayed timber in the North Island. It mostly favours damp localities, and is very plentiful on the east coast south of the East Cape. Children and Maoris collect it, and after being sold to the dealers, it is packed in bales and forwarded to China by way of Sydney and San Francisco. The Chinese use it as an article of food.—*Colonies and India.*

Determination of Potash in Agricultural Substances by means of Perchloric Acid.—Armand Bartraud.—In the first place it is necessary to examine if the substance in question contains an ammoniacal salt. If this is the case, the ammonia must be expelled by boiling with a little caustic lime. It is necessary that the substance should be perfectly clear. The filtered solution of the sample is evaporated on the water-bath in a small procelain capsule with 5 c c. of perchloric acid at 45° B. until the volume of the liquid is reduced to about 10 c.c. The capsule is taken off the water-bath, alcohol at 95 per cent is added; it is let cool, and the potassium perchlorate is collected upon a small filter. The precipitate is washed with alcohol at 95 per cent containing 10 per cent by volume of perchloric acid, until the liquid running through no longer shows the reactions of sulphuric and phosphoric acids. The washing is then completed with alcohol at 95 per cent without the admixture of perchloric acid. It is then dried in the stove. At the end of twenty to thirty minutes the precipitate is detached from the filter and spread out in a tared watch-glass. It is weighed twice, to be certain that the desiccation is complete, and the weight of the potassium perchlorate thus obtained is noted. On the other hand, as there always remains a little perchlorate adhering to the filter, instead of using a tared filter, the author considers it more expeditious to operate as follows:—During the desiccation of the perchlorate in the watch-glass the filter is burnt in a platinum capsule fitted with a lid. The potassium chloride resulting from the calcination is washed into a glass, and the chlorine is determined with a centinormal silver solution. A multiplication indicates the perchlorate to be added to that which has been weighed. This process gives accurate results in presence of lime, magnesia, soda, baryta, iron, alumina, and sulphuric or phosphoric acids, free or combined. The author prepares his perchloric acid as follows:—He dissolves purified barium chlorate in luke-warm water, and precipitates with dilute suphuric acid. He lets settle, draws off the clear liquid with a syphon, and washes the precipitate of barium sulphate. The solution of chloric acid is evaporated in a porcelain capsule over a naked fire until the concentrated liquid becomes yellow and emits a peculiar sound if heated further. It is then divided in capsules of 19 centimetres in diameter, each capable of containing about 700 c.c., and the evaporation is continued until the liquid is completely colourless, and emits dense white fumes. In order to diminish the inevitable loss of perchloric acid, a little water may be added from time to time during the concentration. Four parts of barium chlorate yield in general 1 part of perchloric acid at 45° B. The colourless liquid is distilled in a retort heated on the sand-bath. A long-necked tubulated receiver is adapted to the retort without the use of a cork.—*Chemical News.*

New Products at Avisawella, (Ceylon).—We are having remarkably fine growing weather now for our last year's clearings. The Liberian are beginning to throw out the large light yellowish leaves, which is a sure sign the roots are all right beneath. Cocoa is coming on very well, but goes out mysteriously in small patches, although each month's growth enables it to fight through its various enemies with greater chance of success. Cardamoms are bearing well after eighteen months' growth, they grow to almost any height in that time. Para Rubber wont grow anywhere here, I heard of the last tree in the place having died lately. Ceara comes on wonderfully fast and is a healthy fine looking tree. Will it, or will it not ultimately, pay? Ours is getting a large and a most interesting district to anyone wishing to see low growing products. There are also five large engines sawing timber. It is interesting to watch the elephants working at these mills and the systematic way in which the great saws are worked and the timber transported through miles of jungle cart roads. —*C. Times.*

New Zealand: Beet Root.—Efforts are being made to secure the establishment of a beet-root sugar manufactory in the Waikato, and to induce the settlers to cultivate the beet. At a meeting of settlers last week, it was announced that the Hamburg Company were willing to furnish seed of the best quality for the cultivation of 500 tons of beet, send out a plant capable of manufacturing 10,000 tons per annum, and skilled labour to work it, and to take about 6,000*l* money interest in the undertaking, if the settlers would grow that quantity of beet and provide the remaining capital required—some 24,000*l*. The nett profit for the working of a plant of this kind was expected to be not less than 30 per cent per annum on the paid-up capital. Notwithstanding the fact that the soil and climate in Waikato are very suitable for the growth of beet-root, the settlers appeared indisposed to undertake its cultivation; but in order to prevent a failure of the scheme, Mr. J. C. Firth, a wealthy landowner, and the possessor of many thousands of fertile acres at Matamata, has undertaken to grow from 500 to 700 acres of beet-root per annum for a long term of years. Should the necessary capital be found, therefore, sugar may form one of the principal articles of export from Auckland ere long.—*Colonies and India.*

Useful Ants.—We are told that "many of the leading orchard proprietors in Northern Italy and Southern Germany are cultivators of the common black ant, which insect they hold in high esteem as the fruit-grower's best friend. They establish ant-hills in their orchards, and leave the police service of their fruit trees entirely to the tiny colonists, which pass all their time in climbing up the stems of the fruit trees, cleansing their boughs and leaves of malefactors, mature as well as embryotic, and descend laden with spoils to the ground, when they comfortably consume or prudently store away their booty. They never meddle with sound fruit, but only invade such apples, pears, and plums as have already been penetrated by the canker, which they remorselessly pursue to its fastnesses within the very heart of the fruit. Nowhere are apple and pear trees so free from blight and destructive insects as in the immediate neighbourhood of a large ant-hill five or six years old. The favourite food of ants would be the larvæ and pupæ of those creatures which spend the whole of their brief existence in devouring the tender shoots and juvenile leaves of fruit trees." We have a large variety of carnivorous ants in Australia, some of which, perhaps, might be turned to account as a military force against some ot our insect plagues. Perhaps some entomologist may find it worth while to give some attention to this matter.—*Australasian.*

ORANGE-GROWING NEAR WANGARATTA.

Mr. Brien had been engaged in the orange plantations in New South Wales, and in choosing his site his practised eye discovered a small nook in a gorge at the foot of the ranges that gave every promise of being suitable to the growth of the orange. He cleared off the timber, and having procured some young orange trees from Sydney, made his first experiment, which answered so well that he was induced to plant an extensive orange grove. As it was risky and somewhat expensive to import the young trees from Sydney, he adopted the plan of raising young plants by layering the old ones. The orange trees raised by this process are said never to make well-shaped or vigorous trees. This has not been the case in Mr. Brien's experience, for the most vigorous and shapely trees in his plantation are those raised from layers.

The soil in which the plantation has been formed is a patch of deep kindly vegetable soil, a little over seven acres in extent. It is completely sheltered by the range on three sides, and lies open only to the east. The trees receive but little manure, and scarcely any water, and yet no trees could be more healthy or bear heavier crops. The patch of good soil on which the trees are planted is very clearly defined, and a yard or so out of a certain boundary the trees show by their dwarfed and sickly look that the soil is unsuitable to their growth. Most of the trees on the border of the good soil have been removed and lemons planted in their place; they thrive well, and there is a constant demand for their fruit. Citrons and shaddocks also grow well and bear freely. The varieties of orange grown are St. Michael, blood, navel, Parramatta seedling, Emperor, and thorny mandarins and cumquats. Mr. Brieu is strongly of opinion that fine-flavoured oranges can only be grown on the hills, and that there are very few localities indeed in which they can be grown to leave a profit.—*Australasian.*

TEA DRYING: ROBERTSON'S TYPHOON.

Mr. J. M. Robertson, manager of the Arcuttipore Tea Company's Gardens, has invented a new tea-drying apparatus which he has named the "Typhoon." A number of the planters of his district met at his garden, by invitation, to test the merits of his machine. We quote the verdict recorded by them in their own words, and also append the Brokers' report on the teas which were manufactured in their presence during the trial. The "Typhoon" is a simple and inexpensive construction of brick and iron, which can be erected without skilled labor. The heating material used is coke, and the quantity of coke required for a maund of tea is stated to be one-quarter of a maund. The out-turn from the "Typhoon" we found to be at the rate of one-half maund of thoroughly dried Tea per hour, and the manner in which the work was done was to our entire satisfaction, some of us thinking that the apparatus was capable of doing more. The inventor leads us to understand that the entire cost of construction and material will not be over R300, and we do not see that this sum need be exceeded. We are unanimously of opinion that unless the dryers at present in use are very materially reduced in price, that they will be beaten off the field by the "Typhoon." The following are some of the chief features and advantages of this machine:—*1st.*—The low cost. *2nd.*—Durability, there being nothing except the trays that can suffer from wear and tear. *3rd.*—The small quantity of fuel required—about ¼ maund of coke for kutcha bring 1 maund of Tea. *4th.*—Ease in stoking, the furnace not requiring attention oftener than once every 1½ to 2 hours. *5th.* Absolute and immediate control over the temperature, which can be raised or lowered instantaneously. *6th.*—No "getting up heat" required. In fifteen minutes after beginning to light the fire, the apparatus is ready for work. *7th.*—Requires no troublesome cleaning out. *8th.*—Quantity. The apparatus is capable of drying at least 40 lb. an hour, and has frequently dried over 50 lb. *9th.*—Quality of tea is equal to that obtained by any process hitherto introduced.—*Indian Tea Gazette.*

JACKSON'S NEW SELF-ACTING TEA DRYER.

Messrs. W. & J. Jackson have invented a new apparatus that will deal with the Tea itself throughout the drying process, and thus, they submit, secure a perfection in the dessication of the leaf not hitherto obtained. The objects arrived at by the new invention are as follows:—*1st.*—After the leaf is fed into the machine it requires no more attention until it is discharged dry. *2nd.*—Every individual leaf is simultaneously exposed in precisely a similar manner to the action of the heated air, thus producing an unvaried and perfectly even dried leaf. *3rd.*—The Tea is steadily but very slowly kept in motion, thereby dispensing with the tedious and tiring watchfulness of attendants, hitherto required in Tea drying on the tray system. *4th.*—There are no trays about the machine to handle, and it is, therefore, thoroughly durable and cannot get out of order. In operating with the machine, a boy or attendant has simply to spread the leaf on a slowly-moving feeding web or band, which carries it forward and places it in the machine, where it is steadily but inactively kept in motion, and in due course is discharged dry and crisp from a shoot at the delivery end; so long therefore as the attendant continues to supply the machine with leaf, it will steadily dry and discharge it, and should he have occasion to leave the machine at any time, no injury can take place to the leaf in the apparatus, as it must pass on and be discharged. The leaf is continuously, but very slowly, turned over, disentangled and individually presented to the action of the heated air by a peculiar combination of concentric cylinders, thus ensuring not only the most uniform fermentation, but the drying of each leaf being simultaneously effected alike, must produce an unvaried briskness, and quality of liquor not obtainable from any of the methods of drying at present known. The machine will dry about 40 maunds of green leaf per day, and it will be approximately 9 ft. long, 3 ft. 6 in. wide, by about 8 ft. high. The apparatus will take very little driving, which can either be effected by steam or hand power. It is very simple, easily erected and self-contained. It will be especially suitable for the final drying of Tea, as the chests can be placed under the delivery shoot to be filled and closed up whilst the Tea is hot and crisp.—*Indian Tea Gazette.*

THE TOBACCO TRADE OF INDIA.

The total value of exports of Tobacco from India has increased in the past five years about 58 per cent in value. The export figures are—

1880-81	...	...	1,408,310
Difference more...			516,912

Last year's exports were, in quantity, as follows:—

			lb.
Unmanufactured leaf	...		13,167,325
Cigars	...		207,005
Other manufactured Tobacco			198,811
Total exports ...			13,673,141

The following are the percentages of the Cigar exports :—

To the Straits	...	50 per cent.
United Kingdom	...	25 ,,
Ceylon	...	13 ,,
Other places	...	12 ,,

In the abovenamed export total of unmanufactured Tobacco, the following is an approximate distribution :—

		lb.
Bengal, exports	...	7,866,363
Bombay	...	4,628,078
Other places	...	772,884
Total	...	13,267,325

The exports were to the followiug places :—

Unmanufactured Tobacco.

		lb.
United Kingdom	...	4,176,080
France	...	1,314,642
Italy	...	907,528
Egypt	...	924,134
Mauritius	...	692,938
Aden	...	4,233,401
Arabia	...	398,225
Straits	...	347,338
Other Countries	...	273,139
Total	...	13,267,325

The absence of the colonies from this list, may possibly strike some enterprising shippers of a really superior leaf and make.—*Indian Daily News.*

LIME.

In some parts of the low-lying districts of the country (England) there are spots which grow but little besides sorrel and semi-aquatic weeds. This occurs on peaty or what are more commouly termed fen soils. In this lies an instructive lesson for application in the case in question. If a portion of this peaty soil, which produces the plants indicated be put into a flower-pot and "digested," as some chemists say, with a little lime, and then a mixture of sorrel, kingcup, and grass seeds be sown, the two former, which can and do feed on a free acid, will not grow. This is because the lime neutralised the free acid by again being partially restored to a state of carbouate of lime. But while this chemical transformation has been fatal to the sorrel and kingcup, it has made the peaty soil into a condition for seeds of grasses or cereals to germinate in and grow.

On the contrary, if a pot of the same soil be placed side by side with the one treated as above described, and the soil be left in its natural state, and a mixture of the above seeds be sown in it, then the sorrel and kingcup will germiuate and flourish, but the free acid will prove so noxious to the grass seeds that they will not germinate at all.

The lesson the result of the experiments teaches is clear. Where sorrel and kingcups grow in superabundance—that is, to an extent in which they injure the growth of the grass—it is clear that a dressing of lime or chalk is advisable. Two or three tons of lime per acre, if it be slacked and well broadcasted, will have a due effect for three or four years, while 6 or 8 tons of chalk would be required to have a similar effect, and this would scarcely begin before the second year after it had been applied.

A better plan of applying the lime, if it can be managed, is to raise a quaintity of soil on a headland, or by clearing out a ditch, or by paring down an unnecessarily wide hedgerow in the autumn, and mixing the lime with it. Then, in the spring, or during the frosts of winter, this mixture may be applied at the rate of eight, ten, or twelve cartloads per acre, according to the quantity of the soil available for covering the acreage that needs to be dressed. To mix lime, and soil, and earth in this way has a twofold advantage when applied to pastures. The lime makes soluble or dissolves some of the mineral constituents of the soil with which it is mixed, which act in combination with the lime as food for the most nutritious grasses, while the lime is there at the same time with all its power to neutralise the free acid which fed the sorrel and kingscup, and allowed them to flourish.—*English Agricultural Gazette.*

HINTS ON OSTRICH FARMING IN NATAL.

The information published from time to time in these columns shows that ostrich farming in Natal will probably before long become an important industry. The experience gained by ostrich breeders in the Cape Colony will be of great assistance in guiding intending "feather growers" in the adjoining Colony, and prevent many of the losses which the pioneers of the industry had to undergo. The *Natal Witness* publishes a sketch of the experiences of a successful ostrich breeder—Mr. Noyce, of Uitenhage—the principal features of which will be interesting to many Colonists, or intending Colonists, who are proposing to take up the pursuit of ostrich farming. Some eight or nine years ago, it is stated, Mr. Noyce started sheep-farming on the north-western verge of the Uitenhage province, where all his operations since have been carried on. For about three years he carried on his sheep-farming as successfully as he could expect, but there came a drought, and he lost the greater part of his flock. Persevering, however, he gave sheep-farming another trial, and again was very successful in it, until in 1877 another drought resulted in nearly the entire destruction of his flock. He then came to the conclusion to give up sheep in favour of ostrich farming. Previously to this he had bought a few ostriches, but lacking experience in their management, and having no sources of information in regard thereto, they did not prove a very profitable investment. All of them, with the exception of one pair, were ultimately exchanged for sheep. The one pair retained proved afterwards to be most valuable birds. Nearly, if not quite, ruined by his second failure with his sheep, Mr. Noyce fortunately managed to get some young ostriches on credit. The birds turned out well, and their owner was able by selling some of them, when they were older, to realise more than sufficient to pay for the whole lot of the birds he had purchased. On ten pairs of birds he has been able to make a profit of about £4,000 per annum during the past two years. He has not kept more than ten pairs of breeding birds, and he thinks this number is quite sufficient for one man to manage. Natal, he thinks, is well adapted for ostrich-farming. Very little special knowledge and experience is, he thinks, required for the pursuit—so that it may be readily taken up by settlers. During the short time he has been in Natal he has inspected several ostrich-farms, and on all of them the birds appeared to be doing remarkably well, proving that the Colony is suitable to the pursuit. The best birds for a young beginner to buy are, in his opinion, those of mature age—say from three to four years old. The birds should be placed in good safe paddocks, the fencing of which should be about 4 feet 6 inches high, and the space enclosed about an acre, but of course the area of the paddock should depend on the nature of the soil. Where lucerne is sown in the camp, half an acre for the paddock would be sufficient. Each bird should have three meals a day, and the greatest care should be taken to feed

them at regular intervals. The birds will also have to be supplied with back ground, or salt. When there is a scarcity of grass food, thistle, lucerne, cabbage, green barley, and garden produce must be provided. The birds must also have crushed bones of about an inch in length, and also wood ash in which they can roll themselves to prevent vermin. The sickness affecting ostriches is but little. They are chiefly troubled with stoppage and tape worms. The former may be prevented by a good supply of fresh green food, and an occasional feed on boiled barley with pieces of aloe leaf cut up in it. For the latter, doses of turpentine, mixed up with flour and given in a ball, or administered in milk, with an aloe pill given two hours after the first dose, are best. The food for young birds is somewhat similar to that for the old ones, only it should be cut up very short. The birds generally lay from ten to sixteen eggs, and the period of sitting is generally forty-two days. It is hardly necessary to say that the less they are disturbed during that period the better. The older they get the more reconciled they become, and sometimes they will continue breeding for a long period—perhaps for twenty years.—*Colonies and India.*

AMERICAN CULTURAL HINTS.

The name of Peter Henderson, the American nurseryman, will soon be as well known in this country as in his own. Mr. Henderson's farm raised last season nearly half a million cabbage and lettuce plants, which they sold at £1 a thousand.

"They sowed the seed in February (winter) on one of their greenhouse benches, so thick that they stood 20 plants to the square inch. These they began to prick out in hotbeds just as the first rough leaf appeared, placing 1,000 in a 3 ft. × 6 ft. sash. The handling of that quantity was a big job, but Mr. Henderson doubts if one plant in a thousand failed, owing, he thinks, to a plan used in preparing the bed on the greenhouse bench for the seeds—a plan that is well worthy of imitation in preparing a bed for seeds that have to be transplanted of any kind, whether outside or under glass. He used only 2 in. in depth of the soil for the seed bed, which was made up as follows:—The first layer, of about 1 in., was a good friable loam, run through a ½ in. sieve. This was patted down with a spade, and made perfectly level and moderately firm. On this was spread about ½ in. of sphagnum (moss from the swamps), which had been dried and run through a sieve nearly as fine as mosquito wire, so that it was of the condition of fine sawdust. On the top of the moss the ordinary soil was again strewn to a depth of ¾ in. This being levelled, the seed was sown very thickly, and then pressed into the soil with a smooth board. On this the fine moss was again sifted, thick enough to cover the seed only. The bed was then freely watered with a fine rose, and in a week every seed that had life in it was a plant. When the seed of most plants germinate, where they are quickly sown, the stem strikes down into the soil, the roots forming a tap-root with few fibres unless arrested by something. Here comes the value of the one-fourth of an inch of sifted moss placed three-quarters of an inch from the top. As soon as the rootlets touch the moss they ramify in all directions, so that when a bunch of seedlings is lifted up and pulled apart, there is a mass of rootlets, to which the moss more or less adheres, attached to each. To the practical gardener, the advantage of this is obvious; the tiny seeding has at once a mass of rootlets ready to work, which strike into the soil at once. The advantage of the moss covering of the seed is not so apparent in the matter of a free germinating seed, such as cabbage, as in many others, but in many families of plants it is of the greatest value. For example, Mr. Henderson, last November, took two lots of 10,000 seeds of Centaurea candidissima; both were sown on the same day, and exactly in the same manner, in boxes of soil 2 in. deep, but the one lot was covered with the sifted moss and the other with fine soil. From the moss-covered lot were got over 9,000 fine plants, while from that covered by soil there were only about 3,000. The same results were shown in a large lot of seeds of the now famous climbing plant Ampelopsis Voitchi, and in the finer varieties of clematis. The reason is plain; the thin layer of sifted moss never bakes or hardens, holding just the right degree of moisture, and has less tendency to generate damp or fungus than any other known substance."

We have thought it desirable to quote this fully because it contains such an admirable lesson for amateurs, who complain of their want of success in raising seeds and in transplanting. The preparation of the seed bed, the sowing and subsequent treatment are all items of the greatest moment. Where moss is not obtainable, rotted stable litter rendered dry enough to pass through a sieve in the manner described may be employed as a substitute; or where coconut fibre can be got, that would answer the purpose even better. Mr. Henderson's operations embrace the culture of nearly every known family of plants, and he says that in his long experience he has yet to see a fruit, flower, or vegetable crop that has not benefited, and nearly in the same degree, by a judicious application of bonedust. Our American friends are great in strawberry growing. The *Agriculturist* gives an account of several new varieties, but speaks most approvingly of "The Manchester" as being highly prolific, and, on account of its having been raised in a poor sandy soil, more desirable than seedlings raised under opposite conditions. Oliver Goldsmith and Seneca Queen also came out with good characters, but some others that are mentioned are "too soft for market fruit."—*Australasian.*

CULTIVATION OF THE PINE APPLE.

The cultivation of this valuable fruit, for which there is a gradually increasing demand in the markets of the United States and elsewhere, is a rapidly-progressing industry, and one which cannot fail to return considerable profit to the producers, if proper care be taken in the selection of suitable tracts of land, and a careful routine of culture be adopted. The soil adapted for this industry is one which is best described as a gravelly loam, neither too much clay nor too much gravel, the first of which would render the ground wet, the latter too dry: an intermediate one between the two is therefore desirable, and its value will be greatly enhanced if it contains plenty of decaying fibrous material. The pasture land at present in "ruinate" on the Liguanea Plains offers a most suitable soil, and one which is also to be highly recommended on account of its proximity to the largest seaport of the Island. Commencing the cultivation with a piece of ruinate, the first work is to cut all bush, &c., and, if possible, have it removed from the ground without burning, as by burning the grass and weeds which are on the surface of the land will be destroyed, and we shall see that this is required in our method of cultivation. Having laid off the land in straight lines by placing stakes four feet apart at the ends and drawing lines between them, we commence and hoe out all grass and weeds, drawing them in the centre between the two lines, thus forming a trench. After two rows are done around we commence with pick and shovel and loosen the ground to the depth of six inches in the centre space between

the rows of weeds, and throwing half the soil thus stirred on the top of each row of weeds, we proceed thus till the whole is covered, forming when finished ridges about 18 inches wide and 9 inches high with an interspace of 30 inches. After allowing a few days for the weeds and grass to decay in some measure, and the ridge to settle, the suckers may be planted. These should be selected after the bearing season is over, or indeed any time between October and January, if the weather is not too wet for planting. The lower dry leaves of the suckers should be removed to afford the small roots in their axils ready access to the soil, and then placed in the centre of the ridges to a sufficient depth to render them able to remain upright, to assist which they should be firmly rammed with a wooden rammer, leaving a small basin-like cavity at their base to hold sufficient water to solidify the soil and fix the plant firmly in its place. After the first or second watering no more is necessary unless a period of exceptional dry weather is experienced. The plantation must be kept free of all weeds, and the hoeings may be left in the trenches between the rows; different kinds of vegetable refuse may also be placed there, and will benefit the pines by its gradual decomposition, as well as by the moisture it affords. Pines are not, however, as a rule benefitted by large quantities of manure; a little may be applied at times, but gradually, as it is apt to induce them to rot at the base and thus spoil many a fine plant. The best and most profitable kinds are the Ripley, Black Antigua, Black Jamaica, Charlotte Rothschild and British Queen.

P. L. Simmonds, in "Tropical Agriculture," says that in 1873 the canned fruit shipped from the Bahamas was valued at over £14,000. Considering that their pines are, though much larger in size, considerably inferior to Jamaica Pines in flavour, it furnishes a fact worthy of emulation by Jamaica cultivators. The cultivation of this fruit in Jamaica is known to pay, and an instance is known to the writer in which the return, clear of expenses, for one acre has exceeded £80 per annum.

It is not intended by these specific instructions to convey the idea that the writer's method is the only one by which successful cultivation can be carried on, as no particular method of cultivation can, under all circumstances, be relied upon, and much must therefore depend upon the care and energy with which the industry is developed, and all failures, successes, and other experiences turned to account. Planting on the flat, without any ridge, may be found in many cases to have not a few points to recommend it, but the writer's method, as before described, is one which may be depended upon as supplying to the uninformed the main points which lead to success in the production of large and well-flavoured fruit.—JOHN HART, Superintendent of King's House Gardens, Jamaica.—*Journal of Applied Science.*

COFFEE AND TEA IN SOUTHERN INDIA.

A return has been submitted to the Madras Government showing the number of coffee and tea estates in the different growing tracts in this presidency, the number of existing plantations, the yield of coffee and tea, and the cost of cultivation. The progress which these industries have lately made and the large amount of capital invested in them have induced the Government, for the purposes of preparing the necessary statistics, to obtain these returns which however are not quite what are wanted. The column showing the number of plantations is misleading. Is it to be inferred that there are so many coffee estates in the different districts, or that the estates are divided into so many plantations? We find it stated that, in the Madura District, there are 2,779 coffee plantations containing a total acreage of 4,581, so that each plantation is not quite two acres in extent. It would have been better to give the number of estates and their extent. But to the returns. We find that coffee is now grown in eight of the twenty-one districts of the presidency. In Vizagapatam there are only six acres of land planted with coffee; in Madura 4,581 acres, of which 3,059 acres are filled with mature plants; in the Tinnevelly district 2,844 acres of land have been taken up for coffee, and 2,005 acres are fully planted out. The coffee industry in the district having turned out well of recent years, has induced many persons to open up estates chiefly in the Tenkasi and Nanguneri taluqs. In the Coimbatore district very little progress has been made in opening up estates, for, while about four thousand acres of land have been taken up for the purpose, about 316 acres contain mature plants. In the Nilgiri taluq 22,648 acres are fully planted out, 221 acres contain immature plants, and 21,255 acres taken up for planting have not yet been planted out. The approximate yield of the coffee estates is returned at 10,128,799 lb. at the average of 447 lb. per acre, the cost of cultivation being R100 to R130 per acre. It is to be feared that the next returns will show a large decrease under this head owing to the fact that many plots of land have, since the past ten months or more, been made over for gold mining purposes. In the Salem district the number of plantations is given at 323, the acreage planted with mature plants 3,932; with immature 1,662, and the acreage taken up but not planted 5,073; total land taken up for coffee 10,667 acres; approximate yield of coffee 983,000 lb. The cultivation of coffee on the Shevaroy Hills is being pushed on steadily by the owners of estates, but there is just now not that desire to launch out capital in the enterprise as was the case fifteen or twenty years ago. In many cases, the estates have brought their owner large returns and, as in all other matters, a great deal depends on personal supervision, and where this is properly exercised, success is secured. The present year has not been a very favorable one for coffee on the Shevaroys; the rains have been late, but notwithstanding some of the estates have given pretty fair returns. The Malabar district which includes the Wynaad, has a total of 31,061 acres under mature coffee, the land taken up for cultivation being returned at 62,128 acres, and the yield given at 6,114,826 lb. In Cochin about 7,795 acres have been taken up for coffee, of which only 1,436 have been planted; in Travancore, the extent of land planted with mature and immature plants is 16,775 acres against 37,067 taken up. For the entire presidency, the figures are as follows: mature plants 78,822 acres; immature plants 13,463 acres; not planted out 83,925 acres; total land taken up for coffee 176,210 acres; approximate yield of coffee 21,492,682 lb. The Travancore estates give an average of 175 lb. of coffee per acre of mature plants against 323 lb. in Cochin and 197 lb. in the Wynaad.

The returns of tea cultivation are very small, but the success that has so far attended the efforts of enterprising people, has induced many to take to it. Tea is grown in three districts of the presidency, namely in Madura, Malabar and the Nilgiris—in the two firstnamed districts there are only five plantations, but on the Nilgiris there are 79. The total acreage of land under tea is returned at 2,573 acres against 9,123 acres of land taken up; the acreage of land with immature plants is returned at 1,705. The approximate yield of tea of all the estates is returned at 649,460 lb., the cost of cultivation varying from R50 to R200 per acre.—*Madras Times.*

AGRI-HORTICULTURE SOCIETY OF INDIA.

Tubers of "Chuffa," Cyperus Esculentus.

The Secretary placed on the table some tubers of the above grass recently received in response to his application from the Director of the Botanic Garden, Adelaide, who thus writes respecting it in a recent report:—"*Chuffa* or *Earth Almond*. The American papers praise it, and say that for a few years after its introduction nothing was heard of it, except here and there as a curiosity; but within the past year or two the interest in the plant has revived, and the Southern papers are advocating its culture. It is said that an acre of *chuffas* will produce more pork than an acre or corn. The yield is said to be about 200 bushels to the acre. It is also still extensively grown in modern Egypt. The *chuffa* dies down during winter. It is planted in rows two and a half feet apart, and two tubers should be planted two feet apart, and two inches deep. It does not seem to do so well with us as in America."

It is also alluded to by Dr. Royle in his *Himalayan Botany* as follows:—"The aromatic principle being absent in the tubers of some species, while fecula is secreted in large proportion, they are employed as food, as those of *Cyperus esculentus*, a native of the South of Europe and of the North of Africa, and supposed to be the Malinothalis of Theophrastus. In addition to fecula these roots contain a fixed oil which enables them to be formed into palatable emulsions, which, with the addition of sugar, have been employed as a substitute for coffee and cocoa."

The Secretary added he had also applid to Dr. Schomburgh and received from him some seed of the "Egyptian Pearl Millet," which is apparently our "bajra" *(Panicum spicatum.)* A portion of the *chuffa* tubers had been sown in the Society's garden; the remainder (a very small quantity) is now available to members.

Japan Pea.

Read a letter from Captain J. F. Pogson, forwarding an extract from an American paper *(Mississippi Patron)* respecting a prolific pea raised in Japan, and suggesting that steps be taken towards obtaining a quantity of this variety for trial in India, which was agreed to.

The following is the extract alluded to:—

"Mr. T. E. Martin and Mr. R. T. Rutlege, both American progressive farmers, state that the 'Japan pea' is the most productive, as well as good food that they have ever grown for all kinds of stock; horses, cattle, sheep, and hogs, will eat the peas, stems, and leaves if harvested before fully matured and cured like other hay, with as much relish as they do corn. Then there is no pea for the table, it is soaked in water the night before cooking, that has a more exquisite flavour. They grow on a stout bushy stalk from two or three feet high, somewhat resembling the cotton plant. The main stalk, as well as the branches of the limbs, are literally loaded with small peapods, filled with little yellow peas, similar in colour, size, and flavour to the English garden pea."

As regards cultivation they state:—"But the way to get the greatest yield is to plant in hills two and a half feet each way, allowing but one stock to the hill to remain after the first working. That will give you 6,960 stalks to the acre, and on ordinary land cultivated the same as corn, will average at the lowest estimate a pint of shelled peas to the stalk, or a fraction over 108½ bushels per acre. I doubt not that with high cultivation and good soil it would be an easy matter to double that yield, besides there is no other crops that will yield more hay to the acre. In fact I know of no crop so remunerative as the Japan pea. It is a sure cropper, as clearly demonstrated by my experience with this season's crop. Neither wet nor dry weather materially interferes with the quantity or quality of the yield."

Bael Fruit.

Mr. R. A. Stendale submitted an extraordinary cluster of Bael Fruit, nine in number, with the following particulars:—

"Baboo Hem Chunder Mookerjee, of Jonai, a well-known Zemindar of these parts, has just brought me the accompanying very curious cluster of Bael Fruit which I send over to the Society as a rarity. The bunch consisted originally of ten Baels, but one got knocked off. On the same tree, but almost out of reach, is a similar bunch, but larger. Baels, as a rule, grow singly or occasionally in pairs. I have never seen a cluster like this before, it resembles a bunch of gigantic green grapes."

BANANA CULTIVATION IN JAMAICA.

In 1876, when the Irrigation Works came into operation, the writer thought that with irrigation the light and friable land lying south and east of Spanish Town, which had hitherto only been used for grazing pens, might be used for some more profitable cultivation, and, therefore, in the month of September of that year, he, as an experiment planted 10 acres with bananas. It was not without some misgiving that the experiment was made as the banana had not previously been grown on the plains of St. Catherine, but, after four years' experience, the writer has the satisfaction of bearing testimony to its complete success. Others have been induced to follow his example, so that there are at present upwards of 300 acres in bananas, the writer's 10 acres having been increased in that time to 100 acres. From a monetary point of view the results have been highly satisfactory, and, from his own personal experience, the writer is of opinion that in a fairly good soil, with the command of water for irrigation and under careful and intelligent management, the net return per acre may safely be estimated at £15 per annum; so that any industrious man, with sufficient capital to establish 10 acres in a proper manner, may be considered fairly started in life. Without irrigation, banana cultivation would be impossible on such an arid plain, and even with irrigation close supervision is necessary to ensure satisfactory results. With water at hand for irrigating, the capital required to establish any given acreage can be calculated almost exactly, and such being the case, this cultivation gives perhaps less cause for anxiety than that of any other crop. No return should be counted on for the first 12 months, and the yield will of course vary considerably according to the nature of the soil, which should be of a loamy open nature. The writer had one field of 10 acres which gave in the second year a return of £240 net, whilst another field of 18 acres only gave a return of £70 net. He considers, however, that this disparity is not only due to original difference of soil, but also to the fact that the larger field had been cultivated by the peasantry for twelve successive years. Much has been said about auxiliary crops, and, as the bananas have to be planted at least ten feet apart, it would at first sight appear advisable to utilize the intermediate spaces while the bananas are small, but any quickly maturing crop, such as Indian corn, cassava and pease speedily overtops or chokes the bananas, which are thereby retarded in their growth and often permanently injured, so that the auxiliary crops can never be really profitable.

The following general suggestions, based on experience, may be found useful:—It is of the first importance to select a suitable soil which should be friable and light, but not so sandy as to allow the too rapid escape of the water. It may be accepted

asa fact that any attempt to grow bananas on these plains on a stiff clay soil will prove a failure, and it should be borne in mind that unless the slope of the land be uniform, the cost of irrigating will be materially increased. Before incurring any expense, it will be prudent to obtain the advice of some competent person as to the best way of taking and applying the water, for the inexperienced in such matters would be likely to make some costly mistake. After the land has been cleared and stumped, the irrigation trenches should be laid out and dug before any planting is done, for the suckers should be irrigated immediately after being planted. The writer thinks it best to plant banana suckers at a distance of 10 feet apart in every direction, which gives about 435 plants to the acre. Some people however think a freer admission of light and air are necessary for the growth of large bunches, and, as the smaller ones are not marketable, they recommend that the suckers should be planted at a distance of 16½ feet, from north to south, and of 8½ feet, from east to west. When so planted, the cost of trenching and irrigating is less than when they are planted in squares of ten feet. Good healthy suckers should be selected to plant, and they should, from the time they are planted, be irrigated, regardless of whatever rain may fall, at regular intervals of not more than fourteen days. The nature of the soil has so much to do with the quantity of water required at one time for irrigating, that it would be impossible to lay down a hard-and-fast rule, but it may be accepted that at least 1 cubic yard per hour, per acre, which is equal to about 68 inches rainfall per annum, is necessary. The plants must be kept free of weeds and creepers, and this may necessitate eight cleanings per annum. They arrive at maturity in a period varying from twelve to eighteen months. After the first bearing, the smallest suckers which can be used for planting should be removed, and the one which has borne should be cut up and spread round the root, after which the plant should be carefully moulded up. In most cases this simple process, added to the manurial properties of the water, will be found sufficient, but in others it may be necessary to use other manures after the third year of cropping. The cost of planting and cultivating 1 acre of bananas was found by the writer to be as follows:—

Cleaning laud, if in wood or ruinate	£1	10.
Irrigation trenches, &c, ...	1	10
400 suckers at 6s.	1	4
Planting 400 suckers at 2s. ...	0	8
8 cleanings at 10s.	4	0
Irrigation Water	1	0
Contingencies	0	18
Total per acre	£10	10

The yield of marketable bunches of fruit will probably be about 25 per cent less than the number of suckers planted.

The cost of cutting and delivering the fruit in Kingston does not exceed 4d. per bunch.

The demand for bananas in the United States will probably increase, and it is at present so great that there is no likelihood of the market being overstocked.

Steamers run every week from Kingston to New York, so that banana growers in St. Catherine are perhaps more favourably situated than those in any other part of the Island.—Septimus Feurtado, Jamaica.—*Journal of Applied Science.*

TEA COMPANIES IN INDIA.

A return has recently been issued by the "Planters' Stores and Agency Company, Limited," of the results of the working of eleven tea companies having their offices in London, from which a considerable amount of information is available. A careful persual of this document shows conclusively why some companies are paying dividends and others are working at a loss. The table gives details for each company; we shall here deal with the averages of the eleven companies:—

		1879.	1880.
Gross price of tea per lb. including all receipts ...	*d.*	17·37	14·41
Cost of making per lb. including all charges ...	*d.*	16·03	14·18
Profit per lb. of tea ...	*d.*	1·34	0·23
Divideuds paid ...	%	4·77	3·07
Yield of tea per acre ...	lb.	—	349
Capital employed per acre	£	—	87
Capital per maund of ten maunds ...	£	—	21

To any one who has studied the financing of tea concerns, this table speaks in language not to be mistaken. Here we have an average cost per pound for making for the two years of 15·10*d.*, while the price realised averages only 15·89*d.*, leaving a profit of only ·79*d.* per lb. The cost of making in individual gardens runs from 12·25*d.* to 17·67*d.*; the prices realised were from 9·12*d.*, to 19·37*d.*, and the results per lb. from—4·12*d.* to+·25 to 5·12*d.* Now we can understand without much difficulty why two gardens making an equal quality and having an equal outturn of net profit, should pay different divideuds, as those depend on the amount of capital invested: but after allowing for local peculiarities in the way of expense, we are at a loss to understand why there should be such vast differences in the cost of manufacture. It is no doubt true that a large garden can be worked cheaper per lb. or per acre than a small one, many of the items being constant, but these gardens under notice are all pretty large concerns. We also know that a garden yielding 470 lb. of tea per acre, costs less relatively than one yielding only 192 lb. These latter figures depend, then, on management, and by management we do not use the term in its narrow meaning as referring to the garden management. We do not think the garden management is so often at fault, as there is an *esprit de corps* which impels managers to try their very best. By management, we use the term in the sense of control. If gardens were, first of all, carefully provided with good managers, the proper plan would be to give these gentlemen reasonable discretionary powers, and allow them to do their best, without being hampered by instructions from directors or managing agents, who may be good bnsiness men, but who, in many instances, have little practical experience of tea planting and manufacture.

The difference betweeu the selling prices of 1879 and 1880, *viz.*, 2·96*d.* per lb., is accounted for by the extremely low market ruling in the latter year. The minimum should be 18*d.* or say 12 annas, and in 1879 it nearly rose to that. On the other hand, a useful lesson is learned by looking into the difference between the cost of making in the two years, which amounted to 1·85*d.* On this head 8 annas or 12*d.* ought to suffice, and a little more economy exercised in the direction of office charges would reduce the price to that figure. The column containing dividends is slightly misleading; it does not contain dividends earned, but dividends paid, and as some are guaranteed the column does not give a true idea of the profits made. Perhaps the fairest mode of estimating this is to work out the profit made per acre. We hold that by proper management and control a fairly worked garden should give R100 profit per acre per annum. The Borelli, one on the list before us, made 470 lb. of tea, and made a profit of 5·125*d.* per lb. This at par is exactly £10 0 8¾ per acre, and, given an ordinary good market, we see no reason why this should not be the rule, rather than the exception.

Let us now look at the capital account of those eleven gardens. The figures are given in pounds sterling per acre, a very good method for purposes of comparison. These range from £27 (Jorehaut Co.) to £160 (Eastern Assam Co.), the average being £87. Now we have got reasons for the opinion that £50 is amply sufficient to bring a garden to paying point. How then have some gardens been made for £27, while others have cost £160 per acre? In the early days of the industry, there was no thought of economy; where a speculation was popularly supposed to yield 300 per cent, there was no incentive to saving. Money was recklessly thrown away on land and on establishment, while promoters made fabulous sums. The crisis of 1866 brought all this to an end. Some companies struggled through and are still existing, but being burdened with their original enormous cost, can never hope to pay reasonable dividends; while others succumbed, and new proprietors bought them for a tithe of their cost. Those gardens weighted with excess capital should have this written off. When dividends on the reduced capital could be made, shareholders could not lose by striking off half of their capital and accepting one share for two or three, as the dividends would remain the same absolutely. Another mode of overcoming the difficulty is to pay no dividends, but utilise all profits in extending. Say a garden has 300 acres and its capital is £30,000; let the annual profits be used in extension till the garden consists of 600 acres, when the capital value would be £50 per acre. By this mode the shareholders would lose nothing. Now they would get no annual dividends, but the value of their scrip would steadily rise year by year.

Another column contains the amount of capital invested for each maund of tea produced annually. This ranges from £6 (Assam Co.) to £50 (British India), and the average is £21. Allowing a garden to cost £50, and the outturn to be £400 per acre, this sum should never exceed £10 to bring this estimate within reasonable bounds, the outturn must be good, and the invested capital low, and this brings us to consider the last item in the list, *viz.*, the outturn per acre. In the list before us this item ranges from 192 lbs. (British India Co.), to 470 lb. (Borelli Co.), and averages 319 lb., a very fair average indeed. Keeping out four of the lowest companies, the average of the other seven is 406 lb., proving that our estimate of 400 lb., is not Utopian. We might insist on a much higher average, but are now only concerned with the figures before us. If one company can make 470 lb. per acre, there exists no good reason why others should not also do so. Any cause which operates against this must be either concerned with finances or bad management, or perhaps both. It is perfectly foolish of companies to go on making half of what they ought to do. If the management be at fault—change it; if the directors—change them; and if the cause be want of funds, why, sell the concern and get out of it what may be, rather than drag on a ruinous and bankrupt concern.—*Indian Agriculturist.*

PALMETTO ROYAL PALM OR SABAL UMBRACULIFERA IN JAMAICA.

(*Gardeners' Chronicle*, 4th, Feb. 1882.)

Running parallel to the southern coast of Jamaica, and tending in a north-western direction from Alligator Pond to Black River, are the Santa Cruz Mountains. These mountains are composed of the characteristic white, porous limestone of Jamaica, and rise to heights varying from 2,000 to 2,300 feet. At the foot, and occupying the undulating country between the mountains and the sea, varying in breadth from 6 to 9 miles, are stretches of savannah lands, known as the Pedro Plains or Piratee country.* The prevailing soil of the plains is composed of red marl, with here and there a deposit of gravel and alluvium. The district generally is hot and arid, the mean annual rainfall being about 50 inches, while the temperature is seldom under 80° Fahr. This is the home of Sabal umbraculifera.

The Palm is known locally as the "Big Thatch," or "Bull Thatch," and also as the "Palmetto Royal." A recent visit to these comparatively unfrequented Pedro Plains gave me an opportunity of seeing this magnificent Palm in its native country. On the authority of Purdie, Grisebach (*Flor. Brit. West Indian Islands*, 1864, p. 514) rightly notes this Palm as indigenous to Jamaica, and mentions "Black River savannah" as its habitat. Although sparingly distributed along the plains from Alligator Pond to the westward, even as far as Savanna-la-Mar, it is evident that its true home is confined within the limits of the Pedro Plains, and its abundance and magnificence there very clearly to my mind establish its indigenous character.

It would appear, however, that before Purdie's visit, the original source of this noble Palm was involved in some obscurity. For instance, in Dr. Seemann's *Popular History of Palms*, 1856, p. 337, published a few years before the *Flora of the British West Indian Islands*, we find the following remarks, quoted on the authority of Mr. John Smith, ex-Curator of the Royal Gardens at Kew:—"Although we have long known this species (Sabal umbraculifera) to be quite distinct from the well-known Corypha umbraculifera of the East Indies, yet we are still uncertain about its native country—it is generally supposed to be the West Indies, but we can furnish no evidence of that being actually the case. All the specimens cultivated in England are very old, and it is singular that new ones have never, so far as my personal knowledge goes, been imported."

The botanical characters of S. umbraculifera are well described by Grisebach, and it is only necessary here to add one or two supplementary remarks. The trunk is singularly smooth and straight, free from ring marks, and uniform throughout. It sometimes attains a height of 90 to 100 feet, with an average circumference of 5 to 6 feet. The outer portions of the stem have an iron-like firmness, which is in marked contrast to the somewhat soft and fibrous nature of the inner portions. On this account narrow planks are made from the narrow rind, and pots, beehives and various utensils are obtained from short portion of the stem hollowed out.

The large glaucescent and suborbicular leaves are about 5 or 6 feet across; they are multifid, from one-third to two-thirds of their length, and have loose fibres between the bifid lobes; the segments are very acutely pointed with the ends somewhat pendulous; the unarmed petiole is much longer than the leaves, and remarkably strong. The spadices appear among the leaves, and are about one-half as long; the branches are peneculate, with sessile blackish berries 1—6 inches in diameter. Plants appear to flower and produce fruit at all stages. One was noticed in fruit when quite stemless. This palm is essentially gregarious; it is found covering several thousand acres, literally forming extensive groves in the Pedro Plains. These are known locally as "thatch fields." They occupy chiefly dry elevated banks and strips of land between numerous lagoons and morasses—the haunts of turtles and alligators. Seen across one of these lagoons the effect produced by a view of this Palm forest is in-

* This is the only portion of the island where descendants of the aboriginal Caribs are said to exist in Jamaica. They are very few in number, and are gradually being merged in the surrounding negro population. The Pedro Cayes close by still contain interesting Carib remains.

describable. The tall, straight, cylindrical columns surmounted by their globular masses of fronds, often 25 or 30 feet across, are seen to rise out of a sea of green sedges and grasses, and as no other growths intervene the result—merely as a matter of scenery—is well worth a visit to the tropics to behold. Under such circumstances even the most scoptical would admit that Palms are rightly named "the kingly race of plants." Riding underneath nothing could surpass in grandeur and beauty the effect produced by innumerable tall stems canopied by immense fan-shaped leaves rustling and rattling against each other in the refreshing breeze.

In the adult stage Sabal umbraculifera has all the majestic mien and habit of the Talipot Palm, Corypha umbraculifera, of Ceylon and Southern India. Indeed, to one familiar with the latter there is a great apparent similaritp betwecu the habits of the two Palms. The sharply pointed and pendulous segments of the leaves of the Sabal combined with their characteristic glaucous tint are, however, in marked contrast to the bluntish and slightly bifid segments of the Talipot with its bright green leaves. Again, the free-flowering habit of the Sabal as compared with the solitary and final effort of the Talipot Palm, affords another important point of distinction : and the inevitable death of the latter after flowering would indicate that for avenues and ornamental Palm-groups the Sabal would be, by far, the better Palm to plant. It possesses also the merit of growing in comparatively poor soil, and in a climate very unfavourable for most tropical plants.

The fruit of the Sabal is like a miniature Date, and the sweet pulp with which it is euveloped attracts and supplies food for a large number of jabbering crows (Corvus jamaicensis), blue pigeons (Columba inornata), bald pates (C. leucocephala), and rat-bats. It is owing to these agencies, no doubt, that the Palm is so well distributed throughout the district. Of the economic uses of the Palm mention may be made of the leaves—the chief parts used—which form the only thatching material for both negro and Europeau houses. Mats, ropes, hats, and baskets are made from the younger portions of the petiole and leaves, while, as already mentioned, the hollowed trunks, cut into short lengths, make admirable beehives.

It seems strange that while the Cocoa-nut Palm grows freely everywhere along the coast of Jamaica, it is almost entirely absent from Alligator Pond to Black River, viz., the district occupied by the "Big Thatch." At first, this was taken as an accidental circumstance, but careful inquiry on the spot convinced me that although the soil and climate differ very slightly from those of other portions of the Island where the Cocoa nut thrives luxuriantly, all efforts to establish it in the Pedro district had signally failed. The plants appear to thrive for a few years, and to grow remarkably well, but before coming into bearing they suddenly die off from the top, leaving nothing but a bare stem.

After examining several trunks of the Sabal, and finding them completely riddled by the attacks of the larva of a beetle very closely allied to, if not identical with, the destructive Palm-beetle of the East Indies, I came to the conclusion that one, if not the chief, cause of the absence of the Cocoa-nut Palm in the district was the abundance of this beetle. Further information and inquiry in the neighbourhood has fully confirmed this view. The Sabal appears to exist and, indeed, to thrive luxuriantly in spite of the beetle; but the Cocoa-nut fails. The terminal bud of the latter offers an easily accessible and tempting *bonne bouche* to the larva, and it succumbs to its attacks; on the other hand the Sabal thrives and covers the country.—D. Morris, Jamaica, Jan. 12.

SUGAR-GROWING AT PORT MACKAY, QUEENSLAND.

The success that has attended sugar-growing at Port Mackay has probably been due as much to a fine climate as to a fertile soil. Opening out towards the east, protected by mountains from the intrusion of hot winds from the west, admitting freely into all recesses the entrance of refreshing sea breezes, with a rainfall as seasonable as it is abundant, and never visited by those hurricanes which are not unknown to the north and to the south, it certainly appears to be a district exceptionally favoured by nature for the growth of the sugar cane, no less than for the production, in great abundance, of a large variety of tropical fruits.

With a climate that produces the mango, the papaw, the cocoanut, the banana, and the pineapple as so many weeds, we are apt to associate a fervent heat and a steaming atmosphere throughout the year. And so it generally is : we cannot get the good things of this earth without sometimes paying a disagreeable price. But according to the records of a careful observer, extending over a period of eight years, confirmed by the experience of a great many visitors, there exists a much milder climate at Mackay than might have been expected from its latitude. Situated about 1,100 miles north of Sydney, in latitude 21·10 S., in the tropics, it is within the reach of causes that generally produce a more torrid climate than is really found to exist in this place. But the constant sea breezes which flow in from the south-east so temper the sun's power as to render the weather quite bearable to a resident from the distant south. It would be insufficient testimony to cite my own experience of only five weeks at midwinter, were it not that the weather then prevailing was said to be characteristic of the winter and spring months—warm and sunuy days, with unexpectedly cold mornings ; a cold land breeze until about 9 a.m., then a brisk and mild south-east wind for the remainder of the day, with scarcely any rain ; this favouring in a high degree the crushing of the sugar-cane, and increasing the density of the juice, which rarely falls below 10° Beaumé, and sometimes stands as high as 12 .

It seems a misnomer to say there is positively any winter in the latitude of Mackay; more properly it should be called the dry season, when the temperature is very enjoyable. In this latitude it never is cold during the day, and in the months of July and August it is inexpressibly beautiful—much like October weather in Sydney. There is, however, during this time something remarkable in the low temperature which prevails at night, and especially in the early morning, when on a few occasions even hoar-frost has been seen on the ground; but this occurs only on the low levels, and not on the slopes of the hills ; as, for instance, at Mr. Black's beautiful plantation, The Cedars.

The keenness of the air in some nights in July and the first part of August is one of the surprises which visitors meet on a first acquaintance with Mackay ; and to show that this does not exist merely in sensation, we have only to refer to the thermometer, which sometimes indicates a difference of from 20° to 28° between the temperature of day and night. Notwithstanding this fact, that might seem to militate against the climate, it appears that frosts, so great an obstacle to cane-growing in the south, are at Mackay so slight in their effects as to be practically disregarded.

It is generally admitted that during a part of the summer the heat is excessive; but then it is said to be tempered by a sea breeze, which rarely fails to blow, and though producing some languor is not positively unhealthy. Plantation work, such as ploughing, is performed during most of this hot season

with little inconvenience. But there is a time, mostly in December and January, when the rainy season has fairly set in, during which the wind occasionally veers to the north, and then the combination of increased warmth with humidity renders the weather very oppressive; it is fortunate, however, that this lasts but a brief period, the scarcely endurable atmosphere being soon relieved by the south-east breeze.

Mr. J. E. Davidson, one of the early settlers in the Mackay district and a gentleman of scientific attainments, has recorded the temperature and rainfall at his Alexandra plantation, 11 miles from the sea coast, near the banks of the Pioneer River, for a period extending from 1868 to 1879. The following are the results which he has obtained:—

	Rain in inches.	Number of rainy days.	Temperature. Mean maximum.	Mean minimum.
January ...	15·28	17	95·2	68 7
February ...	12·96	15	90·2	68·1
March ...	15·96	16	88·0	60·5
April ...	6 75	8	86 3	59 0
May ...	4·72	9	78·5	54 6
June ...	2·82	7	77·3	46·8
July ...	1·78	5	75·5	47·6
August ...	0 76	3	77·6	39·5
September ...	1·19	4	81·0	47·3
October ...	2·52	7	88·0	54·6
November ...	2·62	6	88·8	56·8
December ...	7.28	11	88·9	63·5
Mean ...	74·64	108	84·6	55·6

This gives the Mackay district a mean annual temperature of 70 8 degrees Fahrenheit.

The greatest rainfall occurred in 1870, when the rain gauge recorded 108 in.; and the least in 1872, when only 46·14 in. fell; but even this quantity, if it fell at the proper time, would probably be sufficient for the wants of the sugar crop in a climate so abundantly supplied with moisture from the eastward, and so guarded by mountains against dry winds from the west. I do not find that any hygrometrical observations have been made at Mackay; but there are many facts which go to prove that the air is never very dry. The year 1875 was also marked by an extremely heavy fall of rain, 105·42 in. being recorded, and in this year it was that the district was visited with so severe a sugar-cane disease that nearly all the crops were destroyed; but there is reason to think that the calamity was the result of excessive moisture.

The average annual rainfall in other sugar-producing districts of Queensland from 1871 8 was as follows:— Maryborough 50·13 in., falling on a mean of 91 days; Beenleigh, the centre of the southern sugar districts of Queensland, 55·66 in., in 85¾ days; Lower Herbert, 96.24 in., in 128 days which exceeds that of any other station in Queensland.

Great stress is laid, in successful sugar-growing, on having the crushing season comparatively dry. Mackay is peculiarly fortunate in this respect, having a less number of rainy days and less rain during this period than any other sugar district in Queensland — that is, from June to the middle of December.

The prevailing wind in the district is from the south-east, which here is the trade wind. It nearly always blows. It is also the wind that brings nearly all the rain, the fall being exceedingly heavy in January, February, and March, which constitute the rainy season. Towards the end of August the cold land breezes drop off and northerly winds occasionally blow, thunderstorms begin to make their appearance, and the weather passes gradually from the dry to the wet season, though the change is not very marked before the beginning of December.

In salubrity, the Mackay district is held to rank now with the best in Queensland; it was not so in the early days of settlement, when, in common with other fertile localities in the tropics, fever and ague were prevalent. The progress of cultivation has had a most salutary effect in this respect. Except among the Kanakas on their first arrival, whose illness is probably due to a sudden change of diet, sickness is very rare. Whatever the summer may be at Port Mackay, it would be difficult to conceive of a more delightful residence for invalids in winter.

The new ejector vacuum pan, an adaptation of an old invention to sugar-boiling by Messrs. Mackenzie and Maclaren, has been introduced with success in Mr. Donaldson's mill at Cassada, on Baker's Creek, near Walkerston, about 10 miles from the seaside. It is claimed that this apparatus is an improvement on the ordinary vacuum pan, inasmuch as it enables the boiling operation to be conducted with greatly diminished expenditure of steam-power; this seems to be now admitted, but other alleged advantages are as yet not clearly made out. So confident, however, are the patentees of the superiority of their form of this apparatus that, on certain conditions, they will undertake its erection in mills free of cost. A vacuum pan of this description has been manufactured by Mr. Robertson, of Mackay, for a firm in the Clarence River district.

Judging by the quality of the sugar produced at Cassada mill, one might conclude that the superiority of the ejector vacuum pan is demonstrated, if the graining of the sugar be any test in the matter, for of all the sugar I have hitherto examined, the granulation of this was the most perfect. It is turned out in two shades—yellowish-white, and rich yellow, both beautifully crystallised. Cassada estate comprises only 400 acres, of which area 300 acres have been brought under cultivation, and from this year's crushing Mr. Donaldson estimates that he will obtain 200 tons of unrefined sugar. It is remarkable that so excellent a sugar should be made with such rough appliances as are to be found in this mill, but I imagine this to be due in large measure to unusual care in boiling the sugar. The gum-tree forest forms a close surrounding to the cleared land, and a belt of beautiful palm and other trees adorn the margin of the creek, whence is obtained an excellent and inexhaustible supply of water for the mill. In former years the climate is spoken of as having been unhealthy, but the progress of cultivation here, as elsewhere in the district, seems to have had a salutary influence. It has been observed at this plantation that a diminished mortality among the kanakas has resulted from allowing them to inhabit huts of their own construction. These lie squat on the ground, are made principally of thick layers of straw, and have the entrance so low down, that admission is gained by creeping on hands and knees. The superiority of these rude tenements over those made of weatherboards consists in their greater warmth, but their wretched ventilation is an objection to their use.

Beyond this plantation, towards the mountain range, 20 miles from Mackay, lies the Barrie estate, the property of Jack and Son, comprising an area of 1,298 acres, acres of which about 300 acres are cultivated. The open pan system is in use, and there will be produced about 400 tons of sugar in the present season. As yet this is the most remote mill from the coast.

About seven miles from port is the Alexandra plantation, consisting of 2,505 acres of very fertile land on the south side of the Pioneer. The mill is

interesting as being that in which sugar was first regularly made in the district. This was through the enterprise of Mr. Davidson, a West India planter, in 1868, soon after Mr. Spiller's successful experiment at the Pioneer. A vacuum pan by Pontifex and Wood, of London, is in use, and the capacity of the mill is equal to 800 tons of unrefined sugar in a season. There is a rum distillery in connection with the works, the produce of which I mentioned in a former article. This property is now in the hands of an enterprising Melbourne firm, Messrs. Sloane and Co., and managed by Mr. Davidson, to whom we are indebted for a series of valuable metereological observations, which he has made at this place for several years, and by which I was much assisted while discussing the climate of the district. The crop of cane on this estate, as on contiguous properties, is exceedingly heavy and in healthy condition.

Pleystowe Estate is situated on the south bank of the Pioneer River, about 11 miles from town. Of the 5000 acres forming the property, 850 acres are either under cane, or ploughed in readiness for planting. It is owned by Messrs. Hewit and Co., who have recently introduced several valuable improvements, including a 7 feet 6 inches vacum pan by Messrs. Smith and Co., Glasgow, four boilers of 40 horse-power, and a splendid hydraulic apparatus by which an inexhaustible steam of pure water can be pumped from the adjoining river by steam power. The mill, constructed by Russell, of Sydney, is capible of turning out 800 tons of sugar in a season. Here is the distillery which produces the celebrated Anchor brand rum, which has taken prizes at several Exhibitions, and of which I have formerly spoken. The bottling department is very compact, the labelling being ornamental, while the corking and capsuling is done by machinery. The surroundings of the premises cannot fail to attract the visitor as being very beautiful, the residence overlooking the forest-fringed river over a verdant slope, on which the mango, the citron, the cocoanut, the tamarind, and other tropical fruit and ornamental trees luxuriate in splendour.

Foulden estate, owned by Mr. Amhurst, now in England, and managed by Mr. Walker, lies partly on the south, but chiefly on the north bank of the Pioneer, where there is a ford at low water. By the use of the charcoal process, the first sugar is here refined until it equals in appearance the best produce of the Sydney Sugar works, but it is said that it does not surpass in price that made at Te Kowai, without the use of charcoal. The syrup is forced by steam from the subsiders into seven large cylinders charged with animal charcoal, from which the dark-coloured liquid emerges a pale amber colour. The vessels are cleaned out and recharged once a week, the charcoal being purified by heating to redness in a closed oven. By this process it is maintained in a state fit to serve for many repeated operations, but in course of time its powers become diminished, so that fresh charcoal has to be used. This is made on the premises from bones, as is also superphospate of lime to be employed as manure. With an area of 800 acres, this estate has only 560 acres of land available for cultivation. The best sugar made is packed in linen bags, imported from England, the contents weighing about 70 lbs.; mat bags being used only for inferior sorts, but this substance admits the escape of a great deal of fine sugar during the rough handling the bags receive on board ship. There are four centrifugals, four boilers of 85 horse power, and there are 60 horses employed. It is anticipated that the mill will produce 800 tons of sugar during the present year. The molasses from the last sugar is passed through the animal charcoal cylinders in order to make golden syrup, and this is the only place in the district where the article is manufactured, the molasses at the other mills being either sold to a Melbourne firm, or stored up for feeding horses, and for serving out as rations to the kanakas. The manager's residence, close to the mill, cannot but win the admiration of every traveller by the exceedingly beautiful landscape garden that has been laid out in front.

I have before adverted to the fact of southern capital finding its way to Mackay for investment, and notably from Melbourne. Two companies, of whom I may again have occasion to speak, have commenced operations on a large scale, and next year we may learn something of their doings. Property is also changing hands. A few days ago, the beautiful Pioneer estate of Mr. Spiller, of which a brief account appeared in a former issue of the *Mail*, accompanied with illustrations, was sold to Mr. M'Kinnon, of Melbourne, for £95,000 cash and he entered into possession at once.

Since I wrote last the Government have notified that on the 19th of October there will be open for selection in the Mackay district the land which in May last they had withdrawn, and this will serve as the starting-point of a new impetus in the sugar industry.

At the present moment there is an agitation in Brisbane against the introduction of coolie labour from British India, where it is proposed to appoint an emigration agent. It is anticipated that great difficulty will be experienced in the future in obtaining an adequate supply of labour from the South Sea Islands, and the attention of the Government has been directed to India as a country from which that labour can be abundantly obtained to meet the increasing demand, and without which it is alleged the sugar industry cannot be profitably carried on.—*Sydney Mail.*

ARTIFICIAL INDIGO.

The ortho-nitrophenyl-propiolic acid, the colourless substance which on treatment with a reducing agent yields indigo blue, is already in the hands of the Manch ester calico printers, and is furnished by the Baden Aniline Company at the price of 6s. per pound for a paste containing 25 per cent of the dry acid. With regard to the nature of the competition between the artificial and the natural colouring matters, it is necessary to say a few words. In the first place, the present price at which the manufacturers are able to sell their propiolic acid is 50s. per kilog. But 100 parts of this can only yield, according to theory, 68·58 parts of indigo blue, so that the price of the artificial (being 73s. per kilog.) is more than twice that of the pure natural colour. Hence competition with the natural dyestuff is not to be thought of until the makers can reduce the price of dry propiolic acid to 20s. per kilog., and also obtain a theoretical yield from their acid. This may, or it may not, be some day accomplished, but at present it will not pay to produce indigo from nitrophenyl-propiolic acid. Nevertheless a large field lies open to the immediate future for turning Baeyer's discovery to practical account. The proper way of looking at this question at present is, to consider ortho-nitro-phenyl-propiolic acid and Indigo as two distinct products not comparable with each other, inasmuch as the one can be put to uses for which the other is unfitted, and there is surely scope enough for both. Looking at this question of the possible competition of artificial with the natural Indigo from another point of view, it must, on the other hand, be borne in mind that the present mode of manufacturing indigo from the plant is extremely rude and imperfect, and that, by an improved and more careful carrying out of the process, great saving in colouring matter may be effected, so that it may prove possible to produce a purer article at a lower price, and thus to counterbalance the production of the artificial

material. The potential importance, from a purely commercial point of view, of the manufacture may be judged of by reference to the following statistics, showing the annual value of the world's growth of indigo is no less than £4,000,000 sterling.

Estimated Yearly Average of the Production of Indigo in the World, taken from the total crop for a period of Ten Years.

	lb.	£
Bengal, Tirhoot, Benares, and N. W. India ...	8,000,000	2,000,000
Madras and Kurpah ...	2,200,000	400,000
Manilla, Java, Bombay, &c.	—	500,000
Central America ...	2,250,000	600,000
China and elsewhere, consumed in the country...	—	Say 500,000
Totals	—	4,000,000

How far the artificial will drive out the natural colouring matter from the market cannot, as has been said, be foreseen. To Englishmen it is a mortifying reflection that, while the raw materials from which all those coal tar colours are made are produced in our country, the finished and valuable colours are nearly all manufactured in Germany.—*Journal of Applied Science.*

Enterprise in Bee-Keeping.—We learn that Mr. Blow has just started for the East (Cyprus, Syria, &c.) to make a large importation of the bees of these countries. It has always been a reproach that the Americans were more energetic in advancing bee culture than ourselves, especially in the matter of the introduction of foreign and improved races of bees into their country. We shall hear from time to time of Mr. Blow's movements, and get some information, too, respecting bee culture in those countries—formerly flowing with milk and honey. —*Gardeners' Chronicle.*

To Soften Putty.—The following recipe is from the German:—Take soda or potash—the latter is preferable—dissolve it in water and mix the solution with fresh-burnt fresh-slacked lime. After the mihture has stood for a time pour off the clear fluid, and bottle for use. Putty moistened with this fluid quickly softens, and is easily removed. Muriatic acid (spirit of salts), or nitro-muriatic acid, put on with a pencil, also quickly softens putty. Alkalino salt is the best thing to remove spots of paint from glass.—*Pharmaceutical Journal.*

Tapioca Cultivation in India.—The Bitter Cassava or Tapioca plant (Manihot utilissima), which is a native of South America, is now largely grown in Travancore, where the soil seems so well suited to its cultivation as to warrant a still more extended growth. It is stated that, "as the price of Rice has risen of late years, Tapioca has become the more essential as an article of food. It will grow in any soil, and needs but little care, except to preserve it from the depredations of cattle. After the roots are dug the stem is cut into pieces about 4 inches long and planted some 3 feet apart, with a little ash or other manure. The root requires occasional weeding and earthing, and arrives at maturity in nine or ten months. Well boiled it is eaten with fish-curry. It is sometimes given to cattle. In a green state the root does not keep long, but it can be sliced and dried in the sun, or grated and made into farina. A field of this valuable and nutritious root is planted at but little cost; its yield is very large, and its cultivation highly profitable. The produce has been estimated in Ceylon at 10 tons of green roots per acre; this weighs one-fourth when dried, and if the dried roots gave half their weight of flour, it would amount to 2,800 lb. per acre. With some care and attention any amount of the granulated flour might be prepared for home use and export, but though this plant grows almost wild the people do not take the trouble to prepare it."—*Ibid.*

The Climate of New Zealand.—A New Zealand paper refers to some of the floral beauties of a private garden at Taranaki as a proof of the beautiful climate of that Province. There may be seen, it says, four camellia bushes which it would be difficult to beat for size. One is 9 feet 6 inches in height by 34 feet in circumference, another 12 feet by 40 feet, another 14 feet by 45 feet, and a fourth 18 feet high by 50 feet in circumference; besides over a dozen others from 6 feet to 10 feet in height, with circumferences in proportion. In August the owner gathered his first crop of grapes, and the second crop from the same tree would be ripe in a month. The first crop of citrons was at the same time ready for gathering, while, together with the large swollen green fruit could be seen the bloom of a second crop on the same tree. A lemon-tree, again, was discovered with bloom from which a crop of ripe fruit had just been picked.—*Colonies and India.*

Meteorology.—The following resolutions were adopted by the Conference for the Development of Agricultural and Forest Meteorology, held at Vienna in Sept. 1880. (*Q. Jour. Meteorol. Soc.*, VII., published in No. for April):—"Vegetation is materially dependent on the following metereological elements:—(*a*) temperature of the air and soil; (*b*) duration and intensity of the illuminatiou; (*c*) all the hydrometeors; consequently, the vapour tension and relative humidity, precipitation (rain. snow, &c.), as well as the other forms of condensation (fog, dew, and hoar-frost); (*d*) motion of the air. On the other hand the daily march of pressure and of ozone appears to be of less importance for vegetation. Conversely, the meteorological elements appear to exhibit the influence of vegetation in the following way. Vegetation on an augmented scale, such as pasturage, tilled land, forests and moorland, &c., give rise each in their own districts to special conditions of temperature and atmospheric humidity, and perhaps of rain also, and may therefore exert an influence on the climate of the surrounding country in respect of temperature and hydrometeors, and also of springs." "On the whole it appears important that on as many rationally managed estates as possible special observations should be carried on of all the elements recognized as important. These observations should be made in different soils, and with different types of culture, and should be compared with the crop return year by year, so as to investigate in detail the relation between vegetation and climatic factors. The general mean results published by the several central institutes do not furnish values in sufficient detail for the study of individual types of culture or of local conditions. [Then follow instructions in the method to be adopted for observing the various elements, with remarks on the trustworthiness of in truments, which will be given in connection with each element.] It is advisable to organise the system of radial stations, in order to ascertain the effect extensive masses of vegetation, especially forests, exert on the climate of the surrounding region, both in their immediate vicinity and at a distance. This system promises better results the more continental is the character of the region in which it is established. Observations immediately above the tree crown are of importance. Would it not be desirable, with a view to the special observations which must be undertaken (as, *e.g.*, phenological observations) to prepare a general form of instructions? The Conference thinks it desirable to prepare general instructions for phenological observations. The list of plants to be observed should not be too long. They [members of committee] should deal in the first place with cereals and forage plants; secondly, with the more important forest and fruit trees; and lastly, with other plants of importance to agriculture and to the phenomena of animal life."—*Gardeners' Chronicle.*

EUCALYPTUS CHARCOAL.—In reply to a query which appeared in your last issue as to the suitability of any species of Eucalyptus wood for yielding charcoal, I beg to state that in Baron von Mueller's *Forest Resources of Western Australia* (Reeve & Co., London, 1879), Eucalyptus marginata is said to afford one of the least inflammable woods for building structures, and one of the very best in West Australia for charcoal, not burning so readily into ashes as most kinds of Eucalyptus wood; and in a small volume by Elwood Cooper, entitled *Forest Culture and Eucalyptus Trees*, published in 1876 by Culery & Co., San Francisco, Eucalyptus obliqua is described as affording an inferior fuel, but produces the best charcoal for the forge. Eucalyptus amygdalina is also said to be a bad wood for domestic fuel, but is a first-rate smith's charcoal.—F. M. HILLIER, Museum, Royal Gardens, Kew.—*Pharmaccutical Jonrnal.*

A NEW CINCHONA BARK FROM COLOMBIA.—A good deal of attention has been drawn of late to a new kind of Cinchona bark from Colombia, known in commerce by the name of "Cuprea" bark. It is stated in the *Pharmaccutical Journal*, on the authority of a Continental report, "that the district, in the province of Santander, Colombia, in which the bark was originally found, is being worked by two companies, employing between them 1,700 men. As each man is estimated to be able to collect 20 lb. of bark daily, or equal to 8½ lb. of dry bark, this number of men would be able to collect in thirty days upwards of 400,000 lb. of dry bark; and, enormous as this quantity may appear, the consignments being sent in by the collectors appeared to indicate that it would be exceeded. The original 'Cuprea' bark yielded about 2 per cent of quinine sulphate, and if this harvest were of equal quality, it would represent more than 8,000 lb. of quiuine sulphate." It is further stated, in confirmation of the above facts, that some 8,000 serons of "Cuprea" bark were imported into London during the last week of September, and that the effect of these enormous consignments upon the price of quinine is already beingfelt.—*Ibid.*

WEEDS AND SEEDS.—Instances are daily occurring in which the value of grain and seeds of all kinds is almost entirely destroyed by the large admixture of the seeds of pernicious weeds, which are allowed to grow, and are harvested with the good seed. The market value of the wheat and other cereals received from India would be largely increased, if it were not found on arrival that they contain a large percentage of noxious seeds and other "dirt." Only the other day a quantity of Calcutta oats, received at Cape Town, and intended to be distributed for seed purposes in different parts of the Colony, was found to be so full of the seeds of pernicious Indian weeds as to be almost valueless. If such worse than worthless plants were to be planted on any large scale among other crops, it would be a matter of extreme difficulty to rid the country of the unwelcome visitors. Every country produces too large a quantity of indigenous weeds for farmers not to be alive to the danger of introducing new varieties unawares. In some countries severe laws are enacted to force owners of land to keep down the stock of weeds, and to prevent their neighbours' land from being overrun by them, or sown with seed by means of the wind, birds, or any other agency. Planters in tropical countries, where weeds, in common with every other vegetation, are of such luxuriant growth, ought to be keenly alive to this danger. But the export of noxious seeds, mixed with grain, is an even greater evil than the neglect to keep down the natural growth of weeds in their own habitat. It is difficult to see how the evil can be checked otherwise than by appealing to the better feelings of farmers, planters, exporters, and others; and by pointing out that it is to their own interest to keep their produce as "clean" as possible, and free from admixture of foreign seeds, or any other kind of "dirt."—*Colonies and India.*

SILK WASTE IN JAPAN.—The Japanese make a kind of silk wadding, called mawata, from the waste cocoons, which they use for the purpose of lining their clothing. They dip these otherwise useless cocoons into a ley of wood ashes, or ashes of rice straw, and then open those which require it to remove the chrysalis. The silk taken from each cocoon is then expanded by the simultaneous action of the thumb and first finger of each hand, and this thin layer put upon the ends of thick nails placed into an inclined board. When from twenty to sixty such films have been place upon the nail they are allowed to dry. Sometimes the silk will be found in such good condition, that it can with care be spun by hand, in which case it will furnish a coarse thread which is used for fabrics of a lower quality.—*Journal of Applied Science.*

THE ORANGE CROP in Kiushui, Japan, has been unusually large this year, From the two townlands of Arita and Unami, in that province, about twenty thousand boxes of fruit have been sent daily to the Osak and Kobe markets. The number of oranges in a box depends, of course, on the size of the fruits—that of the boxes being generally fixed—but we shall not be far out if we estimate it at one hundred and fifty, at which rate the consumption of the Kobe and Osaka fruit eaters would amount to some three millions of oranges per diem. But indeed eggs and oranges represent something more than mere edibles in Japan. They are messengers of courtesy, the very rank and file of that intrinsically worthless but morally inestimable army of gifts from which all the outposts of Japanese amity and conventionality are garrisoned.—*Indian Agriculturist.*

TIMBER IN BRAZIL.—Within an area of half a square mile, Agassiz counted 117 different kinds of wood, many of them admirably fitted by their hardness, tints and beautiful grain, for the finest cabinet work. The muirapyinima, tortoise-shell wood, undoubtedly the most precious wood in the world, is found in large quantity on the tributaries of the Upper Amazon, where the water can be most easily applied as motive power. The pao de sangre, the rosewood, the pao de ferrow (iron wood), or *Apuleio ferrea*, the various species of jacaranda, known to natural history students under the name of *Dalbergia nigra*, *Machærium violaceum*, and *Platypodium elegans*, the white and black maraquatiara, the macacauba, the pao santo or holy wood, (*Kailmeyera*), and saboarana—both of which are rivals of the most beautiful walnut—are wasted yearly on the Amazon in amounts ample enough to veneer all the palaces of Europe. Maurice Mauris, the explorer, believes that with the facilities which the Brazilian Government is ready to impart to enterprising industry, the export of these commodities would develop immeuse profits in the shortest time, while the capital invested need not be enormous. It is only necessary that these woods be introduced into the market to obtain a decided preference over those now most sought after in the two hemispheres. Still richer is the country in timber for the purpose of construction. The acapu (*Vouacapoua Americana*) is most plentifully found there, and often in the most imposing proportions. Mr. Mauris has seen dining tables six feet in width made wholly out of one piece. The wood, like all its kindred, macaranduba and itauba, or stone wood, furnishes ship timber as durable as teak. The longer these remain in water, the stronger and harder they become. The former will compare the more favourably with the teak, inasmuch as it is more compact. A pistol bullet which will pass through an inch board of teak wood will not penetrate half an inch into a board of acapu. The itauba tree, too, offers many advantages over teak; it branches off naturally into keels and ribs of any size, and is lighter and more resistant.—*Journal of Applied Science.*

TEA IN CEYLON: PROGRESS.

"The Rakwana Tea Factory" will, we hear, be opened by the end of this month, and the enterprizing proprietors will then be ready to cure and prepare tea leaf for the market on account of proprietors, or to buy the green leaf on delivery, or better still to buy the crop on the trees, picking and carrying the leaf from the garden leased with their own factory coolies. Already two contracts under this last-mentioned arrangement have been entered into. Mr. Shaw (who had long experience in India in tea, before he went to Sumatra and Trincomalee to grow tobacco) is now on Barra plantation, and has declared he could not wish for a better growth or appearance of tea leaf to operate on. With the machinery now being erected, Mr. Shaw will no doubt make a name for Rakwana tea, and it will be far better with reference to extra-insular markets and the prospect of good prices, if all the tea grown in the district is bulked.

The machinery on Windsor Forest and Strathellie estates is, we hear, giving the utmost satisfaction, and other proprietors in these favorite tea districts (Dolosbage, Yakdessa and Ambagamuwa) are likely to go in for rolling machines which can be attached to the water-wheels now used for driving their pulpers. Mr. James Blackett (who remembers cutting and rooting out about five acres of Llewellyn's finest Assam tea, to make room for coffee in days gone by) has now an appreciable area of tea on two of his Dolosbagie places, and the additional extent, certain to be planted this season, will be considerable. All through Ambagamuwa, Dikoya, Maskeliya, Dimbula and Kotmale, the tea plant seems to flourish wherever it is put into the ground, and with it there is no question of the return for a whole year's labour depending on a favourable blossoming season lasting only for six or eight weeks.

Mr. Cameron, the Assam planter now on Windsor Forest, has a very high opinion of Kandaloya (Yakdessa) tea; and he has been good enough to send us a series of typical samples of Dolosbage and Yakdessa teas in small packets as follows:—

Windsor Forest:—Broken Pekoe, Souchong. Pekoe Souchong, broken mixed.

Pen-y-lan:—Pekoe (2), broken Pekoe (2), broken mixed, broken mixed.

Seaforth:—Souchong, Pekoe, broken Pekoe.

Kelvin:—Pekoe, broken Pekoe, Pekoe Souchong, Souchong.

Gallamudena:—Pekoe Souchong, broken Pekoe, broken Pekoe.

These we shall be glad to shew to merchants, brokers and others interested: they will be useful for purposes of comparison. We can, from experience, speak in high terms of the quality of the tea manufactured on Windsor Forest, and we have no doubt that, under skilful and experienced direction, the produce turned out from the districts we have referred to will be found equal to a high average of Indian tea.

In this connection we may mention that the S. S. "Vega" carried to Calcutta this time Mr. Jackson, the well-known patentee of Tea-preparing Machinery, who was in charge of a new and very complete machine combining—as we understand—all the operations connected with the rolling, drying, sifting, and final curing of the leaf. Mr. Jackson intended to watch the operation of his new patent on a plantation for himself, and if it answers his expectations, it may be a case of putting the newly-gathered leaf in at one end and receiving the fully-prepared tea warm and fit for packing at the other! The total cost of this very complete and eleborate contrivance, or series of contrivances, is said to be £400; but, if it prove a success, every District Tea Factory at least may find it profitable to provide a set. Mr. Jackson, who is a hard-headed Aberdonian, and whose brother is the tea-planter who has been trying to grow tea to advantage in the Southern States of America (which experiment has proved a failure, as we now learn) is likely to spend a little time in Ceylon on his return voyage, when he will no doubt arrange to make his latest patent known to tea-planters through his local agents, Messrs. John Walker & Co.

MR. HUGHES, THE AGRICULTURAL CHEMIST, ON COFFEE MANURES.

The following letter received by a recent mail contains information of interest to planters:—

Analytical Laboratory, 79 Mark Lane,
London E.C., Jan. 20th, 1882.

Gentlemen,—Many thanks for the original number of the *Tropical Agriculturist*, the receipt of which I should have acknowledged long since. Please put my name as a subscriber and send all past numbers published up to date. I presume future issues of the work will contain information respecting sugarcane, especially after the recent visit of your senior to Queensland. An old friend of mine, who was one of the pioneers of the sugar industry near Port Mackay, writes me by a recent mail that they are actually importing sulphate of ammonia from England as a manure for cane, and that the prospects for next crop were excellent.

I see Mr. Tolipntt has written you yet another letter respecting the results obtained from the use of potash salts for coffee. This gentleman seems to have some strong personal animosity against myself, though why he should cherish such feelings I really cannot account, as I never to my knowledge did anything either for or against him. Mr. Tolpntt certainly conveys the idea, to the readers of his letters, that potash should be the dominant element in his special coffee manures, but he does not give any detailed analyses of his mixtures, and is scarcely willing to allow that I have made, what many would consider, a due allowance of 4 per cent of potash, equal to about 8 per cent sulphate of potash, to be present in a complete coffee manure.

Allow me to quote from page 118 of my report:—"I should consider 4 per cent of potash the utmost that a good coffee manure intended for Ceylon should contain. On most estates it is not potash that is required by the soil, but a cheap source of bulky nitrogenous manure (cattle dung, composts of pulp with cake) and a moderate supply of phosphate and sulphate of lime."

These views, formed after careful personal visits through the principal coffee districts of the island, have been confirmed by Mr. Lawes in his letter addressed to you some months since, and I am quite satisfied to leave the matter in the hands of practical planters, for time lights always on the side of truth. Let me repeat that, in my opinion, bones, cake, fish

manure and similar mixed nitrogenous and phosphatic materials, which must ever form the bulk of economical Ceylon coffee manures, can be purchased cheaper in the local market of Colombo, and that superphosphate and potash salts should be separately bought in the home markets and mixed on arrival with the former materials, and thus make a cheap manure. The superphosphate can be procured from any of the leading manure-manufacturers, while the potash salts, which come chiefly from Germany, can be purchased through chemical brokers. I hope this will be considered by resident proprietors as an indepeudent professional opinion. I may add that potash salts being readily soluble in water (as can be easily demonstrated by adding a small quantity to a tumbler of water) should be most carefully preserved from exposure to weather during transit upcountry. I am certainly not opposed to the moderate use of potash salts, but they should be applied with other materials as indicated. Some friends of mine are now sending out a consignment of 50 tons to be mixed on arrival with cake and bones.—Believe me, with best wishes for the New Year, yours truly, JOHN HUGHES.

COFFEE LEAF DISEASE: ANOTHER CURE.

Mr. Oliver W. Joues, Assistant Superintendent, Medical School, Dindigul, writes to us underdate the 21st February.—The planting community and others interested in the life-history of coffee leaf disease will doubtless be happy to learn that the treatmeut as advocated by me (not only to check and mitigate but to cause a complete eradication of the disease from Ceylon and South India) has, after varied months of trial, proved a complete success in the hands of the Jewish missionaries of this taluq. The Rev. Father Labordier, who has considerable experience in coffee planting, reports that remedial measures, as detailed by me in the columns of the *Ceylon Observer* of the 19th January 1881, were most carefully carried out in March last, on an acreage containing some 30,000 young and diseased plants. The season then being dry, the plants were not dusted with the powder, but the solution of the medicine was used with marked benefit. These plants, he adds, have since been kept quite free from the disease, and they were with the beginning of the N. E. monsoon transplanted to the main plautation, where the disease is of a grave form, and, although these plants have been for the past five or more months in close proximity to diseased trees, the majority have shewn no signs of an attack. This, I must confess, is very encouraging, particularly when it is remembered that the disease is capable of propagating itself by a process of contiguity. The efficacy of the drug consists not only in warding off the disease, but it seems also to impart a natural stimulus to growth, for the plants are looking exceedingly healthy and vigorous. This is easily explained, for the chalk (which forms the basis of the medicine) in decomposing liberates a large proportion of carbonic acid, which is one of the chief elements of food for vegetable life. Buoyed with the success that has been achieved in the past, the mission are now engaged in applying remedial measures to a very large area of diseased trees situated on the Mecnaloor and Scroo Mulai hills. And since it is an established fact that the true cause of coffee leaf disease in Brazil, and South America, is also due to the larva of a little moth, the views promulgated by me obtain greater force than they have done in the past. If I have strennously endeavoured, in the face of adverse criticism, to prove by experiment that Mr. D. Morris and others engaged in the inve-tigation of leaf disease in Ceylon were wrong in supposing that the disease was due to a fungus formation, it was not from a spirit of opposition, but from a sense of duty to science and the planting-world in general.

P.S.—I shall deem it a lasting favour, if others, who have given my treatment a trial, would kindly communicate either directly with me or through the medium of your valuable journal.—*Madras Times.*

REVIEW OF THE COFFEE TRADE BY MESSRS. W. SCHOFFER & Co. OF ROTTERDAM: PRESENT AND FUTURE.

(From *I. A. Rucker & Bencraft's Price Current.*)

London, Feb. 9th, 1882.

Coffee.—At this period of the year, several treatises are published, in which the position of coffee is exhaustively reviewed. These circulars are studied by many who are interested in the past, present and future of the berry, and it cannot be denied, but that they exercise a decided power in guiding public opinion.

Important as statistics are, it being most dangerous to ignore them, they are by no means a certain guide to the future.

Numerous other influences are at work in every market, outside and beyond that of the statistical position, which affect and regulate the action of the pulse, so to speak, of the market. No correct view can be formed of the future of any article, unless the condition of the pulse be rightly gauged, and prices will fall or rise in conformity with its motions, whether they be caused by sentiment or by sterling facts.

The treatise published by Messrs. W. Schöffer & Co., of Rotterdam, attracts great attention, not only on account of its intrinsic value, but also because it emanates from a house, whose opinion is always treated with the very greatest respect.

Few, if any, of our readers see this circular, and we propose today, for their benefit, to epitomize as briefly as possible some portions of it, which are peculiarly interesting. Messrs. W. Schöffer & Co. point out, at starting, that coffee is in a state of over-production, and that according to the statistics of coffee in the principal markets in Europe (including Genoa) and in the United States, there is a surplus stock somewhere, as compared with last year, of about 700,000 cwts (35,000 tons). This over-production consists almost entirely of low coffees, chiefly from Rio and Santos, a class of coffee, which, at present low rates, consumption will probably neglect. Notwithstanding the fact that enormous quantities of coffee have been on offer during the past year, and that the continually falling market must, one would have thought, at one time or other, have offered temptations to purchase, impossible to resist, the United States have managed to end the year 1881 with very moderate stocks. Europe unfortunately has not exhibited the same amount of foresight. Owing chiefly to the heavy speculation in coffee at Havre, European stocks show, as already stated, a heavy increase as compared with a year ago. Had we been as wise as American buyers, the Brazilians would probably have been obliged to keep and store an important portion of their enormous crops themselves. As it is, the bulk of the pressure, caused by over-production, is at present falling upon Europe.

A bad harvest in the Brazils would of course revolutionise the present position. Although this contingeucy may some day occur, at the moment there is not the slightest appearance of it. Again, though it is generally believed that at present prices planters will not extend their cultivated acreages, there is on the other hand every reason to believe that existing plantations will in no way be curtailed, but will be made to produce as much as possible. If we take it for granted then that cultivation will not be extended, the point we must examine is whether there be any probability of consumption over-

taking production. As regards this point Messrs. W. Schöffer & Co. give some interesting figures, which they consider establish the fact that the world's consumption has increased at the uniform rate of 10 per cent. in every five years. In 1872 they reckoned the total consumption at 450,000 tons, today at 550,000. They therefore anticipate that in 1887 consumption will have increased by 55,000 tons. This view is encouraging, but, we think, if anything, not sufficiently sanguine.

The total European consumption may be estimated at nearly 370,000 tons. Messrs. W. Schöffer & Co. prove incontestably by statistics that, in France and Germany, the two largest consuming countries, consumption is steadily increasing at a uniform rate of about 10 per cent. in each five years. With prices at their present low level, we believe we are justified in anticipating that this ratio of increase will be maintained, if not exceeded, over the whole of Europe.

In 1887, therefore, consumption in Europe alone should have increased by certainly not less than 35,000 tons.

But in the United States for the last twenty years the consumption of coffee has been increasing still more rapidly, thus :—

						Tons.
1860/1864	gave an average yearly con. of about					57,300
1865/1869	,,	,,	,,	,,	,, ...	85,600
1870/1874	,,	,,	,,	,,	,, ...	106,900
1875/1879	,,	,,	,,	,,	,, ...	166,000

In 1880 the consumption was 165,000 tons.

In 1881 we have not the figures before us, but unless our memory fail us, it was over 180,000 tons.

A casual glance at these figures will show that the completion of each five years since 1860 has witnessed an increase in consumption of some 50 per cent. on two occasions, and of 25 per cent. on the third.

If, during the next five years, the American consumption increases by only 25 per cent., this will mean an increase in 1887 of some 40,000 tons. But, if the past be equalled, and an increase be established of 50 per cent., the advance in 1887 should be no less than 80,000 tons.

According then to the more favourable calculation, the total increase in the combined European and American consumption in 1887 will be 116,000 tons, or if the less favourable anticipation be verified, the increase will be 76,000 tons—even in this case exceeding Messrs. W. Schöffer & Co.'s calculations by 21,000 tons.

The calculation, that the consumption is increasing steadily at about an uniform rate of 10 per cent. each five years, is based to a certain extent on the fact that in 1872 the total quantity delivered in Europe and the States was about 450,000 tons, in 1881 550,000. But we think this is misleading, because in 1872 markets began to rise, and a range of prices became established, which, lasting as they did for some years, could not fail but to prevent any extension of consumption, if not to actually curtail it. In 1877 the world's consumption was about 450,000, proving that during this period of five years no progress had been made as regards deliveries. The history of the last five years, however, tells a different tale. With a lower range of quotations we find that a fairly steady increase has taken place at about the rate of 25 per cent. for the five years, and, if this rate be maintained, in 1887 the consumption should total say 680,000 tons, instead of the 550,000 tons it does at the present time. The difference is therefore about 130,000 tons, an mount which tends to corroborate the figures given by us above—figures based on statistics which extend over twenty years.

As a matter of fact, if, during the next five years, the American demand remains stationary, and, if the European demand increases by the moderate percentage predicted, production remaining as at present, in 1887 demand and supply should that year virtually balance one another.

Thus it would seem that all increase in the American consumption—and we have already shewn above of what an important nature this increase should be—might at no distant date have to be satisfied at the expense of stocks.

Our friends may think that this argument is invalidated by the fact that it rests in great measure upon the supposition that production will remain stationary, a probability, which, in the face of the history of the last few years may be argued a remote one. But it must be remembered that, however large the increase of late may have been in production, it is doubtful in face of existing prices whether the acreage under cultivation will be extended at present.

Turning to a matter for a moment, which is of great interest to our own home trade, although of comparative insignificance to the world in general, it is to be regretted that in the United Kingdom coffee is making no progress. Indeed, if the consumption per head be the basis of calculation, coffee may be said to be losing ground rapidly. These facts are most annoying, more especially as it is well known that the article in England has not had *fair play*. The masses never taste genuine coffee, and the sickly mixtures that are forced upon them as such are quite sufficient to account for the unsatisfactory position.

Messrs. W. Schöffer & Co. point out that according to some estimates, the shipments from Rio to Europe for the rest of the season will be very light. That they will be light is a certainty, but on the other hand the supplies from Santos will be unusually heavy.

In our circular dated January, 1882, we remarked "at the present time the 1882-1883 crops in Rio and Santos promise to be again enormous, some saying that Santos alone will give 2,000,000 bags. It is estimated that the crops together will total not less than 6,000,000 bags or say 353,000 tons." Such figures must of course be accepted with the greatest caution, as it is still too early to assess these crops with certainty; still the broad fact remains that if their outline be true, the large surplus of low descriptions now current, even if decreased during the next six months or so, must be again augmented either in Europe or elsewhere, when these heavy growing crops come forward in quantity.

Messrs. W. Schöffer & Co. argue that the respective positions of fine and common qualities promise to become more and more divided. Fine coffees, at prices such as are now current, may be said to be within the reach of the multitude, and the consumption of such ought therefore to be very large. The stock of such coffees are small, the prices are low, and now that the estimate of the Ceylon crop has been dropped to 30,000 tons—an estimate which many of our friends believe will not be equalled by the result—there is again a further reason for watching these descriptions.

Messrs. W. Schöffer & Co. very markedly say that they believe the prices of such coffees must soon travel upwards.

Those who buy articles when they are low, and are not afraid to hold them, when they have bought them, ought to watch common coffees. In this manner large fortunes have been made, and, for absolute storing, we believe Rio coffees at 40s to be a better investment than plantation at 75s to 80s. According to past experience, in the one case a rise of nearly 200 per cent is not impossible, whilst, in the other, a rise of 80 per cent. is about as much as history allows us to calculate upon. In the former case you can hold for years, without the coffee deteriorating, whilst, in the latter case, a few weeks' frost or snow will damage the colour very considerably. In these days, when speculative stocks are held often tenaciously till their value becomes *nil* it would not be unnatural if the attention of the speculator was turned to an

article, which would not be likely to show him very severe losses, and might, in the course of time, show him enormous profits.

There can be no doubt but that, owing to the low prices current at the present moment, coffee is carefully watched by the speculator.

One has an article which is certainly in a state of over-production, but whose stocks have only increased after all during the last year by less than a month's consumption. One has prices which for many years have never been known lower for most descriptions, and one knows that the consumption has been for many years increasing steadily at no mean rate—a consumption which at present prices ought to be more stimulated. One knows that at present prices the upkeep of many estates are paid for with difficulty, and that further the profits in others are not sufficient to induce or justify investment, but rather abandonment. At the moment production is beating consumption, but all things change. We do not say that the time has yet come when investments in coffee should be made, but we do say that the fall in prices will probably check production, that we believe consumption to be largely on the increase, and that, in the face of these two facts, it is not surely unreasonable to argue that better times must be before us, if not in the immediate future, at all events, much sooner than many expect. We cordially agree with Messrs. W. Schöffer & Co. that, after such a prolonged and severe fall in prices, the reaction when it comes should be proportionately sharp.

We give the following table of European stocks during the past six months :—

	1881.	1880.	1879.	1878.	1877.	1876.	
Sept	128,450	108,700	95,290	92,490	88,600	85,350	tns.
Oct.	128,350	103,600	86,286	86,830	79,000	74,850	,,
Nov.	122,900	91,950	75,907	80,950	81,250	60.150	,,
Dec.	121,050	88,050	68,790	76,710	75,450	52,350	,,
	1882.	1881.	1880.	1879.	1878.	1877.	
Jan.	127,850	93,850	70,500	66,820	83.450	51,700	,,
Feb.	139,550	100,300	74,970	65,570	95,500	67,250	,,

During January markets fell considerably, and our figures show a heavy increase in European stocks, and also in the surplus stock. Really coloury Plantation coffees have all through the month been an exception, as they have sold with good competition, and are, in our opinion, many shillings dearer than they were.

HARVESTING CINCHONA BARK.

We are glad to be informed, by a gentleman just returned from Helbodde, that Mr. John de Caen, the enterprizing manager of that estate, has invented a machine for removing the bark off cinchona twigs and branches from the smallest size to branches about 1½ in. diameter, which, for cheapness and simplicity, bids fair to supersede all other means of accomplishing this object.

The machine consists of two *smooth* rollers worked with a small cog-wheel, and driving-wheel, in the pattern of a mangle, but, differing in this respect, that the rollers taper towards one end for the purpose of admitting twigs of various dimensions. These rollers are 3½ to 4 feet in length, and are fixed to two common wooden standards, about 4 ft. high, the feet of which are splayed and weighted.

With one man (to turn the wheel) and four women or boys, the machine turns out 600 lb. of wet bark per day, averaging 120 lb. per cooly. Whereas even by the means, commonly known as "the bottle trick," no more than 60 lb. has ever been got off per hand,

Mr. de Caen has secured his rights to this invention, and Messrs. J. Walker & Co. of Colombo and Kandy are the sole manufacturers. This firm will have one or more machines on view next week.

The local "Times" has the following description of the Badulla invention for the same purpose :—

A Cinchona Bark and Twig Quilling Machine.—Messrs. Walker and Greig of Badulla are the manufacturers of this machine, which is a patent and called the "McInnes-McKenzie" after the inventors, residents of this district. An account of this machine may be of interest to your readers who have not yet seen it It is composed of two wooden cylinders a little over two feet long, and about five inches in diameter, placed one above the other and kept in position by a frame and a couple of springs. The upper cylinder is driven by a crank handle. The cylinders are grooved in various sizes and the alternate grooves have an imbedded knife in them ; the machine is worked by the branches being passed through a groove with the knife in at first and then again through a smaller groove which takes about half the bark off, the remainder hanging loosely on and is taken off by a cooly with his hands. It takes about six coolies to work this machine, one turning the handle, one passing the bark through the machine, one cutting, one carrying, one lopping off knots, &c., and one stripping off those pieces of bark still slightly adhering to the branch after passing through the machine. In this way, and when the coolies are thoroughly up to their work, from 120 to 200 lbs. wet bark can be taken off in a day, whereas the six coolies by the old method of scraping, could not possibly bring in more than 60 lbs. and this too with pieces of wood amongst the bark. There is very little doubt that few estates that have engaged in the cultivation of cinchona will be without this machine when its merits are throughly known. Practically it means that we shall be able to realize a little profit from our cinchona fields, a couple of years earlier than we otherwise should, as under the old plan it did not pay to scrape the branches of Succirubra, but by reducing the cost of barking in this way we are enabled to place bark on the market, which, if, sold at one shilling a lb. will leave a handsome profit. I can only recommend those of your readers who have cinchonas large enough, to purchase one of these machines, as the cost will soon be covered, and the trees will then be free of its lower branches and be ready for scraping shortly afterwards.

Papaya fruit makes (unripe) a good curry superior to cucumber and most pumpkins.—*Cor.*

Apples.—Apples (says a correspondent of the *Graphic*) are of more value as food than is generally supposed. They are nearly as nourishing as bread, and far more so than potatoes. In 1801 there was a great scarcity of meat, so apples, instead of being made into cider, were sold to the poor, and some of the Cornish workmen asserted that they could sustain work on baked apples far better than on potatoes.

Umbrellas and Pimento.—The Umbrella trade, according to the *Scientific American*, threatens the existence of the Pimento (Pepper) plantations of Jamaica. It was shown by an official estimate made at Kingston, last autumn, that more than half a million umbrella-sticks were then awaiting export to England and the United States. These sticks were almost without exception Pimento, and it is not surprizing that owners and lessees of Pimento walks are becoming alarmed at the growth of trade which threatens to uproot in a few years all the young trees. The export returns for the last five years show an average of 2,000 bundles of sticks sent out from Jamaica annually, and the returns for the first three quarters of 1881 show an export of over 4,500 bundles, valued at 15,000 dollars. Each bundle contains from 500 to 800 sticks each of which represents a young, bearing Pimento tree.—*Nature.*

THE COFFEE TRADE OF BRAZIL.

We have now received Messrs. Kern, Hayn & Co.'s annual review, and from this interesting and important document we hope to quote largely tomorrow. Meantime, we may say that the tendency of the report is to shew that over-production and lowered prices (the latter falling from 16 to 25 per cent during the year) had told so hardly on the planters that they are now demanding Government aid, not only in such legitimate directions as reduction or abolition of export duties and reduction of railway freights, but by the establishment of a Rural Mortgage Bank which should advance money against security at low interest to the planters. The latter proposal is truly characteristic. It means that on "block" security, which may not only be reduced greatly in value, but become absolutely a burden on those holding it, the Bank should be compelled to lend its funds and at a low rate of nsance: that, in fact, money should be lent on the principles of high risk and low interest. That is not sound finance:—not fair to the owners of the money; but Messrs. Kern, Hayn & Co. express the hope that this concession as well as the others will be granted! They do not seem to see the force of their own statement, that in the case of estates far inland present prices of coffee will not pay cost of carriage to the sea-borde. Persons dealing with their own money would certainly hesitate to lend on such properties, and most decidedly would never lend on them at low interest. But, as the great landholders can influence the Government in Brazil, we should not be in the least surprized to see Government money (if European capitalists would lend it to the Government) used for the purpose indicated. Committed as the Imperial and Provincial Governments are to an immense number of railway schemes, for the construction or guaranteeing of which they calculate on the heavy export duties, it is impossible to see how these can be remitted or even reduced.

As regards railway fares, their reduction by private companies which have been guaranteed would, in many cases, simply mean that the Government, that is the general community, would have to make up what was reduced in favour of a particular interest. It is clear that, by the wild rush into coffee in the past four years, the planters of Brazil have brought a great crisis on themselves as well as on their competitors who did not work with slave labour. It is an obvious case of direct retribution on the greedy wrong-doers, but involving, alas! the suffering of the innocent as well as the guilty. Messrs. Kern, Hayn & Co. take, of course, the sensible view, that big crops will now be the rule for some years to come. Exports, however, will depend on improved prices, and for these the brokers look to the effect of present low prices in increasing consumption. But such increase cannot come all at once, or in proportion to the enormously increased production resulting from the practical concentration of the whole slave labour of Brazil on coffee-growing. To add to the troubles of the Brazil planters, Messrs. Kern, Hayn & Co. anticipate pressure from the abolitionists, while no satisfactory progress in the direction of immigration has been made. Messrs. Kern, Hayn & Co. adhere to their figures for exports from Rio, and they now give those of Santos for the past three years. We find our estimate of an export of 7 millions of cwt. of coffee from Brazil, and our belief in a specially large increase in the case of Santos, fully justified, thus:—

	1879.	1880.	1881.
Rio ...	206,327 tons	202,124 tons	258,313 tons
Santos ...	67,972 ,,	62,615 ,,	80,146 ,,
Total ...	274,299 ,,	264,739 ,,	338,459 ,,

The equivalents in cwt. of the enormous export of last year are:—

Rio	5,166,260 *cwt.*
Santos	1,602,920 ,,
Total	6,769,180 ,,

minor ports making up the round 7 millions. As Santos coffee is that which mainly competes with Ceylon plantation kinds, it is of interest to our planters to learn that *all* the increase in this kind went to Europe, the exports from Santos to the United States, indeed, having fallen from 12,113 tons in 1879 to 11,123 in 1881. But even Rio has far more affected the markets of Europe than it has those of the United States, for, while only 65,622 tons went from Rio to Europe in 1879, and 83,065 in 1880, no less than 109,268 went to lower prices in the markets of Europe in 1881. To the United States the shipments from Rio were actually less than in 1879, the figures being

1879...	131,900 tons.
1880...	105,993 ,,
1881...	130,682 ,,

Let us, however, be thankful that the United States are able to take half the great crop of Brazil, now, and that the certainty is that, amongst their people, consumption will rapidly increase. Increased consumption in Europe will depend on war being averted, and also on stringent action being taken to put a stop to the nefarious practice of mixing chicory and worse with coffee and selling ground dates and other rubbish as substitutes. Why the adulterators of tea should be punished, and those who not merely mix coffee but supersede it should be encouraged, is a great mystery.

Our readers may be interested in seeing the names of the Rio firms which shipped over 80,000 bags in 1881. They are thus given:—

Ed. Johnston & C.	383,362 Bags
Phipps Brothers & C.	306,361 ,,
J. Bradshaw & C.	299,717 ,,
Hard, Rand & C.	252,948 ,,
Wright & C.	230,344 ,,
Norton, Megaw & C.	224,552 ,,
F. Sanwen & C.	219,448 ,,
Mc. Kinnell & C.	212,931 ,,
Ed. Pecher & C.	193,395 ,,
Berla, Cotrim & C.	183,039 ,,
Trinks, Munch & C.	171,026 ,,
Kern, Hayn & C.	160,827 ,,
Arbuckle Brothers	136,261 ,,
Wm. Ford & C.	101,361 ,,
Wille, Schmilinsky & C.	92,345 ,,
C. Mc. Culloch, Beecher & C. ...	84,833 ,,

As 17 bags make up a ton, Messrs. Ed. Johnston & Co., it will be seen, shipped more than 22,500 tons, or 450,000 cwt., not far short of a Ceylon crop. But mere bigness is not in itself an admirable quality. Brazil has the advantage of vast areas of fertile soil. To take advantage of that circumstance was perfectly legitimate. But the soil has been tilled mainly by bondsmen, whose cry at being robbed of their freedom and of the just

wages of their labour will reach the ears of the Lord of Sabaoth and will be heard and answered.

We call the special attention of our merchants and planters to the review of a pamphlet by the great Dutch Coffee House of Schroffer & Co. in another column: it is specially encouraging.

COFFEE "MIXTURES."

The following draft memorial is in circulation:—

To the Lords Commissioners of H. M. Treasury.

London, 6th Feb. 1882.

The attention of your memorialists has been drawn to a minute of Treasury dated 20th January 1882, which directs H. M. Board of Customs to permit the importation, under a duty of 2d per lb., of coffee or chicory, roasted and ground, mixed, without reference to the proportion of the mixture; and the permission to extend to any other vegetable matter applciable to the use of chicory or coffee.

Your memorialists beg to submit to the consideration of your Lordships the following objections to the above order:—

1st.—That it is most unwise to give such sanction to practices which tend to deteriorate so valuable and wholesome a beverage, so well fitted to advance temperate habits among the people.

2nd.—That the legislator has been most desirous of protecting the food of the people from adulterations, and that the order just issued by the Treasury is in contradiction with the letter and the spirit of the Acts of Parliament 38 and 39 Victoria, chap. 63, clauses 6 and 8.

3rd.—That the substances, which it is proposed to admit in a mixed state with coffee, would of themselves find no favour, being of comparatively small value; and it is only because they assume the name of coffee, or are found in association with this name, that they become saleable.

4th.—That no good reason can be shown why coffee should not deserve as fair a treatment as other articles of Indian or Colonial produce, such as tea for instance where regulations prohibit the sale of the pure article, with any mixture whatsoever, and even with "exhausted tea."

5th.—That the chief reason why coffee has fallen into disfavor in this country is the systematic way in which it has been adulterated, and the consequent difficulty experienced by the great mass of population in obtaining not merely a pure article, but a wholesome and palatable beverage suitable to their means. The poor classes purchasing coffee in small quantities will always ask for it ready ground.

6.—That coffee is grown in the British Possessions in India, Ceylon, Jamaica, and other Colonies, at the cost of many millions of English capital, its cultivation and preparation giving employment to many thousands of British subjects: that Ceylon in 1877 exported 105,000,000 lb. of coffee and British India about 50,000,000 lb. that by far the larger of those crops used to find their way to this country, which consumes chiefly Ceylon and Indian coffee; that London is gradually losing a portion of its trade, as the crops are shipped now more and more to the continent direct, to the detriment of British shipping, and of English importers, dealers, brokers and others interested in this article.

7th.—That the consumption of coffee in this country, which, in 1847, with a duty nearly three times as heavy as the present one, was 37,472,153 lb. or about 2 lb. per head of population, has now declined in 1881 to 31,913,400 lb. or less than 1 lb. per head, notwithstanding the large increase of population, and they believe that the consumption, if it had not been checked by unfair legislation, would probably exceed now 60.000,000 lb.

For those reasons your memorialists deem the effect of this Treasury order to be of such injury to the consumption of coffee, and the well-being of the community, that they feel constrained to urge its withdrawal.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special letter.*)

BEET-SUGAR—VACCINATION OF LIVE-STOCK—POULTRY AND RABBIT REARING.

Paris, 28th January.

Farmers have taken stock of 1881, and appear on the whole not to be dissatisfied with the results. The price of wheat, which may be taken as the standard of profits, has been more advantageous, without affecting seriously the pockets of the consumers. The vintage has been better, despite phylloxera and frost; the wine industry of the country is not compromised: new vineyards are coming into existence, and, if proprietors cannot extirpate the phylloxera, they can at least protect themselves against its ravages. Live stock has left not a little to be desired; this is due to short supplies of food: the price for fat stock was high, but then a deficiency of fodder made it difficult to prepare cattle for the butcher.

To protect the beet sugar interest, so-called free-trade farmers demand that the duty of fs. 20 per cwt. be maintained on colonial sugars, and the home tax reduced to 2½ francs per ton of beet delivered at the factory. Agriculture has been endowed with a special minister since over ten months, but how long that business-like arrangement may be continued is uncertain.

In the north of France, sugar beet is viewed by agriculturists as a cornucopia. It possesses the advantage of feeding stock, cheaply under conditions where high farming is practised; the products from beet-sugar, molasses, alcohol, repay in a great measure the expenses of production, while the pulp, varying in price from fs. 10 to 15 per ton, following not so much quality, as locality, feeds working bullocks, then fats them off, in addition to supporting sheep and cows. The value of the manure must not be omitted. In the department of the Nord, 25 per cent of the arable soil is under beet, which realizes on an average fs. 20 per ton. About 2½ tons of pulp are viewed as equal to one ton of ordinary hay. At Roye, Messrs. Pluchet and Frisard cultivate 1,500 acres of sugar beet, less 25 in meadow; the rotation is triennial: beet, wheat or rye, oats and clover. They employ 160 bullocks, 30 horses, and a steam plough. The sugar beet worked up during the season is 150 tons per day.

This establishment was the first to employ the extraction of beet juice by the process of *diffusion*, now so general, and which has superseded the old method of pressing the pulp in sacks in hydraulic machines. The principle of diffusion reposes on osmose and exosmose, the same laws which regulate the flow of sap in plants. If on a glass of water a little wine be carefully poured, and the air kept perfectly still, the wine, being lighter, will float, but in time will be found to have gradually become mixed, layers-like, in the water. Or, if a bladder containing a solution of sugar be hermetically fastened and suspended, not a drop of the contents will escape. But if the bladder be placed in a vase of water, the solution will exude through the pores of the membrane, the water also passing inwards at the same time rapidly. The liquids exchange places. This is the process of diffusion. The beet is cut up into little slices, placed in an iron cylinder, and hot water added, as the change thus provoked is more rapid. The cellules of the beet act the role of the membrane of the bladder; they empty their sugar and salts into the water when the solution is duly drained off, and the pulp taken out and pressed to obtain all the liquid. Under the ancient press method from 4 to 6 per cent of useful substances were lost; by the diffusion process only about a half. In other words 6½ per cent of sugar is now obtained, against 5½ formerly, which on 15,000 tons of roots means 1,000 sacks more of sugar. The labour too is less. The pulp from the beet treated by the diffusion plan contains from 10 to 15 per cent more water, hence, less esteemed by farmers, but then it costs fs. 10 less per ton, and when

mixed with cut fodder, linseed or cotton seed cake, fattens animals well in four months. Chemists allege that no great advantage is gained by having a pulp rich in sugar, for when the pulp is placed in the trench for conservation, the sugar becomes rapidly changed into alcohol, and next into acetic acid. The scums from the defecation of the juice make excellent manure, being rich in nitrogen; as a top dressing for meadows it is invaluable, and ploughed in after a flax crop, is considered as an excellent preparation for stolen crops of turnips. On beet farms the ratio of stock kept is 10 sheep or pigs, or one head of black cattle, per $3\frac{3}{4}$ acres.

M. Pasteur has lost no time in practically applying his important discoveries connected with the vaccination of live stock as a preservative against *charbon* and other maladies. He prepares the vaccine and forwards it in bottles, sufficient for 50, 100, to 300 sheep: the doses for cows and horses are larger. There are first and second vaccines to be employed at an interval of a fortnight, and injected under the skin by a Pravaz syringe. In the case of sheep they are vaccinated inside the thigh, cows behind the shoulder, and horses on the neck, where the collar cannot rub. The syringe employed must be carefully washed after each day's use; the vaccine must be kept in a cool place in a cellar, and a bottle once opened must be used. After being operated upon, cattle exhibit no tremor; sheep do, and horses largely so; no treatment is required for the pustules. An extensive agriculturist asserts he preserves his stock from peripneumonia, by hanging in the sheds planks coated twice a week, not with coal, but Norwegian tar; giving common salt and garlic liberally with the food, purging with castor-oil, and employing lotions of camphored spirits.

M. Lemoine, an extensive poultry breeder, considers the droppings of fowls, if allowed to accumulate, as detrimental to the health of the birds and the profits they ought to yield. His poultry-yard consists of several well-sanded, low-wired over alleys, planted with fruit trees, terminating in a small paddock. The mortality of the fowls is 20 per cent loss, and the eggs one-fourth more numerous by the new installation. Farmers are urged to domesticate the *Cabiai* of South America as ranking next to the pig and sheep. It is commonly known as the water pig, and resembles the squirrel in point of cleanliness and food. In three years it becomes as large as an ordinary pig; it eats little and sleeps much. The head is large, the ears small, it has two terrible cutting teeth, but no tail. When carefully fed, the flesh loses its objectionable oily taste.

A M. Georges proposes, that since meteorology cannot predict the weather for months in advance, and since the telegraph can, for 48 hours, farmers ought to club among themselves during the active seasons, to receive weather telegrams from the Observatory.

Nothing to record relative to the phylloxera: the battle between the invader and the invaded goes bravely on. Much interest has of late been displayed to discover the winter eggs of the insect. In the meantime, several vineyards which had been destroyed by the ravages of thephylloxera, are being replanted by American stocks, so that in five or six years the vines will be flourishing like bay trees.

It has been said that a man could make his fortune by rabbit rearing. M. Bouvyer, of Chatellerault, near Tours, cultivates mushrooms in old quarries: manure and labor, fs. 1,100 per month; receipts, fs. 8,000; profits, fs. 7,900; he gathers about 150 lb. of mushrooms per day; the beds, composed of horse dung, after being sown with spawn from rabbits' excrements, send up the esculent in three months; it ripens on the third day of its being overground.

THE "HYBRIDITY OF CINCHONAS" CONTROVERSY.

We personally feel that there can be no further controversy as to the liability or even the tendency of cinchonas to hybridize. Apart from the judgment of strictly scientific men, like Dr. Trimen and Mr. Moens, confirmed by so-called *practical* planters (who, if educated and observant men, are eminently *scientific*), our own experience, as recently related, of the progeny of seed from calisayas grown within reach of succirubras, has been conclusive. We ought to say that we never doubted the ability of a scientific horticulturist, like the late Mr. McIvor, to produce hybrids by the methods usually practised to obtain new varieties of plants. What we were long sceptical about was hybridization by natural agencies, such as currents of wind or insects. We had two very strong apologies for our sceptical attitude of mind. In the first place, we pinned our faith to the *dicta* of such eminent botanists as Drs. Hooker and Thompson, who, in their *Flora Indica*, strongly insisted that hybridity in nature was exceedingly rare, and, artificially, often very difficult. In the second place, our personal observation of *C. officinalis* had convinced us of the almost illimitable faculty of "sporting" into the most diverse sizes, shapes and other characteristics of foliage, possessed by the plants. We may add that we attached much importance to a concession made by the greatest living quinologist, Mr. John Eliot Howard, that, although real hybridization of the cinchonas in their natural habitat was not probable (and to that position he adheres), yet the various species growing in close contiguity might affect each other to an extent short of hybridization. Mr. Broughton wrote to Mr. Howard that, as regarded the Crown barks, *C. officinalis*,—*Uritusinga*, *Loxa*, *Condaminea*, *Bonplandiana*, or by whatever other names the varieties might be distinguished, those varieties were numerous and extreme, from trees of robust habit, with large and glabrous foliage, down to the shrubby *C. angustifolia*, with its small, pointed, peach-like leaves. Mr. Broughton, however, found seedlings which he was compelled to recognize as hybrids, under trees of *C. succirubra* and *C. officinalis*, which had ripened and dropped seeds. The seedlings were neither *succirubra* nor *officinalis*, but manifest hybrids, although some inclined more to one parent and some to the other. Broughton's grand error was the assertion, which McIvor said discouraged him and for a time interrupted his experiments, that the hybrids possessed the bad qualities of both parents and the good properties of neither. What McIvor did and what nature seems also to have done, was to produce, amongst hybrids of no value, at least a couple (or perhaps only one, leaning in some specimens to one parent and in some to the other) superior in good properties to either parent. Those taking after the red bark parent have been distinguished as *pubescent*; those bearing the impress of the crown bark foliage, *robust*; and, as a name which both sides to the controversy can at once adopt, Dr. Trimen suggests *C. robusta* for what he believes, and his opinion has been confirmed by the authorities at Kew, is a hybrid, * but

* Dr. Trimen cautiously says it may turn out to be a distinct species; but his opinion, that it is a hybrid, is clear enough.

of so valuable a character that it deserves the special attention of cultivators. Col. Beddome was just as favourably impressed with the new cinchona, but under the influence of a foregone conclusion against the hybridization theory and deference to the opinion of Mr. Cross, the able Conservator of Forests (no mean botanist) rejected the idea and the name of hybrid, and accepted the assertion of the *ci-devant* bark collector that the tree was that known in South America as *Pátá de Galinazo*. Dr. Trimen has shewn that this is a mere bark-collector's name and that it includes six different kinds.

We have no prejudice in favour of the aristocracy of science as against the democracy. For a "gardener" like the late Mr. McIvor we entertained the highest respect. In his battle with the Doctors,—men of such mark as Drs. Anderson, Macpherson and Bidie—he may have been self-opinionated and somewhat emphatic. But experience has proved that as regarded planting cinchonas in the open, and barking instead of coppicing the trees, he was right and the learned Doctors wrong. Mr. Moens, after visiting the Nilgiri plantations, very greatly astonished Mr. Cornish of Madras, by insisting as Col. Beddome did and as most candid persons now do that the barking process was *not* murdering the trees. We should equally respect and support the gardener, Mr. Cross, if we saw any evidence in favour of not merely his egotistic self-assertion but his offensive impeachment of the veracity of his former master, Dr. Spruce, and the judgment of the leading scientists of our day. Even Col. Beddome, who accepted Mr. Cross's name for what he (Mr. C.) deemed a distinct species, complained, in his report, to the Indian Government of the contradictory opinions which Mr. Cross had given of this very plant. And then, although Col. Beddome is, as we have admitted, a botanist of no mean mark, if it becomes a question between him and such an authority as Dr. Trimen on a point of vegetable physiology, such as the effect of dimorphic flowers, with reference to resisting or offering facilities to the hybridization process, we suppose the almost unanimous judgment of the scientific world would confirm the opinion of the learned Director of the Royal Botanical Gardens of Peradeniya. Col. Beddome adduced the fact of the male organ being prominent in some blossoms, and the female equally prominent in others, as militating against the idea of natural hybridity. Dr. Trimen holds, rightly beyond doubt, that this very peculiarity in the flower organs favours the process. Mr. Moens shewed us, on the Java plantations, the butterfly and the bee, which he looked upon as the great agents of a process which experience had led him to dread so much as contaminating his best Ledgerianas by the pollen of *C. Josephiana, Schuhkraft, Javanica* &c., that he had advised and obtained authority for the extirpation of the inferior kinds; all but a few plants which, in positions securing them from doing harm, are to be retained for purposes of a series of experiments in hybridization. But to shew how men, especially Scotchmen, adhere to their opinions as tenaciously as a limpet sticks to a rock, we may mention that, when we announced to a leading local planter our conversion to the hybrid theory, he poured out a torrent of objurgatory eloquence enough to make the hair stand on end on the bark of *C. pubescens*. Belief in natural hybridity was an impeachment of the wisdom of providence! and as to our illustration of the care gardeners took of their cabbage seed plants, the *brassicas* were too innately pure to entertain, much less act out, an idea so abhorrent. Moens was a maunderer; a fig for Forbes Laurie; while Dr. Trimen was as much blasphemed as could possibly be the case where actual swearing was not resorted to! What the eloquent advocate of *puris naturalibus* in the cinchona species will say to the able letter which, after delay which we regret, we this day insert, and which is signed "New Products," but to which the name of the author might as well have been affixed, we can only wonder. The case of the practical planter seems to us as impregnable as that of the eminent scientist, and if our anti-hybrid friend is wise he will "keep a calm sough" on the subject henceforth and forever. He is more likely, however, in triumphant tones to quote Mr. Howard's commentary on a cinchona grown in Jamaica (see reports and analyses in today's issue), which Mr. D. Morris (a botanist and well acquainted with cinchonas) as well as his predecessors had always described as a hybrid. Mr. Howard recognized the great merits of the plant, but could see no signs of hybrid origin in the *bark*. Howard, however, had not seen the leaves and flowers; so this case will not largely help the sceptics. That Mr. Thompson, with no previous experience of cinchonas, should, on the other hand, have adopted a hybrid as true *calisaya*, while the real Simon Pures were ranked as *officinalis*, amounts to nothing in the controversy. Mr. Thompson, like the rest of us, had to learn by making occasional mistakes. But the marvellous thing is that true *calisayas* should in Jamaica, flourish specially on bare, windy slopes! That certainly is contrary to Indian and Ceylon experience. The bark of such calisayas was pronounced even at 5 or 6 years old to be worth 8s per lb.; while what Mr. Morris, following the brokers, called a hybrid gave an analysis equivalent to 14s per lb.! In Mr. Howard's opinion the special kinds under cultivation in Jamaica compare favourably with those in India, Ceylon and South America, but our readers will note that many of the trees were so old as 19 years, and that quality seems to have increased with age, instead of deteriorating after the tenth year as Mr. Broughton inferred. Most of the trees, it will also be noted, grew at 5,000 feet elevation and upwards.

Just in time to be added to these remarks, comes a letter from the veteran quinologist, Mr. John Eliot Howard, dealing with the still undecided question, as Mr. Howard deems it, of the place and name of the robust cinchona. The quotation "infallibility" is a good-humoured reference to a correspondence between Mr. Howard and the senior editor of this paper. The latter (in his days of ignorance) had the temerity to break a lance with Mr. Howard on the question of hybridity, going the length of stating that he no more believed that Mr. Howard was infallible than was the old gentleman (Pio Nono) he (the editor) had seen at Rome. Mr. Howard, whose religious stand-point is at the antipodes of ecclesiastical hier-

archies and human pretensions to authority, while he is a decided Christian and a liberal supporter of Christian work, was intensely amused at *his* being compared to the Pope. Though not a sadder, we are a wiser and we trust a more modest man than when we ventured, even in opposition to such an authority as Howard, to refer *all* variations of type in cinchonas (of the crown bark species) to their inveterate tendency to sport. In this case, however, it is Mr. Howard and not Ed. C. O. who doubts hybridity. The bent of his mind is, apparently, quite in the opposite direction to that in which Dr. Trimen leans. But, with the modesty of true science, each waits for "more light." The light from Badulla, which Mr. Howard asks for, will, we feel sure, be readily supplied. This is what Mr. Howard writes:—

"I want your help in reference to a letter from your correspondent 'B. G., Badulla, 30th November 1881.' Can you obtain from this gentleman specimens of the leaves, flowers, and fruit of his *C. coccinea* trees? I should be very much obliged for these and in return would tell him something as to their value.

"Pray do not let him say that Dr. Spruce and I have 'determined' anything about the Pàtà de Gallinazo. 'B. G.' has, perhaps, in his hands information that would help towards this point.

"If the Pàtà de Gallinazo grows in the red bark district, (which seems now certain), it *cannot* be a hybrid, since the *C. officinalis* does not grow anywhere NEAR that part of S. America.

"It may be and probably is 'an intermediate FORM between *C. Succirubra* and *C. officinalis*' unnamed as yet. Such, at all events, is the present state of my opinion, about this *very important* sort.

"You will see, in the account which I gave of this pubescent sort to the Brit. Pharm. Conference, I attached a query (?) to the supposed identification *by Spruce* of this sort with the *C. coccinea*, Pavon. See the Year Book 1881 p. 501.

"You can tell your readers, who are kind enough to interest themselves in my 'fallibility,' that the above (?) has become (??).

"When I am *quite* sure what the (*C. pubescens* Howard?) really is I hope to let you know."

RESULTS OF ANALYSES OF JAMAICA-GROWN BARKS BY JOHN ELIOT HOWARD, Esq., F. R. S.

(From the *Jamaica Gazette*, 27th Oct. 1881.)

Colonial Secretary's Office, 20th Oct 1881.

The Governor directs the publication, for general information, of the following letter from the Director of Public Gardens and Plantations forwarding a memorandum embodying information supplied by Mr. John Eliot Howard, F. R. S., in regard to certain specimens of leaves, flowers and fruit of cinchona plants, and samples of cinchona bark from the Government plantations.—By command, EDWARD NEWTON,
Colonial Secretary.

Botanical Dept., Gordon Town, Jamaica, Oct. 13th 1881.
No. 2030.

SIR,—I have the honor to report that with the view of accurately determining the botanical classification, as well as the value of the bark yielded by the different kinds of cinchona trees under cultivation in Jamaica, I made a complete collection containing eight sets of specimens of leaves, flowers, fruit, as well as one pound by weight of cinchona bark, from every distinct form or variety which had hitherto come under my notice.

2. This collection was forwarded in June last to John Eliot Howard, Esquire, F. R. S., Tottenham, near London, who is believed to be the highest authority on cinchona and cinchona barks in the world. I asked Mr. Howard to be so good as to compare the botanical characters of the specimens sent from Jamaica with those in his large collections from S. America, India and Ceylon; and as he had kindly offered to help me in every possible manner, I ventured to ask him to obtain for me a quantitative analysis, with the probable market value of the various samples of bark which accompanied them.

3. I have now the pleasure to forward, herewith, a summary of the information which Mr. Howard has been good enough to send me, and I doubt not that this authoritative and exhaustive report will prove of the greatest service to those interested in the cultivation of cinchona in this island.

4. It will be noted, in the first place, that, although the late Superintendent of the Botanic Gardens (Mr. Thompson) adopted a "hybrid" variety for the true yellow bark, *Cinchona Calisaya*, and had continued to treat and write of it in his reports as such, there were a number of true *Calisaya* trees already on the plantations, which were included among the Crown bark trees *C. Officinalis*.

5. After a careful inspection of the plantations on my arrival here, I came to the conclusion that these trees were not *C. officinalis*, and I took steps to keep the seeds separate, and to propagate them for supplying steep and windy slopes, for which they appear to be admirably adapted. In references under No. 2 in the accompanying report, it will be noticed that I asked Mr. Howard whether these trees were *Calisaya vera*, *var. Josephiana*? or certain forms of "C. officinalis"? His analysis and report shew that they are true *Calisaya*, and that the bark even at 5 to 6 years old is worth about eight shillings per pound. Mr. Howard, therefore, naturally expresses an opinion that the Calisaya trees "form a valuable portion of the Plantations."

6. With regard to Mr. Howard's remarks on the "hybrid" variety, No. 4, I may mention that although in single specimens of leaves, flowers, etc., it is almost impossible to decide its hybridity, yet on the Plantations where all gradations may be distinguished among these trees, from almost the pure *Succirubra* type to the pure *Officinalis* type, there can be no doubt of their origin. Again, when seed of this kind was sent to Kew, the seedlings and plants were pronounced of a decidedly "hybrid" character; and, lastly, although following Mr. Thompson's classification, I sent the bark at first to the London Market as "*Calisaya* (?)" the brokers in their report drew my attention to it, and remarked "it is not pure yellow bark, but supposed to be a hybrid with *Succirubra*."

7. It is, nevertheless, gratifying to find that this "hybrid" is of so valuable a character, and, as it is a free grower at low elevations steps are being taken to propagate it for general distribution. According to the analysis of the specimen bark sent to Mr. Howard, its market value would not fall far short of fourteen shillings per pound.

8. The other analyses and remarks do not call for special mention. It will be noticed, however, that, in nearly every case, the character of the bark and the special kinds under cultivation here compare favourably in Mr. Howard's opinion, not only with those from India and Ceylon but also with all the best forms from South America. This is generally confirmatory of the results of our late sales.

9. When I shall have obtained a careful analysis of a sample of cinchona bark grown in Manchester by Mr. Swaby, at an elevation of 2,400 feet, we shall have then an authoritative opinion as to the comparative value of most of the different kinds of

cinchona bark at all elevations at which the trees are likely to be cultivated in Jamaica.

10. It may be added that it is to Mr. Howard we are indebted for three very fine growing plants of *Cinchona Calisaya, var. Ledgeriana*, which were sent out from Kew last year; and I am glad to report that Mr. Howard has still further contributed to the success of our plantations by presenting us with several other valuable cinchona plants, which are expected from Kew by the next mail, under the care of Messrs. Harris and Elliott.—I have the honor to be, sir, your obedient servant,

D. Morris,
Director of Public Gardens and Plantations.

The Honorable The Colonial Secretary, Kingston.

References to Specimens of leaves, Fruit, Flowers, as well as Specimens of Cinchona Bark forwarded from the Government Plantations, Jamaica, to John Eliot Howard, F. R. S., Tottenham, near London :—

Cinchona Calisaya.

No. 1. Small trees, about 9 to 10 feet high, 5 to 6 years old, growing at Belle Vue Plantation, 5,400 feet, hitherto classed with *C. Officinalis*, but leaves narrower, slightly tinted underneath; scrobicules abundant; flower buds swollen at the apex; flowers whitish; capsules short ovoid.

Analysis of Trunk Bark.

* Quinine Sulp.	Quinine. Alk.	Cinchonidine.	Cinchonine.	Quinidine.
2.73	2.04	0.70	.55	.07

No. 2. Small trees, very similar to above, habit more robust, leaves broader. Are these trees (Nos. 1 & 2) *Calisaya vera, var. Josephiana*, or merely forms of *C. Officinalis*? Their compact hardy habit and their early maturation render them very suitable for our steeper slopes, and it is very desirable to learn their value as compared with *C. Officinalis*.

An analysis of the bark desired.

Analysis of Trunk Bark.

Quinine. Sulp.	Quinine. Alk.	Cinchonidine.	Cinchonine.	Quinidine
4.93	3.70	0.60	.35	.05

In addition to supplying the above analysis Mr. Howard reports as follows :—"No. 1 and No. 2 appear to me to be true to the *Calisaya* type, and form a valuable portion of the plantation. I should not think that they belong to either of the *Josephiana* or to the *Ledgeriana* form, but that the exact variety is, perhaps, not yet published. In the meantime, it might be well to call them *C. Calisaya* simply.

"There is no appearance of hybridity, nor any resemblance to the *Loxa* (*C. Officinalis*) barks."

Cinchona Officinalis.

No. 4. Specimens of the typical *Cinchona Officinalis* of the Jamaica plantations. Average price per pound of all quantities, viz:—root stem and branch bark obtained during the past year=6s 7d; highest price realized 10s 1d per pound for root bark: lowest 2s 3d per pound for twig bark. The tree from which the specimen of bark was taken was about 9 years old and growing at an elevation of 5,500 feet.

Analysis of Trunk Bark.

Quinine Sulphate.	Quinine Alkaloid.	Cinchonidine.	Cinchonine.	Quinidine.
6.95	5.18	0.22	0.01	0.15

Mr. Howard adds :—"This (No. 3) does not require many observations, as the price per pound agrees with the appearance of the bark, and with the analysis, in shewing that it is good *C. Officinalis* quality, perhaps of slightly varying forms."

Cinchona Hybrid.

No. 4. Specimens of what is supposed to be a hybrid form between *C. Succirubra* and *C. Officinalis*. Up to 1879 it was considered to be *C. Calisaya*. Average price per pound on all qualities, viz., root, stem and branch bark, obtained during the past year 6s. 1¾d.: highest price realized 7s. 9d. per pound for trunk bark; lowest 4s. 6d. per pound, also for trunk bark. The specimen of bark taken from trees 8—10 years old, growing at an elevation of 5,300 feet.

Analysis of Trunk Bark.

Quinine Sulphate.	Quinine Alkaloid.	Cinchonidine.	Cinchonine.	Quinidine.
8·00	6·00	0·73	0·10	0·03

Mr. Howard adds :—"What proof is there that this is a hybrid? What connection with the *Calisaya*? It is an excellent bark, resembles true *C. Officinalis var. uritusinga*." In another communication, Mr. Howard remarks :—"It is very evident that the so called 'hybrid,' No. 4, if only it is a free grower, must be about the most valuable of all the sorts. The price obtained in commerce does not seem proportional to its value, but possibly, as remarked before, it may be an exceptionally fine specimen. So far as I can judge by the botanical specimens it is a true form of *C. officinalis*.†

Cinchona Succirubra.

No 5.—Specimens of common type of *C. succirubra* of Jamaica plantations. Average price per pound on all qualities, viz. :—root, stem, and branch bark, obtained during the past year = 4s nearly: highest 5s 7d for root bark; lowest 1s 3d per pound for twig bark. Specimens of bark sent from trees 9 years old, growing at an elevation of 5,000 ft. Mr. Howard reports on this bark as follows :—"Very good and true *C. succirubra*, agreeing well with my specimens from South America. It is the *sub-pubescent* form."

Cinchona Officinalis—Whitfield Hall.

No. 6. Specimens of trunk bark only from *C. Officinalis* trees 13 years old, the remains of a nursery planted at Whitfield Hall in 1867, probably some of the first *C. Officinalis* trees established in the Island. The trees were 13 years old when barked; they had been totally uncared for, and surrounded by dense forest for the last nine years (see Report on Public Gardens and Plantations, 1879-80, p. 7). The analysis desired in order to test whether the bark had improved with age as compared with No. 3 (see above), or whether the want of cultivation and lower elevation had exerted any influence upon it.

Analysis of Trunk Bark.

Quinine. Sulphate.	Quinine. Alkaloid.	Cinchonidine.	Cinchonine.	Quinidine.
5.06	3.75	0.40	.12	.16

Mr. Howard adds :—"Very good *C. Officinalis*, not of the *uritusinga* form, but of another which is also represented in my specimens from Mr. McIvor (Southern India plantations) and abundantly in specimens of bark from S. America, even in old specimens of mine from the College of Physicians. This is the *Colorado de Loxa* of the Spanish commerce.

"The botanical specimens sent with barks No. 4 and No. 6 agree exactly with both of those sorts from Mr. McIvor in my collection.

"The evident improvement by age corresponds with a like improvement in specimens of the *uritusinga* form recently sent home by Mr. R. C. Cross from Ootacamund."

---

* The value of cinchona bark for quinine manufacturers' purposes may be estimated by taking the unit of percentage of sulphate of quinine at 1s 9d; hence, if a bark yielded 5 per cent sulphate of quinine its approximate market value would be about 8s 9d per pound. D. M.

† See remarks in Par. 6 of attached letters.—D. M.

Cinchona Succirubra—Cold Spring.

No. 7. Samples of bark only ; from one of the first trees of *C. Succirubra* planted at Cold Spring Coffee Plantation (near Newcastle) by Mr. Wilson in 1862-63. The tree was about 19 years old when barked and measured nearly fifty feet in high.

Analysis of bark desired in order to test whether cinchona bark grown at an elevation of 3,400 feet has improved or detericrated with age as compared with No. 5, or whether the lower elevation had exerted any influence upon it.

Analysis of Trunk Bark.

Quinine Sulphate.	Quinine Alkaloid.	Cinchonidine.	Cinchonine.	Quinidine.
2.40	1.80	1.30	3.20	trace.

Mr. Howard adds :—"This (No. 7) shews a kind of bark (*C. Succirubra*) superior to a good deal that is grown in India. It is evident that the more markedly *red* the substance of the bark is the worse the alkaloids become. This is much less red and the alkaloids much better than some I have just examined from Ootacamund (Southern India Plantations)."

Cinchona Nitida—Cold Spring.

No. 8 samples of bark only ; from *Cinchona Nitida* trees planted at Cold Spring in 1862-63. The trees were 19 years old when barked and growiug at an elevation of 3,400 feet. Analysis of bark desired in order to test the general character of the bark and whether worthy of cultivation.

Analysis of Trunk Bark.

Quinine Sulphate.	Quinine Alkaloid.	Cinchonidine.	Cinchonine.	Quinidine.
0.00 trace	0.00 trace	2.10	3.30	0.00

Mr. Howard adds :—"This (No. 8) is very characteristic 'Grey bark' and suitable for druggists' consumption. At the same time I could not recommend its cultivation, except on a limited scale."

COFFEE LEAF DISEASE EXPERIMENTS.

Mr. Schrottky writes to us :—"Illustrating the enormous extent to which the spores of *Hemileia* are disseminated and the rapidity with which areas are likely to become re-infected, if these spores are allowed to successfully germinate and establish themselves in the tissue of the leaf, is the fact that since the unavoidable discontinuance of the carbolic acid treatment at Gangapitiya, leaf disease has been gaining there, slowly but surely. Be it noted at a, for this estate, most unusual time of the year for a fir-t attack.

"Such experience demonstrates with greater force than volumes of argument what absolute necessity there is, for such an uninterrupted continuancy of the treatment as forms part of my programme for operations during next season.

"I have, at an early period of my work, compared the fungus to a weed, and the treatment I adopted last year, to a periodical weeding. The reappearance of weeds after weeding, if stopped for say a couple of months, would ordinarily be expected by a practical planter ; and so ought the re-appearance of leaf disease after discontinuance of the treatment.

"The former fact proves to the practical planting mind the necessity and merit of constant weeding. I am afraid it will take a little more time before the latter part is considered in the same light.

"It was suggested by some practical men that the almost absolute immunity from leaf disease during the time of treatment, *i. e.*, May to January (September and December having for the last six years been the month during which the estate was most severely attacked) might be greatly due to some exceptional climatic circumstances. I have laid before the Planter's Association positive evidence on this point, the correctness of which has not, and, to the best of my knowledge, cannot be questioned. But still men will obstinately hold to some such theory. I recognize of course that the responsibility of unreservedly agreeing with my conclusions would be very great, in the case of leading men, and they have need to be cautious. But still with a great many, it is, I am afraid, a case of 'convince a man against his will.'

"There are even some who will speak of the reappearance of leaf disease at Gangapitiya as greatly, if not entirely, qualifying the success claimed. And among these are by no means wanting men, whose opinion is considered valuable and carries weight. But these very men confess, when pressed, that they really had no time to read even a portion of the papers on the subject.

"I find there are very few in the island who have really taken the trouble to make themselves thoroughly conversant with what has been established by the results of my experiments.

"Of course it is rightly said, that volumes of foolscap may hide a failure, but are unnecessary to prove a success. But it should not be forgotten that we had to feel our way during last year ; that we had to carefully examine whether the failures were failures absolute, or but so many steps to success, and whether apparent success was not really a failure. This has necessitated a good deal of writing, which ought not to be necessary in the future, now that we know how best to deal with the fungus, and can lay down hard and fast rules."

TRAVANCORE PLANTERS' ASSOCIATION.

The Travancore planters held the annual meeting of their Association on the 8th February. The address of the Chairman (Mr. Bourdillon) was a thoroughly practical one with a number of suggestions well worthy the attention of his brother-planters. He advocates the establishment of experimental stations to test manures on private properties, careful notes being kept of the results byindividual planters, which notes could be compared and utilized after a time. What is said about the extreme range of the prices secured of recent years for coffee from one and the same plantation, and of the same crop, is very striking ; but, surely, the great difference of quality is to be attributed to the effects of leaf disease in preventing the trees maturing all their crop. No less worthy of note is the Chairman's anticipation that another rise to high prices may be looked for by coffee planters as the natural result of the present extremely adverse swing of the pendulum. The inclination is, of course, to swing to the other extreme when increased consumption and restricted production, induced by low prices, begin to tell. There is no doubt "a good time coming" for those who can hold on and work through the present dark days of depression.

Manures—Prices for Coffee—New Products.

Extract from the Chairman's address :—

Gentlemen,—I rise to open the meeting of 1882. As the report will shortly be read you will have an opportunity of hearing what has been done by the Association in the past year, and I will not therefore dwell upon the different subjects treated on. I should like, however, to say a few words on one or two of the more pre-eminent topics. Chief among these is the question of experimental stations. During the past year an attempt was made to start them, but owing to the defection of the chief owners of property in

South Travancore, it was found impossible to carry out the scheme, and the recent rapid fall of prices compels us in strict economy to abstain from any expenditure that will not be immediately remunerative. Now, gentlemen, there seems to be a great diversity of opinion on the subject, and a great many suggestions have been properly discussed. The original idea was to have one analysis made of the soil in the Northern districts, and that manures should be sent out for experiment with the hope of forcing a crop. But a little consideration will show you that, however suitable nitrogenous manures may be for wheat and other annuals, it is a most dangerous thing in our forcing climate to apply stimulating manures, even if they are afterwards to be supplemented with supporting manures. We know how coffee in Ceylon and nutmegs in the Spice Islands have been killed out by the indiscriminate use of so highly forcing a manure as guano, and we know from our own experience that, if coffee is in good heart in November, we are pretty sure to get a good crop from it next year. The inference is obvious, that what we require is to keep our trees from overbearing year by year rather than to force them. Now, gentlemen, though we cannot afford to go in for the experimental stations as originally intended, we can do a great deal among ourselves in experimenting with manures cheaply obtainable in the country. So eminent an authority as Mr. Ville tells us that analyses of soils are of little value, because, though the chemist can tell us exactly what the soil contains, he cannot place himself in the position of the plant and say what it can take up at once and what it cannot, and he recommends that experiments should be tried with different combinations of manures with the object of returning to the soil what has been or is being abstracted by crop. Hitherto it has been the custom to apply manures containing scarcely anything but nitrogen, which certainly have a great effect both on foliage and crop, but leave the trees in an exhausted condition afterwards. Now, if we could arrange among ourselves to carry out Mr. Ville's idea, I believe it would be more effectual and much less expensive than the idea suggested by Mr. Macdonald Cameron. It is not of much use, one or two persons experimenting, as their results would only answer for their particular soils and climates; what I should like is, for all of us, to try simultaneously some three or four combinations and keep very accurate notes of the results. I now pass on to another subject, that of leaf-disease, an attempt was made in August last to get up a discussion on it, but the time chosen was unfortunate, and in consequence of the short notice no recorded observations were announced to the meeting, since then Mr. Ward's pamphlet has appeared, and though we must all regret that he was not a practical planter, yet there is no doubt that the report is most valuable. There can be no longer any doubt that leaf disease will remain permanently with us ready to attack sickly plants as potato disease is an ever present scourge at home. It is a great thing to know something of the laws that regulate the growth of this mysterious fungus, and if we know that it will certainly begin to attack our coffee at a particular time and will spoil a percentage of the crop, we must accept the inevitable, and by removing early what would certainly be lost and supporting the trees to ripen what is left, make leaf-disease do as little harm as possible. But we require to know a great deal yet, how much crop leaf-disease will allow to ripen; what kinds of trees stand its effects best; what soils are the least favourable for its production, and what manures most effectual in checking its ravages; all these subjects and many others I commend to your careful consideration for the coming year. Any address would be incomplete without some reference to the present low prices ruling for coffee. Those of you who have an opportunity of seeing the different prices obtained for different sorts of coffee, not merely the average published in the daily papers cannot fail to be astonished at the extreme range of prices between the better and poorer sorts, and not only that, but in a glutted market the burthen of the song is always the same: "a fair demand for coloury, the paler sorts much depressed"; your coloury coffee, therefore, fetches firmer rates in a fluctuating market, as well as higher rates always. Now, gentlemen, there must be something radically wrong, if we send home coffee that fetches 112s and 62s, at the same time. If we can produce the better kind, why cannot we produce it and nothing else? We are all agreed that the same trees produce both, for in a bad crop, the sample is always much larger and finer than in a good one: it therefore appears certain that inattention to the coffee trees themselves produces this great variety of coffee and I quite believe it possible to get 70 per cent, or 80 per cent of the very best kinds, and fair crops, too, did we only know how. Here then is something for you to find out: if it is a question of soil or manure, or, if of curing, the remedy is equally in your hands. I feel confident that if you will give your minds to this subject, Travancore coffee will, in a few years, obtain the highest averages of any country in the world. But, gentlemen, there is a silver lining to every cloud, and though prices are so low at present we may hope that in a few years they will be very high. If you will look at the yearly average of prices extending over a long period, I think you will find that the lowest prices have always been followed in a very few years by very good prices, and the reason is sufficiently obvious, for low prices increase the demand while they check the supply, I may also, I think, congratulate you on the prospect of being able to grow the very best variety of cinchona with profit.

INDIAN AND CEYLON TEA IN MELBOURNE.

(From our Correspondent)

Great Sale of Indian Tea.

Melbourne, 15th Febuary 1882.

One of the best Indian tea sales yet held took place on the 9th February, when 4,639 half-chests of Darjeeling, Assam, Cachar Doons and Dehra Doon teas were sold at prices ranging from 11½d to 2s. 4d. per lb. in bond.

The attendance was very large; all eager buyers, the competition for some of the lots being very brisk. When the present state of our market is considered, this clearly shews that Indian teas are getting a strong hold on the public taste. Our present stocks in bond of all kinds of tea stand at 7,000,000 lb. weight as against at the same time last year 4,000,000 lb. weight or an excess of three million pounds for the present time. As a result, prices of China teas are unreasonably low, even taking into account their inferior quality this year, and yet in the face of this and the large quantity of tea offered, (the heaviest sale yet by 1,300 packages) Indian teas advanced fully 1d. per lb. on the rates obtained at the previous sale of 24th November, or, in other, words every sale of the five public sales held this season, has shown a slight advance on its predecessor.

The enclosed catalogue will give you full particulars, but which may be summarized as follows:—

Assam	sold at	11/½	to	2/4	per lb.	in box.
Darjeeling	,,	1/2	,,	2/3½	,,	,,
Cachar	,,	11/⅜	,,	1/9	,,	,,
Debra Doons	,,	1/2	,,	1/4½	,,	,,
Indian Teas	,,	1/¼	,,	1/8½	,,	,,

Darjeelings as usual in great request.

A donkey has assumed the lion's skin, but getting frightened, the bray soon found out the fraud. On the 2nd February a catalogue was issued by Messrs. Fraser & Co for a shipment of Japan teas under instructions from Messrs. Akita & Co., agents for the Japan Black Tea Company, connected with the Japanese Government and the Board of Agriculture, Japan. With such a long string, people naturally imagined that the vendors would sell and introduce their goods to the people of Victoria, but nothing of the sort occurred and after closely imitating the Calcutta tea syndicate's style, as you will see by the enclosed catalogue. When it came to the point, they would only sell 162 packages at 5d to 1s 5½d per lb. This is the joke of the month. The Japan teas are well made, but lack strength and flavour.

Our old friends, the Javanese, have also tried this market again, but only to sell 200 packages at 7¼d to 1s 1½d.

Altogether Melbourne teamen have had a lively time of it and since the 1st Jany. about 44,000 packages of all kinds of tea have been sold publicly by auction.

No Ceylon tea has been sold at auction lately, but the last mail steamer brings a small lot down, which no doubt will be offered in a few days.

A large parcel of coconut oil has reached this from Mauritius, but our market cannot take off the quantity and it will probably be shipped home.

Coffee shows signs of improvements but the market is still well stocked.

Coir yaru and fibre have small sale, but rope is almost a drug at the moment.

OPERATIONS OF THE CALCUTTA TEA SYNDICATE: INDIAN TEA IN AUSTRALIA, THE UNITED STATES AND CANADA, AND SOUTH AFRICA.

The Calcutta Tea Syndicate, aided by Messrs. James Henty & Co. in Australia and Mr. Sibthorp in the United States and Canada, are pushing Indian teas to the front, and the South African markets are to be tried. We give today, from the Calcutta *Daily News*, the letter in which Mr. Magor, as Honorary Secretary of the Syndicate, announces the wise decision that the Syndicate should continue its operations. It appears that only 700,000 lb. of Indian teas had been shipped to Australia between May 1881 and January 1882, while Messrs. Henty & Co., who have done so much to introduce Indian tea, state that already the demand is equal to 1 million or 1¼ million pounds in a year. This is certainly a good beginning, considering that the brokers and dealers in the China teas whereby they made their large profits, had it all their own way until October 1880, when "the tea of the future" was able to assert its superior merits, in the face of prejudice most bigotted and bitter. It is in spite of interested opposition and of China tea (*much* of which is such unwholesome rubbish that a special law has had to be passed), that Indian tea is making way in Australia. It has to thank its own merits and the brave efforts of Mr. J. O. Moody in Melbourne and Mr. Jas. Inglis in Sydney. Our readers will notice that teas in tins, though objected to at first, sold well in Melbourne, and tinn small neatly made up and decorated packages are desiderated in America. Besides what Messrs. Doane & Co. of Chicago say, there is an elaborate letter from Mr. Sibthorp, which, with suitable comments, we shall give in a future issue. Australia now consumes, in round numbers, 20 millions of pounds of tea, and the United States and Canada together about 100 millions. For South Africa we have not got the figures at hand. In the aggregate here are markets which approach even that of Great Britain in importance. To change the taste of a whole people, even though the taste is a perverted one in favor of burnt teas, as in America, or weak, "fusionless" stuff on the one hand and black "post and rail" tea on the other, as in Australia, is no easy task. But it is being attempted and will be successful, notwithstanding the misrepresentation instead of support which those engaged in the arduous work receive from the "organ of the teaplanters" (?) and others in India as well as the abuse of interested parties in Australia.

Planting in Natal.—We believe that coffee has so far been a failure in Natal, and that a Commission was recently appointed to take all the evidence that could be gathered on the spot, with a view to deciding whether the experiment was worth continuing. The failure of coffee seemed to be due to the presence of the borer, and the insufficiency of the rainfall. Most of the experimental plantations are within easy distance of the sea-coast as are the sugar-cane gardens. Tea is also pronounced a failure in Natal. Large sums of money have been sunk in trying to grow it, but the climate seems to be against it. The new Indian emigrant coolies are not favorably received by the European laborers on the spot, the wages for which are unduly lowered. Those interested in the emigration experiment are divided as to its success, one party holding that it has been completely successful, while the other believes it to be detrimental to the prospects of the colony.—*South of India Observer.* [The same controversy rages in Queensland and all over the Australian colonies. The question is a different one, but if cheap human labour cannot be obtained for sugar and other tropical culture, machinery must be multiplied and so in the end, dear white labour will be largely superseded. There is outdoor and field-work in the tropics which whites cannot perform and live.—Ed.]

Jorehaut Tea Company.—The managing director of the Jorehaut Tea Company (Limited) has issued a circular to the shareholders in which he says that the crop of 1881 has amounted to 1,029,600 lb. of tea being an increase of 36,560 lb. over that of 1880. It was estimated that the crop would amount to about 1,138,400 lb. should favourable weather be experienced and no blights occur to check the growth of flushes. The decrease in the quantity manufactured may be ascribed to unseasonable weather during a portion of the year, to the plants on some of the plantations having been checked in their productiveness by insect blights, and to the removal of the leaves from the plants at an earlier period than usual in order to produce finer teas. So far, the sales of the crop have amounted to 480,958 lb., at an average price of 1s. 6.961 per lb., which is about 4½d per lb. over the average price realized for a similar quantity of the crop of 1880. In consequence, however, of a fall in the market value of pekoes and the finer descriptions of Indian teas since November last, this average price will be reduced by the sale of the remainder of the crop at the rates now prevailing. Taking, however, a low valuation for the balance of the teas, it may be reasonably expected that the average price of the whole crop will yield a profit equival nt to a dividend of upwards of 12 per cent. The uncertainty as to the prices which will be realized for the large portion of the crop yet to be disposed of, and the small amount of reserve fund at present in hand, preclude the directors from recommending the payment of an interim dividend.—*Overland Mail.*

CALCUTTA TEA SYNDICATE.

(*Circular.*)

Calcutta, 26th January 1882.

DEAR SIRS,—With reference to my circular letter of the 10th ultimo, pointing out for your special consideration the extensive demand which has been established for Indian tea in Melbourne, by the operations of the Syndicate, I am desired by the Committee to state that in their opinion the time has hardly yet arrived when the Syndicate should withdraw from the field and give place to private enterprize.

The effect of the above letter has been to induce further parcels of tea to be entrusted to the Syndicate for shipment, but it is probable that the exports during the next three months will be insufficient to provide for the present demand, which our Melbourne Agents estimate at the rate of 1 to 1½ millions lb. per annum.

The shipments of the Syndicate to Melbourne during the season, which commenced in May last, up to the 31st ultimo, have been 375,452 lb., and the total shipments to Australia and New Zealand during the same period have been about 700,000 lb., from which it appears that more than half the total export is due to the operations of the Syndicate, and there is still a large deficiency of about 500,000 lb. required to meet the above estimated yearly demand in Melbourne alone.

The shipments of the Syndicate to America have been only 156,454 lb., and of this quantity only the first despatch of 29,552 lb. to Chicago has arrived at its destination. By a telegram dated the 12th instant, from Mr. Sibthorp, at New York, we learn that these teas were selling well at Chicago, and that more were required. It is therefore to be hoped that the introduction of our Indian teas into the United States will meet with the same measure of success that has attended our operations with Australia. Owing to ill-health Mr. Sibthorp has unfortunately been incapacitated from work for some weeks, and has therefore been unable to furnish the detailed report he has been asked for, upon his tour through the States and Canada, but it is hoped that this important communication will not be much longer delayed.

The attention of the Committee has been drawn to the advantage of opening up a further market at the Cape, and letters have been received from houses at Natal and Port Elizabeth, giving useful information regarding the tea trade in those places.

Under all these circumstances the Committee of the Syndicate are of the unanimous opinion that it would be premature to bring their work to a close at present, and they accordingly propose that the Syndicate shall continue to undertake the despatch of tea to the several markets named, in such manner as shippers may desire, and upon the same terms as have been in force during the season now closing.

I am further desired to hand you an extract from our Melbourne Agents' letter of the 5th ultimo, referring to the sale of the shipments per steamer "Mongolia" and "Khedive," in September last, together with particulars of these shipments, showing the Calcutta valuations at time of despatch and the prices realized.

Since the foregoing was written an interesting letter, dated 13th December, has been received from Messrs. J. W. Doane and Co., the Agents of the Syndicate at Chicago, a copy of which also accompanies this communication. The Committee, having due regard to the telegram referred to above, intend that their next despatch to America shall be sent to Chicago, and they trust that the opening up of that market may lead to an extensive demand for our Indian teas throughout the Western States of America.

I am, dear sirs, Yours, faithfully,

R. B. MAGOR, Honorary Secretary.

Extract from Messrs. James Henty & Co.'s letter, dated Melbourne, 5th December 1881 :—

"On the 24th ultimo we tried our entire stock of Indian teas by public auction, say :—

Chests.	½ Chests.	¼ Chests.	Boxes.	
...	515	...	...	Ex "Mongolia," Account Syndicate.
12	25	...	...	Ditto. do. J. H. & Co.
...	1,162	108	...	Ex "Khedive," Account Syndicate.
...	1,445	59	32	"Carlisle Castle," Account J. H. & Co.
12	3,147	167	32	

"The attendance was large, biddings brisk, and the whole quantity sold without any difficulty.

"Assams show, on the whole, a decided advance; Pekoes 1d. to 2d. higher than last sale, Pekoe Souchongs will average higher rates, whilst prices are well maintained for broken teas. Medium Pekoe Souchongs in tins show a decline—tins as a package being evidently over-supplied.

"Cachars realized fully up to the rate obtained at the previous sale, with broken teas and Pekoes showing rather better result.

"Darjeelings sold at an advance of ½d. to 1½d. on Pekoe Souchongs, but fine Pekoes are 2d. to 3d. lower.

"The Dooars teas being in tins suffered in the same way as Assam medium Pekoe Souchong in tins, and sold at cheap prices.

"Dehra Doons, though very pretty in appearance, did not realize so much as expected, expect for Broken Pekoe, which commanded full prices.

"As the next six weeks are generally given up to holiday-making, we do not anticipate selling any more Indian teas before the end of January or early in February.

"The high prices ruling on your side and our endeavours to force our market up correspondingly on this have resulted in curtailing the number of our buyers and throwing more business into the hands of the wholesale packers and blenders. We have fewer buyers at present high rates, but larger purchasers. What we should like to see, and it would be safer for us in the future, would be more general buyers and larger area for the sale and disposal of Indian teas.

"In the analysis of the Dehra Doon teas, you will notice they show a large percentage of mineral ash with a small percentage of soluble salts in proportion. This brings them below the chemist's standard for Indian teas.

"The 'Connaught Ranger' has arrived, and the samples are just coming in.

"One of our largest China tea-dealers is preparing to go fully into the Indian tea trade, and is inclined to purchase the whole of the 'Connaught Ranger's' shipment. We will try and do business with him after the mail has left. We hear that the buyer of most of the tea in tins at auction has just resold the whole of his purchases at a profit. We therefore advise you to send some more of these packages."

Copy of Messrs. J. W. Doane & Co.'s letter, dated

Chicago, December 13th, 1881 :—

Your favors of the 3rd and 10th Sept. are at hand, and contents have our careful attention. The shipment per S. S. "Compta" is just arriving here, and while we have little or no encouragement to offer yet, in the way of sales, we hope soon to able to do so. We shall not commence advertizing the goods until after the holidays; as business is always very quiet with us at this time, and, in addition to this, the advertisements of holiday goods, which fill our papers at present, attract all the attention.

As you are probably aware, but very little Souchong and Congou teas are used in the United States as

compared to other kinds, and we cannot hope to cultivate the consumer's taste for Indian teas to any marked extent, for some time to come; for, while we might readily succeed in turning our trade for China Congous on to Indian teas (as has been the case in England and Australia) you must remember that, in the countries named, the consumption of China Souchong and Congou teas was far in excess of all other kind; while in the U.S., out of a total consumption of, say, 72,000,000 lb. yearly, only 5 to 6 per cent. are Souchong and Congou teas, while 73 per cent are Green and Japan teas.*

We are fully alive to the actual merit of Indian teas over the other descriptions that are so popular here (Greens and Japans), but it will not be an easy matter to change the taste that has been educated on such teas to a tea so entirely different in every particular as those produced in your country.

Again, the larger portion of Souchong and Congou teas sold here are comparatively low-priced teas under 40c. running as low as 16c. per pound, and at this latter price a great many are placed. Indian teas do not run as low as this, and the trade will therefore be forced to buy China teas for their cheap grades, even if they use Indian teas for the higher grades. Handling so few Congous as compared to other kinds, our jobbers and retailers have come to regard them as rather an outside article; and consequently they charge excessive profits on same, so much so, that teas of this kind, going from the hands of the importer at 40 cents per lb. usually cost consumer $1-00.

We have written the foregoing not for the purpose of discouraging the introduction of Indian teas in this country, but simply to show you *a few* of the obstacles to be overcome before the teas can begin to be called "*popular*," as, in reading over your reports and circulars, we feel that your expectations in regard to the American trade can hardly be fulfilled, as promptly as you anticipate, to say the least. We do not know what the nature of your advices are from your other agents in the U. S., but, from our knowledge of the trade here, we think creating a demand for Indian teas will be a slow process, requiring a great deal of time and attention before the end sought for can be attained.

If the additional cost of so doing is not too great (say 3 cents per lb., or less) we think it would be well to pack a few cases in your next shipment, say half the invoice—4 tins of 20lb net each, in a case, and say 8 tins of 10lb. each in a case. We have had a few teas from Calcutta packed in this way, and they have proved quite attractive.

In regard to the value of your shipment per "Compta," on this market, we do not feel competent to say what these teas will bring, as we have never had an established market for this description of tea. We must therefore feel our way as to prices, until we find at what figure the trade will take them, hoping to be able to increase their value, as we can stimulate the demand. We have made one or two sales as follows:—

†5 Pkgs.	Break	No. 4	45 cents.
5 ,,	,,	,, 11	37 ,,
14 ,,	,,	,, 5	50 ,,

We do not offer this as any standard of value, and in fact we think No 4, for instance, is really worth more money; but the purchasers do a large distributing trade, and we sold the goods more to get them started than with an idea of obtaining what seems to us to be their real value. We are as yet unable to tell you what descriptions are going to suit our market best, but later on we hope to be able to report intelligently on this point.

* Balance probably Oolongs.

FUNGUS PESTS AND LIBERIAN COFFEE.

Whether the Liberian coffee is or is not really proof against the destructive fungus or "leaf-disease" which affects the ordinary varieties of coffee, not only in Ceylon but also in Fiji, Java, the Straits Settlements, Brazil, and other coffee-growing countries, is a disputed point. One planter at least in Fiji asserts that it is not, and planters in Ceylon are not fully agreed that the tree possesses the immunity from this disease, which was one of its principal claims to notice when it first attracted attention. It is evident, however, that the tree is subject to the attacks of another kind of fungoid growth, similar to that which is found in badly-cultivated cocoa and sugar plantations in the West Indies. The experimental plantations of Liberian coffee in the Botanical Gardens in Trinidad are, accordingto Mr. Prestoe, the Government Botanist, liable to this parasitic growth. Most of the trees are in perfect health, but about six years ago a large Tonga bean-tree, in the prime of life, suddenly died, owing to the attack of the fungoid growth at the roots; and since then several of the Liberian coffee trees have been seriously affected, two being killed outright. This pest is liable to work its ravages for a long time unnoticed, but sometimes makes known its existence by developing huge spore-bearing plates of great thickness and solidity. Fortunately the pest has not the fecundity of the *Hemileia vastatrix*, and it is easily detected in the seed-bearing state; but, if measures for its destruction are not promptly taken whenever found, it may easily increase and multiply, and, when once it has established itself in a locality, it is difficult to get rid of it. The Trinidadians are, however, alive to the necessity of allowing the enemy no quarter, for, although Mr. Prestoe has long wished to obtain a specimen containing fully matured seed to send to Kew for ideutification, he has been unable to do so, owing to the fact that the pulbic take good care to destroy the growth whenever it is found.—*Colonies and India.*

COTTON CULTIVATION OF THE MADRAS PRESIDENCY.

The Madras Board of Revenue, in their report to Government on the cultivation of, and trade in, cotton for Fasli 1,290, state that "in most of the important cotton-producing districts, the season was unfavorable for cotton cultivation. In Tinnevelly and Kistna, the rains were insufficient and untimely; in Kurnool, they were excessive in some taluks and scanty in others; and in Bellary, the season though favorable at the outset, proved adverse in the end owing to excessive rains. The crop in this district suffered also from blight. In all other districts, the season was favorable." The report also says that "the cultivation in the year under report is in excess of that in the preceding year by 141,329 acres. The increase is chiefly in the districts of Kurnool, Cuddapah, Madura and Bellary, and is due to expectations founded on the large profits obtained in Fasli 1289, and in some cases to a favorable season. The only districts in which there is a decrease in the cultivation are Trichinopoly, Tanjore and South Canara. The decrease in the last-mentioned district is trifling and that in the other two districts is due to a heavy storm which occurred in November." As to the species cultivated the report says:—"The cotton grown in this Presidency is generally raised from the ordinary country seed. A small area in Bellary was cultivated with Bourbon cotton, but without success. The soil is stated to be unsuited to the crop, and the season was unfavorable. In Coimbatore also the acclimatized Bourbon and American species were cultivated, but the collector does not state to what extent and with what effect." From the estimated outturn of cleaned

cotton in each district it seems that the total yield in Fasli 1290 was more than that in Fasli 1289, but, owing to the fall in prices, the value of the cotton produced was less. The average yield per acre for the whole Presidency was 41 lb. which is less than the average of the two preceding years by one lb. The exports of cotton by sea to places beyond the Presidency amounted to 365,887 cwts. valued at R92,19,371, against 509,889 cwts. worth R1,34,81,370, in Fasli 1289. The exports in every district have fallen off considerably as compared with the preceding year. The decrease is due to the failure of the crop in some districts owing to an unfavorable season, to a reduction of the price of cotton in the European markets, to diminished demand from foreign countries, which are stated to have drawn supplies to a great extent from Africa, and to the increased requirements of the local mills. The collector of Madras says that it is also due to Bellary cotton being sent to Bombay instead of to Madras for shipment. The export to Ceylon in Fasli 1290 was 41 lb., valued at R10, as against 1 cwt. in Fasli 1289, valued at R46. The report further states that "the imports of cotton by sea were trifling. There is no accurate information in regard to the exportation and importation of cotton by land from and to this Presidency." We make some further extracts from the report:—"The number of weavers as reported by collectors was 340,401 against 413,271 in Fasli 1289." "The three cotton mills referred to in last year's report continued to work throughout the fasli under review. The total quantity of cotton consumed by them amounted to 5,452,889 lb, or 338,334 lb. more than in last year. These mills turn out only twists of Count No. 20 and lower numbers. The collector reports that a Spinning Company is in process of formation at Bellary." "On the Saidapet Government Farm about 16 acres of land were cultivated with New Orleans cotton in 1879-80, and the crop was harvested in 1880-81. The yield per acre varied from 363 lb. down to 159 lb. of seed cotton, but this was in addition to a cereal crop produced on the same land in lines between the rows of cotton plants. Some modifications were introduced in the method of cropping land with cotton and a cereal crop, which are likely to lead to good results, chiefly by enabling the land under cotton to be kept more thoroughly tilled."

CABINET AND OTHER HARD WOODS.

We have received Messrs. F. Latinne & Fils' Circular, dated Paris, 1st Jany. 1882, which states that "the past year has been one of considerable falling-off in supplies throughout Europe. The principal English markets have been irregularly supplied with the necessary staple for consumers of cabinet and other hard woods, whilst the continental marts, when taken together, denote a palpable insufficiency, and only in walnut has there been a marked advance in supply." They also say that "importers are not, as yet, showing sufficient attention to the requirements of some of these centres of consumption in the disposal of their ventures." We quote the following regarding special kinds of woods:—

Satinwood.—Arrivals of good large and medium sized logs, good quality St. Domingo, have been extraordinarily scarce throughout the year, and, for the small imports of anything approaching this category, very high prices were commanded. The supply in Havre has been of generally inferior wood from St. Domingo and Porto Plata, and one lot from Ceylon. Figured and sound plain wood obtained remarkably good prices, while poor wood is difficult to realize. Elsewhere on the Continent direct shipments have been comparatively nil; a few logs arrived in Marseilles and Hamburg. The British markets have had several small lots sold at good prices. Some parcels of East India have been sold in London at high figures, but prices are at present lower; a lot has been sent to Marseilles. Of other descriptions no comment is necessary; little has been done on the Continent.

Ebony.—Several transactions have taken place during the year in Madagascar, at prices satisfactory to importers. On the Continent demand has not been so brisk for other sorts, although a comparatively fair trade has been done. A few parcels of Macassar have been negociated. Of the large imports from Calabar, a great portion has been sold, to arrive for Havre.

Lignum Vitæ.—During the greater portion of the year, good thin sap wood of certain dimensions was in great request at extreme prices. This fact induced importers to send forward supplies in large quantities, and their shipments, arriving almost simultaneously, have flooded almost every market. Superior wood of large sizes is in universal request at good rates.

Teakwood.—A fair business has been done for Belgium.

Tulipwood.—Little has been done during the year. Fine wood is in very good demand in France. Bullet Tree, Cocus Wood, Cocobola Wood, Beef Wood, Myall Wood, Letter Wood, Olive Wood, King Wood, Zebra Wood, Zericote Wood, Persimmon Wood, Cornelian Wood, Mexican Ebony or Hard Wood.

"THE TROPICAL AGRICULTURIST."

(Communicated.)

The numbers issued month by month increase in usefulness. In the January number we have our quotum *re* our chief productions as well as suggestions for the products which are yet to play a prominent part in Ceylon. A most interesting notice appears on Mr. Darwin *re* earth-worms and soil, and of still greater interest to a large proportion of planters are the reports of Colonel Beddome on cinchona planting in India and Ceylon. Far too much pains is spent in bewildering the planter with words of perplexity. All we want and all the world requires for keeping in check its various fevers is a febrifuge. There has been and will be a *still greater* diversity of opinion *re* what is Ledger and Pâtâ de Gallinazo and a whole host of others yet unnamed. In many cases the offspring of well-known trees are adapting themselves more and more to the soil and climatic conditions and departing in many respects from the parent plants, this coupled in some cases with hybridization, that to judge of a plant by its appearance as to the yield of alkaloid is nearly the same thing as judging the character of a man by his outward appearance. Perfectly matterless the name: we want well-known cinchona trees, adapted to various altitudes, which are good quinine-yielders, which have been fully established, and propagate that. If it is over a 3 per cent bark all well and good, if it becomes 10 per cent so much the better. Ceylon has yet much to do in the way of cinchona bark. Let us hope that before long the curing, shipping and agents' charges will be utilized in Colombo for making the quinine and other alkaloids.

On p. 604 an article occurs on tanning. There are numerous plants already in Ceylon which could be turned to account, such, for instance, as the patana oak, and further we have large districts *now treeless*, where a little forestry might be turned to account. If it pays in Britain (see article on 629), surely it ought to pay here.

On 622 we have a notice *re* Mr. Karslake's process of barking cinchona trees. It would be a great benefit if the matter was set at rest as to whether slips left upon trees have not deteriorated in value. This part concludes with further notices on *Hemileia vastatrix*.

In the February number we are again reminded of the Forestry branch, and suggestions are given for the introduction of a useful timber, the toon tree for tea boxes, a large number of which will soon be required, considering the good sales effected in Aus-

tralia and the greater energy which is being shown in its cultivation and especially in its *curing*, which is the *all-important item* in the matter.

A traveller lately returned from Madagascar gives an interesting account of the small islands situated between Madagascar and Zanzibar, referring to it especially as a planting region.

Gems and gold mining rights are given on p. 662.

A very sensible letter appears entitled "Shall We Abandon Pruning, Manuring and Weeding in Coffee." We should say certainly not the first two, but weeding in many cases is carried to excess. If the tall weeds were kept down it becomes a question as to whether a short grass would not greatly benefit the coffee when it is so often in a leafless condition, for a soil takes much more harm by having nothing growing upon it than where weeds of any description are. Several items appear on new products. With regard to Rubber, if the yield is as favorable as the growth is, will pay well. We want now to know the average yield per tree of a given age. As to *nutmegs*, a useful account of its culture in Bencoolen is given. In Ceylon, the nutmeg grows well and yields well, and is well-flavoured; the great drawback is the time before the trees begin to bear. Has no one ventured to try the grafting or budding of well-known trees upon the stocks of wild nutmegs, so plentiful in some of the jungles, say of the *Myristica lancifolia* (S. malboda) or of *M. Horsfieldii* (S. rukgaha)? If apples of fine quality grow well on crab stocks, &c., there is not much reason to fear in this case, and then there would be no doubt regarding the sexes of trees, for, if you plant seed you know not what sex will spring from it. In fact, you might have an acre of trees of one sex only. A long account *re* cinchona planting on the Nilgiris is given by Col. Beddome and Mr. Cross—these reports in full, and the energetic Mr. Schrottky supplies further information as to the effects of his treatment of leaf-disease.

NEW FIELDS FOR ENTERPRIZE.

A correspondent sends us a copy of *Camp's Emigrants' Guide* for 25th April 1881, published at Kansas city, Mo., and containing a good deal of information regarding land for sale in that part, as well as statistics of agriculture. On the last page is given a map of Kansas and S. W. Missouri, showing different lines of railways, and localities where lands are for sale. It would seem that not only wheat and other cereals but a variety of products grow well in Kansas, and labor-saving appliances can be used to advantage. The soil is said to be rich, water, coal, and limestone abundant, and timber fairly so, and sheep and cattle seem to thrive. Besides numbers of farms for sale, land can be had at $3·20 per acre cash. The Neosho Valley Land Agency seems to be one of the chief agencies for the sale of land.

A Ceylon planter sends us a long description of a journey taken by him from Georgian Bay to Manitoba in the latter part of 1880. We can find room for only some extracts. With regard to land in the neighbourhood of Winnipeg, our correspondent says:—

"Manitoba, which is the original Red River settlement and 1,300 square miles in extent, and the Great North West Territory are surveyed out into townships each six miles square. Each township has 36 sections one 89 miles in area or 640 acres, each of which section square miles sub-divided into quarters of 160 acres. The whole country is divided into broad belts A B C D lying parallel to, and on each side of the proposed route of the Canada Pacific Railway. The sections of the townships are numbered from 1 to 36. Every odd section is held by the Government as security for the railway bondholders, while every even section is given to settlers under the following conditions. The first quarter, of 160 acres, is grafted to him free. When he has built a homestead and placed the greater part of the land under cultivation, he can purchase the second quarter with the power of pre-emption, and the remaining 320 acres at the market value of $1 per acre or thereabouts, depending on its distance from the commercial centre. In each township a section is set apart for the church, another for the school, and another for the Hudson Bay Company—the vendors of the land to the Government,—while throughout the country there are reserves for Halfbreeds, Indians, French Canadians and Mennonites. In the days of the Red River settlements, the land adjacent to the Red River and Assiniboreie was all apportioned out in long narrow farms having a frontage on the river of 12 chains and stretching back to a distance of 4 miles, with the right to cut hay for a further distance of 2 miles."

The farms between Portage la Prairie and Winnipeg are thus described:—

The farms are mostly worked by the owners themselves and their sons. Hired labour is scarce in summer, and in winter there is no demand for it. The owners are mostly Ontario men who have only been in the country a few years. They all seem to like the country and are well satisfied with their change. This year, however, they, like the home farmer, have their grumble, and it is that the season has been very wet and consequently crop is very late, and all that is not ripe now will never ripen, but will have to be cut green for fodder. Among the farmers there are few capitalists. The class who would seem to be most fitted for the country are men with say from £400 to £1,000, well used to practical work, and having a thorough practical knowledge of farming in all its details, and who are content to do without any home comforts and even many of the necessaries of life, and to live all the year round on bread, butter and pork. Building material of all kinds is costly; wood is scarce, and stone and lime still more so. Only an Englishman would think of putting up a frame house or a frame barn with a stone foundation. A Canadian of equal means would be content to live in a poor log hut, and for his barn and cow-sheds he would rig up a couple of fences 6 or 7 ft. high and as broad, and would roof them with branches and thatch, thus leaving the greater part of his capital available for cultivating purposes. As I said above, labour is scarce. One often sees the owner, a gentleman, drawing his own reapers while his 3 or 4 sons laid up the grain into stooks behind him. Consequently machines for saving labour are very desirable. These, of course, are enormously expensive; so the farmers of a district go shares in a thrashing machine and the more costly implements necessary to the working of a farm; while perhaps, an enterprizing outsider will make himself the "boss" of a steam plough and go from farm to farm hiring out its services. The Winnipeg market for farming implements has, up till now, been supplied by American firms, who excel in this line and whose machines have always given great satisfaction and are thoroughly sound. Lately, however, the Canadian Government has so raised the tariff on American articles imported as almost to exclude them altogether. Consequently the farmer has now to content himself with Canadian waggons, ploughs, &c., which are cheaper but badly made and constantly getting out of repair. I remember a day or two ago, coming upon a party of immigrants who had come to grief far out in the prairie. They had invested in a gaudy much painted waggon of Canadian make before setting out from Winnipeg, and here they were stuck in the first mud hole and up to the hubs of the wheels in mire, with the fine looking axle snapped in two like a match. In time no doubt, good enough articles will be turned out in Winnipeg its self, but at present

the material is very scarce. There are fine forests away to the east from Winnipeg to Lake Superior, which contain abundance of good wood, but there are no means of transit. For a few years to come the farmers will have a good home market of their grain. Winnipeg and Portage farmers have been sending their grain away west to the still unopened country about Rapid City and other places for the highly remunerative price of from seven to eight dollars the bushel.

As to the climate, we read,—

During the winter months the weather is pleasant, fine, clear and dry, but the temperature often goes down to 40 deg. below zero indicating a cold of 72 deg. Then frozen noses and ears are common, but, when one keeps the circulation going well, they say such extreme cold is not felt more than if it were only a few degrees below zero. In fact, it is very healthy and invigorating, provided woollen clothing an inch or two thick all round is worn.

In a recent number of *Colonies and India*, the results of Mr. John Macoun's researches into the physical phenomena of Manitoba and the North-west Territory are given, from which we quote the following :—

In 1879 Mr. Macoun's attention was chiefly directed to an investigation of the causes of the supposed aridity of the district lying to the south. He found a parched surface, dried and withered grasses, and, in short, every appearance of such aridity; but closer examination showed that these indications were illusory. At the point—Blackfoot Crossing in lat. 50° 43'—where the consequences of aridity appeared the strongest, Mr. Macoun came upon ground, broken up in the spring, bearing excellent crops of all kinds, oats being 4 feet high, while on the land outside the fence the grass was burnt up and all other vegetation withered. From this he argued that the rainfall of the district was evidently ample, but that until, the baked crust was broken, it could not precolate the ground as rapidly as it fell; so a great portion was evaporated by the dry atmosphere and lost. Thus the apparent aridity vanished before the first efforts of husbandry.

Having next discussed the questions of temperature and humidity in some detail, Mr. Macoun summarizes the progress of the seasons and the labours of the husbandman. Early in April the hot sun clears away from the earth the last remaining snow, thaws and at the same time dries the ground sufficiently to fit it for the plough, and almost simultaneously for sowing. Germination quickly follows, and the young roots, moistened by the thawing of the subsoil, follow the pores opened out by the disintegrating power of the frosts, and penetrate to a depth inconceivable to those who have not tested the matter practically. By the time that rains come in May and June the roots have a firm hold of the ground, and everything grows in an extraordinary manner, while the July and early August rains nourish and swell the ripening ears of wheat, &c. Towards the end of August the winds change, and the almost rainless period sets in and continues throughout the winter; and the crops are therefore gathered in the best possible condition, and there is no necessity even to thatch the stacks for the winter. The advantages offered to the stock-breeders in this country are equally great. Storms of sleet or wet snow are unknown on the western praries. Such snow as does fall is always dry and light; hence cattle and horses may be left out during the whole winter without the possibility of suffering from wet. No doubt they experience intense cold, but stock-raisers are aware that, where the air is dry, their cattle take no harm from cold. Consequently cattle can be and are raised on the North-West plains without the necessity for buildings for sheltering them during the winter.

From a letter by Mr. D. S. Litlejohn in the *Dundee Advertiser* we quote as follows :—

The first question that will naturally suggest itself will very probably be "How far is this country suitable for settlers from the mother-country, and what are the differences of soil and climate that might tend to render it difficult for farmers bred at home to reconcile themselves to a country so distant?" I will meet this question very shortly. In the first place, I may say that a farmer from home would have much to unlearn as well as much to learn on settling in Manitoba. I would not advise any one to emigrate to that country who is advanced in life. The change of habits, of scenery, and climate would be too severe. But for a young man willing to work and determined to make his way, I do not think that there are much better chances in any field of emigration than there are in Manitoba.

I think I cannot point out the advantages of the country in a better way than by stating the objections that have been brought to it, and giving the answers, which I myself received to the many anxious inquiries I made on the subject.

The chief objections to the climate of Manitoba are stated to be (1) the winter cold, (2) the summer heat, (3) the blizzards in winter, (4) the thunder storms in summer (5) the plague of grasshoppers, and (6) droughts.

Mr. Littlejohn then shows that on each of these points there has been a good deal of exaggeration. Another drawback he mentions, viz. mosquitoes, which seem to trouble the cattle somewhat. As to settling in Manitoba the writer says :—

In choosing land the preference is to be given to the rolling prairie; but no one should settle in that or any other new country without first obtaining some personal experience, and the advice of natives well acquainted with the character of the soil. As a rule, in choosing land the soil that bears luxuriant crops of prairie grass and wild flowers is the finest land, and it is always observed that the wild prairie sun flower is larger or smaller in proportion to the richness or poverty of the soil. * * *

A practical man in Manitoba would not buy land affected with alkali. Grain does not come up at all alkaline spots. The strength of it kills the seed. The presence of alkali is indicated on the prairie by the poorness of the vegetation. The level prairie has alkaline spots, many of them in unexpected places so that you may find a fine farm, and close to it alkaline ground where nothing will grow * * * In regard to settling in Manitoba, I would like to make it very clear that small parcels of land cannot be profitably cultivated except by a farmer working with his own hands, though large pieces of land of 1,000 to 10,000 acres can, I understand, be profitably used as grain-growing land under a manager. I do not consider this part of Manitoba suitable for raising cattle on a large scale, as it would be too expensive to shelter and feed them in winter. For cattle-raising purposes Bow River or Peace River is the most suitable locality, the chinvok winds or warm breezes from the Pacific blowing over the lower ranges of the Rocky Mountains into these countries, and rendering the climate more equable than that of any other district in the North-West. This fits these districts for cattle-raising, as there the cattle can be fed out all winter without shelter.

I made inquiry as to the capital required for a farm with 160 acres under cultivation and 160 lying idle. Of course, price depends upon distance from the town; but I assume the distance to be 12 to 14 miles. A farm of this kind can be got—fair dry prairie land, with about 40 to 60 acres hay land—at from $7-50 to $10 per acre. This, say at $10, would amount to $3200. Breaking costs on 160 acres are $3-50 per acre, or $560; fencing 160 acres costs $350 : ploughing and seed, $720; horses, harness, ploughs, waggons, and agricultural implements, $1320; the house for the owner costs $1500; for the men $500, stables, barns &c.. $1000; altogether, $9150. Deducting 160 acres and leaving the farm at 160 acres only, this cost would be reduced to $7,550. If we add for incidental expenses $450, we would call the total amount $8000 (£1,600). If some things are over others are under what would be required; so that this may be looked upon as a very fair average estimate of the capital necessary to be put into such a farm. Ou a farm of this size, however, the owner must do a great deal of work with his own hands. He will not thrive unless he do so, as the expense of hired labour is great.

Therefore let any young man who thinks of emigrating make up his mind that he is not going to be a gentleman farmer, but must work long and hard if he expects to thrive in these new countries. In America as here economy must also be studied. Many men ruin themselves by going in for all the improved machinery, suitable perhaps for large farms of 5,000 to 10,000 acres, but not at all suitable for small farms of 160 or 320 acres. I saw in

many places such machines lying rusting in the sun and rain, which the farmer had probably half-ruined himself to buy.

The latest information to hand, refers to:—

Land Regulations in Manitoba.—New regulations for the disposal of Dominion lands in Manitoba and the North-west Territory have just been issued by the Canadian Government. They are to take effect from the 1st Feb. 1882. The land is divided into four classes: A. Lands within twenty-four miles of the Canadian Pacific Railway. B. Lands within twelve miles of any other approved railway. C. Lands south of the main line of the Canadian Pacific Railway not included in class B. D. Lands other than those in preceding classes. The even-numbered sections (one mile square) in the foregoing classes are to be held exclusively for free grants and for pre-emptions, with some few contingent exceptions. The odd-numbered sections in class A are reserved for the Canadian Pacific Railway. In classes D. and C. these sections are offered for sale at $2. 50c. per acre cash. In D. the price of such lands is $2. The price of preemption land is the same as for the public lands in the various classes, but the purchase money of the former is payable at the end of three years. In the sale of lands to Companies or individuals for colonisation purposes, two plans are offered for the consideration of the purchaser: 1. The land (odd-numbered sections only) to be bought at $2 per acre, payable in five years, and to be colonized in that period; such colonization to consist in placing two settlers on homesteads on each even-numbered section in the tract, and two settlers on each odd-numbered section. Homesteaders to have the right to pre-emption at $2 per acre, payable at the end of three years. If these conditions are carried out, a rebate of one-half the price to be allowed to the purchaser. 2. A tract of land may be bought at $2 per acre, payable at the time of making the contract; land to be colonized in five years, such colonization to consist in placing sixty-four settlers on each township (thirty-six square miles). If these stipulations are complied with, a relate of $1 per acre will be granted. Leases of land for grazing purposes are to be obtained on the following terms: Twenty-one years' lease, maximum area 100,000 acres; rental £2 per 1000 acres, and one head of cattle to be placed on the tract for every ten acres of its extent. Land for a farm and corral in connection with such may be purchased at $2 per acre.

CEYLON TEA IN THE LONDON MARKET.

It is satisfactory to find "Ceylon Tea" regularly noticed in Mincing Lane circulars. Messrs. Hawes and Hertz, who furnish an "Indian and Java Tea Report" to their constituents, are among those who now always quote our Ceylon product. Thus, in their circular of January 12th, we read:—

Neilgherry Teas.—About 300 packages from the "Curzon" estate have been sold, fine liquoring Pekoe in boxes at 2s 2d, Pekoe Souchongs 1s 7d, Broken Pekoe 11½d at 1s 5½d.

Ceylon Tea.—288 packages have been offered, and sold mostly at good prices. 139 packages "Windsor Forest" of good strength and quality sold as follows:—Pekoe Souchong 1s 3½d; Souchong 1s 2d; Broken Souchong 1s 1½d; Broken Pekoe 1s 6½d; Red Fannings 9¾d; Dust 10¾d. Ceylon teas generally shew improvement in manufacture, and are taken by the trade quite as readily as other Indian growths.

And again from the Report of February, 9th we quote, respecting Java as well as Nilgiri and Ceylon teas what will be of interest to local tea-planters:—

Neilgherry Teas.—About 600 packages have come to hand of varying quality, and sold; Pekoes 1s 3½d to 1s 10½d; Pekoe Souchong 1s 3½d to 1s 9d; Souchong 1s 1½d to 1s 6½d; Broken Pekoe and Pekoe dust 1s 3½d to 1s 7½d; Congou 1s 2½d; Broken mixed 1s 2½d.

Ceylon Teas.—An invoice of Kandaloya growth sold by auction, Souchong 1s 9d; Broken Pekoe 11½d; Red leaf 8¾d. Several samples to hand, not yet on offer, show good quality and great improvement in make and style.

Java Teas.—The small quantity which has come to hand has met with brisk demand and firm prices were realized for almost all descriptions. About 1,500 chests ex "Chye bassa" just arrived should meet with ready sale from the active demand existing for all kinds. 480 packages ex "Almora" were disposed of at auction on the 17th, and 23rd ult. The following represent prices realized:—Dramaga Socpoci pekoe 1s 6¾d; Pekoe siftings 1s 5½d; Souchong 1s 1½d; Congou 1¼d; Bagelen Pekoe souchong 1s 3d; Tjikoya pekoe souchong 1s 1d: Kedoeng Halang souchong 1s 1d. Some of these teas, more especially the Dramagas and Bagelens, were equal in every respect to favorite growths of the Indian tea. About 500 chests Ardja Sarie tea sold at Pekoe 1s 2d; Pekoe souchong 11d; Souchong 9¾d. 1010 packages are offered by auction here today. 7,370 packages are advertized for sale in Amsterdam on the 17th inst. including 1,425 packages withdrawn from previous auctions.

THE COFFEE TRADE OF BRAZIL FOR 1881.

We have now received Messrs. Kern Han & Co.'s Annual Market-Report, from which we quote as follows:—

Looking back upon the year just closed we find that same presented more unpleasant features than pleasant ones.

If the balance of a year were to be drawn with regard to the failures occurred during the same, then the year 1881 might be considered as a favorable one for the Brazilian-import-trade, because during the last 12 months, only a few and not very important suspensions of payments took place here, and it seems therefore that most importers have continued with the prudent system inaugurated last year—say, not to sell any more at credit for very long periods.

We abstain from sifting this point again, as our last year's annual report has dealt sufficiently with this matter.

The fluctuations in exchange during the past year were less than during 1880 and importers have therefore but little to complain of the unsteadiness of the rates of exchange, and in general we hear that business would have been on the whole satisfactory to the import-trade, had not during the last months close competition, caused by over-importation, forced many importers to sell at very low prices.

Now, if business in general was rather favorable to the import-trade, we are sorry to say that the same was by no means the case with regard to the export-trade.

About the principal article, coffee, we report below extensively and have only to state here, that sugar has given lieu ["given lien"?—Ed. C. O.] to various important transactions, especially so during the second half of the year, whereas business in other produce, for exportation from our port, has been diminutive.

All planters complain that with the present low range of prices for any of their produce they cannot exist, and we think that to a great extent their complaints are just, as not only the hands to do the work are very dear, but also the freights by rail and other expenses are much too high in proportion to the prices obtainable at the sea-ports.

The planters have therefore sent a petition to the Government, requesting the establishment of a large rural Mortgage-Bank, which institution should advance money against security at cheap interest to the planters, and they further want either the entire or part abolishment of the heavy export-duties and a reduction of the excessively high-fares of the railways.

On all points the Chambers of Deputies and of the Senate, convoked now, will have to decide, and we trust that their decision may be in favor of the agricultural class and may thereby contribute to the prosperity of the country.

As a very satisfactory progress we have to state that now-a-days on almost every larger plantation there are steam-engines and other machinery in use, and planters try their best to replace the dear hand-work by cheaper machine-work and to improve thereby as much as possible the quality of the coffee,

The low range of coffee-prices and the small remuneration which planters find in consequence thereof has caused them also to take some other steps, which, as they hope may tend to attract more attention to Brazil-Coffee, which according to their ideas is not sufficiently appreciated in the consuming countries with regard to its merit.

By private initiative planters and commissioners arranged during July August of past year an exhibition of Brazil-Coffee, which was opened here in November and which in reality showed many very handsome samples of coffee. It must however be regretted that so far but very little of the fine qualities exhibited have come in the trade.

In order to make propaganda for their coffee and to show to the various markets of consumption, what fine qualities can be had here, it was resolved to exhibit part of the different samples in several larger towns of Europe and the United States and, in fact, towards the end of last month these samples left Rio de Janeiro.

In the interest of the planters it is to be hoped that the propaganda may have the desired effect, but we doubt that it will be the case, as according to our opinion Brazilian Coffee is so well known everywhere that the expenses for the several exhibitions are thrown away uslessly.

The immigration has by no means, made that progress which in the interest of the country should be desired. The government has constantly occupied itself with this point, but so far no satisfactory solution has been arrived at.

The abolitionistic movement in the country counties and the Chambers will doubtlessly have to occupy themselves with the revision of the Emancipation-Act in order to quiet the excited minds.

We have nothing more to state of interest with regard to the interior political position, with the exception that the last elections—effected in November for the first time according to the new law—have taken place in such a quiet and undisturbed manner, as never before.

During the past year foreign politics have had no influence whatever on the inward state of the Empire, this country having had the most agreable relations with all foreign powers.

It is true that our troublesome Latino-American neighbours have constantly been arming, so that the Brazilian Government could not pursue the former apathic attitude, but was forced also to re-organize its army and navy, so that now Brazil is in a position to rebut with energy any attack which might be made.

These armings have devoured large sums, so that the financial position of this country has not improved, which fact is clearly indicated by the present low rates of exchange.

At the close of the last and the beginning of the new year the value of the 6 o/o Stocks was R1:055$000 to 1:060$000 excl. Dividend, that of the 1868 Gold loan R1:290$000 and that of the 1879 Gold loan, which is payable in coupons in Europe and here, R1:118$000.

The customhouse returns of the year 1881 show a decrease of R1,255:550$404 against those of the previous year, being during last year R41,624:171$268 against R42,879:721$672 during 1880.

COFFEE.—If we look back upon coffee-trade in general and specially on that part of it which is done by the Brazils, during the year just closed, we do not find any feature presenting a pleasant remembrance.

With but short intervals the article has pursued a falling tendency and the decline in prices, which is over twenty per cent within the last 12 months, can have been advantageous to but very little* people.

Business on the whole was languid.

In consequence of the heavy failures in New York and Boston during December 1880 the United-States markets, our principal customers, had been weakened, and throughout the year 1881 they operated with utmost caution, purchasing only for immediate wants, whereas the speculation did not touch the article.

In Europe confidence seemed to set in on account of the low range of prices, but it was lost again, when by a speculative consortion [association or "ring."—ED. C. O.] in Havre large quantities of coffee were bought and stored up there and even in the United States the large stocks accumulated in Havre had a depressing effect and proved to be a drawback to any sound developement of business.

People on the whole have the idea, that the production of coffee is no more in a right proportion to the consumption and this question is so far not yet settled.

The principal reason of the rapidly increasing production were the relatively very high prices which ruled during the years 1871, 1872, 1873 and 1874, and as planters made then a splendid profit, they laid out everywhere new plantations and brought the production to the present height, which according to the opinion of many people must be considered as the culminating point, it being taken for granted that a much larger production cannot be reached, if coffee prices do not rise again, as the remuneration which the planters find in present prices does not give them sufficient incitement to increase their production still more.

Now, supposing that we would have for sometime to come the same large supply of coffee, as at present, the question is: can the consumption master the large available quantity of coffee, and if so, which is the lowest range of prices, necessary to call forth such an increase of consumption that production and consumption are again in a right proportion?

Low prices are for an article like coffee the most powerful means for an increase of the consumption, and if—as it is a well known fact—during 1873/74 even the highest prices ever known could not bring down materially the consumption, how quickly must it increase with prices ranging 50 to 60 per cent below those ruling 7 to 8 years ago.

Our opinion is that ere long the consumption will become larger, say rise in due proportion to the production, and that only *one* small Brazil-crop will suffice to re-establish the equilibrium.

One point, and a very important one, must also be borne in mind and that is the fact, that for those planters, whose plantations are very far in the interior, it is at present prices no more remunerative to send their coffee, especially the lower qualities, to the sea-port, as the expenses for freight etc. are in many cases as large, sometimes even larger than the price obtainable at the sea-port.

If coffee-prices decline further, we shall see this occurrence take place still more frequently and hundreds of planters will then be obliged to remain with their coffee until an advance in prices allows them to dispose of their produce favourably.

It is impossible to foresee, whether this point will take proportions which may alter the course of the article, but we deem it right to call thereto the attention of our friends.

The year 1881 began with prices of 5$000 for "Goodfirst", and 4$250 for "Ordinaryfirst"; up till middle of May the movement was a steadily downward one, reaching its lowest point with about 4$450 for "Goodfirst" and about 3$550 for "Ordinaryfirst" towards end of May.

Prices then began to pursue a rising tendency which lasted throughout June, July, up till the end of August and the quotation for "Goodfirst" rose as high as 4$800 and that for "Ordinaryfirst" to about 3$800.

From middle of September towards end of the year the tendency was on the whole again a declining one, and we closed the year with prices of about 4$200 for "Goodfirst" and 3$450 for "Ordinaryfirst", which prices, compared with those ruling at the beginning of 1881, show a decline of about 800 reis per 10 Kilos, say from 16 to 20 per cent.—In the free on board prices the decline is still heavier, say from 20 to 25 per cent, as the rates of exchange as well as those of freights were much lower in December 1881 than in January 1881.

The quality of the 1881/82 crop was on the whole satisfactory, showing on the average a fair proportion of well cleaned coffee of good bean.

"Superiors" were in the beginning of the crop-year very scarce, but later on they were pretty well represented in the stock; "Goodfirst" "Regular-first" and "Ordinaryfirst" were abundant. The latter quality being very much sought after has of late become scarcer. "Goodsecond" and "Ordinarysecond" have not been over-abundant and of late have even become scarce, as it does not pay the planters to send lower stuff to the market, for which they must accept prices, covering in many cases not even the expenses for freight and forwarding charges.

* The worthy brokers mean "few" persons.—ED. C. O.

The total export from Rio de Janeiro during the year 1881 amounted, as will be seen from the table below, to 258,313 tons against 202,124 tons in 1880 and 206,327 tons in 1879, thus showing an increase of about 56,000 tons against 1880 and of about 52,000 tons against 1879. However comparing the shipments during the second semester only of the last three years, the increase of 1881 is only about 4,000 tons against 1880, but about 33,000 tons against 1879.

In our printed report of 1st July 1881, we estimated the 1881-82 crop to be about ...3,200,000 bags and calculating that of former crops there remained in the Interior and in Rio de Janeiro at that date about ... ...1,500,000 „

the available quantity would be about .. ...4,700,090 bags

of which we expected that about ... ...4,400,000 „ would come for export during the 12 months, from 1st July 1881 to 30th June 1882.

As stated already in our report of 1st December 1881, we are still of the opinion that these figures will prove correct, provided, of cour-e, that the weather will permit to bring the total of the available quantity of coffee to shipment up to 30th June a. c.

According to the above table, there were shipped from 1st July to 31st December 1881, 138,396 tons, equal to about 2,372,500 bags, and in order to reach the above-mentioned figure of 4 400,000 bags, there are still somewhat above 2,000,0 0 bags of coffee wanting.

Several of our neighbours, who had put down the 1881-82 crop to amount to only about 3 millions of bags, have—as far as has come to our knowledge—heightened their estimates to about 3½ to 4 millions of bags, and others who had estimated the stock of old coffee on 1st July 1881, in the interior to be only about ½ million of bags, have corrected this figure into a higher one, so that more or less all exportors agree that we shall see an export from 1st July 1881 to 30th June 1882 of about 4¼—4½ millions of bags of coffee.

With regard to the coming crop (1882-83) it is as yet too early to name any approximately correct figure.

The reports spread out in September, October and November, that the coming crop had severely suffered by drought etc., have proved to be exaggerated and premature, because the crop promises to give a very good result, especially with regard to quantity. We consider it, however, our duty to request our friends not to believe too much in very sanguine reports, which of late have been in circulation and which have spoken of fabulous figures, and, if we were to name a figure, we might say that we may count at all events upon a minimum of at least 4 millions of bags.

With the large Brazil crops, which we must expect henceforward, our friends must accustom themselves nowadays to deal with very big figures, and a fair average Rio-crop must now be calculated to be from 4 to 4½ millions of bags., but as stated above—as long as prices are on the present low level—the whole available quantity will not come to the seaports for exportation, as especially the low qualities will be kept back in the interior in expectation of better times.

COFFEE MIXTURES.

The miserable state of the home coffee trade and the constant decline in consumption, in the face of cheaper prices and of far lower duties than of old, are subjects which attract general attention. Twenty years ago the home consumption of coffee was 1·21 lb. per head. Bonded prices were then about 5s per cwt above what they were in 1881, and the duty was 23s 4d higher. Though the first cost of coffee was thus, say, 3d per lb. lower in 1881 than in 1861, the home consumption in the former year had fallen to 0·92 lb per head, a decrease of 24 per cent. In the same period, the consumption of every other article of grocery produce per head of the population had increased in the most marked way; but, if coffee had simply held its own since 1881, we should have used 18,750 tons in 1881, instead of only 14,216 tons. The coffee consumption per head last year is the lowest recorded for forty years, and yet the habits of the country have in that period altered, if at all, strongly in favour of the so-called temperance drinks, such as tea and coffee. It is a moderate thing to say that the coffee consumption of the Kingdom ought to be double what it is. Why, then, is it not so? To give a full reply would be difficult, but one cause is strongly suspected by the trade, and that is, that coffee does not get fair play. It is obvious to all who look into the shop windows, that it seems to be considered a recommendation to offer any sort of "mixture" or "substitute" in the place of pure coffee. The value of that beverage consists in the gentle nerve-stimulant which it contains, and it would surely be unfair to it to offer in its name the most meritorious of compounds, consisting of valuable, though inexpensive, charred roots or stalks, or of roasted peas, or other seeds or fruits—with the addition of only a small portion of the substance with the title of which it is labelled. The extraneous substances may possess every virtue under the sun; they may be dietetic or aperient, or stimulate the liver or other organs, as is said to be the case with some of them but the trade naturally object to their being labelled coffee, for which, however, they do not go so far as to claim medicinal virtues. To what extent these admixtures are carried it is difficult to say, but it has been held by the magistrates that a compound of 80 and 90 per cent of foreign substance and 20 or 10 per cent. of coffee, may be legally sold under the name of the latter, so long as the fact that other substances are mixed is declared at the time of sale. This state of things is considered by the coffee trade to be altogether unjust to themselves. Such a compound, whatever its medicinal or other virtues, would be altogether wanting in the essential constituents of coffee, and the public would soon insensibly find this out. The craving among every race of man for some non-intoxicating nerve stimulant, either in tea,

coffee, chocolate, cocoa, mat tobacco, the kava bowl, the betel nut, or other similar substances, is evidently a natural one, and the system after a time would find that the so-called "coffee" does not impart what it expects, and tea would be taken in its place. If the public simply want a warm drink, why should they not take diluted pea or lentil soup, which would cost far less than 1s. per pound for the raw material, and would be nutritious as well as hot. The practice of mixing is reaching such an extent, that there is a feeling growing among the coffee trade that these admixtures should be treated under the Adulteration Acts, unless the quantity of coffee they contain be clearly declared by word of mouth or by label at time of sale. Further, the long-suffering trade appear to think that no substance ought to be allowed to be labelled coffee at all, even with a declaration of admixture, unless the preponderating ingredient be coffee, and that in any case the name of the substance admixed ought to be stated. It may be mentioned that the latest "substitute" discovered for coffee consists of charred cabbage stalks, the precise value of which, as an article of diet, is not mentioned in the ordinary scientific handbooks. Not even the coffee trade would desire to detract from the dietetic merits of burnt cabbage stalks, and all they ask is that they should be offered under their own name, so that they may owe the large sale to which they may attain, to their own merits, and not to the name of coffee.—*Produce Markets' Review.*

TROPICAL PRODUCE IN AUSTRALIA.

(From *Greig & Murray's Circular.*)

MELBOURNE, 15th February 1882.

SUGAR.—We have to report a large business in this staple during the month, transactions covering 4,000 tons. Notwithstanding the heavy shipments that have come forward the market has shown wonderful elasticity, and nearly all the cargoes to hand have passed to the trade.

QUEENSLAND SUGAR.—The principal feature has been the sale of 140 tons brewing crystals at £33 to £34. The quality shews great improvement, and is fast approaching Mauritius production.

FIJI SUGAR.—50 tons, ex "Suva," principally from the Staplake Lee Refining Company, sold at £31/10 to £32 for yellows. The quality is improved.

INDIAN TEA.—Another extensive sale was held on the 9th instant, when 4,650 halfchests, selected by the Calcutta Syndicate, was offered. As no auction of any importance has been held since last November, the trade were well prepared to purchase, and, as was fully expected, the catalogue, consisting of 143 lots, was run through in a very short space of time. Owing to the prices going at full valuations many of the traders were not able to fully complete their anticipated purchases. A great deal of difficulty is experienced in placing saleable valuations on these teas, consequently the biddings were in many instances started at prices much under which they ultimately fetched; this was very noticeable in broken orange pekoes, which must be quoted at a good advance on late rates. Choicest Darjeelings were not offered in any quantities. Samples that we have seen, representing sales made in London, too plainly show that this District's teas cannot be procured, unless at better prices than we are able to give. In one or two instances doubt has been expressed as to the truthfulness of the marking of this favored tea on the packages; it is to be hoped that such a shortsighted policy will not be of frequent occurrence; the Syndicate brand should be a guarantee as to the genuineness of their teas.

JAPANS.—A bold attempt of the Japanese merchants, aided by their Government, to introduce on a large scale their black leaf Congous was tried on the 2nd instant, when a shipment comprizing a variety of qualities, aggregating 2,390 halfchests, were submitted to auction. The teas however did not seem to please, and the whole had to be passed with the exception of a few small lots.

LIBERIAN COFFEE IN CEYLON: SIZE OF BEANS; "PERPETUAL PICKING": THE UDAGAMA AND GALLE ESTATES.

To some it is a conclusive objection against Liberian coffee that the beans are not large in proportion to the size of the cherries. The question was being discussed on board a recently-arrived mail-steamer, when a Dutch passenger, proceeding to visit his estates in Java, intervened with an emphatic condemnation of the new coffee on this very ground of large cherries but small beans. The objection seems as valid as that of the Irishman to the guinea which he saw lying on the road. "By jabers!" said Paddy, "I'm not going to be *chated* again: I lost two shillings by the last one I found." This was because for a worn coin he had received only nineteen shillings in change, instead of twenty-one. There are, no doubt, varieties of Liberian coffee which give small beans, but surely no one will have the temerity to assert that on the *average* the beans from a Liberian coffee plantation do not considerably exceed in size average beans of Arabian coffee. Certain we are that the beans from selected bushes on UDAPOLLA are larger than the largest which can be gathered from the old kind. Perhaps those interested will institute a comparison between a pound of select Liberian beans and a pound of largest sized plantation, counting the number of beans which go to each pound. [Since the above was written, we had the opportunity of referring the question to so competent an authority as Mr. R. Porter, who writes:—

"You will perhaps be surprized to hear that, in last year's UDAPOLLA crops there were 43 per cent of extra large beans *above No. 1 size*, against 6 to 6½ per cent in very fine high-grown Arabian coffee.

"It is quite true that there are many Liberian beans not larger than Arabian beans, but the above figures show that a very large percentage are much larger."]

If the objection were that so large a portion of the energies of the tree were thrown into the task of elaborating masses of mucilaginous matter, we could easier understand it; although the obvious answer would be that none of the pulp is removed from the soil, but is restored to it, when properly treated as manure.

A very intelligent German gentleman, Mr. Mhor, the advantage of whose company we had on a recent voyage from Java to Singapore, he being *en route* to his properties at Deli, in Sumatra, offered a more valid objection by adducing the number of trees which grew up tall and slim, without sending out primaries. There can be no doubt that from imported seed a certain proportion of these objectionable plants result, but, after all, they are only exceptions, and probably their habit could be altered were they cut down to within a foot or six inches of the ground and allowed to grow up again. We should be glad to know if any experiments in this direction have been tried. A gentleman, who has gone extensively into the culture of the new coffee in the Southern Province, and who deems the experiment successful, writes to us:—

"My experience with stumps does not agree with yours. I had two hundred plants, most of them three feet high and more, sent out. They had been sen

from Liberia to London in ordinary packing cases, and were forwarded to me without any covering and in the original cases. I have got 195 of them growing, over 2½ years old now."

This is reassuring as to the ability of well-grown plants, to bear "stumping," and also long carriage. The gentleman from whom we have quoted, writes further :—

"I send you the daily memoranda sent me by Mr. ——— from ———. Picking is still going on at the same rate, and I don't know when it is likely to stop. We are picking off 30 acres, three years old last November and December. (The first plant was put in the ground on the 21st October). There is another 22 acres about eight months younger, from which we are picking too. The plants are 10 × 10 apart. So far as one can judge the thing is a success."

Our friend might safely use less qualified language. On looking over the daily memoranda, which extend from 12th Jany. to 2nd March, we find that, besides 77½ bushels dry coffee despatched, 141 were drying on 12th Jany., while 10 were picked on that day. Then came 12 picked on the 13th, and so on until the 17th, when 23 bushels were gathered and the remark made, "Crop is again ripening on new clearings.' On the 18th the picking was 25 bushels ; 19th, 27 ; 20th 16 ; (only ½ day at work, owing to rain) 21st, 27 ; and so on, until 25th Jany., when the report is "A good blossom out this morning : picking stopped." Nevertheless 14 bushels were picked on the 26th ; 20 on the 27th until 26 were picked on 3rd February and 27 on the 4th ; the same figure being attained on the 6th ; 28 on the 7th and so on until on 11th February 32 were obtained. Up to 20th February 883 bushels had been picked and a small blossom was out on that day. The total picked from the commencement of the year to 2nd March—a period of two months was—945 bushels ; while there were no signs of cessation, but rather of steady increase. As, in this case, the cherries seem to be dried on the estate and then sent to Galle for preparation, we should be much obliged if our courteous correspondent would afford us information as to the mode adopted to clean the beans, and their quality as compared with others pulped on the place of growth. Are the cherries soaked, or are they "hulled," as the Americans have it, in their dry state ? We suppose the latter, and, although the beans may not be quite so free of "silver skin" as those regularly pulped, we have no doubt of their fine flavour. According to Laborie, the French planters of San Domingo always dried the coffee intended for their own use, in the cherry, and kept it so for several years. By these means, Laborie alleged, a superior flavoured coffee was obtained. What is the result of experience here on this point ?

All the information which reaches us regarding Liberian coffee leads us to believe that, although this new product is not entirely exempt from attacks of insects in its early stages and fungus later on, it remains true to its comparatively robust character, its rapid growth and its exceptional bearing properties. We are, therefore, sanguine of its ultimate success.

After we had written the above, we received a communication stating that the estates at Udugama, in the Southern Province, are well worthy of a visit, which we trust we may soon find time to pay. Meantime, we trust our correspondent will forgive us, if we extract, for the benefit of our readers, information which is probably as new to most of them as it is new and gratifying to us. Those southern estates are believed to be the first where nutmegs and pepper have ever been *regularly cultivated* in the island by Europeans, as they are in the Straits. There are already 87 acres planted with nutmegs and 72 with pepper, which acreage will be doubled in both products this year. Besides this, there are 310 acres of Liberian coffee planted, some of which is in bearing, and 238 acres being planted this year. The small acreage in tea promises exceedingly well, and the land and climate appear well suited to it. There is any extent of jungle in the district suitable and available for the above products. Cinchona Calisaya and Ledgeriana are both growing well. From seed put into the nursery in April, there are plants 2 feet high : will they, it is asked, have any quinine? They look very healthy. The Liberian coffee has had one small, and one very fine blossom, and another is in spike. Malabar cardamoms, 18 months old, are commencing to shew signs of blossom, and their growth is equal to any ever seen in the island. Government have given the district a post office and are thinking of providing a bridle-path, as a short cut to Galle. Any amount of Sinhalese labour is available, and as much Tamil as the planters want. About 400 mangosteen plants have been put out in each estate, and they are coming on well. The distance from Galle is 26 miles, 24 of which is by cart road. A traveller can, by leaving Galle at 6 a.m., get there to breakfast. All the land in the district is felled only in the hollows, leaving all prominent ridges in jungle ; so that it is hoped to have no bad patches on any of the estates. There are 1,000 acres now under cultivation on 6 estates. All this is very cheering in the midst of depression from the position of our old staple. We trust that, besides the main product of Liberian coffee, nutmegs and pepper may be successful, and also that the prince of all tropical fruits, the mangosteen, may at length be naturalized in Ceylon. Mangosteens were in full season—plentiful, cheap and delicious when we were in Java In Singapore the season was over, but we took special note of the fact that the most flourishing mangosteen orchards were in semi-swampy flats.

Before this goes to press, a planter, who ought to know more about "New Products" and especially Liberian coffee than any other man in the island, writes to us in this strain :—

"From all the industries I have seen since my return to the island, I think Liberian coffee looks the most prosperous. Cocoa is very encouraging, and will in time bear well, but it does not give a return as soon as Liberian.

"I do not know how it is in the rest of Ceylon, but here, north of Kandy, we are having far more than our share of rain.

"Returning to Liberian coffee, we have upon Liberia estate every expectation of picking 400 cwt., which, owing to the estate having first been planted 12 × 12 is all really few more than half the right number of trees—say 60 acres."

SPECIMENS OF GOLD-BEARING QUARTZ FROM VICTORIA AND THF GOLD PROSPECTS IN CEYLON.

Apart from the fact that prospecting for gold is going on in our island, the Ceylon Commissioner to the Melbourne Exhibition would have considered it part of his duty to have obtained for the colony he represented representative specimens of gold-bearing quartz and pyrites. As mere geological and minerological illustrations, as indications of the prevailing characters and constituents of gold-bearing strata, the collection would be interesting to scientific men. But the possibility of a paying gold-field occurring in Ceylon adds a fresh interest to the contents of the little box, which the Commissioner owed to the courtesy of Mr. Barnard, F. G. S., Registrar of the Ballarat School of Mines, a most valuable institution, where, for very moderate fees, pupils, including working miners, are taught the whole circle of the sciences, ranging from Mathematics, Drawing and Surveying, Geology and Botany, Magnetism and Telegraphy (female pupils taught) down to Chemistry, Engine-driving, and under-ground mining. As the latter pursuit involves constant liability to accident, the pupils who are qualifying themselves for taking charge of shafts and mines receive a thorough and practical training, not only in Materia Medica and Physiology, but in the treatment of wounds and fractures. We are not likely to forget our night visit to the School at Ballarat, when the enthusiastic surgical lecturer, Dr. Ussher, imprisoned us in his class-room until we had seen a tall, strong young fellow bound and bandaged and pinioned, so that he resembled a mummy! No language of ours can be too strong to express the sense we feel of the advantages enjoyed by the youth of Victoria, in being able, after common school age (15) to receive at slight expense a very high scientific and practical training at either the Mining School at Ballarat or the sister institution at Sandhurst. The life and soul of the latter is Mr. Alex. Bayne, to whom, as to Mr. Barnard, and also Mr. Cosmo Newberry of the Melbourne Technological Museum, the Ceylon Commissioner was indebted for great courtesy and much information of a very valuable kind. We heard and discussed many theories, as probable solutions of the questions we were ever asking. "How came the gold to form in the rocks and especially how came the particles to aggregate?" Our inclination is to believe that gold, like quartz, was deposited from water, but that goes but a small way to clear up the mystery. Before handing over the collection of auriferous quartz from the Ballarat Museum to Mr. Bruce, to be by him placed at the disposal of Government, we sought and obtained permission to place the box at the disposal of our local geologist and mineralogist, Mr. Alex. Dixon, for inspection and report, the report to be published in the *Observer*. We at the same time sent Mr. Dixon our private collection of specimens, of rocks, metals and roasted and crushed pyrites. On the latter Mr. Dixon will have something to say in due time. His report on the collection intended for Government, and which collection we think it probable Government will place in the Economic Museum, we now append:—

Notes on Auriferous Quartz Specimens from Ballarat.

This is a representative collection of quartz, more or less auriferous, presented by the Ballarat School of Mines to the representative of the Ceylon Court. These specimens show the mode of occurrence of gold and its associated minerals from the district around Ballarat. They are well worthy the attention of all interested in gold in Ceylon. Ballarat is situated in the colony of Victoria, one of the richest gold-producing districts of Australia. The geological formation is chiefly metamorphic schist or slates of silurian age.

Our Ceylon rocks are metamorphic, in several parts chistose and no doubt of Palæozoic age.

In Victoria gold was first obtained from alluvium and then followed its extraction from the quartz rock. From this colony from 1851-65, no less than 30,422,591,oz, were exported to the value of £121,690,363. This passed through the Custom house, and it has been estimated that nearly 4,000,000 oz. were sent away otherwise.

From 1868-78 the gold extracted from alluvium was over 6 million ounces, while that from quartz was over 6¼ million oz. There has been a steady decrease from the alluvial deposits; and from the quartz, the amount has not increased since 1877.

One nugget found at Ballarat weighed 184 lb and was valued at £8,376 10s 6d.

SPECIMENS.

No. 1, 2, 3.—This is a milky white quartz veined over with mispickel (arseno-pyrites). Free gold is visible as granules and as plates amongst mispickel. This quartz contains 7 oz. to the ton. The reef is in metamorphic schist 200 feet from the surface and 1,400 feet above the sea level. Locality, Owen's river. In No. 2, the gold is more distinctly visible than in No. 1, and in 2 and 3 it is visible but sparingly.

[Mispickel (arsenical-iron-pyrites) is of a tin or silver white colour inclining to steel grey, crystallizing in rhombic prisms. Its composition is hisulphide and arsenide of iron. Generally from 30 to 36 % iron; 41 to 45 % arsenic and 18 to 21 % sulphur.]

No. 4.—This is a milky white quartz very compact and less veined with mispickel than the preceding. Gold is distinctly visible. The yield of this is 1 oz. to the ton and the reef occurs in metamorphic schist. Depth 1,120 feet at 293 feet below sea level. Locality, Stawell.

No. 5.—Dirty white quartz of great specific gravity, full of iron pyrites which crystallizes in cubic form and faces often striated and of a pale brass yellow color. Note the difference between this pyrite and the former mispickel. No gold is visible. It yields 15 dwt. to the ton taken from a depth of 300 feet at an elevation of 1,600 feet above sea level. Locality Gordon.

No. 6.—A quartz of very loose texture, somewhat resembling a breccia of a reddish colour, due to iron. It is highly ferruginous with most brilliant irridescent hues, due to the films of iron oxide. One or two specks of gold are visible with a magnifying glass. It has a felspathic external surface. It yields 10dwt. to the ton. Depth 250 feet; above sea-level 1,140 ft; locality, Sebastopol, Ballarat.

No. 7.—A dense flaky quartz, somewhat ferruginous with a considerable quantity of metal viz. argentiferous galena and auriferous pyrites. Note the peculiar shade of pyrite differing from the brassy iron one. This specimen was taken from a depth of 60 feet at 90 ft. above sea-level. Locality St. Arnand.

[Galena crystallizes in the cubic form with a perfect cleavage. Its color is a lead grey with metallic lustre. Composition is sulphide of lead and a little

sulphide of silver. If the silver is in sufficient quantity to be worth extracting it is termed argentiferous.]

No. 8.—A dirty white quartz, compact in texture, full of cavities with crystalline quartz. A little mispicked occurs. No gold is visible to the naked eye but slight specks show with the aid of a magnifying glass. Yield 60z to ton. Depth 240 ft.; above sea-level 1080; locality Ballarat.

No. 9.—A whitish looking quartz, somewhat glassy, with auriferous pyrites, a few specks of mispickel occur. Gold is not visible. Yields 18 dwt. to the ton and was taken from a depth of 1,200 feet at 200 ft. above sea-level. Locality, Clunes.

No. 10.—A white quartz stained reddish by iron. A little chlorite is present. It has a curious mammilated quartz surface on one side with an iron casing below. There is a peculiar tinge of iron which is very common in Ceylon quartz. Gold is distinctly visible. Depth 60 ft. at 2080 above sea-level. Locality Daylesford.

No. 11.—Quartz of a milky white character with a slate-wall. Gold is distinctly visible on this slaty-wall along with a little auriferous pyrite. Depth 600 ft. at 1,200 ft. above sea-level. Locality, Blackwood.

No. 12—Dirty white quartz with a beautiful mass of rock crystal, the crystals being a double hexagonal pyramid. A little arseno-pyrite is present but gold is not distinctly visible. Depth 300 feet at 1,150 above sea-level. Locality, Ballarat.

Nos. 13 and 14.—Beautiful, white, milky quartz with auriferous pyrites, blende and galena Free gold is very distinctly visible in both specimens along with the blende. (14 is a very rich specimen). Depth 450 feet at 400 above sea-level.—Locality Maldon.

[Blende or black jack crystallizes mostly in dodecahedrons; it is usually black or brown. Composition is sulphide of zinc.]

No. 15—A whitish quartz much stained with iron, causing it to look reddish. Gold is distinctly visible on the iron ore studded all over its weathered face. Depth 80 feet at 1,400 above sea level.—Locality Ballarat.

No. 16—A bluish glassy quartz; very cavernous. Gold is distinctly visible in the caverns and on other parts. Depth 900 feet at 60 below sea-level. Locality Stawell.

Chief points noticeable in collection :—

1. The great density of the quartz.

2. The compactness of the quartz except in 6 and 7 which show that compactness is not a necessary characteristic.

3. The general association with other metals.

4. The colour of quartz is nil in determining gold. If need not look warm, as has often been stated, for 11, 12 and 13, as far as general appearance goes are cold and decidedly hungry, destitute of caverns and destitute of other minerals. White is the prevalent color in this collection, stained variously with iron.

5. The quartz being in crystalline condition is not a sign of its containing no gold. See No. 12.

6. The visibility of gold is worth nil for Nos. 1, 5 and 8, are rich in gold. It has recently been stated that assayers are of no use. We are told we must be able to see and judge by the eye as to whether a quartz reef will pay and that it is a poor tale to have it tested. However such statements are not worth much. If we see the gold and know that it extends in the quartz, we then know without assay that it will pay and its extraction may be at once begun with.

Assaying of fair samples is very necessary. There is not sufficient sight-evidence in many varieties of quartz to warrant gold being there in paying quantity. Even the rough amalgamation process, so commonly used by the miner is unreliable where the gold occurs with pyrites. Nor can the amalgamation process be successfully used for its extraction in such cases, *e.g.*, three samples of auriferous pyrites were operated upon not long ago.

(*a*) From Siberia which contained 100 grams to the ton.
(*b*) Venezuela ,, 300 ,,
(*c*) California ,, 150 ,,

The first yielded all its gold by amalgamation. The two others, both in the raw state and after roasting, yielded only insignificant quantities. From further experiment, it was inferred that the presence of antimony and arsenic prevent amalgamation.

The tailings of old mines are now being re-worked by the "Chlorine process" or by the still better method devised by Mr. W. A. Dixon. See "Directions for extracting gold, silver, and other metals from pyrites. *Proceedings of the Royal Society*, vol. 20."

Ceylon quartz is rather *too glassy* in appearance and from many localities is *destitute of metal* of any kind, or having caverns either empty or filled with earthy matter. The pyrites are of too brassy a nature. However, we have quartz partaking of the character of Nos. 6 and 16 in Hewaheta and Kamboda. A somewhat similar quartz to 10 and 15 occurs in Balangoda and the district around.

In the Nawalapitiya district, we have a quartz partaking of the nature of 11, 12, 13, but no metal is visible. The mineral galena, mispickel and blende have not been recorded up to the present time as occurring in this island.

Mr. Dixon, we know, has judged rightly in stating that the mere colour of quartz is no certain criterion of its value. We took with us to Melbourne a specimen of gold-bearing quartz from the Alpha Mine in Southern India, and, judging by what we had seen in Dewalah, we expected to find the specimens of Australian gold-bearing quartz sent to the Melbourne Exhibition full of pyrites and rusty coloured. Some such quartz we did find exhibited, but the leading specimens (some of them immense blocks) were pure white, shading away to grey. A person acquainted with only the surface quartz of Devalah would certainly never have suspected the existence of gold in pure white and occasionally crystalline quartz. The uneducated eye, therefore, is here at fault, but the merest tyro soon learns the value of "Black Jack," or blende as an indication of the presence of gold, equally with mundic (iron or arsenical pyrites) and galena. Blende, Mr. Dixon explains, is a sulphide of zinc, while galena is composed mainly of sulphide of lead; sometimes rich in sulphide of silver. We suspect that neither "black Jack" nor galena exist in Ceylon, any more than the special "Lower Silurian" slate formations so strongly insisted on in Victoria. But "mi-pickel," which Mr. Dixon describes as arsenical iron pyrites, ought surely to exist. The first great revolution in the search for gold was the discovery that hundreds and even thousands of feet below the alluvials of Mount Alexander, Bendigo, Ballarat, Arrarat, and other once rich but entirely or partially exhausted gold fields and underlying enormous masses of the basaltic rock known locally as "blue stone," vast stores of the precious metal lay hidden. It is found either *in situ* in the old quartz and slate formations, or washed into the channels of ancient rivers, sent underground, "where Alph the sacred river ran," by volcanic convulsions. Gold has been certainly found down to 2,000 feet, and, as a shaft at Stawell has penetrated to 3,000 feet and will probably go deeper, it is im-

possible yet to fix the lowest limit of underground finds. What with powerful rock borers and especially by means of the wonderful diamond drills capable of piercing at all angles, while cores are taken up and examined at every few feet of progress, shaft-sinking and gold mining generally is fast passing from a precarious lottery to a steadily profitable pursuit. The value and probable effect of the diamond drills cannot possibly be exaggerated. The next great revolution was the discovery that pyrites, which had been rejected as worthless, could, to a large extent, be utilized with great profit. Accordingly every important gold mine has now appliances for roasting and crushing pyrites. Through the courtesy of Mr. Thompson, the able manager of the Walhalla mine in Gippsland, probably the richest gold mine in the world, we were able to bring, amongst other specimens, a sample of pounded pyrites ready for the amalgamating process. On this Mr. Dixon will, doubtless, have something to say. The difficulty of dealing with pyrites is the large quantity of deadly fumes of arsenic evolved in the process of roasting. Tall chimneys, to carry those fumes for dispersal in the higher atmosphere, must be erected under heavy penalties, and the effect of the fumes on vegetation were very apparent on the side of a steep mountain, close to which rose the chimney of the great mine at Walhalla. Trees and grasses, within the influence of the fumes from the flue, were withered or dead. The Walhalla Valley, rich not in alluvial gold but in gold-bearing rocks, differs essentially from the valleys between or at the foot of low, rounded, water-worn hills at Castlemaine, Sandhurst, Ballarat and other places, where scores of miles of alluvial soil have been torn and turned over after a fashion which excites the astonishment of the traveller. We could not help asking if any approximate estimate had ever been attempted of the number of cubic feet of earthwork involved in all the digging and re-digging by Europeans, and the re-re-digging by Chinese over the gold fields of Victoria. Our friends only looked aghast at the idea of so utterly hopeless an attempt. Our own belief is that a girdle of railway round the globe would not be more than the equivalent. Next to the skeletons of a burnt forest in Australia, the most awfully desolate of scenes, is made up of the grave-like mounds scattered as thickly as leaves of Vallambrosa over a deserted gold-field. As the mountains stood round about Jerusalem, so do they stand round the gold valley of Walhalla—real mountains and not water-worn hills such as are seen near the alluvial gold fields which first made Victoria famous. From first to last 50 millions of ounces of gold have been taken out of the soil, worth 200 millions sterling. No wonder if at Ballarat and Sandhurst great towns arose, and a vast city on the shores of Hobson's bay, with the rapidity which is more a characteristic of dream and romance than of real life. Mr. Dixon notices that one nugget was found at Ballarat, which weighed 184 lb., and for which over £8,000 were paid. We do not know if he refers to "the Welcome Stranger," found (at Dunolly, however,) by two Cornish miners, just when one of them had been refused credit for a bag of flour and feared starvation for his family. The scene was soon changed, as will be seen by the following details taken from Sutherland's "Tales of the Gold Fields":—

Deeson plied his pick in some hard bricklike clay around the roots of an old tree, breaking up fresh earth and tearing away the grass from the surface of the ground. He aimed a blow at a clear space between two branches of the root; and the pick, instead of sinking into the ground, rebounded, as if it had struck upon quartz or granite. "Confound it!" he exclaimed; "I've broken my pick. I wish I had broken it, if it had only been over some nugget." A minute afterwards he called out to Oates, and told him to "come and see what this was." It was a mass of gold cropping several inches out of the ground like a boulder on a hill. As each successive portion of the nugget was disclosed to view, the men were lost in amazement at its enormous size. It was over a foot in length, and nearly the same in breadth. The weight was so great that it was difficult for the two men to move it. However, by dint of great exertion, they succeeded in carrying it down the hill to Deeson's cottage, where they commenced to inspect their wonderful treasure. It was so completely covered with black earth, and so tarnished in colour, that an inexperienced person might have supposed it to be merely a mass of auriferous earth or stone. But its weight at once dispelled all doubt on that point, for it was more than twice as heavy as a piece of iron of the same size.

Great was the rejoicing among Deeson's family. The wife piled up a huge fire, and Deeson placed the nugget on the top, while the rest of the family stood around watching the operation of reducing the mass to the semblance of gold. All through the Friday night Deeson sat up before the fire, burning the quartz which adhered to the nugget, and picking off all the dirt and débris. This was so rich that, on being washed in the puddling machine, it yielded ten pounds' weight of gold. Meanwhile Oates had procured a dray to convey the nugget to town, and on the Saturday morning the two men set off for Dunolly. It was a ten-mile walk; but many of the neighbours, having heard the news, followed the dray into the township. * * *

They stopped the dray at the door of the London Chartered Bank, while the crowd grew larger and larger.

Deeson now stepped into the bank, and, having requested to see the manager, he proceeded to open negotiations with him by asking, "How much do you think you would give for a lump of gold as big as your head?" The manager, thinking the digger was drunk, ordered him away, and requested his clerk to see him to the door. But catching sight of the crowd outside, he stepped out and looked into the cart. The tone of the negotiation was altered at once, and the two diggers were politely requested to enter.

When the nugget had been deposited on the floor of the banker's room, it was weighed, and the amount of pure gold was ascertained to be 2,268½ ounces, or nearly two hundredweight. Thus, being nearly 100 ounces heavier than the Welcome nugget of Ballarat, it was probably the largest piece of native gold ever found. Various accounts have been given of a still larger nugget having been discovered in Brazil over a hundred years ago. But this story rests on no good foundation, and even if it is based on fact, it has evidently been exaggerated. All the best authorities on the subject, therefore, set down the Welcome Stranger as the largest mass of gold ever discovered.

We doubt if any such mass of gold exists in the soil of Ceylon, if indeed "payable quartz" for stamping exists. No better aids to the solution of this question can possibly exist than the specimens from Ballarat with Mr. Dixon's notes on them.

We have, on this occasion, merely glanced at a few

salient points on the characteristics and history of a substance and a pursuit, round which cluster more of romance and vicissitude than is connected with any other material substance or human enterprize. The subject is practically inexhaustible, and we hope to return to it in future issues.

Since writing so far we have seen a letter addressed to the *Australasian* on "Gold and where to find it," by Mr. C. F. Nicholls, an educated and observant writer, who has been a practical gold miner. It commences thus :—

Fascinating as all inquiries are into the origin of things, none are more so than the investigation of the origin of metals, more especially that of gold. Writing from memory, and therefore not giving quotations, I may say that there is good authority for affirming that gold is as widel disseminated over the world as any other metal, if not more so. I have seen as fine and rich quartz specimens from Wales as any in Victoria. Gold has been found in the Wicklow mountains, Ireland, on the Duke of Sutherland's estate in Scotland; and Hungary, Austria, Spain, Russia, Mexico, California, and several other countries, not to speak of Africa, have or have had their gold-fields. Silver can be extracted from the ocean, and gold has been found in the roots of the violet and the vine, and sometimes traces have been found of it under such conditions as lead to the conclusion that it must have been in the form or conditiou of vapour.

When attention was drawn to gold about a quarter of a century ago by the operations of Australian diggers in the sands of the Maha Oya, at Nuwara Eliya and elsewhere, we republished a pamphlet by Professor Hopkins of Cambridge, in which the theory was propounded, not that gold was found *in* the roots of trees, but that the precious metals aggregated round the roots of trees and finally took the place of the roots, as particles of ordinary mineral matter replace wood in the so-called "petrifaction" process. This aggregation and replacement must be regarded as processes subsequent to the deposition of both quartz and gold from water (should that theory be tenable,) and subsequently also, perhaps, to the tearing, disintegrating and finally aggregative effects of floods. But we are now dealing with phenomena of comparatively modern dates in geological history and action. The mention by Mr. Nicholls of gold in a state of vapour reminds us of the theory of what we may call original deposition on our globe, and which recommends itself to our reception. We are justified by analogy in supposing that this planet was once what the sun seems to be now, a mass of gases gradually cooling and solidifying. The gases, in the case of our earth as of the sun, included those of the heaviest metals, gold amongst them. As the cooling and solidifying processes went on, it is to be presumed that the various metals agglomerated and settled in masses or strata, according to certain laws of affinity, attraction, magnetism, heat and pressure. The question then arises how much of the gold on the surface of our globe is in *situ*, as deposited during the cooling process, perhaps millions of ages back in time; or whether the whole of it has not been displaced by forces of fire and water: volcanic action and furious water floods; again to form and aggregate under the influence of magnetic and metamorphic agencies? The enquiry is not only curious in itself and in a purely scientific point of view. There is a practical aspect of the question: that of the artificial production of gold. The transmutation theories of the dark ages were deservedly laughed at, because they were not founded on a knowledge of the true laws of matter and the right application of those laws. But, looking at the advances made in the manufacture of rubies and even the diamond, he would be a bold man who ventured to assert that science may not yet discover an effectual and cheap mode of compelling the earth to release her stores of diffused gold, as well as inducing the sea to give up her wealth of silver. At present the problem is how to discover aggregations of gold in other minerals or rocks, in such quantities and conditions as to yield appreciable returns for the labour and cost of mining, crushing, amalgamating, etc.. Mr. Nicholls points out that but a small proportion of practical miners are able to give much help in soloving the problems at issue. Mr. Nicholls seems justified in his blame of the Victorian Government for undervaluing their own great staple. He writes :—

A reference to the Intercolonial Exhibition essay on mining and mineral statistics, 1866 and 1867, is worth any one's reading, who is interested in the subject, as it brings all the known information up to date under review, and suggests one great defect of the late Exhibition which, so far as it was possible in an essentially gold-mining country, kept that industry in the background, and did in no way help to add to the mining and mineral statistics of 1866-67. The mighty intellects occupied in turning us into a nation of farmers without capital and manufacturers without coal could afford to despise an industry that had made Victoria what it is, and employed and sustained, directly and indirectly, 60,000 or 70,000 families, producing four millions' worth of raw material, of which three millions was distributed in wages and payment for tools and machinery, and the balance in dividends. The essay referred to will show that there are many modes of the occurrence of gold that were not generally accepted, and, when we remember that geologists differ greatly on many points—take, for instance the doubts about granite; is it a primary rock or not? is it the production of water or fire? take basalt, agreeing that it is volcanic, was it mud, and did it crystallize, or was it molten lava?—who knows? Evan Hopkins says mud, recognized authorities say molten lava. It does not matter much, as either way it flowed out of the bowels of the earth and spread over plain and valley, thousands, probably millions of years ago, filling in the ancient creeks and rivers, covering table-land and mountain, and concealing from us of today the leads, and gutters, and golden lodes of not only a time before history began, but probably before man was. The immensity of time is one of the puzzles, the slowness of the processes, the difficulty of comprehension. Sir J. Lubbock tells us geologists must recast their theories, and base them on a solid world, and the latest theory of volcanic hills is that the bed rock is not thrust up, making a hill, but that the ashes and lava from the rent in the earth's surface are gradually piled up and rounded as we see here in many cases. But, as in most other things, nature does not work in one way only, and whilst in Mount Greenock we have a hill of that character referred to, so in Wombat-hill, Daylesford we probably have an instance of where the bed rock was raised, and the column of lava burst through the golden lead, and puzzled the miners for many a long day before they picked up the continuation on the opposite side of the solid pipe or column of basalt that had been the outflow of molten lava or overwhelming mud. Spring-hill, Creswick, may be another instance of the thrusting up of the bed rock, whilst Moorookyle and others on the Smeaton Plains may have the deep leads underneath them undisturbed. These facts or supposed facts lead to the inference that when we find quartz pebbles on or near these basaltic hills, as at Mount Hollowback, in the Bowling Forest estate, the volcanic

forces have burst through quartz drifts and thrown those pebbles out with the ashes, leading to the inference of the existence of probably auriferous leads in the immediate neighbourhood, and where we do not find these rounded quartz or any other, to the existence of deep ground under the hills.

The notice of volcanic forces bursting through quartz drifts and throwing pebbles out with volcanic ashes, reminds us of what we observed, during a journey with a gentleman who owns large possessions on the banks of the Goulburn river (a great wheat region) beyond Echuca, a Victorian border town on the great rive Murray. After driving over what appeared to be almost interminable park-like plains, on which timber enough was scattered to give pleasant shelter, we came at last to a rising ground, the manifest result of ancient volcanic action. After admiring the extensive view, which included a lake of waters collected in a volcanic depression, our attention was arrested by the curious mixture of bright fragments of quartz with the dark lavas. We said to our friend, who was talking of building a house on the eminence: "We are probably standing over a formation of quartz rich in gold." "Oh! for goodness' sake" exclaimed the fortunate possessor of 38,000 acres of fine, freehold property, "don't say a word about gold, or shoals of people will come in and tear my beautiful place into holes and heaps!" Our friend felt he had enough and he did not quite see with us that it was his duty to the colony to give it the benefit of such wealth as might be hidden in his soil. Those who know what the presence of miners on land involves, will not wonder at the objection of the gentleman in question. Mr. Nicholls takes the position that although, quartz is always associated with gold, there are many quartz reefs barren of gold. He writes:—

We have more barren quartz reefs than auriferous reefs, and as far as we know more quartz reefs that pay handsomely at shallow depths than at great depths. At present it seems as if about a thousand feet from grass is our limit to in most instances payable stone, and yet there is no sufficient reason given to prove that depth has anything to do with the presence of gold in paying quantities or not, and if quartz is the matrix of gold, why should it not continue if our quartz reefs do, as is well known that they do in several districts, to unknown depths? Gold has been found in granite, in diorite, sandstone, in slate, and in basalt. May it not be true that our silurian rocks are impregnated with gold more or less, and that though under special circumstances there is an accumulation of the metal in occasional quartz reefs and dykes (as at Wood's Point), the denudation of immense areas of bed rock for countless ages may have had much to do with the formation of our alluvial leads, helped by the breaking down of rich quartz reefs, but not entirely dependent upon them. The processes of nature are not only varied but repeated over an extension of time we cannot realize, and under the same as well as different conditions; hence the many puzzling facts that no one theory accounts for. I have seen nuggets taken from the Hard-hills, Buninyong, without a particle of quartz, looking as if they had been poured out of a ladle in a molten state on to the bed rock. The last gold I obtained was a working miner at the head of Cobbler's Gully, Cresick, consisted of a run of coarse gold and nuggets, looking as if they had undergone enormous pressure and grindin force, found on the shoulder of the bed rock, and a few feet deeper, packed against a quartz reef that we could see no gold in, was 3ft. of washdirt containing nothing but fine gold, as if it had dropped out of a quartz reef a few days before we discovered it. The coarse gold came from a yellow bed rock, the other rested on a white pipeclay gutter, and crossing this gutter were several bands of hard greasy pipeclay of an inch or two in width carrying a good deal of gold. Here were three distinct deposits of gold all within a few feet of each other. Is there any theory that accounts for the facts? I have taken out of the bed of the saltwater river at Gisborne and other places large flat pebbles that have in a single pebble contained a perfect miniature system of the five Clunes quartz reefs, and other pebbles showing in miniature quartz reefs of many different kinds. What are we to understand by this? Some of my scientific friends may explain it. I can only record the facts. At Creswick and Ararat, with all the enormous amount of alluvial gold taken out I hardly know of a qartz reef that is paying expenses. As Artmus Ward might say, Why is this thus?

What we do know amounts to this. So far as quartz reefs are concened, they may last to any depth and they may run out at any depth, both quartz and gold, or the quartz may continue and the gold give out, but when the quartz runs out the gold never continues. Some quartz reefs run with the strata and some across the combs of the bed rock. Some thin out at all sorts of depths, and some make again and some do not. Some continue well defined to great depths, but the gold runs out. They all vary in yield, but some continue to pay and some do not In the upper silurian bed rocks we have, as a rule, small but rich reefs, with some notable exceptions, like the long Tunnel Reef, Walhalla; and in the lower silurian, as on Ballarat, the main body of the stone is poor and the spurs from it are rich, and so on *ad infinitum*, which to some extent justifies the practical miner, who says of gold, "Where it is there it is, and you have to work to get it," but we may do so with all the lights of ascertained fact, or go groping about here and anywhere in a costly and expensive bewilderment.

He goes on to say that the unknown may be inferred from the known; that there are belts of ascertained auriferous country and the richest and longest continued lines *run north and south*. Mr. Nicholl states:—

Whether gold travels far or not I think depends upon the forces brought to bear upon it. If the forces are strong enough to rouge out the bed rock the fine gold will travel with the clay and *debris* as long as that force continues. I have seem a flood at Clunes that carried a twenty pound lump of basalt rock half a mile, and that washed away a heap of puddled washdirt, but did not carry the gold fifty yards. As to alluvial deposits, I have found payable gold in the grass and black soil, and no payable quartz reef in the neighbourhood; I have seen gold in the black clay in Melbourne on the top of the basalt, but what we know is that the east and west runs of gold pay out; that the north and south runs of gold continue apparently so long as they twist and turn within the area of one or more belts of auriferous country, as the Golden Point lead did and as the Creswick, Kingston, and Smeaton leads are now doing.

Wherever gold is found, the lines north and south of it should be followed. The conclusion is startling, and will, we suppose, be disputed. It runs thus:—

In conclusion, permit me to say that all reports based upon the yield of gold per ton are illusive unless the cost of obtaining the gold is stated. Returns from Anderson's Creek, Diamond Creek, Gipps Land, and Reedy Creek would surpass anything from the neighbouring colonies if compiled in the same way, but "distance lends enchantment to the view." There is one test that may fairly be applied as between Victoria and any other colony. Let the investor ascertain how many dividend-paying companies there are in Tasmania and New South Wales, or (what is the same ithing) the percentage of profit on the total investment in each colony, and I do not hesitate to say that whilst in Victoria we can show a profit of sixty per cent. upon our total expenditure for 1881, that the neighbouring colonies cannot show any profit whatever on the total expenditure for the past year.

Our own opinion is that, in the other Australian colonies as well as the golden colony, *par excellence*, Victoria, the use of the diamond drills will develope mineral wealth rich beyond experience or even imagination.

As regards Ceylon, the question is: have leads of auriferous quartz yet been discovered, rich enough to justify the introduction and use of machinery, for sinking shafts, including not only ordinary borers, but that true "divining rod," the diamond drill? The presence of one in Ceylon might give the country Artesian wells, where water is wanted, even if payable gold reefs failed to be discovered.

Artificial Increase of Quinine.—We call attention to the advertisement in our daily paper, in which Mr. Schrottky expresses his readiness to increase, artificially, the value of cinchona bark about to be cut down. We understand that the chemical inoculation of the living bark (on succirubra trees) has, in some of the experiments, raised the analysis by from 25 to 50 per cent of the previously existing percentage of quinine.

Economic Products in India.—We have to acknowledge the receipt, from the Director of the Department of Agriculture and Commerce, N. W. P. and Oudh, of a copy of Part V of "Notes on the Economic Products of the North-western Provinces," by Mr. E. T. Atkinson, B. A., F. R. G. S., of the Bengal C. S. This part treats of gourds; vegetables; spices and condiments; greens; fruits, cultivated and wild; and uncultivated edible products. Prefixed are a general index, a botanical index, and an index of Hindi terms.

De Caen's Patent Cinchona Branch and Twig Machine.—Messrs. J. Walker & Co., of Kandy, wrote to us on the 3rd instant:- "We have tried a sample machine at our works today and find it works admirably. The machine is simple, portable and very strong; it is capable of turning out more than 400 lb. of wet bark per day under favourable circumstances, but we give 400 lb. as a fair average. There are no knives, but tapering rollers are employed to suit the various thickness of twig and branch. The machine promises to be a most valuable invention, rendering the harvesting of both possible and profitable."

Caju Wine.—In a notice of the recent exhibition of Brazil "Nacional" manufactures, we find the following notice, and we should like to know if wine from the "kaju pulan" has ever been made in Ceylon:—"Of caju and other wines from native fruits there are several agreeable samples which would lead to the belief that a large trade might be done in them, but the unaccountably high price, considering the cheapness and abundance of the fruit, must militate strongly against the generalization of an article credited rightly or wrongly with valuable medicinal properties." —*Brazil and River Plate Mail.*

Jaffna.—Our trade in tobacco with the Galle market is large, and extensive. Traders always seek the service of the steamers to have a good supply sent there periodically, but, during the last two months, there is a stand still in the trade. People can hardly realize the money that is invested in the trade. The tobacco now in hand, both here and at Galle, is rotting in store for want of purchasers. It is hoped that the trade will renew when the new season's tobacco comes into the market in April or May next. We are glad to find that we have a good market for the surplus produce of this commodity at Colombo, Galle and Batticaloa. A large consignment for Batticaloa shipped last time was overcarried, the "Serendib" not being able to discharge cargo at Batticaloa owing to bad weather. Chilly, instead of being left to rot for want of buyers, or being sold almost for a song, fetches now a good price, and is being shipped daily to Colombo. We presume that Tuticorin, from which place Colombo generally receives large supplies, has failed this year to supply that market.—*Cor.* "Jaffna Patriot."

Discriminating Charge in the United States on Ceylon and East India Coffee.—Although coffee is admitted into the United States free of duty, the present tariff laws impose 10 per cent upon all Ceylon or East Indian coffee if shipped from any country west of the Cape of Good Hope.—*Rio News.*

"Fiber."—Mr. John C. Branner, who has been collecting specimens of vegetable fiber in Brazil for the Edison electric light during the past year, left Pará for New York on the 10th ultimo. Mr. Branner had travelled over a very large portion of the country and had made extensive and valuable collections of fiber. As the value of these can only be determined by long and careful experiment, it will probably be sometime before the results of this exploration are published.—*Rio News.* [It is surely a new idea that vast stores of "fiber" (which we English still spell fibre) should be required for the electric light. Why?—Ed. C. O.]

Florida.—Mr. Hamilton Disston, of Philadelphia, has sold 2 000,000 of the 4,000.000 acres of land he purchased in Florida about a year ago. The negotiations began last summer, when an agent was sent to Europe to find a market for the lands. Sir Edward J. Reed, member of Parliament, who is a representative of the purchasers, is a wealthy Englishman who has large interests in America, and who is engaged in building the Atlantic and Gulf Coast and West India Transit railway, which runs from Fernandina to Cedar Keys in Florida. This route has branches from Waldo running south to Osceola, and is being rapidly pushed to Tama Bay and Charlotte harbor. Its course is through a great portion of the Disston purchase, and it must eventually add largely to the value of the land. Sir Edward J. Reed was Mr. Disston's competitor for the land at the time of the original purchase. Sir Edward has associated with himself Dr. Jacobus Wertheim, of Amsterdam, and other capitalists of Holland, who were interested in the bond of the Florida railroads and other American securities of like nature, and a syndicate was thus formed to buy half of Mr. Disston's purchase. The lands of Mr. Disston, which he reserves the right to select from the whole, and also those of the European capitalists, will now be offered for sale to immigrants.

Insect Pests.—A planter in Kurunegala writes:—"I enclose a few specimens of a poochi which has killed several cocoa trees on this estate and appears to be spreading. I should be very much obliged if you could tell me what it is, and suggest a remedy. At present I have men on, killing them by hand, but am not very hopeful of catching them all." The specimens enclosed are the larvæ of a small moth belonging to the family Tincidæ. Westwood, in his "Modern Classification of Insects," vol. ii, page 409, says:—"In their preparatory states, these insects are variable in their habits; but their larvæ are generally naked or slightly hairy, many residing in portable cases [as those received from Kurunegala], formed of various materials, in which they undergo their transformations." Another correspondent wrote early last month:—"I am sending by today's tappal, under separate cover, a piece of cinchona stem with a fungus of some kind or other growing out of it. I hope it will reach you intact, and I should be glad to have your opinion as to how it got there. The plant it was on was about 3 feet high, and the fungus was situated about 6 in. from the top. The leaves of the plant were all drooping, but whether from the effects of the fungus or canker (which it appeared to have) I cannot say." The cinchona stem was sent to Dr. Trimen about three weeks ago, but he did not get it until last week. He writes:—"I do not know what the dried-up object on the cinchona twig may be, but I scarcely think a fungus; one cannot now decide.' Our correspondent should send us a fresh specimen.

Correspondence.

To the Editor of the Ceylon Observer.

SLAVERY IN BRAZIL:—No. IV.

Dollar, N. B., 19th Jany. 1882.

Gentlemen,—I said the decrease by the law of 1871 was 2½ per cent. I mean 2½ per annum for the last ten years, during which time there has been only two distributions of the Emancipation Fund, in 1875 and 1880. The amount set apart for these was 8 128·612$309—say £800,000 English money—in ten years

Before we go more into figures let us see what this law is. Let us make ourselves acquainted with the provisions of the law before we decide to abuse the administrators of it. Here then is a rough summary of law, No. 2040 of 28th Sept. 1871:—

Art 1. Children of slave mother born after date of law to be free. Master has to rear the children and he can avail himself of their services until the minors are 21 years old. If the master likes, he can hand over the child at eight years of age to Government and receive a bond for $600 (£60) bearing interest at 6 per cent per annum to become extinct in thirty years. (In either case the minor is a slave and lives and works among slaves until he is twenty-one years).

do. 2. Government may deliver over the minors—whom slave-owners do not care to keep after they are eight years—to authorized Associations to use their services until they (the minors) are twenty-one years old.

do. 3. An emancipation fund is to be formed and so many slaves are to be liberated annually.

do. 4. A slave can save money and call it his own, can receive gifts, legacies and inheritances; and his master can consent to his receiving money for work done to a third party (such as working for some one on Sunday or any time his master may not require him).

do. 5. Emancipation Societies may be formed, but must be under the Judge of Orphans.

do. 6. Declares free slaves belonging to the crown slaves belonging to intestate estates, slaves abandoned by their masters, slaves liberated under this law; but all to be under Government inspection for five years.

do. 7. A slave may open a case in court for his liberty. The process will be summary, and an *ex-officio* appeal made to higher court, if the decision is against liberty. (This is rather an impossible contingency.)

do. 8. Enforces registration of name, sex, condition, aptitude for labour, and lineage, if known.

do. 9. Government may impose fines and simple imprisonment in the carrying out of these regulations.

10. *do.* All dispositions to the contrary hereby revoked. Regulations were made for carrying out the provisions of the law and an imperial decree issued for their enforcement.

It will be seen that next in importance to the declaring free the child of the slave-mother, after he is twenty one years, is that referring to the liberation of so many slaves each year by means of an emancipation fund.

The emancipation fund shall be derived:—

1. From a tax on slaves.
2. From taxes on the transfer of slave property.
3. From the proceeds of six annual lotteries, to be drawn in the capital of the Empire, and a tenth part of all lotteries conceded by the Government.
4. From fines imposed under this law.
5. From funds set apart in the General Provincial and Municipal budgets.
6. From subscriptions, gifts, and legacies for this purpose. The rules laid down for the distribution of the fund are a little complicated, which has made it quite impossible to arrive at the exact number of people benefited by the fund by the two distributions. Remark that there have been only *two* instead of *ten*, as the law provides. Each province and each district decides as to the manumissions according to the quota disposable from the emancipation fund.

Class I. Families have precedence of
Class II. Individuals.

Families are arranged in the following order:—

1st—Married people, slaves of different masters.
2nd—Married persons, who have children born under this law and under eight years.
3rd—Married persons who have children under 21 years.
4th—Married persons who have children minors and slaves.
5th—Mothers having children minors and slaves.
6th—Married persons without children.

For individuals the orders are:—

1st—A mother or father with free children.
2nd—Those from 12 to 50 years of age, commencing at the youngest in the feminine sex and the oldest in the masculine sex.

In the order of emancipation of both families and individuals, those will be preferred

First: who can either himself or through some one else enter with a quota towards his liberation;

Second: those who, in the opinion of their masters are most deserving. If the conditions are equal, it will be decided by lot

We thus see that, as far as the frame-work of the law stands, no objection can be offered to it.

The emancipation fund, if it were large enough, could do a great deal; but it is small and is not distributed annually, as intended by the law. Moreover a quarter of it has been kept from the special object of emancipation and placed to the credit of the general revenue on the paltry excuse that the Government has to provide establishments for the children of slave-mothers. Two years have elapsed, during which the slave-owners could have sent the children they did not wish to retain and use the service of during their minority, but none were offered to the Government. In the present state of the labour market, fourteen years' work of a slave is of more value to a coffee and sugar planter than a payment of a paltry seventy-two shillings a year for thirty years.

The total slave population, according to the census of 1st August 1872, one year after the passing of the slave law, was given at 1,510,806. Several parishes had not given in their returns, and altogether this general registration was considered defective. The law, however, provided for a special registration up to 30th Sept. 1873, and all slaves who were not registered before that date were declared free. These returns were given as complete from all the provinces except four—Parà, Pernambuco, Miras Geraes, and Goyaz. The total registered at that date—Sept. 1873—are given 1,431,300. This is, no doubt, very defective, but, if the law is properly carried out, those not included in this number must be free. As we have not heard of the freeing of any of those illegally held as slaves under the law of 1831 and other laws confirming it, we need not look for the rigid enforcing of this law.

Several attempts have been made since then to get a proper census taken, and a return was got in 1878 from eight of the provinces and the capital. Twelve provinces gave incomplete returns, or gave numbers calculated from the returns of 1875 and 1876. From these the slave population was set down at 1,419,168 to end of 1878, or only 12,000, less than that given to Sept. 1873. From twelve of the provinces and the capital that had recenely sent complete returns, we find the changes in the slave population from 1873 to 1878—five years—registered:—Sept. 18 3, 683,497

Slave population Dec. 1878 611,057

Relative decrease 72,440

But the authority from which I take these gives emancipated	.. ...	24,654
Died	... ...	60,996
Absolute decrease	...	85,647

The difference between *relative* and *absolute* decrease is shown thus :—

Registered arrivals	...	86,274
Registered departures	...	73,067
Difference	..	13,207

The relative annual decrease, counting 5½ years, is only 2 per cent, and the absolute annual decrease is 2½ per cent.

Death emancipates nearly three times as many as the emancipation fund, but for all that the death-rate is low, only 17 per thousand per annum. At the above rate the benefits of the emancipation fund can reach only 7 per thousand annually.

A. SCOTT-BLACKLAW.

LIBERIAN COFFEE IN NEW GALWAY.

New Galway, Feb. 27th, 1882.

Dear Sir,—With reference to your notice of the Liberian coffee in this district and request for further particulars, I may state that four of the six plants given by you to Mr. Cotton are doing fairly well. One of them produced several blossoms about five months ago, but, of the resulting "pingee," only one bids fair to arrive at maturity, the rest having been knocked off, or probably rotted, during the abnormally wet weather we have had during the past five or six months.

The four surviving plants all look well, but have not made very rapid growth, being now only about 3 feet high, though, perhaps, the fact of their being surrounded by Arabian coffee may, in some measure, be accountable for their slowness of growth. They are in a comparatively sheltered hollow amongst the limestone rocks, which, as you are aware, are very plentiful in this locality, and get all the benefit of the morning sun. I cannot speak with certainty as to the elevation, but, judging from the Wilson's Bungalow resthouse, distant by the road about three miles, I should say it is fully 4,300 feet. Particulars as to temperature and rainfall I regret being unable to furnish, as no record has been kept.

I tried several cocoa plants in the same vicinity, but none of them succeeded. Can you give me information about the wax-yielding tree of Brazil, seed of which was lately advertized? [See *Observer* of 27th February.—Ed. C. O.] I would suggest that Government be asked to open an experimental nursery in the low-lying land between Fort McDonald and Wilson's Bungalow. A few acres under the supervision of the Hakgalla superintendent would suffice and need not cost much. This is the more desirable, as the elevation and position of the present gardens render them unsuitable for such experiments.

—Yours faithfully, ARTHUR J. KELLOW.

COCOA (CACAO) CURING FOR MARKET.

Matale, Feb. 28th.

Dear Sir,—The *first* stage of cocoa curing has already been fully described, (see page 810, where the process described is that observed on Pallakelly estate, Dumbara,) and all who have carried out Mr Vollar's instructions are, I believe, satisfied with the result.

The *second*, and not less important is the *drying*. In bright clear weather, *that* is, of course, a simple matter; and I have adopted Mr. Vollar's recommendation of 1½ to 2 days' exposure to the sun, on mats immediately after washing, with success.

But the bright sunny days, take all the year round, are *few*, and the cocoa beans won't keep wet in the cistern for days (?) like parchment coffee: or with only the water dried off in heaps turned over frequently in the store. And the certain consequence of failure to dry *thoroughly* after washing is MILDEW, which is simply fatal to the sample—if a paying price is looked for! How is cocoa to be dried in wet weather is *the important question*.

Pallikelle has settled that by the alteration of a coffee store into a "clerihew" with heated air if requisite (and it probably is requisite when the air is surcharged with moisture) worked by the steam-engine already on the spot. Others can utilize the water-wheel used in olden days to pulp coffee.

Yet the *expense* of a "clerihew" store: the air-tight chamber, fans, belts, stove and water-wheel (or steam engine or turbine) is *considerable*, and would be needed on a new cocoa estate, *i. e.*, one not forming part of an old coffee estate. And some of these items even on an old coffee estate, where the "clerihew" process was not employed, which it rarely was at the elevation at which cocoa can be grown.

Is there any way to lessen this pretty heavy outlay? I am inclined to think that there is, and that a modification, if modification be needed, of the "Sirocco" tea drying stove, and trays, will give us exactly what we want. Perhaps, Mr. Shand would be kind enough to cure a bag or two of cocoa *pro bono publico*, and give us the result?

With a "Sirocco," to be used *only* in damp weather as a substitute for 1½ or 2 days sun drying, there is only the cost of the stove itself, say R800, and providing a supply of fuel, which could be secured during the interval between the crops. In fact, where a steam engine is employed to drive a "clerihew" fan, the supply of fuel would be much larger, I believe, to say nothing of what was required for the clerihew stove.

A *lower temperature* for a *longer time* would have to be substituted, in the case of cocoa, for the brisk heat to which the tea in its last stage must be subjected; but *that*, I presume, having never seen the "Sirocco" at work, is an easily managed affair and a mere matter of supply of fuel and regulating the draft.—Yours, etc.,

KAKAO.

CINCHONA HYBRIDITY:—"PUBESCENS."

NEW PRODUCTS:—*Cera Rubber*.

Dear Sir,—I have been very much interested in the various subjects before the Ceylon planting public of late, more especially what has been recently written relating to *Cinchona* Pubescens. The subject of hybridity among cinchonas is surely far too much a settled question among practical men to require any further doubts or comments upon the fact that it does hybridize. If any one be a doubter still, it would be well for him to reserve his opinion until he has tried a very simple experiment. All that is requisite is simply to personally gather some seed from *succirubra* trees out of a field where this variety grows alone, and to *personally* gather another quantity from a field where *officinalis* and *succirubra* are growing interspersed with each other. From one he will obtain few or no hybrids; from the other a large number—indeed a very large percentage. I feel so confident of this conclusion, founded as it is on my own experiments and from my experience in many ways; and, among other facts, I may say I have often been able to distinguish from plants growing from their external character the source from whence the seed was obtained. I know of clearings of Succirubra in Ceylon with few hybrids up in them, and of others with a large number, and, upon investigating parent plants, I have found that invariably too [illegible] have resulted, or otherwise, always according to the proximity of *officinalis* to the parent [illegible] trees and

vice versa. Mr. Moens referring to Mr. Cross was quite right in saying that the opinion of a cinchona grower in this, and many other respects, was of far more value than of a cinchona collector. In my own mind I have proved the question beyond doubt by the above experiments, and, if these are not conclusive, I maintain that no observation of the plant in nature, or a casual though careful inspection of it cultivated, can lead to more convincing evidence. One has naturally a very great respect for science and for scientific men, but they are very likely to be wrong, especially if occupied with any of the natural sciences in their wider relations, when they suddenly express their opinions on plants removed from their natural conditions and placed under the modelling hand of man, in whose hands most of our cultivated plants have become like the clay in the hands of the potter: still more so, when the habits of these plants have become almost the sole study and care of the cultivator himself and his daily bread depended upon their successful growth. Nor do I see any reason why, if steadily persisted in, the knowledge of the cultivator should not become as scientific and his observation just as keen and accurate as those of the so-called scientist.

There has also been much comment upon the relative merits of *succirubra*, *pubescens*, *Uritusinga*, *and officinalis*, and much confusing discussion on nomenclature; and upon this latter even the wise men differ largely. I care not for the specific name as it accords with collectors, except simply as an identification of the various useful kinds meant, any more than I do of the contradictory statements of the early fathers on church government, and look for just as much unanimity in the one as the other. Most planters, who have given much time to cinchona, have noticed the intermediate character of *pubescens* between *succirubra* and *officinalis*, and many will have noticed the result of seed from unmixed and mixed clearings, and will form their own opinion on hybridity and whether *pubescens* be a hybrid or not.

To return to the practical and useful: I have frequently had *pubescens* bark analyzed, and generally have sent some *succirubra* bark along with it gathered from adjacent trees, for my aim has always been relative, which, in my mind, appears the only practical way. I,—Without exception the quantity of Quinine Sulphas has always been one hundred per cent greater in *pubescens* than in *succ rubra* and rarely inferior to ordinary crown bark. II,—The yield of bark per tree of *pubescens* has also always been equal to *succirubra* and consequently much greater than crown bark.

I am now having more analyses made, and, as they are to represent the average quality of bark from several of each kind of cinchona I possess, taken from many trees of the same species, so as to shew what may be expected from a whole field rather than a tree, I look to rather conclusive results, and the particulars I shall be glad to send you later on.

It is very satisfactory to read that Messrs. W. Smith, Christy and others have true Ledgers in flower and seed, of which it is well to know that at last we have some accurate data to go upon; for I maintain irrespective of the names of the varieties that analysis is the only true test of what is valuable from a planter's standpoint.

Mr. Eliot Howard has very kindly shewn me over his exceedingly valuable collections, and has given me important information and advice on the deposition of the akaloids, which was quite new to me in connection with this interesting plant, of which I shall write more anon.

From the wide extension of cinchona cultivation all over the world, I should strongly advise Ceylon men not to run that to death as they previously did coffee, but to seek for other useful plants for their poorer ridges and exhausted lands. Before I left Ceylon I saw Ceara rubber growing well in Colombo cabook soil and rushing up vigorously in Rangala, at an altitude of 4,000 feet above the sea. The seed will grow if sowed at stake, if the precaution has been taken to soak it and file or grind its edges before sowing. A better plan is to raise it in baskets, the plants being put out when six inches high, which they reach in about a month's time. After this it will rapidly become a tree; so that, if planted from 15 to 20 feet apart, it can take full care of itself irrespectivr of weeding, after it is 4 months old. What a difference Kadugannawa would present now had this tree been planted in the declining coffee, for it appears to grow well in very indifferent and exhausted soil. The time too is not far distant when rubber will be in very great demand, for the trees from which supplies are now being derived are being destroyed by the ruthless manner of collection.

NEW PRODUCTS.

CHAMPION RED BARK CINCHONA TREES IN CEYLON, 14 YEARS' OLD, ON GLENCAIRN, DIKOYA, GIVING 112 LB. DRY BARK.

Kandy, 6th March 1882.

Dear Sir,—What will Mr. Campbell of Kelburne and Mr. Lavie of Glenalpine say to the following?

Mr. Fowke, of Glencairn estate in Dikoya, uprooted a succirubra tree about three weeks ago. and gives the subjo ned particulars of its dimensions and the quantity of bark harvested. I may mention that the tree was probably 13 or 14 years old and bad a single stem only.

Height, 42 feet.

Girth at lowest part of stem, 4 feet 6 iuches; girth six feet above ground, 3 feet 3 inches.

	Wet bark.		*Dry bark.*
Stem quill	142lb.	...	70 lb.
Root	92 lb.	...	30 lb.
Branch	40 lb.	...	12 lb.
	274 lb.		112 lb.

E. S. G.

[Some of the pieces ought to make splendid show bark for druggists, for which, perhaps, as much as 7s to 10s per lb. may be paid.—Ed.]

CASTOR OIL PLANTS AND INSECTS.

Dimbula, 6th March 1882.

Dear Sir,—The paragraph, in a recent issue of the *Ceylon Observer*, contained information which, as regards Ceylon, was certainly not accurate. The cutting taken from a French paper has, perhaps, been wrongly translated.

So far from the castor oil plant being "an excellent remedy against flies," I find it peculiarly subject to the attacks of insects. I know of four kinds of larvæ that feed on its leaves; many species of *diptera* may be found (uninjured) on its flowers, and I have had more than 2,000 castor oil plants of both varieties, entirely destroyed by aphides.—Yours faithfully,

B.

[The paragraph was quoted from an English paper and we are not responsible for the translation.—Ed.]

THE VALUE OF SULPHATE OF QUININE:—A CORRECTION.

March 7th, 1882.

Dear Sir,—In your issue of 4th instant, in the article on Jamaica Barks by Howard, there is a footnote signed D. M., stating that value per unit of sulphate of quinine is 1/9. This is not correct, and is misleading to people valuing their bark.

The cost of manufacture must be taken into account, and this is about 30/ per lb.; so that the approximate value at present price, of quinine sulphate is about 1/3 per unit.—Yours faithfully,

Q.

THE HYBRIDITY OF CINCHONAS.

Rockhampton, Rapatale, March 7th.

Dear Sir,—I read with great interest "New Product's" letter, and your article on "The Hybridity of Cinchonas," in your issue of the 4th instant; and, as I consider it every planter's duty to add to the accumulation of facts, in reference to tropical agriculture, whenever any crop up, during his daily search for cause or effect, I place the following facts at your disposal.

On this estate there are "Succirubra" trees, "C. Condaminea" approaching "C. Uritusinga" and "C. Officinalis" about medium "Bonplandiana" growing side by side, about 11 years of age. These trees were planted along the edge of the coffee about a chain apart, forming a kind of boundary there are only some 300 or 400 of them: there not hybrids amongst them, at least not of the Robusta variety.

I have taken seed from the succirubra trees and sown it, and the result has been, on every occasion, succirubra plants.

I have sold some 40 lb. of succirubra seed. I never heard of its turning out anything but succirubra plants.

On the other hand, the seed from the Condaminea and Bonplandiana varieties has never produced plants like the trees from which the seed was taken, but produced hybrids, the greater majority being Pata de Galinazo, a few having a somewhat Succirubra appearance.

There are some young, self-grown "Robusta" growing amongst the Succirubra and Condaminea trees, and I have only noticed seed on one, for the first time this year. My experience as regards the seeds spoken of above commenced in 1878.—I am, dear sir, yours faithfully, H. V. MARGARY.

Florida Notes on Sorghum.—The amber is too small to be of any value for syrup, growing only five or six feet high and very slender, but it makes excellent forage, producing three crops of full size in one season from one planting. The Chinese is much larger, growing from eight to ten feet high and producing more and better seed than either of the other varieties, but it is not equal to Honduras for syrup. The Honduras is a very large and late variety of sorghum. On rich land it will grow from fifteen feet high. It not only makes more syrup to the acre than the other varieties, but syrup of a better quality.—*Florida Agriculturist.*

Give Trees Room.—A Petaluma man tells the *Courier*: "When I first set out my orchard I set my trees 16½ feet apart each way. After the trees came to maturity, the fruit began to deteriorate; it was not so good nor abundant and the trees became more or less diseased. Five years ago I began to thin my apple orchard by taking out one-half of the trees alternate in the rows so as to give them a space of 33 by 28 feet. The first year after making the change I did not perceive any difference, but the second year I got more than double the quantity of fruit that I formerly had from the same ground with all the trees standing, and of better quality. It is my judgment that standard pear and apple trees should not stand nearer than 33 feet apart each way after they get to be 15 years old. Other kinds of fruit trees should be planted from 20 to 30 feet apart. I had about the same experience with my vineyard. I first set out my vines 6 feet apart each way. After the vines became about 12 years old the fruit was of inferior quality and the yield small. I then commenced thinning them by digging up every third row; finally I dug up three-fourths of them until I made them stand 18 by 6 feet apart."—*Australasian.*

The Importation of Chicory and Coffee.—In connection with a question asked in the House of Commons last session by Mr. Barran, M.P., that gentleman has received from the Board of Trade a communication stating that the Government have now decided to allow the importation of coffee mixed with chicory, which was formerly forbidden. The conditions under which the same mixture may be exported have now been extended.—*Daily News.*

Cinchona.—In March, 1866, General Morin sent out seeds furnished by Sir J. Hooker, Kew, to Dr. Vinson and his son at Réunion, and in August, 1879, there were 5,000 plants of 1 to 6 metres in height and 25,000 "boutures" fit for transplanting. In view of the large quantity of quinine required in France, it is intended to essay the cultivation in Algeria. In 1878 nearly 3¾ million pounds of quinine, valued at over £35,600, was imported into France. There are in Algeria, in the region of the Sahel, certain territories which appear to be favourable to the culture of the cinchonas. The success which has attended the English and Dutch efforts in the East appear to give encouragement to the attempts.—*Journal of Applied Science.*

Agricultural Experiment in the Bellary District.—Mr. A. Sabapathy Mudaliyar, writes to us from Bellary:—"With reference to Dr. Cornish's letter, published in your issue of the 20th ultimo, regarding my experiments in cotton planting after ploughing with European ploughs and manuring with poudrette, I enclose you copy of a letter addressed to the Collector of Bellary for such notice as you may think necessary. The letter will give you some notion of what I have done, and what I am proposing to do. It will also show you how little help the Board of Revenue are disposed to afford persons willing to enter upon agricultural pursuits with improved implements and a more rational system of culture than exists at present. The result of my venture so far has been very encouraging. During my inspection last week and this I found the cotton crops on my lands in very fine condition, in spite of a deficiency of rainfall. I think I may fairly estimate the outturn of my crops at 200 per cent more than the probable outturn of the lands that have not been ploughed with the English plough, nor manured."—*Madras Weekly Mail.*

Queensland Timber.—In the jungles on the east coast of Cape York Peninsula much valuable timber exists, especially the highly prized red cedar (*Cedrela Australis*, Mueller) and bands of lumberers penetrate their gloomy recesses for the purpose of felling the trees and rafting the logs for export. It is calculated that from two of the rivers, known as the Mossman and Daintree, four million feet of cedar had been exported between November, 1874, and April, 1878, and that three million feet were at the last named date lying ready for shipment, besides another lot of half-a-million feet at the Johnstone river. The market value of cedar in the log is from 35s. to 40s. per 100 feet in Melbourne. The market value in Brisbane was stated at the Queensland Exhibition of 1878 to be £7 10s. to £8 10s. per 1,000 superficial feet. The value of this minor industry therefore can easily be calculated. This tree is a mere variety of the Singapore cedar (*Cedrela Toona*, Roxburgh), which ascends the Himalayas to 8,000 feet. It attains a height of 200 feet and the foliage is deciduous. The Rev. Dr. Woolls noted in New South Wales trees so large as to yield 30,000 superficial feet of timber. This light, beautiful wood, easily worked and susceptible of high polish, is much in request for furniture, for the manufacture of pianofortes, for boat building and a variety of other work. The timber from the junction of the branches with the stem furnishes the choicest veneers. The bark contains a considerable quantity of tannin which produces a purplish leather.—*Journal of Applied Science.*

PLANTATION COMPANIES IN MAURITIUS.

We need not remind the Ceylon public how some twenty years ago the name and credit of Mauritius and its plantations were at the lowest ebb, and how it was sought to bolster up enterprize in that island by a Company which should bear in its title the name only of the then prosperous Coffee Colony. Times are changed to some purpose; for while here we are suffering from short crops, depression and scarcity of capital for most promising undertakings in new products, in Mauritius we read in the papers received today (13th March) of Plantation Companies declaring dividends of from 14 to 18 per cent per annum! These Companies were formed in the time of depression to buy and work estates, and now that the dark cloud has passed away, they are profiting by the foresight of their directors. There is a lesson in this for capitalists who are watching the present period of depression in Ceylon: the swing of the pendulum will assuredly be found before long to tend in the opposite direction, and returns of 14 per cent and over will then be as freely experienced here as in Mauritius.

RETAIL AUCTIONS OF INDIAN TEA.

Mincing-lane may be amused to learn that some of the Calcutta papers have been writing in favour of a Company it is proposed to form for the sale by auction, in all the chief towns in the United Kingdom, of Indian tea in packets to suit all pockets. It is not likely that these auctions would have the mixed attendance and support the promoters expect, but they may rely on a pretty big crowd of idlers and loafers every Saturday night, and among them a sprinkling of those decent folks who always attend sales in the hope of securing bargains. The venture would not, we believe, further the sale of Indian tea, nor repay the Company for their labour and outlay.—*H. and C. Mail.*

THE RICE CROPS AND SEASON IN INDIA.

(For the Week ending 7th March.)

There has been slight rain during the week in a few districts of Madras and Bengal, in two districts of the North-Western Provinces and Oudh, in three districts of the Punjab, and generally in Assam. General prospects continue much the same as in the preceding week. The spring crops promise a favourable harvest in the Punjab, and are being reaped in the Central Provinces and Bengal with a fair average outturn, excepting in a few places in the latter Province. In the North-Western Provinces and Oudh the yield on unirrigated lands in the central tract will probably be light. In the Bombay Presidency the rabi harvest has been completed in some districts and is still progressing in others, as well as in Berar. In the Madras Presidency standing crops are in need of water in some parts. In Mysore the sugar-cane and vaisakh paddy, the only standing crops of importance, are suffering from scarcity of water, but prospects are reported to be generally fair, prices being steady and pasturage sufficient. No remarks seem necessary regarding other Provinces, and the Native States, except that scarcity of water is felt in the Nizam's Territories.

Madras.—No rain except in Ganjam, Tanjore, Madura, and Travancore; general prospects good.

Bombay.—Rabi harvest completed in some districts, in progress in others; scarcity of drinking water in parts of Dharwar continues; fever and cattle disease disappearing; prices generally steady.

Bengal.—The hot weather has now set in; the late rain has generally much improved prospects; rain is still much wanted in Rajshahiye and Cuttack; harvesting of the *rabi* and tobacco crops has commenced, generally with prospect of a fair average outturn, except in places where they suffered from previous want of rain; sugarcane is being cut and pressed with a good outturn; ploughing for autumn crops is in fair progress; sporadic cases of cholera and small-pox continue to be reported in some places; cholera is spreading in almost all the sub-divisions of Nuddea; cattle disease reported in places in the Orissa and Chota Nagpore Divisions.

N.-W. Provinces and Oudh.—Light rain has fallen in Gorakhpur and Moradabad; the crops are being cut, and prospects are on the whole good; although in Benares the outturn of wheat and barley is poor, and there has been some further injury from insects in Agra; prices have risen slightly in Gorakhpur and Lucknow, but have fallen in Allahabad and Kumaon, while in other districts they are stationary; cholera still lingers in Allahabad and South Gorakhpur, and small-pox in Moradabad and Kumaon, but the general health continues good; there is still some cattle disease in Kumaon.

Punjab.—Harvest prospects favourable; health good; prices fluctuating.

Central Provinces.—Weather warmer; *rabi* crops being reaped, fair outturn expected; small-pox reported from a few districts; cholera fast disappearing; public health good; prices remain stationary.—*Madras Mail.*

MR. STORCK'S REMEDY FOR COFFEE LEAF DISEASE, NEARLY IDENTICAL WITH THAT OF MR. SCHROTTKY.

The above is, we believe, the opinion which will be arrived at after reading Mr. Storck's paper in the *Gardener's Chronicle*.—only it must be remembered that Mr. Schrottky began his experiments with carbolic acid vapour on an extensive scale long before we had heard of Mr. Storck. To the local experimentalist undoubtedly belongs all the credit of priority, and the fact that he has, through a very little good, and a great deal of evil report patiently persevered in his work among our planters constitutes a strong claim on the esteem of this community. Not long ago an old planter, Mr. Wm. Sabonadiere, called for a special Government grant of money and a monopoly by patent to encourage Mr. Storck to visit and apply his remedy in Ceylon. The only reason why Mr. Schrottky has not got a patent a year old now, for his carbolic acid vapour process, is that after receiving the usual formal application and deposit of fees, the Government of Sir James Longden (while retaining the R350 paid in stamps and fees!!) threw out the application as inadmissible. We well remember the decisive way in which Mr. Schrottky after his return from Dolosbage at an early stage of his experiments, said if ever a practical cure for leaf disease is to be found it must be in the vapour of carbolic acid, and he has most consistently adhered to that belief, in the face of much adverse scientific criticism and no little ridicule from planters and merchants. Mr. Schrottky is now more than ever convinced that the leaf fungus must be dealt with as a noxious weed—a persistent and much injurious "white weed" which can be successfully combatted by continuous treatment all the year through, more particularly if the attack is begun in the dry season. In this opinion, Mr. Storck, if he were acquainted with the conditions of climate and of the planting enterprise in Ceylon, would no doubt fully agree, so far as we can judge from his paper to the *Chronicle* which is as follows:—

[We have received a lengthy communication from Mr. Storck (now resident in Fiji, and who was assistant to the

late Dr. Seeman in his mission to these islands) on the means for combating the leaf-disease Hemileia. Mr. Storck reviews the previous attempts that have been made, and then details his own method, which he claims to be effectual, and the principle of which is the diffusion through the plantations of carbolic acid vapour, injurious to the fungus. It is obvious that the success of the plant depends upon very many circumstances, which should indicate cautious experiment on a small scale before embarking on a large one, such as the depth to which the fungus penetrates, the state of the weather, the condition of the coffee-plant, the influence of the poisonous vapour upon it, &c. Should Mr. Storck's experiments prove in other hands as successful as according to his statements, supported by other testimony before us, they are in his own, he will prove a veritable benefactor, and should receive the reward of his public-spirited endeavours to remove a great scourge. It is obvious that the principle is applicable *mutatis mutandis* to the treatment of other plants affected with superficial moulds.—Ed.]

My own method of application, says Mr. Storck, is purely atmospherical, and for the benefit of the countries and planters suffering from the ravages of Hemileia vastatrix I will now give a description of it. In doing this I rely, as regards my rights of priority and proprietorship in an invention of great importance, upon that spirit of justice and fair play so generally obtaining in the scientific and planting world.

An acre of coffee land contains thirty-six centres of vaporisation formed by tin vessels to be mounted upon short sticks, and covered in a peculiar manner, to protect the contents from rain and rubbish, thereby preventing waste and undesirable dilution by rain of the fluid contents of the vessel. They consist of a mixture of carbolic acid and water in the proportion of from 3 to 10 per cent. of Calvert's best No. 5 acid, at the option of the operator. Any strength not exceeding 25 per cent. may be used, since nothing touches the plants or the soil, nor injures the tenderest young leaf or flower-bud. In starting the treatment I would recommend a first charge of 10 per cent. (5 per cent. is sufficient), and then a weekly supply of a density of 5 per cent., which will keep the strength of the fluid up to 3 per cent. for many months. An average labourer can in this manner attend to at least 50 acres per week. The first season's outlay per acre, including the first establishment of the system over an estate, will not reach £2 10s. per acre, and for any subsequent year it will not exceed £1. The present model of the vessel has an evaporating surface of 4 inches, but I am contemplating an improvement in it, which will better regulate evaporation, and do away with weekly supplies, while a farther reduction in the item of labour will be effected. The vessels, holding rather over half a pint, can be manufactured wholesale at 4d. each, and are so modelled as to allow of the closest packing, the two parts separately; they will last for many years.

After eleven months of immunity from leaf disease enjoyed by the trees treated and cured by me, and of a new nursery I had made in the meantime, a gang of labourers from the Upper Rewa carried infection back to the place. Among the subjects infected were two Liberian coffee trees, one among a cluster of five, and another some short distance off in a small plantation of forty, all just in full spike, and to my dismay I also found the nursery badly infected. As soon as I could get the materials I started my system of vaporisation (July 4th last). The two Liberian trees I simply furnished with a small bottle each, partly filled with my mixture of only 3 per cent., hung into the angle of the lowest branches. Both trees have now been perfectly free of the fungus for some weeks, and not a single one of their close neighbours has been infected. They prove to have been completely isolated by the treatment, not a single spore living to reach and infect the others, although in some instances almost touching. With the nursery, covering about three-quarters of an acre, I proceeded in the following manner:—Judging that with so small an area as the above I should be working at a disadvantage through the gas escaping beyond the limits of the area and going to waste in every direction, I arranged my centres of vaporisation a little closer than would be necessary on a large field, and put them 8 yards apart each way. The receptacles of the fluid and their covers were represented by ordinary cups and saucers, pressing the cups slightly into the ground and mounting the inverted saucers upon three or four short sticks stuck closely round the rim of the cups, I left a clear space of about 1 inch in depth between the rim of the cup and the cover. They were then charged with a dilution of 3 per cent., and the effects noticeable after a few days were most startling. The ripe spores with which the plants, then some nine months old, were fairly reeking, began to change colour from the well-known bright orange to a dull ochre, until they subsequently turned into dirty yellow and then greyish-white. They all, instead of as usual dispersing, remained in a manner glued to the leaves, and afterwards dropped with them, dead, harmless, incapable of propagation. As time went on, all rust which came out began to look dull in colour and sickly, quite different from a healthy crop of spores. By degrees pale rings round the rust patches began to show, indicating the circumference of the mycelia and where their farther development had been arrested. In the third month a large proportion of the spots appeared pale green, whitish round the edges, and as if drying up in the middle; some pushed out a few sickly spores, but very frequently none at all. The spots turned into dry tissue, and most of those leaves, unless too severely attached, remained on the trees. Thenceforth a little dirty-looking rust still continued to appear, but the presence of the disease, up to its complete disappearance, was chiefly indicated by dead and dying mycelia. From what I have witnessed, bare contact with the vapourised atmosphere seems, if not immediately to kill the spores, to effectually incapacitate them from germination. From moving round in the nursery, examining the effects of the treatment, as I frequently did, I would often go in among healthy trees, handle their leaves, pull suckers and the like, but not a single instance of further infection took place among those trees, Liberian and Arabian, which were healthy when the process was started. With grown trees, having leaves of denser texture and more uniform age than nursery plants, which are almost always growing, the effects, although apparently slower at the beginning, are in the end still more pronounced. They lose a greater proportion of leaves at the start, but all disease upon them and in them is dead before the fall, at once neutralising a fruitful source of re-infection. In the case of fairly vigorous trees a new coat of clean foliage, never again to be soiled by the devastating parasite, will have formed by the time the last spore has disappeared.

My method of permanent vaporisation is specially adapted for a country like Ceylon, for instance, where self-sown coffee in the forest and native garden patches present a standing menace of re-infection, which will defy any other treatment. With the permanent atmospherical treatment any spore of Hemileia vastatrix which comes in any way whatever within the radius of its influence must die. As I have asserted elsewhere—"Any one employing my process will reap the full benefit of his outlay, even though his neighbour's field next adjoining or just across the road may be reeking with disease for want of treatment. No live spore can be carried out of the area under treatment—nothing carried in can live, and re-infection becomes impossible."

For the guidance of any planters who may wish to give my system a trial, I will here give the following directions:—Before my treatment comes into general use, so as to induce the wholesale manufacture of the specified tin vessel, planters will have to make shift as I did, with cups and saucers, which must be so placed that they will not be overturned or buried by stormwater coming down the hillside, which contingency is avoided with the tin-vessel mounted on a stick. Presuming the distance between the rows and in the rows of coffee trees to be as usual (6 feet), commence at the corner of the fields, say working from right to left, start with the third tree in third row, then follow the base line, placing a vessel in every sixth row between the third and fourth tree. When the base line is thus marked off, start at right angles along the rows, count six and place your vessels between the sixth and seventh trees in a line with the trees, so as not to obstruct work and passage; put down your cups, drive three to four short pegs immediately round the cups so as to steady them, and let the inverted saucer rest on the top of the pegs. They must be of even height and long enough to allow the spout of a watering-pot or other feeding vessel to pass through under the roof to save the trouble of lifting it every time—but they should not be so

high as to allow rain and rubbish to be blown in by the wind; and then place a stone up to the size of a fist to make all more secure. This done you may go on charging your vessels with a density of at least 5 per cent., but, as said above, I would for the first charge recommend a density of 10 per cent. The effects of the first week's dense vapour will amply repay the extra outlay in striking a deathblow, not only against the rust in full developement but—which is the greatest triumph of my system—against the mycelium of the fungus. This first blow will under these circumstances save a large proportion of the foliage unless too far gone, by instantly arresting the development of the fungus, and killing all that may be still alive on the dead and dying leaves strewing the ground. If the disease is not visibly present, all the better; the carbolic vapour will in a short time force it to show itself, chiefly in the character of dying mycelia, and save still more or all of the foliage which would have gone in the next attack of disease. The treatment may be started at any time with equal advantage. One week's ordinary weather will be found to evaporate about one-third of the contents of the cups, and thenceforth weekly supplies of 5 per cent. will be quite sufficient. Should at any time during a spell of wet cool weather so little water have evaporated (evaporation of the acid goes on continually) that there is not room in the cups to receive the ordinary quantity of diluted acid, raise the density of 15 per cent. or more, or only give a few drops of undiluted acid. All this is easily calculated, and must be left to the discretion of the operator.

If planters are disinclined to make larger experiments, they may try my system with as few as 10 acres, and they will soon see the contrast between them and the untreated portions of the field. One acre with another will only take thirty vessels. Six months after starting the process those 10 acres and a considerable margin all round will be in full foliage and crop, when the area outside the limit of effective vaporisation may be standing without a leaf, and the crop shrivelling and starving for want of shelter and food conductors. Choose your trial patch right in the centre of a good 100-acre field, and the experiment, conducted with ordinary intelligence and regularity, will in a few months convince the most sceptical of the value of my method.

The chief merits of my method of permanent vaporisation may be summarised in the following:—

1. Undeniable simplicity.
2. Economy of material and labour.
3. The most perfect control.
4. Complet isolation of material from soil and plants.
5. Complete and unconditional immunity from leaf disease.

I could bring the evidence of several neighbours who have witnessed the conditions of the nursery and the few solitary trees, and the effects of my process, but as it could serve no practical purpose I abstain from doing so.

Some months ago I applied to the Fijian Government for protection of my invention, and was refused on the strength of the reading of the local Patent Ordinance, which only partly covers the subject of my discovery, and only applies to inventions of a purely mechanical nature. My process has to be exhibited for many months in the open field, and cannot be kept under lock and key like a new machine not to mention paltry matters patented every day. Therefore I commend myself and my interests once more to the good-will and love of justice of the public. *Jacob P. Strock, Belmont Estate, Rewa River, Fiji Islands, November 25th 1881,*

Mr. Storck's mode of application may have some advantages over that of Mr. Schrottky.

CEYLON CLOVES.—We call attention to the interesting report in another column from Messrs. Brookes & Faith on a parcel of locally produced cloves: it is satisfactory once more to see that whatever we grow and ship from Ceylon is sure to be about the best of its kind. We wish the pioneers in cloves all success.

STRAY NOTES, 5th March.—Before settling down to work, my friend and I continued our rambles through the districts that have their outlet *via* Nawalapitiya. We found old Kotmale in the same spot as it was when I knew it first, but I regret to say some of the fine old coffee is now of little good, but other places look as fit as they were years ago and I must say in far better order than they were when I knew them first. I can't but think that large doses of forcing manure have caused some of the "red braes" you see in the old district. You will there see the advantage of *Sombreorum* in the zigzags of old Kataboola. Ambagamuwa and Lower Dikoya I found looking fairly well The former shows well up in tea, and, if it continues to grow as well as it is doing, it will certainly take the shine out of all the tea I have hitherto seen. The coffee in the latter district is certainly not so good as it ought to be, or as it was a few years ago; the cause is not far to seek: want of cultivation and Colombo management. To prove I am correct take Abergeldie estate as an instance. It looks as well as it did five years ago, and I am led to believe is giving fair returns even in these bad seasons, and it looks to me as if it was to do well this coming crop. There is no denying the fact that cultivation checks leaf-disease; any one can see that in the abovementioned estate. In my last I spoke about seeing the future Ceylon in the lowcountry. Don't for a moment conclude that the new districts are not to play a good part for years and years. Only give us seasons and fair cultivation, and coffee will come down to you as of yore. The fine fields of coffee are still to the fore. I will challenge any one to say otherwise than that coffee is now as fine in Dimbula as ever it was, barring a few places that are said to have been eaten with grub, but still they will improve. I saw one place last year like a new clearing; this year it is a fine cover of coffee. Anyone that doubts coffee being again king let him go through Dikoya and then go to the top of Dimbula, the Agras, Wallaha and Kattagaloya Valley. Coffee there is as fine as it was six years ago. The other part of Dimbula I have not seen for some months, but, from what I hear of the crops it has given, I conclude it is in as good fig as the places I have mentioned. I also did Maskeliya and I was glad to see that the places that were done up with the grub are improving and look quite another thing to what they were some months ago. Maskeliya is a district that is very much run down; the reason I don't know. I think the blame lies in the style of management. If the managers would let a little more light into their trees, coffee would again do as well as it has done in days gone by. I was told by a visiting agent that it was "want of cash and too much lawn tennis" that was the reason many of the estates were in such a matted state. All I know is that the estates in that valley don't look so well managed as they are in the other two districts. I was glad to see cinchonas were promising so well in all the districts I went through, but there is no doubt that the Agras are head and shoulders to the front boat in coffee and cinchona. I find the estates there are managed, or mostly so, by the residents, and not from Colombo offices. Another fact I learned in my travels was that all the estates that have given a decent crop and are promising to give another are so managed by the managers on the places. Strange but nevertheless true. So the conclusion I have come to is that coffee if fairly dealt with, will again pay the planters quite as well as it did four or five years ago. Crops may not be so heavy, but then the lesson planters have had in cheaper working will compensate for a year or two of less heavy bearing. As I have already said, don't blame the coffee. We still have the trees; bad seasons and bad management bad to account for our short crops. If proprietors and agents think they can get crop from places that only shew an expenditure of £30 per acre and places that have not been weeded or suckered for four or five months, they are certainly mistaken. It is after treating places in the way I have mentioned that the cry has got up coffee is doomed.—B. W.

MARKETS FOR INDIAN TEA IN THE UNITED STATES AND CANADA.

Our readers will have noticed that Messrs. Doane & Co. of Chicago estimated the consumption of tea in the United States at 72,000,000 lb. Mr. Sibthorp's calculation is not so high, his figures being a little under 70,000,000 lb. The population of the United States being fully fifty millions, it follows that the consumption of tea is considerably under 1½ lb. *per caput*. In Britain, the consumption of tea last year exceeded 160,000,000, lb., which, for a population of thirty-five millions, gives, for each individual, over 4½ lb. In regard to coffee, the position of the two countries is more than reversed; for the people of Britain have been so thoroughly cheated and disgusted in the matter of coffee, that they do not now consume anything like a pound a head of this beverage. England is as eminently a tea-drinking country as the United States people are coffee drinkers; but, unhappily, while it can be said that in the United States the consumption of tea is increasing, of England it must be confessed that her consumption of coffee—that is of true coffee is decreasing. Mr. Sibthorp shews that the Canadians in adhering loyally to Britain have preserved to a good extent the national predilection for tea. Canada with a population of only 4½ millions consumed last year 13,400,000 lb. of tea, or, as nearly as possible 3 lb. per head. In Canada, however, the consumption of tea is not now increasing at the same rate as prevails in the United States; but, if Indian teas are "pushed," which they never yet have been, Mr. Sibthorp believes that Canada will afford a splendid market for them. It may be interesting to see what the consumption of tea by the leading countries inhabited or colonized mainly by the British race (Anglo-Saxon, Celtic. &c.,) amounts to. We have not the exact quantity for Australia now before us, but as the figures were 15,000,000 lb, a couple of years ago and the imports in 1880 were over 22,000,000 lb., we do not think we can err greatly in taking the consumption by 2¾ millions of population in 1881 at 18,000,000 or 6½ lb. per head. If, as we believe, we are near the mark then we get for

The United Kingdom	...	160,000,000 lb.
The United States	...	70,000,000 ,,
Australia	...	18,000,000 ,,
Canada	...	13,000,000 ,,
Total	...	261,000,000 lb.

Figures, these, which are capable of great expansion, if the peace of the world can be preserved and its progress in population and wealth allowed to go steadily on. There ought to be no stronger opponents of the wicked war spirit than producers of articles which enter larger into the food of human beings. China still supplies the vast proportion of the tea consumed beyond her borders as well as about 1,200,000,000 lb. said to be used internally. But Japan and India, are competitors with the Celestial Empire, the progress of the latter, in the western as well as the eastern world being clearly destined to be great and rapid. Why the Americans should have taken so specially to Japan teas, which may be described literally, as "all-fired" teas, we scarcely see, unless it be as atonement for having compelled the land of the Tycoon to enter into "the comity of the nations." Our first taste of the amber-coloured, burnt flavoured tea, which is such a favourite with our Yankee cousins was in Paris, a good many years ago. It was provided for us as a treat by the then correspondent of the *Daily News*, but we could not honestly say that we admired it. Taste in regard for tea is, however, very much a matter of education: some people do not take kindly to Indian tea at once, and a few persons are so depraved in taste as not to admire even the Ceylon leaf, until the second or third time of tasting. The extreme cold of the climate in Canada and parts of the United States, may, perhaps (?) account for the preference given to highly fired and green teas, which have almost ceased to be used in Britain and which, recently tried on the Melbourne market, found but scant favour. The "Japs" are an enterprizing race, and they are straining every nerve to push their peculiar teas and their imitations of China and Indian produce. India, however, (including Ceylon) is likely to take, ere long, first place in the tea markets of the world. Admirers of the American ladies must grieve to learn that they are not good, honest, orthodox tea drinkers and tea dispensers, like their English sisters, but that they take the infusion of the fragrant leaf in the shape of an iced drink! If it be true, as stated, that the people of the United States, and especially the female portion, are of defective physique, it ought to be matter of serious consideration whether improvement might not be secured by abandoning the limited and perverted use of tea and consuming it as it ought to be consumed in large quantities and after the orthodox fashion! It is a maxim amongst chemists that the degree of civilization to which a country has attained can be tested by the quantity of sulphuric acid it uses. A still better test, we submit, would be the aggregate consumed by the population of such "diffusive stimulants" as tea, coffee and cacao, to the displacement of alcoholic drinks and narcotics. It is evident that during last year an exceptionally large proportion of low class, inferior and positively exhausted or deleterious teas were shipped from China, to the markets, not of Europe and Australia merely, but to those of the western continent. The result was for a time, to lower the standard of prices of Indian as well as China and Japan teas; but the Indian article has at length asserted its superiority beyond all doubt, and the shippers of the cheap rubbish from China could not have acted better if their direct object had been to promote the sale and consumption of the superior tea. Such is ever the result of "ways that are dark and tricks that are vain" as opposed to honesty, which is the best policy in trade as it is the right course in morals. For the present it is Japan tea as against China, which is finding increased favour in the United States (although last crop is complained of as inferior) but when Indian teas are really "pushed" as they are about to be in the United States as well as Canada, the superior quality of the new candidate for favour will be recognized in America, as it has been in Britain and is daily more and more the case in the British colonies of the south. As to America gives

ing her own tea, no doubt that vast country has suitable soil, if not climate; but unless the working classes abandon their attachment to good wages and their hatred of the "Heathen Chinee"—welcoming hordes of the latter to their land and their bosoms—the question of cost of labour stands an impassable barrier in the way. The wages of 10 cents per diem, which the American journalist mentions, is, of course, composed of cents of a Spanish dollar. It is, therefore, whether applied to wages or the prices of tea, somewhat more than twice the value of two of our cents: say 1 American cent = 2½ Ceylon cents, Will experts in tea, excusing our ignorance, inform us what is the precise meaning of "basket fired" teas and whence their superiority? We should also like to know if any considerable proportion of tea planters or tea experts in Ceylon have abandoned the old idea that the special fumes of charcoal are essential to the good quality of tea, and accepted the conclusion that teas dried by "Sirocco" or other machines, or by mere artificial heat, without charcoal fumes, are as good or better than teas roasted over charcoal fires

We again attract attention to the fact that, in the United States and Canada, as in Australia, packages not larger than from 38lb to 45lb find most favour; while the dealers desiderate attractive boxes in all cases. The tin boxes are always nice-looking, and wooden boxes can be made so by pasting over them paper adorned with neat printed or lithographed designs.

We copy below the main portions of Mr. Sibthorp's interesting report:—

REPORT ON THE TEA TRADE OF THE UNITED STATES AND CANADA, BY D. A. SIBTHORP, ESQ.

130, Water Street, New York, 7th Dec. 1881.

B. R. MAGOR, Esq., Honorary Secretary,

Calcutta Tea Syndicate.

The Americans cannot be called a tea-drinking nation, for, with a population of 50,000,000 persons, the imports of tea last year only amounted in all to 69,765,000 lb., of which the proportion of Congou was very small indeed, viz., only 5,154,000 lb., the balance, 64,610,000 lb. being Japans, China green teas and Oolongs, while Canada with a population of only 4,500,000 persons consumed last year 13,400,000 lb., the proportion of black tea being 5,560,000, the balance as in the States, *viz.*, Japans, China Greens and Oolongs.

"Tea" with the trade of this country means Japan and China green tea, just as a home dealer would mean black tea or Congou; if they want to speak of Congou they name it, just as we in England would name "Oolong" or "Scented Orange Pekoe." This will perhaps give a better idea than the statistics do of the hold that Japans and green teas have on this market.

There being no duties on teas in the United States, (except on those imported from countries other than the place of growth, which are liable to a 10% *advalorem* duty, in consequence of which there is little or no trade with Great Britain) it is impossible to do more than estimate the actual consumption of the country, as the usual guides, *viz.*, the Custom's returns, are here entirely wanting.

New York is the largest and most important market for tea in the States, supplying, it may be said, the whole of America. Following is a comparative statement for the past three seasons, which shows a considerable falling-off in the consumption last year, but which the *Trade Review* accounts for in the following words:—"The statistics given show an apparent decrease in consumption from the Port of New York during 1880 of about 8,500,000 lb. but, in analyzing these figures in connection with the general course of trade throughout the year, and the indications of continued prosperity in the country, to say nothing of increased population, it is impossible to adopt the conclusion that there has been a falling-off in the consumption of this article of food. The distribution in progress during the year has developed the fact that very considerable quantity of stock withdrawn from first hands during the year 1879, under the influence of the "boom" which led to such an inflation of the volume of business, as well as of values, had not been consumed on the 1st January as was then supposed, but was in reality carried over, and formed an important part of the actual available supply for the year under review. In other words, the sudden spirit of speculation infused during the Autumn months of 1879 led to an extensive stocking-up by second-hand dealers and small traders throughout the country. The sluggishness of the distributive demand all through the year has made this fact more and more apparent, thereby demonstrating that the business, which ordinarily should have been spread over six months, was, in the prevailing excitement, crowded into as many weeks. Unquestionably, therefore, a large percentage of the consumption heretofore set down to 1879 must be credited to 1880."

The bulk of the tea is sold on this market at prices ranging from 20 cents to 30 cents per lb., but during the last year a great deal of low class tea from both China and Japan has been sold at 10 cents to 12 cents per lb. Formosa Oolongs with fine quality command high prices, as also do fine Japan uncolored and basket-fired, sometimes ruling as high as 80 cents per lb., but this is considered a fancy price, and can only be obtained for small quantities. The bulk of the Congou sold here is of fair quality, selling at from 12 cents per lb. for common, up to 40 cents per lb. for fine tea. Sometimes it is mixed with green tea and sold under the name of "English breakfast tea," but this mixing is done mostly on this side by the retailer. The retail price for all kinds of tea ranges from 30 cents to 80 cents per lb. Small quantities are sold as high as a dollar per lb. by some of the fashionable dealers.

The following are the latest market quotations:—Greens, finest chops, none, 34 to 36 cents; fine Teen-kai and Moyun, 28 to 32 cents; Ping Sung, 27 cents: Medium chops, 23 to 25 cents; common, 19 to 21 cents. Japans, choicest, 48 to 50 cents; choice, 40 to 43 cents; finest, 35 to 38 cents; fine 29 to 32 cents; medium and good, 17 to 26 cents; common, and good common, 12 to 16 cents. Formosa Oolongs, choicest, 55 to 65 cents nominal; choice, 43 to 48 cents; finest, 36 to 38 cents; fine, 33 to 34 cents; superior, 28 to 31 cents; good cargo, 22 to 25 cents; fair, 18 to 20 cents, good common, 16 cents. Amoy Oolongs, fine, 25 to 26 cents; superior, 22 to 23 cents; common to fair, 12 to 16 cents. Foochow Oolongs, choice to choicest 50 to 60 cents; finest, 37 to 40 cents; fine 30 cents; superior, 24 to 26 cents; fair 18 cents. Congou and Souchong, choice, none; finest, 37 to 40 cents; fine, 28 to 30 cents; superior, 23 to 24 cents; good cargo, 19 cents; fair, 17 cents; common, 12 to 15 cents.

Some small parcels of fair liquoring Indian teas, direct private shipments, have been sold on this market at from 23 to 45 cents per lb., but being small quantities I cannot take the prices obtained for them as a guide to what may be expected for the first shipment of the Syndicate, but the prices are, I should say, satisfactory.

Chicago is an important and rapidly-increasing market of all kinds of teas. It is impossible to report the actual business done here, as a great deal of the tea sold is purchased on the New York and San Francisco

markets, the actual quantity imported direct from China and Japan last year being 6,975,223 lb.; but this is only a small proportion of the trade. From Chicago all the great Central and Western States of America are supplied with the tea consumed, the quality and price being almost identical with New York; as all the large New York dealers, or "jobbers" as they are here called, have travellers constantly on the road. The quantity of tea sold through Chicago is variously estimated at from 10 to 15 million lb. yearly, but, as there are no guides to go by, it is impossible to say exactly.

Indian teas have been sold by Messrs. J. W. Doane & Co., the Agents of the Syndicate at Chicago, at, I believe, satisfactory prices, but they were private shipments, and I have no particulars. The first consignment from the Syndicate is now in their hands, and I hope shortly to be able to report sales. I expect samples of the breaks daily, and on receipt of them will forward you a report immediately.

San Francisco is an important market for tea, for through it the whole of the Pacific States and Territories draw their supplies. The amount of all kinds of tea imported last year was 4,210,000 lb., of which only 760,000 lb came from China, and the balance 3,450,000 lb. from Japan. The consumption of Japan tea is steadily increasing, while that of China tea is falling off. China green teas are used very little west of the Rocky Mountains, Salt Lake City being the only place to which they go. Congous sell in San Francisco at from 20 cents to 30 cents per lb., for the lower grades, and for the best kinds as much as 55 cents per lb. is obtained. Oolong teas from Formosa are popular, selling readily as high as 60 cents per lb., and they are gradually taking the place of English breakfast teas, which were at one time in great demand. The prices ruling for Japan teas range from 15 to 25 cents per lb. for the lower, to as high as 45 to 55 cents per lb. for the finest grades.

I could find no trace of any sales of Indian teas on the San Francisco markets during my stay there, the samples I had with me were admired, but small hope of business was held out. I hope that the shipment now on the water will do well and lead to further business.

The other large cities of the United States import very little tea; they do most of their business with New York, Chicago or San Francisco, so the particulars given respecting these markets are a guide to the whole tea trade of the United States.

Auction sales may be said to command the New York market now. Speaking of this the *Review* before quoted from says: "An important feature in the business of the last year has been the increased distribution through the auction room. Not only have the offerings been much larger, but the year has witnessed the establishment of a second firm who make a speciality of this mode of distribution. In 1879 there were sold by public auction 149,167 pkgs. of sound tea, while during 1880 the quantity so disposed of increased to 232,375 pkgs., comprizing one-fifth of the total distribution from the Port for the year. This method of selling has undoubtedly grown in popularity with that class of buyers who can afford to wait at the unreserved sales for values to reach their limit, but the problem yet to be solved is whether in the long run this method of selling will prove as remunerative to the importer as well as the jobber, as the system which heretofore required the services of a broker. Undoubtedly the auction sales have thus far had the effect of concentrating the demand in New York from a much larger number of interior buyers, and in this way increased the importance of this market as a distributing centre."

American grown Teas.—I have seen some fine samples of these grown and manufactured in the State of Georgia. The black tea resembles our Assam makes, and the green teas imitate closely fine lignoring Moyun teas from Shanghai, but the samples were only experimental, and the high cost of labour in this country will always, I imagine, prove an insuperable bar to the successful production of American teas. Reviewing this subject, the authority I have before quoted from says:—"The experiments of Commissioner Le Duc, in his efforts to prove that the tea plant can be grown in this country and the leaf successfully prepared for use, have attracted a good deal of newspaper notice during the past year, and some of our local *cha sees* have enjoyed the privilege of tasting the beverage drawn from this home production and been asked to vouch for its character, but it will probably be many years before the tea crop of the United States will become of sufficient importance to more than merit the notice and approval of the ladies of the White House, who, upon their accession to the honor, have heretofore been presented with a cup, and, as requested, have given the enterprize their support. The expensive efforts of the Agricultural Bureau may thus far have been highly successful as landscape gardening and in the interests of fancy agriculture, but, as for providing a beverage for the people, the experiments have proved futile. Until the American labourer is content with wages not exceeding ten cents a day, it is hopeless to think of competing with the heathen Chinee."

Tea is not yet the important beverage in America that it is at home, and in the Australian colonies. Such a thing as an afternoon tea is almost unknown in purely American society. Ladies—always the planters' best friends—are here seldom confirmed tea drinkers such as one meets in other English-speaking countries; the little tea they do drink is generally Oolong or Japan tea made very weak, and well iced, taken without milk or sugar, generally out of a tumbler, and a very fair drink it is for the hot weather, although my "insular prejudice" compels me to confess to a preference for a cup of good Indian tea with cream and sugar.

The Canadian tea trade, as before noted, bears a much better proportion to the population than that of America, for with a population in 1880 of 4,350,933 persons the total consumption of tea was 13,400,217 lb., but the trade in Canada is not increasing nearly so rapidly as it is in America, as ten years ago with a population of 3,670,400 the consumption was 10,959,000 lb.

Montreal and Toronto are the two great markets for tea in the Dominion, the city of Quebec doing little or nothing, but nearly all the Provinces import a little. [Table omitted.]

The above figures show that the Provinces of Ontario and Quebec, of which Toronto and Montreal are respectively the centres, do the bulk of the business, Ontario being a good deal ahead, as the greater part of the black teas of the better kinds imported to Montreal is sold in the Upper Provinces, and the duty being paid in Montreal, further trace for statistics is lost. You will doubtless remember that it was for this reason I recommended Toronto as the head-quarters of the agency for the Syndicate in Canada.

Black teas sell in Canada at prices varying from 12 to 15 cents per lb. for common, up to 50 cents for finest, and Japane-e and green teas sell from 10 cents per lb. for low class up to as high as 60 cents per lb. for the highest grades of basket-fired teas, which have a fast growing popularity with the Canadians, as also have Oolongs which sell at prices varying from 20 cents to 60 cents per lb. These prices do not include the duty, which is on, green teas 3 cents per lb. and 10 per cent. *ad valorem*, and on black teas 2 cents per lb. and 10 per cent. *ad valorem*, also an additional 10 per cent. *ad valorem* on all teas imported from countries other than where grown. These duties the present Government have pledged themselves to take off in the coming session, but I doubt if they will withdraw the 10 per cent. leviable on the other than direct shipments. As things stand at present, the importer sells his tea at a duty-paid

price, he paying the duty and recovering the amount along with the value of the teas on the same terms as in the United States, viz. four months.

Most of the large London dealers have agents in Canada, as also have many of the New York firms, and some of the Canadian houses have branch offices in this city; there is, in consequence, a considerable business done notwithstanding the extra 10 per cent. The agents of course have a constant supply of samples of all kinds of tea, including Indian teas from the London market, in which there has been a small trade done at prices equal to London quotations. The trade has never been really pushed, and there is here a splendid opening for our teas.

Following is a comparative statement of the export of all teas, from China and Japan to the United States and Canada for the past three years up to 31st October. These figures I have compiled from the latest advices from China and Japan, and are, I think, to be relied upon. They will serve to point out how rapidly the tea business is growing in this country, and should prove a powerful incentive to all interested in the development of the Indian tea trade to make an effort to secure a footing on these markets, which as yet may be said to be only in their infancy, and which will, before a great many seasons have gone over our heads, be as important as any in the world.

[This table is omitted as its results are indicated.]

The falling-off in the shipments from Japan this year is accounted for by a late crop, but it is expected that when the season closes the exports will be quiteequal to those of 1880.

Tea is tested here in an odd way, and, instead of weighing the sample to be tasted into a tea-pot and allowing it to draw for five minutes, as we do, the pot is discarded altogether, and the tea turned directly into the cup, the boiling water then being poured on. When it has sufficiently cooled, the taster commences taking out a few of the leaves on his spoon to examine them, and when satisfied, returns them to the cup, and so continues through the "batch." The weight used is not so heavy by nearly half as ours, and it would probably be equal to the weight of a four-penny piece The plan is a more speedy one than ours, but I do not think it is possible tobe so accurate.

No doubt the most rapid way for our Indian teas, to obtain a footing on these markets would be, as I I advised you in July last, to manufacture them to assimilate as far as possible the teas already in demand, but I am inclined to agre with the decision of the Committee of the Syndicate, that it is better to allow our teas to stand on their merits, as I think it may be assumed that the reason the consumption of tea is so small in this country is due to the fact that the article now offered to the public is, on the whole, an inferior and not very palatable one.

Before I close, one thing I would like to impress strongly on those who take an interest in working up these foreign markets, is, that the present style of packing considerably retards the sale of indian teas. *Large packages are unsaleable, except at a considerably reduced price, half-chests containing* 28 *to* 45 lb. *nett will sell most rapidly.* They should be neatly finished and marked, so that, instead of being, as they are considered here, an eye-sore in the retail dealer's shop, they would prove an attractive ornament. There is a stronger feeling here against rough packing (of any kind of goods) than I can give you any idea of. A retail dealer will not purchase a rough package as he "calculates" it would be likely to keep customers out of his "store." One reason, I think, why the Japanese have got such a strong hold on these markets is the remarkably neat way in which their packages are made up, they are neatly matted and papered with a stylish label seteing forth the class they claim to contain. I cannot see why we should not vie with the Japanese in this, and that the trouble taken be well repaid I have not the would slightest doubt.—I am, dear sir, yours faitfully D. A. SIBTHORP.

EXPORT OF INDIAN TEA TO AUSTRALIA AND NEW ZEALAND.—The quantity of tea exported from Calcutta to Australia and New Zealand in the months of January and February last was 126,657 lb. Last year, 135,899 lb were exported in the same period.—*Calcutta Englishman.*

CINCHONA.—A consignment consisting of 138 bales of cinchona bark, weighing in the aggregate 24 tons, from the Government cinchona plantations, Dodabetta, Nilgiris, were shipped to London during the past month, and intimation of the same conveyed to the Secretary of State.—*Madras Times.*

TOBACCO IN KAFFRARIA.—Our coutemporary, the *Colonies and India,* says tobacco has long been grown successfully in Kaffraria, and its cultivation is rapidly extending. On a farm about 15 miles from the mouth of the Kli, Mr. Keighley is planting out about 9,000 plants. In virgiu soil the weed grows most luxuriantly, quite rivalling anything produced in America or elsewhere.

DR. FORBES WATSON.—This gentleman, who was for several years Director of the Indian Museum at South Kensington, and who arrived in Madras last week from Calcutta, will leave Madras tomorrow for Dharwar and Bombay, whence he will proceed to England. He has been engaged on enquiries into the production of rhea fibre in Upper Bengal, and in gathering information about the cotton trade in various provinces.—*Madras Mail.*

MANITOBA.—The *Liverpool Journal of Commerce* says:—"The land fever in Manitoba remains unabated, and Brandon is now the centre of attraction. A three nights' sale by the Canadian Pacific Railway of lots in that town realised $133,000, and it is said that one speculator has cleared $60,000 by a quarter section just added to it. Brandon would rapidly become a town of considerable extent but for the want of building material. A new town, named Garfield, has been formed twenty-five miles from Winnipeg, and town lots are being offered by auction in that city. It is reported that the travelling over the St. Paul and Manitoba road to Winnipeg is 100 per cent. over that of last year at this season. Wheat has been selling in Winnipeg at 95 cents., and oats 70 cents. per bushel. The high prices are due to local consumption, the supply not being equal to the demand."

AGRICULTURAL SCHOOLS should be established in Ceylon as in India, where the pupils can acquire a knowledge of improved methods of culture. New implements of cultivation, used in England, America and other places, should be introduced and facilities afforded for poor cultivators to buy them as cheaply as possible. New products and better seed-plants suitable for different soils with directions as to their cultivation should be distributed broadcast over the land. Agricultural shows should be made in the chief towns periodically and prizes awarded. These are obvious and legitimate duties of Government, much more, that of one whichprofesses to be paternal. It cannot be pretended thatthe functions of a paternal despotism like that of Ceylon should be passive and restrictive, as in more civilized countries—particularly, in matters which touch the very existence of the people. Spontaneous growth of the natives in these things will be at best a thing of the distant future. Hence, active encouragement of Government is all-important. Without offering such aids or encouragement, Government may waste enormous sums of money in the repair of tanks and anicuts, and wait for centuries before either they themselves orthepeople reapa ny benefits.—*Lanka Snahan.*

COFFEE ADULTERATION.

With my last there was enclosed the extract of a letter from the *Globe* relative to coffee adulteration. Its publication was followed almost immediately by an article in the same paper on the 11th in comment upon it, of which the text is subjoined :—

"CHICORY AND COFFEE."

A correspondent recently complained grievously of the compound now so generally sold instead of coffee. The pure article, he affirmed, is being driven out of this country, and certainly recent statistics appear to bear out the statement. The Board of Trade returns for the first ten months of the year 1879 are now before us, and they show that home consumption of genuine coffee was 265,083 cwt. For the same period in 1880 the amount was 243,277 cwt. and last year the first ten months showed only 240,369 cwt. During the same periods the home consumption of chicory rose from 87,217 cwt. to 93,101 cwt. and than to 94,959 cwt This show clear that while we are drinking every year more "coffee," our import is declining and our consumption of chicory is increasing. The real facts are probably much more serious than these figures show, because the Board of Trade, we believe, take cognizance only of foreign chicory, the "home consumption" being arrived at by deducting exports from imports. It is well known, however, that whilo all our coffee is imported and can be accounted for to a pound, only a part of our chicory comes from abroad. Large quantities are grown in this country. Indeed, if we are rightly informed, the best of our chicory is home-grown and usually fotches a shilling or so a hundredweight more than the foreign. It grows wild in almost all parts of Europe, but the north of England appears to suit it admirably, and it is grown in Yorkshire very extensively. All authorities, we believe, agree that a decoction of the root is harmless enough, and that it affords a good deal of nutriment in the shape of sugar. They are equally agreed, however, that it has none of that invigorating character which alone makes coffee worth drinking. The best that can be said for it is that it is harmless. Yet we are assured on good authority that much of the article bought by those who consent to take a "mixture of chicory and coffee" contains not more than one part of coffee, good bad, or indifferent, to seven parts of chicory.

It was new to me to learn by this article that so much chicory is grown in England, and that the home production is considered so superior to that of foreign importation. The figures quoted in the *Globe* from the Board of Trade returns show conclusively how extensive the evil is, and the necessity that some steps should be taken to check the increasing practice. On the 15th, the *Globe* published a second letter having reference to the points raised in this article of the 11th, a copy of which is as follows :—

ADULTERATED COFFEE.

TO THE EDITOR OF THE "GLOBE."

SIR,—May I ask the favour of some small space for an extension of my former remarks under the above heading which your article of February 11th renders desirable in the interests for which consideration is sought? As regards a certain admixture of chicory with coffee, it suits so many people's taste that it will probably always be practised to some extent. The present system of allowing the mixture to be sold without any guarantee as to the proportion of the ingredients, leads, however, to that excessive adulteration to which your article referred. But, even supposing such guarantee given, what ordinary purchaser, can test its genuineness? And if fraud be discovered, what obstacle is a fine of forty shillings, as recently imposed, to the dishonest trader who can make 100 per cent. on every transaction? But the evils of adulteration go far beyond the comparative innocent chicory. From abroad come all sorts of preparations which the best authorities in the trade state to be composed of roots, fruit stones, turnips, carrots, acorns, and cabbage stalks. Freely advertised under high-sounding names, and exhibited in temptingly-coloured packets this worthless stuff is palmed off on the English working man as the coffee which he is told on all sides is the best stay for labour, and the right substitute for that beer against the use of which he is so constantly warned. It is to the extension of a system so detrimental to our people that the recent Treasury Minute referred to in my former letter lends the further aid and countenance of the Government.—I am, sir, faithfully yours,

ARTHUR FOLKARD.

Thatched House Club, St. James's, S.W., February 14.—*Globe*, Feb. 15.

The more the subject can be ventilated by the leading journals of the home press, the greater the chance will be that members of the House of Commons may be disposed to advocate some legislative restriction upon the disgraceful proceedings which are now so common. In a conversation held with a gentleman, who disputes that there is any hardship in permitting what he calls "freetrading" in these mixtures, I learned the views entertained by what may be termed the opposition party, which is mainly composed, it may be suspected, of those who have some direct or indirect interests to serve by the maintenance of the existiug scandalous state of thiugs. He considered that coffee is really better than the substitute offered for it,—it must in the end triumph—and that any limitation placed upon the sale of mixtures will be an interference with the liberty of the subject. Precisely : the liberty to pay for stuff, which cannot be considered innoxious, and certainly can possess no nutriment, a price which, in the long run, is dear, as compared to that of the real article. By such means, the use of coffee is discouraged, for people buy and drink most of these mixtures under the belief that they are drinking "coffee," and finding none of the beuefits expected, but rather a sickening result, will turn from its use altogether. No sane or disinterested man can, it must surely be believed, fail to see how great an evil it is that the food supplies of the nation are not what they profess to be. *A propos* of this matter, it is to be noted that that horrible date coffee is again the subject of litigation. An application has been made this week to wind up the "German Date Coffee Company." Wiser than our own authorities, the Government of Germany has declined to grant a pateut for the manufacture of this, to me, nauscous mixture, and does all it can to discourage the sale of similar impostures. The Judge's remarks wheu granting the winding-up order are worthy of preservation. As he theu pointed out, how could the Date Coffee Company sell a right to manufacture such a mixture in Germany? There was and is nothing whatever to prevent anyone grinding auy rubbish they like and calling it coffee in that country, and yet—it scarcely seems possible—this German Date Coffee Company had agreed to pay the English Date Coffee Company no less a sum than £50,000 for this presumed right. No wonder, as the judge observed, that the shareholders in the former Company objected to such a payment, and that the application to close the affair was before him! This fact shews pretty conclusively how the dividends declared by the English Date Coffee Company have been earned, for many other such branch Companies are said to have paid heavily for similar illusory rights. At the same time, it is with great regret to be noticed that this nasty compound sells here with a freedom that its merits certainly do not warrant ; but the fact affords strong evidence of the necessity of legislative restrictions.—London Cor.

REVIEW OF THE COFFEE MARKET.

With reference to the Brazil crop of 1882-83 several Brazil firms estimate the

Rio crop at a minimum of	4,000,000	bags
And the Santos crop at	2,000,000	,,
Together	6,000,000	bags

But Messrs. R. Wursten & Co. estimate the total

quantity available for shipment from the two places at only 5,000,000 bags.

As regards the effect of low prices upon production of coffee in the Brazils, Messrs. Wursten & Co. write: —"We have not as yet arrived at prices which cease to be remunerative. With intelligence and economy the planter finds, even at present prices, a moderate profit. Whatever may take place, we are inclined to believe that the low prices will have the effect of increasing the production, as no other article of export rivals coffee, and all parties interested are endeavouring, by every means in their power, to increase their production, in order to repair the losses made by the continual decline in prices."

Messrs. Kern, Hayn & Co. write that a fair average Rio crop must now be calculated to be from 4,000,000 to 4,500,000 bags, but that, as long as present low prices last, the low qualities will be kept back in the interior in expectation of better times.

In Mr. Schöffer's celebrated circular of 1879, he gave the following table of the average production of coffee during two periods of 5 years ending respectively:—

	1872.		1879.
Brazils	200,000	...	283,000
Java	65,000	...	90,000
Ceylon	47,000	..	45,000
East India and Manila	20,000	...	23,000
St. Domingo ...	20,000	...	30,000
La Guayra ...	16,000	...	40,000
Costa Rica and Guatemala ...	10,000	...	27,000
Porto Rico and Jamaica ...	4,000	...	6,000
Mocha Africa ...	5,000	...	6,000
	387,000	...	550,000

Since Mr. Schöffer's circular was written, the production of coffee in the Brazils has further increased, say 100,000 tons, and the other countries of production, taken as a whole, will probably also now yield more than in 1879, but no corresponding increase in consumption has taken place, and no large increase is likely to take place, till there has been some continuance of low prices, and until the low prices reach the consumers, which we hardly think they have done so far.

The fact that stocks in Europe have been steadily increasing for the past 4 years is an undoubted proof that the production of the world is in excess of the consumption; the equilibrium can only be re-established by a continuance of low prices.—*Robert Von Glenhn & Sons' Monthly Coffee Circular.*

RIVALRY IN SILK AND TEA.

A Chinese tradition attributes the discovery of silk to one of the wives of the Emperor of China, Hoang-ti, who is said to have reigned about two thousand years before the Christian era; and since that time—so the tale runs—a special spot has been allotted in the gardens of the Chinese royal palace to the cultivation of the Mulberry tree—called in Chinese the 'golden tree'—and to the keeping of silk-worms. Without waiting to discuss the probabilities of this item of folklore, which has possibly as much foundation in fact as most other popular notions on similar subjects, we proceed to known facts. The Mulberry plant is a native of Persia, from which country the secret of silk manufacture was introduced into Italy *via* Constantinople, and over Europe, becoming domiciled in the South of France as a great manufacturing industry before the close of the fifteenth century. This is a brief historical summary of an article now used in nearly all countries as a luxury in apparel, but only befitting those of a higher social gradation, or those whose means permit of the indulgence of wearing such a comparatively costly textile fabric. Sericulture is now extensively practised in various parts of the world, temperate and tropical. The conditions which favor the plant are prejudicial to the insect, and *vice versa*. The Mulberry thrives better in a cold climate, which implies a larger size of tree bearing a more abundant crop of leaves than in warm regions. But in these latter the silk-worm develops more rapidly and obtains maturity in less than half the period in the former or colder localities. This is an overwhelming advantage, as it minimizes attendance and risk by a saving of more than three weeks. Cards of seed carried from China and Japan have been found to reproduce successfully in those countries where the mulberry can be cultivated. The silk-worm has been introduced into various parts of America with favorable results; but the most interesting sericultural experiments of the period are those now undertaken in reference to the acclimatisation of the insect and plant in Australia and Ceylon, in both of which countries there are reasonable grounds for believing that silk-growing may in course of time prove a profitable industry. "In Europe the silk-worm takes about forty-five days to obtain maturity, but it has been found by experience that in the temperature of Colombo only from twenty-three to twenty-five days are required." This quotation supports what we have already stated on this subject. It is a most important consideration, as the shorter period reduces the liability of loss from disease, and other well-known causes which prey upon the worm, as well as lessening the cost and trouble in looking after it. We have been induced to dwell upon this subject from the apparent fact that local products, which at one period were almost exclusively confined to China, have been produced successfully elsewhere, and, in some instances, left China far behind in the competition. This is particularly conspicuous in the matter of porcelain wares. The chief exports of China are, as our readers are doubtless aware, tea and silk. India is fast assuming a position in reference to China tea that, judging from the progress made during the past few decades, there is every possibility in the immediate future of its becoming something more than a powerful rival. In silk, China will have to dread a more wide-spread competition. It forbodes ill, as regards the future of this industry in China, that sericulture is commencing to be developed in intertropical countries, which will preclude China from monopolising the advantage she possesses *re* cheapness of production. It has been already acknowledged that silk-growing cannot be remuneratively carried on by white labor in Australia; which objection does not exist or militate against the industry in Southern Europe. The conditions are, of course, different in Ceylon were coloured labor is the only agency that could be employed for the purpose, and it is chiefly from such countries that China and Japan have to dread rivalry.—*China Mail.*

CINCHONA BARK: MARKET PROSPECTS.

It must be remembered, that though on paper present stocks appear very large, a certain portion of them, perhaps a larger portion of them than is generally supposed, is very common Bark. We all know that some of the Cuprean Barks, a description which has so much helped to augment stocks, have been very common. If then a very large proportion of the stock, carefully chosen and selected, is held by speculators, who, if circumstances favor them, will sell only on their own terms, the remainder being in the hands of importers, who, even if they disapprove, cannot well help assisting this speculation, it may be that manufacturers, if forced to buy later on bark in quantity, in order to fulfil their contracts for delivery in Quinine; may find prices

materially altered. We are unable ourselves to give an opinion as to the probable result, not being sufficiently behind the scenes. The above is the ordinary gossip of the trade.

The consumption of Quinine, we believe, is supposed to be increasing yearly at about the rate of 7 to 8 per cent. Satisfactory as this may be, we should like, for the sake of our friends in Ceylon and India, whose bark in another year or two ought to be ready for shipment in quantity to see, this rate still further increased. Such a result is more likely to be obtained if we have a course of moderate prices, based only on the relative position of supply to demand.

Our friends will be glad to hear that Mr. Howard speaks very favourably of the shaving system. The first shavings must not be taken as a proof of what this system can do, it being the second operation which generally gives satisfactory results. The Bark is then practically renewed, and Mr. Howard believes that the tree has suffered little or no harm. Messrs. Howards quote Quinine Sulphate at 10s; Quinidine Sulphate at 5s, Cinchouidine Sulphate at 2s 6d, and Cinchonine (Mur.) 1s 3d.—*I. A. Rucker & Bencraft's Weekly Price Current*, 16th Feb.

PUBLIC SALE OF CINCHONA BARK.

Mr. E. John put up for public sale this morning the following lots of bark :—

			R.	c.
Nonpareil—Succirubra,				
240 lb.	12 bags twigs sold for...	...	0	10
Rossmore—Succirubra,				
929 lb.	5 large bales chips...	...	0	50
	5 bags root and small chips...		0	30
	8 ,,twigs ...	...	0	16
Greenwood—Succirubra,				
1,240 lb.	27 bags twigs ...	...	0	27½
Hangran Oya—Succirubra,				
146 lb.	3 bags twigs, chips and shavings ...	...	0	32½
	1 ,, broken quill ...	...	0	77½
Bridwell– Succirubra,				
75 lb.	3 ,, shavings ...	...	1	25
Lindoola—Succirubra,				
562 lb.	11 ,, twigs ...	...	0	25
Bunyan & Avoca—Succirubra,				
2,326 lb.	56 bags stem chips and shavings ...	...	0	90
	2 ,, dust ...	...	0	17
Florence—Succirubra,				
[2,165 lb.	10 ,, chips and shavings	...	0	45
	30 ,, bold twigs and chips	...	0	47½
	27 ,, shavings ...	...	0	87½
	3 ,, branch ...	...	0	25

LIBERIAN COFFEE.—The Manager of the Udapolla plantation reports a very fine blossom out and the suspension of crop-picking "for a period of twenty days" after which the gathering of ripe cherries will once more be in full force! It is hard to say where this satisfactory state of things is going to stop; a chronic state of picking seems to be the distinguishing feature of Liberian plantations with trees in bearing. We hear that several Colombo mills have an appreciable quantity of this coffee now being cured for the London and New York markets.

THE TEA AND COFFEE TRADE AND CUSTOMS REFORMS.—In connection with the work at the docks and wharves, it is understood that great changes are to be shortly introduced in the system of the customs. At present the work of keeping an account of goods liable to duty is done twice—once at the central office, and once at the dock or wharf. It is stated that this apparently useless repetition is to be put an end to, and that the work will be done at the bonded warehouse only, and that it is proposed at the same time to sweep away a mass of useless formalities which have so long hampered the tea trade. At present, for instance, for every chest of tea that is cleared the customs ask for the ship's name, the place from which the ship came, the name of the person who warehoused the goods, and the date on which they were warehoused, to be repeated on two separate papers. By the new system this clerical labour will be more than halved, for one paper alone will be asked for, and that will bear a customs number only, instead of all the above details. Further, instead of the 48 separate papers now required to clear 24 chests of tea by different ships at one warehouse, one piece of paper will do the entire work. The details of the proposed change have not yet been published, and the particulars which have been made known as to the new mode of paying duties are not altogether clear, but there appears little doubt that the tea trade is about to be released from a considerable portion of the almost intolerable customs routine that has hitherto oppressed it. It is to be sincerely hoped that the opportunity will be taken to simplify the antiquated warrant and weight-note system and that the wharfingers will at any rate keep abreast of simplifications effected by the customs, by contenting themselves with the customs rotation number and the package number, for the identification of goods. At present on documents with regard to tea or coffee, the wharfingers require, in addition to the package number, the ship's name, the port of export, the dock rotation number, the ship, the mark and the weight. That there is room for much simplification is evident, as with all other groceries, including costly spices, delivery can be obtained by simply naming the ship, the mark, and the numbers In some cases the date of import is also required, but in no instance does anything like the extraordinary complication of the tea system prevail, nor, it may be added, is there any other article sold by grocers in which such interminable delays in delivery take place. Whether this is due to the piling up of precautions and routine, which have been abandoned in every other modernized trade, is hardly open to question. The tea trade, on the other hand, have the consolation of enjoying ingenious, intricate, and indeed theoretically perfect documents in the warrant and weight-note, while it is mainly the retail grocers who suffer by the cost and delay of the system of clearing. In all probability the "smalls" charge of the railway Companies which inflicts such hardship on the grocers, would not have been invented had it not been for the complications in obtaining deliveries of tea. Now that there is an opportunity for simplification it is to be hoped that it will be taken advantage of.—*Produce Markets' Review.*

Asbestos, it has now been discovered, cian be turned to good account in the preparation of pant. We are told in *Nature* :—"In a finely divided state, it is mixed with a fluid material, and is used in a similar manner to other paints. Unlike them, however, it is uninflammable, and not only so, but is capable of communicating this valuable attribute to such substances as it may be applied to."—*Pioneer.*

The Indian Tea Association has compiled a return of the actual outturn of the tea districts for the last season, which they put down at 47,063,194 lb. as compared with, 45,245,569 lb. for the previous season. This was divided amongst the different districts as follows :—Assam 24,390,732, Kachar and Silhet, 13,903,016. Darjiling and Duars 7,403,293, Chittagong 746,895, other districts 619,258. It is considered the total exports for the season will be about 47,500,000 —and of this rather over 46,300,000 will be available for Great Britain.—*Madras Mail.*

Coffee Production during 1881 has gone on steadily increasing, and there has been some improvement in sugar production. As to the former, however, there are grave doubts as to the wisdom of increasing production at this time. There is already over-production throughout the world, and over *two million bags* of Brazilian coffee are now stored at the principal ports waiting for a market. And besides all this, the export business during the past year has been anything but satisfactory, the apparent losses being from twenty to twenty-five thousand contos. When liquidation comes we shall know where to locate thisloss.—*RioNews.*

The trial shipment of Java black tea placed on the Melbourne Market, on 2nd Feb., was not a success. We quote the descriptions of the few lots which sold :—

11 half-chests Japan Oolong, olive black even twisted leaf, very strong rich pungent Oolong	1s 0½d per lb in bond.
48 half-chests Japan green tea 48 do do do even twisted green leaf, very pungent rich fresh young Hyson	11d.
13 cases (each 100 1-lb packets) Japan pekoe, handsome small even wiry black leaf very full rich ripe true mellow pekoe	1s 3½d
25 cases (each 18 5-lb boxes) Japan pekoe small even wiry black handsome leaf, pekoe tips, choicest full rich mellow pekoe	1s 3½d

The Japan Black Tea Company, the catalogue states, has been specially formed with the co-operation of the Japanese Government, for the purpose of growing, manufacturing, and packing teas suitable for the Australian markets.

Slavery in Brazil.—We take the following from the *Anglo-Brazilian Times* of January 8th.—"The Legislature has continued the tax of 1,500 mils. on the registration of slaves brought into the province, including those brought in under colour of mere contracts for hire. The tax on the transmission of slaves has been raised from 30 mils. to 50 mils., but that on transfers to another municipality has been abolished. The tax of 1,000 mils. on slave dealers has been continued. All these taxes go to emancipatory purposes. The municipalities have been authorized to impose 1,000 mils. to 3,000 mils. annual tax, and exact security, besides, for 2,000 mils. on country stores and liquor shops away from settlements and State and provincial roads, as a check on the illicit trading with slaves which encourages the prevalent serious nuisance of theft by slaves. The Custom-house of Rio de Janeiro collected in 1881 from taxes on imports and exports 41,567,576 mils. against 42,835,564 mils. in 1880 and 41,7(5,522 mils. in 1879—viz., from imports 32,346,178 mils. against 33,314,931 mils. in 1880 and 31,903,964 mils. in 1879; and from exports, 9,221,437 mils. against 9,520,628 mils. in 1880 and 9,801,323 mils. in 1879.—*Brazil and River Plate Mail.*

Additions to the Zoological Society's Gardens.—A Toque monkey (Macacus pileatus) from Ceylon presented by Mrs. Evans.

Colonel Howard, (nephew of the great Quinologist) left Ceylon by the last French mail-steamer after a run through our planting districts and a good look at the cultivation of cinchona and other new products. He first visited the Pangwella and Doombara districts, and then as the guest of Mr. E. G. Harding, he saw cinchona (with which he was highly satisfied) in Dikoya, the Agras, Lindula, Udapussellawa and Maturatta. Colonel Howard (who is a director of a Nilgiri Plantation Company and largely interested in gold mines,) carried away a very favourable impression of our planting industry and prospects in Ceylon. A merchant writes :—"Just a line to let you know that Colonel Howard kiudly promised to write a letter giving us his ideas on cinchona cultivation here, which we are to let you have for publication. Meantime, you will be glad to know that he was *most favourably impressed* by what he saw in Ceylon, during his visit upcountry, and considers the success of this enterprize well assured."

Indiarubber Trees in the Royal Botanic Garden, Ceylon.—The *Gardeners' Chronicle* for February 25th contains a very striking full page engraving of this group of trees accompanied by the following remarks :—

Ficus Elastica.—We owe to Dr. Trimen the opportunity of figuring the remarkable group of indiarubber trees which bound one of the entrances to the Royal Botanic Garden at Peradeniya, Ceylon (fig. 38). The curious aërial roots, descending Banyan-fashion from the branches, and the bold, undulating buttresses which run along the ground, are very striking features, and must tend to prevent the trees from being overthrown by hurricanes. We cannot hope, even with the resources of a Kew, to produce such growth in this country, but as the means of travelling increase the numbers of those privileged to witness such marvels increase likewise. The mode of formation of these buttresses and the reason are not generally understood, and would form a good subject for further investigation. They are not confined to figs, but occur on many other tropical trees, as may be seen in several fine sections in the Wood Museum at Kew. A figure of these buttresses, taken from an isolated tree, was given at p. 681 of our volume for 1873, after a sketch by Captain Oliver.

An American View of Manitoba.—Mr. Horatio Seymour, ex-Governor of New York, a gentleman whose position renders his utterances of more than ordinary value, has paid a visit to Manitoba, and has conveyed the result of his experience in the form of a letter to a friend. He declares, without fear of successful contradiction, that if Great Britain were to impose a tariff of 10 or 20 cents per bushel upon American wheat and grain, allowing Canadian wheat and other products to enter her ports free, she would bankrupt the farmers of the American north-west. He saw thousands of acres of wheat clearing 40 bushels to the acre and weighing 63 lb. to 65 lb. to the bushel. People, he says, are crowding there rapidly, and towns are springing up as if by magic. The Great Canada Pacific Railway will be at Puget Sound before the North Pacific of the United States, and the distance to Liverpool will be 600 miles shorter that any American line which could convey Dakota wheat for shipment thither. The best steel roads are being placed on the road—100 tons to the mile at $56 per ton, whilst on the parallel American line, the North Pacific, the same rails cost about $70—a difference of $1,400 in rails alone in favour of the Canada Pacific. Mr. Seymour is equally demonstrative on other points, and he has evidently been strongly impressed by his visit.—*Field.*

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE CULTIVATION AND SLAVERY IN BRAZIL:—No. V.

Dollar, N. B., 26th Jan. 1882.

GENTLEMEN,—The returns given, although relating to only eight of the provinces of the Empire, give us a pretty fair idea of the working of the emancipation fund for the whole twenty provinces into which Brazil is divided. Your readers, however, as coffee planters, are more interested in knowing how the labour market of the three great coffee-producing provinces can be affected by it. A decrease in the labour supply of these would very sensibly diminish the exports of coffee from Rio de Janeiro and Santos.

I mentioned that, for the last eight years, there had been a general migration of the slave population from the northern, to the three coffee-producing provinces, Rio de Janeiro, São Paulo and Minas Geraes, and that this movement corresponded with the gradual extension of new coffee fields, and the increase of the shipments of coffee. An agitation was started against this interprovincial slave trade, and, strange to say, was carried on principally by the class who had benefitted most by it—the São Paulo planters In 1879, a law was passed by the Provincial Assembly at São Paulo, imposing a tax of 1,000$000 (£100) on each slave entering the province of São Paulo from another province. This law was vetoed by the Government as unconstitutional. In 1880, the Provincial Assembly of Rio de Janeiro, when passing the supply bill, included in it a tax of L1,500$000 (£150) on each slave being registered, coming from another province, and this part of the bill passed almost unnoticed, and became law on 1st January 1881. The province of São Paulo immediately followed with a law, imposing a tax of R2,000$000 (£200) to come in force in February, and Minas Geraes with one for the same amount to come in force also in February 1881. These taxes were to be paid on registration of slaves coming from one province to another, excepting only three to accompany each family and exempting those that come by inheritance and through judicial execution.

The law of 1871 regulated the machinery for collecting a tax on the transfer of slave property, and, as sales took place, an entry was made in the collector's book. These new provincial laws were prohibitory, inasmuch as the tax was much more than the value of the property, the value of a field hand being about £200. The collector is liable to a fine of 3,000$ (£300) for each slave neglected to be so registered, and the owner liable to a fine of 1,000$ (£100) if he exceed the time allowed for registration, namely, thirty days.

It is difficult to conceive the motive which prompted the introduction of these laws, for the planters of these provinces were loud in their outcry about the scarcity of labourers, and they were the people who benefited most by the entry of slaves from the Northern province. It seems uncharitable to suppose that the real object the lawmakers had in view was the extension of the time when slavery should be extinct. There is strong circumstantial evidence to show that it was so.

I am unwilling to inflict on your readers a prosy review of the events which agitated the public mind previous to the passing of these provincial acts, but they will have a better idea of this Brazilian slavery question if I do so. You will remember that a congress of agriculturists, called together by the Government, was held in Rio de Janeiro in July 1878. This congress was to consider the various questions that were depressing agriculture, and the principal outcome of this great gathering was the decision of the Government to send an embassy to China to negociate a treaty of commerce, and get the sanction of the Celestial Government to Chinese immigration. This latter measure was considered the best means of averting the inevitable crash which must fall on the agriculture of the country, should anything happen to accelerate the emancipation of the slaves. The allowing of the vote necessary for paying the expenses of this mission was warmly opposed by Deputy Joaquim Nabuco, who was supported by other able men in the Chamber of Deputies in Rio de Janeiro. The vote was allowed; the Government promising not to bring in Chinese coolies by any Government scheme, their object being to pave the way for their introduction by private enterprize.

This discussion and the subsequent arrival of the envoy in London, on his way to China, attracted the attention of the British and Foreign Anti-Slavery Society, and this body not only sent a petition to the Chinese Minister in London against the Brazilian movement, but wrote a letter thanking Senr. Nabuco for the stand he made against the introduction of Chinese labourers into Brazil. Deputy Nabuco, in reply to the British and Foreign Anti-Slavery Society dated 8th April 1880, declared his intention to introduce a bill into the Chamber of Deputies in Rio de Janeiro establishing the date of 1st January 1890 for the entire abolition of slavery throughout the Empire. Here is what he said himself:—"that bill will not be converted this year into law, but introduced every session in a Liberal house by myself or some of my friends, and in a Conservative house by some prominent Conservative abolitionist like Mr Cusmão Lobo; increasing every year in votes, it will triumph at last. The date remaining immoveable, every delay would render the transition period shorter, but it would not be our fault. The frontier of next decade, I hope, will not be passed by any man calling himself a slave." This letter, as might be expected, caused a great commotion throughout the Empire.

True to his word, Nabuco commenced his campaign in August 1880 by a forcible speech in the Chamber of Deputies when the voting of supplies for the department of agriculture came on for consideration. He denounced the sale of slaves imported since 1831, the misappropriation of the emancipation fund, the public whipping of slaves at the request of their masters and other cruelties. A fortnight afterwards he brought forward his bill for emancipation in 1890. The Chamber fixed the 27th of August for the discussion of it, two of the ministers voting in the majority granting leave. The minority, however, pressed the Prime Minister; so that next day he announced that, if the discussion of such a measure were forced on, the Ministry would resign. The Chamber thus boarded by the Minister, and having fixed the 27th for the discussion by its vote on the 24th, did not hold sessions on 26th, 27th, and 28th August. On the 30th Nabuco again asked leave, but the Chamber this time rejected the motion for the introduction of the bill by 77 to 18. The Prime Minister, on being pressed for his reasons for making a Cabinet question of the introduction of the bill declared that the Emperor and the Government had made up their minds that slavery was to remain as it was fixed in 1871.

Congratulations came pouring in from all parts of Empire. The minister had saved the country. Agricultural Societies were formed for the purpose of resisting any attempts at upsetting the arrangement made in 1871, and at all these meetings addresses were framed thanking the Government for the stand they had made.

It was thought that this slave question was settled, but Nabuco, nothing daunted by his defeat in the Chamber, called his friends together at his residence, and formed an Anti-Slavery Society.

A manifesto was issued on the 7th September 1880, the ninth anniversary of the passing of the slave law. Some able men joined this Society and Branches were established in some of the other towns. The agricultural interest was entirely against the movement.

The American Minister in Rio de Janeiro wrote a letter detailing the prosperity of the Southern States in North America since the abolition of slavery there, and a banquet was given to this gentleman, Mr. Hilliard, by the Anti-Slavery Society. The speeches on this occasion, particularly that given by the American Minister, enraged some of the members of Parliament. The Government was called on to interfere, for here was a minister of a friendly state interfering in their domestic affairs. The debate was an angry one, and showed how they would resent outside interference, and how they could abuse nations and individuals, who did not respect the time-honoured institution of slavery. The Government, however, saw no reason either to praise or blame the American Minister, and, in justice to the Prime Minister, we must give him credit for saying that, although the Government were for slavery remaining as it is, they respected those who held opposite opinions. It was during these stormy times that the provincial laws were passed putting a stop to the inter-provincial slave trade. Can it be said then that it was a step towards abolition? During these debates, the Northern Provinces were accused of being anti-slavery, and the Deputies from the South, while openly declaring themselves as on the pro-slavery side, used threats to compel those from the North to hold on to the arrangement of 1871. One illustrious orator from the South used these words: —"You wish to sell your slaves to us, and then you will by-and-bye ask us to liberate all slaves, within the Empire." Another said, alluding to the Deputies from the North:—"I look on these people as highwaymen, and for such as these I have my revolver."

We must look to the stoppage of the inter-provincial slave-trade as putting a check on the labour supply to the coffee-producing provinces, and putting a limit on the exports of coffee from Rio de Janeiro and Santos. The Ceylon coffee planter may console himself that the competition in that direction will not be more than it is at present, but, if slavery is not reduced more rapidly than the death-rate, and the working of the Emancipation fund has shewn during the last ten years, we will have to wait some time before there is much diminution in the coffee exports.

We have also to consider that, although all the children are nominally born free, they are really slaves and are of the same value as slaves to the coffee planter, until they are twenty-one years of age. Slavery, we may say then, will remain in the same actual condition until the year 1892, when those born of slave mothers in 1871 will be released from bondage. The death-rate and the liberations through the emancipation fund taken together is not more in these days than the death-rate alone was in former times, when there was not a prospect of slavery becoming extinct. This latter fact has made slave-owners see well after the health of their slaves, and very strict precautions are taken to lessen the death-rate among the negroes. The rate now, as we have seen in examining the returns from eight provinces, is for death and liberation by the fund together 25 per 1,000 annually. But supposing the fund were increased by a tax on slaves, which has not yet been imposed, although mentioned in the law of 1871 as the first factor in making up the fund —and suppose that the fund were better administered and that including the death-rate the number would reach thirty per thousand, this calculating 1,300,000 as the number of slaves at present (a very low calculation) the decrease would be only 40,000 per annum. Against this we have to set off the children, which are said to be born free, who will fill up the gaps made in the estate gangs through death and emancipations up till 1892.

The physical condition of the slaves in the coffee producing provinces is good. As a class, they are robust and healthy. The slaves brought from Africa were generally young. The most of the native Africans one meets were brought over when they were boys and girls of 12 to 18 years old. The gangs of slaves brought from the Northern Provinces to the South, were young. The dealers would buy only those that would sell highest to the planters of São Paulo and Rio Janeiro. The purchaser had to calculate in his own mind how many years work he could get out of the negro before he bought him.

Looking at a gang of slaves working on a coffee plantation, one is struck with the large proportion of young and strong-looking people amongst them. Were I asked to say what would be the average number of years of work that could be got out of the gangs I have seen working on the coffee estates—very few being above forty and most of them between the ages of 15 to 30 years—I would be safe in calculating thirty years as the average workable time. As I said before, the diminution from deaths and emancipation can be made up from the young under twenty-one years. It is a matter of opinion to say that slavery can continue for thirty years: that is to suppose that the settlement of 1871 can last until that time.

It interests us Ceylon planters to know if there is any probability of that settlement being disturbed. I have before said that, in the event of any political disturbance the slave may benefit by it. But there is little prospect of any serious question disturbing the public mind until the Emperor dies, and he is 57 now.

The Brazilian nation having been colonized from Portugal, Brazilians are a quieter race of men than those which form the other South American States. Although internal troubles do not occur in connection with the election of rival presidents, owing to there being a constitutional sovereign, at the same time party feeling runs very high on very insignificant questions.

There is a party composed of the shopkeepers in the towns in the interior that would benefit by the land being cultivated by free men receiving wages; these complain of all the money drawn from the produce of the soil being spent in the large towns at the coast or at the capital. The professional classes would also benefit by it, but all these are too much dependent on the wealthy coffee planters to openly stand up for abolition In the event of a revolution, these would side with the negro.

The free labourer of the present day is also a pro-slavery man. He thinks if the negro were free he would work for small wages, and therefore lower the labour rate. The free labourer looks down on the slave and does not like to look forward to the time when they will be on equal terms. Even the free negro is despised by the half-Indian *camarada*. The free labourer now and then comes in for a handsome sum for catching runaway negroes. Supposing he were for, humanity's sake in favour of the slave, and would like to see slavery at an end, he is afraid to tamper with the negro in the way of pointing out to him the benefits of freedom. He knows that the punishment would be death, if he were found intriguing.

It is well for the Fazendeiro that the free labourer is a pro-slavery man, as he could do incalculable mischief if he were not. A few free labourers by entering the lock-fast slaves' quarters, on a few estates, and telling the slaves how easily they could get freedom, if they would revolt, could put the whole country in a blaze. There is no police force that could quell a slave disturbance. Around the town near where I lived, there were five thousand slaves. There were only some twelve' policemen that could be taken to help the

authorities. These policemen were used for nothing but to keep watch over the jail. It would take two days to get some two hundred soldiers from the capital. The slave does not know how easily the thing could be done, else he would free himself. Slaves are locked up at night, and the eye of the overseer is over them all day; so they have no way of knowing anything. The Brazilian Government do not calculate on such an event as a negro insurrection, and are not prepared for it. The slaves would succeed with no other weapon than their own hands. There is a very small organized army to bring against them. The police force is so small and inefficient that the beginning of a disturbance, however small, could not be stopped.

A slave rebellion will not happen, unless influences from outside the plantations were brought to bear on the minds of the slaves. That is not a likely event for some time. It is but natural to expect that those born of slave mothers since 1871 will try to free their relations and old friends, but, as they have to be slaves under their mothers' masters until they are twenty-one—the first of these—(and only those born in 1871 can be liberated in 1892) it is very probable that some measure will be brought forward before that time to have these kept under police inspection for some years after being set free.

The Emancipation Society, which was formed a year ago, and so ably supported by Senr. Joaquim Nabuco could have done a good deal in the way of disseminating anti-slavery opinions. Although Nabuco and the other able men who started the Society have courage enough to carry through what they intend, there is a great want of moral support from among the public men in Brazil. The influential people of the nation seem to disregard it. Nearly every Brazilian who can afford it has slaves; if he has not, his relations and friends have. The question of property is an important one. The leader of the movement visited Europe last year. He was entertained by those of anti-slavery opinions in all the countries that he visited, and the British and Foreign Anti-Slavery Society in London gave a breakfast in his honour. But on his return to Brazil he was looked on as a traitor, and accused of the worst of all treason, that of asking the aid of foreigners to further revolutionary movements. Not long after his return came the general election under the new law, and neither Senr. Nabuco nor any of his anti-slavery followers were elected. Either in despair of doing anything to forward abolition while residing in Brazil, or thinking that he could aid the cause more by remaining out of it, he went to practice his profession of lawyer in London. I leave your readers to form their own opinion on the slavery question from the facts I have set before them.

I shall no doubt be asked: "But is there nothing else that can interfere to check the heavy exports of coffee from Rio and Santos"?

Possibly the low price of Brazilian coffee may have some effect in withdrawing labour from the cultivation of it. The low price of cotton, and the large export duty put a stop to the cultivation of it, and the planter sought another agricultural product and gave his attention to coffee. The same may be said of sugar planting. Improved machinery and a better mode of cultivation have been applied to sugar cane since with success.

Both cotton and sugar are yearly plantings and harvestings. Coffee, on the other hand, is a plant of five years' growth, and has a capital equal to five years' expense of cultivation lying on it, and it cannot well be thrown out of cultivation like cotton or sugar-cane without great loss of capital. Even with low prices planters will continue to cultivate their coffee fields with expectations of a rise in prices of coffee.

A Brazilian coffee planter free from indebtedness can easily wait. The expenditure on his estate is represented by food and clothing for his slaves. The food—Indian corn, beans, rice, mandioca, and pork—he produces every year, whatever the price of coffee may be. He can grow some cotton and rig up the old spinning-wheels and the looms which have been concealed in a corner of the coffee store for the last few years while coffee was selling high, and make clothes for the negro men and women.

The planter, who has his estate and slaves mortgaged, will not be able to bear up at present prices of Brazilian coffee. Interest must be paid and that is not under 12 per cent. per annum. That charge can only be paid by coffee, and coffee has to bear transport to the sea-port, and municipal taxes and church taxes taking up on all about 20 per cent of its selling price. Before it is shipped it has to be further taxed 13½ per cent on value.

I do not know of anything to take the place of coffee. Cotton is produced cheaper in the United States than it can be in Brazil. Sugar cane will not grow well in many of the coffee lands; and, supposing it did, the capital required for the erection of machinery and buildings necessary would not be forthcoming. Coffee is the entire support of the Brazilian Government; as the duty on it is *ad valorem*, the low prices affect the revenue.

We have been accustomed to look at the labour question only, as influencing the future of Brazil. This, it will, in time, do, but unless some other settlement of the slave question than that of 1871 is come to, we cannot expect it will not do so for some years.

We have to seek for other causes and the only one at present is the low price of Brazilian coffee. This will tend to embarrass the Ceylon planter also, but not to the same extent. Ceylon seems to have a market of its own, which Brazilian coffee cannot well supply, and Ceylon coffee has not fallen in the proportion that Brazilian coffee has.

A. SCOTT-BLACKLAW.

No. VI.

Dollar, 1st February 1882.

GENTLEMEN,—I intended to have finished these papers without saying more, but, as I have mentioned the low price of coffee as one of the reasons likely to diminish the exports from Brazil, your readers will expect that I should give them some idea of what is the lowest selling-price at which Brazilian coffee will give no profit to the grower.

This leads us to consider the amount of capital invested in and the cost of labour employed on a coffee estate in Brazil. The labour has been pronounced a failure. It never can exist alongside slave labour. At 3s a day for labourers, your readers at once will pronounce free labour impracticable. In any case, it is by slave labour that Brazil's large crops are picked, and we must confine our calculations to it. The average size of a Brazilian coffee plantation is 200,000 coffee trees; these planted at 16 palmas (11½ feet) apart give 333 trees to the acre. Coffee land represents about a third of the estate, two-thirds would be pasture land and low-jungle for growing corn, beans, rice, mandioca, &c. The whole estate may be about 2,000 acres, 600 acres being planted with coffee.

Many planters count on a slave for every 5,000 trees. This is too much, however; most of those of my acquaintance calculate on 3,000 trees to the fixed hand, and, if the crop is large, it will not be all picked without extra assistance. We will, however, take this as a basis to go on.

For 200,000 coffee trees there will be 80 slaves required, thus:—

For field work at 3,000 trees per hand	65 slaves	
House-servants, cattle-men, horse-keepers and sick	15 ,,	80 slaves.

The average crop from such an estate is 10,000 arrobas.

The present price of good coffee in Rio and Santos is 4$000 per 10 kilos., say 6$000 per arroba; for calculation we will take the milreis at the value of 3s. The value in gold is 27*d*, but at present rate of exchange currency is only 21½*d* *to* 22*d*.

The arroba, by which all Brazilian calculations are made, is 32lb. (3½ to the cwt.), although sales take place by 10 kilos., and a sack of coffee is 60 kilos.

Value of an estate with 200,000 coffee trees :—

Pasture, land for growing provisions, houses, machinery, cattle, horses, mules, &c.	R300,000$000	(£30,000)
Value of 80 slaves at 2,000$000 each	160,000$000	(£16,000)
Total value... ...	460,000$000	(£46,000)
Yearly expenditure, clothes for negroes ...	1,600$000	(£160)
Medicines for do.	400$000	(£40)
Loss by death amongst negroes 2½% ...	4,030$000	(£400) 6,000$000 (£600)
Repairs to machinery, wages of mechanic and engine-man ...	3,000$000	(£300)
Repairs to buildings, &c.	5:000$000	(£500)
Administration, overseers, &c. ...	6,000$000	(£600) 14,000$000 (£1,400)
Transport, say 10,000 arrobas (2,857 cwt.) at 1$500 per arroba ...	15,000$000	(£1,500)
Commission, &c. at sea-port at 300 arrobas	3 000$000	(£300) 18,000$000 (£1,800)
Total expenditure on crop of 10,000 arrobas	38:000$000	(£3,800)
value of crop at present prices 4$000 per 10 kilos. or 6$000 per arroba (2,857 cwt. at 43*f*.) ...	60.000$	(£6,000)
Deduct expenditure as above ...	38,000$	(£3,800)
Leaves profit	22.000$000	(£2,200)

This would be 4⅔ per cent on capital 460.000$000 (£46,000) invested. Some will say that 10,000 arrobas is a very small crop considering that a great many give an arroba for every 10 trees. With young coffee 6, 7, 8, and 9 years old this can be got, but only when the cultivation is good, i. e., when the coffee is kept clean. Most of the estates are kept in a dirty state, and a great many do not give over an arroba to thirty trees. 35 arrobas per 1,000 trees was given as the average crop by a planter at the Agricultural Congress; and, although many people cried out "not so" the speaker was not *publicly* contradicted. Taking the average for a number of years more, estates give under the estimate I have given than above it. As regards the price of coffee sold in Rio or Santos that can give a profit to the grower, Mr. Robert Clinton Wright, a coffee merchant of Rio de Janeiro, who had an experience of over fifty years in the country and died about a year ago, gave 7$500 the arroba as the price required to give 6 per cent on capital in 1875; my figures, as stated above, 6$500 per arroba would give 6 per cent. This shows that I have not overstated the expenditure of the Brazilian coffee planter.

The late Mr. Wright also stated that at 7$500 per arroba and adding 13 per cent export duty cost of bagging, shipping expenses, commission freight, and insurance involved a sale price in the United States of about 18½ cents per lb. without profit to the shippers —meaning thereby the coffee buyer in Rio de Janeiro and Santos.

The present price of Rio and Santos coffee in the United States is 10½ *cents per lb.* No doubt coffee was produced formerly at a cheaper rate in the Province of Rio de Janeiro, but the bulk of the crop was grown near the coast on hills around the city of Rio de Janeiro on ground now abandoned. Formerly a slave could have been bought for £30 or £40; now a good negro cannot be got under £200. At that time little coffee was grown in the Provine of Sao Paulo, owing to the distance from the sea, of land fit for growing coffee and the rugged range of mountains that had to be crossed. The same applied to the interior of the Province of Rio de Janeiro and Minas Geraes where the coffee crop now shipped at Rio grows. Railways have changed this state of things.

I have said that only those who had no indebtedness would be able to carry on at the present price of coffee, and that those who were working with borrowed money would become insolvent. I do not require to demonstrate to the Ceylon coffee planter the hopelessness of the coffee estate proprietor's case, when he gets into difficulties with regard to money matters. I shall content myself by saying the case is a great deal more so in Brazil, where money cannot be got under 12 per cent per annum, even by giving good security.

The proceedings of the *Congress Agricola*, held in Rio de Janeiro in February 1878, showed not only that a great many were wishing for some relief financially, but the majority were really feeling embarrassed, and were pressing the Government to take in hand the formation of Agricultural Banks, or establishments for advancing money on the security of agricultural holdings. In fact the settling of the financial question seemed to be considered the principal—indeed was to be the great cure of—agricultural depression. The minister of agriculture said, in his report in February 1877 :—"The want of money still continues to aggravate the difficulties of the planters, especially those of the north, who have had to pay in some provinces 18 to 24 per cent, and in some cases even 48 to 72 per cent. The obligations of the Bank of Brazil to lend 25,000,000$000 (£2,500,000) in long loans to planters has rendered much service in the provinces of Rio de Janeiro, São Paulo, Minas Geraes, Esperito Santo and Santa Catherina."

At the Congress a great many speakers lamented that the law of 1875, giving a Government guarantee to the Bank of Brazil for advancing money to agriculture, was a complete failure, owing to the strictness of the conditions under which loans to planters could be given.

But you will ask: "Are there many of the Brazilian coffee planters really in money difficulties?" This is a very difficult question to answer. Many amongst those who live in great style in the cities of Rio de Janeiro and São Paulo are said to be owing money, and the affairs of deceased persons often exhibit a state that one would not have expected of the principals when in life. Planters, whom popular opinion believed to be rich, have been found to have had estates and slaves heavily mortgaged.

The old Fazendeiro, who made money at cotton-growing during the American war and left the cultivation of that in time to have coffee in bearing during the period that high prices ruled, in 1872-73-74-75, is well off. But during the last five years a great many estates have changed hands. The sales were generally time bargains, and at very high valuations. The new proprietors of these must feel the effects of the low price of coffee; a great many of these will go to the wall.

Under this head we must not forget to note that of, the 850 miles of railway open in the province of São Paulo, 800 miles were made by local capital, and the original shareholders were the coffee planters.

But the labour is in the country. Supposing coffee to be at a price that cannot pay the Brazilian planter, what can the labour be employed on, if taken off coffee cultivation? This can only be answered by asking another: what was the labour employed on, before it was concentrated on coffee-growing? Cotton was only grown in Brazil during the American war and for two years afterwards, but now the production of cotton by free blacks in the United States is greater than it was before the war and before the slaves were emancipated. Already in the valley of the Parahyba, in the Province of Rio de Janeiro, many coffee drinkers are devoting their attention to sugar-cane growing. This shows the direction to which agriculture would incline. The coffee lands are all suitable for sugar-cane. Those in São Paulo could be very easily cultivated by the plough. No doubt coffee fields that are getting exhausted will be abandoned, and something else will be cultivated. We would suppose that coffee clearings will for a time be neglected, while coffee does not show prospects of giving a profit on capital invested.

I must now draw my remarks to a close. I hope I will not be understood to have advanced opinions of my own as regards the future of coffee planting. My object has been to place the *facts* concerning the coffee enterprize in Brazil before your readers, leaving them to form their own opinions. They will particularly note that the emancipation law, which we all looked upon as having an effect on Brazil's labour-supply, has not answered the expectations formed of it at the time it was passed. This need not surprize us much, when we see that the treaty of 1825 with Great Britain for the suppression of the slave trade; the law passed, in Brazil in 1831, declaring all Africans imported after that date free; and a similar one in 1850, were all wilfully evaded. I do not require to draw the attention of Ceylon planters to the railway system of Brazil, for you yourself have over and over again done so. We have here a convincing proof of what railways can do for new countries

You will note also that, since the production of Brazilian coffee has so exceeded the demand for consumption, the price has fallen. It will be expected, if the cost of production amounts to more than the selling price of the article, the producer will transfer his skill, energy and capital to something else.

I noticed before that Ceylon coffee has not fallen in the same proportion as Brazilian. Ceylon with her cheap labour and her freedom from export duties, if it could get rid of leaf-disease, could afford to wait for prices to rise again. I do not apprehend such disastrous effects on her agriculture, as I fear for that of Brazil, owing to the present low price of coffee.

It will be well for us all to watch carefully the course of events. A. SCOTT-BLACKLAW.

1st Feb. 1882.

P. S.—The latest returns I have seen from Rio de Janeiro give the total exports for year ending 31st Decr. 1881 at.. ... ... 4,217,600 bags

I have not seen returns but, Santos and other ports will be ... 1,500,000 ,,

5,717,600 ,,

equal to 6,700,000 cwt. There is over 600,000 cwt. stock on hand in Rio and Santos.

CEYLON PRODUCTS—NEW AND OLD—IN LONDON.

London, E. C., 16th February 1882.

DEAR SIR,—We have to report a continued dullness in our coffee market, although we trace a better feeling during the last day or two. tWha with the stagnation of demand, the wish of holders to realize, drooping prices in Brazil, and downward tendency in New York, the inactive position here is sufficiently accounted for.

The turn of the year has brought forward a good many annual circulars from competent authorities, which go fully into the prospects for the ensuing year. All agree in ascribing the present situation to over-supply, but it is stated also that consumption is increasing at a considerable rate and that the reduced prices must needs greatly restrict the use of all substitutes. Remarkably enough, however, this country makes one exception from the experience as to the world at large, the consumption of coffee having, during the past thirty years, rather decreased a little, while that of tea has augmented manifold. This is a fact which should not be lost sight of by those engaged in the younger industry. As the excess in present stocks in the United Kingdom is estimated at as equal to only about one month's consumption, the situation does not look so gloomy; only the uneven location of these stocks will render their distribution and absorption a matter of greater time and difficulty.

There is nothing to report in the quinine market, nothing worthy of note having been sold. Sulphate of quinine continues quiet, Howards is quoted at 10s, French 10s, and German 9s 6d per oz.

We have received from Barranquila, South America, the following information in reply to our inquiry for rubber and cinchona seed:—

"We shall with much pleasure try to comply with your wishes. This, however, will only be partly possible, as you will see by the following information, which we take the liberty to give you on the subject. The cinchona ledgeriana originates from seeds of Peruvian calisaya by fructification with other kinds, and is an irregular hybrid, which very seldom gives seeds, and is, therefore, to be propagated by cuttings. The cinchona calisaya Sta Fe has nearly been extirpated, years ago; therefore no seeds can be got of this kind. The seeds we could get you would be of the 'cuprea,' but this species, as well as the 'quina of Payta,' which came to the markets a few years ago, are not real cinchonas, and are the only false cinchonas (cascarillas) which contain quinine, and it is therefore probable that the cupreas from seeds are valueless. The seed of the cinchona lancifolia, the only valuable kind which grows here, is very difficult to get, and then in a condition that does not germinate.

"With regard to rubber, it is found in some abundance and of good quality throughout the Central Andes, which form the western boundary of this state, and grows at an elevation of 5,000 to 7,000 feet. The best class is found near the latter figure. We have desired several of those who bring in the rubber to procure the seed you wish, and hope to send you some at an early date.

"A gentleman brought at one time some seed of the 'Lancifolia Roja,' which is one of the best varieties, and has started a plantation on the high plains. We hope to receive some seed from him per return post.

With regard to Ceylon tea, there has been a little sold during the last week:—R, 1881, 33 cases (tin canisters) pekoe souchong at 6½d per lb.; Agarsland, 27 boxes pekoe souchong at 11½d per lb. For sale next week, there are 14 half-chests souchong under mark Courthope, Bosanquet & Co The tea first-mentioned under mark R was of very bad quality and make,—Yours faithfully, HUTCHISON & Co.

BORER IN COCONUT TREES.

Noakhally, Bengal, 23rd Feby. 1882.

To the Editor of the "Tropical Agriculturist."

DEAR SIR,—With reference to "E. A.'s" letters anent borer in coconut trees in our issue of Feby., page

665, I would be obliged by "E. E. A." informing me (1) at what seasons of the year the salt is to be applied? (2) If the salt is to be applied to every tree in the plantation twice a year, whether the trees are attacked or not? (3) Is it any use applying the salt to attacked trees?—Yours faithfully, SIGMA.

COMFORT FOR PLANTERS: FINE COFFEE SAMPLES.

DEAR SIR,—The annexed will show that Ceylon coffee can hold its own against the world.

The proprietors of Stockholm, I imagine, echo the wish of the London agents that there was more of the coffee to place on the market, but with adverse seasons "what can do?"

The coffee referred to was cured and shipped by Messrs. Sabonadiere & Co.—I am, yours faithfully,

E. J. T.

Messrs. Runciman & Smith, London agents for Stockholm Estate, write to this effect:—We have pleasure in forwarding account sales of the last shipment of Stockholm coffee and congratulate the proprietors on the very favorable results realized. There was a regular scramble in the Lane for the Stockholm coffee which was certainly a very fine sample and fetched extreme prices in the present state of the market, as under:—

1 c l barrel	...	...	113s
9 c l t	...	...	99s 6d
2 c l t	...	...	107s 6d
1 c l t	...	...	67s

CINCHONA COCCINEA.

Badulla, 10th March 1882.

DEAR SIR,—I was glad to see, by your paper of the 4th inst., that Mr. J. E. Howard the quinologist, is anxious to get some of the leaves, flowers, fruit, &c., of the cinchona tree, I wrote to you about on the 30th Nov. last, and which I then suggested was *C. coccinea*, as it answered to the plate of this variety in the "Illustrated Nueo. Quinology." At your suggestion, I then sent Dr. Trimen some specimens of the leaves, flowers, fruit, &c. These got dried and mouldy, as Dr. Trimen was away at the time. In his reply he said:—

"From what I can make of them they differ from *C. succirubra* in several particulars, but I am not prepared to give any particular name. Very little is known about *C. coccinea* beyond what can be gathered from Howard's plate; from which your plant differs in the smooth leaf-veins and more obtuse leaves. Unless our 'Robusta' turns out to be it, there is no reason to suppose that *C. coccinea* has ever been brought from South America to the East." On my sending Dr. Trimen a second lot of specimens, he replied:—

"I have examined your cinchona, but I am not able to give you a name for it. I shall place it near *succirubra* and think it probably one of the forms of *C. ovatæ*, but without authentic specimens for comparison it is not possible to name with any kind of certainty. There are points of resemblance to *C. cordifolia*, and, also, as you suggested, to *C. coccinea*. I have not seen quite that form before. From your account of its source, however, there should be others in the Badulla district."

In describing the tree to Dr. Trimen, I think I said it was from 9 to 10 years of age, and originally came from Hakgalla. It answers Dr. Trimen's description of *C. cordifolia* (Owen's Manual) in some respects, but grows to even a greater length than *C. sucirubra*.*

I send you by today's post some of the leaves, flowers, and fruit of this tree, and shall be glad if you would forward them to Mr. Howard at my expense. Should he require a little of the bark for analysis, I shall be glad to send him some of that as well.—Yours truly,

B. G.

[The leaves resemble those of *C. succirubra*, but are smaller and more elegantly veined with pink. They will be duly forwarded.—ED.]

* It is quite unlike the Robusta varieties, Pubescens Urituisinga, &c., &c., og which we have great numbers now in the District.—B. G.

COFFEE CULTIVATION AND MANURING EXPERIMENTS:—6 CWT. PER ACRE OF COFFEE 4 YEARS RUNNING, IN CEYLON.

Maria estate, Wattagama.

DEAR SIR,—I have carefully looked over Mr. Bosanquet's letter of February 1st, in your *Tropical Agriculturist* of March 1st, about his manuring experiments, for which he deserves the thanks of all planters.

He will excuse me for a few remarks I now make on the subject of manuring.

No. 1.—Coffee from eight to nine years old, which was never manured, if the earth is well forked, the trees will certainly throw out wood and give good crop for one year without manure, and may even do fairly well the second year, but, if not manured in the second year, in the third year the trees will be exhausted.

No. 2.—Cattle manure 25 lb. with ½ lb. bone dust. This is no doubt well, when you can afford to give so much cattle manure to each tree, but cattle manure is expensive and I have found that 2 to 3 lb. cattle manure with ½ lb. of a mixture (ashes, lime, fish and poonac) mixed with soil in holes or trenches one year, and the next year a forking with a top-dressing of ½ measure lime and ashes mixed to a tree, has given me in a certain field about 15 cwt. per acre in 1880 and 12 cwt. per acre in 1881. I have this year holed it again and applied the first mixture and the trees promise again a good crop. There was a fair blossom out on the 4th and 5th instant, which has set well, and lots of spike showing. Whenever there is any sign of leaf-disease I at once apply country lime* (from a lime kiln close to this estate) and wood ashes both over and under the trees, and have always been able to kill some and drive away the rest.

As regards the other mixture, I would suggest putting some cattle manure with *all*, even if only 1 lb. a tree. These are *some* of my experiments at an elevation from 2,000 to 3,000 feet.—Yours faithfully,

J. HOLLOWAY.

P. S.—I am glad to add another year, this now being the fourth year of this estate having given its 6 cwt. per acre on coffee in bearing, and parts of the estate promise to make up for another fair average during the coming crop.

GOLD IN CEYLON.

Colombo, 11th March 1882.

DEAR SIR,—With reference to a paragraph *re* gold in Ceylon, I beg to state that each *successive* find of auriferous quartz is *not* the most promising. The order of merit, so far as I am aware, for auriferous reefs is, Ramboda, Hewaheta; Rangala. The quartz on Castlerea is not at all of a very promising description, the majority of boulders being full of cavities with decayed felspar. No *mispeckel* was found there. No *nugget* was ever found in Ramboda, but only gold in fine grains.

ALEX. C. DIXON.

ANOTHER CHAMPION SUCCIRUBRA TREE.

Gampola, 11th March 1882.

DEAR SIR,—I measured a succirubra tree on Gampaha, Udapussellawa, which is 5 feet 6 inches in girth near the ground. This is 12 inches more than the Glencairn tree. The tree is about 17 years old; it had

originally 3 stems, which were cut down 6 years ago, and it has now one stem about 30 feet high.—Yours faithfully, T. H. S.

No. II.

Kelburne, Haputale, 10th March 1882.

DEAR SIR,—I have seen the letter from your correspondent "E. S. G." which appears in your paper of 7th instant. It is alleged that this Dikoya tree was about 14 years old, a single stem 42 feet in height with a girth of 3 feet 3 inches at a point six feet above the ground. One of the large trees I measured was about 20 years old, a single stem, 44½ feet in height, with a girth of 4 feet at a point, free from knots, one and a half feet above the ground. There is accordingly little difference in the size of the trees and I have no doubt mine was the larger tree. I did not root up my tree. The figures for bark, which "E. S. G." quotes, are as follow, and I set mine beside them:—

	Wet bark.	*Dry bark.*		*Wet bark.*	*Dry bark.*
	lb.	lb.		lb.	lb.
Stem quill	142	70	Stem quill	75	26
Branch	40	12	B. & twigs	42	11
	182	82		117	37

How is it to be accounted for that this tree in Dikoya gave more than twice as much stem bark as mine? I observe that my wet stem bark lost 65¼ per cent weight in drying against 50⅔ in the case of the Dikoya stem bark, and my branch and twig bark lost 74 per cent as against 70 per cent in the other case. It is curious to note that the branch bark was almost of same weight in both cases.

I have still standing some old trees which I feel very confident cannot be matched out of Haputale. Mr. G. Maitland frequently stood under them, and pronounced them the finest in Ceylon, and I have yet to be persuaded that the "champion" tree of Ceylon is, or was to be found in Dikoya.—Yours faithfully,

JOHN H. CAMPBELL.

NEW PRODUCTS *vs.* CEYLON CLOVES SELLING WELL.

Colombo, 14th March 1882.

DEAR SIRS,—At the suggestion of Mr. Peter Moir, we beg to hand you copy of a letter addressed to him by Messrs. Brookes and Faith, London, with respect to the sale of a parcel of Ceylon-grown cloves. Mr. Moir thinks the communication may perhaps be found suitable for insertion in the "Tropical Agriculturist."—We are, dear sirs, yours faithfully, GEO. STEUART & Co

Copy.

25, Minciug Lane, E. C. London, 15th February, 1882.

PETER MOIR, Esq.

DEAR SIR,—We beg to advise that at to-day's sale the first parcel of cloves grown in Ceylon was offered, and consisted of 8 cases fine bright heads and short stems, bearing a great resemblance to Penang, and sold with strong competition at 2s. 0½d to 2s 1d per lb. This, we believe, is the first shipment that has taken place to any port and we are given to understand that the trees have been imported from Penang, from which place we receive the best quality.

We think the prices realised must be very encouraging and remunerative to planters, and as the supply from Penang is at all times, small we think there is plenty of room for moderate shipments.—Your obedient servants,

(Signed) BROOKES & FAITH.

COFFEE LEAF DISEASE AND THE CARBOLIC ACID VAPOUR PROCESS.

Colombo, 15th March 1882.

DEAR SIR,—I have read with considerable interest Mr. Storck's paper published in your issue of yesterday. His mode of using the carbolic acid is, of course, extremely simple and is indeed identical with my own, in principle, differing only in the form of application. When after some months of constant experiments I stated, early in 1881, that "*unmistakable evidence had been collected that so long as the atmosphere was tainted with the vapour of this most powerfully antiseptic chemical, leaf disease could make no progress*," Mr. Wm. Smith, one of your oldest and most experienced planters, asked me whether or not some such method as exposing carbolic acid in vessels could be made to answer the purpose. After the preliminary experiments I had one goal before me viz: to devise a practical method by which with the *minimum* expenditure in Carbolic Acid, we could obtain *maximum* and *sufficient* results, and the programme I outlined for this year's operations has been drawn up with that chief object in view. I would have been glad to borrow anything from Mr. Storck which might have tended to more absolutely ensure the success of my work, but apart from a certain want of practicability and the danger of giving the pure strong acid into the hands of the cooly, Mr. Storck uses carbolic acid in the least *economical* form in which it can be used for a *permanent* treatment. The large expanse and contiguity of coffee estates in Ceylon would necessitate here the use of a much larger quantity of carbolic acid than Mr. Storck found sufficient in Fiji.—yours faithfully,

EUGENE C. SCHROTTKY,

PEARL OYSTERS AND SHELLS.—There are on oysters and scarcely any pearl shells on the Barbadoes reefs, but a good pearl is now and then, at long intervals, got from the conch, some of which have brought £5. Mr. Archer has heard of *one* that was valued in London at £50.—*Trinidad Chronicle.*

INSECTS.—The Doctor's Correspondence, in the *American Agriculturist*, contains some amusing as well as useful information respecting insects and their habits. Persons were rather astonished to learn that one of the cockchafers spent three years of subterranean life before seeking daylight, but some of the cicadas, it appears, spend from thirteen to seventeen years underground! We quote as follows:—"As usual in summer, the letters from my young friends are, almost entirely, about insects. It is very natural that this should be so, as there is nothing concerning which less is known, than about our most common insects. These appear in such a manner as to attract our attention merely as objects of curiosity, or they may come upon the plants in our fields and gardens in such numbers, as to make it necessary for something to be done to check their ravages. I am always glad when a boy or girl asks me about an insect, for two reasons: I am glad that it shows a desire on their part to know something of the common things about them, and secondly, it often leads me to study up and learn about the insect myself. You must not think that "The Doctor" knows about everything, in a tolerably long experience, the most that I can claim is a fair knowledge of the means of finding out about the things I do not know. The men who knew the most about the greatest variety of things, of any persons I ever met, were Prof. Charles Pickering, and Prof. Louis Agassiz, yet, I have had both of these say to me, "I don't know." So when the most learned of the world can say "I don't know," you and I need never feel ashamed to say the same. But that should not be the end of it; the fact that we "do not know," should set us at once to finding out."

NEW PRODUCTS: CANDLE TREE (PARMENTIERA CERIFERA) IN TRINIDAD.

From Mr. Prestoe's long and interesting Report on the Botanic Gardens, Trinidad, we quote as follows in reference to a tree which has been already introduced into Ceylon, although not much is known of its products :—

It is now some seventeen years ago that Mr. Bull of Chelsea introduced this rather peculiar tree to the attention of cultivators, having obtained it from Panama. It received its name from the resemblence of its fruits—borne in masses from the stem and larger branches—to hanging candles. So far, I do not find that any use has ever been made of this tree in cultivation, not even that special one as fodder for horses and stock of all sorts, and for which it was originally recommended. The tree now well established in the Orchard and Nursery Grounds has the habit of an erect-growing and thinly-branched English plum-tree. Of moderate habit or rate of growth, it is eminently adapted for field cultivation where the ground might be too uneven or stony for annual cropping. It is also well suited for hill-side positions. The highly satisfactory manner in which this tree has thriven and produced its highly nutritious fruits—together with the fact that all kinds of stock devour them greedily—induce me to give it special meution here as a fodder-plant specially adapted for tropical or sub-tropical countries where the annual or occasional severe drought occasions a scarcity of fodder for certain periods, such indeed as occurs and is a notable drawback to prosperity in some parts of India, tropical Australia, Natal, &c. In this latter colony it is stated on good authority, that the one great obstacle to breeding stock is the scarcity of fodder for a few weeks annually, and occasionally for longer periods. It appears to me that this tree is well adapted to meet this vital want as it exists in Natal. The one drawback with its cultivation in the rough and ready style of farming in the colonies, and the absence of fences is, that owing to the fondness of stock for the leaves and branches as well as the fruit, young trees would always be in danger of being injured or devoured if left unprotected. There appears, however, to be a set-off to this drawback in the character of the fruit. It is usually 18 inches long, and one inch or more thick, and of so firm a texture as to admit of being tied in bundles, and in this form would be quite capable of bearing transport in waggon or by rail 3 or 4 days without injury, provided ordinary precaution be takeu against immediate *heating*. Thus the fruits might be grown in one quarter out of reach of cattle, and be conveyed to another quarter for consumption. The tree is evidently not particular as to soil, but like most trees it thrives best in good soil. Yet it is heavily fruitful in very poor soil, such as that in which it grows here. It may be said that it is never without *some* fruits, but a strong point in its character is that of fruiting most heavily just at the approach of and through the dry season. With these characters I regard the tree as being capable of supplying the tropical dry season with a source of fodder for stock, just as the temperate winter has its supply of fodder in mangles, and swedes, &c. As to yield according to what the trees bear—in the December and January crops—and which is less than half for the year—25 to 30 tons weight of fruit to the acre may be regarded as the average for 10-year-old trees. The deciduous character of the tree in dry weather, and its readiness in producing foliage and remaining green when the weather is not excessively dry, lead me to conclude that the natureof the plant is decidedly accommodating, *i.e.*, it will thrive and be fruitful under much greater extremes of climate as to temperature—than it has to bear here, but still a minimum should not be below 50° Fah.—*Trinidad Chronicle.*

Sandwich Islands Coffee.—The coffee of the Sandwich Islands, known by the name of *kona coffee*, is of excellent quality and easily cultivated; it is sold at the rate of 12 cents the ½ lb in the country. It is consumed without mixture; there is no need of an auxiliary, as with some kinds. Its export, which rose in 1878-9 to 180.000 kilograms, decreased in 1880.—*Journal des Economistes.*

Tanks for the reception of liquid-manure from the stables or cow-houses and for house sewage are useful adjuncts; especially is this the case where the supply of ordinary farmyard manure is limited in quantity, and for use on fruit borders, where it is considered unadvisable to fork in much manure, because of the number of surface roots, and where continued surface-dressings may be raising the borders higher than is desirable. Heaps of loam or compost in stock may be thoroughly enriched by being frequently favoured with a supply when available. Where the subsoil is a retentive clay, tanks may be constructed at a trifling expense, as a 4½-inch brick-wall, set in cement, will generally be found sufficient for the sides, provided they are well puddled around: but on light soils and stony ground two such walls may require to be built with a half-inch cavity between, which can be filled with cement.—*Gardeners' Chronicle.*

Coffee-leaf Disease.—Mr. Marshall Ward has made his third and concluding report on the Coffee-leaf disease, which has caused so much mischief in Ceylon. The disease is caused solely by the Hemileia, a parasitic fungus originally described in these columns by Mr. Berkeley. The whole direct damage done by the fungus is loss of leaves, whence, of course, arise evils consequent on starvation and suffocation. The spores are carried by the wind, germinate in moist weather, and run their life cycle in about three weeks, to begin again their course of destruction. External applications, owing to the countless number of spores and the impossibility of reaching them all, are useless, nor have the attempts made to combat the fungus while growing within the tissue of the leaf been of any service. Mr. Ward recommends the collection and destruction of diseased leaves, not by burning, but by burying them and covering them with caustic lime, sheltering the plantation from spore-laden winds, and cultural proceedings so contrived that there may be as little young foliage exposed during the time when the monsoons prevail, and the spores are most blown about.—*Gardeners' Chronicle.*

Palms.—One of the prettiest novelties among these is the new Caledonian Kentiopsis divaricata, which has pinnate leaves, the leaflets of which are broadish and alternate; the leaves when first developed are of a rich brownish-red colour, and in this stage the plant is very effective. Another new pinnate Palm is the Pinanga patula from Sumatra, which has a dwarf, slender stem from 5 to 6 feet high, the leaves 4 to 5 feet long, with broadish leaflets. In Synechanthus fibrosus, from Guatemala, we have another dwarf and graceful species, with a trunk 4 feet high, and a crown of pinnate leaves, the linear-lanceolate leaflets of which are from 1—1½ foot long; the flowers of this Palm are succeeded by orange-red drupes. Ravenea Hildebrandtii, from Johanna Island, attains to 10 or 12 feet in height, and its pinnate leaves are made up of numerous narrow lanceolate leaflets. In Nunnezharia tenella we get what has been designated as perhaps the dwarfest known Palm, the entire plant, in a fruit-bearing condition, being only 9 inches high; its obovate-oblong nervose leaves are bifid at the extremity, and the yellow flowers are produced in long drooping slender spikes, almost as long as the plant itself. The beautiful Pritchardia grandis, which has figured with such excellent effect in Mr. Bull's prize collections, has been named Licuala grandis by Mr. Wendland.—*Gardeners' Chronicle.*

GORSE AS FOOD FOR STOCK.

It is worthy of note that gorse takes but a small percentage of mineral ingredients from the soil, in comparison with other fodder plants. This is clearly shown by Johnstone, whose statement may well be reproduced:

	Green.	Dry.		Green.	Dry.
1. Lucerne	2·6	9·5	3. White Clover	1·7	9·1
2. Red Clover	1·6	7·5	4. Gorse	0·82	3·1

In Ireland gorse is much grown for purposes of stock-feeding. In the western part of County Cork, and, in fact, in many parts of north Ireland, it occupies a prominent place as food for both horses and cattle. One large farmer has been known to feed for many years two or three hundred head of cattle from Nov. 1 to the following May on chopped furze only, Sunday excepted, when they were regaled with turnips. And these cattle were said to be as fine and healthy as any in the country. But, generally speaking, horses in work, or cows in milk, are not fed conclusively on gorse by farmers who have experimented with it. Youatt used to say that, "If 20 lb. of furze are given to a horse, 5 lb. of straw, the beans, and 3 lb. of oats may be withdrawn." Experience has shown that horses thrive well on gorse and a feed of boiled potatoes once a day. In every case where furze-feeding is practised, it is desirable to mix a small quantity of salt with the other food, particularly for horses, as furze is of a heating nature. Furze-fed cows yield milk rich in cream, and the butter produced from it is of a fine natural colour —far superior to that made from the produce of cows fed on hay and turnips.

The following table will be serviceable as showing the high rank which furze takes, among different kinds of winter fodder:

	Flesh-forming matter.	Fat-forming matter.		Flesh-forming matter.	Fat-forming matter.
Furze	3·21	9·38	Swedes	1·94	5·93
Cabbage	1·63	5·00	Carrots	0·60	1·018
Kohl Rabi	2·75	8·62	Turnips	1·80	4·43
Mangolds	1·54	8·60			

It is matter for surprise that English farmers have not long ago extensively brought into use such a valuable food for their stock. Probably the true explanation is that they are, as a body, ignorant of its suitability for this purpose.—G. G.—*Field*. [Gorse or furze (in Scotland whins) grow freely at Nuwara Eliya.—ED.]

A PLANT TO REPLACE THE VINE.

We have received the following communication from M. Auguste Delcuil, agriculturist, member of the Agricultural Society of France, &c.:—

Everyone has heard of the great losses our national agriculture has sustained during the last twenty years from the ravages of the phylloxera; more than half of the French vines have already disappeared, and none can foretel the extent of the devastation to come. Vainly have all kinds of remedies been tried, but without success. In spite of the thousand and one recipes employed in turn to combat and to destroy it, the phylloxera continues to ravage at will our splendid and luxuriant vineyards. In the face of such a disaster, an energetic agriculturist, whose labours have already received the sanction and encouragement of our learned societies, after many fruitless efforts to remove the evil, has succeeded, not in destroying the effects of the phylloxera, but in bringing forward another wine-producing plant. Thus, leaving the vine to its fate, he turned his attention to find out if possible another plant to supply the elements of prosperity which we are losing by the disappearance of the precious vine.

At last this plant has been found. It is a variety of red beetroot, unrivalled in the whole world for its incomparable qualities, which will in time replace all that we have lost in the vine. Beetroot produce alcohol of superior quality: why, then, should not its pulp, treated like the must of the grape, produce an equally luscious beverage? In fact, this has been done; the very sweet red beetroot produces by fermentation a wine quite as good as many of the *soi-disant* wines of our southern vineyards. It possesses the additional advantage of accommodating itself to all soils, and flourishes in most climates.

We wish, then, to make this fact known, if it be only to stimulate new discoveries or develope further resources in wine growing.

With the view of popularising this plant, the propagator places himself gratuitously at the disposition of agriculturists, to furnish them with the seeds they may require. Application can be made to M. Auguste Delcuil, Agronome, à Gardanne, près Marseille, France.—*Field*.

DATE COFFEE.

In view of the efforts now being made to popularize date coffee in this country, the following opinion of a chemist who has recently given the subject much attention will prove of interest. Coffee, says he, referring to the genuine article, is eminently the beverage of the masses and one of those things that should be kept in the best manner, at the most moderate price, for the sake of common commercial morality. It is by all food authorities claimed to be a powerful respiratory excitant, and has a crystallized nitrogenous element, called caffeine, upon which the action chiefly depends. It decreases the vaporizing action of the skin, and therefore dries that organ; it lesseus the loss of heat of the body, and increases the action of the heart. For these reasons coffee is also eminently the drink of the poor and feeble, because it augments energy and pulsation. But in date coffee the vegetable fibre strongly predominates, and but for brown extractive matter and sugar, little volatile properties can be expected. On trial, the chemist above referred to found that it coloured well, but possessed a taste not agreeable, and a burnt flavour of a peculiar character, rather sickly than otherwise. In his opinion, all other known combinations in which coffee plays a part, such, for instance, as the Eichel coffee of the Germans and others, have a more aromatic taste than this peculiar offshoot of the brain of an enterprising man. "There have been testimonials given that date coffee is a healthy beverage," says he, "but these testimonials are not comprehensive enough to make us change our grand old beverage for one which is far inferior, really does not carry out the purpose it is intended for, and need not be fetched so far at an immense expense. The Arab has the date and coffee, but he prefers the latter as a beverage when he can get it; and we have various substitutes of native growth less costly than the date, which would answer the same purpose if the genuine article were scarce." Although date coffee does not belong to the class of food adulterations, but to that of food imitations, it should of course be sold for what it is, if sold at all. There is here a danger of fraud against which it is proper to guard.—New York *Commercial Enquirer*.

UMBRELLA AND WALKING-STICK PLANTATIONS.

When Beau Brummel defied public ridicule in order to found that useful institution the umbrella, he probably little thought to what enormous proportions the industry of manufacturing those now indispensable articles would grow: and we may take it for granted that neither he nor his representatives of the "crutch and toothpick" order ever imagined that the demand for certain kinds of walking-sticks and umbrella handles would threaten with destruction a valuable and important West Indian planting industry, which had its origin in the supply of spices. American statisticians have calculated how many trees are required every year to supply the wooden toothpick which on that continent takes the place of a familiar quill. The *Jamaica Gleaner* now

tells us that the pimento or allspice walks in Jamaica are threatened with destruction owing to the ruthless way in which the young plants are pulled up in order to supply the demand for umbrella and walking sticks, for which purpose the beautiful shape and grain of the wood render these sticks great favourites. A month ago it was estimated that in Kingston alone there were half a million sticks awaiting export to England and America, to be made into walking-sticks and umbrella handles. These sticks were almost without exception pimento, and it is not surprising to hear the owners and lessees of pimento walks are being alarmed at the growth of a trade which threateus to uproot in a few years all their young trees, and deprive them to a great extent of their income. The export returns for the last five years show that an average of 2,000 bundles of sticks has been sent out of the island annually in the ordinary course of trade, without taking account of the numbers taken away by hand, by casual travellers, and those consumed in Jamaica itself. The present year has seen a large increase in this trade, the returns for the first three quarters of the financial year showing an export of over 4,500 bundles, valued at more than £2,000. When it is remembered that each bundle contains from 500 to 800 sticks, each of which represents a young bearing pimento tree, the extent of the destruction may be realised. Even then a large addition must be made for faulty sticks, pulled up but rejected by the exporter. The pimento crop of Jamaica during the last ten years is estimated to be worth over half a million annually; and, although the plant is indigenous, and grows wild, those who make its cultivation an industry complain that walking-stick collectors do not confine their attention to the wild crops, but prefer the better-shaped plants on private "walks." The plants destined to provide walking-sticks are pulled up by the root, so the destruction is complete; and the walking-stick trade, whether carried on by legitimate collectors or not, bids fair to seriously interfere with the production of pimento, unless steps are taken to protect a due percentage of the stock.—*Colonies and India.*

SULPHURIC ACID—ITS USE AS A PROMOTER OF THE RAPID GERMINATION OF SEEDS.

The following extract from the *Statesman* on the properties of Sulphuric acid for hastening the germination of seeds, together with some notes thereon from a correspondent, J. N., will doubtless prove of interest to our readers:—

Certain experiments recently made by Professor Tyndall, upon the use of sulphuric acid in promoting the more rapid germination of seeds, or rather fruits, contained in shelly capsules, such as nuts, almonds and stones, have been attended with such marvellous results that attention may well be directed to it in India, where the difficulty of raising fruit trees from imported stones with a view of improving stock, has been the frequency of mildew setting in before germination takes place. Seeds and stones soaked in a solution of the acid receive such a germinating impetus from this tonic that they shoot in a space of time hitherto unknown to agriculturists. This should be good news to those residents of our hill stations who have failed hitherto in raising plants from English or Australian stock: many seeds of aquatics, such as water lilies, have been known to remain dormant for two years, sorely trying the patience of those enthusiasts who have essayed their growth; tea seed need no longer be forced in trenches but soaked for a few hours only in the solution.

* * * * *

The properties of vitriol, as an agent for imparting vitality to wheat seed and also as a preservative against the charcoal-like appearance of the ears of the corn, are well known to some of the agriculturists of the South of France. The latter say that wheat seed, scalded with vitriolated water, produces a healthy crop, and some of the seed, which, sometimes, would indubitably rot, if it was sown dry, has its powers of germination restored by the action of vitriol. I have no doubt that if tea or any other seed were treated similarly, a good percentage would be saved every year to the planter or to the cultivator.

I saw the scalding process some 25 years ago, and if my remembrance does not deceive me, the operation is as follows:—First of all put in a basket the quantity of wheat you wish to sow the next day. Raise to boiling point enough water to scald your seed. Remove the vessel from the fire and pour in the boiling water the vitriol stones; stir the water with a stick, froth or scum will be produced, I believe, and the water will rise in the vessel; do not be afraid; no explosion will take place.

When the vitriol stones are dissolved, which ought to be done in a few seconds, pour the water on the wheat in the basket. As the water is poured on the wheat, free escape must be allowed.

I could not prescribe the proportion of vitriol stones, but I think half pound of stones to a maund of wheat should be sufficient.

As the process is simple and cheap, native cultivators ought to be induced to try it.—*Indian Tea Gazette.*

TOMATOS PLANTED OUT.

The beds we plant in are 2 feet wide and 1 foot 6 inches deep, and are formed by building up the sides with turf, commencing on the floor of the house, which is formed of rough gravel, and this acts as drainage for the beds. The soil for the Tomato when planted out should be open and porous rather than rich. A good fibrous loam, with one part of lime rubbish and a sprinkling of bone-meal, will be found to answer well, and retain its porosity for a considerable time, not readily becoming soured with frequent doses of liquid manure which will be required when the plants get over their first flush of vigour, and commence to fruit the whole length of the rafters. The greatest mistake generally made in growing the Tomato is in the training of the plants, which are allowed to run in all directions till they become a confused mass, and this is often aggravated by stopping the plants above every show of fruit. The method we adopt is to train the plants as single, double, or triple cordons. For the first method of training we plant about 10 inches apart, and for the other methods we give room according, that is, about 10 inches for each growth. These cordons are allowed to run from the bottom to the top of the house without being stopped, and we never find them fail to show fruit about every six inches; and if the temperature and atmospheric conditions of the house are kept right, every flower will set perfectly, and the result is a perfect wreath of fruit from bottom to top, and from end to end of the house.

As fast as the first fruits ripen and are gathered from the lower part of the cordon, another leader is brought away from the base, and is allowed to proceed as fast as the fruit is gathered on the first cordon. The second shoot soon commences to show fruit, and with a little thinning of foliage and the removal of the greater part of the foliage from the lower part of the original shoot, the young fruit has room to develope, and the result is that the house is kept continually furnished with fruit, without the growths getting in any way entangled or confused. A little care must be exercised in watering when there are many fruits ripening on the plants, as they are very liable to crack with a sudden dose of water, especially if the plants have been allowed to get very dry, but the most prolific cause of cracking is closing the house, and watering and syringing the plants at the same time.

The varieties of Tomatos to select from are now plentiful enough; our favourites are Hathaway's Excelsior

and Trophy. The former is a handsome variety of medium growth and a sure fruiter; the latter is one of the largest varieties, very prolific, and perhaps unsurpassed in quality. Seed of some approved variety should be sown at once in brisk heat, shifting them on as they fill their pots with roots, and confining them to single stems till they reach the height of the trellis to which they are to be trained, when they should be allowed to grow as single or double cordons.—F. ROBERTS, Gunnersbury.—*Gardeners' Chronicle.*

THE COFFEE AND SUGAR PRODUCING COUNTRIES OF THE WORLD.

HAYTI.

This island was discovered by Columbus in 1492, and is next to Cuba the largest of the West India islands. It is upward of 400 miles in length, from east to west, and averages more than 100 in breadth, covering an area of 29,540 square miles. During the past sixty years Hayti has at times been a kingdom, an empire, and a republic after a series of revolutions, which finally, some forty years ago, enabled the Spanish portion to separate from Hayti and set up as an independent republic.

Sugar-planting has never revived in Hayti, but coffee-planting has. In a good crop year Hayti produces 30,000 tons of coffee, against half that much thirty years ago. On the whole Hayti coffee is prepared for market slothfully, containing most of it little stones which have to be picked out by hand, too expensive a method for this country. Hence the bulk goes to Europe, and even the greater portion of what arrives here is reshipped to Havre, Antwerp, and Hamburg. Its quality is tolerably pure, but in appearance it is irregular, and in Europe, we presume, it is greatly used, to be mixed with other sorts. The present government is prevailing upon the petty planters in the interior to bestow more care and attention upon the preparing for market of this, the chief product of the island, and issued a circular the other day to its consuls abroad promising a notable improvement in this respect in the future.

That in this item President Solomon and his cabinet may have their efforts crowned with success, we sincerely hope. Various sorts of Hayti coffee are very fine indeed, not only in point of flavour, but in looks, and with a more diligent and intelligent planting, picking and preparing, the entire crop may in the course of a few years show a great improvement, and easily average 10 to 15 per cent more, which would be an annual gain of $300,000 to $500,000, not to be despised in a comparatively poor country.

Cocoa production does not amount to much in Hayti, the quality being too bad; no doubt likewise susceptible of improvement by better treatment. The next important export to coffee is logwood, and there is some honey, a good deal of fine mahogany and some other woods.—*Rio News.*

THE WHITE GRUB ON PASTURE.

E. M. Beach, Sangamon Co., Ill., writes us an account of the pasture of his neighbour, "T. H. E." The writer states that the pasture, several years established, had never been fed very close, and last year, especially, the grass made quite a strong growth. This year about one-half of the pasture is quite killed by the White Grub. In places every root is so completely destroyed that the grass can be swept off "as you would sweep snow from a plank." He asks, "where do these grubs come from?"—and "will the pasture rest itself, or must it be broken up and resown?" He concludes his letter by saying: "The grub question has become a serious one, and our people do not understand it." If our friend's neighbour's do not understand the "grub question," it is not because the *American Agriculturist* has not kept them informed upon it. When we published a few years ago, the remarkable destruction which we witnessed upon the lawn of one of the finest places in New England, described the grub, and gave the remedies that seemed to be the most useful, it is probable that our friend took but slight notice of it, as it was so far away from home. So to begin anew, and answer the question, "where do these grubs come from?"—They are the larvæ or grub state of the brown beetle, that is commonly known as the "May-bug," "June-bug," or "Dor-bug," which, when it enters the house, attracted by the light in May and June, bounces about and knocks its head against the walls and ceiling in such a manner as to attract notice. When a few of these enter the house, it is probably that there are many more elsewhere. If the fruit trees in the neighbourhood be examined, no doubt but large numbers may be found; they especially harbour in cherry trees. In early morning, when they are torpid, large numbers may be shaken down, caught upon cloths, and killed. Every female beetle thus destroyed prevents the laying of over 100 eggs, some say over 200. The eggs are laid in the ground, and the grubs require three years to complete their growth. They feed upon young roots, but they do not appear to be large enough to do their worst mischief until their last year, when their work upon the grass roots is often most disastrous. Our friend is right in saying that the "grub question is a most serious one," and it appears as if it were to become to our farmers what the "Cockchafer question" is in England, and the "Hamneton question" in France. In those countries, a closely related insect, with very similar habits, is such a pest that prizes are offered by Government, in France at least, for its abatement. With us the complaints are each year more numerous, and the plague appears to increase rather than diminish. But a few days ago, a fruit grower came to us with a doleful face to tell of the complete ruin of his strawberry plantation from this cause. What can be done? The presence of the grub itself is not suspected until the mischief is done. The most effective help against the grub is the crow, but that, should it be seen after a grub and its keen senses allow it to go for and destroy it—would be at once shot or driven away. Crows are the most active helpers, and should be protected by law. That unpopular animal, the odoriferous Skunk is another friend of the farmer, but war is declared against him, because he is suspected of varying his diet of grubs with an occasional spring chicken. No human help can avail while the insect remains in the grub state. Aside from shaking the beetles from the trees, they may be caught by means of lamps, so placed in lanterns that the beetles in flying against them, will drop into water. We gave a year or two ago a method employed in Texas for thus trapping the beetles.—*American Agriculturist.*

TREE PLANTING.

It will no doubt be readily admitted that the best time to plant deciduous trees of all kinds is soon after the leaves have fallen. It may hardly be necessary in all cases to wait for this event taking place, but where planting has to be done in a large scale, the planting season has necessarily to be considerably extended, and planting may be successfully performed at any time from the end of October until the beginning of March, when the condition of the weather will admit of its being done. Few seasons have hitherto proved so favourable for planting operations as the present. It will also be admitted that the best method of preparing the soil for the reception of young trees is to dig or trench it at least two spits deep, and if poor to give it a good dressing of manure or fresh soil if it can be obtained, which is not often the case. We may also allude to what is possibly the worst method of planting trees,

and which is unfortunately the one too frequently practised, viz., that of digging a hole or pit so exceedingly small that the roots of the tree can with difficulty be crammed into it. This method is infinitely worse than what is known as the T form of planting, which is sometimes practised on poor rocky soils in Scotland and elsewhere with tolerable success; and where anything in the form of digging or trenching is out of the question.

Trees planted in this way must necessarily be of comparatively small dimensions. The operation itself is exceedingly simple, and consists of the operator merely making a slit in the turf with his spade, and then inserting the same at one end of the slit, at right angles with it, and by pressing down the handle of the spade the slit will be forced to open more or less, when the assistant passes the roots of the tree into the opening thus made, and a slight amount of pressure with the foot is all that is required to steady the tree, care being taken to leave it in an upright position. By this method an immense number of trees can be planted by a man and a boy in a comparatively short time.

In cases where pits or holes are dug out for the reception of trees, the same should always be of considerable dimensions as regards width as well as depth, and corresponding, of course, with the size of the trees about to be planted, but always sufficiently large to admit of the roots of the plants being spread out to their full extent, and sufficiently deep to admit of a portion of the best of the soil being placed in the bottom of the pit, in order to raise the bottom to the requisite height, and to allow the roots of the tree a portion of friable material into which to extend themselves.

But it is to the planting of trees in properly prepared soil—that is, in soil which has been drained and dug, or trenched, that these remarks are intended principally to apply. Too deep planting of trees on such prepared soil has been no doubt deservedly condemned; but it is to be feared that some planters in their endeavours to avoid Charybdis have fallen upon Scylla, and on some kinds of soil too shallow planting is as necessary to be avoided as too deep planting. On heavy and imperfectly drained land deep planting should by all possible means be avoided, and the trees may in such cases with advantage be planted on a slight mound, or slightly elevated above the level of the surrounding soil; while on very light land the converse of this practice should rather be followed, as in the event of continuous dry weather setting in several inches of the surface of such soil becomes perfectly desiccated, and before the roots of recently planted trees can penetrate the soil to a greater depth, many of them must inevitably perish. Many years ago we had occasion to know something of a large estate, a portion of which consisted of very light poor land, and a considerable part of this about the time alluded to was being planted with forest trees of various kinds, chiefly Larch, and the planting of which was entrusted to an old trustworthy man of great experience in such matters, whose invariable practice was to plant somewhat deeply, and in addition to this to form, as it were, a shallow basin round each tree, as is done in the light soil at Kew, thus securing for it as ample a share of the rainfall as was possible, or, at all events, to effectually prevent the same running from it during sudden or heavy falls of rain. This practice was generally attended with every success that could reasonably be expected, considering the nature of the soil and the prevalence of ground game. But a change happened to occur in the management of the estate, and the new manager, or agent, changed to be one of those who fancy they have nothing to learn, and who had possibly been accustomed to land of a different character. So he demurred to this method of tree planting, declined to discuss the matter with the old planter, and peremptorily ordered him to plat as he (the agent) desired, which was accordingly done. The weather during the following spring months proving dry, the result was in all respects a complete failure.—*Gardeners' Chronicle.*

FLOWERS OR SHOOTS.

In the *Gardeners' Chronicle* of January 7, there is a very interesting and suggestive extract from Count du Boyson, which I would like to notice. Gardeners very well know that whether plants will flower profusely, sparingly, or not at all, depends to a great extent on the state of maturation to which they have been brought previously. This is true alike of Apple trees, Rhododendrons, or Orchids, and almost all flowering plants cultivated in gardens, as well in the open air as under glass. The idea that after flower buds are formed they may be changed into leaf shoots is, to me, a new one, and so extraordinary that I venture to think some misinterpretation of the facts has occurred [and so do we]. We are all perfectly aware that when shoots, bulbs—what you will—of Dendrobes are imperfectly ripened, they in many instances, notoriously so in the case of D. nobile, produce leaf-stems where flowers generally appear. This results, as has generally been understood—and as I, for one, still believe—not because of any particular treatment the plants receive after the buds begin to grow, but because of the want of due exposure to the light the previous autumn.

Many, very many, plants have the power of modifying their manner of propagation according to the circumstances under which they are placed. Common Leeks, for instance, in cold climates produce many miniature bulbs on the top of the flower-spikes instead of the seed which they form under more favourable circumstances; not because of an extra supply of nutriment, but because of the want of enough light and heat. Other instances your readers will readily recall. The idea presented to me in the extract referred to is that a certain measure of starvation will make matters right. So far as regards plants growing under climatal conditions which we cannot modify, such is the only course left us, and has been pursued by us for many years; for it is with this end in view that we have used grit in our fruit tree borders, and have employed loam without much manure, and have rammed it hard to prevent a too rapid taking up of even what limited supplies of food were available. And when I did feed it was by surface-dressings, which would encourage the roots to seek the sun-warmed food, so that no lowering of the temperature of the trees might occur through cold sap. All this I have done, and so far it agrees with what is hinted, excepting that we never dreamed that a wet spring would change our blossom-buds into "leaf-shoots," although it might spoil the flowers that did form.

It is, however, more particularly to house plants, and especially Orchids, that the Count refers. As we differ altogether from the opinion that extra supplies in spring do the mischief, we think that, generally speaking, any degree of starving should be avoided, because we have the climate of hot-houses in our own hands to a great extent. I by no means mean by this that Dendrobiums at all stages of their growth should be liberally supplied with water, either in the soil or the air, for such would certainly defeat our purpose if flowers were our aim. At the same time I think that it is not good to starve in *any* degree. The right thing in the case of Dendrobium nobile, and many other plants—Vines, for instance, is to start early in the season, so that the growth may be made up early, and fully matured under the influence of the sun ere yet the sun's beams have lost their power to mature. No plant requires the same moisture at the root while ripening that it does while pushing out shoots and leaves rapidly, and in many instances disaster will result if growing conditions are maintained for ripening plants.

In the case of Dendrobium nobile and many others, we find that when the growths are fully made up by August, in a house not too moist or shaded, and afterwards exposed to the full sun and abundance of dry warm air, that a very free state of flowering results. When the growth is made up late, and in moist shady quarters, the result of this drying and exposure later on is shrivelling, debility, a scarcity of flowers, and a predisposition to produce "leaf-shoots" in spring, no matter what conditions they are then subjected to. This year our Dendrobiums are flowering less profusely than they did last year, and yet they had both years the same treatment. The seasons, however, were in this district very different: 1880 was fairly sunny, while the autumn was particularly bright; 1881 was cold and dull, especially in autumn. The consequence of this was that all our indoor plants, even although helped by extra fire-heat, were later in making up their growths, and finished them under unfavourable circumstances. In the case of our Vines we fired on later to make up for deficiencies; but our Dendrobes (for want of sun in autumn, not because of too liberal supplies now), are producing flowers less freely than usual, and many more "leaf-shoots." Those later on, as with the Count's, produced more freely at the tops of the bulbs, while the former are, like his, produced lower down. This, we consider, is owing to the tops being less fully ripened, and not to any special determination of sap to the tops. Such a flow of sap may help to produce larger, finer flowers, but I cannot think it would change flowers into shoots.

In the case of many other orchids which grew freely but flower sparsely, or not at all, all they want is more air, more light, and more heat, rather than a withholding of supplies. Odontoglossum cirrosum, which, in a cool, moist, shaded house grows so very freely, and throws up long spikes which never flower, or only produce one or two blossoms to the yard of spike, change for the better when grown in a light, airy position in an intermediate house, but they will grow less freely. As a matter of fact, Nature strives to reproduce the species by seed, and when the atmospheric conditions for that are unsuitable, she falls back on the vegetative method as a last resource. Taking advantage of this fact we can produce the majority of plants at will by whatever mode promises the best results. Taking advantage of this we improve the artificial climates in our vineries by firing—not by starving—so as to prepare the Vines to propagate themselves by seed to as great an extent as possible. Taking advantage of the knowledge painfully and slowly acquired, we limit the food supplies to our outdoor trees, where that is necessary, and secure the same result; when the trees are young and scarce we follow the opposite course to secure, not seeds, but "leafy shoots" to graft with.

It is the same with all our fruiting and flowering plants, Orchids not excepted. It is this knowledge which causes us to adopt so very different practices where different results are wanted; and this which makes us adopt quite different modes, according to the subjects we cultivate and the latitude in which we practise. It is this which shows one course to be right under bright skies and in dry localities, and wrong when clouds lower and rains reign, and *vice versa*.—Practical.—*Gardeners' Chronicle*.

SUGAR PLANTING IN JAMAICA.

This article is so able and good that we give the whole. It is an entirely new view of things in Jamaica, especially in regard to cooly immigration, compelling the negro to work. It has also a bearing on Ceylon in some things.—Ed.

Kingston, Jamaica.

As the Sugar Bounties question is playing so prominent a part just now in regard to foreign treaties in England, it is important to hold correct idea concerning the prospects of Sugar-growing in the West Indies. Our here people have been much exercised at the behaviour of the Home authorities. For, instance, the Board of Trade letter to the Refiners' Working Men's Committee has been read with very qualified satisfaction. The allusions to the Sugar Colonies are neither flattering, nor do they exhibit a proper grasp of the facts of the case. We read, "It would be unfair to ask the consumers of the mother country to forego cheap Sugar," in order to encourage Sugar-growing in the colonies, for to do so would be "to make the possession of the colonies a burden, and not a gain, to this country." Such language not only savours of the old-world colonial policy which it was supposed England had discarded for ever—a policy which, contrary to true and wide principles of economic science, regarded colonies and mother countries as rivals, and not as allies—but also savours of a trust reposed in representations made in England which have in truth little connection with the actual state of affairs out here.

It is, perhaps, well that we can take Jamaica as a sample of West Indian Sugar-planting, for the reason that Jamaica is generally allowed to be the worst off and the Sugar industry there is painted as in a decidedly "ruinate" condition. The question remains, does this particular industry, even though in such bad repute, either need or claim any self-sacrifice on the part of the consumer at home to enable it to survive? And the question is completely answered, and altogether in the negative, if we regard the price per ton at which Sugar can be grown here.

But the answer has to be arrived at through an immense amount of misconception that extends even among people who live in Jamaica. The very planters are, many of them, entirely misinformed as to their actual position. Some of them are indignant, for instance, if asked to believe the fact that year by year Jamaica is exporting more and more Sugar and Rum. Yet these are the official figures of amounts exported:—

Years.	Total tons of Sugar.	Total Puncheons of Rum.
1850-59	320,000 ..	170,000
1860-69	330,000 ..	180,000
1870-75	350,000 ..	201,000

Thus, since matters have arranged themselves after their upsetting in the abolition of slavery, the Sugar industry has shown steady growth.

There is, indeed, one great apparent contradiction to these figures, and that is the constantly quoted fact of the abandonment of Sugar estates. This process has been proceeding until quite recently, but local experience yields the true explanation that it is a process altogether beneficial, and in truth a putting off of the old system, and not a failing of the new. It is true the older planters themselves see but little consolation in the dismal fact that where once they and theirs reaped fortunes now all is worthless scrub. But if we remember that in the old days Sugar was at £60 a ton, and that now £20 is the price for the same, we shall see some reason for a change. The fact was that in those good old days vast areas of soil were cultivated at enormous profits, which areas at present prices can yield none at all. That these areas should get out of cultivation is a gain and not a loss to the industry. In those days the "margin of cultivation" was lowered to a degree altogether untenable now; and it was, moreover, incidental to Jamaican affairs that long after the real conditions of their prosperity had passed away, many of these estates continued in cultivation at the first, in the hope of better days; in the end, because such estates had for the most part fallen into the hands of mortgagees or holders of jointures and charges upon them. Thus, as a rule, two or more estates came under the same absentee ownership, and what was lost

on those that ought to have been at once put out of cultivation was more than made good by the profit from the others more favourably situated. But this was obviously a serious drag on the aggregate prosperity of the industry. And of late years a wholesome change has come. The mortgagees have been largely realising, and a new class of unfettered and resident proprietors has arisen and bids fair to increase. These men will not grow Sugar unless the soil and aspect are sufficient to make the cultivation pay at present prices. And some of the shrewdest local men are investing largely in such cultivation. It is the inauguration of a new order of things, in thorough and wholesome keeping with the times and their needs.

There was much that was altogether wrong and "uneconomical" in this survival of a state of things hopelessly out of accord with the times. The case was pithily put to me the other day:—"Each estate of 300 acres is expected to keep five carriages—the owner in England must have his brougham; the merchant in England must drive his barouche; and the merchant in Kingston, the owner's attorney, and the overseer on the estate must each of them maintain his buggy." In the old days of £60 a ton such maintenance was perfectly practicable, but when receipts fell from £18,000 to £5,000 per annum, such claim on the resources of the estate could no longer be met, for expenses at the least remained the same as of old. And now each one of these five classes, from his own point of view, declares Sugar-growing hopelessly ruined for ever. It has now been found that when the profits are lowered by two-thirds similar profits are still to be made, provided the number of those who share in these profits is reduced *pro tanto*. And this discovery is the secret both of the calumniations and of the present prosperity of the Sugar-growing in Jamaica.

Thus, if we penetrate these and other misconceptions, we shall appreciate aright both the present actual cost of production of Sugar and, above all, its future prospects. These costs divide themselves under two great heads, respectively dealing with cost of cultivation on the one hand, and cost of transferring the commodities and putting them up for sale in the English market on the other. In regard to the present cost of cultivation, a wide experience of estates leads to the decided opinion that so long as Sugar commands £12 or £14 a ton in the local market fair profits are made by the growers. Beetroot-growers should pay attention not only to this fact, but to the further consequent fact that there are many improvements in prospect, or at all events possible, that will considerably modify even this low first cost of Sugar grown in Jamaica.

For some time past there has been a forward movement in Jamaica in regard to Sugar-planting, and those who enjoy local knowledge are fairly nonplussed at some of the evidence tendered to Mr. Ritchie's committee as to the backward and unintelligent state of Sugar cultivation here. It is true that in Jamaica there is a greater variety of estates than in other colonies; this is due to the fact that they extend over a far greater area, and an area of far greater natural variety. Consequently, there is no one uniform type of procedure, and on many estates it is reckoned far more profitable to produce the coarser than the finer types of raw Sugar. This is specially so on estates where a large proportion of rum is made. But every year more care is being given to improvements. The great item of cost, "hauling" the cane from the fields to the works, is now receiving much scientific treatment. Tramways and wire railways, laid down steep slopes and over ravines, are being introduced for this purpose. It was no uncommon thing in the old days for the working beasts to survive for but two, or at most three, years. Now on many estates, by better handling and more skilled treatment, the oxen work for six and seven years at a stretch, thereby reducing largely the cost of production. Better machinery is being introduced for the crushing of the cane and the manufacture of the Sugar; in fact, the very ruined windmills and water-mills that one meets in the country are the evidence of the introduction of the more economical steam-power.

The actual cultivation is also capable of vast improvement. At present the tendency is to cultivate too much soil: this is plentiful and cheap, and the temptation to cultivate roughly is stronger than the reasoning which shows that such cultivation enhances the evils, and fails fully to utilize the advantages of the work. The difficulties of weeding, of planting, of hauling, of manuring, of irrigation, all implying extra labour, are simply increased by this system of working roughly a large area, rather than carefully cultivating a smaller area. It has been repeatedly proved that the smaller area, if really thoroughly cultivated, will often yield two, three, and even more tons to the acre, whereas by the rough-and-ready method barely one ton will result, while all the necessary expenses, as above detailed, will increase rather than be lessened. This item of improvement alone would double profits in many cases.

Thus, the reasons for entertaining high hopes of yet cheaper production of Sugar in Jamaica are many. They are greatly dependent on the fact that Jamaica has, since the old state of things was definitely done away with, become more and more a flourishing community in itself, and less and less a mere exporting farm existing for the benefit of distant propriet rs. Thus, though Sugar continues to increase in output, it does not do more than keep pace with the increase in other Jamaican products; and so the planter is now enabled to cultivate in other crops large areas that were valueless unless they could be devoted to Sugar. Pimento, logwood, coffee, and more especially fruit of all sorts, have largely developed as articles of export. The breeding of cattle, too, has become most profitable, chiefly because of the rise of a local demand, which already consumes over 1,000 beasts per annum, and there are prospects of a large export trade to Cuba and other neighbouring islands.

The consequences of this new-born activity is that the negro population is in a condition of much material prosperity. Its numbers increase year by year, and that they are successful is seen by the fact of their increasing expenditure in "luxuries." They buy largely the beef above alluded to, which fetches 6d. a pound. They are large consumers of bottled ale and stout, and, the crucial fact of all this in regard to Sugar planting is that this wholesome growth means an increasing and reliable supply of labour. Even at the present it is difficult to find a district where negro labour cannot be had for under 1s. a day. This is an advantage of no mean significance when we find it reported that similar labour in the Sugar States of the United States costs over 2s. a day. The negroes are well known to be capable workers; the sole difficulty hitherto has been to prevail upon them to work. However, both the incentive and the threat have been discovered in the importation of coolie labour. The present Government of Jamaica has wisely seen that this coolie labour is not of mere direct use to those who actually put coolies on to their estates, but that it is far more than this—that it is of high benefit to the whole community, black as well as white, in rousing the negro to exertion in his own interest. In this respect the importation of a few Chinamen would, no doubt, add additional stimulus. The negro can and will work, and work well, provided he can be roused from its natural inclination to "save his strength," prone on the broad of his back in the sun.

Thus the prospects of reducing the cost of cultivation are good and sure; but there is also a very good prospect of reducing the other item—viz., the cost of putting the Sugar into the English market. Steam is assisting greatly; and it is now possible to transfer Sugar cheaper by steam than by sailing vessels, even

though freights are nominally higher. The shorter passages of steamers do away with a great deal of that drainage that so lessens the bulk or value of many of the coarser-made Raw Sugars. Then, too, Jamaica is a large island with many ports. The Sugar estates near these ports ship their Sugar from them. In the old sailing-ship days, such was the expensive delay of loading from port to port—a few hogsheads at each, and subject to every change of weather—that freights from the north side of the island were actually £1 more per ton than from Kingston. The present Governor has in a great measure obviated this difficulty by his inauguration of weekly and regular steam service round the Island.

But where most hope is looked for in regard to this transferenee to big markets is in a coming era of new commercial freedom, which shall emancipate the new order of proprietors from that complex commercial system by which the transference of all Sugar to the English market fell to the monopoly of a group of individuals in Englaud. From the days of slavery downwards capital has been advanced to planters from extraneous sources, and in course of time estates became not only mortgaged heavily, but encumbered with jointures and charges of all kinds. The capitalists held tó their liens, and the intervening merchants, both in the supply of stores and machinery to the estates and in the carriage of the Sugar to Eugland and its sale there, found scope for the making of great profits. But the low prices that have come in late years show that there is no longer su Eicient profit for all, and the middleman must be content to transfer much of his activity to other fields. His profits on the cost of transit alone have been placed by good authorities as high as 2s. a cwt. But already this system is passing away. The mortgagees are selling for what they can get; old proprietors are setting their houses in order to meet the new necessities of the times. Thorough change is neecssary, and even old planters have already so far thrown off their trammels as to be enabled to ship their Sugar direct to the United States market—a market at present highly favourable for coarser raw Sugars. Some of the most shrewd and most successful local men are buying up old Sugar estates under the new free conditions, and there seems every prospect that Sugar will soon be produced in Jamaica at even cheaper cost than at present.

There are authorities in Eugland who have lately been speaking "on behalf of proprietors interested in the West Indies," but there is arising a new class in Jamaica of proprietors, not only interested in, but actually resident in the West Indies; and these men will have a different, an altogether different, argument to put forward in regard to the bounties about which so much has been said and written. These men notice that the most extreme leaders in this bounty agitation allow two points—one, that a duty of 2s. a cwt. on Sugar from bounty-fed countries would altogether countervail all the efforts of the bounties; the other, that of 700,000 tons of Sugar we annually import, only 250,000 tons come from bounty-giving countries. In other words, bounties, even if the worse case be made out of them, lower the price of West Indian Sugar only to the amount of 9d. a cwt. Even so the price has not as yet been forced down to the lowest level at which Sugar can be now grown in Jamaica at a profit; and, as we have seen, any single one of the numerous improvements in producing actually promised in Jamaica would far more than counterbalance the asserted effect of these bounties, and all the other body of improvements would be so much clear gain. It may, indeed, be argued that it would be a great benefit to Jamaican planters if this temporary effect on the bounties should rouse them to improve their methods of production, for in bringing about such improvements, far greater advance would be made than would be sufficient to countervail this small effect.

To those who have studied the case it is well known that the bounties are nowhere more unpopular than in the countries that give them, and the only and sole method of retaining them in those countries is persistently and eloquently to point out to the growers of Beet that the bounties are destroying the production of Sugar from Cane. To persistently and eloquently urge that this is their actual effect seems to be the strange policy adopted by the present representatives of the West Indian Sugar industries in England. It is to be hoped others will now come forward, establish the facts of the case, and so put forward the opposite argument. These will at once show that so far from destroying rival industries in British colonies, the bounties, even if we allow them their full effect, have been altogether unable to lower prices even to the level of the profitable cost of production of Cane Sugar possible in the fertile soils and genial climates of the West India Islands. Thus, even setting aside the asserted plea that so long as we consume Moist Sugar so long must we grow Cane Sugar, we find that in Jamaica, at all events, Cane Sugar can be grown cheaper even than "bounty-fed" Beet Sugar, and that so far as the bounties have been intended to destroy Cane-growing in the West Indies, in so far they have resulted in signal failure.—*London Times.*

TEA CULTURE: THE BEST MODE OF RETAINING TIP.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

DEAR SIR,—In reply to "H. T. C. K.'s" queries anent "Tip," I have found that the best way to get tip is to pluck it separately and spread it out thinly on mats to dry in a warm atmosphere. When there is sun, an hour or two's exposure to it's rays gives it a good finish; otherwise finish off the drying process over a slow fire by thinly spreading the leaf on a dolla, covering up with another, and not touching it again until it is ready. If the tips be rolled at all; they will lose the silver "spangle," which will turn golden and then black according to the amount of rolling, which causes the juice to ooze out and discolor the leaf.

Pure Assam plants give the best silver tip, and pure China the best golden tip. You can't roll together all your leaf (especially if you pluck five leaf shoots) and expect to get much tip, but in such case I should advise heavy withering (spreading the leaf thinly), rolling slightly, fermenting to an even copper color, and quick firing.—

Yours faithfully,

'SILVER TIP.'

TEA PLUCKING.

SIR,—There seems to be some diversity of opinion on the subject of plucking, so as to obtain the greatest amount of leaf from one's bushes. The question is, whether it is best to pluck two or three *whole* leaves and the bud, as the case may be, or to pluck two and a *half* or three and a *half*, and half the one below if soft, leaving the axis of the third and fourth leaves and the interlode or stalk between them. I am an advocate, after years of fair trial of both systems, of the second plan. My reasons are briefly these:—

1*st*. The rapidity with which the next flush comes on.

2*nd*. The absence of unsightly stalk in the tea.

3*rd*. The greater facility in sorting the roll before fermentation, and separating the fine from the coarse leaf, so as to be able to treat each according to its requirements.

The first reason is the most important, as the difference in yield I think is very marked. By leaving a whole leaf below, experience shews that that leaf must, and does fully mature itself before the new shoot breaks away, whereas, by leaving the axis with a small portion of the third leaf, the sap of the plant goes directly to nourish the young shoots, instead of wasting itself on maturing the whole leaf left by the other plan. A not unpleasant appearance is to see the whole plucking surface of a bush covered with hard dark green leaves,

which go on maturing and absorb all the vitality of the bush, and keep back the young flush until they are satisfied, and as hard as leather.

The difference of the two systems is very marked at the beginning of the season, when the bush is recovering from its pruning. I have known five weeks to elapse between a first plucking and the second, when bushes plucked two and a half leaves have gone on growing without a check.

If a whole leaf is left, this maturing process goes on repeating itself after each plucking, always delaying the new flush and retarding the growth of the plant.

The only argument I have ever heard brought forward in favor of leaving the whole leaf is, that it strengthens the bush. This may apply to young gardens being plucked for the first time, but cannot to old established bushes. Even the most bigoted upholder of this theory ought to be satisfied with the four or five leaves always left on the first shoots after the pruning, and those usually left after each plucking, for the good of the plant.

Reasons two and three are also important, but I will not encroach further upon your space,

EXPERIENTIA DOCET.

TEA DRYING-MACHINERY *VS.* CHARCOAL.

DEAR SIR,—Tea drying by machinery *versus* tea drying by charcoal fires over choolahs, is, I believe, still discussed as to the relative merits of each. I will try and give you a fair estimate of cost, and speak from experience as far as I know relative to the merits, ills, &c., &c., of both modes of firing.

1*st.*—*Charcoal firing and its merits.*—Except for those who persist that the fumes of charcoal are necessary to make good tea, I can see no merit whatever in charcoal drying, either in cost, quality, rapidity, saving of labour, or anything else, over machine-dried tea.

Cost per maund tea of tea dried over choolahs by charcoal.

	As.	P.
Charcoal at 8 annas per md. 1½ mds. =	12	0
1 Battiwallah at ans. 4-6, kutcha firing =	4	6
Do. do. pucka firing say =	0	6
Cost of firing by charcoal R	1	0

N. B.—Notice the labour staff required for 3 months in the year to make charcoal. The immense space (and heat) taken up by choolahs. Cost of timber used for charcoal. The number of trays, gauze, iron, &c., &c. required. The masonry and carpenter's work always more or less out of repair. Loss of small tea falling through trays, &c., &c.

Now let us take

Cost of machine-dried tea per maund.

	As.	P.
1st. Those machines which dry by coke, say cost of coke =	8	0
3 men at as. 4-6 per 5 mds. tea = about	2	8
Cost of drying per maund tea for a machine, drying by coke 5 mds. in 10 hours	10	8

I now give an estimate of cost of 1 md. tea dried by a machine of similar capabilities, but drying with any sort of fuel—coal, wood, grass, bamboo, &c., say 2 mds. of firewood at 6 pie per md. = 1 anna per 1 md. tea.

N. B.—Price of firewood at 3 pie per maund should be nearer the mark.

3 mens' pay as. 4-6 for 5 mds. in 10 hours = as. 2-8 per maund. The analysis of the above comes to this—

		R.	A.	P.
Charcoal drying ...	=	1	1	0
Coke ,, ...	=	0	10	8*
Wood fire ,, ...	=	0	3	8

We read of machines drying with any fuel, and doing double the tea of what I have estimated above, and how people can still stick to charcoal, beats me.

Again we generally see large gardens furnished with drying machines: surely is the small gardens that want them most.—Yours faithfully,

A. C. J.

P.S.—Price of the "Sirocco" is £85 f. o. b. in Liverpool, which means R1,020—at 1*s.* 8*d.* exchange, and the cost of carriage out to India extra to pay; still the machine, if it does 5 mds. tea in 10 hours, should pay itself in one year, always considering it turns out well fired and no burnt tea. But there are better (or anyway cheaper) machines then the "Sirocco," I see, advertized, in the *Englishman* of the 8th instant, *viz.*, a description of Robertson's "Typhoon," doing ½ md. tea per hour, and probable cost to be R300. And in your issue of 3rd instant a machine (Allen's patent), but the cost is not given, doing one maund per hour, and burning any fuel.

RAISING SEEDLINGS.—Mr. Peter Henderson's method is thus described in the *American Agriculturist*:—"Mr. Peter Henderson having hit upon a method which greatly increased the certainty with which he could raise seedling plants, not only of such rapidly growing things as Cabbages, but of slower starting greenhouse plants and of shrubs, employed it in his own establishment to his great advantage. It is very simple, as most valuable things are. In his seed-beds or seed-boxes—1st, he puts down a layer of good loam, run through a half-inch sieve, and patted down moderately firm. Over this about one-fourth of an inch of dried spaghnum—common peat moss, such as is used for packing, thoroughly dried, and run through a wire sieve about as fine as a mosquito-wire gauze—this powdered moss, about in the condition of fine sawdust, being evenly spread. Upon this moss is placed a coating of loam about three-fourths of an inch thick, and well levelled. The seed is sown thickly on the loam, pressed down by a smooth board, and fine moss sifted on sufficient to cover the seed, and the whole watered with a fine rose. The top layer of moss keeps the surface always moist, preventing all drying and barking, and allows the young plants to easily reach the light. The layer of soil below it affords nourishment to the seedlings, which, as soon as their roots reach the layer of fine moss below, form a mass of fibrous roots. No one familiar with raising seedlings need to have the advantages of the method pointed out."—*Gardeners' Chronicle.*

MEXICAN COFFEE.—Much has been published of late in regard to the probability of Mexican coffee becoming a dangerous competitor of Brazilian coffee in the United States, the greatest consumer of the Brazilian product, and that there is serious basis for the grave fears expressed is proved by the following extract from a letter received by one of our leading export houses, and dated New Orleans, 1st June, 1881:—"The receipts of Mexican coffee at this port since the 1st January are in excess of previous seasons; and one firm alone expects to receive 100,000 bags of 100 lb. each out of the present crop. The same firm has had cargoes of 5,000 to 6,000 bags arrived to them this spring. The demand for this coffee is mostly from Chicago and St. Louis, but a fair quantity is sold here to grocers at 1 to 1½ cents *above* the price of Rio coffee!"—*Anglo-Brazilian Times.*

* I should be glad to be set right if I have not rightly calculated the price of coke.—A. C. J.

THE NUTMEG IN TRINIDAD.

The Nutmeg trees, always a striking and beautiful feature in the Gardens, have conspicuously benefitted by the mild character of the last dry season, and the younger trees planted in 1873 and 1874 developed rapidly into the fruiting stage. The yield per tree, nett in the market, of those in bearing, has again been over twenty pounds of prepared nutmegs, with an average price of two shillings and two pence per pound during the year. This gives a surprising return per acre per annum. For instance, trees at the (ultimate) distance of 30 feet, would stand 50 to the acre. Allowing only 30 of these to be female or fruiting trees, the value of the yield would be £60 per acre per annum. It is somewhat remarkable that there has not been any considerable fluctuation in price during the last 15 years, but on the whole, the price has risen. That the nutmeg tree is perfectly at home in Trinidad needs no further confirmation. It might be desirable however for persons contemplating the planting of Nutmegs to examine the trees at the Gardens carefully, as also account-sales at my office. It might further be mentioned that a batch of young trees planted in August 1878—25 inches high—from bamboo pots, are now five feet high and stoutly branched.—*Report Trinidad Gardens.*

THE COFFEE AND SUGAR PRODUCING COUNTRIES.

Mexico.

Coffee production in Mexico is at present confined to the mountain plateau, most of the plantations being situated in the valleys which stretch out around Orizaba and Cordova. It grows on volcanic soil, always the best for coffee so far as requisite flavor is concerned. Both in point of outward looks and superior quality, Mexican coffee from those localities need not shrink from comparison with Costa Rica. Production does not now exceed 20,000 tons, about one-third of which is exported, mostly to the United States, where it is very much liked. Should American capital ever take charge of this agricultural branch, even but to a moderate extent, the yield would soon be carried to five times what it is at present. And this is one of the possibilities, not to say probabilities. Indeed no better investment could, we believe, be made, provided always the revolutionary period is closed for good.

The expense of transportation on mules' back, especially during the rainy season, was too heavy to foster agriculture and mining in most parts of the country with a view to export, except so far as vanilla, cochineal, indigo and rich argentiferous ore were concerned. Even for coffee the overland freights down to the coast were excessive till the railroad from Vera Cruz to Mexico was built, which traverses the main coffee region.

Our imports from Mexico last year amounted to $14,524,898, including $9,115,824 worth of specie, while we exported thither $6,069,315 worth of domestic goods. Coffee was received from there to the extent of 4,400 tons, being more than five times our import thence eight years ago; this certainly promises well.—*Rio News.*

NEW TANNING MATERIALS.

TO THE EDITOR OF "THE BRITISH TRADE JOURNAL."

Sir,—As a result of the offer made through the medium of your journal in June last, I have received a sample of the bark of a tree growing in the upper provinces of Buenos Ayres, known by the natives as "Curupoe." Unfortunately the sender did not enclose the bark whole, or any portion of the wood, lest some qualified botanist might have passed judgment as to the family to which the tree may belong. Any other of your readers who may send similar specimens should forward the fruit, leaves, or wood of any plant, so that it may be readily identified with known species.

Judging from the texture, colour, and taste of the bark before me, my own opinion is that it is closely allied to the mimosa, and is probably an *Acacia*. It much resembles the *Acacia Dealbata*, of which large quantities reach us from Australia, the best mimosa giving 24 per cent of tannin. This new variety, if it be so, yields 13·55 per cent of tannin, and if found in sufficient quantity might be worth exporting to England. If roughly ground, to economise space, it would probably be worth 9*l.* or 10*l.* per ton.

I have also received from India specimens of the bark of the babool tree (*Acacia Arabica*), which gives a percentage of 18·95 of tannin. One fact worthy of notice with this bark is the beautiful creamy white colour it gives when precipitated with gelatine, this being at present the only bark or tannin material that gives that colour. The baboot is very abundant in India, and might be worth sending to England, were, for the best kind of work, it would probably be worth from 12*l.* to 14*l.* per ton.

Thanking you for the space accorded to this letter, I beg to remain, Yours truly, W. N. Evans.

Tanners' Laboratory, 13, Canon Street, Taunton,

FELLING TIMBER.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—In a late issue of the *Mail*, there appeared a letter from a correspondent of your signing himself "Bob Sawyer," asking for information as to the proper time of felling timber, and as I have seen no answer to it, the following remarks may be useful:—The old received idea in Europe is that the winter, *i.e.*, the time of inaction, when the sap is out of the tree, is the proper time for felling, because then the wood having the minimum of sap in it, and the drying of the wood being more gradual than in hot weather, it is less apt to crack badly in seasoning. It is therefore usual to fell in winter. But on the other hand, many proprietors fell in summer, and assert that provided the tree is barked immediately on its being felled, the timber turns out better than that felled in winter. "Bob Sawyer" will thus see that the question is not settled even in Europe, where there have been Forest Departments for centuries; so it is to be hoped he will not be very hard on the Indian Forest Department if it is not able to give him cut and dried rules, as it has not been going for as many decades. Not being aware of any such rules I can merely give him my ideas on the subject. The old practice pursued in Europe will not apply out here. The hot weather is the dead season for most of our deciduous trees. The consequence of felling then would be a too speedy drying under the fierce heat of the sun, untempered by the foliage of the surrounding trees which has then fallen. The timber would consequently crack badly. It seems to me then that the best time for felling is the monsoon and cold weather, when the drying goes on more gradually, I would recommend too that the bark and white wood be cut off immediately after felling, by which means the portions charged with sap would be got of.

Jungle Man.

THE SAMAN TREE IN TRINIDAD.

The great Saman trees occurring in the ravine, ever extending their gigantic arms more widely and with denser growth, have rendered the larger part of the

ravine unavailable for the growth of trees requiring sunlight for the development of their flowers or fruits. Many of the Coffee trees there are in consequence non-productive. This fine tree has lately attracted some attention from having ascribed to it in South America the peculiar capacity of exuding a moisture in the form of fine rain. It thus became invested with the name of Rain-tree. The trees in this quarter however have never exhibited any such peculiarity. Its character as a pasture tree is in high esteem everywhere, bearing as it does large quantities of highly nutritious beans which are an excellent fodder for cattle, and ripening at a time, February and March, when grass is most scarce—except that, by their astringency apparently, they certainly have the effect of diminishing the yield of milk in cows. There would appear to be an erroneous notion abroad as the character of its wood, conclusions having been arrived at from the study of the character of wood found in *young* trees—say below 20 years, and the wood had been pronounced sappy and worthless. Such, however, is not the case with wood of matured trees. In such, the wood is almost exactly that of old chestnut, and that too with a very small amount of sap-wood. Moreover the wood is specially valuable as check blocks for the Railway brakes, and indeed for any purpose in which non-liability to wrap even in our sun, great strength, combined with toughness, and durability above ground are essential. The saman trees raised from seed and planted in the Queen's Park in 1866—14 years ago, now measure at 5 feet from ground nearly 8 feet circumference, and with a spread from opposite sides of 96 feet. This about equals the size attained by Elms in Europe in 50 or 60 years. The young trees planted on the western side of Belmont pasture 18 months ago, have done well, and now make some effect: Inga saman is 20 feet high.—*Report Trinidad Gardens.*

CHANGES ACCOMPANYING THE RIPENING OF CERTAIN PLANTS.*

BY P. P. DE'HE'RAIN AND BRE'AL.

Déhérain explains the loss in weight of dry matter which occurs during the maturation of the seed in the cereals and other plants. The formation of the seed involves the transport of carbohydrates and nitrogeneous bodies from one part of the plant, to be afterwards stored up in another part. In the case of the carbohydrates, this transport does not necessitate any loss in weight, since they exist in the form of reserve materials (starch, etc.), which take no active part in the phenomena of growth. But in the transport of nitrogeneous bodies a certain quantity of protoplasm has to disappear from the living cells in the form of asparagine, to reappear in the seed as legumin, glutin, etc. Assimilation then ceases in the cells thus deprived of protoplasm, but oxidation still goes on, and thus a loss of weight is produced. The authors distinguish three cases. In those plants which flower rapidly and bear simultaneously, a large number of flowers in proportion to the size of the plant (*Sinapis nigra, Colinsia bicolor*), there is always a loss in weight of dry matter; assimilation suddenly ceases throughout a large portion of the plant, but oxidation still goes on. In plants which do not produce many flowers at once, nor in too great proportion to the leaves, ripening is accompanied with only a temporary loss of weight; a sufficient number of chlorophyll granules remain intact to carry on the work of assimilation, which proceeds with renewed vigour after the seeds have ripened (*Eschscholtzia Californica, Delphinium ajacis*). When the flowers are very few and the leaves numerous (*Papavera somniferum, Hesperis maritima, Silene pendula*), the dry matter increases in weight during the ripening of seed.—*Pharmaceutical Journal.*

* *Ann. Agronomique*, vi., 398—400. Reprinted from the *Journal of the Chemical Society*, January 1882.

SOME EFFECTS OF HEAT AND LIGHT ON VEGETATION.

A curious modification of the normal structure of plant stems has been observed by M. Prillieux on making the temperature of the ground about the plant higher than that of the air above. Beans and pumpkins gave the best results. The seeds were placed in earth in a large dish, in which was inserted part of a brass rod bent at a right angle and having a gas flame applied to its horizontal end. The chamber was moist and cold. The seed germinated well; but on coming above ground the plants acquired a peculiar shape, they grew but little in length and became unsusually thick, the latter growth involving much tension in the surface layers, so that deep rifts before long appeared (mostly transverse) and made further growth impossible M. Prillieux found the enlargement traceable mainly to an increase, not of the number, but of the volume of cells in the interior (cells of the cortical tissue and the pith). The excessive growth of these cells occurred not only in the cell wall, but in the nucleus, which was often multiplied. The excess of temperature of the ground over the air was about 10 deg. Again, the view adopted by the older botanists that light is either without effect on germination, or as an adverse effect fails to harmonize with some results lately arrived at by Herr Stebler, in the case of many seeds of agricultural importance, such as varieties of meadow grass *(poa)*, the germination of which he finds to be favoured considerably more by light than by heat. Thus, with two groups of 400 seeds each of *Poa nemoralis*, in one experiment, there germinated in light 62 per cent, and in darkness 2 per cent. Similarly with *Poa pratensis* in light 59 per cent; in darkness 7 per cent, and so on. Sunlight being a very variable force difficult of determination, experiments were further made with gaslight, and with the same result—that light favours the germination of certain seeds, especially grasses, and that these germinate either not at all, or very scantily, in darkness. The fact was verified by Herr Stebler in quite a series of seeds, *Festuca, Cynosurus Alopecurus*, &c. In the case of seeds that germinate quickly and easily, such as clover, beans, or peas, he thinks light is probably not advantageous.—*Planters' Gazette.*

MATÉ.

Mr. L. Couty, after a special visit to South America, contributes to the *Revue Scientifique* an article giving the results of his examination of the food question on that continent, especially with respect to nutrious beverage known as maté, which he believes is destined to replace coffee and alcohol to a great extent. The leaves are derived from the *Ilex Paraguayensis*, which grows to a height of from three to six metres, and covers acres of ground throught Paraguay, Rio Grande, Paraná, and the province of St. Catherine. This represents an extent of country larger than France and Germany combined. The leaves, which are thick and oblong in shape are only picked every three or four years. They are dried by artificial means in the woods by the peasants themselves, who send them in a rough state to the factories. Here they undergo a separating process by means of sieves, and are afterward packed ready for sale. In preparing the beverage the leaf is boiled for one or two minutes, the liquid furnished being less limpid than tea, and not so dark as coffee. The aroma is less pronounced than that of good tea,

and the maté is sweeter to the taste than coffee, and may be drunk without sugar. Moreover. it may with advantage pass throu.h seven or eight successive boilings each time in fresh water, and the last infusions will be better than the first, but in this case it must not be allowed to get cold.

This product is now sold at the rate of 5s 6d and 6s 6d per 15 kilogrammes (33¼ lb.), delivered at Antonine, a shipping port in Paraná, and as each kilogramme furnishes 40 litres (about 36 quarts) of a strong infusion, the cost per litre is less thau a farthing. But this rate would be still less if there were proper means of traffic from the woods, carriage being three times as expensive as the original article. A great reduction might fairly be anticipated if railways or even good roads were constructed; but at present the transit is made by means of mules aloug steep and rugged paths. From a chemical analysis of this plant, it appears that it contains the same properties as coffee, an alkaloid, with oleaginous essences and resinous gums, but as the quantity of the latter present is much greater than in coffee, the nutritive element is superior. This analysis is confirmed by experience. The inhabitants drink nothing else, and with maté and meat they live well, without experiencing any desire for bread or vegetable, although the country is favourable for the cultivation of maize and potatoes, if necessary. The cattle tenders often remain absent for days from all human habitation with their herds, and are content to forego their usual meals if only they have a good supply of maté, which thus appears to be an active element of food, and, unlike coffee, produces neither sleeplessness nor palpitation.—*Planters' Gazette.*

MATÉ DRINKING.

The following communication has been addressed to a contemporary:—

SIR,—For some two or three years I have been a "maté drinker," and am delighted to find myself not alone in my "indulgence." Considering the easy communication and frequent intercourse between England and the Argentine Republic,, it has been a source of wonder that the drink of Paraguay has not loug ago been popularised in this country. In the Paris Exhibition of 1878 the "yerba," as it is called, was sold, but, juding from an extremely musty and stale specimeu which I saw in a friend's hands, was perhaps not calculated to inspire confidence. The tea (or herb rather) will keep in perfectly good conditiou for a long time, if preserved in a cow-skin bag in which it is sold; in fact, I have some by me now tbree years old. Tho chief difficulty is to make the tea. Although, to quote the advertisements, it is done by "simply pouring boiling water," yet this requires to be done very deftly, or else the pipe through which the drink is sucked becomes clogged with dust and twigs, and the cup which does "not inebriato" fails also to "cheer." The process of making, to be successful, is thus performed:—Having procured your "maté," which is the small gourd from which the tea is drank, put into it two or three spoonfuls of the "yerba," or tea, and then closing the top of tho maté with the hand, turn it upside down, and shake it well. The object of this proceeding is to bring the dust to the top and the twigs to the bottom (when the cup is returned to its normal position). Having shaken it thus, turn the gourd slowly round till the "yerba" has fallen back just enough to enable you to remove your hand from the orifice without spilling the contents. Then take the "bombilla," a silver tube with a pierced bulb at the end, and ship the same carefully under the "yerba," and turn the "maté" upright, being very careful uot to shake the contents. Then "pour the boiling water," adding sugar if desired, and the drink is ready when it has stood (say, one minute). Each "charge" will bear watering perhaps three times, after which it should be cleaned out. I fear that some Europeans will be inclined to object to the process of drinking, which is as follows:—The servant, either black or white, always has first suck (in order to clear the tube of dust), the "maté" is then handed to the party one by onc, and all draw in the liquid through the same pipe. But use accustoms one to anything, and I have drunk contentedly from the steaming cup in ever mixed and somewhat questionable company ere now, upon the prario, and should be quite ready to "repeat the dose." The drink has one great advantage—it is cheap; if my memory fails me not, it is about 1s. per lb. The maté and bombilla cost, say, 10s. I believe moreover, that it has great "staying powers." The Gauchos in South America say that if you want to ride "long and strong" take a piece of bread and a "maté." A Chileno I once met on board ship said that he went through the famine of the Commune in Paris on "maté." Possibly, like Alexander Selkirk, "his right there was none to dispute," and while his hungry but unenlightened fellow-sufferers would have quarrelled over his boots, they allowed him to take his cup in peace. Apologising for consuming so much of your space in singing the praises of "another drink," I remain yours,

ERNEST GELDART.

Little Braxted Rectory, Witham.

SOMETHING ABOUT THE POTATO.

The general cultivation of the potato, as made known to us by the chemists who have been studying this branch of the tuber. Generally speaking, large seed produces more large potatoes than small seed. Most people might take this for granted, without corroborating the supposition by numerous experiments, as the chemist does, for the chemist must bring forward positive results only to bear out his suppositions.

The influences of the blossoms makes a great deal of difference in the yield of the crop, as the following results show:- 208 centrs. 19 lb. of tubers were obtained from plants from which the blossoms had been removed, and only 181 centrs. 48 lb. from plants not so treated. I do not think many readers of *Knowledge* would have thought that the difference could have been so great.

It has been found that the growth of sprouts on potatoes depends on their nearness to the apex of the tuber; if they are treated with water in sunlight, the growth increases forty or fifty times, although this not the case in the dark. Absence of light is necessary for the growth of young tubers.

Heat produces very beneficial results to the growing plant. On this account too early planting is injurious, for potatoes require the same total heat to bring out the leaf buds; so, should the plants be planted too soon, it would require, as experiment shows, perhaps forty days instead of fourteen to bring them to this stage, but it is well, at the same time, to bear in mind the fact that if they are left too late, the ground will become equally unsuitable.

Potato rot is the next point to be considered, of which there are three kinds—viz., dry, wet, and sweet rot. In the dry and wet rot it has been found that the potatoes with the maximum starch resist the disease most effectually. Potatoes grown on moist soils and soils containing much organic matter are most liable to the disease. The starch in diseased potatoes is yellow, but can be used for manufacturing a second quality of dextrin. In dry rot the tuber is loose and spongy, coated on the outside with

mould. The disease is originally due to Bacteriæ, and another parasite is often present at the same time. Wet rot, I forgot to say, differs from dry rot in this respect, the interior of the tuber is partially liquid and the outside coated with mould. During rotting, the potato loses half its nitrogenous constitutions and the whole of the sugar.

The Sweetwort is formed by a parasite called *Mucor mucedo*. The mycelium of the parasite travels to a certain distance inside of the potato, and then disappears. Bacteria rapidly destroys the plants. There is another parasite, called *Aspergillus niger*, which produces a similar result. It seems rather uncertain as to whether cane sugar or glucose is formed: some chemists say the one, others the latter.

We all are familiar with frozen potatoes, but not many of us know in what manner the frost affects them. Frost has the effect of doubling the amount of sugar in the tuber, the starch diminishing in proportion; part of the protein passes from the congulable to the soluble form.

To prevent rot in potatoes, the tubers, whether sound or diseased when taken from the ground, are left in a weak solution of calcium chloride—one part to a thousaud of water—for half-an-hour. They are then transferred to a soda solution of the same strength, after which they are washed with clean water and air dried. Half kilo of calcium chloride and the same amount of soda is sufficient for 250 kilos of potatoes. A kilo is a little over 2 lb. 3 oz.

Even though potatoes are badly diseased, they are still useful for cattle food. They are best cut up and boiled or merely scalded, mixed with chopped straw or chaff, and stored in narrow trenches covered up with clay. So stored, they will keep for many years. If steamed, they should be kept in casks, as there is more adhering moisture. If it is not convenient to heat them as above, they should at once be sent to the distillers.

With regard to the best kind of potato for yield and quality, there seems to be a good deal of difference in opinion, as the following examples will show. 1. For quality and quantity: Champion, Richter's Imperator, Eos, &c. 2. Richter's Imperator for yield is far the best; is of a hardly nature, smooth, and the stalk is tall and straight. Next in order are Violet, Victoria, Irlachin, Richter's Snowrose, &c. 3. For starch and yield: Eos, Aurora Alcohol; lower in yield but very high in starch, Achilles and Ceres. Richter's Imperator Early Rose, &c., very heavy yields. The above forms three opinions of three chemists; they all seem to agree that the Imperator is the largest yielder.

The most successful way of manuring is to partially dig the manure into the ground. The application of nitrogenous and phosphate manures without farmyard manure is much less to be trusted on a poor soil than on a rich one. Manuring on fertile soil is not productive of any great gain. Sheep-dung produces a yield of 50 per cent higher than any other artificial manure, and 60 per cent higher than if no dung be applied at all. Extra supplies of ammoniacal and superphosphates produce no increase. Compost has the same effect as if the land were unmanured, except that there is an increase of starch. The unmanured plots are highest in disease. A good mixture is Chili saltpetre and Baker's superphosphate in the propotion of one of the former to two of the latter mixed with stable manure. Bone meal, one author says, increases the weight of product, and it is also very likely that the whole plant likewise increases in weight. There is another substance which has been tried, viz., peat, and good peat is found to give even better results than good stable manure.—F. C. S.—*Knowledge.*

GOVERNMENT GARDENING AND FARMING.

The report of the progress and conditions of the Government Botanical Gardens as Saharanpur and Massoorie is an interesting record of the progress of botanical science in Northern India. Mr. Duthie remarks:—"There is no hard-and-fast line of division between results of scientific and those of practical interest, so that one set of facts could be grouped as scientific, and another of practical, for science does not cease where practice commences, but is rather made manifest by its application. There are, of course, certain subjects which may be rightly termed practical, and others unmistakably scientific; there is also a third set which may be said to partake of the characters of both. It is the preponderance of this latter in my present report which has made it impossible for me to divide it satisfactorily into the two sections as desired."

With Australian grasses we note the usual failure in an economic point of view, none of them equalling the common Indian dub, or hurrialee. Indeed, when properly treated it would be difficult to find its equal, either green, or as hay in any country, for though we miss in it the sweet *Authoxanthum oderatum* of English pastures, we know its aroma to be excellent, while its nutritive qualities are incontestable. In the hotter parts of Australia which most resemble India, both *dub* and *guinea* grass are decided acquisitions, so it is doubtful whether any great assistance can be given from the Adelaide Gardens to those in India in furnishing improved forage or fodder plants. In South Australia one is struck with the fact that the fields once ploughed are for years weedless, and only at length become weedy with the inroad of imported plants run wild; yet the greatest friend to the *hurrialee* is the plough, when used in moderation. But if Dr. Schomburg cannot send grapes from his lovely Gardens at Adelaide, he has contributed in the earth almond what may be a most desirable tuber. Although Australia has not so far yielded a grass of marked value we note no deficiency from other countries. The *guinea* grass, for which Jamaica now pays taxes on over 100,000 acres is at Saharunpore, as elsewhere in India a success, just in proportion to the attention it receives. *Tambokie* grass is also reported favorably on, as having been received from the Cape of Good Hope, and as being relished by cattle, and *Lucerne* is valuable as a perennial.

We now turn to the report of the Cawnpore Experimental Farm Operations for 1880-81, and learn that during the *Rabi* season, the farm was the means of bringing to light some interesting agricultural facts. With a rainfall amounting to only 2·21 inches in eight months, irrigation had to be employed to germinate the crops, most of which were sown between October 15th and November 7th. As a natural consequence 'patchy' crops were the result, a deficiency of the moisture in the subsoil being inimical to healthy root growth. The effect of two kinds of manure were brought very prominently into notice, both of this being nitrogenous. These were, first enriching the land by green soiling, that is ploughing a leguminous crop into the land before it begins to form seed; and secondly, using human excreta. As both were highly successful, and were contrasted with cattle dung, and the ashes of cattle dung as well as other manures, the following results of the experment are worth attention. The figures show the increase per acre.

Per cent in gross outturn. Manures yielding nitrogen	Grain.	Straw.	Net profit. R. a. p.
Green soiling ...	151	91	26 0 9
Poudrette ...	166	109	25 4 5
Cattle dung ...	83	47	6 0 2
Cattle dung plus gypsum	73	39	Loss R1·1·1

Manures without nitrogen	Grain.	Straw.	Net profit.
Ashes of cattle dung	56	23	Loss ,, 0-2 5
Bone superphosphate	39	8	Loss per acre
Bone dust ...	12	Loss 5	Loss R2-2-4

The most prominent fact shewn in this table is the great superiority of the nitrogenous over the non-nitrogenous manures. Under the heading Irrigation the value of a late watering is prominently brought forward, for while one, two, and three waterings gave increases in grain of from 300 to 370 per cent over a plot unwatered which was a total failure, a fourth wateriug ran up the percentage to 500 in grain, and 350 in straw, or in other words an extra watering, costing R4-14-0 per acre, gave an increase of R20 in the total produce. Again, a useful experiment is recorded as an off-shoot of this, although it is given as a difference of ploughing time, as in the one case ploughed-up land received and retained the rain, while it would to a great extent be wasted on unploughed lands :—

Outturn per acre.	Grain. lb.	Straw. lb.	Value. R. a. p.
Portiou ploughed in July ...	1,630	2,676·4	55 9 10
Not ploughed till Sept. ..	983	1,493·8	32 13 10

Hence the difference in value of outturn made by early ploughing amounted to over R22 per acre. Following on as a natural sequence, we learn that a crop of castor oil grown on the Farm on deeply cultivatsd land, was the only crop of any kind gathered from land of the same descriptiou for miles arouud.

Of new staples tried we may dismiss Cape oats as they do not thrive in Southern India, with the remark that they yielded remarkably well, giving 2,299 lb. of grain and 3,993 lb. of straw per acre. Some trials were made with acclimatized American corn, of such a variety, named the American Canada corn yielded no less than 4,382 lb. of hulled corn per acrs, giving the handsome profit of R64-8-7. This should not be overlooked by Eurasians who would be agriculturists, for in Southern as well as Northern India maize under competent managemeut yields one of the heaviest possible crops, as those who remember the late Bangalore Experimental Farm can testify. In the section devoted to the development and constructiou of Improved Agricultural implements, we are amused at the account of an attempt to introduce a winnowing machine. First an English winnowing machine costing R200, and therefore beyond the means of the average ryot, was tried; theu an implement of Farm construction value R35 was used; aud lastly the native method was tested. The following results are record :—

Method of winnowing.	Number.	Cost.	Time to winnow 100 mds.	Cost of winnowing.
English winnower	4 Men.	6½ An.	18*h.* 58*m.*	15·4 Aus·
Farm ,, ...	3 ,,	5½ ,,	32 ,, 16 ,,	21·1 ,,
Native method ...	3 ,,	5½ ,,	28 ,, 33 ,,	18·7 ,,
English winnower	4 ,,	6½ ,,	20 ,, 50 ,,	16·9 ,,
Farm ,, ...	3 ,,	5½ ,,	40 ,, 39 ,,	26·6 ,,
Native method ...	3 ,,	10½ ,,	51 ,, 41 ,,	67·8 ,,

The idea that wind can be usefully converted into a motive power by means of an American windmill is disproved, and the experiment is consequently valuable in exploding a widely entertained idea. The working of the windmill, costing when delivered R300, was, with the wages of a boy to look after it 5 annas a day, which is proved to be more than the dhenkoli, worked by two men, and the windmill was totally disabled by a dust storm, apparently of no more than ordinary velocity. This windmilll was obtained at the suggestiou of the Government of India who are ever on the look-out for a happy panacea for the ryot in lieu of persuading him to carry out the ordinary agricultural practice of an enlightened age, deep cultivation, the use not the abuse of water, the conservation of manure, selection of seed, and so on.—*Madras Mail.*

THE SUPPLY OF CINCHONA BARK.

Though the enormous advance during the last few weeks in the price of quinine sulphate and of the bark from which that important medicine is manufactured has been caused probably by speculative operations, the fact is suggestive of the necessity for a more assured regularity in the relation between the supply of the raw material and the demand for it. At present the South American sources of supply, though naturally abundant, are under conditions which leave room for some apprehensions as to their continuing to be available in the same manner that they have been hitherto. The cultivation of cinchonas has indeed been undertaken in some parts of the country, but from the unsettled state of political affairs and the insecurity of property, it may be a long time before this work is so generally entered upon as to provide a more constant supply of bark in place of that derived from the natural forests.

Under these circumstances the cultivation of cinchona in India, Ceylon and Java acquires an especial importance, and any step that promises to conduce to the successful prosecution of this enterprise deserves to meet with encouragement. In this relation we are glad to mention the publication of a small work in Ceylon, under the title of the 'Cinchona Planter's Manual,' in which the author, Mr. T. C. Owen, has furnished a *résumé* of the information, scattered through blue books and other difficulty accessible works, concerning the experience which has been acquired since the attempt to cultivate cinchonas was first made by the Dutch and British Governments. Within the space of 203 octavo pages, Mr. Owen has given a very lucid account of what is known on the subject, free from scientific technicalities and well adapted for guidance of planters engaged in the cultivation of quinine-yielding cinchonas.

In preparing this manual the works of Dr. King, Dr. Bidie, the late Mr. MacIvor, and the reports on the India aud Java Government plantations have been laid under contribution, while a most useful classification of such members of the cinchona genus as are of interest to planters, with the characteristics of each, has been furnished by Dr. Trimen, the Director of Peradeniya Botanical Gardens.

After giving a concise sketch of plant physiology and a general description of the cinchona alkaloids, as well of the species and varieties of the alkaloid-yielding cinchonas and of the results obtained by their cultivation in India, Ceylon and Java, Mr. Owen proceeds to treat of those matters which demand the special consideration of the planter, such as the choice of land in regard to soil, situation, climatic conditions, elevation, etc., the several operations of clearing, weeding, laying out of roads, draining and planting. Then follows a chapter on the management of nurseries, on manuring, and harvesting, while in the succeeding part of the work the diseases and enemies of the cinchona trees are dealt with.

In speaking of the important subject of hybridization, Mr. Owen endorses Mr. Broughton's opinion that the numerous so-called hybrids are in many cases rather sports or forms developing into races which probably occur in South America. Thus trees of *officinalis* obtained by cuttings from two apparently identical plants showed all the varieties kuowu as *officinalis*, *Condaminea*, *Urituainga*, *crispa*, etc., the tendency to vary being so strong that even a twig in a tree showed foliage different from the parent

types. This seems borne out by the fact that in plants on a twig of which variegated leaves have been developed, other twigs of the same plant, when grown as cuttings, will not develope variegated leaves. A writer in the *Ceylon Observer* states that at the intermediate zones, where climates of inferior suitability to the growth of various species are met with, a large number of hybrid forms have developed, better suited to the climate they grow in than the parent trees. Dr. Trimen also is of opinion that some of the so-called hybrids may be new or at least previously unobserved forms, while others are more or less similar to those already noticed in South America. The true relationship of the various forms, however, probably requires a wider consideration, in which the microscopical structure of the bark and the alkaloids yielded by the different forms, making allowance for difference in climate and elevation, are each allowed due weight.

Mr. Owen expresses his opinion that locally prepared febrifuges will never be able to compete with the cheaper crystallized alkaloids prepared in England, the great manufacturers having appliances and probably secret processes which give them enormous advantages. Thus while Sikkim febrifuge was being sold for 20 rupees per pound, sulphate of cinchonine could be bought for 5 rupees and sulphate of cinchonidine for 17·50 rupees in England. He also believes that there is but little fear of the supply of quinine-yielding barks exceeding the demand, whilst if the local preparation of febrifuge from the red barks proves a success there will be less fear of the latter flooding the market. Mr. Gammie, of Rungbee, is said to have discovered a cheap process, whereby the sulphate of quinine, mixed with a small proportion of cinchonine, can be extracted so as to be sold at about the same low price as the Sikkim febrifuge. The great difficulty experienced, however, is the thorough exhaustion of alkaloid from the bark.

In speaking of the use of bark for pharmaceutical purposes, Mr. Owen remarks that sometimes the large druggists are obliged to buy *officinalis*. When this happens they usually resell the bark to the manufacturer, after extracting by their method a part of its contents, and it not unfrequently happens that the bark proves to be almost as rich in quinine as it was before it had been subjected to the treatment of the druggist. His method fails to extract the whole of the quinine, or even of the inferior alkaloids. It is obvious that the chemist does not want a valuable quinine bark, but rather a softer bark, like the *succirubra*, rich in total alkaloids, which are separable by his method, but comparatively poor in quinine. Though the alkaloids are not completely extracted by the process he uses, they yield to infusion sufficient to justify him in styling the result a "tonic mixture." As a cheap bark, but yet rich in the more easily separable tonic and febrifugal matter, the *succirubra* may then rightly be termed, *par excellence*, "druggists' bark."

The features which Mr. Owen describes as having most weight with the druggist are the boldness and firmness, the regularity of the roll, the length and evenness of the quill. With a quiet irony he observes that these points are "evidences of care in "preparation of the bark, and they therefore in- "directly testify, for the satisfaction of the chemist "and his customers, to the identity and, as a "necessary corollary, to the medicinal virtues of the "bark."

Another point to which he calls the attention of exporters, viz., the presence of a silvery coating of the epidermis of the bark and if possible the presence of crustaceous and stringy lichens, to which, he goes on to say, tradition has given a fictitious importance, having declared it to be, together with the bitter taste of the bark, the greatest safeguard of the chemist against deception and the strongest proof of the identity of the parent tree. He shows that bark possessing this appearance will realize as much as 50 per cent, or sometimes even 100 per cent, above its intrinsic value. This is because the druggist may be said to buy on appearance only, and with little reference to the intrinsic value of the bark.

These remarks are very instructive and show that this little work is well worthy of perusal by the wholesale and retail druggists as well as by the cinchona planter. There is no doubt some truth in the remarks that are quoted above.—*Pharmaceutical Journal.*

TRADE AMONG THE DYAKS OF BORNEO.

As considerable attention is being directed to the prospect of increased commercial relations with Borneo, owing to the grant of a charter to an English colonising company, whose operations will be conducted on the east coast of that island, we extract from Carl Bock's work, just published by Messrs. Sampson Low & Co., entitled the "Head Hunters of Borneo," the following paragraphs descriptive of the commercial products of the island at present utilised by the natives:—

"During the dry season the Dyaks, especially the women, go out in numbers and collect *damar*, a sort of resin, which is produced in abundance by certain kinds of trees, three different kinds being recognised —viz., dark brown, yellow, and nearly white and transparent. The 'damar' runs from the trees to the ground, and is often mixed with earth and very dirty. When this is the case the natives make a sort of putty which they call *doempoel*, first pounding the resin, then adding to it a little chalk and cocoanut-oil. When packing up my collections of birds, &c., I found that the wood was split in several places, leaving cracks sufficiently wide to admit ants and other destructive insects. Observing this, a Dyak made me some 'doempoel,' and filled up the crevices, making the case prefectly tight. This putty hardens quickly after it is applied, and is very durable. The 'damar' is also used in the manufacture of torches, which are made of bundles of leaves mixed with powdered resin. When burning, these torches emit a very feeble light, but a very strong smoke and smell. The superior advantages of petroleum will, no doubt, soon be appreciated among the Dyaks, as they are already among the Malays, who have for some years burnt this oil, which they call *minia tana* (earth oil).

"The cutting of rattan is, however, the chief occupation of the Dyaks. This is carried on in the rainy season, when they make excursions to the very numerous rivers and creeks, on whose banks the several species of this valuable prickly climbing plant are found growing in great abundance. There are three sorts in special demand in trade—the *Rotan irit*, which is the best, the *Sankolirang*, and an inferior variety. The price at Samarinda varies from ninety-five florins to twenty-five florins for 100 *ikkat* or bundles—each bundle containing forty rattans. The apparent difference in quality is so slight that it requires an experienced eye to detect it. The rattan is sold to Malay traders, and by them brought down to the shipping ports on immense rafts—those on the Barito river sometimes measuring 300 or 400 feet long and 60 or 70 feet wide, made of a number of large trees tied firmly together by means of rattan rope. . . . .

"Besides forming the chief article of trade in its raw state, rattan furnishes the material for the manufacture of an endless variety of useful objects. Take away his bamboo, and you take away the Dyak's

house. Take away his rattan, and you deprive the Dyak of half the articles indispensable to his existence. What crochet-work is to the European lady, rattan plaiting is to the Dyak housewife. She is always manufacturing either sleeping mats, sitting mats, sirih boxes, baskets of all shapes and sizes, and for all kinds of uses, besides long pieces of plait to be used as cords, ropes, or threads, in dressmaking, house-building, raft construction, and the hundred and one other purposes of daily life in the forest.

"In some parts of the interior I have seen baskets made from the bark of the trees which are prefectly watertight.

"The next product which claims the Dyak's attention, and is largely exported, is gutta-percha (*mallau*), which is yielded by many different species of trees. The tree yielding the best gutta-percha is called by the natives *Komallau Durian* from the resemblance of its leaves to those of the Durian. Another variety is known as the *Komallau Ramas*. The natives eat the fruit, which is somewhat sweet in flavour. The juice when first extracted is of a milky-white colour; but it turns chocolate-brown as it hardens by exposure to the air. The Dyaks have not yet graduated in the science of forest conservation. Instead of making incisions at regular intervals in the bark of a tree, and extracting a portion of the juice at different periods, by which its further growth would not be prevented, they usually adopt the radical expedient of cutting the whole tree down. The consequence is that the material is becoming more and more difficult to procure, and will eventually become scarce, if not extinct, in the island. . . .

"Another occupation is gathering wax (*liling*) from the nests of the indigenous bees. Along the banks of the rivers may be seen hundreds of high straight trees, covered with from twenty to sixty nests. It is a curious fact—at variance with the almost universal habit among all animals to conceal their nests as much as possible—that the bees always select for their nests a tree with a light grey bark, against which their dark-coloured homes stand out very conspicuously. These wonderful architectural structures, again, are always placed near the river, never in the interior of the forests. If this is done by an instinctive desire to protect the nests from the ravages of monkeys and other animals inhabiting the woods, it is strange that the insects should defeat this object in the colour of the nests. I was told by the Dyaks that the Orang Poonan* (the forest people) are the chief collectors of wax, pulling down the nests in the night, when it is very dark, and driving away or suffocating the insect communities by means of their smoke-producing damar torches. They often get stung during the operation, but bear the pain with indifference. The honey (*madoe*) is nearly all kept by the natives for home consumption, and the wax exported, the price, uncleaned, being 80 florins per picul of 120 kattics.

"The natives, and especially the Orang Poonan, also make it a regular industry twice a year to visit the caves in which a species of swallow, the *Hirundo esculenta* breed, and to collect their nests, which form the basis of the celebrated Chinese dish of birds-nest soup. These edible birds-nests (*sarang boeroeng*) are of two varieties, and fetch high prices, the whiter kind realising from 160 to 180 florins per six kattics, and the coloured or inferior quality selling for from 110 to 115 florins per six kattics.

"A curious industry is the collection of *galiga*, or bezoar stones, which are also mostly secured by the Orange Poonan. These *galiga* are highly prized for to the Boegis, who re-sell them to the Chinese medicinal purposes, and are sold at fabulous prices. There are two sorts, the *galiga landak* and *G. boehis*. The former, the more expensive of the two, are derived from an external wound on the porcupine. They are very light in weight, and of a brown colour. They taste exactly like quinine; and so strong is this property that when a piece is held inside the hand, and the tongue applied outside, the bitter taste can be detected. It appears to me that these *galiga* are composed of bits of leaves, &c., gradually collected on the wound, and formed into a ball by the congealed blood. The other sort, the *G. boehis*, are found at times, the Dyaks tell me, in different parts of the body of the boehis monkey (*Semnopithecus cristatus*), called in the interior *boehis*. They are of a greenish-brown colour, often beautifully polished, and are mostly kidneyshaped, though varying in colour. They are nothing else than gallstones, similar to those found in human bodies. The Chinese grind the *galiga* to a powder, and take a little of it in a tumbler of water. The curative properties attributed to this draught are legion; there is not an ailment that it is not able to cure. It may, indeed, be called the 'Holloway's Pills and Ointment' of the Chinese, rolled all into one."—*Colonies and India.*

* A race of fair-skinned Dyaks, described and sketched in his book by the author, who was the first European to penetrate into their forest homes, and to see the women of the tribe.

THE ALKALOIDS OF CUPREA BARK.

Mr. David Howard's letter, in reference to a note which appeared in the *Chemical News* last week, gives good reasons for withholding assent to the suggestion that the crystalline alkaloid, observed in cuprea bark simultaneously and independently by several chemists, is merely a compound of quinine and quinidine. If that were the case we should have to admit that by the combination of these two alkaloids the capability of one of them to form a very sparing hydriodate was obliterated, and that by the union of a dextrogyrate alkaloid with one of lævogyrate action the rotatory power was augmented in one direction instead of being reduced to nothing, as analogy would suggest in such a case. Moreover the occurrence of quinidine together with quinine is not a circumstance peculiar to cuprea bark, but is frequent in other varieties, though the crystalline alkaloid obtained from the former has not been observed in them. It seems to be unquestionably peculiar to cuprea bark, and from that point of view to rank with the unusual crystalline form of the sulphate obtained from this bark as one of several reasons for believing that it contains a hitherto unknown alkaloid.—*Pharmaceutical Journal*, January 14.

NOTE ON A COMPOUND OF QUININE AND QUINIDINE.*

BY C. H. WOOD AND E. L. BARRET.

(*Pharmaceutical Journal*, 21st January 1882.)

The discovery of a new alkaloid, closely resembling quinine, in that description of cinchona bark known in commerce as "cuprea bark," recently made by D. Howard and J. Hodgkin, and almost simultaneously announced by B. H. Paul and A. G. Cownley, and by W. G. Whiffen, will doubtless attract much attention. As these chemists all describe this newly discovered alkaloid as chiefly remarked for its property of crystallizing from an ethereal solution, it may be of interest to briefly refer to a peculiar crystalline body which we also first became acquainted with in working on samples of these cuprea barks.

When cuprea bark first came into the market, we noticed that an ethereal solution of the total alkal-

* From the *Chemical News*, January 6, 1881.

oids extracted from it would frequently furnish a notable quantity of crystals that did not resemble those of any of the known cinchona alkaloids obtained under like circumstances. As the analysis of the total alkaloids, however, had not revealed the presence of any distinctive base, and as the cupreas are chiefly remarkable for yielding an unusually large quantity of quinidine,* it seemed probable that these crystals were a compound of the quinine with the quinidine. We, therefore, took two grains of the pure quinine and one grain of the pure quinidine, both yielded by the bark, and dissolved them together in ether. The solution furnished an abundant crop of the same crystals. These crystals, when collected, washed with ether, and converted into neutral sulphate, furnished a quantity of pure sulphate of quinine, and the mother-liquor from which the sulphate had been separated yielding a like quantity of quinidine.

The quinine and quinidine used in the experiment had been carefully tested, they had each given the correct angle of rotation to a ray of polarized light, the one to the left and the other to the right, and the quinine had remained dissolved in ether for some weeks without furnishing a trace of crystallization.

To satisfy ourselves that the power of forming this crystalline compound was not peculiar to the quinine and quinidine yielded by cuprea barks, we took some pure quinine prepared by ourselves from South American yellow bark, and also some quinine made in India from the calisaya grown in Sikkim. We fortunately possessed some pure quinidine that had been purchased from an eminent maker some time before cuprea barks came into commerce. Either of these quinines dissolved with the quinidine in ether furnished a crystalline compound identical in all respects with that just described. There could be no doubt, therefore, that ordinary quinine and quinidine possess the power of combining together to form a crystalline compound very sparingly soluble in ether; also that the compound is easily separated into its constituents by converting it into neutral sulphate, when the quinine sulphate crystallizes out by its greater insolubility, the quinidine sulphate remaining in solution.

Perhaps the easiest way of obtaining this compound is to dissolve 1 part of pure quinine in 30 or 40 of ether, and add to the liquid a saturated ethereal solution of a like quantity of pure quinidine. Upon mixing, a crystalline precipitate of the body forms in abundance. Its solubility in ether is much less than that of either of its constituents, 100 c.c. of ether at common temperature only dissolving 0·5 grm. of it.

It is more soluble, however, in ethereal solutions of quinine or of the amorphous alkaloids, and these solutions frequently exhibit supersaturation very well, remaining clear for some hours and then suddenly giving an abundant crystallization. The compound, when isolated, may be re-crystallized from ether, apparently without change. Our results up to the present moment indicate that it contains the quinine and quinidine in equal proportions. Pressure of other work had much retarded us in the study of this compound, and the announcement of the newly-discovered alkaloid by the chemists above-named took us somewhat by surprise. We at once commenced the examination of all the alkaloid products we have accumulated from several hundred samples of cuprea bark in the hope of getting some of the new base, but as yet our attempts have been unsuccessful. We have thought it best, therefore, to publish our results thus far, and reserve further particulars for a future communication.

* We have met with several samples yielding over 1 per cent of crystallized sulphate of quinidine.

In reference to the foregoing Mr. David Howard wrote in the next number of the *Chemical News*, that the note by Messrs. Wood and Barret did not explain the new alkaloid described by three independent papers, since all who have found it agreed that the neutral sulphate recrystallized unchanged from water, the mother liquor giving no sign of the presence of quinidine, See also the following letters from Mr. D. Howard and Mr. W. G. Whiffen and Mr. C. H. Wood.

The Alkaloids of Cuprea Bark.

Sir,—A note of Messrs. Wood and Barret in the *Chemical News* of last week may seem to throw doubt on the existence of the new alkaloid observed in cuprea bark, and described in the paper read at the last meeting of the Chemical Society. The specimens, however, which we have experimented upon before publishing the results cannot have been such a compound of quinine and quinidine as is described in their note, as the sulphate or repeated crystallization showed no signs of separation into two bodies, but remain unchanged in solubility and action on polarized light. The alkaloid also failed in all cases to give the familiar hydriodate of quinidine and yielded a tartrate of extreme insolubility. If it be proved to possess these characters and still to be a molecular compound of quinine and quinidine it is a very remarkable phenomenon. Undoubtedly in estimating this alkaloid we must be on our guard against such a combination as may easily be mistaken for it.

David Howard.

Sir,—In a note by Messrs. Wood and Barrett in the *Chemical News*, of January 6, they refer to the new alkaloid found in cuprea bark as being "chiefly remarkable for its property of crystallizing from an ethereal solution." A reference to the papers already printed in your Journal on this subject will shows that it is more remarkable in the similarity of its salts to those of quinine, and in the great action its solution exerts on polarized light.

The compound of quinine and quinidine which these chemists have noticed in their analysis, and described in the note referred to, does not resemble the new cuprea alkaloid in any respect, and I should not expect it to be mistaken for that. Moreover, a compound of equal proportions of quinine and quinidine, such as they describe, should exert a slight right-handed rotation, whereas the cuprea alkaloid is powerfully lævogyre to the polarized ray.

In my experience the new base is contained in varying proportions in almost every sample of cuprea bark, and from a sample which arrived in London in February last I have obtained as much as ·9 per cent of the sulphate of the new base.

W. George Whiffen.

Sir,—Mr. Howard in his letter in your current number says, that "the note of Messrs. Wood and Barret in the *Chemical News* of last week may seem to throw doubt on the existence of the new alkaloid observed in cuprea bark." I would point out, therefore, that we did not make this suggestion, and did not in any way question Mr. Howard's results.

We simply described a combination of quinine with quinidine that is crystalline and very slightly soluble in ether. It might be mistaken from the new alkaloid, as Mr. Howard states in his concluding sentence, for it easily crystallizes from an ethereal solution of the total alkaloids of many cupreas, and it can yield a crystalline sulphate which, when isolated, may be as lævogyrate as quinine sulphate and give no hydiodate of quinidine.

Yet, I may add, the improbabilities that you put

forward in your editorial note are not involved; these are fanciful suggestions of your own that find no warrant in our article. C. H. WOOD.

[*** If the purport of Messrs. Wood and Barret's note was different from what Mr. Howard and others have understood, it is to be lamented that they did not furnish the explanation of its meaning before. We have their own assurance that they failed to obtain the new base, and a comparison of the above letter with their original note shows that they may have made the mistake referred to by Mr. Howard as possible and requiring to be guarded against. At any rate, we have their own authority for the inference, since they describe the molecular compound of quinine and quinidine which they "first became acquainted with in working on samples of these cuprea barks," as being separable—by crystallization from water in the state of neutral sulphate—into "crystals of pure sulphate of quinine" and a "mother liquor" containing the quinidine; while we now learn on the same authority that this compound "can yield a crystalline sulphate which, when isolated, may be as lævogyrate as quinine sulphate and give no hydriodate of quinidine." The possibility of mistaking one thing for another is therefore the only point on which we, like Mr. Howard, can agree with Messrs. Wood and Barret.—ED. PHARM. JOURN.].

ESTIMATE OF THE COST OF MAKING A 300 ACRE TEA GARDEN IN DEHRA DOON, INDIA.

I have read with much interest the statement in your late issues of how to start a garden in Assam and make it pay. As the cost of starting a garden in the Dehra Doon, and the probable profit to be obtained from it, might be interesting to some of your readers, I have been at some considerable pains to make out a true statement of the cost of a 300 acre garden, and the profit to be obtained by the end of the tenth year. As some of your numerous readers may have objections to urge with regard to some of the items, my best plan will be to refer to them one by one. First we have rent. Although only 300 acres are to be planted with tea, I have allowed an extra 50 acres for buildings, roads, &c. Land fit for tea can be obtained in the Doon for R3-4 per acre, but as land is rising in value, I have considered it advisable to estimate the rent at R5 per acre per annum.

Establishment.—The pay of bildars in the Doon is R4-8 per mensem, but as there might be difficulty in getting a large body of men together in a short time at that rate, I have given their pay as R5 per mensem. The cost of Assam seed, thatching seed-beds, &c., is taken from actual accounts slightly increased. The supply of tools is very ample, and the cost is taken from actual accounts. The cost of the bungalow is only an estimate, and I think a liberal one. The cost of the bildars' lines is taken from my books. Contingencies are meant to cover little petty expenses, such as stationery, postage, &c., &c. Bullocks food is estimated for the whole year, but as they are not fed on Sundays and on days that they do not work, the charge for this item can be considerably decreased. Three pies per pound is the amount paid in the Doon to coolies for plucking leaf, but as the weighing is never so exact as I have represented it to be, a saving will also be effected here.

I believe that in Assam five coolies pick a maund of tea per day, but as our tea has evidently more stick in it than the Assam, I have allowed double that number per maund.

The cost of the tea boxes and lead lining is slightly exaggerated, as they cost at present R2-9, and not R2 10.

The railway carriage is exact. The Calcutta Agents' charges are calculated on the tea selling at 10 annas per lb., and not at 8 annas as represented; so this item can also be considerably reduced.

The estimated cost of the factory is a very liberal one for a 300 acre garden.

Charcoal, oil for lighting and for engine and wood for engine are merely estimates, but even if underestimated they would not affect the total much. The manure statement is made from actual experience.

I have allowed R10,000 for Rolling Machinery, &c., —a very ample allowance I consider.

If any one with a knowledge of the subject will take the trouble to go over the different items, I feel sure that he will confess that every one of them is over-estimated, and that the garden could be got up for a smaller capital than I have fixed. In your Assam correspondent's letter I notice very heavy charges for labour, but as the men come up to us for nothing from the N. W. P. (or if we bring them up, their railway fare only costs R5 per man), we have none of these heavy expenses to meet.

It may be objected that the yields per acre in the 8th, 9th and 10th years, *viz.*, 400 lb., 450 lb., and 500 lb., is too high, but it must be remembered that the class of plant is Assam Hybrid, which is supposed to yield better than the China variety. I have a large area of 8 year old China which will this year yield 400 lb. per acre, and I know of another garden where the 8 year old plants are expected to do more than that.

I know a large area of old China bushes, the manager of which assured me that last year they yielded over 800 lb. per acre. I don't think that any critic will quarrel with the rate at which I have estimated the tea to be sold at, and considering that the variety is Assam Hybrid, it most likely would bring one or two annas per lb. more.

In conclusion, I beg to point out that the Doon is in no way behind Assam in the point of profit from tea, and considering its delightful, healthy climate, is I consider infinitely preferable to it.

PROFIT ON 300 ACRE GARDEN IN 10 YEARS.

1st YEAR.

	R.
Rent of 350 acres at R5 per acre	1,750
Establishment—Manager at R150 = 1,800, Horse allowance at R20=240, Mali at R6=72, 3 Tindals at R8=288, 150 Bildars at R5=9,000, 1 Carpenter at R10=120... ...	11,520
250 mds. Assam Hybrid seed, landed here at R60 per md.	15,000
Grass and sticks for thatching 25 acres of seed-beds at R72 per acre	1,800
Tools: 200 Pharrahs =335·0, 100 Coorpas = 20,600 Pharrah handles =37·8	392
Buildings—Bungalow and Out-houses for Manager, 3,000, Lines for 200 bildars, (mud walls) 1,050·0.	4,050
Contingencies, say... ...	1,000
Receipts nil. 1st Year's Expenditure ...	35,512

Remarks.—One acre of seed-beds will plant out 12 acres of ground 4' × 4' allowing for fair germination, so 25 acres of seed-beds will be required to plant out 300 acres of tea. 10 maunds of seed sown 6" × 6' four seeds will sow one acre of seed-beds, therefore 250 maunds of Assam Hybrid seed will be required. Bildars employed this year in trenching, making, sowing and thatching seed-beds, keeping beds clean, laying out roads and digging 100 acres of pits.

2ND YEAR.

Rent	1,750
Establishment, same as last year	1,520
5 acres of seed-beds=50 mds. Assam Hybrid seed at R60 per md.	3,000
Grass, sticks, &c., for thatching 5 acres at R72 per acre	360
Tools, same as last year	387
Contingencies	1,000
2nd Year's Expenditure ...	18,017
Receipts nil. Add 1st ,, ,, ...	35,512
Total Expenditure to date ...	53,530

5 acres of seed-beds are necessary for filling up vacancies. Bildars to be employed this year in trenching, making, sowing and thatching 5 acres of seed-beds; keeping seed-beds clean and digging 150 acres of pits.

3RD YEAR.

Rent	1,750
Establishment.—Manager at R200 = 2,400, Horse allowance at R12=240, Máli at R6=72. Moonshee at R12=144, 4 Tindals at R8=384, 2 Carpenters at R10=240, 1 Blacksmith at R10=120, 200 Bildars at R5=12,000	15,600
Additional labour required for two months to plant out 300 acres of tea.—400 bildars at 5-0 for 2 months=4,000. Bringing them from the plains at 5-0 each =2,000 ...	6,000
Cost of 10 carts and 10 pair bullocks at 100-0 per cart and bullocks	1,000
Tools—200 Pharrahs=335, P. Handles=37-8, Spades for digging out seedlings, 200 at 8 annas each=100, 400 baskets at 2 annas each R50	522
Building.—Grass huts for additional men=700-0 Repairs to bungalow and lines, thatches 200-0	900
Bullocks' food during year at 2 seers per pair per diem	360
Contingencies... ...	1,000
3rd Year's Expenditure ...	27,132
Receipts nil. Add 1st and 2nd years' Expenditure...	53,530
Total expenditure to date ...	80,662

Bildars to be employed this year in keeping seed-beds clean, digging 50 acres of pits, cleaning out 250 acres of pits, planting and deep hoeing 300 acres of plants.

4TH YEAR.

Rent	1,750
Establishment, same as last year	15,600
Tools—200 Pharahs=335-0. Handles 37-8-0, Baskets 50-0	422

—*Indian Tea Gazette.*

TREES TO PLANT FOR ORNAMENTAL PURPOSES.

The most widely distributed of North American Coniferæ, and one little changed in appearance, is the Red Cedar (Juniperus virginiana). This tree is found as far north as latitude 50°, and south to the Gulf of Mexico, extending from the Atlantic to the Pacific. At its extreme northern limit it is only a shrub; on our own sterile hills it becomes a rugged tree, and is of no little economic value for many purposes; while in the warmer climates of Florida the same species is banished to the swamps, and furnishes that clear, soft wood used the world over in the manufacture of the best lead pencils. The Douglas Spruce, which is one of the most valuable of American forest trees, has a less extended range. It is common from British Colombia to Mexico, extending east into the Rocky Mountains of Colorado. The most interesting point is this; children inherit the characteristics of their parents; and even the seeds of trees carry with them and perpetuate the constitutions, delicate or strong, that the region in which they were produced developed in the parent plants. The seeds of the Douglas Spruce from the Rocky Mountains produce trees which are as hardy here in New England as the Cedars on our hillsides; while plants raised from the seeds of the same tree growing in the milder, moister climate of the Pacific States, fail entirely to adapt themselves to our New England climate, as, indeed, do all the trees, with hardly an exception, from the region west of the Rocky Mountains. Therefore, having an insufficient knowledge of the distribution of a species, we cannot say that any particular tree is hardy, and will serve our purpose as material for forest or ornamental planting; but we must know, in the case of widely distributed species, the exact physical conditions of the particular locality from which the individual was obtained. The [illegible] Larch is said to be a better timber tree in New [illegible]

land than the American variety, the English Elm (Ulmus campestris) in dry situations than U. americana, and Salix alba than the American kinds. The trees of North-eastern Asia, Northern China, and Japan are as well suited, it seems, to the North Atlantic States of the Union as to our own climate. Of Rocky Mountain trees, the Blue Spruce—Picea pungens—better known as P. Menziesii, is a tree of rapid growth, great hardiness, and of a peculiarly charming blue-green colour. We cannot say as much of it here either as to colour or hardihood, for in some places it has been severely injured by recent winters.—*Gardeners' Chroniele.*

ADULTERATIONS OF COCOA.

Cocoa is a seed of a tree called Theobroma cacao, which is cultivated in Mexico, West Indies, South America, and various tropical parts. The tree is an evergreen, and grows about 20 feet in height. The leaves are dark green, and about 6 inches in length by 3 inches in breadth, the flowers are small and white. The fruit somewhat resembles a cucumber, and is about 6 inches in length and 4 inches in diameter, although some are much larger. These pods generally contain about 25 to 30 seeds, although some contain more. These seeds, after drying, roasting and winnowing from their husks, are broken into coarse fragments and known as cocoa-nibs.

Cocoa, as a food, is highly nutritive, and will sometimes nourish when all other things have been tried and failed; but cocoa, as prepared direct from the nibs, by boiliug, is apt to disagree with some persons on account of the large quantity of fat it contains. This, in a great measure, was overcome by mixing starch and sugar with the cocoa in such proportions as to make a very palatable article; but this was soon followed by adding the starch and sugar in such very large proportions to a very small quantity of cocoa and red ochre that it was very difficult, except by analysis, to know what was soluble cocoa and what was a mixture of old sea biscuits, sugar, red ochre and cocoa husks.

For the detection of adulteration of cocoa the microscope plays an important part, and in many cases a microscopical examination will be found sufficient for all ordinary purposes. For the examination a small quantity should be placed upon a slide and a little water added, and then examined with a ½ inch o. g., when the structure of the cocoa-bean will be plainly seen, also the presence or absence of starch; but all cocoas that thicken in the cup contain starch. The sugar can be estimated either by standard solution of copper, or by first mixing a weighed quantity of the cocoa with water and filtering; the sugar will dissolve, and pass through the filter, while the starch will remain behind, and the filtered portion can be evaporated and weighed. For the estimation of the starch, it should be converted into sugar by boiling it with a few drops of hydrochloric acid. You may know when all the starch is converted into sugar by testing it with a little iodine; the red ochre can be detected in the ash. The ash of pure cocoa when thoroughly incinerated should be nearly white; if red, it shows the presence of bole Armenian. The copper test is made in the following manner:—Dissolve 69 gr. of sulphate of copper in 276 gr. of distilled water; add to this 276 gr. of a saturated solution of tartrate of potash, then add 80 gr. of sodic hydrate, previously dissolved in 1 ounce of distilled water; shake well together, and place it in a vessel holding 2,000 gr., graduated into 1,000 equal parts, and fill up with distilled water. Every 200 gr. of this will decompose 1 gr. of glucose.—ALBERT SMITH.—*Oil and Drug News.*

SOME FACTS ABOUT CONIFERS.

ECONOMIC VALUE.—The economic value of the Coniferæ surpasses that of all other forest-trees together, supplying a larger proportion of timber used. The woods of the Fir, Pine, and Cedar are valuable for all purposes, and some of them are of immense durability. The money value of the Fir timber imported into Great Britain into 1879 from Scandinavia and Russia alone was about £5,000,000 sterling, the total value of the imported coniferous wood in this country being about £9,000,000 per annum. Most countries of Europe depend largely for fuel and timber upon their plantations of Fir and Pine. Even in our own country Pinus sylvestris, which formerly spread over a great part of Scotland, has been a source of wealth to its owners. The forest of Rothiemurchus, between Cairngorm and the Spey, 16 miles in extent, produced, according to Sir T. D. Lauder, sometimes as much as £20,000 per annum in Pine timber. From the adjoining forest of Glenmore, sold by the Duke of Gordon for £10,000, were produced forty-one sail of ships of upwards of 19,000 tons burthen.* The indigenous Scotch Fir is now, however, to a great extent superseded by the Larch. Between 1759 and 1830 the Dukes of Athol planted 10,000 acres with Larch alone, and on their Blair and Dunkeld property the total number planted was 14,096,719, calculated at the time of planting to produce at the age of seventy years £6,500,000 as timber for naval purposes. An instance of indirectly remunerative Fir planting is shown at Bournemouth, where some years ago plants of Pinus maritima were introduced in marshy land between Christchurch and Poole, which, spreading in all directions, partly by its own seed and by planting, soon gave the country the appearance of an American Pine barren. The shelter and presence of these trees has been found so beneficial to invalids that one of the largest watering-places on the south coast has sprung up with almost unexampled rapidity, and sites which were formerly worthless have recently become extremely valuable. Similar plantations have been made elsewhere. M. Javal has planted 80,000 acres of the barren Landes of Gascony with seedlings of Pinus maritima. Others have planted lesser areas. In Madeira the same Pine has been introduced, and now covers all the southern slopes above 2,000 feet, the inhabitants being almost entirely dependent on it for fuel.

In other parts of the world the Coniferæ are of equal importance. The quantity of Deodars, for instance, used in India is immense. The Punjab Forest Administration Reports show that between 1874-75 40,000 logs of Deodar, besides those of Pinus excelsea and other Conifers, were floated down the Punjab rivers. In 1870 over 100,000 cubic feet of the timber of Araucaria Cunninghami reached Sydney market per week, and about as much more was exported to Melbourne and elsewhere.

The seeds of many of the Coniferæ are edible, those of the Chilian Araucaria especially forming the staple diet of the Indians of Chile, and in Italy the seeds of the Stone Pine are made into cakes. The sweet and nutritious nuts of Pinus Sabiniana are great favourites with the Indians of North-West America, who collect vast quantities of the cones. A sugar exudation occurs from the bark of the Sugar Pine. The leaves of the Himalayan Yew are dried and used as tea, while the bark of P. sylvestris is formed, in years of scarcity, into bread by the Norwegians. A species of Juniper (J. squamata) is used in India in the preparation of an intoxicating liquor and for making yeast, and in Europe the common Juniper berry is used for flavouring gin. A large number were formerly, and several are still, used in medicine, and the Larch for tanning.

The value of the various gums and resinous and other productions of the Coniferæ is also large. The chief importations in 1879 were—of Kawrie gum 50,439 cwt.,

* Selby, *Hist. Brit. Forest Trees*, 1842, p. 401.

value £122,901, from New Zealand; pitch, 57,188 cwt., value £12,979; tar, 140,507 barrels, value £93,482—the greater part of those products from Russia; Spruce-beer, 1,756 barrels, value £12,027; resin, 1,155,523 cwt., value, £328,021; turpentine, 258,054 cwt., value £290,647, nearly the whole coming from the United States. Other products are amber, Canada and a large variety of balsams, creosote, frankincense, sandarac, &c.—F. STAERKE GARDNER.—*Gardeners' Chronicle.*

INDIAN FIBRES.

The following Memorandum by Messrs. Ahmuty & Co., Calcutta, has been published in the *Gazette* by the Government for general information:—

Coir.—This fibre is very valuable for its extremely elastic qualities, and in cases where "give and take" is required, no other known rope fibre, except hair, can approach it. This fibre, of good quality, will not grow beyond the influence of sea-air, and cannot for any great length of time be preserved beyond the influence of salt-water. Immersion in fresh water without immediate dryage results in deterioration and ultimate rot, while constant or occasional immersion in salt water will, with fair wear and tear, preserve it for probably three or four times as long as a rope of any other fibre would, under the same conditions, last. Where a dead strain or heavy lift is required, coir is not recommended as a safe or reliable rope, the fibre being too short and elastic. Coir is very largely used by the Marine Department for riding cables and springs for the Light Vessels and for towing hawsers, warps and running gear for the Marine Service. For the Marine Service, the Superintendent of Marine annually invites tenders for the manufacture of coir ropes and cables, and the Marine Storekeeper supplies the successful tenderer with coir yarn, which is laid up to order, and returned to the Dockyard. We may note here that we at present hold this contract, and, with the exception of two years, have done so since 1858. We attach some certificates from the Marine Department regarding our supplies of coir ropes and cables.

Manilla Hemp.—Is the strongest of vegetable rope fibres, and where heavy lifts of hard usage are required, is the most reliable of ropes. During the recent campaigns in Afghanistan we supplied large quantities of this rope for contractors in Bombay, Kurrachee and the Punjab presumably for the Ordnance and Commissariat Departments for the haulage of guns and stores over the mountain passes. For such purposes it is admirably adapted. It is lighter, stronger, and more endurable than ordinary hemp rope, and weight for weight per coil is about the same price.

Calicut Hemp.—Is grown on the Malabar Coast, and is of very great strength and fineness, and is especially suited for small ropes and lines. It is very little inferior to the best Russian hemp, and is a most reliable rope for heavy purchases, second, in this country, whose Russian hemp is not used, only to Manilla.

Jubbulpore Hemp.—A much coarser fibre than the above is in general use for heavy cordage. In utilizing this material there is much wastage, but it turns out a very satisfactory and reliable rope, is tough and strong, and will stand much rough usage. Hemp ropes are largely used by the Marine, Ordnance, Commissariat, and Public Works Departments.

Sunn Hemp.—This fibre is of a soft and somewhat silky texture, and when laid up into cordage looks well, but has not the advantage of possessing much strength. It is usually made up into spun yarn for engine packing, or into light lines for packing dried fish, or for baling hides in the interior for transport to screw presses.

Aloe Fibre.—Is produced in large quantities in the Sonthal hills, and when new is of fair strength, stronger than coir, but inferior to Manilla or Calicut hemp. It is, however, incapable of resisting the action of water without serious injury, becomes black and unsightly, and soon ceases to be a rope on which dependence can be placed. Natives manufacture this material by hand-power into rough ropes, and these are extensively used for the haulage, mooring and running gear of country boats, but presumably only for its cheapness.

Jute.—We manufacture this for the Marine Department for maroons used on board the Light Vessels at the Sandheads, and also in considerable quantities for export to Australia, where it is used for packing loose wool for transport to the coast. It is also very extensively used about Calcutta as lashings for jute bales. The fibre does not possess much strength, is unfit for heavy lifts or hard usage, and quickly rots if kept wet or even damp.

Cotton.—This we manufacture into tent ropes and lines and into fine cord for driving gear for cotton and jute spinning machinery. The yarn we obtain from the local cotton mills and lay up to any size to order, but its high price prohibits its very extensive use unless in the case of mill gearing, where smooth running is a desideratum.

Cannabina hemp pineapple Fibre.—About up to thirty years ago there was considerable demand for cordage made from these fibres, but they have been superseded by the introduction of Manilla hemp and by the greater facilities for obtaining Calicut and Jubbulpore hemp. The fibres are, however, of considerable strength, and will stand a deal of hard haudling. This manufacture is now confined to native hand-laid lines for cargo boat and household purposes.

Steel wire rope, iron wire rope.—This wire is imported from England and is laid up to order. The quality is the best procurable. These we supply for bridge-work in the hills and for standing rigging for vessels of the Marine Service.

We would condense the foregoing as follows, viz:—

Coir.—For marine uses, light work, rough usage.

Manilla Hemp.—Hard work, heavy lifts, and where great strength is required.

Calicut Hemp.—For fine lines and ropes, heavy purchases, and where great strength is required.

Jubbulpore Hemp.—For heavy ropes, rough work, hard usage, and where great strength is required.

Sunn Hemp.—Engine packing, baling lines little strength.

Aloe Fibre.—Cargo boat uses, gooning lines.

Jute Fibre.—Maroons, baling ropes and lines, very little strength.

Cotton Staple.—Tent ropes, mill gearing, driving bands for machinery.

Cannabina hemp pineapple Fibre.—Almost obsolete. Boat ropes and lines, household purposes.

Steel wire rope, iron wire rope.—Bridgework across khuds. Standing rigging.—*Madras Mail.*

OLD ORCHARDS on grass frequently become worn out for want of some such assistance, for which time and manure cannot often be spared. All crowding of branches should be prevented by regular attention, for the sudden removal of quantities of wood is not unfrequently attended with loss of crop and impaired energy for years after; therefore, where necessary, remove annually a few of the worst of the crossing branches, and prevent other young ones from proceeding in wrong directions by cutting back or removal. Where it is necessary to replant any trees, see that the old roots are carefully grubbed out, and that the fresh stations are trenched and enriched with manure over as large an area as may be consistent with due care for the preservation of the roots of adjacent fruit trees.—*Gardeners' Chronicle.*

Mr. Jacob Reese, is a paper read before the Engineers' Society of Western Pennsylvania, remarks: "The great want of the present age is a process by which the static caloric of carbon may be set free by non-luminous combustion, or, in other words, a process by which coal or oil may be oxidised at a low degree within an insulated vessel." This cannot be too prominently brought forward. "If it can be accomplished," as Mr. Reese says, "we would be able to produce from twelve to fifteen million foot pounds of electricity from one pound of petroleum, or from ten to twelve million foot pounds of energy from one pound of good coal."—*Athenæum.*

The Orangery in England.—Perhaps of all fruit trees Oranges are the most easily managed, if only they can be kept clear of insects. They require pretty much the same treatment from week to week, and when the fruit is ripening a high temperature, whether it is winter or summer, and as far as my experience goes the fruit is of as good quality in midwinter as it is at midsummer. The main features of success are to obtain good varieties and good healthy trees to begin with; and not only so, but they must be grafted on the right stock. The Lemon stock is the best, and gives the most vigorous trees, which are quite fruitful enough. They never lack a sufficient quantity of blossom. The fruit will not be good if it is ripened in a low temperature; 65° as a minimum is the best, and when it is ripening do not allow too much moisture in the atmosphere, else the fruits will not be firm and good; and at that time the trees require more care in watering. Good turfy maiden loam is the best potting material.—F. Douglas.—*Gardeners' Chronicle.*

Roses on their Own Roots.—I myself for the last five years have tried Rose cuttings, and I think I may say, on the whole, with a fair amount of success. My first year was a failure. I placed the cuttings in pots in an old Melon-pit, and the result was they nearly all damped off. The following year I tried again, but this time placed the cuttings in the open ground. In November I gave the ground a good coating of burnt earth; forked it in, and when dry on the top made it quite firm, like an Onion-bed. I then put in the cuttings by thrusting them into the ground as deep as I could get them. I find this is a much better plan than using a dibble, which is liable to leave a vacuum round the base of the cutting, and if this happens, the cutting, of course, dies. It is necessary to use a good thick pair of leather gloves to plant the cuttings in this way. Last winter, in spite of the cold, about 60 per cent of the cuttings rooted (they were protected by a little short litter), and most of them bloomed last autumn. I am trying the Baroness this year for the first time; at present every cutting looks as healthy and fresh as possible. Teas I am trying in pots, in a cold frame on cinder ashes, and at present I am satisfied with them. There is no doubt that the great secret of getting Rose cuttings to do well is to select ripe wood. I am quite aware that one does not get a splendid maiden bloom from a cutting; on the other hand I find that Roses on their own Roots come in rather later than budded ones, and are very useful for a late show. On my soil (stiff clay) I never could get Charles Lefebvre to grow, either budded on a standard or on the seedling Brier. I tried cuttings, and it grows "like a weed," and gives me splendid blooms. The following Roses I find do well on their own roots:—C. Lefebvre, Marie Baumann, Miss Hassard, La France, Thomas Mills, Madame Nachary, Countess Serenyi, Marie Rady, Alfred Colomb, Captain Christy, Jules Margottin, Edward Morren, Mad. S. Fropot, Sir Garnet Wolseley, Madame V. Verdier, Auguste Rigotard, Dupuy Jamain, Abel Grand, &c. To sum up, I consider Roses on their own roots a great help to the amateur; but he must bud too, if he wants fine maiden blooms for exhibition.—Edward L. Fellowes, Wimpole Rectory, Royston.—*Gardeners' Chronicle.*

Bees as Flower Fertilisers.—Mr. Donbavand is mistaken in supposing that bees never visit buttercups. Whether the hive-bee in particular does so, I cannot say with certainty; but I am sure that the common bumble-bee is often found among the flowers. Of course, other insects also aid in fertilising them.—Grant Allen.—*Knowledge.*

The Government Experimental Farm and Agricultural College.—The section selected for the Government Experimental Farm is about six miles from Gawler and three from Roseworthy Station. It contains 728 acres, 100 of which are still uncleared scrub, another portion being light poor soil, and the remainder fairly representing the ordinary soil of the district, which has been cropped for many years, thus being well adapted for experiments. The situation near the Roseworthy Station is central and easy of access from different districts, it being a little over one hour by rail from Adelaide. Should an institution be established in connection with the Experimental Farm for the training of young men in practical and scientific agriculture, it is important that the College should be near Adelaide, especially as it may be necessary to obtain assistance in the instruction of students from gentlemen residing in Adelaide. We presume that as soon as the land can be cleared, a series of experiments will be commenced with the object of obtaining results likely to benefit the farmer, and of procuring accurate and positive information on disputed points of great moment.—*S. Australian paper.*

S. Australia: The Northern Territory.—The *Northern Territory Times* of December 10 states:—"Private advices from Adelaide by the "Tambora" state that a Company, called the North Australian Company, has been formed in that city by a few gentlemen, acting in conjunction with European capitalists, who believe that the Territory offers a legitimate and profitable field for the judicious investment of capital in mining, agricultural, and pastoral ventures. The shareholders have nominated one of their number (Mr. Thomas Harry, who arrived here by the "Tambora") to inspect and report upon the resources of the country. Mr. Harry informs us that he proposes to proceed to Hongkong and thence to London, after spending a few weeks in the Territory. One very good feature in connection with the Company is that some of its most prominent shareholders have resided in the country for years, and are well acquainted with its great capabilities. The present Government appears very anxious to do all in its power to further the interests of the Territory, and will no doubt make such arrangements as will facilitate the Company's projects."

The Para or Brazil Nut.—Mr. Morris, the Director of Public Gardens, make the following remarks on the Para or Brazil Nut, the seeds of which he has been endeavouring to distribute throughout the island, and have propagated as an article of commerce. He says:—To those who have lately received supplies of seeds of this valuable tree from the Botancial Department, it may be well to mention that owing to the horny character of the shell and the nature of its contents, they will probably take several months in germinating. Care should therefore be taken that the seeds are not neglected till all hopes of germination have passed away. The Para Nut—*Bertholletia excelsa* comes into bearing in some parts of Brazil, according to Dr. Hansen Erch, in ten or twelve years, and it may be mentioned that in addition to the value attached to its fruit, the tree itself is described as one of the most majestic in the South American forests. Should the climate of this Island be found suitable for the growth of this desirable tree, there is no doubt that together with the export of the fruit for purposes of desert, a valuable oil might be obtained by pressure from the seeds. The fibrous bark of the tree is also used for caulking ships as a substitute for oakum.—*Australasian.*

THE FUTURE OF SOLAR PHYSICS.—The fundamental problems now pressing for solution are, "first a satisfactory explanation of the peculiar law of rotation on the sun's surface; second, an explanation of the periodicity of the spots, and their distribution; third, a determination of the variations in the amount of the solar radiation at different times and different points upon its surface; and fourth, a satisfactory explanation of the relations of the gases and other matters above the photosphere to the sun itself—the problem of the corona and the prominences."—*The Nation.*

TOBACCO has the same effect upon the nerve-cells that water has upon a coal fire. Apply water in small quantity, and your fire will burn more slowly; apply a large-enough bucketful, and it will cease to exist. When the cook rakes up the ashes, and covers her fire before going to bed, she performs the same physical experiment as her master, who soothes his nerves with tobacco before retiring for the night. The cook wishes her fire to smoulder during the night. She therefore applies an agent which will check combustion by partially excluding oxygen from her fuel; her master applies to his nervous system an agent which diminishes oxidation, and thus seriously interferes with vital action. In both cases there will be less material burned, less coal and less explosive food. But is this a real advantage to the usefulness of the fire or of the human machine? The cook would be very late with breakfast if she trusted such a fire to boil the kettle, and the work accomplished by a brain much affected by tobacco is both small in quantity and inferior in quality. It is as difficult to send proper messages along a nerve which is under the influence of tobacco as it is to fire a train of damp gunpowder. "Praise God, and keep your powder dry," said the great Oliver Cromwell; "Praise God and keep your brain clear," would have been his burning advice had he lived in these latter days.—*Knowledge.*

WATER AREAS OF THE UNITED STATES.—An interesting table appears in the American *Field*, extracted from the U.S. census returns of 1880, which gives the water area of each State in the Union. The gross areas included are 3,025,600 square miles; Alaska—placed in the census of 1870 at 577,390 square miles—not being here reckoned. The total water area is 55,600 square miles, or 35,584,000 acres. The relative proportions of water and land vary considerably. New Mexico, for instance, with an area of 122,580 square miles, has a water surface of no more than 120, and Arizona only 100 to its land surface of 112,920. Florida, in the extreme south-east, contains the largest water area of any of the States, 4,440 square miles, and is followed, next in rank in this respect, by Minnesota, with 4,160, located in the extreme northern part, and well to the westward. Then comes Texas, with 3,490 square miles in the extreme south-west; North Carolina, with 3,670, on the eastern sea coast; Maine, with 3,145, in the extreme north-east; Louisiana, with 3,300, bordering on the Gulf of Mexico; and pursuing our course to the western boundary, we pass through Utah, with 2,780, reaching California, with 2,380, and Oregon with 1,470 square miles of water area. Then take the inland states, and we find a very uniformly defined water area, ranging from 300 to 600 square miles in each. "Nearly all of this immense extent of water," says our contemporary, "is susceptible of cultivation by the intelligent fish culturist, and can be made to yield a much larger proportion of marketable product than the same quantity of land of average quality. We, as Americans, are prone to boast of our country's resources, and with good reason; but how many have ever taken into consideration the wealth to be derived from 35,584,000 acres of water, properly stocked and cultivated. Can any man set a limit to the value of the aqueous product?—*Field.*

BETEL-NUT AND FEVER.—In No. 12 of *Knowledge*, I find betel-nut chewing given as a specific against fevers. The Javanese and Sundanese are inveterate betel chewers, and yet they have been dying literally by thousands during the past few years from fever. When I left Samarang, Java, in September last, the natives were dying by hundreds of fever. My experience, extending over nearly four years in various parts of Asia, has been, that the natives who universally chew betel (with lime, and the leaf of the sirih-pepper-plant), are much more easily affected by fever than are Europeans.—EDWIN SACHS.—*Knowledge.*

PRESERVING FRUIT FOR THE WINTER.—Dry sand of all substances is found, from the experiment of P. Sarauer, to be the best in which to preserve fruit for the winter. The germs of mould attack the rough portion of fruit packed in paper, with great avidity, through the openings in the silk paper. If packed in straw, the least dampness of the straw imparts a musty flavour to the fruit. Sand has another advantage, which is that the damaged specimens do not infect their neighbours. Choose the most perfect fruit with the waxy covering perfect. Leaving the stalks on makes the fruit shrivel up quickly.—F.C.S. —*Knowledge.*

TARAXACUM.—During the year 1880-81, several interesting experiments were tried at the Saharunpore Botanical Gardens. Not the least interesting was one with *Taraxacum officinale*. An indent for 200 lb. of the extract having been received from Calcutta, an attempt was made to grow the plant and prepare the extract on the spot. It is satisfactory to find that the experiment was thoroughly successful. From half an acre 109 lb. were made, at the following cost:—

To cultivation, &c. ...	...	13	8 0
,, preparing extract ...	...	62	8 0
Total ...	...	76	0 0

or 11·156 annas per lb. The average price of the drug in England is 2*s.* 2*d.*, so that when freight charges and loss by exchange are added, the cost in India will not be less than 1 rupee 8 annas per lb. From this experiment it will be seen that an acre will produce over 200 lb. of the extract, and as improved modes of preparation will no doubt be found out, the cultivation of this valuable medicine will become one of our industries.—*Indian Agriculturist.*

MANURE.—The value of human excreta has been repeatedly brought to notice, but we almost despair of making any progress in introducing this valuable manurial agent to the notice of the Indian rayat. The only form in which they will use it, is in the form of *poudrette*. At the Cawnpore Experimental Farm a careful experiment was tried, with marvellous results. The crop grown was barely. The following were the results:—

	Manured.	Unmanured.
Grain	lb. 2,851	1,842
Straw	,, 3,603	1,968
Value of crop ...	R66-7-1	40-12-9

The manure cost practically nothing beyond the labour of incorporating it. The cultivation in both cases was good, and if the prejudice held by the rayat against this manure were got rid of, much good would result. Two example set our Municipalities by Poona and Umritsur, might be followed with advantage all over the land. Umritsur conveys the excreta, deluged with water to large tanks where it is precipated, but Poona goes to the root of the matter, by changing the excreta into *poudrette* in which form it loses all its noxious properties, and is valuable as manure.—*Ibid.*

The proper time for plucking tea leaf is of importance to tea planters, the time, however, when a flush is ready to be taken off depends so much on climate and cultivation, that a hard and fast rule must fail. In Darjeeling a correspondent of a contemporary informs us that "a shoot from the axil of a leaf just plucked is about ¼ to ⅜ of an inch long eight days after, at 20 days it is about an inch long, at 30 days 3 inches, at 40 days 6 inches. On these Hills, if the pruning has been well done and weather favourable, the young shoots ought to be nine inches high in six weeks, when picking should commence. The shoots should not be picked off too quickly, or the tea will be too tippy.—*South of India Observer.*

The Scarcity of Indiarubber.—Unless some means are speedily taken to prevent the reckless destruction of the rubber trees, this important and now world-wide manufacture will be greatly retarded owing to the scarcity of the raw material. The great and growing demand for rubber has stimulated the rubber hunters of Central and South America to supply the same, but the result is, in their eagerness to meet the extra demands, they destroy the greater portion of the tree. In many places where the rubber trees were seemingly exhaustless a few years ago, the forests have been decimated. The result is that the rubber gatherers have to go further and further into the interior and to the mountains for the present supply. Unless the Government of Colombia and South American States do something for the protection and propagation of this valuable tree, the export of raw rubber from these countries will cease in a few years.—*British Trade Journal.*

Insect-Destroyers.—Some years ago the Massachusetts Horticultural Society offered rewards for a cheap and effectual method of destroying the rose fly or aphis. This brought forth a preparation in the shape of whale-oil soap, with the dictum that it would destroy the insect whatever state it was in. The recipe is to dissolve 2 lb. of whale-oil soap in 15 gallons of water, or if the soap is of a weak strength, diminish the proportion of water by two gallons. The method of using it is to strain the liquid through a fine sieve, when the composition is dissolved, and then apply with a syringe to the leaves and shoots affected. It is asserted that the remedy is effective also for thrips, red spider, canker worms, and the mildew on trees. As the remedy is so simple it might be applied to orange trees affected with scale, as at the above strength it is quite innocuous to vegetable life, and as it can be used *ad libitum* any falling on the ground will act as a manure. Considering how troublesome the brown beetle is on fig-trees, it might be employed in destroying those pests.—*Australasian.*

Influence of Forests on Rainfall.—In the *American Naturalist* for January appears an article by Dr. Anders on the influence which forests exercise upon the rainfall. The practice of ringbarking has lately been advocated in Australia, on the ground that the amount of surface water is thereby increased, though this effect is not demonstrated to be anything but temporary—indeed, by the nature of the case, it would seem self-evidently so—and the effect of this scanty surface water upon the humidity of the atmosphere would be nearly *nil.* How forests affect the humidity it was the object of the writer's experiments to show; and his experimeuts appeared to prove that, while no moisture is absorbed by plants from the atmosphere, they yield to it a considerable quantity by transpiration of water gathered through the roots—the rate at which aqueous vapour is given off by plants amounting to more than an ounce and a quarter per square foot of leaf surface in the twelve diurnal hours. The evaporation from a forest area is probably more than from an equal area of water; and the conditions of the soil penetrated by the network of roots render it a reservoir of the rainfall, to be gradually utilised by the leaf surface above. This humidity imparted to the atmosphere tends to equalisation of temperature by preventing undue radiation of heat; and though it cannot increase the general rainfall—rain being generally formed from one to two miles above the surface of the earth—yet there seems reason to believe that light local rains are really increased over forest land, besides the abundant dews by which it and its vicinity are visited. Experiments of two French observers are cited, which gave a total rainfall for six months over forest land of 192½ millemetres, and of 177 in the open air, showing a difference in favour of the forest of 15½. The action of forests is, of course, more or less local; and therefore their distribution, as sources of humidity, as well as for the shelter they afford from sweeping wind, is a matter of much importance.—*Field.*

Bifacial Oranges.—In the *Provence Agricole* M. Heckel tells us how the fruits which on one side present the characteristics of Oranges, and on the other those of Lemons, are produced. A nurseryman at Cannes, M. Tordo, takes scions (*bourgeons*) of various species of Citrus, Orange, Lemon, &c., and grafts them circularly along the trunk of a Citrus, arranging the scions closely together in pairs so as to bring about complete fusion of the scions. When the grafts have adhered the tree is headed down to within a short distance of the grafts, and in spring branches are seen which give rise to monstrous fruits, having the characteristics of the different grafts blended together. The branches which originate from the ingrafted shoots produce leaves which are greatly changed in form and differ from those of either species, thus affording a striking proof of graft-hybridization. The flowers of the two species are also fused.—*Gardeners' Chronicle.*

The Divi divi Plant.—The Divi-divi pods are employed for tanning purposes, as they contain 50 per cent of pure tannin. I have been told that in Bangalore there is a large plantation of this tree, and that its pods are largely used for giving the skins that superior smoothness remarkable in the Madras and Bangalore skins. I have also used Divi-divi in dyeing, and I have employed a solution of acetate of iron after the bath in Divi-divi tincture. The ink used in most of the Government offices in Fort St. George is made with this plant. The cultivation of this elegant shrub is very easy. The seeds should be sown in March, and the young plants can be removed from the nursery during the following rainy season; they require some watering till they have attained the height of three feet, after which no more care is necessary. This plant grows luxuriantly in a clayish, calcareous soil, but very slowly in red soil, as I have observed at the Red Hills near Madras. I think the difference in the growth in the two soils results from the clayish soil retaining moisture for a very long time in the summer, while in the latter the young plant is exhausted by the strong dry winds blowing then. But I think it still possible to cultivate this shrub in red soil with some success by adding dry mud from tanks to the soil before replanting the young tree from the nursery. Cow dung ashes will prove useful round the plant. The great difficulty to contend with, however, in such soil is the want of water. The cultivation I have made for the last few years is quite a success, and I have made experiments in both soils, clayey as well as red. I shall feel obliged if any of your readers will give me some information regarding the market current price of this dye in London or elsewhere. I think that the high rate of freight from India to Europe will not allow a margin of profit in the shipment of Divi-divi husks.—Searcher.—*Madras Times.*

LIBERIAN COFFEE, COCOA AND INDIA RUBBER.

A correspondent, dating from a "Lowcountry Products" estate about twenty miles north-eastward from Colombo, writes :—

February is usually the driest month in the year over all Ceylon. On the present occasion, and in this locality, it could not be called a wet month; but there was rain enough to prevent any check in the growth of our cultivated plants. Indeed, if I were called on to name the period of most rapid growth, during the last twelve months, I would say, from the middle of January to the end of February. The coffee trees, in their second year in the field, have in that time, added two pairs of branches and two pairs of leaves on all those pre-existing, and such of the cacao trees as were previously thriving have made much wood, and got more and more into form.

The older coffee has had a heavy blossom every ten days during the month, and there has been a considerable sprinkling on that in its second year, and more is still to come. There are no abortive flowers. All that open, set, and, on trees planted in November 1879, 2,000 fairly-established cherries are an exceptionally small crop, many of the larger trees having or promising more than double this standard.

The larger cocoa trees produce masses of blossom continually, but the few pods that have formed drop before they attain the size of a coffee cherry. I have about 800 plants, of the Carracas variety, thriving in baskets, to fill in vacancies; but I live in terror of the white ants, when I am obliged to plant them out.

The rubber plants, resulting from seed obtained four months ago, are now four feet high, most of them in flower, and some of them with pods that bid fair to ripen their seed. There is now no question about the success of the plant. It only remains to be settled whether the produce will pay for collecting. Should experience decide this question in the affirmative, Ceylon will be able to allay the anxiety felt in Europe about where the rubber of the future is to come from. As the rubber is not a *pernickety* plant as to its treatment, or the soil it grows in, it may be extended over all the abandoned coffee, in the lower districts, where the soil is too much exhausted for tea, cocoa or Liberian coffee, to say nothing of the vast plains of the north and east.

Cardamoms are rather slow coaches in the early stages of which alone I have any experience; extremely tender as seedlings, of slow growth, and the prey of very minute insects. They seem now, however, inclined to make a start, and so far as I learn, how. shall meet with all due encouragement. I am advised to plant out under shade and will do so, though no friend to the system of hiding away cultivated plants from the light of the sun. In Ceylon, the Arabian coffee has long placed the question of shade beyond the region of debate, and the Liberian is asserting a like predilection for solar influence. Under even moderate shade it becomes a large, open, long-jointed, large-leaved, brilliantly-green tree, but it yields *little* or no *crop*. Shade for cocoa is still an open question, but the decision will probably turn out the same as for coffee. Everyone who attempts to grow this plant where wind blows soon learns that shelter for the young plant is a necessary element of success, and, young or old—so far as my observation has hitherto enabled me to judge—it is as much a sun-loving plant as any of its fellows. Shelter, by all means: temporary shelter for the young plants, and closely-planted lines of jak would answer, or any other valuable timber tree with heavy foliage at regular spaces across the course of the wind. I name jak as the most suitable tree I know, for shelter belts in the lowcountry, but there may be others of equal value. In soil fit for Liberian coffee or cocoa cultivation, it will reach a height of 20 feet in three years; branches low, has dense foliage, and is worth money, in the course of 20 years, to say nothing of the fruit it bears in the mean time. I have been thinking about the ceara rubber for this purpose, but its appearance is not favourable to the idea; it has not the look of a good wind-resister, with its sparse foliage, and brittle-looking branches. We will however see how it behaves when further advanced.

The *Hemileia* has not been spreading lately, and some of the plants formerly suffering seem to be throwing it off. There are however many to which it still clings, and which will furnish abundance of spores when the suitable season for its propagation arrives.

It is said that leaf-disease has not killed out one Arabian coffee tree in the island, but it killed many young Liberian plants here, all grown from one batch of seed *highly recommended*. I have no doubt the liability was inherited from the parent trees, and, whatever others may do, I accept the warning, never henceforth to take seed from an affected plant.

I saw a curious whirlwind here the other day, travelling across the estate from south to north, at the rate of about three miles an hour. It was some 15 feet in diameter at the base; it picked up all the loose leaves in its course, carried them fifty or sixty feet high, where they gyrated like a flock of swallows, and then gradually settled down, as they passed out of the influence of the storm. I have seen the same sort of thing before, but never had so long or so good a view of it.

Our readers will notice that our correspondent's experience of the rapid growth, and precociousness and heaviness of bearing of Liberian coffee is consistent with that of others, including Mr. Prestoe of the Trinidad Botanical Gardens. In a very interesting report on Liberian coffee, which we hope to publish in an early issue, Mr. Prestoe says his fear is the trees may exhaust themselves from bearing too heavily in the early years of their existence, and he suggests thinning out the cherries. Of course this would mean taking away the smaller cherries, if the crop came on at once, as in Arabian coffee, but in the case of this wonderful coffee, the ordinary process of picking must be one of constant thinning out. But, no doubt, what Mr. Prestoe means is that all the cherries should not be allowed to ripen. In the case of cocoa, nature seems to interfere so as to prevent the evil effects of premature bearing. But, if we understand our correspondent aright, Ceara rubber trees excel all others in precocity. Trees four months from the seed, four feet high and *most of them in flower*! Does this experience square with that of other growers, and what degree of longevity can be expected for trees which flower and even fruit at four months from germinating and which will be tapped for the juices of their bark? What our correspondent says about jak trees for shelter belts is worthy of attention. The prunings for fodder will be useful as well as the fruits for food, while the tree is maturing for timber purposes. But mangoes and oranges might also be put in with reference to supplying the Colombo markets, which will be heavily drawn upon by the passenger and mail steamers about to resort to the port in increased numbers.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special letter.*)

Paris, 25th February.

At the end of May, the sugar manufacturers intend to hold a Congress, when, among other matters, will be discussed the comparative value of beet pulp by the two processes for extracting the juice and refining the latter. In the meantime, the sugar beet growers have met and exchanged views as to the best means for cultivating the root &c. In point of practical utility, the Congress was very remarkable. What are the most favorable conditions for the culture of sugar beet? Deep tillage, in order to have roots uniform and not forky; abundant manurings, but manures easily absorbed and not rich in nitrogen, for excess of nitrogen produces roots poor in sugar and difficult to be worked up; sow as early as possible, when frosts are no longer to be feared, and the soil has been dried after the winter; select good seed; no supplemental manures during the growth of the plant, as such develope the bulb at the expense of the sugar; above all, no stripping of leaves during summer and autumn. Eleven roots to the square yard are considered fair spacing, and it is better to have the rows rather distant, and the plants rather close. Good seed is essential, and to obtain such, the bulbs for bearing ought to be selected under normal conditions of growth and analyzed to test their richness and purity of juice, for it is possible by special conditions of culture to produce a bulb exceptionally rich in saccharine matter, without the root being able to transmit that quality hereditarily: further, such culture might produce an unbranching root, yet the next generation would display all the forkiness.

Beet extracts a great deal of potash from the soil; so the necessity of restoring that salt is urged upon the attention of growers. A deficiency of potash in the soil induces a premature fall of leaves; holes in the neck of the root, and a resumption of vegetation in September—which revival takes place at the expense of the sugar-cells. Phosphates are excellent, and the more so if wheat be intended to follow the beet. Some recommend applications of magnesia. Respecting the period of sowing: in cold regions early sowing is to be recommended, while, in warmer districts, the plant is held to resist the heat in proportion to its youthfulness. It was ever a knotty point what ought to determine the monetary value of beet, for till lately it was the only agricultural product where quality was ignored? To test the industrial value of the root was not less an essential factor in price than determining the weight. Two methods were proposed; estimating the density of the juice, and that is now generally employed, and analysing its richness—a process abandoned as being laborious and unreliable, although the densimetric standard has also its drawbacks.

The question of pulp did not raise serious discussion, as practical stock fatteners corroborated the scientists: when the pulp is too aqueous, correct the defect by dry rations in increased proportions. The sugar interest of France has two grievances: the inland duties and foreign importations. It is proposed to double the tax on the bounty sugars of Russia, Austria, and Germany, and reduce the tax on the consumptive home product still farther. As to levying the other inland impost, on the beet-root, as in Germany, instead of at present on the *brut* sugar in the factory, it was agreed to leave that subject as it is.

Since June last M. Pasteur has vaccinated 90,000 head of stock, among which were 10,000 oxen, cows, and horses. In every instance his process was successful: the animals vaccinated escaped the *charbon* malady, while those non-vaccinated fell victims to that plague. M. Pasteur, and other who have corroborated his view, lays down that the effects of his preservative vaccine do not last longer than eight months; so that vaccination must be repeated annually, and that April is the best month for executing the operation.

Perhaps there is no city in the world, where so much is made out of the soil in its vicinity as Paris; its early kitchen garden delicacies are proverbial; there are veritable fields of asparagus, peas, strawberries and violets. Of fruits I say nothing; only that they abound. Of late years the cultivation of violets has taken an enormous extension, as also of figs in pots. Nice and Parnia violets have more than a rival at present in the rich market gardeners of the suburbs. It is not the less singular than true, that the inhabitants of the suburbs have to obtain their vegetables purchased in the city markets. From 1,500 to 2,000 fr. per acre is the net average produce of a kitchen garden. The commercial cultivation of flowers is also becoming very productive, and, as for mushrooms, they are a veritable "gold-diggings." France alone consumes the esculent to the value of nine million francs per year.

The irrigation of vineyards in autumn is universally recognized as efficacious against the phylloxera. Some proprietors now resort to summer irrigations, and small doses of sulpho-carbonate. At best, such can be but a check, as water is an insecticide, and in summer it augments the vigor of the vine, by causing it to throw out fresh rootlets: but no process can so far place the vine beyond the reach of re-invasions of the insect, under the form of swarms and the hatching of its winter eggs.

Coco-nut cake is being tried for feeding purposes. The analysis of Petermann shows, that it is rich (20 p. c.) in nitrogenous substances.

The reports respecting winter crops are satisfactory. No complaints are made respecting wheat, which bears up well. Indeed farmers are here so contented that their attention is chiefly given to agitations for the suppression of several small and vexatious taxes, the making of good roads, and the reduction of railway transport rates.

EXPERIMENTS WITH MANURES.

Here is a paragraph on the relative value of some manures you may think worth preservation in the *Tropical Agriculturist*:—

Experiments with Manures,—Mr. Cardno, Fraserburgh, has sent us the following result of experiments with manures made by him for turnip crop grown on Kinbog Farm, season 1881, without dung, four drills 12 yards long by 27 inches wide, in centre of field, the proportion given per acre in each case being seven cwt.:—

Weight Turnips, 12th Dec.	Equal per Acre to	Cost per cwt.	Cost per acre.	Description of Manure used.
Lb.	T. Cwt. Q. L.	s. d.	£ s. d.	
106	25 8 3 24	3 9	1 6 3	Odam's Super-phosphate.
73½	17 12 3 18	4 0	1 8 0	Huon Guano.
71	17 0 3 18	6 6	2 5 6	Dissolved Bones.
68	16 6 2 0	7 3	2 10 9	Bone dust.

Prices of potatoes continue ruinously low. Retail dealers offer to deliver orders at 4d per stone. Large consignments are being shipped for America. A cargo by steamer is to go from Aberdeen to New York; another cargo from Dundee to Baltimore; a third of 1,700 tons from Invergordon to New York, the last costing less for freight to New York than railway carriage to London would have been. Large shipmeuts continue to be made at Glasgow, and Ireland has been exporting surplus crops of her staple tatil. The Belfast correspondent of the *North British Agriculturist* writes:—"The

exportation of potatoes to America this year is something extraordinary. The State Line alone during one week shipped from Glasgow and Larne 3,000 tons of potatoes for the American market and have been obliged to refuse cargo. The steamship 'State of Florida,' which sailed from Larne, took with her the largest cargo ever shipped from Ireland to America."

The local presbyteries of the Established, Free and United Presbyterian churches recently appointed committees to consider the proposal to abolish fast-days. These committees held a conference and compared notes. The United Presbyterians were unanimous for abolition, the Frees by 21 to 4 were also in favour of doing away with the fasts, but Old Ziou by a large majority objected to any change being made. Considerable discussion took place and adjournment, without any resolution being come at.

A Company has been formed hers that is about to commence steam trawling. A tidy little steamer of 75 tons register and 100 horse-power has been purchased for the undertaking.

A COFFEE EXCHANGE.

A coffee exchange is in the process of organization. It will be the first of its kind in the world, and bids fair to be an important addition to the trade of this city. Articles of incorporation have been drawn up and signed by a majority of the brokers and some of the jobbers and importers. As soon as the signatures of the others are secured the organization will be proceeded with. There is no opposition to the enterprise, and the idea appears to be well received throughout the trade.

The intention is to organize an Exchange on the model of the Produce and Cotton exchanges, and to enact uniform rates of commissions and rules prescribing grades for coffee imported. Samples of coffee will be exhibited by all the jobbers; "calls" will be instituted, and coffee sold for future delivery, the same as cotton and grain.

The object sought is not so much to facilitate speculation, though this is a feature of the enterprise, as to revive and restore the trade of New York. Western cities are now importing direct and often undersell New York. Rio de Janeiro, by its cable communication, thoroughly understands our market; and her merchants, instead of selling to our importers, are consigning goods to this market and disposing of them through agents Then, auction sales have been instituted, which the brokers claim will drive them out of the business. Altogether, the trade is said to be in an extremely unsatisfactory condition, and is rapidly decreasing. The exchange will, it is believed, harmonize all interests and furnish a powerful inducement to outside buyers to purchase in New York.

There has always been more or less speculative trading in New York, and cargoes are now sold to arrive months ahead. This has, also, to a certain extent, been done abroad. The Exchange will facilitate future trading as well as increase cash transactions. The coffee trade is very large. About $80,000,000 worth of coffee is imported annually.—New York *Commercial Bulletin*, November 30th 1881.

COFFEE AND ADULTERATION.

A slight improvement in the Havre market at the commencement of the week imparted some firmness here, and prices lightly recovered for all descriptions. Towards the close, however, the public sales showed much irregularity, for, while the finest parcels of Plantation Ceylon have advanced from 2s. to 4s., low to middling grades have slightly given way, and good medium qualities have sold without much change. Other kinds have been more inquired for and have sold readily, the demand from the Continent having been much better than for some time past. The weak points of the market are still the excessive stocks held upon the Continent, and the continued enormous production in Central and South America. Until, therefore, the production is reduced, or the consumption very materially increased, there is little probability of prices being much higher than they are at present. It is true that the consumption on the Continent increased during last year about 6 per cent., but the imports also increased at the rate of 7 per cent.

The ferment among the importers on the subject of the adulteration of coffee has gathered strength through a recent Treasury minute permitting the importation of roasted coffee mixed with other commodities, on payment of coffee duty. The exact object of this permission is unknown, but those who have asked for it have, of course, their own interests in view. The importers of coffee think that these interests must be inimical to their business, and they ask why the Government should treat their commodity so differently to what they do tea. If tea, mixed with other substances, is imported, it is seized and destroyed by the Customs' authorities, whom the Treasury now allow to sanction the importation of coffee mixed with any extraneous matter whatever, so long as the importers pay the duty. The revenue officers, apparently, will not even require the most general declaration that the coffee is admixed with anything else, but will content themselves with receiving the money. Yet, if a retail grocer received money for a commodity marked coffee, and made no declaration of any existing admixture, he could be sent to prison for the offence, even with an article with which such extraordinary "substitutes" are apparently legal. The action of the Treasury has naturally intensified the feeling of the coffee trade as to the way their commodity is allowed to be treated. They fear that the result of the recent order will be that the market will be flooded with cheap foreign imitations of coffee, and that the public taste will be still further depraved. In any action that may be taken, it is seriously questioned whether the growers of chicory should not be asked to join, for even chicory appears too dear for modern "coffee," and it is quite possible that the recent Treasury order may prove even more injurious to chicory than to coffee.

No doubt, vested interests have been created by the admixtures which have been allowed with coffee, accompanied by only the vaguest declaration to the purchaser of the kind of goods he was buying, and people know more or less that they do not get pure coffee, and both the seller and the buyer have got used to the idea. But the coffee importers argue that it would be no more just to allow a baker when asked for bread to supply beans, or for a draper asked for silk to supply flannel, than for a shopkeeper asked for coffee to supply something entirely different—however nutritious, or medicinal, or valuable in other ways the other commodity may be. If other roots, or fruits or seeds, or woody fibres, improve coffee, the importers of the latter commodity argue that the full declaration of the improvers used, could only do good to the vendors. If admixtures, on the other hand, spoil coffee, instead of improving it, it is argued that the public ought to be put on its guard. These are some of the arguments freely used in the coffee market, but the practices complained of have reached such a height, and so many similar things are done under the cover of a simple declaration of admixture, that very great difficulty would be encountered in any attempt to apply to coffee something like the French law, by which the proportion of admixture has to be declared. On the other hand, the English law appears to go a long way in the other direction, for it seems to cover nearly per cent. of so-called "admixture" so long as, on some portion of the label, the fact is

stated that the commodity is not pure. Whatever difference there may be as to any proposal for a change in the law—and the subject is too intricate to be dealt with here—everyone will agree that the coffee trade is justified in feeling uneasy, when even the Revenue officers turn against it, and sacrifice its interest to those of cheap substitutes. The Board of Inland Revenue has been the main defence of the genuine coffee trade for many years past, but with what countenance can their analysts continue to search for, and report, on spurious coffee, when the Lords of the Treasury themselves have signed a minute allowing its importation? Is the retailer to be prosecuted for selling "coffee as in Kamscatka, specially examined by Her Majesty's Customs, and found to contain all the aroma of the berry, and to be improved by the addition of highly nutritious and delicious substances"? Supposing that a retailer were prosecuted, and it was found that the packer, without the knowledge of the shopkeeper, had put in 90 per cent. of charred cabbage stalks or of burnt peas, what would the public think of such a governmental imprimatur, followed by the prosecution and acquittal of the grocer? The latter would apparently, even in this extreme suppositious case, be quite protected by the declaration of admixture on the label.—*Produce Markets' Review.*

TEA CLEARING.

The new Customs regulations will, it is anticipated, simplify the payment of duty upon tea, and the opportunity is thus a favourable one for considering how far the present system of delivery, with the endless delays to which it leads, can be improved. In the tea trade the "weight-note," a document abandoned in most other businesses, still forms the key-note of the system. A tea weight-note, as is well known, is an extremely complicated document, for, in addition to containing full particulars of the goods, it forms a contract, an invoice, and a delivery order. In theory, all this is very perfect, but in practice there is so much routine that despatch in delivery becomes impossible. In times of pressure the tea trade comes almost to a deadlock, and, even when the deliveries are small, the delays are quite out of proportion to the work done, simply because of the complication of the system.

One of the reforms wanted in the tea trade is the abandonment of weight-notes. Payments on account should also be made to the actual holder of the warrants, and the balance be settled with him at the prompt. Deliveries, as with most other trades, should be made by sub-orders, and the whole of the present complicated system of clearing or delivery should be rendered as simple as that in use in coffee or sugar. The tea trade, however, is the most conservative in its ways in the Kingdom, and there is little chance of such sweeping reforms being carried. As the subject will shortly have to be discussed in connection with the new Customs regulations, it is quite possible, nevertheless, that some improvements may be effected.—*Produce Markets' Review.*

LEAF-DISEASE AND MR. STORCK'S CURE.

A correspondent writes:—"I see the editor of the *Gardeners' Chronicle*, in his preliminary observations, says that success depends on circumstances 'which should *induce cautious experiment on a small scale* before embarkation on a large one.' He, therefore, does not regard Mr. Storck's statements as conclusive. These are: 'that the spores turned dirty yellow and incapable of propagation' that, if it did not 'immediately kill the spores, it effectually incapacitates them from germination' and 'all disease is *dead* before the fall of leaf.' All these are strong statements, but they are apparently mere statements, unsupported by any tests; either of the facts themselves, or of the cause having certainly been the carbolic vapour—*post hoc* does not necessarily mean *propter hoc*, and our past experience shows so many cases of similar *appearances*, that the facts could only be accepted as effects of the particular cause, after they have been themselves proved and the *connexion* established. I well remember a case where the *appearance* of the spores in six experimental sealed cases was the same in all! The spores in the case where no remedial or other process had been carried out were exactly the same in *appearance* as the rest! I still consider, after reading Mr. Storck's remarks, that the first step towards a *settlement* of the question is to *prove* that mild vapour, harmless to coffee, does actually and undoubtedly *kill* the spore. I have seen the appearances Mr. Storck describes where no treatment whatever had been applied. I have also seen spores yellow as guineas, when *strong* vapours had been long surrounding them. If any of our planting friends should think it strange that the *spore* should be materially more proof against treatment than the mycelium, they might be reminded of the difference between a *seed* of ceara and a growing leaf and of the same!"

MR. GRAHAM ANDERSON ON FUNGUS-RESISTING COFFEE; "G. W." ON THE "CARBOLIC ACID" EPPERIMENTS.

Mr. Graham Anderson of Mysore is a coffee planter of such wide experience, so close an observer, and, manifestly, so careful a student of plant-life and behaviour, that anything from his pen on the subject of coffee culture, is deserving of respect and attention. In the midst of depression such as never before affected the coffee enterprize in Ceylon, it is cheering to find this experienced and intelligent Mysore planter uttering words of confident hope for the future. He, at least, does not despair of the revival of the sorely-tried Arabian coffee enterprize. No planter or intelligent observer can possibly dispute Mr. Anderson's statement that, in the vegetable world, as in the animal, there are causes and conditions which predispose to disease. When cholera, for instance, becomes epidemic, it finds its first and its most numerous victims in subjects debilitated by drunkenness, wasting disease or innutrition. But unfortunately the epidemic does not stop there, but proceeds, as it increases in virulence, to strike down the strongest and those who have most religiously observed the laws of sanitation in regard to body and abode. The deadly fungus has visited our coffee with all the destructive effect of an epidemic, and, while trees originally weak, or which have become weak from improper treatment or want of culture, including the application of fertilizing substances—while these suffered first and worst, the most vigorous and most carefully and scientifically cultivated do not finally escape. As *hemileia vastatrix* seems to stop short of absolutely killing its victims, contenting itself with reducing vitality and fruitfulness to the lowest ebb, of course the analogy with cholera cannot be pushed too far; but it is close enough, and it might be better for the planter in the end if his plants were at once killed outright, rather than reduced to an invalid condition, equiring constant and expensive treatment with but

poor and unremunerative results. If, at the commencement of the plant-pestilence, some thirteen years ago now, (Tytler's cycle), the plants had been killed, they might have been replaced by the seed of those disease-resisting varieties for the existence of which Mr. Anderson so strongly contends. As matters stand, the existence of such varieties, none of which seem as yet to have reached Ceylon, (unless Liberian coffee prove an exception*) can benefit only those who have the courage *now* to commence a pursuit on which so much of disaster has fallen. The question at issue is the existence of disease-resisting plants. Mr. Marshall Ward's contention was that trees which had apparently resisted attacks of the fungus, owed their temporary immunity merely to position with reference to prevailing winds and he recommended tree-planting not for shade, but for shelter. Mr. Graham Anderson, with all his faith in the processes of cultivation and manuring, has, it will be observed, no belief in the possibility of warding off attacks of the fungus by such "mechanical" means as shelter belts. In this, we hope, he may be mistaken. We surely, all of us, in Ceylon, fully believe in the value of the ground treatment of the coffee plant, even if, as Mr. Marshall Ward said, a certain portion of the food supplied to the tree roots went to feed the fungi in the leaves. As for root-pruning, the cockchafer grubs have done and are doing only too effectually what is equivalent to that process, and we trust that ultimately all estates in the colony will benefit, as some have already done, when the insect pruners have ceased to graze on the feeding rootlets of a plant, the leaves of which are simultaneously used as food by the fungus. Light pruning too, we imagine, is the rule in regard to trees which have not strength enough left to put on sufficient wood for a profitable crop. But surely due attention to the root-culture of the plant ought not to justify neglect of topical treatment, especially when, as in the case of Mr. Morris's lime and sulphur and Mr. Schrottky's carbolate of lime, the topical application must benefit the soil and so the roots of the plants. The vast majority of those connected with the coffee enterprize are much more anxious to know what will cure the plants already in the ground than to learn that "fresh blood," in the shape of seed from distant sources, might give them fungus-resisting trees. That involves beginning *de novo*. Alkalies and phosphates were deficient in the period anterior to 1869, and yet there was no visitation of fungus. Indeed it is certain that never in its history had coffee received more justice in the shape of cultivation and manuring than in the period when *hemileia vastatrix* first developed over the Ceylon estates. If the coffee planters violated any law at all, it was that, if it exists, in nature's code, which forbids extensive areas of one particular culture. Certainly the effect of the visitation has been to break up uniformity and direct attention to new and varied products. In one of these, Liberian coffee, there seems to exist, as yet, very strong evidence in favour of Mr. Graham Anderson's theory of fungus-resisting trees. Our recent visit to Udapolla, as well as reports of experience on other places where the plants are cultivated, all tend to the conclusion that trees of a specially luxuriant and dense habit of growth, do resist—at least have as yet resisted—the fungus, which may prevail in a virulent form on trees in close proximity to those which can claim a clean bill of health. We ought also to add that, in Capt. Bayley's experience, coffee trees from seed obtained from Mocha are specially vigorous and disease-resisting. Seedlings from West Indies seed, on the other hand, were at once and badly attacked.

Mr. Graham Anderson does not, in the present letter, indicate the coffee of any particular district as noted for its disease-resisting powers. A writer in the *Asian* (a Calcutta paper) is, however, positive and definite, as will be seen by the letter which we quote, placing it after Mr. Graham Anderson's elaborate argument. The habitat of the disease-resisting coffee is the district of Nalkhnaad in Coorg, and curiously enough this coffee resembles the Liberian species in great size and deep colour of foliage. The habit of the branches, however, is drooping, or what planters call "umbrella" shape, much as we remember Haputale plants in 1874. The Coorg plant is said not only to resist disease but to give crops larger by 25 to 30 per cent than ordinary coffee. We believe coffee from seed of this variety is now growing in Ceylon, (imported in 1880) and we should much like to know how far it has fulfilled the conditions claimed for it? The statement as to its superiority in Coorg is strong and unqualified. Has any Ceylon planter visited Mr. Chisholm's estates?* All possible information is calculated to be of value, although at present our hopes of revival for our old coffee, as a whole, rest more on the "cycle" and "effluxion of time" theories than on anything else. Let us adopt for our motto, however, Mr. Graham Anderson's sentiment: "*Nil desperandum.*"

Since the above was written the letter of "G. W.", a well-known veteran writer on planting topics, has come to hand. His object, it will be seen, is to shew that as regards the efficacy of carbolic acid in checking and destroying the leaf fungus, we are still at the very A. B. C. of scientific investigation. This conclusion of our correspondent took us by surprise and we directed his attention to Mr. Ward's last report and to Mr. Storck's paper in the *Gardeners' Chronicle* with the result given in the postscript to his letter. But "G. W." must remember that a grave reflection will rest on Mr. Ward himself if he gave up his special mission in this island, declaring he had done all that was in his power to investigate the *Hemileia* and the means of fighting it, while at the same time he had not given careful and due attention to the virtues of an antiseptic universally admitted to be of so much efficacy as carbolic acid. The very ex-

* We believe small consignments have also been received here of Nalkhanaad seed: Mr. J. S. Middleton of Mysore in 1880 having first called local attention to this variety.

* Mr. R. H. Elliot ("the Mysore planter") attributed the freedom of his coffee from the fungus to "shade"; far more probable causes are the isolated position of his property surrounded by forest and the long dry season experienced in Mysore. Mr. J. S. Middleton, an old Ceylon planter, now holding property in Mysore for twenty years, mentioned how an estate of his planted with ordinary coffee was snuffed out, and how he had planted again with the "Nhakanaad" variety and which successfully resisted leaf disease.

periments which "G. W." desiderates, are just those for which we should like to have the aid of the Cryptogamist. There is however, a very striking contradiction becn the experience of Mr. Ward as given in his Report (page 523, "Tropical Agriculturist," vol. I.,) and the statement of Mr. Storck (who was Assistant to the well-known Botanist Dr. Seeman,) which is corroborated, says the editor of the *Gardeners' Chronicle*, by independent reliable authority :— (this will be found on page 911 of the "Tropical Agriculturist" *et seq*). We give the two passages for purposes of comparison :—

Mr. Ward.

Carbolic acid is very slowly volatile, and with difficulty soluble in water, and where drops of the acid touch a leaf, &c., destruction of the tissues ensues. Carbolic acid has, moreover, a powerful odour, and it appears to be assumed in the experiments that the odour is a measure of so much vapour passing off from the mixture to be dissolved in the water on the leaf. I do not find, however, that the destruction of *Hemileia* spores in the neighbourhood of the mixture is commensurate with the alleged results. It is true that, where water is in contact with the powder, a solution is obtained sufficiently strong to kill germinal tubes, but the diffusion of this over the leaf is a very slow process. Under any circumstances the results of experiments with carbolic acid powder are not as yet encouraging, though I am of opinion that more might be done with some modification of it,* if it were not for the fact that the *accumulated powder and solution are a source of danger at the roots.*

I will pass on to the description of a few illustrative experiments before reporting further on the larger ones. A sturdy coffee plant, of which two leaves were diseased with "rust patches," was placed in a small wardian case, the whole of the inside of which was painted with a saturated solution of carbolic acid in water. In the overpowering atmosphere produced the plant was tightly enclosed. After 24 hours I opened the case and removed the plant: the odour of carbolic acid was so strong, that one could with difficulty hold the head in the enclosure. Nevertheless, spores taken from one of the patches germinated nominally in 24 hours. It is thus clear that in using carbolic acid (as with other reagents) the germinal tubes will have to be attacked with a solution of the acid.

* As, for instance, using the weak powder alone on the leaves, and the caustic lime separately as a top-dressing to the soil.

Mr. Storck.

An acre of coffee land contains thirty-six centres of vaporisation formed by tin vessels to be mounted upon short sticks, and covered in a peculiar manner, to protect the contents from rain and rubbish, thereby preventing waste and undesirable dilution by rain of the fluid contents of the vessel. They consist of a mixture of carbolic acid and water in the proportion of from 3 to 10 per cent. of Calvert's best No. 5 acid, at the option of the operator. Any strength not exceeding 25 per cent. may be used, since nothing touches the plants or the soil, nor injures the tenderest young leaf or flowerbud. * * Two Liberian trees I simply furnished with a small bottle each, partly filled with my mixture of only 3 per cent., hung into the angle of the lowest branches. Both trees have now been perfectly free of the fungus for some weeks, and not a single one of their close neighbours has been infected. They prove to have been completely isolated by the treatment, not a single spore living to reach and infect the others, although in some instances almost touching. With the nursery, covering about three-quarters of an acre, I proceeded in the following manner:—Judging that with so small an area as the above I should be working at a disadvantage through the gas escaping beyond the limits of the area and going to waste in every direction, I arranged my centres of vaporisation a little closer than would be necessary on a large field, and put them 8 yards apart each way. The receptacles of the fluid and their covers were represented by ordinary cups and saucers, pressing the cups slightly into the ground and mounting the inverted saucers upon three or four short sticks stuck closely round the rim of the cups, I left a clear space of about 1 inch in depth between the rim of the cup and the cover. They were then charged with a dilution of 3 per cent., and the effects noticeable after a few days were most startling.

Another experiment throws light on this subject. A thin layer of the mixture of carbolic acid powder and lime was sprinkled on the surface of the mould around two coffee plants, and at once watered. The watering was continued at intervals for three weeks, when one of the plants had but one yellow leaf left, and the leaves of the other were pale and drooping. The effects of even a dilute solution of carbolic acid at the roots are disastrous, though in the case of a large strong tree they may be to a certain extent marked by other changes.

But observations on whole estates prove the same, and I have failed to discover the good effects said to have been produced on estates by the treatment. That the germinal tubes are killed wherever a solution of carbolic acid comes in contact with them is true; but such a solution is not produced in the way described in the experiments on Peradeniya, Glenegles, Pallakelle, &c.

If carbolic acid powder could be used with safety, it would be more efficacious without the lime, which could be used with benefit as a manure; but in face of the fact that whatever external application were used, it would have to be repeated at least every three weeks or so, it would be highly injurious to permit such an increase of carbolic acid in the soil as would be the case here.

Mr. Storck. (Continued.)

mend a density of 10 per cent. The effects of the first week's dense vapour will amply repay the extra outlay in striking a deathblow, not only against the rust in full development but—which is the greatest triumph of my system—against the mycelium of the fungus. This first blow will under these circumstances save a large proportion of the foliage, unless too far gone, by instantly arresting the development of the fungus, and killing all that may be still alive on the dead and dying leaves strewing the ground. If the disease is not visibly present, all the better; the carbolic vapour will in a short time force it to show itself, chiefly in the character of dying mycelia, and save still more or all of the foliage which would have gone in the next attack of disease. *** Choose your trial patch right in the centre of a good 100-acre field, and the experiment, conducted with ordinary in-

The ripe spores with which the plants, then some nine months old, were fairly reckoning, began to change colour from the wellknown bright orange to a dull ochre, until they subsequently turned into dirty yellow and then greyish white. They all, instead of as usual dispersing, remained in a manner glued to the leaves, and afterwards dropped with them, dead, harmless, incapable of propagation. As time went on, all rust which came out began to look dull in colour and sickly, quite different from a healthy crop of spores. By degrees pale rings round the rust patches began to show, indicating the circumference of the mycelia and where their farther development had been arrested. In the third month a large proportion of the spots appeared pale green, whitish round the edges, and as if drying up in the middle; some pushed out a few sickly spores, but very frequently none at all. The spots turned into dry tissue, and most of those leaves, unless too severely attacked, remained on the trees. Thenceforth a little dirty-looking rust still continued to appear, but the presence of the disease, up to its complete disappearance, was chiefly indicated by dead and dying mycelia. *From what I have witnessed, bare contact with the vaporised atmosphere seems, if not immediately to kill the spores, to effectually incapacitate them from germination.* From moving round in the nursery, examining the effects of the treatment, as I frequently did, I would often go in among healthy trees, handle their leaves, pull suckers and the like, but not a single instance of further infection took place among those trees, Liberian and Arabian, which were healthy when the process was started. With grown trees, having leaves of denser texture and more uniform age than nursery plants, which are almost always growing, the effects, although apparently slower at the beginning, are in the end still more pronounced. They lose a greater proportion of leaves at the start, but all disease upon them and in them is dead before the fall, at once neutralising a fruitful source of re-infection. In the case of fairly vigorous trees a new coat of clean foliage, never again to be soiled by the devastating parasite, will have formed by the time the last spore has disappeared.

* * You may go on charging your vessels with a den-

telligence and regularity, will in a few months convince me the most sceptical of the value of my method.

Mr. D. Morris used carbolic acid in one per cent and two per cent solutions, but nothing was said in his lectures of the result of his experimeuts. Professor Stevenson Macadam of Edinburgh recommended in 1879 the washing of the stems and stouter branches of the coffee tree with a solution of one part by volume of carbolic acid to nine parts of water, but that was with the view of destroying Mr. Morris's "filaments."

COCOA CULTIVATION IN CEYLON.

We owe many apologies to the able and experienced writer of the letter in another column on this subject for the oversight which has delayed publication of his letter. It is still in good time, however, and well worthy the attention of those engaged in cultivating the source of *theobroma*, the food of the gods. As to having no serious enemies to contend with, however, our friend "W. L." differs *toto caelo* from "W. F. L.," and thinks mole-crickets and wind, especially the latter, most serious enemies for the young plant to contend with. Indeed, "W. F. L." himself deprecates planting on windy ridges. Our own observation leads us to the conclusion that to no plant, when young, are tearing winds more fatal. Shelter in the earlier stages, is, therefore, in the case of this culture, a *sine qâ non*, while "W. F. L." has also found a degree of shade beneficial. If cocoa will "make soil" and continue bearing, as is hoped, for sixty years, we can surely wait four years for the full bearing stage. For "cocoa," as for Liberian coffee, we cannot doubt there is a great future in Ceylon. Has the hardier character of the "caraccas" variety of cocoa been observed: the seed of some pods of white caraccas got from Heneratgoda have produced the quickest growing and hardiest plants we have yet seen in the island.

CINCHONA AND CINCHONA HYBRIDS.

Amongst papers which have accumulated we find a letter, from which we quote as follows:—

I have been somewhat amused at Colonel Beddome's report upon cinchona. I cannot see what benefit can arise from bringing new men continually upon old subjects. For my part I can show every connecting link from a succiruba pure and simple in every gradation until we reach an ordinary officinalis, calisaya what else you like. I have also had bark from both the pubescent and glabrous leaved hybrids analyzed with the average result of the pubescent form proving the richer in quinine, often as much as 1 per cent. above the smooth leaved or glabrous form, the analyses having been made by Dr. Paul. I look upon these new (?) questions as matters settled by MacIver 10 years ago, now to be theorized and brought up as new again, owing to the inexperience and want of discrimination of one man. My experiments, as regards results, prove Mac Iver to be right in all his points, except in extent, wherein alone, I think, he is wrong in a slight exaggeration of the qualities of his pets. Remove this, and the main facts coincide with my knowledge, far more than with either Cross or Beddome. Cinchona, as a wild plant, is as much removed from cinchona as a cultivated one as an uneducated rustic is from an educated man. I am very much mistaken if cinchona has not the power of crossing and producing fertile seed. Possibly some special kinds have more potent influences in this respect upon other special kinds than they have on others, but the degree to which this law applies has not yet been determined, but undoubtedly it exists.

Another correspondent, however, remains a sceptic in the face of all evidence, and writes:—

"I have read your article on the hybridity of cinchonas. I am sorry I cannot accept a baseless theory, in place of my own knowledge obtained after 16 years' close observation of the identical plants now in dispute. I will reply in due form, notwithstanding your kindly warning, to keep a calm sough. My friend 'W. F. L.' (alias 'New Products') is sensible as usual, and I am glad to welcome him back at this juncture."

This mail has brought us the analyses of some barks, we had sent to Mr. Eliot Howard for his inspection, and he accompanies the figures with the following remarks of general interest:—

March 3rd, 1882.

I cannot say anything about the trees from which the bark was taken, except that the analysis seems to indicate that they are all *hybrids*. This is a very *easy* explanation I know and much too freely resorted to, but in this case it is all I can offer.

"The Spanish botanists and recently Dr. Weddell were very careful in their description of *species* to pay particular attention to the barks. This has been too much neglected since in some quarters and consequent confusion results.

"I have heard from Col. Beddome, but have not received the specimens he promised. I suppose they have gone to Kew.

"Is the *bark* of the (misnamed) *magnifolia* the same as that of *pubescens*? That of this latter is very distinctive. The name *C. robusta* seems well applied to the *pubescens* of which I have a flourishing specimen some 8 to 10 feet high."

The Quinologist therefore approves of the name suggested by Dr. Trimen for the vigorous Ceylon pubescent hybrids. In referring to some of the analyses of the bark from these hybrids, we shall give particulars of the trees.

ON THE HILLS OF CEYLON.

Beyond and around Nawalapitiya is the region of tea, extensive plantations of which are preparing traffic for the railway which is scoring the hillsides and passes through many abandoned coffee estates. Sir. Wm Gregory, in the discussion on the precariousness of coffee, took care to say that in his opinion we were only at the beginning of discovering the various products which could be cultivated in Ceylon. Our late Governor would have been delighted had he seen what we saw at "Strathellie" two days ago: 300 acres of luxuriant tea and a Jackson's tea roller at work on the green leaf, which a Davidson's Sirocco was converting into dry, of as good or better quality than that tired over furnaces of charcoal. To get to Mr. P. R. Shand's property the traveller proceeds to Ginigathena; then about a couple of miles down the Yatiantote road, and finally along an estate road to the right: 9 or 10 miles in all from Nawalapitiya. The place is in old Ambagamuwa and was blazing hot when we walked over and admired it: perfect contrast as it is to the comparatively low and level tea land we saw in Java. But it *can* rain there, to the extent of 220 inches per annum. Tea can grow with 60 inches, but it flourishes under from 100 to 250. There is no question as to the actual success of tea here and at Galboddé, or the prospective success of the large acres on old Carolina, Mount Jean, &c. Up here and all

the way between, as also all the way down to sea-level, tea is equally successful, and Ceylon will yet be a great tea country. Of that there can be no doubt. Tea drying by such machines as the "Sirocco" removes one of the great objections, that of hot, night work, which formerly weighed against tea in comparison with coffee. I was sorry to learn, *en route*, that coffee grown in Ceylon from seed obtained from Nalknaad, in Coorg, possessed no immunity from leaf-disease. The questions now are, if the variety of Liberian coffee which resists disease can be grafted on Arabian and up to what altitude it will grow? In Kottiagalla Oya valley I saw the great contrast between still vigorous old coffee, and some only six years old, but from seed of trees enfeebled by leaf-disease. For the present, the planting of Arabian coffee is at a standstill, unless there are small exceptions in Uva.

I have now paid my third visit of inspection to Ledgeriana grafts placed on succirubra plants in *situ* and in the open air. There can be no further doubt of the perfect success of the discovery which, and all the consequences that must result to the planting enterprise of Ceylon, the country owes to Mr. Wm. Smith. Mr. Moens deals with stocks in flower-pots, uses only the tips of Ledgeriana branches, and not only one covering of glass, but two are desiderated in his process. Mr. Smith grafts in the open air, with no shade beyond a bottomless, up-turned basket and a bit of sacking. He can graft ripe wood on well-grown trees, and not the tips merely, but all the branches of a good Ledgeriana tree are available.

I hope soon to deal fully with this grand discovery which, while conferring incalculable benefit on Ceylon, will, I trust, result in fortune to the owner of the 150 fine Ledgerianas which he says he owes to seed I gave him. Apart from the wonderful analyses, which are the true tests, I can say that the foliage-features of the trees are just perfect reproductions of Mr. Moens' celebrated Ledgeriana grove in Java. The precious seed of the Mattakelle trees is being carefully collected by means of calico cages which envelope stems and branches.

Close by them, in a beautiful shady piece of the original jungle, the genial owner of the Ledgers (one of which he values at £5,000, which, in fact he would not part with at that sum,) gave, a few days ago a ladies' and children's party which was a delightful success in the large numbers present and the perfect enjoyment which prevailed. The Laird of Mattakelle is not one of those who despairs because depression has overtaken the old coffee enterprise. He believes as I do that there is life in the old colony yet, and that robust vitality will fully return.

EXHIBITION OF CEYLON PRODUCTS.

We are glad to see that our friends in Ceylon are setting themselves to work to secure in the museums of the island space for the exhibition of the different kinds of coffee produced in various countries. Their efforts have been backed up, and there has not been much difficulty in obtaining the required concession. One would have thought that it would have been hardly necessary to ask for room, because coffee is a produce of such interest to Ceylon that every assistance to examine what grows in other places ought surely to have been tendered by the Government. As we have often remarked, private enterprise does a great deal, and will do more, but there are little things in which the authorities can show an interest, and which act as a stimulus to efforts temporarily checked by bad seasons and unfavourable circumstances. The collection of natural products is one of these ways of showing interest, and from the means at the command of the Government it is very easy for them to bring within the observation of planters many things of great use to them. Seeking as they are to find some new article to add to the producing powers of the country, it behoves the Government to give them all the aid that is possible, and, in view of the losses sustained in recent years, nothing should be left undone which will conduce to a revival of prosperity. Moreover, the expense to be incurred in making such a collection is very small, and can hardly be reckoned as anything beside the possible beneficial results. It is not too much to ask the Government to see to this, but there seems an amount of supiness and lack of energy in what should be the guiding star. They should encourage in every way the opportunity for bringing to the notice of the planters all and every product which may be introduced with success into the island.—*L. & C. Express.*

MR. EDGAR LAYARD IN NEW CALEDONIA.

From a long paper in the *Field* of Feb. 4th, we extract a few sentences of some local interest as much on account of the writer as of the substance :—

In *The Field* of the 16th April last will be found an account of the unexpected fishing I met with in the, to me, then unknown river at Moindou, on the west coast of this Island. I there and then "promised and vowed three things in my name," and I now intend to redeem my promises better than most godfathers ordinarily do.

First, I promised, if I lived, to go back again; secondly, to try the fish with spinning bait and artificial fly; and, thirdly, to write and tell my brethren of the angle all about it in *The Field*.

I wanted to revisit Moindou in the months of August and September, when the huge old Erythrina trees that grow on the river bottom, or flat, through which the river meanders, were in all their glory—one gorgeous mass of scarlet and gold, and, as my kind friend Mons. Boyer told me, swarming with parrots. I wanted to find one special kind of parrot—Glossopsitta diadema—which I have not yet seen, and which is very rare. Alas! man proposes, but God disposes.

First, I got pitched out of my phaeton, and disabled my left arm, which leaves me with a permanent stiff wrist. Then my "better half" had a serious illness; and so it was not till the first days of October that I found myself steaming along in the lumbering old "Croix du Sud," with her head pointed to Téremba. Our voyage was not a very eventful one. It was a dead calm, and the only living things visible were dozens of a brown-coloured sea-snake, which surrounded us on all sides for miles. Some were swimming lazily along, others lay motionless and heedless of the steamer as she ploughed past them; some extended at full length, others coiled up.

I see a discussion in *The Field* as to the climbing powers of these reptiles. I cannot say I have ever actually seen them climb up a hawser or rock either; but I have heard so often of their being found on board vessels lying at anchor that I have no doubt they can climb up a hawser or chain, and I have both heard of and seen them in places on land to reach which they must have had some power of climbing and locomotion. Here they are not dreaded as venomous; but in the eastern seas I have heard of many accidents. * * * *

In my former account I mentioned that one of the fishes I caught, a kind of fresh-water herring, was said to be very abundant in the marshes and ponds.

There was a lovely pond, or "tank," as we should have called it in Ceylon, within view of the house. It lay right on the boundary line of the coffee plantation; so one side had been cleared of all but the gigantic erythrina trees, the other was still covered with fine forest, the branches of some of the trees sweeping down to the water. The big trees were still in flower, a grand mass of colour; and, as the

setting sun shone on the placid water, lit up the scarlet of the flowers to a brighter flame, and rendered the dark sombre shade of the forest doubly dark by contrast, I thought I had rarely seen a more lovely bit of scenery.

Day's latest glance on the brown hill beaming
Lingers like lover, loath to say farewell,
Cradled below, the lake lies calmly gleaming.

* * * * *

I bade adieu to my kind friends, rode into Téremba again, slept under the hospitable roof of the commandant, and at 4 a.m. boarded the old "Croix du Sud," and "screwed" back to Noumea. The rain that had bothered me almost every day of my stay accompanied me to the last. I saw a heavy thunderstorm travelling parallel with us along the mountains, and as we sighted Noumea it burst over the town. Such a violent downpour has, I believe, never before visited the place; and three flashes of lightning and accompanying thunder (of which we rarely have any) will long be remembered by the inhabitants. My box was full to the brim with birds; I had several new birds'-eggs and nests, a lot of land shells, a stock of health, and, above all, fulfilled my desire and killed fish with the artificial fly in New Caledonia.

E. L. LAYARD.

British Consulate, Noumea, Nov. 1881.

AGRICULTURE IN EGYPT AND ON THE CONTINENT OF EUROPE.

(Special letter.)

Attention is being drawn to Egypt as a country admirably suited for agricultural emigration. Despite the bad administration of the country, the advantages are many and real. In point of climate, it would be perfection for the farmer. It never rains, hails, snows or freezes. The water necessary for irrigation is stored in reservoirs and distributed by canals; so the cultivator can have the equivalent of rain when he pleases. The Nile marks the limit of fertility: where its waters reach not, there the desert commences. The soil is in great part derived from the sediment of the Nile: it is relatively deep, and, by a little amelioration in tilling, could be made to yield three times more than at present. Hand labor is abundant, and costs only half a franc per day, and no food. Land can be bought out for fs. 500 an acre, and farming pays about 5 to 6 per cent on capital. The system of cultivation is simple. When the Nile commences to rise in the middle of June, rice or maize, &c., is sown; in autumn, wheat, beans, or clover; and in March, cotton or cane-sugar. Agricultural operations can be effected at all seasons, since there are no meteorological drawbacks. No manure is employed, for the natives dry the excrements of animals for the purposes of fuel. The same kind of plough is employed today, as in the time of the shepherd kings, say, 8,000 years ago: the soil is scratched to the depth of two inches: the plough is drawn by two bullocks, or a camel and an ass: no care is observed in the selection of sowing seeds: the grain is never cut till it commences to self-shell; consequently threshing operations are easily conducted: the latter are effected in two manners; by a kind of roller armed with knife-teeth, when the grain is intended for human consumption and exportation; the second consists in trampling it under the feet of oxen, where the excrements of the animals also mingle. Cotton is the most profitable product to cultivate: but it is very exhaustive, become none of it is ever restored to the soil: the fibre and the oil are not exhausting products, but the seed or cake, which contains the fertilizing soil elements, are also exported to other countries for cattle feeding. Mulberry trees could be grafted and so produce food for silkworms, while the vine could be made to yield fruit capitally suited for raisins, and hence meet the want now much felt in the manufacture of wine. Every domestic animal has degenerated in Egypt, save the ass, owing to want of adequate food, suitable care and healthful conditions. Green fodder is much needed in the warm weather, and trench-preserved food would admirably fill the void. Ordinarily, there is not more than one head of cattle for every 30 acres, while in farming districts, in other lands, one beast is estimated for 2 to 3 acres. The drawback is the taxation, which amounts to about one-fourth of the total revenue of the land: some holdings, and where the soil is of identical quality, pay four times higher taxation than the other. But this is the result of mal-administration.

M. Ladureau, Director of the Agronomical Station at Lille, has published his annual report on experiments with beet, to show that richness in sugar and relatively large-sized roots are not incompatible. These desiderata can be obtained by cultivating the plants at close distances, securing good seeds, and selecting appropriate manure, superphosphate of lime especially. These conditions fulfilled, the meteorological drawbacks can be counteracted. A question has been raised, whether the pulp, the result of extracting the juice by the now general process (in France) of *diffusion*, instead of the old practice of pressure, demands an increase of dry matter, such as hay, chaff, cut straws, &c. The pulp from the press contains but 70 or 75 per cent of water, while that from diffusion is as high as 88 or 90. The augmentation of hay, &c., ought then to be about 25 per cent.

M. Desprez, on his farm of Cappelle, near Lille, established a laboratory ostensibly to control the richness of the root cultivated on 250 acres, grown simply for seed. Some 2,000 to 3,000 analyses can be made daily, and the beet found richest in sugar is kept for seed; from 12 to 15 per cent of sugar is what is anticipated: roots yielding less are thrown aside. Indeed it is every day becoming more and more a certainty in beet culture that success depends chiefly on the quality of the seed. This secured, the roots ought to be purchased proportionate to their richness.

The French Government organizes and subsidises a series of regional agricultural shows annually; they are official and so have many drawbacks, one of the chief being the constitution of the juries. The number of jurors is five, being two, too many, and the jury that awards prizes to sheep does the same duty towards pigs and barn door fowls. In the case of black cattle, matters are still worse: the same jury awards prizes to several different races of stock. It is proposed to nominate jurors with a special knowledge of each class of animals exhibited. It would be well to exercise greater severity towards exhibitors who merely purchase stock to fatten and carry off a blue ribbon.

M. Lemoine has conducted a curious experiment to determine the ratio between the food consumed by barn-door fowls, and the quantity of manure produced. He enclosed a cock and six hens of the Dorking breed. A hen, it appears, consumes annually 374 lb. of food, of which it excretes 272 lb.: the remaining 102 lb. representing that serving for the sustenance of the body. The value of the manure was only one franc!

The phylloxera continues its ravages, and some vineyard-proprietors flatter themselves to have conquered the foe. The Government is certainly not niggardly in its grants to experiment on all agents reputed efficacious to destroy the scourge. A very complete history of the plague has appeared, replete with illustrations of the insect in all its stages: its mode of propagation, of attack, and of its ravages: healthy and diseased vines are so grouped that it is impossible even for a child not to take in the history of the calamity. The volume speaks to the eye, and must be invaluable wherever a vineyard exists, or natural history is taught.

PROFITABLE GOLD MINING IN AUSTRALIA.

Mr. Thomas Cornish, M.E., in the *Mining Journal*:—The late accounts of gold mining from Australia, whether in Victoria, New South Wales, Queensland, Tasmania, or New Zealand, are of a most encouraging nature, and tend to show the rapid progress the colonies are making in developing their resources, and the ample room there is for legitimate investment in gold mining with every prospect of profitable returns, and I can but think if capitalists and investors would but turn their attention to Australian gold mining investments they would be more certain of obtaining substantial results in the shape of good dividends than they are likely to get from other countries which appear to obtain their special favour. The colonies that have produced such an enormous amount of gold during the past 30 years, amounting to over £275,000,000, and the gold-fields which are still producing such excellent results, are worthy of more serious attention than has hitherto been paid them. The *Australasian* Insurance and Banking Record, of Nov. 10, 1881, gives the following as a portion of a list of dividend paying mines in Victoria :—

Name of Compauy.	District.	Capital paid up.	Dividends paid.
Long Tunnel ...	...Walhalla	£12,000	£786,000
Pleasant Creek Cross Reef	...Stawell	21,250	780,742
Garden Gully United	...Sandhurst	21,614	680,949
New North Clunes	...Clunes	37,008	487,734
*Band of Hope & Albion Consols ...	...Ballarat	449,000	413,640
Great Extended Hustlers	...Sandhurst	24,500	336,300
†Egerton	...Egerton	93,750	219,680
Great Extended Hustlers, No. 1 Tribute ...	...Sandhurst	4,200	194,600
Queen's Birthday ...	...Dunolly	6,750	186,750
United Hustlers & Redan	...Sandhurst	4,800	109,200
Extended Cross Reef	...Stawell	37,399	95,089
Clunes	...Clunes	30,000	109,438
John's Reef ...	...Sandhurst	69,300	130,199
Lazarus No. 1 ...	...Sandhurst	48,375	75,375
New Chum Consolidated	...Sandhurst	14,000	71,400
South Clunes ..	...Clunes	40,000	71,000
Ellesmere ...	...Sandhurst	14,616	73,850
North Old Chun ...	...Sandhurst	16,200	68,175
North Johnsou's ...	...Sandhurst	825	64,425
Old Chum ...	...Sandhurst	10,800	59,062
Lazarus Company ...	...Sandhurst	47,250	51,750
Ellenboro	...Sandhurst	15,300	51,300
Black Horse ...	...Egerton	12,750	62,250

There are many other companies not mentioned, such as the Port Philip and Clunes Companies, which have raised gold from their mines to the value of £1,625,529, and paid in dividends and royalty £366,166, as mentioned in the reports ending June 30, 1879.

PLANTING ENTERPRISE IN PROVINCE WELLESLEY: THE STEAM PLOUGH.

(From the *Straits Times*, March 18th.)

The steam plough has, it appears, been introduced into Province Wellesley by Mr. Daniel Logan, Solicitor-General for the Straits Settlements, and who is also, the *Pinang Gazette* says, an enterprizing and persevering agriculturist. The steam plough under notice is what is called the "Single Engine Set" and is manufactured by the well-known firm of Messrs. Fowler & Co., Leeds. The mode of working is as follows. To the plough (which is a four-furrowed one) is attached two steel ropes, one of which works direct into the back winding drum of the engine; the other crosses to the opposite side of the field and passes round a pulley fixed to a movable anchor, from there it runs at right angles passing through an ingeniously fixed anchor and then back again to the front winding drum on the engine. From this description, it will been that, when the engine is ready for work, the wire rope forms a triangle, of which the engine movable and stationary anchors are the corners.

The plough works between the engine and the movable anchor, and on its arrival at the latter, by a neat arrangement it is carried forward a distance of eight furrows, and likewise when it reaches the engine, it (the engine) being a traction one as well, moves forward the same distance. The work we had the pleasure of seeing performed was in every way satisfactory and much superior to what could have been done by the best Chinese coolies both as regards quality and quantity; it was done apparently at a moderate cost, and it was a pleasure to see the Lalang grass so ruthlessly torn up and exposed to the sun. During the day of ten working hours it finished the creditable area of nearly seven acres.

We will now place before our readers a rough estimate of the cost per mensem, as well as the cost per orlong, incurred by ploughing with steam; in all our calculations we take as our data that the plough can only work nine months during the year and twenty days per month.

Estimate of expenses of steam plough per month.

Depreciation on cost $6000 at 12 per cent, per annum...	$ 60.—
Interest 9	45.—
Engine Driver's wages	35.—
Coolies &c. &c.	36.—
Firewood at 800 pieces per day	120.—
Oil, Tallow, &c.	20.—
	$320.

20 days' work at 8 acres per day	160 acres
Cost per acre	$2.—
Cost per day	$16.

To do the same work per day it would take 200 Chinese coolies, and, calculating their wages at the lowest figure at 20 cents per day the cost would be forty dollars, or more than double what it cost by the steam plough.

Besides ploughing, the engine can be used for harrowing, pumping water for irrigation, and thrashing, if necessary.

We have considered and looked at the bright side of the question. As we have said every thing worked satisfactorily, the soil was dry and not over stiff, the weather favorable; but on a previous occasion, when we saw it at work, frequent stoppages had to be made owing to the plough sinking into soft soil: this might be remedied by constructing a lighter machine, but at the same time equally as strong; this is, however, a matter for the consideration of the manufacturers.

In addition to the steam ploughing machine above mentioned, Mr. L. C. Brown, of Glugor, has lately imported what is called the Lalang grass cutter, which is a machine intended to be worked with either a pair of bullocks or a single buffalo, but, judging from a trial recently made in a plantation at Balow, buffaloes would no doubt be more suitable for working the machine.

In a little under two hours, one orlong of thick Lalang was cleared, which was deemed exceedingly satisfactory. Owners of coconut plantations well know the difficulty and expense of keeping their plantations clear with cattle, now that disease is so rife; and, Indian labour being expensive and scarce, this machine is no doubt of great importance, seeing that it can be managed by three coolies and one buffalo, and, in a fair day's work, four to five orlongs could be cleared, although we understand that in several plantations some expense would first have to be incurred in levelling the ground and getting rid of the white ant nests, which are very numerous and so

bard as certainly to break the knives of the machine should they come in contact with any of the mounds. There is another use to which this machine may probably be put, *i. e.*, in gathering the paddy crops.

We understand that certain Chinese planters, who were present at Mr. Brown's trial of the cutter, were so satisfied with the result, that they have desired him to procure from England cutters for their respective estates.

The machine is a very light one and not at all expensive; the blade is so arranged that it mows about three feet at a time and continues its action as the animals drawing it walk along. The men required are a driver, a machine-guide, and another cooly to occasionally clear the blade when coming in contact with roots but two men would be enough after some practice.

FLYING FOXES AND MANGOES IN NORTH QUEENSLAND are thus noticed in the *Mackay Standard*:—Owing to the severe depredations of the flying foxes, the crop of mangoes is suffering greatly The fumes of sulphur have the effect of causing them to fall off their camps during the day time, and probably they would avoid orchards at night where a moderate amount of sulphur fumes are floating about. The experimont is worth a trial.

EARLY FLOWERING OF C. OFFICINALIS AND REMOVAL OF THE BLOSSOMS.—A correspondent writes:—I have noticed what you have said from time to time about *C. officinalis* dying out in the second and third year. I am glad to say that on this estate we do not suffer in that way. I have some 4½ to 5 years old quite healthy and strong and only trees in damp situations die off. We are troubled with our *C. officinalis* trees seeding in two years and even under; that is a proportion of them do so. I have cut off a great deal of flower and seed, and I believe the trees have improved since that was done.

PROGRESS IN JOHORE.—Mr. R. W. Fowke writes, under date March 9th.—"I am felling a share clearing for cacao. I have about 120 acres down, but it is not all cleared. My district is in the opposite direction to Pulai, and the highest poiut is only 300 feet above sea-level." My bungalow is about 30 feet above the sea, but the thermometer at half-past 5 in the morning frequently registers only 69 degrees. This, I suppose, you would consider low. I saw a letter in the *T. A.*, saying that the safest way of sending cacao seed was packed in sawdust. I have had two batches (the seeds out of 1,000 pods); both batches were complete failures. I found that the pods packed in shavings had the fewest percentage of bad ones."

CINCHONA IN JAVA.—"*Batavia, 1st Feb.*—From the official report on the Government chinchona culture in Java for the 4th quarter of 1881, we take the following:—In November a beginning was made with planting out, and the number of plants growing in the prepared ground was thereby increased by 65,220 Ledgerianas, 54,000 officinalis and 40,000 succirubras. These plants grew vigorously after rain had fallen. Formerly it was always noticed that chinchona trees in general, but especially the Ledgerianas, flowered abundantly after a regular long-continued dry season. The same circumstance also happened in the period under report. The trees originally planted are now almost all covered with blossoms, so that in October next abundance of seeds may be expected. As soon as the present wet weather admits of it, a beginning will be made with the partial peeling of the trees. The whole bark crop of 1881 amounted to fully 165,000 Amsterdam pounds. This quantity was despatched from Bandong in December last, in time to be sold by auction at Amsterdam in April next.—*Handesblad.*

LEDGERIANA SEEDLINGS AND A SNAIL ENEMY.—Some of the merchants in Colombo who went to expense and trouble to give a fair trial to the early packets of the "precious seed" from Java, have found to their disappointment that although nearly all the seed germinated, the young plants have been killed off. In one case, the seed was sown in boxes carefully attended to daily in the Fort office, and everything promised well until the dying down began. An examination with the microscope shewed a tiny spiral snail to be the enemy, and this experience is a warning to have the soil used for such purposes carefully selected and *baked* beforehand to kill off insect life.

THE EDIBILITY OF COIR ROPE has recently been proved. In lat. 43 N., long. 143 E., a boat containing the capt., his son and eleven men, the crew of a Japanese fishing vessel, was picked up by the "Abbie Carver." Their vessel had been blown out to sea and capsized in a storm, and they had been in the boat fifteen days when the "Abbie Carver" fell in with them. For ten days they had eaten nothing but coir rope boiled in salt water. When rescued the fishermen had a fire in their boat and a large pot on the fire with rope boilingi in it. The men were in an exhausted condition when taken on board the barque. Medicine and nourishment were administered to them, and they subsequently regained their strength.—*Madras Mail.*

CINCHONA PLANTS ON THE SIDE OF THE MAHAWILAGANGA.—A correspondent writes to us:—"In surveying the Mahavillaganga I have come upon three young cinchona plants growing together, below flood level I fear: I believe them to be robustas but am not sure. What will you advise me: to chance their removal into the jungle or leave them alone where they are. Being near the Bellihuloya, where lots of jungle is available, it would be interesting, I take it, to see if these plants would flourish and how grow at this elevation. I this is at all interesting, I will take the elevation &c." The fact is certainly interesting, and, if the plants can be taken up with masses of earth and placed beyond danger from floods, it would be interesting to watch their progress.

LOWER MASKELIYA, 19th March.—We had a nice blossom out on 15th and 16th, which seems to have set well. This is No. 3 (a small one end of January and small in February), and now we have a very fine one in spike, which only requires a few days like today and yesterday to bring it out. Seasonable weather now will give us a good crop this coming season There are a few estates that cannot give crop. They say it is grub. If so, why not catch the beetles now flying at about six o'clock every evening in millions? Those who do not believe that catching beetles does good, should go and see Forres estate. The portion said to have been most affected by grub is now the best coffee on the estate. No one now would believe that at one time it was, as described, the very worst in the district. Now I will defy any field of coffee in Ceylon to beat it, in appearance or show of spike. Unless seen, no one can form any idea of the numbers of beetles that come out of the ground. Watched from a road looking up a line of coffee it seems like a swarm of bees rising out of the soil in any patch affected by grub. Monday night's catch was 272 chundoes (3 to a measure). 550 to each chundoe gives 127,600 beetles. 6 cents a chundoe I pay; dear, but worth it. Maskeliya planters should all join in trying to reduce this plague, if we cannot destroy it. I have seen a good deal of cinchona in many districts, and I think our succirubra and hybrids can hold their own against all comers. Not to speak of St Andrew's Mahaudin Ledgerianas, which are worth gold, and, still more to the point, money also.

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE CULTIVATION AND LEAF DISEASE, BY A MYSORE PLANTER.

Dear Sir,—As one who has for many years devoted attention to the cultivation of coffee, I feel you will most obligingly permit me to join in the renewed friendly controversy about leaf-disease and to offer a few more remarks in support of my long-cherished opinion both as to the existence of special predisposing causes for the attacks of fungoid parasites and as to there being ways and means of raising trees from well-prepared and carefully-selected seed of hardy varieties, which will at any rate to a certain appreciable extent, have disease-resisting powers.

Having maintained in all my essays and letters during the last six years that constitutional debility, either hereditary or acquired, renders the plant more liable to disease, and that this susceptibility increases in a corresponding ratio to the persistence with which we continue either to propagate from a deteriorated stock or maintain a system of imperfect cultivation of the soil, or neglect to supply those constituents which frequent crops of coffee are known to remove from the land, I do not desire to escape from a just share of any censure which I may deserve for continuing to believe that all remedies must go into and affect the soil so as to strengthen and invigorate the constitution of the plants.

As you are aware, I have advanced a theory that *Hemileia Vastatrix* finds the best conditions for its development during the abnormal continuance of an otherwise transitory condition of the starchy and sugary constituents of the cell-sap, and I have ventured to assert on the authority of certain humble attempts at experimental observation, that a want of alkalies and phosphates in an available form, at certain seasons of the year in a soil in defective mechanical condition, is at least one of the principal causes of our troubles.

As fungi without exception present the peculiarity of never forming starch (Sach) I have concluded that it is probable fungoid parasites obtain their food in the most suitable form from such hosts as are temporarily (if I may be permitted the expression) either of a lymphatic temperament, or are unable to obtain a supply of some staminal principles in sufficient abundance for their requirements.

I am far from believing that our soils are suffering from absolute exhaustion, but I venture to think that each variety of plant of the same species undoubtedly possesses different powers of collecting from the land an adequate supply of inorganic plant-food necessary to maintain certain obscure functions in healthy activity. We know that healthy plants contain more alkalies than weak ones (Harman) and agricultural chemistry clearly points out that it is rather the condition than the quantity of the elements of plant-food which influences fertility.

I have carefully perused the able and elaborate report of the Government Cryptogamist, together with the interesting explanatory letter which appeared in your issue of the 13th December, and I feel that every planter is placed under the deepest obligations for the untiring zeal and ability which has been brought to bear on the investigation of the scourge, and for the courteous manner in which the arguments and suggestions of others, who have interested themselves in the matter, are dealt with.

Taking advantage of the encouragement offered, I am induced, although with the greatest diffidence, to venture a few remarks on certain points touched upon, in the explanatory letter above referred to, which having appeared in your columns, I presume may be considered debatable :—

"It should be remembered that the crop obtains its principal nutriment from the leaves just as does the fungus and unfortunately both take similar materials."

A most important consideration is involved in this observation. Although the plant and the fungus may require similar food-materials for their principal nutriment, still surely each can only utilize them under special favoring conditions. If this is not the case, there can be no further use for studying physiology.

The planters' prospects are indeed poor, if the only requirements of the fungus are a supply of healthy coffee cell-sap and little moisture.

Why was this not the case before?

We know that the ash of the coffee bean contains potash, lime, and magnesia, together with phosphoric and sulphuric acid, and we are taught that these constituents are required for certain physiological purposes in the economy of plant-life, and, although it were impossible to gain accurate information regarding the likes and dislikes of *Hemileia*, I entirely fail to comprehend why the investigation connected with the nutrition of plant-cells, even though it should require the "appliances only to be found in the well-equipped laboratories of Europe," should be for an instant considered as unworthy of peculiar attention, when making further research relative to the pest under notice.

The following extracts from Sach's Text-book on Botany explain what I mean :—

"The combinations of food-materials must be subject within the tissues to progressive changes of position in addition to and in consequence of their chemical transformations."—"The nutrition and growth of all plants hitherto examined for this purpose is impossible or abnormal if any of these elements are wanting."—"The constant occurrence of compounds of phosphoric acid in company with albuminoids as well as of potassium salts in organs containing starch and sugar, points towards definite relations which they may possess to those chemical processes that immediately precede the processes of construction in plants.

"Nobbe has recently shown that if plant-materials, otherwise complete, but possessing no potassium, are supplied to plants (as buckwheat) they behave as if they were absorbing only pure water instead of a solution of food-material. They do not assimilate and show no increase in weight because no starch can be found in the grains of chlorophyll without the assistance of potassium."

Professor Wortbington Smith on *Peronospera Infestans* says :—"I have got my most abundant materials from the tuber when soft and almost transparent like painters' size ; in this state the starch is utterly destroyed and what is more curious there is no offensive smell. The tuber frequently decomposes with a horrible fœtor and turns whitish inside ; the starch is then all present and not much injured and very little indeed can be seen of the fungus."

"Predisposition to infection implies that the tree must have undergone some profound in ernal change before it could be attacked * * * Healthy coffee is as easily infected as any other."

The analogy which exists between the life of a plant and that of a human being must of course be treated with caution ; but is nevertheless useful for explanatory purposes. The various works I have consulted lead me (however erroneously) to believe that the word *predisposition* as generally understood does not imply the absolute necessity for any such extreme condition ; but may simply mean either an acquired or hereditary fitness, liability or adaptation to admit of any change, affection or influence under certain favoring conditions, which, under ordinary circumstances, would have been insufficient to admit of a similar

effect. Thus we read in Harper's—"Physician's Vade Mecum:" "There are original and acquired differences between man and man consequent on the various and complicated influences to which the body is exposed in all states of society" and there are certainly analogous distinguishing peculiaritics among plants of the same species.

In the same manner, therefore, as in the human being, "a want of power to assimilate one or other of the staminal principles may often be traced to hereditary predisposition or to those causes which impair the general tone." (Harper). Is it unreasonable to suppose that certain obscure functions of the plant may be influenced by errors in cultivation, or by long-continued neglect of those precautions which are known to every horticulturist as calculated to prevent the gradual deterioration of stock?

"A residence in large towns tends to reduce the strength and vigour of the frame and *predisposes* to disease characterized by want of tone and power. Next to impurity of air as a cause of diminished health and vigour comes scanty and unwholesome food * * *. A diet not merely unequal to the wants of the frame but unsuitable to the age or destitute of some essential element of the growth of the body."

"The constitution may have been brought by the continued action of one or more causes into a state which shall cause the disease itself to assume a more or less severe form or even to depart in some respects from its usual characters and course." (Harper.)

I presume all will allow there are such things as deteriorated stock, hardy varieties, &c. My own experience of 19 years as a planter leads me to entertain the opinion that the benefits resulting from a change of seed and variety have only to be known to be properly appreciated. When we have to deal with ordinary well-conditioned coffee, much may be done to modify even a constitutional tendency to disease, and, as a proof of this, we have only to notice the superb improvement which follows even the holing operation in a field of very old coffee about to be entirely replanted, or the beneficial effects resulting from efficient digging, draining and mixing of the soil.

All these operations, however, can at the best only be regarded as measures calculated to give temporary success by assisting nature the more rapidly to give up to our trees the store of plant-food in our soil. Under any rational system of coffee cultivation the use of phospho-nitrogenous and alkaline manures must have special attention; otherwise sooner or later a want of tone or some other indication of decreased vitality will inevitably result.

Owing to the varying conditions of climate and the immense number of poorly-worked native estates, Mysore is peculiarly well suited for making accurate observations relative to the influence of culture generally.

Even the most casual inspection of one or two densely shaded native properties will at once dispel the idea that there is any chance of mechanically preventing infection.

I have had under my observation several large fields of apparently magnificent old coffee under which the new varieties have long since been successfully established. Leaf-disease annually attacked the old trees in September, but the plants below, although in a position to catch every spore that was shed from the umbrella above, generally remained perfectly free from disease.

If therefore plants which have been raised from a change of seed do not possess some peculiar disease-resisting power, it is indeed strange that among the thousands of plants under my careful observation it should be invariably found that every sheet of luxuriant coffee in September is composed of trees raised from carefully selected and imported seed, while every uninviting collection of plants attacked with *Hemileia* is found to belong to that variety which has been persistently propagated from old trees which have been growing in the same soil for the last 25 years.

It is quite true that even the hardiest varieties sometimes get slightly attacked later on in the season; but generally only during, or after, a heavy crop, or in places where there is either an undoubted want of manure or of some measures for mitigating those results which are clearly attributable to peculiarities of the mechanical or physical condition of the soil.

Under these circumstances, I fail to see why it should be either rash or unreasonable to infer that the hardier variety has certain disease-resisting powers, which are only placed in abeyance when the constitution of the plant is obviously suffering from debility; or to think that the older class of trees has susceptibilities which are more readily influenced by less perfectly understood causes.

Be it simple recuperative energy or actual disease-resisting power, it matters little, so long as the fact remains that one tree is virtually free from disease at the most critical period of its growth, while the other is unable to mature a crop owing to the immense loss of foliage.

If the experiment of growing coffee plants in "baked soil from England" was not calculated to weaken the constitution of those plants, on the leaves of which the fungus was successfully cultivated, planters, however reluctantly, must in the future believe that any sort of soil will do for coffee.

Personally I am led to take a most favorable view of the future of coffee cultivation and cannot for an instant bring myself to believe that *Hemileia* is an unconquerable enemy. Just as there are hardy and delicate varieties of garden plants and vegetables, so are there several different sorts of coffee which can be introduced without any very great difficulty. Each variety differs in appearance, habit and requirements. At the same season of the year, in close proximity to each other in the same soil, and subject to an identical system of culture, the representatives of one sort indulge in vigorous growth, while those of the other sort, although quite as healthy in appearance, are at a stand-still. Earlier or later on in the season, no such difference is noticeable.

This must certainly be the result of some peculiarity of constitution and doubtless disease-resisting power may be attributed to a similar cause.

It is well, while considering this subject, to carefully regard assimilation, growth and nutrition as distinct processes.

Experience clearly proves that hastily-grown ill-nourished plants possess the least disease-resisting power, and we may therefore often truly say that trees which are outwardly the picture of health are just as liable to attacks of fungoid disease as any others; but who shall be the judge as to whether constitutional vigour actually exists or not? It is surely reasonable to believe that, while assimilation, growth and nutrition proceed simultaneously, parasitic fungi have less favorable conditions afforded for developing in the living tissues of our trees. Visible lethargy frequently succeeds a period of excessive growth, and doubtless when a healthy-looking plant is suddenly attacked with disease it is during the period when vital activity is diminished.

The use of tonic and alterative manures would therefore appear to be clearly indicated, and although slowly acting preparations, which would neither force the plant nor fail to give it support at critical periods of its growth, are of paramount importance for use early in the season, still we must also keep in hand some rapidly acting agent for all cases of emergency. Each operation of culture must also be

arranged so as to help the plant to tide over that brief period during which leaf-disease does so much damage. Heavy pruning, which induces the rapid extension of immature succulent shoots, must assuredly be discontinued as calculated at least to cause subsequent debility. Although much mischief has been done by hacking and cutting the roots, still this should not prevent systematic root-pruning being regarded as an indispensable operation of culture, although one which, to perform properly, requires a little extra supervision. Having read the superb lecture recently delivered by Professor Pasteur on the wonderful influence of oxygen in maintaining "a mycelienne culture" of the minute organisms which are associated with anthracoid disease, and Professor Claude Bernard's graphic account of the destruction of the yeast fungus by the same agency, the idea suggests itself that it may yet be found that the oxygen evolved from the stomata of healthy leaves during the process of assimilation has at least some power of restraining the advance in the development of those vegetative processes of *Hemileia* which not being parasitic are comparatively harmless. Although, owing to my limited experience relative to the use of chemical manures, I am naturally desirous to express my views with the greatest possible diffidence, yet the humble experiments which I have already conducted have given me very great encouragement to continue my study of the effect of phosphonitrogenous and alkaline preparations in checking fungoid disease, and in conclusion I would venture to hope that, before my brother-planters agree to acknowledge *Hemileia* an unconquerable foe, they will at least try on a small scale some of the remedial measures indicated by me.

GRAHAM ANDERSON.

Barguai, Mysore, February 1882.

COFFEE: "NALKNAAD."

TO THE EDITOR OF THE "ASIAN,"

SIR,—Though, in the heading of your paper, only tea and indigo of planting industries are mentioned, I hope you will accept a letter about coffee, in which I will give some slight account of a new variety, which seems likely to produce a revolution in the planters' favour.

This variety is termed the "Nalknaad," having first been found in the district of Coorg. The leaf is broader, thicker and of a darker green than any coffee leaf I have seen, except that of the Liberian. The branches neither sweep upwards, like the Manzerabad variety, nor are they horizontal, as in that of Ceylon, but droop all round the stem like an umbrella. This gives each shrub the appearance of a small, softly-rounded billock, clothed with intense dark green: in spring covered by the bridal veil of blossom, and in autumn, like "the rowan tree," with berries red. This variety has hitherto resisted the leaf-disease, and been unhurt by the borer. In the opinion of those most qualified to judge, it has a stronger and more enduring vitality than any coffee we have as yet seen in India, and quality, perhaps, most valued by planters, yields from 25 to 30 per cent. more crop.

A new variety, however, it is not; very possibly, indeed probably, it is the oldest variety in India, but new to Europeans. The Arabs have traded with the Western Coast of India for thousands of years. Likely enough, long before the days when they brought the spices of Ind to the Queen of Sheba, and carried the gold of Devala to adorn the temple of Suliman Ben Daud. From their intercourse with the women of the Coast, a race called Moplahs has arisen. They are strict followers of the Prophet of the Sunni sect, and have much of the Arab in look and demeanour. These Moplahs to this day look upon, and talk of, Arabia as their proper land, much as men born in Australia still call England "Home." Now the legend in Coorg is:—In prehistoric ages some of these Moplahs, who had obtained Mocha coffee seed from the Arab sires, sowed it in the wilds of Nalknaad. For long years the Moplahs tried hard to keep this industry in their own hands. They told wild legends of the fearful death and doom which would descend on any attempting to interfere with it except true believers. Richter, in his history of Coorg, says:—"Its successful and profitable cultivation was at first concealed from the Coorgs But these were shrewd enough to find out for themselves that, whilst none of the fabled fatal consequences followed the cultivation of the shrub, there was a ready and lucrative sale for the produce."

When Stewart, Mann, &c., settled in Coorg about 1854-57, they introduced the Ceylon and Manzerabad seed, and the whole of Coorg—in European hands—was rapidly planted up with these varieties. For a time all went comparatively well, but about 1866 came the borer. This pest, often in a single season, left whole estates filled with nought but bare sticks, that might never bud nor blossom more. Then in 1871 the terrible *Hemileia Vastatrix*, or leaf-disease, attacked the plant in its lungs, weakening it till it could barely live a faded, feeble life, unable to ripen crop.

Over twenty years ago, at his residence in Mercara, Mr. Mann planted a garden, one acre in extent, with seedlings from Nalknaad. This one acre has continued to give crops of from ten to thirty cwt. to date. It now seems in full health and luxuriance, and all this time has never been, so to write, either sick or sorry. In 1867 a 64-acre block was planted on an estate called Pallikerry with seed from this garden. In 1872, Mr. James Chisholm, of Elk Hill, planted Hunchi Betta coffee estate with seedlings from the Pallikerry clearing. This estate—Hanchi Betta—the present writer has seen, and can speak to the fine appearance it has ever had, even to a superficial observer, while its crops have always been the highest in the district. When sold after the late Donald Stewart's death, it brought a price, I believe, unparalleled in India.

As Mr. Chisholm was the first to discern the superiority of this variety to all others, so he has been the most energetic in its cultivation. On writing to him for information he replies:—"Since 1874 I have planted nothing else, and have now over a thousand acres growing the same umbrella-shaped tree." He further writes, that the demand for this variety is yearly increasing, and that he has had enquirers from such out-of-the-way places as Fiji and Perak, as well as Ceylon, and all the planting districts of India.

I think the subject well deserves the attention of coffee planters everywhere. It may be that by this means the long unprofitable lane in which they have been walking since 1866 may find a turning, and the white blossom of the Nalknaad coffee be the silver lining of the cloud that has so persistently overshadowed them. I sincerely hope it may. For this end I write, and because I believe the *Asian* is more widely read in *all* the various coffee districts than any other paper, I write to you.

I am not, as I dare say you are aware, engaged myself in coffee cultivation, and may add, am neither directly nor indirectly interested in coffee, except as a beverage.

A. L. T.

Camp Kutempolli, 31st December 1881.

GERMINATION OF CINCHONA LEDGERIANA SEED: CALISAYA VERDE NO. I.

Igoor, Munzerabad, Mysore, 8th March 1882.

DEAR SIR,—Seeing the letter of "One who bought and was sold," in your February issue, I feel it is but

justice to Mr. Symons that I should state that I have recently put down some C. Ledgeriana seed that he was good enough to forward me, and that, although it was sown but 18 days since, it is germinating very freely, more so even than that supplied me of the best class of "Yarrow" seed. I am so pleased with it, from what I can see at present, that I intend to invest in some more of the same.

I think I noticed, in a recent *T. A.*, some remarks about the reason of silver skin in some instances adhering more firmly to the coffee bean than in others, and attributing its doing so to slow drying. In Mysore, the crop reason is a hot one, almost invariably free from rain, and our old hands (I have been at it here for the last 20 years) always dried their parchment thoroughly before despatching to coast for preparation; so much so that I have on several occasions been told by various curers that they like getting crop to prepare from this district, as it is generally fit to put almost at once into the peelers, and, I believe, it is a well-known fact that Mysore coffee is remarkable for the large amount of silver skin adhering to the bean. If our parchment coffee, after drying, becomes damp and is again dried, the silver skin becomes loose and is easily removed by trituration. I have, therefore, concluded from my experience that the quicker the parchment coffee is thoroughly dried after removal from the cisterns the less chance there is of silver skin peeling off.

In the *Planters' Gazette* of February 1st, it is stated that, "supposing that a large tree of Ledgeriana gives 300 lb. of bark, yielding 6 to 13 per cent of sulphate of quinine, a large tree of C. Verde of the same age would yield 600 lb., containing 5 to 9 per cent of sulphate of quinine, and thus give actually double the amount that the Ledgeriana does in the same time." From statistics of cinchona cultivation that I have been recently reading, and having no other experience of it, I had concluded that at most a few pounds of bark could be harvested from each tree, and am naturally much astonished all at once to hear that Ledgerianas give only about 300 lb. per tree. At that rate it would not require many acres of it to make a man's fortune, even though the market falls much below its present rate. Have any of your energetic Ceylon planters procured either C. Verde or C. Morada seed, and, if so, would they kindly give their neighbours a wriukle as to their success or otherwise and elevation at which they thrive?—I am, dear sir, yours truly, MAHSEER.

P.S.—I enclose my eard.

NO. II.

CINCHONA CALISAYA VERDE AND HYBRIDS.

Uva, March 7th 1882.

DEAR SIR,—The following is an extract from the columns of a local contemporary headed "From Our London Correspondent":—

It is difficult to credit all that has been said of late in certain periodicals at home, as to the marvellous yield of the latest new variety of cinchona, the *Calisaya Verde*, but however this may be, we are assured that there has been quite a scramble for a small parcel of the seeds imported by a London firm. The price was £10 per oz., and yet we are assured the importers had two offers for the whole lot, one from the Dutch Government and the other from a Mincing Lane firm. The price looks heavy at first sight, but considering that an ounce contains about 65,000 seeds, it does not really amount to very much after all. We learn that several little parcels of this seed will find their way to Ceylon.

In your own columns or elsewhere, I have seen it stated that trees of this variety of cinchona (Calisaya Verde) yield *each over a ton of wet bark* or from 500 lb. to 600 lb. *of dry bark from each tree*. Can you tell me, if such statements have been made on reliable authority, for, if so, we ought to know without loss of time more about this extraordinary variety of cinchona said to be exceedingly rich in quinine. One would like to know, for instance what amount of dry bark they would properly yield when 5, 7 or 10 years old, and the probable percentage of quinine at these ages. Whether or not the world comes to an end in fifteen years, one would certainly not care to invest in a plantation of trees, yielding *eventually* such prodigious results, if they did not come to some sort of maturity within a reasonable time. Surely, trees yielding 500 lb. to 600 lb. of dry bark *rich in quinine* must have been planted ages ago? If, however, they should turn out to be quick-growing trees, producing appreciable quantities of quinine at a comparatively early stage, then the sooner we take them into serious consideration the better. It would also be interesting to know at what elevation trees of this description have been grown.

Hybrids (C. robusta).—The information you have lately afforded your readers with respect to the great value of this variety of cinchona will doubtless be much appreciated. Quite recently, I have heard of purchasers of seed taken from C. robusta trees, 7 years old, growing in Maturata and now giving seed for the first time, the bark of which trees yield over 4 per cent of pure sulp. of quinine and 6½ per cent of total alkaloids, such seed being valued by the analyst at fully R10 per ounce. Seed from other C. robusta trees (which matured earlier) has shewn most favourable results, the consequence being that thousands are now growing on the estate where it is in contemplation to bark and uproot the succirubra trees, planting up in their place C. robu-ta, which, it is said, are faster growing and stronger than succirubra.

If any of your reader's experience in any way differs from the above, they would do the planting community a service by making known their facts. But there are hybrids and hybrids, but all are not necessarily C. robu-ta hybrids, nor are all C. robusta necessarily of equal value.—Yours truly, PLANTER.

[The followiug is Markham's reference to the "Calisaya verde;" but when he speaks of from 300 lb. to 1,000 lb of bark from single trees, whether wet or dry is not mentioned, he undoubtedly means old full-grown trees:—

Gironda and Martinez told me that there were three kinds of Calisaya trees; namely, the *Calisaya fina* (*C. Calisaya a vera*, Wedd), the *Calisaya morada* (*C. Bolivana* Wedd.), and the tall *Calisaya verde*. They added that the latter was a very large tree, without any red colour in the veins of the leaves, and generally growing far down the valleys, almost in the open plain. A tree of this variety yields six or seven quintals of bark, while the *Calisaya fina* only yields three or four quintals; and Gironda declared that he had seen one, in the province of Muñecas in Bolivia, which had yielded ten quintals of *tabla* or trunk-bark alone. —ED.]

INFORMATION ABOUT MANITOBA FROM MR. REA.

Lindula, March 10th, 1882.

SIR,—My attention has been directed to a letter in the *Observer* of the 28th ultimo, in which further information regarding Manitoba is required. I shall endeavour as briefly as possible to answer your correspondent's questions, and then offer some observations of my own on Manitoba and its advntages.

The winter in Manitoba is no doubt long snow setting in generally from the beginning of December, or even from the middle of Novembe and remaining on the ground till the mouth of March, when it rapidly disappears, and by the 1st April ploughing is general. Although the thermometer records a much greater degree of cold than in England yet the air

is so dry and bracing that little inconvenience is ever felt. Several men, whom I know in the old country, told me that, after an experience of two or three seasons, they preferred the winter of Canada to that of Great Britain.

So far from the winter being a dread, the Canadians seem proud of it, and have quite a round of visiting and amusement. Unless there is some chronic disease I am confident the climate of the North-west is the best that could be elected by one whose health had been undermined by a residence in the Tropics.

One man told me that, on arriving in Canada, he was not expected to live many weeks. "Now," he said, "I am as well and strong as anyone could be."

It is difficult to say whether a man going out with a capital of £300 could retire on a competency in 12 years. I can safely say many have been able to retire in that time on a competency. A man's success depends so much on himself; his shrewdness and energy. One man will become rich, when another man will starve. From what I have seen of Ceylon, I think the settler in Manitoba would be much better off for neighbours than here. In the one country he is surrounded by half-naked coolies; in the other by his own race, and tongue, who are invariably most kind, civil, and hospitable to a stranger. In my opinion no one should go to Manitoba who is not prepared to rough it for a year or two; after that it is plain sailing. I never met with anyone who could be induced to return to England to farm.

The *Chicago Tribune* U. S. paper, says:—"The wheatfield of the Great North-west of which Winnipeg is the key comprizes 200,000,000 acres which in full crop would yield 5,200,000,000 bushels of wheat, more than tenfold the greatest wheat crop ever raised by the whole United States. This reckons the average yield at 26 bushels. The average yield of barley is about 40 bushels, oats 5[illegible], potatoes 300. The Syndicate that is building the Canadian Pacific gets $25,000,000, and 25,000,000 acres of corn It will, when done, not only control the trans-continental carrying trade up north, but *dominate the wheat market of the world!* The road is being constructed, and its land department is already in receipt of thousands of applications for land. Winnipeg is at the confluence of the Red and Assinniboine Rivers. The Canadian Pacific will have its general offices there. The Northern Pacific, St. Paul, North Western, Burlington, and Rock Island roads will all eventually build into the world's great wheatfields. Mind may not conceive, nor fondest anticipations foreshadow the future of this magnificent country equal according to all accounts to four Utahs, supposing every acre of land in Utah to be equal to Colonel Winder's farm, or any of the farms bordering Salt Lake City or any of the land at Bountiful." To quote Lord Dufferin (no m an authority):—"Wherever I have gone, I have found numberless persons who came out without anything, and have since risen to competence and wealth. I have met no one who did not gladly acknowledge himself better off than on his first arrival: and amongst thousands of persons with whom I have been brought in contact no matter what their race or nationality, none seemed ever to regret that they had come here." To give a short sketch of the new railway route to Churchill Harbour on the side of Hudson's Bay, may also be interesting. It is understood to be the best harbour on the bay; is entered by a channel about half a mile wide and twelve fathoms deep. The east side affords admirable sites for wharves, etc.

How important this is, may be estimated from the fact that the distance between Churchill harbour and Liverpool is only 2,926 miles, while from Montreal via Cape Race it is 2,950 miles, and from New York, via Cape Clear 3,040 miles. This will furnish a seaport 1,500 miles nearer than Quebec to the centre of the North-West territory. Churchil Harbour is only 400 miles from the edge of the great Wheatfield. A line of railway of 30 miles. will connect this port with lake Winnipeg, and hence by navigation to Winnipeg city, or by a comparatively short wanch from the head of lake Winnipeg, it will connect with the railway system of the North-west Supposing there be only four months of open navigation in Hudson's Bay and Hundson's Straits; thiline is probably destined to become the most important, for its length, on the continent.

I ommitted to say that the Nelson Valley Railway and Transportation Companies have selected Churchill harbour as their point of junction between the railway and navigation.

A man with two or three grown-up sons, all determined to work, cannot fail to succeed in Manitoba. The following is the expense of starting a small farm:—

One yoke of oxen	... ...	$ 120·00
One waggon	... ...	80·00
Plough and harrow	... ...	25·00
Chains, axes and shovels	...	30·00
Stoves, bedsteads	... ...	60·00
House and stable	... ...	150·00
Provisions	... ...	135·00
Total	...	$ 600·00

A settler can get a grant of 160 acres of free land from Government. This, however, can only be done where land is not yet selected, either far to the west or removed from railway accommodation. I should recommend, rather than this, that he invests in good land, where railway and market facilities exist.

Plenty of such land can be obtained at from 20 to 40 shillings per acre.

The best houses for settlers are made by Wade & Co., Washington, St. Chicago, and are sent ready to put up. Two men will in four days put together a comfortable double wood house of four rooms with doors and windows complete. This will cost even with railway carriage less than the common log-house of the country. I should advise the settler immediately on arriving in Manitoba to go to Mr. Hespeler, or any other Government Agent, who will be glad to give every information to the new comer. But above all things, let him beware of the *confidence men* who are often to be found prowling about stations and too frequently rid the emigrant of his hard-earned cash.

In some cases, it is advantageous for the settler to place his money in a bank where he will get good interest and look about the country before he finally decides upon a locality, or he may engage him self to a farmer giving his services for his board, and pursued. thus become acquainted with the mode of operations

I need scarcely say that the settler must be careful to adapt himself to those methods of cultivation which experience has found to be the best rather than try to farm on a new country those practices which he has been accustomed to at home.

I shall only mention, as an instance, the necessity of a light and wide furrow in breaking up prairie land in June or July, and the hark setting in the fall of the year. Land thus prepared is ready for sowing in the following spring:—

The probable profits on a farm of 160 acres may thus be put down:—

160 acres of wheat at 25 bushels per acre and 75 cents per bushel	... ..	$ 3,000.
160 acres at $ 5 = $ 800 Ploughing and sowing ... $ 6 = $ 960 Harvesting and bringing to market ... $ 4 = $ 640	... ...	$ 2,400.
Profit	...	$ 600

with land free for ever.

The above figures are regularly paid by contract in working land and bringing the produce to markets. 75 cents is low; in October last, wheat was 90 cents per bushel. CHARLES REA.

P. S.—Since writing the above, I have had put into my hands your paper of yesterday, containing some very valuable information regarding Manitoba, and am glad to find that the views therein expressed are nearly identical with my own. I am happy to say I saw no signs of grumbling amongst the farmers in the autumn of last year. On the contrary, the crop was most prolific and the quality unsurpassed I also saw many excellent machines made in the Winnipeg factories. C. R.

HOW TO SELL CHINA TEA.

Kandy, 16th March 1882.

DEAR SIR,—I have taken the following advertisement from a recent number of *Chambers' Journal*:—"TEA Dealers can save money and obtain good sound teas by purchasing of the London and China tea Company. Chests, half-chests, Caddies, and packets. Prices, *duty paid*, 9½d and upwards. Circulars, Price List, and samples free, by addressing—O. D. STOTT, Manager, 8 George Street, Minories, E.C. F 3

Your will notice the very moderate cost at which sound (?) China tea can be bought. Why, the duty alone is almost double the cost of the tea.

It is an impossibility that these can be sound teas; but grocers no doubt find that, with the addition of a backbone, in the shape of a pure Indian or Ceylon tea, the mixture is saleable, and, as the profit is large, the system of mixing up our teas with rubbish of this sort will always find favor with a certain class of shopkeepers. It is satisfactory, however, to think of the probability of loss which the producer of those "sound" teas has incurred. Even a Chinaman could not do much manipulation and pay shipping and other charges for 3½d per pound COULD HE?

THE LARGE CINCHONA TREES ON GLENCAIRN, DIKOYA.

Glencairn, Dikoya, March 21st, 1882.

DEAR SIR,—Mr. Campbell appears to think there must be a discrepancy in the account given of dry bark as compared with wet. Perhaps it would explain matters if I mentioned that much of the wet bark was fully ⅛ of an inch thick.—Yours faithfully,

F. FOWKE.

CEYLON CLOVES AND OTHER NEW PRODUCTS FOR COFFEE LAND.

March 21st, 1882.

MY DEAR SIR,—A short time since, about a fortnight ago, I saw a sale of Ceylon cloves which quite topped the market, and ever since then I have felt somewhat curious to know where these were grown. Possibly, through the medium of your paper, the public might be informed, and more particulars of this agreeable surprise may be placed at the disposal of all. From what I can see in my travels, every plant which pays deserves a trial, especially in coffee land.—Yours truly, W. FORBES LAURIE.

[Mr. P. Moir has been written to, to say where the parcel of Ceylon cloves which sold so well, was produced.—ED.]

COFFEE ADULTERATION.

DEAR SIR,—Your London correspondent, in his letter of February 17th (appearing in the *Observer* of March 16th) asserts that it is a fact new to him that chicory is grown in England to any great extent. To shew that the growth of chicory as well as the adulteration of coffee has been flourishing (?) for considerably over *thirty* years, I send you an extract from *Household Words*, Saturday, April 12th 1851.

Extract referred to:—

Grocers wanted power, now, to sell chicory and coffee mixed. They got that inestimable privilege. Nobody could be sure, when he paid for "Mocha," that he was not paying for a mixture of two-thirds chicory. At once the British farmer bestirred himself; foreign chicory (taxed six-pence) was driven out of the market, and now the home crop is *a most important agricultural production*. Ceylon soon found itself, (like Frankenstein) bearded by its own monster "Protection." It was opposed by a rival at home worse than the foreigner against whom it was "Protected!" The feelings of the Ceylon coffee-growers, when they found their own "Protection" had driven us here, in England, to drink decoctions of home-grown chicory, must have been very like the disgust of Polyphemus's butcher when the monster took to dining off pine tops. Mr. Armitage, in forwarding the last of their memorials, says, that "even the most benighted of the colonists, are, at length, awakening to a conviction that any further clamour for protection is worse than useless," and that "many of the coffee planters are nearly ruined." The memorial complains that "chicory and other adulterated substances"—being "sold as coffee"—are "subject to no customs duty or excise, in Great Britain; while coffee itself is burdened with an import duty of nearly forty shillings per cwt. or one hundred per cent on its average value." The melancholy gentlemen wish no persecution of the "chicorian" sect: they are for fair toleration: free coffee; unadulterated coffee; or taxed chicory. At the words "other adulterating substances" the reader (who has just breakfasted on old "Mocha:" and perhaps, being of a fanciful turn, has been thinking of Mecca, with a distant view of a mosque) turns pale. But let his imagination carry him as far as it will in conjecture on the subject, it will fall far short of the realities. It is not enough that simple chicory should adulterate coffee; but even *that* must be villainously compounded, the adulterations itself being adulterated. Chicory begins but worse—that is to say, beans, corn, potato-flour; horse-chesnuts, acorns, dog-biscuit, rope yarn, Russian glue, brick-dust, mahogany saw dust, rotten coffin wood, soot, and "other manures"—remain behind. It reads like a bill of some Falstaff of tragedy—one halfpenny worth of coffee to this intolerable deal of adulteration! A competent authority tells us of cases which came under his special observations:—first, of a large quantity of beans—which decomposition had *animated* into an unfit state for feeding horses—being sold to a chicory grinder: and, secondly, of large quantities of "spent tan" (the refuse of tan yards) being systematically ground up to form part of these floating masses of commercial pollution. There lies on our table, as we write, a red powder, (red ochre) commonly used to 'colour" the floors of cottages: it is known that waggon loads of this have been seen discharged at the door of a well-known and extensive, "coffee manufacturer"!! Look at the summary of the results: The colonists complain; the shopkeepers become fraudulent and the poor suffer E.

COFFEE LEAF-DISEASE: CARBOLIC ACID AND MR. SCHROTTKY'S EXPERIMENTS.

DEAR SIR,—It is probable that the planters will be asked ere long to recognize in some substantial manner the services of Mr. Schrottky in his efforts to cure the leaf-disease, and, whenever they are so called upon, their general wish will be to do justice to whatsoever claims that gentleman may reasonably establish. Mr. Schrottky and his method have been before the planters now for a considerable time, and the experiments that have been carried out under Mr. Schrottky's own supervision and direction have been numerous and extensive. In some instances, a certain degree of success has been admitted; in others it has been altogether denied. There have been cases, in

fact, in which Mr. Schrottky's own treatment has been declared to have aggravated rather than abated the disease. In the present state of matters, any equitable decision is simply impossible. There are probably few planters who would altogether reject Mr. Schrottky's claims, but there are fewer still who would admit them, unless, perhaps, to some very limited extent, as a sort of compromise. How then shall the planters determine as to the fact of success or its measure, and adjust the balance fairly between the two parties? That is the question.

If fairly and scientifically treated, the question admits of an easy and conclusive answer. There is no doubt whatever as to the efficacy of carbolic acid as a powerful antiseptic. I suppose that there are few, if any, planters who have had the least doubt as to the fatal effect of carbolic acid on all living vegetable tissues. It may, therefore, be assumed without experiment or question that this agent, if applied to growing *hemileia* would destroy it. It is equally certain that it is capable of destroying growing coffee. The problem for solution, therefore, is so to apply carbolic acid as to kill the *hemileia* without materially hurting the coffee also!

Mr. Schrottky has certainly succeeded in applying carbolic acid in such measure and manner as to do no appreciable harm to the coffee; but it has yet to be shown that in these cases he killed the *hemileia*. He thinks that he did, but in nearly all the experiments he has tried, he certainly failed, and in a few only has partial success been claimed. In the most favourable case for Mr. Schrottky's claim, that of Gangapitiya, it is a matter of opinion, and the very judges themselves are doubtful. In fact, the question cannot be settled by any such experiments as have yet been publicly tried. The scientific procedure would be to submit *spores and growing hemileia* in the laboratory to acid of ascertained degrees of strength, and to test the vitality or otherwise of the mycelium and the spore by subsequent microscopic examinations. If mild fumes such as inflicted no injury on the coffee plants in the laboratory were found to have destroyed the vitality of the *hemileia or* its spore, both or either, then one important step in the inquiry will have been established. The only remaining question would then be as to whether the same treatment could be practically and economically carried out on a large scale in the field which had succeeded in the laboratory.

Up to this time, however, it does not appear that any one knows whether fumes of carbolic acid, mild enough to be harmless to coffee, would be fatal either to the *hemileia* or its spores. Until that question is settled the application of such fumes to hundreds of acres of coffee is simple folly, neither more nor less.

Carbolic acid in powder was one of the very first remedies tried for leaf-disease before Mr. Schrottky ever came to the country. It would be interesting to know why it was abandoned by the origiual experimenters. Was it found that even in strength sufficient to severely injure the coffee the *hemileia* spores came off scatheless? I rather think so.

You will remember that, when Mr. Morris tried his sulphur cure, his first step was to examine its effect on the spores and filaments, and the result was the discovery that the spores retained their vitality and the filaments only were killed. It was this effect on the filaments that inspired faith in his treatment and encouraged many planters to prosecute experiments on a large scale. And the last phase of the Morris sulphur and lime cure was that the application must be so timed as to kill the filaments. To kill the spores was proved impossible by any such means. We all now know that in fact the filaments had nothing to do with *hemileia* at all; and there was an end of the sulphur cure.

The tenacity of life in those low organisms is marvellous. I germinated *hemileia* spores after they had been subjected to fumes of sulphurous acid which would have killed the coffee, root and branch! I remember my old friend Thwaites putting some acari under his microscope after they had been immersed in spirits 50 per cent. over proof for many hours and they quietly walked away under his eyes! Likewise the germs and spores of some infusoria possess a vitality which is proof against conditions usually regarded as absolutely incompatible with life. I wonder whether Mr. Schrottky knows what strength of carbolic acid would kill a spore of *hemileia*, and what effect that same strength would have on coffee! But until that is definitively known, *nothing* whatever can be said to have been done effectually in regard to the cure of *hemileia* by carbolic acid fumes.

G. W.

P. S.—I thank you for directing my attention to Mr. Ward's last report and subsequent letter; and also to Mr. Storck's remarks; which I have read since writing the above letter. The highly dangerous nature of carbolic acid, as pointed out so forcibly by Mr. Ward, and the doubtful results of most of the experiments which have been made with this agent on a large scale, seem to confirm strongly my recommendation to study the treatment, and to work out the results to a definite issue, on a small scale, before attempting further extended application. Mark also that Mr. Ward actually *germinated* spores which had been for 24 hours subject to an "overpowering atmosphere" of carbolic acid, thus confirming the suspicion expressed in my letter to the same effect.

NEW PRODUCTS:—PATCHOULI; INFORMATION WANTED?

Maskeliya, 21st March 1882.

DEAR SIR,—I shall be much obliged if you, or any of your numerous correspondents, can give me some information about the cultivation and preparation of patchouli.

I procured a few small patchouli plants from Peradeniya about 18 months ago, and they are now shrubs from 18 ft to 22 ft in circumference, a mass of foliage, but with no sign of flower or fruit.

Is the scent extracted from the leaf, seed or root? How is it obtained? What is the market value of the produce? And what is supposed to be the yield of each bush or 100 bushes? Also, could it be grown at a profit in a wet district, elevation 3,000 ft?

Answers to any, or all, of these questions will greatly oblige.—Yours faithfully, W. T. M.K.

[All we can give is from the "Treasury of Botany" as follows:—

Pogostemon.—A rather numerous genus of *Labiatæ*, consisting of tall herbs found in various parts of tropical Asia, but principally in India and Ceylon. They have opposite stalked leaves, and flowers collected into dense clusters or whorls forming terminal interrupted spikes or close panicles. The flowers have an unequally five-toothed calyx; a somewhat two-lipped corolla, with the upper lip three-lobed and the lower entire and rather longer; and four nearly equal stamens longer than the corolla, and sometimes slightly bent downwards, the filaments usually covered with long hairs, and the anthers one-celled.

P. Patchouly affords the celebrated Patchouli perfume or Pucha-pat of the Hindoos. It is a shrubby herb about two feet high, a native of Sylhet, Penang, and Malacca; and has broadly egg-shaped stalked leaves between three and four inches in length, with the margins slightly lobed and round-toothed, and both terminal and axillary dense spikes of small whitish flowers tinged with purple. Although the odour of Patchouli is certainly peculiar, and even disagreeable to some people, it is highly popular not only in Europe but in India, where it is one of the commonest perfumes found in the bazaars. The odoriferous

part of the plant is the leaves and young tops, and by distillation these yield a volatile oil from which essence of Patchouli is prepared; sachets of Patchouli, however, are made of the coarsely-powdered leaves. Genuine Indian shawls and Indian ink were formerly distinguished by their odour of Patchouli, but since the perfume has become common in Europe the test does not hold good. Ill effects, such as loss of appetite and sleep, nervous attacks, &c, have been ascribed to the excessive employment of Patchouli as a perfume. [A.S.]—ED.]

"JAK" TREES AS SHADE FOR COFFEE; WIND BELTS AND LEAF-DISEASE.

24th March 1882.

DEAR SIR,—I hope some more experienced pen than mine will take up, *pro bono publico*, the question of the benefit jak trees afford to coffee, or any other cultivated thing beneath them.

Meanwhile I submit, with all deference, my opinion of this tree, viz., that it does far more harm than good on a coffee estate. Has any one known coffee bear heavily, or even fairly well, when under the influence of the artocarpaceous foliage? I have not. This I will say, that, where jaks are encouraged, coffee will fail.

Years ago I remember being struck with the luxuriant *foliage* of some coffee (Arabian) which was growing beneath these trees, but *crop* there was none. The constantly-falling leaves too choke up drains and litter the ground for a considerable space around.

As for the value of the timber in 20 years' time, that is as problematical, not to say ridiculous, as the belief that half our island's backbone will retire to the old country during 1882 millionaires. No! no!! Jak trees may be all very well for a year or two, and promise to do as much as the bubliest of bubble Companies, but after that period has become incorporated with the past, and their roots begin to know their way about, look out for your coffee near them, and wonder till doomsday, if you like, why it never bears and appears to be fading away.

It may seem ridiculous to say so, but, I take it, you require to sacrifice 10 acres for windbelts to secure to half that area of coffee immunity from wind.

Many think that leaf-disease may be shut out with the wind. Even if this be granted, will it pay?—Yours truly,

P. T. L.

CARBOLIC ACID AND THE COFFEE LEAF FUNGUS:—MR. SCHROTTKY'S EXPERIMENTS.

Colombo, 25th March 1882.

DEAR SIR,—Your esteemed correspondent "G. W." has overlooked the circumstance that all during November and December 1880 and the early part of 1881, I did very little beyond watching and observing in detail the effects of carbolic acid, used in various ways, in solution in water, as vapour, etc., upon the different forms of the fungus, both in the field and under the microscope, and that I recommended the use of this agent only after careful comparison with the effects on the fungus of nearly all other chemicals that I, as a chemist, could think of as *likely* to prove useful remedies against coffee leaf disease.—Yours faithfully,

EUGENE C. SCHROTTKY.

COCOA CULTIVATION IN CEYLON.

DEAR SIR,—No doubt whatever can exist in the mind of any one that cocoa will grow and grow profitably, in any well-selected locality in Ceylon. It has no very serious enemies to contend with, and what there are, appear only to attack it to any degree during the two first years of its growth, and as it gets up, their harmful influences decrease rather than extend. Throughout Ceylon there are several well aged cocoa trees all bearing largely, most of them averaging upwards of 100 pods to the tree. At Baddagama, in the Galle district, a few years ago, I saw trees said to have been planted by Mr. Winter forty years ago bearing heavily, and of great size and girth. On Pallakelly the oldest cocoa is reputed to bear at the rate of one ton an acre. In the Mudaliyar's garden at Kurunegala, there is an old tree which yields nearly an hundred pods yearly, and in other places at Kadugannawa, Saffragam, and in Haputale, without any special care, and, in some instances, where the coffee around it has become "all stem and sticks" and almost all gone out, the cocoa retains its vigour and goes on bearing. All these facts any one who chooses to travel and make inquiries can ascertain for himself. The one great objection in the eyes of many will be its slowness in coming into bearing. In the lowcountry for three years no crop can be expected, and in the fourth year it will only yield sufficient to pay expenses for that year's cultivation. After that, however, it will steadily yield paying crops, and will year by year increase in its yield probably up as far as say to the 10th year. As far as any experience goes in the North Western Province, I find that R50 per acre will pay all expenses of cultivation and upkeep, except what is necessary for securing the crop, and which should not, as far as I can calculate exceed R3 more per cwt. Thus, a crop of 5 cwt. the acre should be placed in Colombo at about R80 per acre and would at present prices realize R200, leaving a profit of R120 per acre, *i. e.* R12,000 for 100 acres—which is not a very sanguine expectation when compared with the bearing of the many matured trees before referred to. There will, however, always be great care necessary in selecting land for its growth; windy ridges must be avoided, and rich sandy loam above all other soils suits it best.

As far as our experience goes, we have been far more successful in growing it under shade, our best clearings being where the large trees and underwood have been removed leaving sparse shade of jungle from 20 to 30 feet high. The drip and roots of the larger forest trees are decidedly injurious and harm the young cocoa. The shade left would average about 20 feet apart at first, and we have found it better to supplement these by a few planted Halmalila jaks, to take the place of the irregular forest trees and forming the earlier shade. Planted thus we have found the cocoa grow stronger and faster than in open clearings, where its progress appears to be continually stopped by the heat of a wholly unshaded sun.

Next year we hope to have 250 acres yielding 4 cwt. the acre, and the following year's crop will no doubt very much exceed that. I have had no experience of what cocoa will do in old coffee, but from what I have seen in Doombera, where the soil is good, it certainly appears to thrive and carry out what Mr. Fraser says of it, "that cocoa will make the soil." The great drawback to its growth upon new land will always be the length of time before it comes into bearing. Yet with all those who can afford to wait, they certainly cannot do better than benefit by the first full crops secured by a plethora of plant food, which can only be found on new land. From the information adduced it would appear that, practically speaking, cocoa is a permanent tree, which would in no way fall off in its bearing qualities for sixty years at least. W.F.L.

[N. B.—We use the word "cocoa" instead of cacao and spell "coconut" without the "a" to distinguish the palm.—ED.]

CEYLON TEA IN LONDON.

33, Basinghall Street, LONDON, E.C., 3rd March 1882.

DEAR SIR,—The tea market is still very quiet, but the demand is better than it was. The following Ceylon tea

has been up in public sale since we last wrote, fetching fairly good prices:—

			s.	d.
Dunedin	24	half chests Pekoe Souchong	1	3¼
	12	do Brok. Pekoe	1	4½
Ruanwella	8	do Pekoe Souchong	1	2
	7	do Brok. Pekoe	1	2
M. R.	24	chests Pekoe Souchong	1	3¼
	1	half chest „ „	„	„
	18	do Brok. Pekoe	1	2
Sembawatte	10	do Pekoe Souchong	1	3¾
	6	do Brok. Pekoe	1	2½

The tea under the mark M. R., which sold so badly in December, has evidently been improved upon. There is, we hear, some Rookwood tea up next week, which will probably go cheaply, on account of the accident to the vessel bringing it home, although this has not, we hear, affected the quality of a large consignment of Indian tea by the same steamer,—Yours faithfully, HUTCHISON & Co.

REMEDY FOR SCORPION STINGS.—A very simple, but effectual, remedy for scorpion stings is to apply *heat* to the part affected. I have tried it for several years, and never on a single occasion found it to fail.—*Madras Mail.*

SCORPION STINGS.—With reference to a small extract from the *Madras Mail*, which appeared in our issue of the 22nd instant, we are reminded by an old correspondent that moistened quick lime, or *chunam*, as it is called in Ceylon, if applied at once, is a sovereign remedy for all stings including the sting of a scorpion, and the next best thing is a poultice of ipecacuanha. Of course this remedy does not apply to the stings or rather bites of snakes, in which case excision of the bitten part is all that can be done.

CHASERICULTURE is a new term used to describe the combined industries of tea and silk. It includes the planting, cultivation, and the manipulation of tea and the mulberry, and the rearing of the silkworm. "Cha" means the dry prepared leaves of the tea-plant; "seri" comes from sericum, silk; and the remaining word is obvious. Tea and silk are advantageously cultivated together, hence the compound term.—*Chemist and Druggist.* [Mr. WM. Cochran, brother of Mr. M. Cochran of Colombo has been advocating attention to these industries in New Zealand in a paper read before the Society of Arts from which we mean to extract.—ED.]

SALE OF CINCHONA BARK.—The Deputy Conservator of Forests, in charge of Cinchona Plantations, Neilgherris, in a report to the Conservator of Forests, dated 18th January last, says that the auction sale of cinchona bark took place on the 11th instant at Messrs. Oakes & Co.'s sale-room, Madras; the attendence was fair, and Messrs. Croysdale & Co., and Parry & Co., were the only purchasers. According to the list of prices realized, one hundred bales were sold for Rs. 16,106. The upset price of the above fixed in accordance with orders of Government being Rs. 15,106, there was a surplus of Rs. 592, considered as pure gain over the net sale proceeds, which the 100 bales would have fetched in the London market. The Deputy Conservator considers the experiment of a local sale satisfactory. He does not think there is any advantage gained by selling bark in the country; in fact the reverse. On the above report the Government passed the following order. Individual applications were being made to Government for the bark, and it was resolved to try a few auction sales with the object of developing a local demand, which private growers might supply. The present is the only sale that has yet taken place, and the net result shows more profit than if the bark had been sold at home. A couple more sales should be made in the course of a year, and the results published for the information of private dealers.—*Madras Times.*

THE SILK INDUSTRY in Bengal has for some time past been in a languishing state. The immediate cause is believed to be the degeneracy of the Bengal worm through want of care and cleanliness on the part of the native rearers. At one time silk producers and silk manufacturers prospered. The supply of "eggs" and the rearing of the worms till the cocoons are spun are left by the European manufacturers entirely to native enterprise. And from indolence and the desire to avoid any outlay that does not appear to be absolutely necessary, the native grower goes on annually rearing worms from seed that is degenerating.—*Madras Mail.*

FLEXIBLE IVORY.—Ivory, which in its normal state is so hard and rigid, can nevertheless be softened artificially by the following process:—It is to be first immersed in a solution of pure phosphoric acid of specific gravity 1·3 until it loses, or partially loses, its opacity, and becomes translucent. It is then washed in clean cold water, and dried, when it will be found as flexible as leather, but it speedily hardens on exposure to dry air. Dipping it in hot water will, however, soon restore its pliancy and softness. Another method consists in plugging the ivory into a mixture of three ounces of nitric acid and fifteen ounces of water, and leaving it to steep for three or four days, during which it soften.—*Home Paper.*

CALISAYA VERDE.—The seeds of some valuable new species or varieties of cinchona that have not, it seems, as yet been introduced to the Indian plantations, have recently been consigned to Messrs. Christy & Co. of Fenchurch St. These new forms are very rich in quinine. It is said that better results are to be obtained by cultivating the *calisaya verde* than the *calisaya fina*, because although the former yields only 6½ to 9 per cent. of pure sulphate of quinine, yet it yields twice the amount of bark as the *fina* or ledgeriana. The produce of the *calisaya verde* is equivalent to from 13 to 18 per cent of quinine. Moreover from the fact that the *calisaya verde* is a more vigorous tree than the delicate ledgeriana and will grow at a lower elevation, it is obvious that it can be cultivated to a much greater extent and may be extremely valuable for grafting the ledgeriana upon, more especially since the attempt to graft the ledgeriana on C. succirubra has proved unsuccessful.—*Nature.*

INDIAN STUDENTS OF AGRICULTURE AND LAW.—A resolution was passed in 1879 by the Government of Bengal for the establishment of agricultural scholarships for the benefit of natives, graduates of the University of Calcutta, at the Royal Agricultrural College, Cirencester. The first two scholars entered this college in January 1880, and are now making there a very successful career. These were Babu Ambika Charen Sen, M.A, and Syed Sekhawat Hosein, B.A. The *Indian Daily News* states that the two new students appointed by the Bengal Government to enter at Cirencester in January next are Baboos Brojobullub Dutt, M. A., and Greesh Chunder Bose, M. A. The former is the head master of the Sreebeur Bungshedhur School at Nawabgunge, and is the Gold Medallist of 1880 in Physical Science, and latter a lecturer on chemistry at the Cuttack College. An allowance of £200 a year—tenable for two and a half years—will be granted to each of these candidates, and an outfit allowance of 1,000rs. has also been sanctioned to each of them. Mr. Muncheerjee Dadabhoy Dadysett, a Parsee gentlemen from Bombay, late magistrate and sub-judge in Baroda, and now of the Middle Temple, who was awarded, in January 1881, the second prize, worth £25, in Common Law, was yesterday again awarded by the Council of Legal Education a further prize of £25 in Common Law. Mr. Dadysett is the first native of India who has twice succeeded in a competitive examination annually held by the four Inns of Court.—*Colonies and India.*

Rice.—The Bengal Government estimates the stocks of rice in and around Calcutta for the first week of March at 22,22,308 maunds, of which eleven and a half lakhs were available for export.—*Madras Times.*

The Shipments of Coffee from Venezuela to the United States in 1880 amounted to 44,415,994 pounds, against 28,676,541 pounds in 1879—an increase of nearly 55 per cent.—*Rio News.*

The Duties on Tea in the Australian Colonies vary from 3d per lb. in Victoria, New South Wales, and South Australia, to 4 l in Western Australia and New Zealand. and up to 6d in Queensland and Tasmania.

Conroy's Malt Coffee.—This preparation has been brought before the trade by Messrs. Evans, Sons & Co., of Liverpool, and the process of its manufacture has been devised by their well-known chemist, Mr. M. Conroy, F.C.S. It contains no ingredients except malt and coffee, and the former is certified by Mr. Edward Davies to contain malt diastase in an active form, that is we suppose, the malt has not been roasted with the coffee. The combination appears to be a happy one, as coffee is generally taken with starchy foods, the digestion of which, it may be expected, in this form, to aid. We can testify to the excellent flavour of coffee made from this compound, while the style in which it is put up for sale leaves nothing to be desired.—*Chemist and Druggist.*

Oleum Ricini Insipidum.—Pharmacists in no way justify their existence in the community better than by improvements in the preparation of useful medicines, rendering them less nauseous or more convenient for administration. By producing a tasteless and odourless castor oil Messrs. Allen & Hanburys may be congratulated on having achieved a really notable triumph of mind over matter. Their product certainly has no trace of odour, and it is as free from taste as pure olive or almond oil. It is rather difficult to exactly appreciate this fact, and it is probable that the present generation will hardly fully understand what has been done for them. Castor oil has an evil reputation clinging to it, which it is impossible for any of us to forget as we approach it. It is only necessary, however, now to dismiss all prejudice from the mind and a dose of castor oil need no longer inspire the dread which clusters round its name in every household.—*Chemist and Druggist.*

The "Clerihew" Process Applied to Hay and Straw.—A Correspondent of the London *Times* writes:—Two methods of artificially drying wet grass and corn are now before the public. By years of labour and heavy expenditure of capital Mr. W. A. Gibbs, of Gillwell-park, Chingford, Essex, has perfected his apparatus for instantaneously converting grass into hay, or as quickly drying grain in the straw, load by load, as fed into his hot-air machine, and finished in proper condition, open to inspection before being delivered upon the stack. And I believe that a Company of influential shareholders proposes to extend the use of these machines either by supplying them to hay and corn growers or by purchasing grass next summer and making it into first-quality hay undamaged by storms, which would be a profitable adventure in case of a rainy season. Lately, however, another system known as "stack-sucking" has been spoken of, in which the wet grass or corn is dealt with in bulk by its own fermentative heating in the stack, from which the excess of heat and vapour is drawn out by an exhaust fan. The mechanical apparatus is of two kinds, portable and fixed. The success of Mr. Gibbs's plan has been demonstrated on many farms. It remains to be shown on authoritative trial whether the other is safe, economical, and satisfactory in the condition of the hay or corn treated by it, and if so, which of the two systems may be offered with the greatest confidence to farmers.

The Cost of conveying Machinery to the Gold Mines in Southern India is thus noticed by the Nilgiri paper:—We know of one case in which, in addition to draught cattle, two elephants were employed at the rate of a hundred rupees a day to tug up some heavy machinery. The draught cattle and supervision cost as much again, and this expenditure of two hundred rupees a day continued for no less than seven weeks, when the machinery arrived at its destination on the trunk road. Such expenses as these, and such difficulties, have had to be incurred and encountered, and those who were not eye-witnesses cannot form any idea of the difficulties overcome.

Paper from Elephant Grass.—The Bally Paper Mills recently tried an experiment in paper-making from specimens of elephant grass received from the Chief Commissioner of British Burma. The specimens consisted of 144 bags of the grass, weighing 45 maunds, or 3,690lb. The grass had been collected by Mr. H. Buckle, Deputy Commissioner, Maoobin. The upper half had been cut off and thrown away, and the lower half crushed and washed in water and dried, undergoing in the process a loss in weight of 62 per cent. The dried grass, on receipt at the mills, was boiled in caustic soda at 20 per cent, and bleached with bleaching powder at cent per cent. The paper made was pronounced a fair sample for a first trial, though the colour, it was said, did not "come up particularly good." The stuff is described as easy of treatment. The authorities of the mills suggest that better results might be obtained by greater care in the production of the fibre.—*Pioneer.*

Wattles.—Some interesting facts in connection with the wattle bark question were elicited yesterday during the prosecution of the inquiries which are at present being instituted by the Tariff Commission relative to the leather industries. Mr. Frederick Wm. Reed, tanner, endorsed the evidence given on the previous day relative to the rapidly-decreasing supply of the necessary article, and suggested as a remedy the imposition of an export duty. Mr. Bosisto said that magnificent returns had been obtained on capital invested in wattle planting, and suggested that the tanners themselves should embark in the cultivation of the trees. He further observed that the Government of the day had taken immediate action on the report of the royal commission appointed to inquire into the question, and acres of trees were planted along the railway lines. Subsequent Governments had ignored the commission's suggestions, and wattles were becoming scarce. In the Geelong district the trees planted would be ready for barking in three years' time, and would yield the Government 100 per cent. on their outlay.—*Australasian.*

Improved Farming at Madras.—A very interesting experiment has been attracting attention at Madras. Some land had been thrown out of cultivation in consequence of the famine. This land was taken up by Mr. Sabapathy Mudaliyar, who determined to try the effect of deep ploughing, and manuring with Town Sewage, on the cotton and cholum crops, which are the ordinary staples of the district of Bellary, in which the experiment is being tried. The results were so effective, that the neighbouring ryots have been at once converted to Sabapathy Mudaliyar's mode of cultivation, and they have gone to him with orders for 300 ploughs of the same description as that he himself had been using. This is a repetition of what we have often found in Bengal, *viz.* that the ryot is wedded to his own systems, only so long as he thinks those systems will give the best and most profitable results. The Indian cultivator is by no means blind to his own interests, and if he can be convinced of the value of a change, experience has shown, both in Bengal, Madras, and Poona, that he is by no means slack to adopt that change.—*Indian Daily News.*

CALISAYA LEDGERIANA IN CEYLON.

We delayed the letter, given in another column, from Mr. North Christie, with the intention of embodying it in a comprehensive notice of the Ledgerianas, which we have not been able as yet to overtake. We, therefore, now publish Mr. Christie's interesting and important facts. As Mr. Christie, like ourselves and others, obtained his seed from the late Mr. McIvor, there can be no doubt now that the Neddiwuttum plants, in which Mr. Howard could not trace the characteristics of Ledgeriana, were yet true Ledgerianas, altered in character by adverse climatic conditions. The bark of the spindly bushes realized 12s 8d per lb. and seedlings from them, planted at a suitable elevation, have resulted in such extraordinary results as Mr. Christie sends us. It is important to see that seed in this case and in that of McIvor's hybrids has come true to type, for seedlings have the great merit of being rapidly and cheaply propagated. What the result of seeds from Mr. Christie's trees may be, we should be curious to see.

Our readers are already aware that Mr. Wm. Smith, of Mattakelle, obtained results equally good with those obtained from the Maskeliya plants. A second set of analyses have reached Mr. Smith, which give for

	Crystalized Quinine Sulphate.	*Crystalized Cinchonidine Sulphate.*

Mr. Smith, in sending us Dr. Paul's analyses, wrote :—

"I have got 12 more analyses from London by Dr. Paul, they range between 7·50 to 12·16 per cent sulphate of quinine. This is very gratifying, considering they were from trees rejected by Campbell and Fairlie. Taking the 30 samples which are now in Messrs. Howards' hands, this 12·16 per cent is the highest we have attained to, being from a strong robust tree without seed, which will afford a splendid lot of grafts."

It is now quite clear that *Calisaya Ledgeriana* has been established in Ceylon and that the bark is likely to give results equal to the average obtained in Java. The fact is of great importance to the future of our planting enterprise in connection with what we hope will be only the partial and temporary failure of the Arabian coffee enterprize. The grafting process has been here even more successful than in Java, as we have already mentioned.

CINCHONA CALISAYA LEDGERIANA IN CEYLON.

St. Andrew's, Maskeliya 23rd March 1882.

To the Editor of the Ceylon Observer.

Dear Sir,—The following analyses of Ledgeriana bark from this estate, made by Dr. B. H. Paul, of London, will be of interest to your readers :—

	Crystallized Quinine Sulphate.	Crystallized Cinchonidine sulphate.	Cinchonine (alkaloid.)
No. 1	11·55	1·04	trace.
,, 2	12·03	0·30	,,
,, 3	12·79	0·40	,,
,, 4	4·63	0·64	,,
,, 5	11·10	0·40	,,
,, 6	10·20	0·84	,,
,, 7	11·09	1·52	,,
,, 8	7·65	2·84	,,

Omitting No. 4, which was sent as a curiosity, it being from a solitary tree of peculiar type, which has never blossomed, the average of the samples is almost 11 per cent sulphate. As the trees were but five years and four months old, and never manured when the samples were taken, I think this result is second to none. Dr. Paul remarked about No 4 that it was remarkable for the redness of the bark compared to other Ledgers that he had examined and concluded (erroneously) that this redness must have been due to manure or soil. With a little care in selecting a good type of tree, I have no doubt that a Ledgeriana clearing would at six years of age, *average* 11 per cent. Next to Ledgers, though at a distance, follow hybrids, and from their robust habit they will doubtless oust the much abused ephemeric officinalis, for the growth of which Ceylon, as a rule, seems about as unsuited as Java. The analyses of two 4½ year old "hybrids" grown here are :—

No. 1 5·33 sulphate quinine.

No. 2 6·35 total alkaloids, 3·15 sulphate quinine.

In forwarding them, Mr. Symons said :—"No. 1 is very fine, and I venture to think it is a Ledgeriana, and of a very good type, as it contains but little of the inferior alkaloids, particularly cinchonidine. If the tree is seeding it is well worth taking care of and protecting from adjoining blossoms that might cause hybridization. Of course I cannot say positively that it is a Ledger but it gives all the appearance of being one, during analysis. No. 2, although good is quite a different species and contains a large quantity of other alkaloids."

The analyses of these trees are interesting because, as far as I know, they are the oldest hybrids, planted out as such, in the island and the only known progeny of a hybrid, yet analysed in Ceylon. They were grown from some of the seed from Mc Ivor's original hybrids, given to me by himself, and it is gratifying to see that with good hybrid seed the value of the parent tree is transmitted. At maturity No. 1, would, I think, show quite one per cent sulphate for every year of its age. But of some 2,000 trees raised from Mc Ivor's seed, there are very few exactly alike and this fact, together with their hardy habit and rapid growth, proves, I think, their hybrid origin, or rather that they are the result of the cross-fertilization of two varieties.

The opponents of the "hybrid" theory, in its technical sense, could hardly deny that a mongrel between a succirubra and an officinalis was just as possible as a mongrel between an English and an Indian sheep.—

Yours faithfully, THOS. NORTH CHRISTIE.

COFFEE ADULTERATION.

We call attention to the interesting and weighty letters on this subject in another column, That of Mr. Pasteur, the well-known London Broker, appeals more particularly to the home public, while "G. W.'s" review of the case is calculated to revive the local in-

torest of planters and merchants at a time when the fortunes of our staple are apparently at their lowest ebb. Surely in the face of the analyses now produced and of the evidence of further mischievous intermeddling on the part of the Lords of the Treasury with the legitimate trade in coffee, there will not be a single dissentient voice on this side of the water, to the claim preferred for redress. Shoulder to shoulder, the members of the Planters' Association and Chamber of Commerce ought to put forth their whole strength to make the appeal as forcible as is compatible with the respect they owe to the home authorities concerned. Ceylon far more than any other coffee-producing country perhaps, has suffered through the abominable and long-continued English adulterations. London is still the great depôt for our coffee, and if the home consumption had been a healthy one uninfluenced by mixtures and adulterations as is the case with tea, we may feel sure that our fine coffees would have been in greater request. The sooner the undeniable mischief of the present system is remedied the better: the immediate effect may be slight, but unless the English coffee trade is placed on a sound basis once for all, the decrease in consumption which has gone on for several years back will continue until only the most trifling quantity of the genuine bean is required for Great Britain. We trust the hands of Messrs. Pasteur, Dickson and other friends of Ceylon in this matter, will be heartily and unitedly supported henceforward by the local public until a grave injustice and a scandal to honest fair trade is removed.

COFFEE ADULTERATION AND MIXTURES.

To the Editor of the Ceylon Observer.

SIR,—It is satisfactory to see the energetic and effective manner in which this subject has been taken up by our enlightened friends at home. Their action contrasts strongly with that of the Committee of our local Chamber of Commerce, who did not think the matter of sufficient interest or importance to be referred to the members of the Chamber, but disposed of it themselves in a curious and disrepant style. Our good friends at home must not be left to fight the battle alone, however; for victory will not be easily or quickly won. The retailers are a large, powerful and unscrupulous body, who exercise a great influence at the poll. Ministers would be very chary of exciting their opposition or displeasure. Moreover, the profit gained by the substitution of spurious and worthless imitations which are sold in the name and often also *at the price* of genuine coffee, is far too large to be conceded without a desperate struggle. We ought, therefore, to buckle on our armour, and enter the lists in hearty support of those who have so vigorously espoused our cause and commenced the siege of the enemy's stronghold.

The existing law, as now administered, is entirely against us; and offers the greatest facilities and encouragement to the fraudulent dealer, who can palm off in the name of coffee any trash whatsoever, however worthless it may be, not only with impunity, but under the direct sanction of the law, provided only that the composition or substitute be labelled a "mixture," and contain a proportion, however insignificant, of genuine coffee. There are those amongst us who would have us believe the dealers are our *friends*, and that the mixtures they vend are intended to make our coffee palatable! These credulous persons contend that the consumers buy these mixtures by *preference*; that they could easily procure genuine coffee, but they prefer the dear and dirty stuff which the good-natured retailers substitute. We are asked to believe that the sale of our genuine, wholesome coffee is *promoted* by the well-meaning, kind procedure of those who cater for the British public; and that, if it were not for the ingenious devices by which it is commended to the palate of the people by association with horsebeans, lihngs, and such like toothsome articles, our coffee would fall into utter disrepute!

This argument, were if it worth answering at all, would be sufficiently refuted by a reference to the way in which the consumption of real coffee is proved to have declined in proportion as these practices prevailed. But, though the argument itself is utterly unworthy of any notice, and could only originate in ignorance or in the defence of fraud, the fact on which it rests its only claim to common-sense cannot remain uncontradicted but must be proved to be a great mistake. It is certainly true that the existing law provides for the supply of genuine coffee, and for the punishment of its fraudulent adulteration; but it is also true that the protection the law affords against fraud applies practically to only a very few persons, who do not need it; and is utterly unavailing to the million whom it should benefit. The fact is that customers of the higher class applying at the best shops for *coffee* would certainly be supplied with the genuine article, because, in that case, both vendor and vendee are aware of the penalty for a breach of the law, but the working man asks for *coffee*, and is supplied with substitutes more or less vile, at prices little, if at all, below the value of the genuine article. The fact is that the *million* do *not* receive genuine coffee even when they ask for it. They are supplied with a mixture *or* a substitute, either in bold defiance of the law, (what avails legal redress to a customer of this class whose dealings are in *ounces* and whose means are in *pence!*) without label or description; or under shelter of a precautionary *label*, perhaps in type too small to be noticed.

In inviting the attention of friends at home to this subject on my recent visit, I laid much stress on this aspect of our case; I begged them not to rest satisfied with the analyses of samples purchased by messengers of respectable appearance, or who might be suspected of an object. In order to ascertain what is regularly supplied to the million in the name of coffee, I pointed out the necessity for obtaining samples purchased by persons of that class, at the shops to which they resort. Acting on this principle, I obtained samples from London, Liverpool, Manchester, Sheffield, Chesterfield, Preston and other large towns; and our London friends also have obtained samples from London and its environs. In all these cases the purchasers were instructed to ask for *ground coffee*, and to accept, without question or remark, whatever should be given, and to pay the price demanded. And what was the result! Of 37 samples purchased as *coffee* by our London friends, *two* only were genuine! 18 were mixtures, and were so labelled for the protection of the vendors;—3 were labelled as specialities, but even these were not what they professed to be! They were adulterated substitutes! The remaining 14 were handed across the counter, without any attempt at disguise, in open defiance of the law, and proved to be mixtures in which the proportion of real coffee varied from 7 to 54 per cent! The rest of their constituents were chicory, linings, dates, dandelion and some other unrecognized substances. Such are the articles the working man receives from his purveyor when he *asks for coffee!* Such in practice is the operation of the law as regards the retail trade in coffee!

As regards the samples obtained from the towns in the country, 48 in number, a preliminary examination of about 20 proved them *all* to be mixtures. Not one of the 20 was genuine! Further examination and analysis was precluded, as my eyes would not

bear the strain of microscopic research. The samples will therefore be handed to the Planters' Association to be made such use of as they may deem proper.

Be it remembered that the samples above mentioned, those which were bought in London as well as those from the country, were supplied as *coffee*. They therefore represent what the million receive as coffee and accept as exponents of the *flavour* and *qualities* of the genuine article! The working man's taste and opinion of *coffee*, based on his experience of the stuff sold to him as such, is not likely to be very high! No wonder he complains that "coffee" does not agree with him. A gentleman who procured some of the samples for me, said that his workpeople had ceased to drink coffee, because it disagreed with them! No wonder that the genuine article, as so fraudulently substituted has fallen into disuse, and that the trade has become almost monopolized by *proposed* substitutes. The great bulk of the retail trade in coffee in the United Kingdom now consists of substances which do not even *profess* to be genuine coffee. They are advertized in flaming posters in almost every grocer's shop, as *French*, *Date*, *Dandelion*, or *pig* coffee, or as Pearson's, Branston's, Frank's and everybody else's coffee, except *Nature's* own. In all these substitutes the proportion of real coffee is only just so much as will serve to palm off the other constituents. The proportion which the trade in real coffee bears to that of its substitutes may be inferred from the fact that, at the great Food Exhibition in the Agricultural Hall in London last October, I could see only one poor plate of coffee beans with about half-a-pound of genuine coffee on it, though the counters groaned under piles and pyramids of canisters, with flash labels, representing many tons of substitutes and mixtures, all deriving such virtue as they possessed from the small admixture they contained of the article they so effectually supplant.

Let struggling coffee planters form their own opinion from the foregoing facts as to what is the practical effect of the existing law as regards coffee adulteration and mixture, and let them join hand and heart in the effort now on foot to obtain some amelioration of the present condition. The arguments set forth in the draft memorial, submitted to the P. A. last year, are substantially the same as those adduced by Mr. Pasteur and his energetic allies; and they are more than confirmed by the facts of the case, as recently ascertained. Let the planters exhume that draft, and amend it if they please; but let them not indulge the delusion, which led to the shelving of the movement last year, to wit: that the million in our country know the flavour and qualities of genuine coffee, and buy the substitutes with that knowledge in preference!—Yours faithfully,

G. W.

COFFEE ADULTERATION.

The following is Mr. H. Pasteur's second important letter on this subject:—

LONDON, 20th Feb. 1882.

The more the late order of the Treasury concerning the importation of coffee, chicory, and mixtures is considered, the more unfair and unjust the action of Government must appear, not only to those engaged in the coffee trade but to the general public. To state that coffee is one of the best and most useful of beverages, and that its use ought to be encouraged on economical as well as sanitary and moral grounds, is to repeat a truism It is esteemed as such, and its use encouraged in all countries, save one, and its consumption is steadily increasing everywhere except in Great Britain. In America the consumption is at the rate of over 8 lbs per head per annum; in Germany, with a duty of 2l. per cwt., it is 5 lb. per head; in France, with a duty of 60s per cwt., it is 4 lb. per head. In England it was nearly 2 lb. per head in 1847 with a duty of 36s per cwt., but now, with a duty of 14s per cwt. it is less than 1 lb. per head, and yet we import annually some 70,000 tons of coffee or five times the quantity consumed. The reason of the growing disfavour for the article is *solely* and *entirely* owing to the wholesale system of adulteration, which flourishes under the regulations permitting the sale of, and since the 20th January, the importation of *any kind* of stuff mixed in *any proportion* with coffee. That the regulations hitherto in force did not protect the revenue is amply proved by facts; the duty on coffee yielded £216,800 in 1879, £203,500 in 1880, and £199,600 in 1881; and the aggregate received in 1881 for duty on coffee and chicory is actually less by some £4,000 than the amount received in 1880. Do the Lords of the Treasury believe that, by extending the duty to other vegetable substances imported mixed with coffee and chicory, they will protect the revenue under that head? They might know, and they ought to know, that the result will be exactly the reverse; the public will leave off more and more drinking the wretched stuff which is sold to them under the name of, or coupled with the name of coffee, and they will take to beer and spirits instead.

But, setting aside the question of revenue, another aspect of the case appears to have entirely escaped the attention of their lordships. Is it just, or right or fair, that the name of coffee should be used as a sort of decoy? and that, by tacking to it some other name or epithet such as *chicory* or *French*, *Jersey*, *Date*, or *Tig* coffee, any kind of worthless or nasty substances should be allowed to be mixed with it for the sole object of getting a profit which could not be got, if those articles were sold under their proper name. The public are powerless to protect themselves against those practices although we are gravely told that the persons who infringe the regulations of the *Sale of Food and Drugs Act* render themselves liable to prosecution; the endless formalities required, and the expenses of analyses, &c., are such that the offending person is almost sure of immunity, or at the most, if prosecuted by the excise officers of a fine so light as to be a matter of perfect indifference to him.

The Government can scarcely disclaim any idea or intention of inviting adulteration by their recent action. If proclaiming to the world that henceforth permission is given to import *any kind of vegetable substances* mixed with coffee, *without any restriction as to the proportion of the mixture*, is not an invitation to adulterate, then words must have suddenly ceased to have the meaning they have always had before. In fact the foreigner is told:—"We allow you to mix any quantity you like of saw-dust, of acorns or roast carrots or cabbage stalks with coffee or chicory, and you may import them here; our customs officers will charge you a duty of 2d per lb.; but, as you will be infringing the Adulteration Acts our Board of Inland Revenue officers may then proceed against you or your agents, and levy fines for such infringement."

The Treasury allow the importation of stuff which they know to be spurious and of no value, and unsaleable here or anywhere else, except under a fictitious name. I repeat: is it right or just, or moral? Why countenance or allow the importation of those mixtures? What are the interests which appear to Government so worthy of being encouraged and protected at the expense of the British public and of all those eugaged in an important article of trade? It cannot be for the sake of placing within reach of the million a wholesome and pure beverage at a a reasonable price; for those wretched mixtures are sold at 1s per lb., whilst good pure coffee can be bought in the shops, roasted and ground, for 10d or 11d per lb.

We are told that mixtures and adulterations can be prepared here privately, without paying duty, on the

retailers own premises. This is had enough, but is it a reason why Government should open the door to the foreigner so as to double or treble the quantity of spurious stuff with which our towns and villages are already inundated? *Cheap* and *free* are two grand words applied to trade, but on condition that they are not supplemented by the words *nasty* and *adulterated*, which legislation, during the past thirty years, has done its best to tack on coffee.

H. PASTEUR,

38, Mincing Lane.

LONDON, 21st February 1882.

Result of analyses of samples of coffee purchased at various shops in and about London, February 1882, and submitted to Messrs. G. W. Wigner and R. H. Harland, Public Analysts, of 79 Great Tower Street, City.

N. B—In nearly every instance the article asked for was *coffee*.

Number of Sample.	Labelled.	Estimated percentage of Coffee.	Remarks.
1		52	Adulterant, chicory.
2		25	do. chicory and some so-called finings.
3	A mixture of chicory and coffee.	32	Adulterated with chicory and probably dates.
4	do	31	Adulterant, chicory and finings.
5	Specially prepared French coffee.	34	Adulterated with chicory and finings.
6	Taraxacum.	10	Dandelion and some chicory
7		26	Adulterated with chicory and finings.
8		21	Adulterated with chicory and dates.
9		12	Adulterated with chicory, dandelion and some dates.
10		37	Adulterated with chicory and finings.
11		10	Adulterated with 90 per cent. of chicory. [containing some dates.]
12	A mixture of chicory and coffee.	32	Adulterated with chicory,
13		100	Genuine coffee,
14	A mixture of coffee and chicory.	47	Adulterated with chicory and dates.
15	A mixture of coffee and chicory.	44	Adulterant, chicory and so called finings.
16		7	Adulterant mainly but not entirely chicory.
17	This compound contains no injurious ingredient.	57	Adulterant, chicory.
18	A mixture of coffee and chicory.	31	do. do.
19	A mixture of coffee and chicory.	41	do. do. and finings.
20	A mixture of coffee and chicory.	38	do. do. do.
21		36	do. do. and dandelion.
22		54	do. do. finings.
23	A mixture of coffee and chicory.	17	do. do. probably dandelion.
24	A mixture of coffee and chicory.	28	do. do. and finings.
25	Admixture in which no injurious ingredient has been used	14	do. do. at least 85 per cent.
26	A mixture of coffee and chicory.	37	do. do.
27		26	do. do. and finings.
28		100	Genuine coffee.
29	A mixture of coffee and chicory.	63	Adulterant, chicory.
30	A mixture of coffee and chicory.	50	do do. and probably dates.
31	A mixture in which no injurious ingredient has been used.	44	Adulterant, chicory.
32		23	do. do. and finings.
33		39	do. do. and so-called finings.
34	A mixture of coffee chicory.	10	Adulterant, chicory and large proportion of some other—probably dandelion.
35	A mixture of coffee and chicory.	10	Adulterant, chicory at least 90 per cent.
36	Date coffee.	57	Adulterants, roasted date and chicory.
37	Dandelion coffee.	none.	Dandelion root and probably some other substances.

The names and addresses of the vendors, represented in the above table by numbers, are in the possession of the Analysts.

H. PASTEUR, 38, Mincing Lane.

COFFEE ADULTERATION.

(From a London Correspondent.)

There is yet more to add this week to the subject to which so much space has of late been given in my letters, viz., the coffee adulteration question. As regards notices in the public press, they have been confined this week to *Colonies and India*, and, although aware that you received this paper and have probably seen the reference referred to, it may be as well just to quote it here before passing to my own experiences during the week relative to this matter. The paragraph runs thus :—

"Strong as is the case of the sugar-growers in the colonies and of sugar-refiners at home, the case of coffee-planters and coffee-consumers is, perhaps, even stronger in their protest against the new Treasury order, allowing rubbish of all kinds, so long as it is called "coffee," to be imported on paying the same duty as pure coffee. Hitherto an additional duty has been imposed on coffee mixed with chicory and on the pseudo-coffees which have lately come into prominence : but now the admission of coffee adulterated to any extent with chicory, beans, sawdust, or any other trash, is to be allowed on the same terms with the pure berry. Surely the interest of the authorities in the health of the people, if not in the welfare of the colonies, is great enough to lead to the abrogation of this most impolitic regulation. The admission of spurious articles of food should be placed under greater disabilities, instead of being made more easy than ever."

There is an error in the above paragraph relative to the duties on coffee and these mixtures being identical, the pure bean paying only 1½d per lb, while the latter are charged 2d. The difference, however, can in no way compensate for the disadvantage of coffee being exposed to competition with valueless compounds. During an interview with Mr. Thomas Dickson this present week, he informed me that a petition for consideration of this question has been signed by 130 of the leading brokers and others concerned in the coffee trade. It was intended to have sent this to a certain Government Department, and to have sought an interview with its head by a deputation, but it became known to those interested that that head is largely interested in a concern by which a certain mixture is manufactured in Jersey. It was, therefore, thought to be impolitic to present the petition in such a quarter, and it has therefore been forwarded to the Treasury. What its fate will be there it is impossible to say, but, as Mr. Dickson has secured the promise of co-operation

from a considerable number of members of Parliament, and has also been assured of the sympathetic action of all the leading Chambers of Commerce in the North, it may reasonably be hoped that this petition will not be burked. To the letter addressed by Mr. Dickson to Lord Cairns, he has received no reply. This cannot but be considered discourteous, but it is thought that his lordship probably considers that coffee adulteration and fiscal arrangements properly come only under the jurisdiction of the House of Commons, and that on that ground he deems it wiser not to commit himself to the expression of any opinion. Mr. H. Pasteur, of Mincing Lane, has issued a further notice concerning the late Treasury order, and you will find it enclosed. It reviews the facts of the case with much strength and clearness, and you will probably like to reprint it in full. You will also receive with this the result published by Mr. Pasteur of the analyses of 37 samples of coffee purchased at various shops in and about London. Of these, as you will perceive, only two were genuine coffee, the adulteration of the others varying from 32 to 90 per cent! One instance, indeed, exceeds even those figurese, the sample containing no coffee at all, but then it was sold as "Dandelion Coffee"!

Passing along the Strand this week, an announcement in the East India and Colonial Tea Agency's window struck my eye. It was simply a placard announcing "Ceylon Tea, 2s 9d per lb." Now, as very recently the same window announced Ceylon tea at 2s 3d per lb., it is evident that it is rising in public favour, and its sale extending. A tremendous future (this is not too superlative an expression) lies before Ceylon tea.

COFFEE ADULTERATION IN ENGLAND.

An interesting and most important document relating to the consumption of coffee in the United Kingdom has recently been issued by Mr. H. Pasteur, of Mincing-lane. It appears that in 1847 and 1848 duty was paid upon over 37,000,000 lb. of coffee for home consumption, and that, during the past year, with an increase of population on 1848 of at least 10,000,000, the home consumption of coffee was just under 32,000,000 lb. There can be no doubt that the consumption of "coffee" (the inverted commas are very necessary) is much more general now than it was in 1848, and that the consumption of genuine coffee has fallen off to the extent of 5,000,000 lb. is a startling fact which every purchaser of coffee should take to heart. The consumption of spurious coffee is likely to increase still more, for a Treasury Minute was issued, on January 20th, 1882, directing Her Majesty's Board of Customs to permit the importation under a duty of 2d. per lb. of "coffee, chicory, or any other vegetable mattter applicable to the uses of coffee or chicory, roasted or ground, mixed without reference to the proportions of the mixture." Those who like to know what they are buying will do well to buy their coffee whole and raw, and to roast it and grind it for themselves. Coffee contains an alkaloid, *caffeine*, and certain aromatic principles which gave to it its stimulating and pleasant qualities, and the larger or smaller proportions of which in the various samples imported determine the market value. It certainly seems odd, to use the mildest term, that the importation of chicory, turnips, carrots, cabbage-stalks, and various other vegetable rubbish which our continental neighbours choose to roast and send to us, should be encouraged by the Government, to the detriment of the dietaries of the masses, and the business of colonial merchants who have a soul above vegetable refuse. It seems little short of disgraceful that the fine coffee of Ceylon should find a readier market on the Continent than in the parent country, the good people of which are about to turn (as some appear to think), from the drinking of adulterated alcohols to the consumption of still worse adulterated "coffee." One well-known firm that deals in coffee incites the British public by its advertisements to "call a spade a spade"—a wholesome doctrine, and we trust it will soon be penal to apply the name of coffee to anything but the genuine article; for it is not well that the public should pay 1s. 4d. or 1s 6d. per lb. for materials which are dear at a quarter of that price. We have heard much in times past of a "free breakfast table"; we hope soon that it may become an unadulterated breakfast table, and that those who have a fancy for drinking decoctions of strange things will be able to do so without the expense of having the name of coffee given to whatever may happen to be able to impart to boiling water a brownish colour and a bitter taste.—*Lancet.*

THE AGRICULTURAL INDUSTRY IN BRAZIL.

We now quote the whole of the document alluded to as mentioning "the plague" in coffee. It is a remarkably outspoken paper, and, although its authors look to Government for a central sugar mill, as well as roads and instructions, they yet deplore the want of private enterprise and the selfishness of the wealthy classes. Neither do they spare the free population for leaving most of the production to slave labour. The picture drawn of the state of a society where the slave population considerably outnumbers the free is not flattering, and to those interested in the future of Brazil not reassuring:—

In an extra session of the Municipal Council of Santa Maria Magdalena, the following address to the president of the province of Rio de Janeiro was adopted:—

SIR,—In compliance with the orders of Your Excellency in the official letters of the 21st of last month and of the 11th of the current month, in which you ask for information regarding the state of agriculture, stock-farming, silk and bee-culture in this municipality, the Municipal Council have to say as follows:—

The lands of this municipality are in general extremely fertile and are suited to a great variety of products, such as coffee, cereals, sugarcane, tobacco, grapes, cotton, mulberry, potatoes, rice, mandioca, etc. The only article of export from the municipality, however, is coffee. The production of corns, beans and sugar is scarcely sufficient for home consumption, and already there has commenced a considerable importation of sugar, rice, tobacco and rum.

The cultivation for export in the municipality is therefore limited to coffee, and this cultivation is carried on in the rudimentary routine system which leaves much to be desired both as to the quality of the product and the quantity produced in relation to the population.

The number of slaves in the municipality being 13,010, and supposing that only 10,000 are employed in the cultivation of coffee, there might be produced, giving an average of 150 arrobas for each laborer, 1,500,000 arrobas; the exportation is however only 900,000 to 1,000,000 arrobas. The free inhabitants, numbering 10,366, might very well produce, if nothing else, the articles of home consumption, as we have no other industry, no important trade, nor mechanic arts.

The planters whose profits can be calculated at more than 10 per cent. are rare, and these live on exceptionally good lands and consume but little. In general the planters obtain from 8 per cent. downward. It may be added that a terrible disease, called

the plague, is progressively destroying the coffee trees and is assuming alarming proportions without the cause of the evil or the means of combating it being discovered.

As the municipality has excellent lands for sugarcane, it would seem to be of great advantage for the Government to encourage the planters, where the coffee trees are being destroyed by the plague, to plant cane by giving an interest guarantee for the establishment of one or more central sugar mills. With 100,000$000 there might be established a mill with American machinery with a capacity of 400 arrobas per day, since the Figueira mill in Campos, belonging to Jose Pereira Pinto, with a capacity of 200 arrobas per day, cost 50,000$.

It would also be advantageous for the Government to encourage the planters by means of diplomas and money prizes, to establish free labour and to give attention to the cultivation of cereals and stock-breeding, especially the breeding of swine, independent of coffee and cane. By reducing to the lowest possible figure the railway freights on these products, the Government could also contribute in favor of the division of labor.

There are many obstacles to the development of agriculture in the municipality which, although due to various causes, may be summed up in two principal ones: lack of roads and schools.

With the exception of two kilometers of the Barao de Araruama railroad belonging to a private Company there are no railroads in the municipality. We have not even waggon roads which will enable us to abandon the pack mule, "our best vehicle." This lack, which in a rich municipality can only be endured through ignorance or extreme resignation, prevents our varying products or attempting a division of labor which must be our means of obtaining the maximum production and perfection of agriculture, and which might lessen for some years to come the lack of laborers that is already beginning to be felt.

Roads are a prime and inherent necessity in a mountainous and eminently agricultural municipality such as this. Your Excellency will pardon the frankness, born of the confidence that the good judgment of the president of the province inspires in the municipal council, with which we say that the attention of the Government has not yet been awakened to the roads of this municipality The same may be said of our people who appear to ignore the fact that private enterprise is an indispensable factor in the prosperity of any country.

No one knows better than Your Excellency that the people must have instruction in order to understand their duty as citizens and to labor best in the interest of Society and in their own private interest.

Our capitalists although possessing about 8,000,000$000 of available funds prefer investment in 6 per cent. government bonds, to embarking their capital in industrial enterprises, and thus the spirit of association, which might contribute powerfully to the development of the industries of the municipality, remains unproductive.

The stock-raising industry is here very backward and of limited proportions. The cattle are neither good for work, milk, nor beef. All the *carne secca* consumed, and the quantity is not small, is imported; and for the last six years the price has varied between 6 and 9 milreis. Butter-making is almost unknown, and the small quantity of cheese that is made is of poor quality and not readily salable.

Only a few amateurs, and these rare, have attempted to breed a horse or so, of a badly made and degenerate race. Perhaps this neglect of horse-breeding is due to our bad roads for which mules are more suitable.

Sheep-breeding is almost unknown. The few sheep that we have are of very ordinary stock and only serve as food for invalids, the wool and hide being thrown away.

Bee-culture is only carried on by a few for their own use, and silkworm-breeding is entirely unknown in the municipality.

Our best public establishment, although it has not the necessary accommodation, is the municipal hall. The churches of this village and of São Sebastião do Alto are in ruins, although this last has been somewhat improved at the expense of the parishioners. The few schools that we possess are in houses without sufficient accommodation and without furniture. There is no benevolent institution in the whole municipality. A small jail is being constructed in São Sebastião do Alto: the jail of this village is intolerable.

Such is the state of this municipality, its agriculture and industries, its drawbacks and its most pressing needs.

Santa Maria Magdalena, Nov. 23rd, 1881.

INDIAN TEA DISTRICTS ASSOCIATION.

The annual meeting of this Association was held at the offices, 14 St. Mary Axe, on Feb. 22, Sir Douglas Forsyth, K. C. S. I., C. B., president of the Association, in the chair. There was a good attendance of members, including Col. R. H. Keatinge, V. C., vice-chairman; Mr. H. Wimshurst, of the Assam Company; Mr. W. Roberts, Mr. Burkinyoung, Mr. Parke Pittar, and Mr. Sangster, of the Jorehaut Company; Mr. Carpmael, Noakacharee Company; Mr. R. Lyell, of Messrs. George Williamson & Co., representing the Borelli, Dejoo, Luckimpore, and Mungledye Companies; Mr. D. H. Sefton, of the Land Mortgage Bank of India; Mr. A Lawrie, of Messrs. Alex. Lawrie & Co,; Mr. J. H. Williamson, of Messrs. Williamson, Magor & Co.., Calcutta; Mr. Samuel Ward, of the Lebong Company; Col. Probyn; Mr. George Seton, of Messsr. Octavius Steel & Co. &c. The notice convening the meeting having been read by the Secretary, the Chairman briefly introduced the report. Commenting on the law relating to the inland emigration of labour to the tea districts, the speaker congratulated the meeting upon the result of the labours of the Commissiou appointed to inquire into the matter—viz., the passing of the Inland Emigration Act (1882), on January 5th. He thought that this Act would promote the interests both of employers and labourers, although it had been unfavourably criticised by the native population of Calcutta. The Chairman said that, by a minute of the Goveruor-General referriug to the Act as a whole, the Governmeut of India observed that it was of neccssity a measure intended to meet a transitional state of affairs. The maiu reason for maiutaining at this date a special law was that communications between most of the labour districts and the rest of Iudia were still imperfect. The improvement of commuuication with Assam was engaging the earnest attention of the Government, and, with the gradual attainment of this object, it was hoped that it might become practicable to leave both the employers and the employed to settle their relations in all cases under the ordinary law, as they do in other parts of British India. Steps might be taken under the fourth section of the Act leading to this result. Local Governments are empowered, with the previous sanction of the Governor-General in Council, to declare that any labour district within their respective territories shall cease to be subject to all the provisions, or any specified provisions of the Act. The successful introduction of a system of free emigration will fulfil the wish of the Go-

vernment of India to gradually withdraw the application of a special law. The next thing noteworthy in the report was the establishment of an Indian Tea Association at Calcutta. This was advocated in the first instance by the Home Association. It was working on the same basis, and therefore should meet with approbation. Referring to the general state of the affars of the Association, the Chairman said he had much pleasure in informing them that they were in a good position. Last year one of the members proposed some form of protection for Indian tea in its competition with that of China; but he believed that the time was not far distant when the popularity of Indian tea would render all movements of this kind unnecessary. He congratulated the meeting on the improved tone of the tea markets of late. With reference to the great injury done to tea by exposing and bulking it at the Custom House, the Chairman said that this had been, and still was, a subject of discussion, and a very important one. Memorials asking for some reform had been frequently sent to the Commissioners of Customs, but hitherto without success. He hoped, however, that they would eventually obtain redress. He thought that it was a very difficult matter to procure boxes of a uniform weight, as in most of the tea districts, the wood was difficult to deal with. The report of the meeting having been seconded by Col. Keating, it was unanimously adopted. Mr. Sangster remarked that he advocated the same policy he had pursued at the last meeting of the Association—namely, to have the duty on Indian tea reduced to 3d. per pound. He thought also that it would be advisable to give reports of the meeting to suburban grocers, and push trade with them. He was of opinion that Indian tea ought to be represented at the International Exhibition in Melbourne. He suggested also that some reduction might be made in the cost of the making of Indian tea, as the present rate was too high. Mr. Sangster said that he had received a letter from Mr. McIver, the member for Birkenhead, who would give his assistance in Parliament on the duty question at a favourable opportunity, as the subject was one which had long occupied his attention. The Chairman said that it would be a very useful thing to get a protective duty of 3d, but he could see no prospect of that object being attained. Referring to the proposed American agency for India tea, he reminded the meeting that the Calcutta Syndicate was established for the purpose of creating a trade with Australia and America, and he thought its operations would be successful. A discussion then arose on the advisability of leaving the question of Parliamentary efforts to a working committee. Messrs. C. Sanderson, Octavius Steele, and P. R. Buchanan were unanimously elected members of the general committee, and the meeting separated after giving a vote of thanks to Sir Douglas Forsyth for presiding.—*Overland Mail*, March 3rd.

BRAZIL COFFEE PROSPECTS.

An error in our last issue made us say that the aggregate stocks of coffee in the principal ports of Europe on the 1st of January last were "over twice the normal export there from Brazil." We should have said *nearly* twice the normal export. Although the average export during the last eight years has been 1,235,230 bags, the normal export has been between one million and eleven hundred thousand bags. The extraordinary large shipments for 1881—1,905,241 bags—which was due to speculative influences rather than to any actual demand, increased the average for the eight years since 1874 to over twelve hundred thousand bags. Our purpose was to show the enormous accumulation of coffee in those ports which has not yet entered the market for consumption, and which represents nearly twice the normal export there from this country. Some of this coffee has been held for two years, and now represents an enormous loss. It is reasonable to presume that these stocks can not be held much longer for a better market, because the stocks already accumulated and the constantly increasing production all tend to keep prices at the minimum—even at rates lower than those now ruling. These accumulated stocks in Europe represent about five months' consumption there, and if thrown upon the market early this year, as they undoubtedly will be, they will cause a heavy decline in imports. More than that, they represent an aggregate loss which can not fail to cause widespread disaster in the trade, of which Brazil must unavoidably bear no small share. We do not expect ministers of finance to take any account of these ominous facts, but merchants and planters will do well to take them into thoughtful consideration.—*Rio News.*

COFFEE AND SUGAR IN BARZIL.

The official value of the exports of Rio de Janeiro, in the past year, was 97,251,128 mils., of which coffee represented 94,465,116 mils.; sugar, 880,676 mils.; hides, 909,598 mils.; tobacco, 535,050 mils.; rosewood, 309,685 mils. The export of gold and silver from Rio de Janeiro in 1881 amounted to 4,113,078 mils., of which 2,816,340 mils. was to England; 189,168 mils. to France; 963,662 mils. to the River Plate; and 140,906 mils. to Brazilian ports.

The export of coffee last year was 4,377,418 bags of sixty kilograms, being 814,364 bags more than 1880 [Of this quantity the United States took 2,241,976 bags, and Europe, etc., 2,135,442 bags. It should be noted that, of late years, the United States would seem to be "taking proportionately a decreasing quantity of the Brazilian crop." The prices realized per kilogram last year, as compared with 1880, show a very serious reduction for all qualities, as follows:—

	First half 1881:	First half 1880:

His Majesty the Emperor of Brazil has been systematically visiting and examining the factories and workshops of Rio de Janeiro and its vicinity, with the object of judging, by personal investigation and by hearing the views of the proprietors and experts, of the claims put forward by the manufacturers for higher protective taxation of foreign products of a similar kind, and for the reduction of import taxes on substances employed in the Brazilian manufactures.

To the friends of Brazil in this country it is very satisfactory to observe any movement in the Empire favourable to the extended cultivation of additional articles of export to the consuming markets of the world. The soil and climate of many of the provinces are suitable for the production of tea, vines, and silkworms, as well as sugar and coffee. With regard to the latter, we quite agree with a correspondent, who writes to us as follows:—"Coffee has seen its best days. They now mix seven parts of chicory to one of coffee with it, and many people prefer the compound. Many doctors say it is more wholesome, as pure coffee heats and thickens the blood too much in cold climates."

There is also the practical fact that the production of the world is in excess of the consumption, according to the most reliable statistical information attainable, by so much as 90,000 tons annually, being equivalent to 1,500,000 bags of 60 kilograms. In view of this it is not surprizing that the prices of coffee have been so seriously reduced as to render its cultivation almost unremunerative to the growers. Undoubtedly the Brazilian Government has acted wisely in promoting the larger production of sugar by the granting of guaranteed concessions for the creation of central sugar factories where likely to prove commercially successful and of real service to agricultural industry. Unlike coffee, the consumption is in excess of the supply, and is steadily on the increase. It is encouraging to observe that the Brazilian production and export of this important article of merchandise is assuming larger proportions. The *Journal de Commercio* in its able commercial review for the past year, makes the following statement:—

In 1881, compared with 1880, there was an increased production of sugar in the province of Rio de Janeiro, and also in the northern ones, a result which must be largely attributed as to the south to the central sugar factories, which permit of a more advantageous and rapid treatment of the cane, and as to the north, to the use of new apparatus and improved methods of working, together with increased planting, encouraged by the firmness of sugar abroad and its greater consumption.

According to the "Economiste Français" the beet resources of 1881 were only 348,042 tons against 385,630 tons in 1880, whilst the consumption is steadily enlarging, so that the prospects of the sugar-makers are auspicious. Dr. Paes Leme has put down the production of sugar cane at 1,875,000 tons, viz:

Cuba	700,000
British West Indies	250,000
Java	200,000
Brazil	170,000
Manilla	130,000
China	120,000
Porto Rico	80,000
Louisiana	75,000
Peru	50,000

Rio imported in 1881, chiefly from Campos and the north, 633,526 bags against 407,778 in 1880. The quality, especially of that from the north, showed in 1881 no appreciable improvement. The Barcellos factory improved and the Quissaman maintained their quality. It is said that many planters, especially in Sergipe, are disposed not to purge their sugar, the extra price not paying for labour.

The export from Rio was 84,635 sacks, being much more than in 1880, which was one of the best export years. Among the shipments from Rio was a lot of white to Loudon, an unprecedented occurrence, and a small cargo of white went from Maceio to the same place. The export to the River Plate has to struggle with the cheaper sugar of Europe and with the products of the Argentine province of Tucuman.

A development of the culture of tobacco is also noted by our contemporary, which remarks that "both the Bahia and Rio Grande do Sul tobaccos are in a relatively prosperous state."

A plan for completing the Rio Grando do Sul railways has, it is said, been drawn up by Mr. Edward de Mornay, who has asked permission to make surveys for a line from Tagnary to Torres, on the seacoast, and for the construction of a port at the latter. Mr. de Mornay has also asked the Government to declare the projected works to be of public utility, with a view to obtaining the legislative sanction to an appropriation for the payment of a guaranteed interest on capital raised for their realization.—*South American Journal.*

THE "NEW CEYLON:" THE DIFFICULTIES OF PIONEERING.

Ludvig Verner Helms, a traveller who has spent something like 25 years of his life in the most important islands of the Eastern Archipelago, who has visited China and Japan, traversed the Northern Continent of America, and explored the mineral treasures of Lapland, ought to be able to give an opinion on "Pioneering in the Far East." The formation of a new English Company to develop the resources of North Borneo is a step which the author says is, at least from a philanthropic view, deserving of sympathy and success, but the task of the Company will not prove an easy one. He remarks:—

In many respects, doubtless, the northern part of the island may be considered the most valuable. . . . . Still, if the Company anticipate an easy conquest of their difficulties, they have not read the chronicles of Borneo aright. It is true that Sir James Brooke, his followers, and successors have, to a great extent, cleared the ground for them. The natives have learned to associate the English name with the noble work done by them, while the mighty advance of commerce during the last decades has been gradually encircling this stronghold of barbarism in its irresistible folds. But, even so, savage natures will not easily yield to civilizing influences which make rapid strides only when paying their way. Steamships, telegraphs, and railways are costly things, which a savage country with a scanty population can ill support.

Mr. Helms points out that the 20,000 square miles the Company holds contain a population of upwards of 100,000 aborigines and Malays, who, it may be assumed, will contribute but little towards the labour or development of the country. "The sponge must indeed have been squeezed dry when such rulers as the Sultan of Brunei and his ministers consent to part with it;" and the author is much mistaken if trouble and intrigue do not result, particularly if the Company become monopolists. Sir James Brooke's great influence over the natives, he remarks, was in a great measure due to the fact of his standing aloof from trade, and if the Company's position and status are different from those of Rajah Brooke, the condition of their respective countries also materially differs, as Sarawak possessed advantages which North Borneo does not. Mr. Helms thinks that it is to China that Borneo will look for population and labour, and this will help the Company, but when the Chinaman begins to feel his strength the anxieties of government will be felt by them. The author continues:—

But if the Company is paving the way for a great Bornean Empire, under the British flag, it will be doing a good and useful work. A settlement that should embrace the territory ceded to the North Borneo Company, as well as Brunei and Sarawak, would prove no contemptible acquisition to the British Crown, and has, unquestionably, much to recommend it. . . . . A glance at the map will show how very important the harbours of North Borneo might become to an English fleet, if the day comes that England has to fight to protect her commerce in the China Sea, or the Pacific. These harbours are backed by vast coalfields, the country is healthy, with a moderate temperature, and the island possesses unrivalled resources. What is wanted is population, and under a strong Government the country would very soon be entitled to the name of "New China," rather than "New Ceylon," as some writers already call it; for to the Chinamen, and the race which will spring from their union with the Dyaks, and not to the decaying Malays, belongs the future of Borneo.

According to Mr. Helms, therefore, the British North Borneo Association has a difficult and delicate task before it, but if it succeeds in raising the island

from its present condition, and in extending the commerce of the Eastern Archipelago, it will do good work. —*British Trade Journal.*

BRAZILIAN REVIEW FOR 1881.

During the year slavery, sapped by the Free Birth of 1871, by official emancipation, by the five-fold more energetic operation of private benevolence, and by the silent but rapidly progressive action of death, continued its accelerating march towards extinction. The year was also made notable by the prohibitory measures, against the introduction of slaves, adopted by the central provinces, measures which have practically destroyed the interprovincial trade in slaves, and by the open extra-legal popular opposition in Ceara against the obnoxious export. Moreover, the general sentiment of the cities appears favourable to a revision of the law of 1871, with the object of hastening the happy day when Brazil will have shaken off the shackles of her inherited curse of domestic slavery.

[The *Rio News* gives a far less creditable account of the slavery question and the state of public opinion in regard to it.—ED.]

Agriculture during the past year was prosperous, the crops of our main staples, coffee and sugar, being considerably beyond the average. Unfortunately, the low prices of coffee gravely diminished the receipts of coffee planters, affected trade generally, and curtailed the Government collections from that chief source of export revenue. The cattle industry of the south continued in its decline, and grave losses occurred in Rio Grande do Sul through droughts which prevailed during the early part of the year. But the extractive industries* of the Amazonian valley proceeded in an ascendant march throughout the year, extending their arms widly into rich and virgin fields of exploration.

Of the finances of the country we are as yet without definite information, no meeting of parliament having led to the customary publication of official returns. But on the whole, the revenue collections are likely to have exceeded the estimates, inasmuch as, though the receipts of the Southern provinces have at best been stationary, from the causes already touched upon, those from the northern half of the Empire will undoubtedly show a considerable increase. Economy has also been the order of the day in the "ordinary" expenditures, and we shall not be surprized to find in the coming exposition of the Ministry of Finance that Senor Saraiva has already attained his desideratum of a balanced ordinary expenditure and income, notwithstanding the rather considerable increase in the former by the depreciation of exchange and by the interest on the floating debt, incurred chiefly for the service of the Government works of internal improvement in hand, and in part for the acquisition of naval and military material in view of the increasing armaments of the Argentine nation.

[Then follow long details of a wonderful series of railway lines which will open up the Empire,] Taken in all, the various lines in traffic fall little short of 7,000 kilomcters and many hundreds of kilometers more are in a condition of advanced construction.—*South American Journal.*

ARTIFICIAL INDIA-RUBBER promises to be soon a fact. Bouchardat has found a compound by treating isoprene (C^5 H^8) with hydrochloric acid that has all the properties of rubber.—*Chemist and Druggist.* [We have no fear of artificial rubber any more than of artificial quinine.—ED.]

* Extractive industries"? We suspect that not mining India but rubber collecting and similar pursuits are referred to.—ED.

A RHEA MACHINE.—The Government of India have asked the Secretary of State, to send out to this country a rhea machine, by Messrs. Mar in, Dennis and Albert Angell, for the preparation of the fibre of jute, for the use of the Government experimental farms, as soon as the machine can be procured —*Madras Mail.*

INDIAN TOBACCO.—All interested in the growth of tobacco in India will be glad to learn that a late shipment of thirty tierces of Pusa tobacco to London has been pronounced by the experts, both merchants and brokers, to be of excellent quality. fully equal to American, and that good prices were realized.—Calcutta *Englishman.*

WHITE BUG ON CINCHONA.—Mr. Smith of Mattakelle has sent us a number of cuttings of cinchona (?) branches and stems terribly "bugged" (with white bug), but the stems are also freely covered with the larvæ of the lady-birds which have been feeding on the bug and which will no doubt do much to clear off the enemy.

WATER.—In seeking for a substance which would destroy the microscopic animals in water without injuring it for drinking purposes, Dr. Langfeldt found that citric acid (one half gramme to every litre of the water) killed all the living organisms, except cyclops and those with thick epidermis, within two minutes.—*Chemist and Druggist.*

THE BARK SPECULATION.—The principal of the Milan Quinine Works writes to the *Pharm: Zeitung*, to contradict a statement which had appeared in that journal to the effect that that firm and a few German houses had formed a syndicate to buy up a large part of the London stock of bark, with the object of forcing up the price. He says:—"The present advance is the exclusive work of a London import house, and we have in no way shared in it. On the contrary, we consider it ruinous to the trade, if the article should fall into the hands of speculators, and we believe it is the interest of all manufacturers to prevent, so far as possible, all such arbitrary advance or depression in the price occasioned by speculation."—*Chemist and Druggist.*

CONSUMPTION OF COFFEE.—It is generally thought in England that the French are the greatest consumers of coffee, but it appears that this is far from being the case. From reliable statistics we learn that in England, in spite of the great consumption of tea, every person consumes 1⅛ lb of coffee every year, in Germany the average consumption is 4 lb a year, in Denmark 5½ lb, in Switzerland 6 lb, in Belgium 8½ lb, in Holland 10½ lb, in the United States 7½ lb, whilst in France it is only 2½ lb. With the exception therefore of England, there is less coffee consumed in France than in any of the other countries above-mentioned; the highest average, however, is found in California, where 20½ lb are consumed per annum —*La Patrie.* [The consumption of coffee in England now is less than one lb per head per annum!—ED.]

THE SANTOS COFFEE CROP DAMAGED BY RAIN.—The *Provincia de Sao Paulo* of the 4th Feb. extracts the following from a private letter written by a planter in the interior of Sao Paulo:—"The continued rains, often torrential, are injuring, in a discouraging manner, the next future crop of coffee. For more than thirty days the rain has not stopped, there resulting from such continued humidity the rotting of the peduncle of the coffee fruit and, in consequence, its destruction. We have seen coffee orchards strewn with fruit, in great part nearly matured, and beside that the fall of these had been caused not only from the trees most loaded, but also from those where the fruit is scarce. If the weather does not improve shortly, great, very great will be the loss of the cultivators of our already too greatly depreciated product."—*Rio News.*

PATCHOULI OR PUCHA-PAT.—A herb named Pogostemon Patchouli (Nat. Ord. Labiatæ.) The dried tops with leaves and flowers are imported in bundles about one foot in length. They yield, by distillation, an essential oil, in which form the perfume exists, and by digestion in weak alcohol, a tincture called essence of Patchouli or Patchouly. It is imported from India, in chests and half-chests, the former weighing 110 lb each.—M. M.

SEVERAL BAGS OF CLOVES received in London lately from Zanzibar were actually found on arrival to contain artificial cloves neatly manufactured by machinery instead of the real spice. These cloves were made of soft deal, stained a dark colour, and soaked in a solution of essence of cloves to give them the required scent. They were traced as having been imported into Zanzibar from America.—*Madras Mail.*

MANURE FOR TEA ESTATES IN THE DUN.—Baring, in his financial statement for 1882-83, gives the ollowing figures as the tea exports for 1880-81 :—

Quantity ...	Lb.	...	46,413,510
Value ...	£	...	3,054,240
Average declared value per lb.,	Annas	...	10.6
	Shillings at average exchange		1.09

Exports for the first ten months of the year, from 1st April 1881 to 31st January 1882 :—

Quautity ..	lb.	...	43,667,412
Value ..	£	...	3,261,579
Average value per lb.		...	0-11-11.—

Indian Tea Gazette.

AN AGRICULTURAL COMPANY FOR TRAVANCORE.—We (*Pioneer*) learn that an Agricultural and Industrial Company, with limited liability, has just been formed in Bombay, under influential auspices, the principal object of which is the cultivation on a large scale of coconut, sugarcane and cinchona in Travancore, where the soil is peculiarly adapted for the purpose. The shares are nearly all taken up, and it is believed that the Company will receive every encouragement from the enlightened Maharajah of Travancore, who, not long ago, wrote a pamphlet on the agricultural and mineral resources of Travancore, in which he strongly advocated the cultivation of the sugarcane and the manufacture of sugar by modern appliances.

CHINESE EXPORTS consists of tea, silk, sugar, and sundries. Tea is still the chief export, accounting for over 45 per cent of the gross value In earlier periods it constituted more than one-half the entire commerce ; but, during the last five years, it has been run close by the silk trade, which is averagely worth 40 per cent of the whole. Sugar accounts for 3 per cent, and the residue is apportioned between a number of minor items. Of the tea sent away in 1880 (2,204,754 piculs) by far the greater portion (1,456.747 piculs) was taken by Great Britain and her possessions, the former alone taking 1,112,874 piculs. Hongkong and Australia were the next best customers, with 168,467 piculs and 143,870 piculs ; while India—to carry out the old adage of "carrying coals to Newcastle"—took 13,297 piculs. Among foreign nations Russian orders immensely predominated, no less a quantity than 464,961 piculs being imported into that empire, while, practically, the whole remainder went to the American States. With regard to the silk trade, the best customers are Western Europe—France, in reality, as she takes nearly the whole continental supply—England, Hongkong, and the United States. To the world's other quarters the exportation is extremely small ; India, however, buys about a thousand piculs per annum. Chinese sugar goes principally to France and England, but a fair amount finds its way to American ports, Bombay, and the Straits. Other features of the commerce of these interesting people must be left to another and fitter occasion to discuss.—*O. Mail.*

TO KEEP MACHINERY FROM RUSTING : take one-half ounce of camphor, dissolve in one pound of melted lard ; take off the scum and mix in as much fine black lead as will give it an iron colour. Clean them achinery and smear with this mixture. After twenty-four hours, rub clean with a soft linen cloth. It will keep clean for months under ordinary circumstances.—*Exchange.*

EUCALYPTUS LEAVES AND INSECTS.—We have heard much of late years of the virtue of the Eucalyptus tree ; but, according to recent reports from Australia, its good qualities are by no means exhausted. We now learn that it is held in so much awe or dislike by fruit-loving insects, that a few of its leaves spread round the trunks of the trees will protect them from spoliation.—*Graphic.*

TOBACCO.—The export of tobacco to the Malabar Coast in India is carried on very briskly and hurriedly, as the North-East monsoon is approaching to its close. The services of all sailing vessels are availed of and after the end of this month cargo to those ports must be sent in steamers till September next. The B. I. steamers will call here as we require their services from time to time.—*Cor.* [Surely here is an opening for the "Lady Longdeu."—ED. C. P.]—"C. Patriot."

DIGGING BY STEAM.—The principle of the Darby steam-digger, referred to in these columns some time ago, has been improved upon by different manufacturers, and a new digger made by Messrs. Proctor & Co. has just been subjected to a very thorough trial at Stevenage, Herts, with successful results. The machine is sufficiently light in its construction to go upon any land in a fit condition to work, and the digging appliances are quite distinct from the motive power, so that the engine can be used for traction purposes when not digging. The digger, when at work, travels at the rate of 1,250 yards per hour, and as it digs 12 feet wide it can cultivate more than one acre in that time, allowing for turning, &c. The machine can be easily managed by a man and a boy, and works equally well at various depths—1 foot, 1½ feet, &c.—*Colonies and India.*

STICK PRUNING—Our correspondent "F." refers to what he conceives to be a mistake in denuding bushes of their leaves. We entirely agree with him, and can find no ground, theoretical or practical, to justify the practice. At the same time it may be said that few agree on the subject. Still it may, we think on grounds of common sense, be safely affirmed that to deprive a bush entirely of its leaves is virtually to kill the plant, and render it valueless for the purpose for which we desire to use it Pruning, which aims at cutting out dead or unprofitable wood, or with the object of producing a larger flush, is one thing, and can only result in good, since we do not cultivate the tea bush as a tree, but as a *leaf-yielding* plant ; but denuding the bush of its leaves in the hope of stimulating vitality, we hold to be an utter mistake —*Indian Tea Gazette*, March 21st.

CALISAYA BARK.—The Belgian Consul at Arica (Mr. E. Wichtendahl) states that the total annual production of bark from the chinchona calisaya in Bolivia is between 8,000 and 10,000 quintals. The price has, on account of the great destruction of the trees, gradually risen from 50 sols in 1866 to 104 sols per quintal at the present time. The continued difficulty of obtaining the bark has directed attention to the cultivation of the tree, which has been found so successful in the East Indies, and there are several such plantations now existing in Bolivia which promise well. A German firm of La Paz have bought large estates near Mujuri in which they intend planting 900,000 trees, part of which will be ready for barking in one or two years The Consul goes on to say that the cultivated bark gives a far better result than the wild form, some of the former yielding as much as 5 per cent, of sulphate of quinine.—*British Trade Journal.*

The Treatment of Jute.—At the Atlanta Exposition a Louisiana gentleman had on view three baled of jute, which were almost white, and had been treated only by water. The jute was simply put into water and allowed to rot, a process requiring from seven to nine days in stagnant water, and above 20 in running water. After this process the jute comes from the water without a vestige of bark, and with the fibre thoroughly separated. After washing it is ready to be manufactured.—*Brtsh Trade Journal.*

Your (late) staple, Coffee, is undergoing a further trial of endurance. A bill has been introduced into the Austrian Parliament heavily augmenting the duties on tea and coffee, and, as the bill is sure to pass, every effort has been made by importers to push both these articles into the empire under the existing tariff. To such a pitch have these efforts been carried, that 20,000 tons of coffee were introduced in a fortnight! To permit this evasion of future duty proceeding any further, on Wednesday last a special bill was carried in the Austrian Parliament declaring all such importations after yesterday liable to the higher rate of duty. It is to be hoped that the recent improvement in the price of coffee is not alone due to the heavy buying which the importations above referred to has occasioned. It may have considerably influenced, it.—*London Cor.*

Agriculture in Burmah.—The Burmese agriculturists in the interior will have very little surplus cash to spend, and they can hardly yet realize that the price of paddy has gone down to something like the price it stood at ten or twelve years ago. Generally in the month of March, eager buyers from Rangoon, Burmese, Chinese and natives of India, flocked to every village on the banks of a creek, and outbid each other to get paddy at rates varying from R75 to R85 per hundred baskets, according to the rates ruling in town. The buyers being so exceedingly anxious to get grain, Jack Burman, of course, accommodated them, and insisted on measuring with a small basket, whilst he took no great trouble to sift the grain, and dirt and paddy husk formed a proportion of every boat-load sent to Rangoon. When there was such a brisk demand, what need to take extra trouble to clean the grain, and if buyers did not mind paying a high price, there was no reason not to measure with a heap, mixture of a few baskets of husk and earth from the paddy-field which increased the bulk. All this is changed now. A Burman cultivator, who recently arrived here from Mawoon, one of the richest paddy districts, tells me that at R45 per hundred baskets last week there were no buyers in his village, whilst, where speculators had come up from Rangoon to purchase, they were most particular in seeing that they got good measurement, and also that the grain they bought was really grain without added husk or dirt. This man seemed to think that cheap rice meant wholesale ruin and desolation to the people. Where nearly every one cultivates either for sale or for his own use, it no doubt means that there will be very little surplus cash at the end of the season to spend in finery, or in visiting distant pagodas, or giving feasts and theatricals to friends. But with low prices, perhaps, we shall get more honesty and less fraud and deception in the rice trade, and those who do not cultivate, but have to buy their daily food, viz., the residents in towns, will benefit from cheap food. The Burmese cultivators have for so many years had high prices and a brisk demand for paddy and rice, that they hardly understand that the European market is overstocked, and that it is only low rates which can induce shippers to send more rice out of the country. Another good result which will doubtless follow from low prices is that the poorer classes in Europe may be induced to use rice more generally as an article of food. Its nutritious qualities are well known, and if the poor find that they can obtain a sustaining food at rates much lower than have hitherto prevailed, they may, perhaps, be induced to overcome the prejudice which exists among so many classes of people regarding changing ordinary articles of diet. The last administration report for the province showed that Burmah rice had penetrated to Iceland, and, if in such a cold climate rice is generally used by the people with advantage, it would surely be a valuable food for the labouring classes in Great Britain and Ireland. And yet in how few households at home is rice ever seen on the table, unless in the form of rice pudding, or unless it is cooked in honor of come Anglo-Indian who happens to be at home on fourlough. —*Friend of India and Statesman.*

Strawberries.—It is estimated, says the *New York Tribune*, that during the "Strawberry month" Chicago receives 10,000 bushels of this fruit per day.

Vine-growing in Germany.—I was very much interested this year in the different modes in which they grow vines in the wine country which fringes the Rhine for so long a distance. I observed them chiefly at Newhausen on June 10, and found two modes of culture pursued. In the first instance the vines were trained up a 6ft. pole, and stopped at that height. Six or seven stems were trained up the pole from the same root, encouraging side growths for the fruiting wood. In the other method, one leading stem was grown up and bent down, and tied to the footstalk, so as to form a hoop, round which the growth was made and the fruit borne.—J. Allen. —*Australasian.*

Exports in the shape of Coconut Oil of a superior quality, sleepers, and logs of timber, from the Andaman Islands, are gradually increasing. The oil, by the way, comes originally from the Nicobars, where the islands are belted with coconut trees. It is a curious, though well-known, fact, that the coconut, indigenous to the Cocos Islands to the north, and to the Nicobar Islands towards the south, was not to be found some years ago in the Andamans. Every coconut tree in the settlement owes its existence to our colony. The wealth of the Andamans in other kinds of valuable timber fully makes up, however, for the absence of the coconut palm.—*Pioneer.*

The Mauritius Sugar Estates We have more than once said that almost the only means of setting the sugar-making interest on a sound and solid footing is the creation of *Sugar Estates Companies*. By this means all mortgage debts will gradually be liquidated; the Colony will not pay so much interest to the capitalists of other countries; the estates will be administered at a much cheaper rate, and the public will be more generally interested in the chief staple of the colony. A large number of persons who can command only a few hundreds of rupees or dollars will be able to take a few shares. The rivalry among the Estates Companies will be of the most legitimate kind; it will be, which estate can produce the largest quantity of sugar of the best quality. What has given the impulse in this matter has been the success of, we believe, the first company, *the Sugar Estates Company* of which Dr. Icery is the manager. Another Company is now forming to be called the *Central Sugar Estates Company.* It will comprise the following estates, viz:—*Bonne, Veine, Esperance, New Grove, Rose Belle, Mare d'Albert.* We perceive by an advertisement that *Mon Tresor* is selling off every thing. We are sorry to learn this. If it had formed part of a Company this might not have happened. The Northern Sugar Estates Company and the Highlands Co., are very successful. Thirty shares of the Northern Company were withdrawn on the 26th instant at R286.—Mauritius *Mercantile Record.*

TROPICAL FRUITS.

TO THE EDITOR OF THE "FIELD."

SIR,—Acting upon the suggestions of F. T. P. and T. D. M., I have made inquiries at the fruiterer's (Porter, 278, Oxford-street), and find that the mangoes came from Madeira; so my supposition that they were from Bombay was erroneous, which shows that people should not jump at conclusions. The lot I saw arrived late in November. Their price is from sixpence to a shilling, which strikes me as moderate.

F. T. P. mentions the custard apple and liechie. I saw one variety (Anona reticulata, similar to what is called in Java "buah nyonya"—ladies' fruit) of the former and the liechie in a dried state at the same shop. Also the avocado pear (Persea gratissima), and a thing called the chew-chew, a substitute for the vegetable marrow, both from Madeira. After the mistake I made in the case of the mango, it is needless to say that I have never been to Bombay, but I have eaten the mango in Ceylon very early in February. They were not quite ripe, though. I had always cherished a hope that mangoes and mangosteen could be brought over in a frozen state. I mean literally frozen—not merely put in an ice-house. The case quoted by T. D. M. seems to explode this idea.

I am by no means sanguine that the mangosteen could be satisfactorily reared in European hothouses. I say this from my knowledge of the fruit, and not from my acquaintance with hothouses, which is *nil*. The only places where it reaches perfection are Malaya and South America. In Malacca it grows absolutely wild in the centre of the peninsula. Attempts have been made to grow it in Burmah, with but scant success. It is impossible to say what are the climatic or other conditions at the bottom of all this, just as it is impossible to say why the Primula imperialis will only grow to perfection on the solitary mountain-top of the Pangerango, Java, and deteriorates when transplanted to other mountain-tops.

F. T. P. mentions grapes and peaches from India and Assam. Does not this suggest that it would be far more to the purpose to introduce these fruits into Asia where it is proved they would flourish, and thus provide a really needed luxury for the sweltering Anglo-Indian in the plains? What would one not give for a bunch of good grapes in Calcutta in June? At Mandalay, Upper Burmah, I have seen a grape vine as fine as ever I saw it in Germany; and I was assured that the crop was splendid. When I arrived there was not a bud to be seen; and when I left, a month later, the vine was covered with tiny bunches of fruit, so rapid was the growth. The vine was the only one in Mandalay. In the same garden were some fig trees, the fruit of which I tasted, and found it perfect. This was in the month of September. As a proof that vine culture would pay in India, I may mention that the owner of the Mandalay vine was offered fifteen hundred rupees for his 1877, '78 crop.—E. T. S.

THE TONGA PLANT.

(EPIPREMNUM MIRABILE, SCHOTT.)

"Tonga, the specific for neuralgia." Such is an advertisement of Messrs. Allen and Hanbury's that has now been before the public for many months past. Tonga is a vegetable drug, and the material from which it is prepared is stated to consist of a mixture of bark and fibrous matter, the botanical origin of which was for some time unknown. The Tonga plant itself is an ornamental climber of rapid growth, with bold dark green pinnatisect leaves in the adult state, and large flower [illegible], resembling those of a Monstera or Rhaphidophora. It is a very valuable plant for training up pillars, trunks of Palms, Tree Ferns, &c., or the back wall of a stove, and besides its ornamental character it is specially interesting for the manner in which the plant changes in appearance as it developes from its juvenile state with small entire leaves, to its adult flowering state with large pinnatisect leaves; as well as for its medicinal qualities, which appear to have long been known to the natives of the countries the plant inhabits, since Rumphius in his *Flora Amboinensis*, vol. v., p. 489 (where at t. 183, f. 2, a very good figure of the plant is given), states that the natives of Java and Baly cook "the horns" (terminal buds of flowering stems) a little over a fire, bruise them and squeeze out the juice, which is given to lean and feeble horses and cows, and it is said to cure them and bring them into a fat and healthy condition. The internal substance is pounded and used in the form of a poultice as a remedy for sprains. It is also used as a dentifrice to whiten the teeth, the heart or internal substance being chewed with Pinanga and chalk. Cows feed upon the leaves, especially during the hot months when the fields are destitute of grass; they seem to be very fond of them, and also of the stems, as they are not acrid. Altogether the Tonga plant appears to be a rather useful one, all the more so considering the order to which it belongs, whose members are more noted for their doubtful and poisonous qualities than for their good and useful ones.

The following is a description of the Tonga plant, chiefly compiled from Mr. Bull's specimen, omitting here the full synonymy:—

EPIPREMNUM MIRABILE, Schott, *Genera Aroidearum* p. 79.—Stem climbing, in juvenile plants slender, about one-tenth inch thick, in adult flowering plants about 1 inch thick, clothed towards the apex with the persistent fibrous remains of the scale-leaves.* Smallest leaves of juvenile plants, with a petiole $1\frac{1}{4}$—$1\frac{1}{2}$ inch long, vaginate for about half its length, and a lamina 1—$1\frac{1}{2}$ inch long, $\frac{3}{4}$—1 inch broad, obliquely cordate-ovate, acute or shortly cuspidate, entire, without perforations; as the plant gets older the petioles elongate and the lamina increases in size, becoming obliquely oblong-ovate, or lanceolate-oblong, acute or shortly acuminate, with small perforations or pellucid spots, mostly arranged along the sides of the midrib; from being quite entire these gradually pass to a more and more pinnatifidly segmented form, until the adult stage is reached. Petioles of adult leaves, stout, 8—15 inches long, including the 1—$1\frac{1}{2}$ inch long geniculus, convex on the back, channelled down the face, and vaginate nearly up to the geniculus. Lamina 14—20 inches long, 7—12 inches broad, shining dark green, oblong or elliptic-oblong in outline, acute, cordate or subcordate at the base, more or less oblique, pinnatisect nearly to the midrib, and having numerous small perforations and pellucid spots scattered along the region of the midrib, but not confined to that part; segments varying from 4—10 in number on each side, but more numerous on one side than on the other, straight or somewhat falcate, all except the lowest of about equal breadth throughout their length (usually 1—2 inches broad), apex truncate or somewhat convexly truncate, the upper edge produced into an acuminate point; the terminal lobe more or less diamond-shaped, much larger than the rest. Primary lateral nerves 2—3 in each of the basal segments, one only up the centre of the other segments, or sometimes two or more, when two or more segments are united into one, spreading, running out straight almost to the margin, and then curved into the acuminate point; midrib and nerves rather impressed above, very prominent and rounded beneath. Peduncle 4—9 inches long, terete. Spathe [illegible]—$4\frac{1}{2}$ inches long, ovate, boat-shaped, shortly cuspidate, [illegible], green outside, puce-coloured inside. Spadix sessile, much shorter than the spathe, cylindric obtuse, green, about two-thirds of an inch thick. Ovaries cuneate, sub-hexagonal, truncate, one-celled, with a septiform placenta projecting one-third across the cell, bearing two ovules, one on either side at its base (rarely only one ovule); stigma sessile, linear.—Schott, *Prodromus Aroidearum*, p. [illegible]. Engler, in DC. *Monog. Phanerog*, ii., p. 249! &c.

Widely distributed, inhabiting Java, Sumatra, Baly, Amboina, Timor, Fiji Islands, Tropical Australia, and in the Kew Herbarium is a specimen of what I take to be the same species from Whampoa, China (Hance, No. 15,600)—N. E. Brown, Herbarium, Kew.—*Gardeners' Chronicle.*

* If I understand the [illegible] of the various authors [illegible] I [illegible] [illegible] the [illegible] of the [illegible] for [illegible] the [illegible], which [illegible] until the plant [illegible] from [illegible] to a [illegible] of growth of the stem, exactly as occurs in Philodendron, for example P. Simsii.

ORANGE CULTURE IN CEYLON.

We have more than once touched upon the subject of the cultivation of fruit in Ceylon, as a means of affording a livelihood to young men with limited means who can find no opening in professions, or in general business. The question assumes more importance as the time approaches for Colombo becoming the port of call for so many more steamers than hitherto. Our attention is re-called to orange culture by a notice which this industry has received in one of the consular reports which enters at some length into the cultivation of and trade in oranges and lemons. The trade in oranges from the West India Islands, Malta, and Egypt to Great Britain has been of considerable importance for many years past. The first crop of the season is looked for with great eagerness by the London dealers, and there is as much rivalry between clipper fruit steamers with the new fruit of the seasons as there is with the China clippers with argoes of new Teas.

But the trade to which our attention has been directed by a consular report from Beyrout, is that of the two Syrian districts in which oranges are most plentiful, those of Jaffa and Sidon. The orange trade from these two places we are told, began to assume considerable proportions some forty years ago, when the new Government of Egypt took shape, and it is now one of the most profitable industries in the two towns abovementioned. Unfortunately the inhabitants, allured by first gains, commenced planting gardens and expending money beyond their resources, the result of which has been that, in spite of all remunerations for small outlays, their improvidence has placed most of them in the power of money-lenders, who continue to advance at interest of 15 to 20 per cent. However a company has lately been formed in Jaffa to negotiate loans with orange cultivators, and if its operations be carried on fairly, we may expect an extension of horticulture, with benefit alike to the company and the borrowers. At the present moment Jafta possesses some 340 gardens, averaging from 2,000 to 2,500 trees in each. The crop of fruit from these may be put down at about 36,000,000.

A garden costs from 40,000f. to 50,000f. and brings in 4,000f. to 5,000f. per annum. For several miles round Jaffa extends a fertile plain on which water is always to be found at a depth of 40 ft. or 50 ft.

The cultivation of the orange is not generally carried on with much enterprise or skill, and it appears but little is done to aid the trees beyond irrigating them, and even this is carried on, on the most primitive system. At present unplanted land close to Jaffa able to support 2,000 trees is worth 2,000f. to 3,000f.; but at two or three hour's distance it will fetch only 5f. to 6f. a deanum. The export is carried on chiefly by sailing-boats for Egypt and Constantinople, and by steamers for Russia, Trieste, and Marseilles. Exportation in cases is a comparatively recent introduction, which has given considerable impulse to business with Europe. The orange gardens of Sidon are cultivated on the same principles as those of Jaffa. An acre of land at Sidon is generally valued at from 6,000f. to 7,000f., and is capable of bringing in an income of about 600f.

An abundant supply of water appears to be a necessity for the orange tree, if it is to produce abundant crops. It will be seen that the growers there receive not more a return than ten per cent upon the value of their properties, the largest profits being realised who purchased them for the supply of foreign markets, those markets in the present case being Turkey and Russia.

Oranges are likewise cultivated to a considerable extent in Tasmania, whence a large trade exists to the other Australian Colonies. We are, however, without data as to the returns yielded by this industry, but seeing how little labor need be expended on the tree after it has arrived to maturity, beyond that involved in its irrigation, the return in this country should be very considerable. The produce of a tree is said to range from 200 to 800 fruit per annum. The demand for such fruit as these, will very shortly be far greater than the supply can satisfy; and considering at what a low rate suitable land can be purchased or rented on long leases, and having regard to the pleasant and not by any means laborious occupation of a fruit-grower, an orangery should have attractions for the young men of this country. Hitherto the fruit has been grown without care and attention, and certainly without irrigation, and we cannot wonder therefore that quality does not form a very prominent feature in the article. In the western province oranges are planted chiefly on rising ground, under the impression that it thrives best in a dry situation, but this is not the case, and the absence of moisture in the soil may go far to explain the poverty of some of the fruit. We are assured that oranges grown in the manaar district are of a very fine description and very refreshing to the quality of juice they contain; this is probably explainable by the fact that irrigation is easily obtained from some of the many water-courses flowing through that part of the country.

We would advise any intending cultivators of the orange to select land capable of being irrigated by means of wells and water channels, and without that trees can scarcely be expected to yield abundantly. A very little mechanical contrivance will unable water to be raised from the wells and distributed through an orangery. especially if bullock-power be available. To what extent the demand for this fruit exists in Syria alone may be gathered from the fact that 30,000 cases of the fruit are annually shipped from that country.—*C. Times.*

COCONUT CULTIVATION ON THE MALABAR COAST.

One of the chief agricultural pursuits on the West coast, as also in different parts of the peninsula, which ranks only second in importance to paddy cultivation, is coconut planting, which is considered so profitable a speculation that the mania for getting possession of reclaimed lands, and lands along the river side, favorable for the above purpose, is ever on the increase; and if it is cultivated on scientific principles, the profit will be ten-fold more than under existing arrangements. As things now stand, particular attention is paid to the following points, which those interested in the promotion of this branch of industry will do well to bear in mind. In the first place, great care is taken in the selection of the nuts for growing. Only large-scarred nuts of trees that have passed their middle age, will fit for the same, and these, when they have attained their full maturity, have to be gently let down in baskets, and not violently dropped on the hard ground as ordinary nuts are; but those who consider this process rather too troublesome, generally select trees growing on the banks of tanks so that the fully-ripe nuts might drop down into them, which is considered less injurious. These nuts are generally planted on the ground only half-covered at a distance of one feet from each other. In some cases they are simply slung, two by two, over a large horizontal pole, while the more common plan is to place them on house-tops in a similar manner. In each case they are fully exposed to the weather, and remaining thus for about three months they generally begin to germinate; and when they put forth four leaves, or when they are about four or five months old, they are carefully transplanted, while on high roads, only plants three years old are considered fit for transplanting.

The pits into which they are to be transplanted must be prepared with due care, at least six months before they are to be used. One essential element in the preparation of these pits is observing a proper distance between each, which necessarily varies according to the nature of the soil, a distance of 24 feet being considered sufficient in low ground, while in higher regions they

must be located at least 30 to 40 feet apart, and in every case they must be 2 feet square by 2 feet deep. After these pits are thoroughly burnt, which practice is by the way restricted to high grounds only, marine shells are put in to form the first layer, over which comes another layer of sand. These processes not only add to the fertility of the soil, but prevent the encroachments of white-ants, which object is also gained by planting two or three arrowroot plants in each pit along with the young coconut plant, the strong pungent smell of the former having a very destructive influence upon these injurious insects. Young coconut plants of the proper age for transplanting can also be purchased at about R12 per hundred, but these cannot always be depended upon, as dealers very often bring up for sale plants that have grown up from nuts promiscuously stored up for the manufacture of *Copprah*, as the dried kernel usually exported is called. The plants require to be watered till they are firmly rooted, and throughout the hot season, which will have to be repeated even in the case of grown up trees if on a purely sandy soil. A sandy, clayey soil is best adapted for its growth. Filth and refuse of fish form the chief manure, while ashes and sand are also commonly used for the same purpose, the former being generally restricted to large coconut *topes* along the seashore very often occupied by a long succession of fishermen's huts, and where possible, deposits of rivers considered highly fertilizing are largely used. In addition to all this, the base of the young plant is yearly dug up and covered with a thick coating of sand which practice, if kept up even after they become trees, will tend to benefit them much.

The time at which the tree begins to blossom varies according to the nature of the soil, the earliest instance whereof being five years from the time of planting, and the latest twelve years, while there is a particular species which begins to bear when it is 18 months old, but this is not likely to be of much use as it does not last long. A full-grown tree averages in height between 60 and 90 feet, and if in a favorable locality, produces between 90 and 100 nuts, while the smallest number obtainable from the worst specimen of the kind, ranges from five to ten, and these nuts are gathered every month or at least ten times a year. A tree under favorable circumstances will go on thus bearing for about 80 or 90 years, and live to the age of 120 years, though by this time the produce will dwindle considerably. Toddy-drawing for the first three or four months after blossoming, is considered beneficial to the trees in that the treading down of the branches is calculated to give them fresh life, but if continued, the annual income derived thereby will in no way stand comparison with that obtained by the sale of nuts.

Beetle and other insects sometimes eat up the tender shoots of the young coconut tree. These are carefully removed by means of a sickleshaped pointed iron instrument, and the part affected well stuffed with salt, ashes and sand which cure it in no time. If this means be not resorted to, the tree will wither and die away. Leaving this out of account, we know of no other baneful agencies to the trees, excepting of course such natural causes as lightning and excessive drought, over which human precautions, however, can have no control. The data given above are, we hope, sufficient to enable those interested in this cultivation to draw their own conclusions as to the paying character of the enterprise, which is all the more to be pursued, as it is a well known fact that there is not a single part of the tree that is valueless.—*Madras Standard.*

THE NEW CEYLON AND ITS PRODUCTS: THE GUTTA TREE.

The following extracts from the diary of Capt. Witti (for which, as before, we are indebted to the directors of the North Borneo Company) describe the chief features of his journey in May and June last from Marudu, Bay, his former starting point in the extreme north of the island, to Elopura, Sandákan Bay, on the northwest coast:—

May 14.—We crossed the Upper Bengkoka at a point to the south of Mandurian, where we had to stop, as the next village, Toyon, takes a whole day's travel. The reason that kept us was the want of water between this and Toyon. Tomorrow we shall have to carry our supply in bamboo-pipes as if we had to cross some arid plain, and yet we shall move through a luxuriant forest as we did this morning.

This is the region pronounced by a professional planter to be the Ceylon of the future. He may be right, though he passed his judgment on a distant view (from the mouth of the Tandek). The ground between this and Tandek rises along our route to 900 ft.; its *maximum* is scarcely 200 ft. higher, and is confined to the ridge forming the watershed between the direct drainage to Marudu Bay and that to the Bengkoka river. The remainder undulates between 200 ft. and 450 ft., and is moderately sloped and well watered. On the Tandek side the alluvial plain comes to an end near Kalimo; the elevation of the Bengkoka bed is 200 ft. above the sea. The vegetable detritus is on an average one foot and a half thick, a brown friable mould; the subsoil is disintegrated sandstone. The growth is very dense; trees of more than 3 ft. girth are scarce. None of the industrial plants are known to grow hereabout in a wild state.

The Bengkoka river, forty yards wide, could in time of floods be ascended thus far, but the current must be very strong then. A clearing indicates the site of a former Dusun village. The people evidently found themselves between two fires, through visitors both from Bengkoka and Bongon, for they retired to some uninviting mountain top and only show themselves on market day. We passed one market, held in the bed of the Tankalanan, a tributary of the Tandek.

We spent the night camping *al fresco*. The leaves of wild plantains would have afforded a roof in case of rain; but, although wished for, it did not come. Thus we kept waking all night, slapping at mosquitoes. We had made a large fire, just as if we were in a Hungarian plain at winter time, trying to keep the wolves off; but the mosquito is an undaunted brute.

May 16.—The tract we have entered is decidedly hilly. From the Bengkoka river we rose to 1,350 ft. in a steep pitch, and then, from a comparative clearing, we could see that there are four different ridges in the east, with their main axis running north and south.

The village of Penenian, situated to the north of the path of Toyon, is a little community of Mamagun Dusuns, who live a quiet existence on the rice and vegetables they grow, on the fowls they rear, and never bother themselves about indiarubber and the outer world.

Ascending from Penenian to the south-eastward, we came through a heavy timber forest, the highest level above sea being 2,300 ft.; and we are now in the Sonzogan country, the source of nearly all the gutta percha that finds its way over to Marudu.

Emerging from the thick forest, what a burst of landscape! How the mountains crowd towards this peninsula! A coffee planter would find it worth while to examine it. He could select his elevation up to 3,500 ft., and the Bengkoka offers water carriage. The forest is partly the same growth as on the range between Tambunan and P[illegible]r. The soil is very porous.

May 17.—The ridge along which we are moving connects those mentioned before; we already passed two of them. The slopes are steep, no water is to be had for miles, and there is no higher animal life noticeable in consequence. The rainfall, during the other seasons, must be copious; this is shown by the presence of gutta plants. We travelled some miles over [illegible] timber forest. The soil is open and porous, [illegible]

no signs of surface drainage, and the gullies are at this season all overgrown. Whenever a spring occurs on the hillside there nestles a village close by, but villages are few and far between. This comparative paucity of water applies by no means to the valleys.

Around Tinaan a considerable space is under cultivation, while with the other villages the planting grounds lie at a distance. These people live on the Dioscorea bulb (yam), but they grow rice for sale. The grain is not to be had at a short notice; our hosts were busy during the night in husking the padi for our consumption. The Bajows coming from the coast only buy the padi for the sake of a trifling profit, and to give their women at home something to do.

May 18.—The country traversed today is watered by the Sonzogan rivulet, an affluent of the Bengkoka, and is a dense jungle instead of timber forest. In it we saw both the gutta creeper and the gutta tree. The latter, a Spotaceous plant, yields the stiff variety known in the Singapore market as "Guttah kras," or "Guttah merah" (gutta percha). From the former, representing "Roxburgh's Urceola elastica," is obtained the "Guttah lichak," or "Guttah susu," the indiaraubber proper, I believe. It is a pity that these Dusuns cut down the tree just as they do the creeper. They extract the milk by a number of circular incisions from eight inches to one foot apart. The milk of the "Urceola" we found snow white, but of little consistency at the time. The stem in question was one foot in diameter, and but recently tapped. Among the Dusuns to the south of Kinabalu a fine is imposed for cutting a tree down; at the Upper Kimanis the offender has to pay a buffalo. As gutta collecting gradually comes under the practical control of the company's officers, a sort of jungle-conservancy might be established with advantage. Thus, the collectors ought to be taught the South American (Pará) method. Dusuns are a tribe open to sensible advice.

The rock here is sandstone. In the Sonzogon we found nothing but crabs, which however delighted our men, who are very keen on them.

May 19.—In the jungle today we saw trunks of the gutta-percha tree having a girth upwards of six feet and nearly a hundred feet in height. One of them seemed to overbridge a crevice. We halted at Palin, the last village in the Sonzogon country. These Dusuns have the peculiarity of pronouncing the *yo*, *ya*, as *zo*, *za*. But their indifference to the use of salt is much more peculiar. A brine-spring in the vicinity of Palin is scarcely ever resorted to, and they never give anything for salt brought to them from the coast. This applies to the whole Sonzogan people, who live, as already stated, on sweet potatoes and water. The returns for their rice and gutta they hoard up in the darkest recesses of the bush, consists of brass in every conceivable shape—the only thing their heart is set on.

May 25.—Between Nolumpis and Kagasingan the country does not rise to more than 1,100 ft. It is mostly covered with old forest, and well watered. In the fields around Kagasingan the Nicotiana strikes the eye most; badly cured, it yields a good second-class tobacco.

June 12.—Where the nominal alteration of the river occurs, there stood formerly a village, Sapaan, and there also joins a rivulet, named Luon do Parei, on the left shore. Below there the shores are flat, and the jungle is interrupted by abandoned planting ground. The stream is fifty yards wide, easy, and too deep for snags. The principal growth is rice and sugar-cane. The Tambonuas know how to prepare raw sugar. The welcome gift of Orang Kaya Bimua consisted of a cupful of molasses and a lump of bay-salt. The quality of tobacco is even lower than the grounds whereon it is grown. I quite understand the troubles we had with the rain (which I hear from Mr. Pryer was rather unseasonable), on seeing the rice stalks here two feet high. At Tampassuk the season is not so advanced; there they just commence to dress their rice fields. On the other hand, the rains "behind" Kinabalu—that is, to the S.E.. E., and N.E. of it—set in much later than on the west coast.

Having had occasion to observe Tambanuas in four different rivers pretty far apart, I can safely assert them to be superior to the Dusuns proper in several respects. Industry and quick perception are common to all the aborigines in northernmost Borneo; but the Tambonua is free from drink and dirt, and there is about Tambonuas not only nothing ferocious known, but they are possessed of the only redeeming feature of the pure Malay race, namely, a sense of decency and politeness.

June 13.—On the way to the Kinabatangan we counted no more than twenty-five houses, scattered over five miles of the river-course. The remaining portion of the latter was found today fifteen miles and a half long. That gives the whole Lukan river twenty miles throughout—at floods, even for a steamer drawing 10 ft. To that the Koun Koun would add, for small craft, thirty-six miles, of which, however, only eleven are below the rapids. It is, on the whole, a respectable waterway into the zone between Kinabatangan (Meliao) and Labuk (Linogu). I understand the Lukan Koun Koun to be the most considerable of all affluents to the Kinabatangan, keeping its head-waters apart.

That the long stretch of country between Labuk and Kinabatangan is almost uninhabited will hardly prevent its being resorted to as a source of gutta, rubber, camphor, beeswax, and rattans. There is but a small tract on either end of the Koun Koun where collecting produce has been initiated, but that scarcely breaks into such a vast field.

On the general appearance of the Kinabatangan shores, &c., I have little to remark: the jungle is less imposing than that up Koun Koun, the Linogu and Sugut, but will be so much the easier cleared of for agricultural purposes; and the constant accession of fresh soil should guarantee great fertility. Just now the banks are flooded and a considerable area seems converted into a lagoon; the sediment is of truly Nilotic proportion. By estimate the river has here (below the Lukan fork) 30,200 cubic feet every second, and the Lukan has about one-twelfth of that quantity. Dry and rocky spots are but few, and on them I cannot discern flood marks above the present level. The river is seven to ten fathoms deep; it strikes one the more to see in mid-stream some grounded log peeping out like a hippopotamus.—*Field.*

MANURE ADULTERATION IN SCOTLAND.

(*Field*, 11th February, 1882.)

During the last few years the greater part of Scotland has been covered by the operations and influence of district analytical associations—*i.e.*, associations formed in the various districts with the view of checking manure and feeding-stuff adulteration by providing increased facilities for analysis. While the operations—indeed, the bare existence—of these associations afforded farmers a considerable degree of protection from the dishonest manure manufacturer and the unscrupulous agent or disseminator, it was found by the more intelligent independent farmers that something of a stronger character was required—something of the nature of a central organisation. Accordingly, the Highland Society was moved to reorganise its chemical department, so that dishonesty might be not only detected, but also exposed, as was done by the Royal English Agricultural Society, so fearlessly and effectually.

Last year was the first under the new *régime* of the Highland Society's supervision over the whole of Scotland, and it has revealed an amount of fraud that few expected could at this of day be practised with impunity.

The local analytical organisations are not only continued, but are subsidised by the national society. The Highland Society give a money grant for each analysis to the local societies who conform to certain conditions laid down by the central society. Thirteen of the district associations were able to avail themselves of the Highland Society's aid the first year, and many more are about to qualify for the grants.

These thirteen Societies, representing the counties of Forfar, Perth, Caithness, Aberdeen, Inverness, Roxburgh, Kincardine, Lanark, Ross, and Orkney, had last season 195 analyses of manures and 26 of feeding stuffs made, and the Highland Society's chemist (Dr. A. P. Aitken) summarises the results of these analysis in an interesting and instructive fashion. The Highland Society's contribution for each full analysis is 5s., and for each partial analysis 2s. 6d.; but the total sum thus spent by the society is at present limited to £250 a year.

With reference to the undissolved bone manures, the chemist found good value sold as a rule, though a few samples were from 18s. to 30s. per ton short in estimated value, according to ascertained composition. The average composition of undissolved bone samples represented 51 per cent of phosphate and about 4½ per cent of ammonia. Some samples sold as bones, however, contained less phosphate and more ammonia than genuine bones would yield, while a few others contained too high percentages of both. They had, in Dr. Aitken's opinion, been mixtures of nitrogenous and phosphatic substances, evidently not pure bones, and costing about 20s. per ton less than genuine bone meal. Such mixtures may be good enough manure, but Dr. Aitken very properly suggests that they should be sold only as what they are—nitro-phosphates or bone-nitro-phosphates.

Next came dissolved bones, which formed the largest portion of the manures tested. It was found that a great deal of stuff was sold under that designation which had no claim to the title. The practice is still common of selling nitrogenous matters in combination with soluble phosphate as dissolved bones, with very little bone in it. It is here the unscrupulous manufacturer or dealer obtains his big slice of profit. Dr. Aitken suggests that those mixtures which are palmed off as dissolved bones, but have not much trace of bone, should by chemists and manufacturers be designated nitro-superphosphate. Dr. Aitken's conclusion is that farmers pay too dearly for their bit of sentiment in favour of the term "bone manures." Great difficulty is experienced by chemists in determining whether samples are made from pure bones or not, unless the mixture of the substitute for bones has been unskilfully made, and then the distinction is quite easily traced. Sixteen of the samples of so-called dissolved bones which came under the chemist's notice could not have been pure bones dissolved in sulphuric acid. They had too low a composition for that, and had been evidently manufactured from cheaper material; while the average value of the samples conforming to genuine dissolved bones was £7 9s. per ton. That of the mixed samples, calculated on the basis of composition, was only £5 8s., and their average selling price was £6 17s. per ton; so that farmers were paying at least 29s. per ton too much for the manure. With several of the samples there was an overcharge of £2 per ton, or about 25 per cent. Dr. Aitken finds that, if the Caithness Association has paid £7 per ton for a manure called vitriolated bones, whose value is £5 per ton, the Strathearn Society in Perthshire has paid £7 8s. for a manure whose value is £5 2s.; and the Lanark hire Association has actually paid £8 10s. for a manure whose value, reckoned at the highest, is only £5 6s. per ton. The Carse of Gowrie Society paid £9 5s. per ton for so-called dissolved bones, which were only value for £7 2s.

In Scotland, more perhaps than in any other part of the Kingdom, farmers have almost a slavish reference to the word "bone" in manure. Dr. Aitken now gives them one more proof that their sentiment on this score is being taken advantage of by unscrupulous merchants, who sell as bone manure that which really contains very little bone.

Experimenters and experienced chemists have in recent years endeavoured to persuade Scotch farmers that they need not trouble themselves about the sources of the phosphates and ammonia they use as manures, provided they get an article showing a reasonably good composition. Dr. Aitken now tenders further advice in the same direction when he says: "If a farmer gets a manure with 20 per cent or upwards of soluble phosphate, and 2½ per cent or upwards of ammonia, he need not trouble himself to inquire whether it was derived from bones or not, and the less bone he is able to see in it the better. Visible fragments of bone in such a manure may seem a satisfactory thing to a farmer who has a respect for bones, but they are really an indication that the bones have been imperfectly dissolved, or perhaps added to some other phosphate of different origin." The dissolved phosphate in bone is at last believed to be no better than any other dissolved phosphate, and the ammonia in bones is slower in action than ammonia in some other forms.

The samples of superphosphate analysed showed a high range of quality, averaging about 30 per cent of soluble phosphate, and costing only about £4 15s. per ton. With three or four exceptions, the samples were quite up to the guaranteed analysis. One sample from the Buchan district of Aberdeenshire, costing £4 5s. per ton, was so inferior in quality, that it was still about £1 12s. per ton above its value. A sample from Easter Rossa was £1 15s. per ton over its value.

The Peruvian guano was well sustained in phosphates, but fell considerably short in ammonia. Almost all the samples were at least 1 per cent short, and some were as much as 3 per cent under the guarantee, representing an overcharge of £2 per ton. One sample from Lanarkshire contained only about half the guaranteed amount of ammonia, and was valued at £3 8s. 6d. less per ton than the selling price. Some of the samples of guano dissolved in sulphuric acid showed very unfavourable results. Their composition indicated an overcharge in price of about 50s. per ton. One sample of dissolved Peruvian guano from the Strathearn district of Perthshire, sold at £11 8s. per ton, was value for only about £6 6s. The application of sulphuric acid to Peruvian guano is discouraged by Dr. Aitken, and seemingly is not a cheap means of applying fertilisers to the soil.

The so-called special manures, however—such as potato manure, turnip manure, cereal manure, grass manure, &c.—are a yet more unsatisfactory result. Taking the turnip manure first, Dr. Aitken found that for these about £1 per ton more was paid than the corresponding value of dissolved bones could have been obtained for. Potato manures are still more deficient. Calculated on the same scale as the composition of dissolved bones, it was found that the potato manures which cost on the average £9 7s. per ton were only value for £7 1s., showing an overcharge of £2 6s. per ton. One potato manure from the Carse of Gowrie had been valued at £3 8s. per ton below its selling price; another from Strathearn, sold at £11 per ton, had only value for about £6 7s. So-called barley manures in Strathearn had been yet more dear purchase. One sample, costing £9, was at most worth no more than £6 17s. per ton, indicating an overcharge of nearly £2 per ton. A few of the special manures are up to, and now or two over, the guarantee; but the greater proportion have been found to be over value. The average overcharge Dr. Aitken found to be about £2 per ton.

The results should prove an invaluable lesson to farmers who persist in buying special manures, instead of purchasing the materials themselves and mixing for themselves. The whole of the standard manures, for

instance, analysed by the Strathearn Association, showed a deficiency in value of 3s. 6d. on the average per ton; while the special manures—turnip, potato, barley manure, and dissolved guano—indicated on the average a deficiency of £2 13s. 5d. per ton. The oldest analytical association in Scotland (that at Kelso) seems to have banished the unscrupulous dealer from its domains. The manures analysed for it last year yielded results on the average 12s. per ton over the buying price in value.

Dr. Aitken remarks: "One is apt to conclude, from a consideration of these analyses, that if manure is made to contain a little of everything, you may call it what you like. If it is called dissolved bones, you may get it for £7 per ton; if it is called turnip manure, you may pay £8 per ton for it; while, if it is called potato manure, you will probably require to pay £9 per ton for it, or perhaps a little more. The chief difference seems to lie in the name, and the name commands the price."

It is to be hoped that the farmers, not only of Scotland, but of the United Kingdom, will profit by Dr. Aitken's investigations and reports, of which, for 1881, the above is a summary.

Briefly stated, his advice to farmers is to buy artificial manures only by guaranteed analysis, to purchase the staudard articles and mix for themselves, to avoid so-called "special manures," and not display such an attachment to the word *bone*.

A CHEAP APPLIANCE FOR SULPHURING VINES.

The following letter has been addressed to the Editor of *The* (Melbourne) *Argus*:—

SIR,—Allow me through your columns to make known to my fellow vignerons a very simple and effectual contrivance for applying sulphur to vines.

Anyone who has sulphured on a large scale with bellows knows how unsatisfactory they are. Expensive to begin with, they always get out of order. The thin wire gauze which covers the narrow outlet becomes constantly choked with sulphur, and besides, on account of the force of air wanted to get it out, most of the sulphur is sent beyond the vine it is intended for.

Some Italians in my employment suggested to me last year small bags of cheese cloth, filled with sulphur and shaken over the vines, something of the kind being used in their country. This, however, did not answer for any length of time, the cloth becoming soon closed up by sulphur.

The idea struck me to take four pieces of deal, each 8in. long and 6in. broad, and to nail them together into a box, top and bottom open, 8in. high, and 4in. or 5in. inside. I closed the bottom part with a square piece of very strong wire gauze, 144 squares to the square inch, and nailed across the open top a round piece of wood to be used as handle. This answered admirably. The sulphur only comes out when shaken. The man who applies it holds the box with one hand over the vine, or alongside, if there is any breeze, and a tap on the side of the box with a stick in the other hand, just causes an even spray of sulphur to fall through the wire gauze.

I have just sulphured 20 acres with this simple machine, using about half the quantity of sulphur which the same amount of ground required in former years, and yet this time the vines were more thoroughly and more evenly sulphured.—I am, &c.,

VIGNERON.

OSTRICH FARMING

The subject of ostrich farming has been engaging a good deal of attention in South Australia. Mr. W. Jones, who has lately returned from a visit to the Cape of Good Hope, has contributed in the form of a letter to the Agricultural Society particulars of an interesting character in relation to the conduct of the industry. The *Observer* quotes Mr. Jones as follows:—"Good breeding birds may now be obtained at an average of £150 a pair. So-called 'breeding birds' may be bought for less, but birds of six years old and upwards are not easily obtained. For export birds should be not under five years old, and should have bred at least two seasons, as these birds are much stronger and are not so easily impaired as younger birds. The latter are very apt on being removed to cease to breed. This pairing of birds is a matter involving much care, as the ostrich is very fastidious in choosing its mate, and sometimes it is necessary to change the bird three or four times before pairing takes place. A pair of ostriches landed in Adelaide by Orient line would cost at least £200, unless a reduction of freight could be obtained by exporting a considerable number; but of course if a sailing ship were chartered the cost would be less. Assuming the larger price, say 50 pairs at £200 each, £10,000; a farm of 100 acres at £25 per acre, and necessary buildings, £4,000. The buildings required would be of a cheap character if constructed under the superintendence of a practical ostrich farmer. About 20 incubators would be required. A pair of good birds would produce, stating a low estimate, 60 eggs per annum, of which at least 75 per cent would be hatched, giving 45 chicks per annum per pair, equal to 2,250 for 50 pairs. From this 2,250 take off 20 per cent for loss during the first three months, leaving 1,600 young birds, worth from £7 to £7 10s. each. This mortality may be greatly reduced by properly constructed buildings to guard against sudden changes of temperature or rain, which latter is most injurious to young birds. The returns would thus show 1,600 birds at £7 each, equal to £11,200. The food necessary for a full-grown pair of breeding birds is 7lb. of oats or barley per diem, and about a bushel basket full of cut green food, cabbage leaves, lucerne, clover, green barley, or anything of this description. The best place for keeping ostriches is on a light soil, sandy in patches, sloping down to a river, so that green food—an absolute necessity—can be depended on all the year round. During the late long-continued drought in the Cape Colony birds have died in large numbers where no water was to be had, but on farms near water they have not suffered at all. Young birds should be kept for feathers, as it is not advisable to pluck breeding birds. A few long feathers may be taken from the cocks, but they are not of much value owing to the habit breeding birds have of moving in a peculiar manner, which spoils the feathers. The value of feathers is about as follows:—About eight months old the feathers cut are worth about 13s. to 16s. per bird; at 16 months, about £4 per bird; at 24, about from £5 to £7 per bird, and thereafter about from £5 to £8 per bird every eight months, according to quality."

The *Bairnsdale Advertiser* mentions, as showing the confidence evinced in the hop industry, that the area hitherto planted has been about doubled this year, making a total of close on 200 acres under cultivation at the present time. All the growers are now busy poling, and if the yearlings yield as expected there will be plenty of employment for a large additional number of pickers at the beginning of next year. —*Australasian.*

RASPBERRIES IN TRENCHES.

In the following, from the *Journal of Horticulture* we think many of our readers may find a method of growing raspberries successfully in the metropolitan and other rather warm and dry districts:—

Some years ago an account appeared in your columns

of how a gardener formed a most fruitful raspberry bed, by opening trenches and burying a large quantity of vegetable refuse, I think. Will you kindly repeat the advice as an appendix to the article on raspberry culture last week?—J. E.

The following is an extract from the article referred to, which was communicated by Mr. Luckhurst. We saw the raspberries in question when in full bearing, and the canes and crop were remarkable:—

"Having had occasion to pay more than ordinary attention to the culture of this fruit, a few words concerning a failure and its remedy may prove useful to others. In planting a few rows about four years ago no particular care or preparation of stations was thought necessary, although the soil was obviously the reverse of rich. Unbroken success had very likely given me an impression that the raspberry would thrive anywhere and in almost any kind of soil, and this feeling was strengthened by the sight of a bed of 'wild' rasps growing luxuriantly in an alder swamp within 100 yards of the garden. The soil was therefore simply trenched, manured heavily as for vegetables, and the raspberries planted. A tolerably vigorous growth yielding fruit in due course was the result. But I was not satisfied; the fruit was neither so large nor plentiful as was required, and I resolved to start afresh, reserving the old plants for present exigencies.

In making the new bed particular attention was given to ensure a robust growth, which in the raspberry implies an abundance of fruit, and to arrange the whole so as to make it an easy matter to protect the fruit from the ravages of birds. This was managed successfully by making the rows side by side 5ft. apart, and with the plants 1ft. apart in the rows. Trenches a yard wide, 2ft. deep, and filled with the soil—leaves and dung of some old hotbeds well chopped and mixed, being prepared for each row. Large fruit and plenty of it was the object in view, and Prince of Wales was chosen as the best kind for culinary purposes, its fruit being very fine; but as it is not so sweet as some it would probably not be generally liked for a dessert fruit.

"It was reasonable to suppose that this careful preparation of the bed would produce proportionate results, but I must confess I certainly did not expect to see anything like the extraordinary vigour of the first year's growth. Not only did the roots spread over the trenches, but they quickly met and became interlaced in the alleys, the entire surface soon bristling with suckers, which could only be kept under by repeated hoeings. The canes left to grow in the rows were wonderfully robust; and the old canes, which had been shortened to about a foot at the time of planting, put forth some shoots bearing such good fruits as to cause one to regret having shortened them so much. I do not, however, think it good practice to leave the canes of a new bed unpruned as is sometimes done, but would always reduce them to 1ft. or 2ft. In autumn when the leaf had fallen two wires were strained along each row, one 2ft from the ground, and the other about 3ft. 6in.; the canes were then pruned a uniform height of 4ft., tied upright to the wires, and the work was complete.

"The bed has now been in full bearing for two seasons, the fruit being both abundant and fine. A heavy annual top dressing of manure is given to the alleys. The soil is never disturbed, but remains intact just as it was left after the planting. As the fruit ripens the bed receives one or two thorough soakings of water or some liquid manure, which proves very beneficial to the crop, making the latest pickings of fruit quite equal to the first in size and colour."—*Australasian.*

THE ESPIRITU SANTO PLANT.

Of all the orchidaceous plants that grow on the Isthmus of Panama, there is none that appeals to the religious sentiment and popular imagination so strongly as the celebrated dove plant or *Espíritu Santo* orchid. The exquisite mimicry of this class of plants is seen in this species to take the form of a dove with outspread wings, sheltered in the bosom of the flower. While other and more gaudy orchids excite the wonder and curiosity of the beholder in seeing the wonderful likeness to bees, butterflies and other insects, the Espíritu Santo appeals to a higher and nobler sentiment. The plant produces a long spike of yellowish white waxy flowers, yielding a very peculiar fragrance. On looking at the flower the centre of it exhibits a column which, with its summit, and the projecting gland of the pollen masses, bears a very striking resemblance to the figure of a dove, whence the English name of the genus.

The Spanish ladies, with that respect for the imagery of the Roman Catholic Church, in which the dove takes so prominent a place, associated the name with the bird selected by the Holy Spirit to witness the Baptism of our Saviour, and by this name it is still known. To call it the Holy Ghost flower sounds harsh and even irreverent to Protestant ears. The effect of the Espíritu Santo flower is at once devotional and poetical. That it should form a striking subject for the exercise of some of the Spanish American poets, who have seen the plant in its native wood is natural and to be expected. They have not only celebrated the flower in their verses for its natural beauty, wonderful structure and fragrance, but have seized on it to express and mourn over the sorrows of poets in general, to whom the gift seems inseparable, from worldly disappointment and privation. Many of them, in order to produce the works that continue to charm the world, "had no time," as the lamented Agassiz said, "to make money." Thomas Martin Feuillet, of Panama, who wrote some exquisite pieces of Spanish poetry, and died young, has a poem on the Espíritu Santo flower of Panama, addressed to a lady. In the two last verses, he expresses a hope, when he is laid to rest in the grave, that although he expect no one to shed a tear to his memory, some kind hand will lay on the black pall that covers his coffin a few flowers of the Espíritu Santo. The verses are as follows:—

> "Ah! Cuando à fuerza de tormento horridos
> Cese de palpitar mi corazon:
> Cuando deje esta vida triste y mísera,
> Para dormir tranquilo en el panteon,
> Yo sé que nadie verterà una lagrima;
> I ojalà que siquiera por favor,
> Alguien coloque en mi enlutado feretro
> Del Espíritu Santo alguna flor"

The love of flowers is very common in Panama, and few balconies are without them.

The Espíritu Santo plant or *Peristeria elata* was a favourite of the Nuns, but cannot be made to go on flowering in Panama. The bulbs may be preserved alive for a long time, but they refuse to produce flowers. They must have a period of rest in a comparatively cool atmosphere, but during their growth and flowering they require a cool and very moist atmosphere. The hot and dry seasons send them to sleep, and sleep on they will in the air of the coast and city, while such conditions of the requisite moisture and temperature are kept from them.

The supply, however, is kept up by several Panamanians who make it a business to look for them on the forests that skirt the higher regions through which [illegible] passes, especially [illegible] Lion Hill Station. They are [illegible] found [illegible] in Veraguas or Chiriqui, though the Cordilleras of both these departments abound in exquisite and rare orchids. These

plants are often offered for sale in the streets and before the Grand Hotel of Panama, where passengers obtain them at from three to five dollars the dozen of bulbs in flower. They flower in July, August and September. Though the Espíritu Santo plant belongs to the terrestrial orchids its bulbs should never be covered with earth as is generally done. They should be put in pots when they begin to grow, and though they require a stronger compost than those that adhere to trees, do not need so much drainage as the latter. The Espíritu Santo is best grown in pots with fibrous loam, leaf mould, and sandy peat, with a good quantity of water during their period of growth after which they must have a good season of rest, and kept nearly dry at the roots; if allowed to get wet during their rest they are apt to rot. In the hothouses in Europe this plant continues blooming for two months when the flower spikes are strong. In Chiriqui the species there called by the same name is a *Cycnoches* having no resemblance at all to the Espíritu Santo plant of Panama, and is an epiphyte growing on trees, and so named from the flowers taking the form of a swan. There exists on the Isthmus a variety of the Espíritu Santo with yellow flower, and the dove a fawn colour.—*Journal of Applied Science.*—[In Ceylon the Pigeon plant is common, cultivated on the stems of coconut palms or other garden trees.—ED. *T. A.*]

TWO "NEW PRODUCTS" DISTRICTS IN CEYLON.

Some information regarding two districts in which new products are being cultivated with undoubted success; one of them being an old district rejuvenated with new products; and the other entirely new, being cultivated with Liberian coffee and tea, with a little rubber here and there. The first of these, namely the district of Matale gives promise of as good results as any other part of the island; and all who have witnessed the cocoa and Liberian coffee which are the principal products there cultivated, agree in opinion that these could be nothing finer than is to be seen there. How it comes to pass that estates that have for years refused to yield profitable returns in the "Arabica" variety of coffee, are doing so remarkably well in other products is, a matter with which we do not intend to deal; our sole object at present being to set forth the progress made in these new industries, and what is likely to be obtained from them. Although we have said that the old-fashioned coffee *Arabica* has not been answering expectations of late years, much of it is undoubtedly at the present time promising remarkably well, and in a number of instances will give larger crops than most of the estates in the new districts. The estate to which attention is particularly directed is situated about three miles from Matale, in a north-easterly direction. For a year or two the old coffee on this estate suffered terribly from the inroads of *hemeleia*, and most proprietors would have lost heart by successive failures of crop, and probably have abandoned the estate, or at any rate ceased to to have any care for it. But not so the stout-hearted proprietor who has never lost faith in the ultimate results of careful and systematic cultivation; not the cultivation which means simply pouring in cart-loads of manure, but the cultivation which is directed to mortal combat with *hemileia*, and this object has never been lost sight of on the property of which we are now writing. Diseased leaves have been carefully gathered and dug into the soil, the trees have been carbolised not profusely, but sufficiently, and the result, after an interval of time, is quite sufficient to encourage the proprietor to persevere in his efforts. Every one who has visited this property admits that the coffee looks as well as coffee can look; and that if vigorous vitality can fight disease, these trees have are bound to do it.

But it is to the new products such as cocoa and Liberian coffee to which attention is more particularly drawn. On passing through this estate one might well imagine on looking at the splendid cocoa trees now bursting into fruit, that they have been planted in virgin soil. The red ripe fruit on the Liberian coffee have a cheerful, pleasant look, and assures us that there is something good in store, and one only regrets that something of all this was not done a dozen years ago instead of so recently. This, it must be remembered, is in a district not over-favored with rain, and in that respect very much the reverse of the conditions to which new products in low-country districts are cultivated.

One of the newest opened, and certainly one of the most flourishing of the lowcountry districts is that of Kalutara, where, although the first Liberian coffee estate was opened three or four years ago, yet the district itself is comparatively of recent date, and much of the land is still being opened and planted. The only product which does not seem to have thriven in this district is cocoa, which has hitherto been a failure. Opinions are somewhat divided as to whether this is owing to too much wind or an insufficient depth of soil, but its non-success is a fact all the same. The first estate on entering the district is that of Putupaulla, now a thriving Liberian coffee estate, almost in full bearing, and shewing a crop on the trees that is refreshing to look upon. There is no sign distinguishable of hanging back or refusing to ripen, as asserted by some writers; and those who are interested in the property declare they are well satisfied with the result of the venture. Perhaps we can mention no more certain indication of confidence in new products in this district, than the action of one of the latest pioneers,—one of the contractors for the Nawalapitiya and Kalutara Railway lines, who has purchased four or five hundred acres in this part of the country, and intends to open the whole of it out for Liberian coffee and tea, as being the most promising products for lowcountry cultivation.

Nothing could possibly surpass the appearance of the Ceylon Company's tea estate in this district. The trees are strong, healthy, and with a magnificent show, of wood and leaf-just what one would desire for a good paying tea estate, and there is no doubt that the Company is fortunate in possessing this property. There are other products cultivated in this district, such as cardamoms, rubber, &c., but these are at present of small extent. All that this district now requires for its development is a good road, which shall open up the bulk of the estates, and connect them with the blocks of Crown land situated beyond them, in an easterly direction, where a large extent of fine forest is available. By the end of January the road being completed, a visit to these properties will form a pleasant excursion from Colombo, and we can imagine no more attractive objects than the number of new products in high cultivation and yield, which most of these will shew next year.—*C. Times.*

PHYLLOXERA.—According to the *Queenslander*, a remedy for phylloxera is claimed to have been discovered by a Mr. D. M. Johnson, of Pelham Manor, New York, who states that he finds crude petroleum an excellent destroyer of the insect. He makes numerous holes in the ground with a sharp-pointed stick all about the vines, and into each pours about one ounce of the oil, which soaks into the soil and destroys the insects on the roots of the vine. Mr. Johnson intends to claim the reward offered by the French Government for a practical phylloxera destroyer.—*Australasian.*

ANALYSES OF CINCHONA BARK.

There is now a very general consensus of opinion that, however much distinctive characteristics of flower, fruit and foliage (in the *Ledgerianas*, for instance) may indicate the probable quality of the bark which trees will yield, the only certain tests are analyses of the bark of typical trees at different ages and in different circumstances of soil, elevation, aspect, &c. These we might more correctly than the writer of a short editorial in our local daily contemporary call "features": only we cannot well see how "records kept by the various "District Associations of the results of analyses of "bark * * * would form a very interesting and instructive "*feature*, which [the *feature*, of course] might properly "be communicated to the parent body and printed [the "*feature*] for general information in the annual volume "of proceedings"! The objection to frequent and numerous analyses is the heavy expense, but, if a "feature" is to be printed, the cost of a photographer's services will have to be added to that of the chemist's analyses. The same writer states that

It has further been noticed by those engaged in systematic analyses of cinchona that the act of separation of the bark from the tree has frequently the effect of increasing the secretion of quinine in the removed bark, which has been found to yield a higher percentage of the alkaloids three months after removal from the tree, than at the time of separation.

We have had some experience of cinchona, but this fact is entirely new to us. If bark increases in yield of alkaloids up to three months *after removal from the tree*, the rate of increase may be so great with each succeeding month, that it might pay to keep bark in estate or Colombo stores for a year or more. All would depend on the rate of increase, and we desiderate information as to the percentage at the end of three months. Bark absolutely removed from the tree is evidently meant and not bark partially separated, as in Mr. Karslako's process. That process had in view the protection and improvement of the renewed bark and not any improvement in the partially separated strips of original bark. In favourable weather, however, we should think that strips adhering to a tree at both ends would be more likely to improve in alkaloids than bark finally removed from all contact with the juices which fed it and circulated through its cells when alive. We do not dispute the statement made: we only say we do not understand it in connection with the "shock to the tree" theory, and we should like to have further information. Has bark been known to improve in quality between analyses in Colombo before dispatch and analyses in London before sale? Mr. C. E. H. Symons, with reference to a question asked in the local *Times* replies as follows:—

I must say that, without tables for comparison, I do not think the analysis of bark of a two year old tree would be any guide as to the value of the bark at maturity: but, with tables for comparison, such an analysis would be of great value and satisfaction to the planter, and I would offer the following suggestion to the District Associations, explaining at first that a comparative analysis of one estate bark would be no criterion of the value of another, as altitude soil, aspect, wind, and many other things incidental to a plantation, would make such an analysis simply useless for general comparison. An average analysis of the bark from the district should be made. Each planter should be asked to send a small piece of bark of a certain weight, from a certain height on the tree, from an average tree (of course keeping varieties separate) or trees, with different aspects on his estate. He should give a separate sample from trees grown at 2,000 to 3,000, from 3,000 to 4,000, and 4,000 to 5,000 feet and so on; and of 2 years old, 3, 4, 5, and 6 and so on at these several altitudes. An analysis should then be made of the mixed bark of the two year old at 2,000 to 3,000 feet

do do 3,000 to 4,000 ,,

and so on, and also of the 3, 4, 5 &c., years old at various altitudes. The result would be a fair average of the district for the several elevations and ages; and then, and then only, could comparisons be made. A planter could send his two or three year old bark and have it analyzed, and the result would show him if he were up to or better than the average of his district, and what his bark would eventually be worth.

In taking the samples, the season of the year must be taken into consideration. as I think it has been clearly shewn that harvesting bark to the best advantage for the grower cannot be done haphazard at any time of the year.

No doubt Mr. Symons' doctrine of averages is correct, but what is really wanted is a system of very simple analyses, for quinine and cinchonidine only, which would be so cheap as to enable each particular planter in a district to have his bark at all ages and in all situations examined and reported on. If 20 or 30 planters in a district got a series of such reports, those reports could periodically be combined and compared in a general report, and then deductions of great value, founded on extensive and reliable experiments, could be made. There can be no doubt that on many an estate trees of great value, Ledgerianas or "hybrids," exist, the true worth of which is unknown to the proprietor because he cannot afford the expense of analyses. What is wanted is a system by which the chemist could be fairly remunerated by a very large number of analyses, instead of trusting as at present to payments on a high scale for testing samples few and far between.

FORESTRY IN INDIA AND CEYLON.

Our readers are well aware that we are not of those who believe that in regions such as Ceylon and Western India, exposed to the influence of monsoon moisture and with cloud-attracting and moisture-condensing ranges of mountains and hills, it is possible by denudation of forest to lessen the absolute amount of rainfall. We do not believe that this would be the case, even if nothing were substituted for the original forest. So long as the hills and mountains exist, they will squeeze out the moisture borne inland from the sea. On the ranges of Ceylon large areas have seen coffee bushes only 3½ feet high take the place of forest, averaging 40, or 50, or 60 feet in height; but, instead of complaints on the score of diminished rainfall, it is excess of moisture, with its consequences, which is charged with much of the disaster that has overtaken the coffee enterprize. Excessive moisture has generated fungus and destroyed blossom and so reduced crops to a minimum. With coffee, tea, cinchona and other products of a similar nature, planted where the primeval forest stood, and

the ground tilled and kept open, the really injurious consequence of forest denudation on mountain sides —the rapid escape of the rain in the shape of floods —is reduced to a minimum. Of course, if estates are abandoned and no trees have been planted on them, this objection would apply. There is fanaticism in Forestry, as in everything else, and, if Mr. (? Dr.) Brandis, in the lecture, report of which we quote from a Madras paper, was deprecating the destruction of forest in a river valley for purposes of coffee or tea or cinchona culture, our sympathies do not go with him. We think the Government of a country quite justified in preserving the forest on the tops and ridges of mountain systems. Such a course is beneficial even to cultivated lands at lower elevations on the sides of the mountains. We also believe in a rule, not for preserving the *original* forest on the sides of rivers—experience has proved that device to be of little use, as the isolated belts rapidly perish, besides being nests of weeds and vermin. But planters should be bound to plant up one or two chains on each side of considerable streams with fast growing trees, such as Australian gums or acacias. Such trees Government ought to supply for the purpose at moderate rates. With such precautions, the great planting enterprise, so beneficial to the country, ought to be allowed to run its course.

Restriction of what in India is called "joom" cultivation and in Ceylon chena (or, as the learned pundits will have it, *hena*) is far more called for, because, in this case, forest is absolutely destroyed for the sake of one or perhaps two poor crops. The limit of restriction should be where danger of famine might occur. But with the spread of railways, roads and canals, in India and Ceylon, there cannot be much danger in this direction. The question has, we know, been hotly debated, and the native side in the chena controversy warmly supported by good well-meaning Europeans. But here, as well as in regard to the wasteful and dangerous custom of setting fire to forest grasses, Mr. Brandis's arguments of present convenience being postponed to future good comes into full force. We are, of course, talking of firing forest and grass in lands, which are still the property of the Government; that is of the general community. If a man has purchased a piece of land outright, we suppose he may do what he likes with his own and indulge his taste for conflagration, so long as he does not so act as to endanger the property of his neighbours or that of the public. Those who have not travelled in India, in the dry season and at night, can have but a faint idea of the brilliant lines of fires which light up the darkness and define the features of the hill and mountain ranges. On some mountain ranges, as in the Eastern Himalayas, below Darjeeling, the explosions of the air-filled large bamboos add the idea of battle to that of uncontrollable conflagration. Absolutely to restrict or properly regulate such practices, so that forest reserves may be enabled to yield regular supplies of good timber, a Forestry Department is of great value; as also for the purpose of growing and distributing plants and encouraging their growth, *wherever they can be made to grow*, as in the dry regions of Coimbatore and in the north and east of Ceylon. In Coimbatore, which lies extended below the Nilgiris, even the coconut palms are grown by irrigation, and up to a certain point, irrigation streams and tanks should be scenes of tree-growing there and here. Although we do not believe that trees, grown with great difficulty in arid regions, can create rain, any more than tree denudation can lessen rain in hill regions—and while we hold that, over large regions, trees do not exist because there is no rain, instead of the popular notion that the absence of trees is the cause of the absence of rain—yet we most thoroughly believe in the beneficial influence of belts and groves of trees in modifying and improving climate locally. Our heartiest good wishes, therefore, go with the efforts of Forcsters, free from the fanaticism to which we have alluded. Trees are so valuable as well as beautiful, that much enthusiasm is commendable in those whose object it is to preserve, improve or create forests and groves and avenues of trees. And by no means can the great object be better attained, where forests exist, than by the judicious removal of old trees, so admitting light and air and encouraging the growth of young and healthy saplings. But men of one idea can do harm as well as good, and, if Mr. Brandis meant that he would not allow a tree to be cut in a mountain valley through which runs a large river, we certainly dissent from his views, and for the reasons already given. As far as the Ceylon planting enterprize is concerned, it is probable, now, that one of the great benefits it will confer on the island will be the introduction and culture of exotic trees, faster growing, and yet quite as valuable as many of our indigenous forest trees. There are many hundreds of thousands of beautiful and valuable trees scattered over estates already, and we believe that an increase of the number would be good for estate owners and for the whole country.

MR. BRANDIS ON THE FOREST QUESTION.

(*From the Madras papers.*)

Mr. Brandis, C. I. E., Inspector-General of Forests with the Government of India, at present on deputation in this Presidency, delivered a short lecture on some aspects of the forest question at Coimbatore on Saturday last. Amongst the audience were Mr. Stuart, the Acting Collector, Major Campbell Walker Conservator of Forests, Mr. Peel, Deputy Conservator, Mr. Wedderburn, Assistant Collector, Mahomed Ally Sahib, Sub-Assistant Conservator, a number of the judicial and revenue officials, and most of the leading members of the native community. The Acting Collector, in introducing Mr. Brandis, drew attention to the Governor's remarks on his recent visit regarding famine, and the influence of forests on the climate, and supplies of fuel and fodder. Mr. Brandis had had great experience throughout India, and had kindly agreed to give them the benefit of his opinions, before leaving the district. Mr. Brandis said:—

"I regret that my visit to Coimbatore has been very short, and, as I am leaving by the train this morning, my remarks must necessarily be brief. Coimbatore is a beautiful place, but it might be a desert. The climate is dry and hot; the hills dry, rocky, and devoid of trees. The great beauty of Coimbatore is due to the fine stretch of paddy cultivation, and the palm forests. I have

been told that these last yield from R. 50 to R. 100 per acre, but I think even R. 200 would not be an excessive estimate. These form the sources of the wealth of Coimbatore, and are dependent on water for their permanency. But whence does the water come? Not from the rainfall, which is very small, but from the Noyel river. This river so called, though really it is only a small stream, is the source of fertility, pleasure and happiness to Coimbatore and its people. It is a most remarkable stream. As you are aware, it takes its rise in the Bolampatti Valley, and it is on the rain which falls there, and on the mountains which surround it, that the prosperity of Coimbatore depends. I examined the valley the other day with mixed feelings of grief, disappointment and pleasure: grief at the destruction of forests, which I saw on every side; disappointment that such wholesale alienation had not been prevented; and pleasure that there was still something left, and that the damage was not irreparable. The effects of heavy rain falling on hillsides devoid of forests is well known; the water rushes off as it falls, causing disastrous floods, and none is retained to ensure a moderate and permanent supply. The certain result of the destruction of the forest remaining in the Blumputte valley would be that the water in the river Noyel during the dry months would become gradually less and less, and Coimbatore would become a desert. It is a very pretty, I might say, a grand sight to see the hillsides round your towns lit up at this season each night by forest fires, a lovely sight, but ruinous to the forests. The fires gradually but surely, eat into them, destroying twenty trees this year, ten the next, and killing all youth till the sponge, which retains the moisture, will gradually cease to exist. These fires are supposed to be necessary, and have become an annual institution. It is said that they are necessary to enable the cattle to get fresh fodder. There is a good deal to be said in favor of the argument, but I think we can effect the same thing in another way. Forests in other parts of India have been protected from fire, and the food for cattle has improved both in quality and quantity. The great difficulty which is everywhere experienced in this, as in most other matters, is that the present has more weight with us than the future, and it is not easy to forego present gain for future benefits; but you have children and I would ask you to think of them, and what will be their condition, if this lovely Coimbatore of yours, with its fertile fields and palm groves, be reduced to a desert, with the tanks, which are reservoirs in which the water from the hills is stored, empty and the river dry! It is necessary to put up with a little temporary inconvenience for future benefit, and the permanent welfare of yourselves and your descendants. I would next call your attention to the benefit of trees in a hot and dry country. I have seen forests which formerly consisted of only a tree here and there, become thick, close, and moist. The effect extended to fields in the neighbourhood; where formerly only one poor crop has been obtained, two good crops were obtained after the protection of the adjoining forests. The temporary inconvenience was well repaid by the permanent advantage. It has been said that forestry is an exotic, and not necessary or suitable for India. This is not the case. I have seen forests in other parts of India, which have been carefully protected and improved by native chiefs with the best results. I would instance Keshilghur, in Rajputana, where the reserves yielded a plentiful supply of grass and leaves for fodder during the disastrous famines of 1867-68 and '69, whilst the surrounding country was devoid of the scantiest vegetation. Besides conserving the existing forests, great benefit would result from planting the drier and higher parts of the district between the rivers Noyel and Umravutti. A man who plants a tope, or even encourages the growth of trees and shrubs on his grazing waste, confers a lasting benefit on the community. You are doubtless aware that your collector has proposed a system of 'fuel and fodder reserves' throughout the district, and I know of nothing more likely to promote your happiness and prosperity, and to mitigate, if indeed it does not prevent, the effect of future famines. The Noyel river already irrigates a very large area, considering the small extent which it drains; but I have little doubt that, with careful conservancy and extension of the woodlands, that area might be increased, and the water-supply rendered more certain. My visit to Coimbatore has afforded me great pleasure, and I hope you may continue prosperous and happy."

Mr. Stuart on behalf of the audience thanked Mr. Brandis for his interesting lecture, the gist of which he trusted the native gentlemen present would not fail to communicate to those who, through want of knowledge of English, had been unable to understand, and to the people of the town and district generally.

COFFEE ADULTERATION AND MIXTURES.

The following is the Memorial got up in London and the reply received:—

To the Lords Commissioners of H.M. Treasury.

London, 6th February 1882.

The attention of your memorialists has been drawn to a minute of Treasury dated 20th January, 1882, which directs H.M. Board of Customs to permit the importation, under a duty of 2d per lb., of *coffee ex chicory, roasted and ground, mixed, without reference to the proportion of the mixture; and the permission to extend to any other vegetable matter applicable to the use of chicory or coffee.*

Your memorialists beg to submit to the consideration of your lordships the following objections to the above order:—

1st.—That it is most unwise to give such sanction to practices which tend to deteriorate so valuable and wholesome a beverage, so well fitted to advance temperate habits among the people.

2nd.—That the legislator has been most desirous of protecting the food of the people from adulteration, and that the order just issued by the Treasury is in contradiction with the letter and the spirit of the Acts of Parliament 38 and 39 Victoria, chap. 63, clauses 6 and 8.

3rd.—That the substances which it is proposed to admit in a mixed state with coffee would of themselves find no favour, being of comparatively small value; and it is only because they assume the name of coffee, or are found in association with this name, that they become saleable.

4th.—That no good reason can be shown why coffee should not deserve as fair a treatment as other articles of Indian or Colonial produce, such as tea for instance, where regulations prohibit the sale of the pure article, with any mixture whatsoever, and even with "exhausted tea."

5th.—That the chief reason why coffee has fallen into disfavour in this country, is the systematic way in which it has been adulterated, and the consequent difficulty experienced by the great mass of population in obtaining not merely a pure article, but a wholesome and palatable beverage suitable to their means. The poor classes, purchasing coffee in small quantities, will always ask for it ready ground.

6th.—That coffee is grown in the British Possessions in India, Ceylon, Jamaica, and other Colonies, at the cost of many millions of English capital, its cultivation and preparation giving employment to many thousands of British subjects; that Ceylon in 1877 exported 105,000,000 lb. of coffee, and *British India* about 50,000,000 lb.; that by far the larger of those crops used to find their way to this country which consumes chiefly Ceylon and Indian coffee; that London is gradually losing a portion of its trade, as they are shipped now more and more to the Continent direct, to the

detriment of British shipping, and of English importers, dealers, brokers, and others interested in this article.

7th.—That the consumption of coffee in this country, which, in 1847, with a duty nearly three times as heavy as the present one, was 37,472,153 lb. or about 2 lb. per head of population, has now declined in 1881 to 31,943,400 lb. or less than 1 lb. per head, notwithstanding the large increase of population, and they believe that the consumption, if it had not been checked by unfair legislation, would probably exceed now 60,000,000 lb.

For those reasons your memorialists deem the effect of this Treasury order to be of such injury to the consumption of coffee, and the well-being of the community, that they feel constrained to urge its withdrawal.

Reply:—

"The Lords Commissioners of Her Majesty's Treasury have carefully considered the statements made in your memorial, which reached them on the 6th ultimo, complaining of a recent order whereby coffee and chicory mixed were permitted to be imported upon payment of the duty charged upon coffee or chicory separately; and they have communicated it to the Board of Trade, upon whose recommendation the concession was originally made. I am to explain that the effect of the Treasury order is simply that the articles, which formerly might be imported separately, and then mixed and sold in England, may now be mixed outside England and imported together. This permission was given, because there appeared to be a trade demand for it, and my lords deem it their duty to remove restrictions on trade where practicable. It involves no alteration of the conditions under which mixtures of coffee and chicory may be sold in England. The question of the advisableness of allowing the sale of mixtures under prescribed conditions is one which should be considered rather in connexion with the adulteration Acts than with the Customs tariff."

HIGH CULTIVATION OF ESTATES.

In the midst of all the depression around us, it is refreshing to receive, from Mr. Wm. D. Bosanquet, letters of such cheer, confidence and commonsense, as those in this issue, following others of a like nature. Some profess to have lost faith in manure, but the large majority of planters are simply unable to cultivate, as they could wish if means were available. Crops are low, because the trees are enfeebled; and because of low crops planters cannot afford to pay for the fertilizing substances they would gladly apply. Happy those who, like Mr. Bosanquet, can carry out, even in such "hard times" as the present, what they believe to be the right principles of cultivation, and all honour to him for giving his fellow-planters the benefit of his valuable and costly experiments. Apart from the commonsense about bulky matter and its value, the great point now insisted on by Mr. Bosanquet is the reversal in manuring of the popular formula of two parts of castor cake to one of bones. He would use two of the phosphatic manure to one of the nitrogenous. It is not the bones but the nitrogenous manure to which over-forcing is due. This quite accords with experience related to us by the late Mr. Anton, who believed in the value of steamed bones *alone*. As a "complete manure" Mr. Bosanquet recommends that of Messrs. Crossman and Paulin, and his recommendation will carry weight with his brother-planters. There never was a crisis when wise manuring was more required than now, and gratitude is due to Mr. Bosanquet, for placing the results of his experience at the disposal of the whole body of planters. We suppose however, that many will share the wish we feel to know the constituents of the "complete manure." It is probably prepared after one of the formulæ in the book of M. Ville, which we copiously reviewed in the *Observer* about three years ago. In that case, we should think the modifying influences of tropical sun and rains must be taken into account?

In any case, there is the great lesson:—use twice as much bones as castor cake, and in all except very high places remember that bulky matter resulting in humus is an essential to good manure.

As Mr. Hughes has been referred to, we cannot help recalling his fearful calculation, founded on observations by the Rev. Mr. Abbay. The computation is that one ton per acre of soil is washed away from estates by every 12 inches of rain. This means 5 tons per acre per annum, where the annual rainfall is 60 inches; 10 tons per annum where the fall is 120 inches; and 20 tons per annum where, as in some places in Ambagamuwa, the rainfall is 240 inches! In the face of such figures, apart from combustion by solar heat, how utterly insignificant are the quantities of fertilizing matters we are able to add to our properties, much of which, with the richest particles of our soil, goes down to the sea to be upheaved for the benefit of a posterity so distant as some millions of years, probably. If Mr. Hughes' calculations *are not exaggerated* (?) no wonder though estates, especially those with steep features, get exhausted. But the calculation is surely far too high? What have Mr. Bosanquet and other planters to say to it?

THE HIGH CULTIVATION OF COFFEE PLANTATIONS.

No. I.

To the Editor of the "Ceylon Observer."

Yoxford, Dimbula, March 31st, 1882.

DEAR SIR,—It has been borne in upon the convictions of most planters, and would be an opinion now generally accepted by the agents but that they are frequently ill advised by those who should be better instructed, that the future well-being of coffee in Ceylon depends mainly upon high cultivation and liberal manuring.

As the general teaching of my experiments on Yoxford seems to have been by many but partially apprehended, and, as it is most desirable that there should be greater clearness of view as to what constitutes a safe system of manuring, I am constrained to publish what my experiments and general practice have led me to regard as the true course to pursue, in order that others may compare their practice with mine and see in what points we differ, and in the hope that discussion may tend to throw additional light upon a subject which has such a deep interest for all of us.

In the first place, I consider that the perfection of manuring is attained by mixing bulk in some form, *i. e.*, cattle manure, pulp or decayed vegetable matter of any kind, with artificial manure, as the vegetable matter, by providing a constant source of carbonic acid in the soil, gives the fertilizing properties to the roots in the most readily available form and makes the manure doubly effective and lasting. Therefore I say instead of using a full basket of cattle manure alone to each tree, add ¾ lb. of bones to half the

quantity, and you will get a better result with less exhaustion to soil and tree. With pulp or simple vegetable compost, use ½lb. of a complete artificial manure. In manuring low-lying estates, I would never apply an ounce of artificial manure without some vegetable addition. On estates at high elevations I believe that this is of less importance, as the exhausting power of the sun is less felt by the vegetable matter originally existent in the soil.

In the second place, instead of using the customary mixture of 2 of castor cake to 1 of bones, I would advocate the reversal of the proportions, adding 2 of bones to 1 of castor cake by weight. It is, I believe, the popular delusion, and one that I certainly laboured under a short time back, that the ill effects following the use of any large application of the former mixture are due to the over-forcing power exerted by the bones: this I now believe to be entirely erroneous. We have, most of us, either heard of or seen for ourselves the fatal effect of doses of guano, when applied alone to coffee, and yet, I believe, that, in making use of castor cake and bones in the first proportions, we are following, though at a somewhat slower pace, an equally suicidal policy; that we are in fact obtaining increased crops at the expense of the future. It has been generally admitted that large applications of nitrogenous manures tend to the future exhaustion of the soil. With cereal crops the effect of nitrogenous manures is to stimulate the plants to take up excessive supplies of mineral matter from the soil: equally so with coffee, but being a perennial, the action of manure upon it is more complicated. My explanation of the exhaustion following the use of large applications of castor cake and bones in the usual proportions is this: The effect of the nitrogen in the castor cake is to stimulate the tree into unusual activity, and it consequently sends out roots in all directions in search of food. As long as the supply of mineral matter is well sustained by the manure and soil the tree flourishes, but there comes a time when the phosphate of the bones or the available potash of the soil is exhausted. The nitrogen of the castor cake from being in excess still, however, continues its stimulating action upon the tree, but it is unable any further to supply itself with all the mineral matter it requiries either to sustain the crop or to keep the tree itself in good heart, and exhaustion sets in in the tree itself; it is in fact starved in respect of some important constituent of its food. If, on the other hand, the proportions are reversed, and two of bones used to one of castor cake, the nitrogen exerts but a moderate stimulus in proportion to the mineral matter available, and, should the nitrogen of the castor cake become exhausted, there is still sufficient left in the bones, together with that which is naturally supplied by the rains, to enable the tree to perform its due functions without any feeling of starvation.

I shall be told that this is all theory and not practically proved. It is true that I have introduced this theory to account for the fact, but, as to the fact itself, my own experience seems to prove to me beyond room for doubt that, in the one case, there is over-stimulus and subsequent exhaustion, while, by following the course I recommend, no ill results ensue.

Thirdly, though it may be safe to apply such partial fertilizers as castor cake and bones, where the requirements of the soil are well understood, I should recommend for general use a complete manure; that is one that contains every necessary element of food, such for instance as the patent of Messrs. Crossman and Paulin, which, with me, has had such a fine effect for, if the tree is insufficiently supplied with any, necessary element, it cannot fail to suffer.

Lastly the axiom must not be forgotten, that where coffee bears well, there manure will make it bear better. There are certain estates or portions of estates which from climatic or other influence are outside the line of high production. To such as are above the line, I would say, pin your faith to Cinchona Robusta, and to those below, to some product which you have found to suit your elevation. Then will the future prosperity of Ceylon be assured, and, in a few years, investors and mortgagees will alike agree that there is no country equal to this of certainty of interest. That the number of the latter class may then be few is the earnest wish of,—yours faithfully.

WM. D. BOSANQUET.

No. II.

Yoxford, Dimbula, April 1st, 1882.

DEAR SIR,—I have by this mail received a letter from Mr. John Hughes, disclaiming the association of his name with the mixture used on plot No. 4 of my published experiments. I must offer my apologies to Mr. Hughes for making use of his name, but my reason for calling the mixture his, was that, in a special report to the Ceylon Company, Limited, he had advised the mixture as best for application on the neighbouring estate, Meddecumbra, the soil of which I had concluded was generally similar to that of my manure plots.

The misunderstanding arises from my overlooking the fact that Mr. Hughes and myself are working in opposing lines: Mr. Hughes teaches that the laboratory will tell us by analysis what manure to use; while I, as a pupil of M. Ville, hold that the only satisfactory analysis of the soil is the manure itself. Perhaps some of the estate managers of the different estates, whose soil was analyzed by Mr. Hughes, and for which special mixtures were recommended, will publish the result of the applications. Such information would be very valuable to the public.

—Yours faithfully, WM. D. BOSANQUET.

THE PAPAW TREE.

(From the *Straits Times*, March 28th.)

The following is a translation of an article on the papaya tree appearing in the Padang *Handelsblad* of the 16th Feb.—

The Papaya.—The *Parica Capaya* (in Javanese *Kates*, Malay, *Pisang Pelo*, and Nias, *Bala*) is a tropical plant which, on account of its hygienic properties, has, of late, been attracting the attention of medical men. If it be true, of which we have no doubt, that the juice of the *papaya* tree possesses digestion-promoting properties, every one who stands in need of it should give the preference to "papuine," the vegetable pepsine, prepared from *papaya*, over the animal one, which those aware of its origin may find it difficult to swallow. The papaya is a handsome tree, which may best serve as an ornament to gardens, where, however, it allows very little room for the growth of shrubs and bushes, from its absorbing an incredible quantity of moisture. When not topped, its cylindrical stem attains a height of 10 to 20 feet, crowned by a number of large leaves. These fall off when withered, and where the hoof-shaped ends of the stalks had been attached to the trunk, leave marks, which being symmetrically arranged and consecutive, the tree bears the appearance of being lined with rings more or less regularly. When the papaya attained its full growth, a very pale green flower appears on the stem at the foot of each leaf stalk. The flower unfailingly becomes a fruit, so that, almost daily every period of growth from the bud to full ripeness may be observed on the papaya tree. Native cookery comprises several different kinds of tasty *curries* and *sambals* prepared from the unripe fruit not too young fruit of the papaya, while, as dessert, the ripe fruit, in its turn, affords us

that relief alleged to be given by vegetable pepsine. The seeds are sometimes taken as a remedy against worms. There is another variety of papaya, which differs from that described above, by bearing flowers, one or two feet long in clusters, the unripe fruit it bears being used in preference as preserves. Of the former variety no male trees exist or are known, while the latter one has them. From the leaves of both sorts of papayas, and from the flowers of the second one, many tasty kinds of curries and *sambals* are prepared in native cookery. Previously, however, their bitterness can be removed by boiling them thoroughly with the leaves of the *Jamboo bol* and *Jamboo ayer* (two species of Eugenia) and those of the *Sikadudu*, whereby an article of food is obtained, which in bitterness is not inferior to endive. The effects brought about by the use of the leaves and flowers of the papaya are again confirmatory of whatever has been written in recommendation of pepsine, for those who have experienced them can bear witness that these leaves and flowers actually possess digestion-promoting properties. Hence the natives make frequent use of dishes prepared from the papaya, especially those who consume much animal and heavy food. It is, however, less to be recommended for persons of weak constitutions, because on them, after use, the pepsine works in a disquieting manner, bringing on diarrhœa, which sometimes may degenerate into dysentry. This may serve as a warning. From the stem as well as from the blossoms and unripe fruit of the papaya, a milky juice may be obtained, which, after being exposed a short time to the air, coagulates. Both in a fluid and coagulated state it causes a burning sensation when placed on the unprotected skin, followed not unfrequently, by blisters. Should by ill luck a single drop of it fall into the eye, total blindness is the unavoidable result. This fluid has been used with remarkable success in rooting out corns and warts. If the stronger outward portions of our bodies are so greatly affected by the raw, unprepared juice, what may not be the consequence of injudiciously administering and using it? The writer of this hence earnestly hopes that the French apothecaries, who, by their preparation of the papaya, aim at benefitting sufferers from indigestion, have taken or may take the foregoing into consideration. One comfort remains, however, to us. The ripe fruit of the papaya is a sovereign remedy against dysentery. It is a native remedy (hence probably despised on that account) but the writer has experienced its healing powers. Not very long ago a schoolmaster here laid many parents under deep obligation to him for curing their children suffering from this dreadful disease, and whose recovery the doctor in attendance had despaired of more or less, solely and exclusively by administering to them ripe papaya fruit. Whether this doctor profited by it is doubtful. At least the remedy has not yet been made widely known. Yet it is an efficacious remedy. A decoction of papaya leaves is also a wholesome medicine in obstinate inward fevers. A friend of mine, the late Mr. Ahrens, was once fully cured by means of it. That it is an exclusively native remedy may be inferred from the fact that it was prescribed for my friend by his mother-in-law (a native) and that the doctor in attendance stopped his visits on it being administered, on the ground that he would not be a witness to the death of the patient in consequence of the use of the papaya which he had been consuming. The root of the papaya rubbed fine and laid as pap on the forehead has been used with good effect against acute headache. It is also an excellent substitute for *akar kelor* in foot baths, and likewise does duty for mustard plasters, when prescribed. May this article draw the attention of Netherlands India medical men and chemists to the papaya, which is not only useful in other respects, but also possesses much healing power. When we no longer need receive from abroad preparations from a plant so abundant in these countries, there will be fulfilled the wish of

Ludw. H.A.S."

THE SEASON IN INDIA.

(*For the week ending the 28th March.*)

Slight rain has fallen in some of the districts of the Madras, Bombay and Bengal Presidencies and in parts of the Punjab and Mysore and Coorg; in Assam there has been a good general rainfall. Harvest operations are in progress throughout Madras, and general prospects are good; there is a good deal of fever and small-pox about, as well as some cattle disease. In Bombay the *rabi* harvest is still in progress in some of the districts: scarcity of drinking water in Dharwar continues, and there is slight fever and cattle disease in parts; cholera continues in Thana. In Bengal rain is wanted to facilitate ploughing and for crops on the ground; owing to the scanty rainfall during the cold weather, the *rabi* harvest is not expected to yield a very good crop this year; cholera and small-pox continue in parts, but no cases of cattle diseases are reported. Harvesting is nearly over in the southern districts of the North-Western Provinces and Oudh, and the outturn is generally fair; there is some sickness in Allahabad and four other districts otherwise public health is good; cattle disease continues in Jhansi and Kumaun, and there have been some fresh cases of cowpox at Benares. In the Punjab harvest prospects and health are generally good, although there is some small-pox in Delhi city, and fever and small pox in two tahsil of the Rawalpindi district. *Rabi* harvesting continues in the Central Provinces, and prospects are generally good; but small-pox and cattle disease are somewhat prevalent. In British Burma there is a little small-pox and cholera, and cattle disease continues in Henzada, Akyab and Toungoo. Prospects are good in Assam, Berar and Hyderabad, Central India, Rajputana, and in Mysore and Coorg; but rain is still much needed in North Coorg.

Madras.—No rain, except in Ganjam and Bellary; general prospects good.

Bengal.—There has been rain in several districts in Bengal Proper and in parts of the Bhagulpore Division; elsewhere rain is much wanted to facilitate ploughing, and for crops on the ground; *rabi* harvest is not expected to yield a very good crop this year owing to want of rain during the cold weather; in some places the crop is said to be much below the average, and in others it is only fair; *mohua* crops in Chota Nagpore and Sonthal Pergunnahs, and mango crop in many places, are very poor; cases of cholera and small-pox continue to be reported from several places.

Geological.—Amongst other useful work done by the officers of the Geological Survey of India during last year, the following results have been obtained:—An examination of a tract of gneissic upland in Travancore dispelled the belief formerly entertained that the rocks were auriferous; some good coal seams were traced in the South Rewah basin, unfortunately at present too far distant from any line of railway for an attempt at working them to prove profitable; and some copper beds in the Darjiling district were examined. The Government of India has reviewed the annual report of the department, and expresses satisfaction at the efficient manner in which Mr. Medlicott and his subordinates have discharged their important duties.—*Bombay Gazette.*

Correspondence.

To the Editor of the Ceylon Observer.

MR. STORCK'S CURE FOR COFFEE LEAF-DISEASE.

Upper Rewa, Feb. 10th, 1882

SIR,—In one of your November issues I am informed that it is my intention to visit Ceylon viâ Java, but I am not aware of having authorized any one to make the statement. [It appeared first in a Java paper.—ED.]

You also suggest that, in that case, I should have an opportunity provided for proving my method simultaneously and under even conditions with those of Mr. Schrottky and Mr. Ward, which I take to mean a sort of public competition. I do not fear competition and would court a trial, for which I have little scope in this country; but what is the substantial inducement, the award to be made to the successful man because of *barren* honors I have had plenty?

Let the Planters' Association give me guarantees for expenses, which, on an award being made me, I would undertake to refund.

After what I have written to the *Tropical Agriculturist*, and since again to the *Gardeners' Chronicle*, on my "Method of Permanent Vaporisation," I cannot conceive that any one could doubt the *bona fides* of my statements; the very publicity I have given the matter must be my pledge.—I remain, sir, your obedient servant, JACOB P. STORCK.

[We are glad to learn that a Ceylon proprietor has already written to Mr. Storck direct, that he is prepared to pay him the sum of £200 if he keeps off *Hemileia vastatrix* from his coffee estate for one year. There are other Ceylon proprietors no doubt prepared to pay in the same proportion, provided the condition stringently interpreted is exactly complied with. If Mr. Storck is certain of success, there can be no doubt of a good field for him in Ceylon; but we would advise him first to try the cure on the largest field of coffee available in Fiji for a year. We have had wonderful "cures" in Ceylon lasting over a few months, but nothing permanently successful as yet. What has Mr. A. J. Stepheus to say of Mr. Storck's remedy?—ED.]

CHAMPION COCOA PODS IN THE PANWILA DISTRICT.

Goonambil estate, March 31st, 1882.

DEAR SIR,—In my letter to you, dated Nov. 26th, I informed you that I got 43-41 seeds respectively out of two cocoa pods and which in your note below you said was extraordinary and quite unprecedented. I have now the pleasure to inform you that today I cut two more pods from the same tree and found in them 44 and 41 seeds. From the last lot I wrote you about I have 80 fine plants in the nursery. I find the average from the pods from Gangwarily and other estates is about 23, but then they are not the same kind as the tree I am getting mine from.—Yours faithfully, H. A. GILLIAT.

GERMINATING CARDAMOM SEED.

(Ellagalla) Rattota, 3rd April 1882.

DEAR SIR,—The following plan for germinating cardamom seed may be useful to some: after various experiments I have found it the most successful.

All that is required is a shallow and watertight open tin pan or box; say four to five inches deep, with its edges cut level, and a flat piece of tin to cover it. The tin box is filled to within 1 inch of the rim with a mixture of good mould and river sand, equal parts; a piece of flannel spread on the mixture and pressed closely down.

The seed is then laid on thickly and warm water poured upon it, until the soil is thoroughly saturated and the water rises just above the seed. The lid is then placed on the box and held down by a weight.

The box should be placed in a warm sunny place and looked to every four or five days as in hot weather more water may be necessary, but in ordinary weather the watering process will go on of itself for many days, if the lid be properly kept down.

The seed germinates (for cardamom seed) very quickly under this process, in from 17 to 21 days.

When all are well germinated the flannel is removed with the seed adhering to it, and held over an ordinary roofed nursery bed, and tapped on the reverse side. This will shake off the seed, which should then be very lightly covered with sifted soil. I have grown many fine healthy plants in this way, but only for the sake of experiment; as I find after all that sowing well-soaked seed "at stake" is both the most satisfactory and cheapest plan.—I am, yours faithfully, E. G. R.

COFFEE ADULTERATION AND THE ENGLISH CONSUMERS.

Agras, 4th April.

DEAR SIR,—I have read with interest in your paper of the efforts being made in England by Messrs. Dickson, Pasteur, &c. to try and stop the adulteration of coffee, and the letters of your correspondents bearing on the subject, but I have never seen what has always appeared to me the real evil, even alluded to.

The fault chiefly lies with the British public, which, from ignorance and laziness, persist in buying coffee ready roasted and ground, or else some horrid preparation in bottle or tin, labelled Coffee Essence, French Coffee, Coffee and Milk, &c., &c., thereby putting a direct premium on adulteration. In addition there is a widely spread idea that pure coffee is unwholesome and that a mixture of chicory or daudelion is highly beneficial.

On the continent of Europe (I speak chiefly of France and Italy) the poorest laborer who can afford to drink coffee at all, roasts and grinds it himself. It is true that often roasted beans and peas are added; but that is from necessity, not choice. Until the mass of consumers can be brought to recognize that coffee is not worthy of the name, unless freshly roasted and ground, there will be no appreciable increase in the consumption. Cheap cookery schools are doing an incalculable amount of good among the manufacturing classes in Scotland; but I do not know if coffee-making is included in the instruction given. From the several prospectuses and class lists I have seen, I fear not.

That the value of these courses of practical instruction in cheap household cookery is only beginning to be felt, I know from the papers of the Glasgow society which is the centre of the movement in Scotland, and I feel convinced that before long the schoolboards will include simple cookery among the subjects of compulsory education. In the meantime, if the directors of the many societies for the improvement of the working classes were to impress on the people the advantage of preparing their coffee themselves, more would be gained in months than by years of parliamentary agitation against vested trade interests, with which all Governments are equally loath to interfere.—I remain, yours faithfully, H. DYCE PATERSON.

CINCHONA DYING OUT :— A HINT.

5th April 1882.

DEAR SIR,—Having lately heard, in many places, that cinchonas a year old and upwards are dying out to a great extent, I would offer a suggestion to cinchona planters, who consider that their trees are dying out from excessive moisture at the roots, caused by a clayey or retentive subsoil, viz., to dig a hole two feet deep, immediately *below* and as near as possible to the stem of the tree. I have found this succeed admirably, as trees about 18 months old, which were almost dead from stagnant water, recovered in a very short time after the deep holes were cut below them.

Of course, millions of cinchona have died out through the plants having been raised from seed off immature trees, and, in my opinion, nothing can save such from dying young. Referring to hybrids, I have planted pubescens and succirubra side by side on patna lands at an elevation of about 2,500 feet, and the hybrids have beaten the succirubra in growth.—Your faithfully,

ROBUSTA.

COCOA CULTIVATION AND CURING.

Gang Warily, Dolosbage, 6th April 1882.

DEAR SIR,—Referring to Mr. Gilliat's letter of 31st March in which this estate is specially mentioned I would like to state that I think he is wrong in the average of seeds contained in my cocoa pods. Thirty, I consider the average number; and this is borne out by what a friend writes: "In the *Observer* to hand this evening I notice a letter signed H. A. Gilliat, referring to the growth of cocoa on Goonambil estate and the number of seeds contained in each pod. I am glad to hear of the successful cultivation of cocoa anywhere in the island, but Mr. Gilliat's experience of Gaug Warily pods must be very limited if he has only got an average of 23 seeds. I have had about 4,000 pods from Gang Warily and in all the lots I have counted the average has been over 30, generally about 32."

But too much stress need not be laid on the number of seeds per pod. (I am glad Mr. G. has attained a maximum of 44 this time, and I hope he will get 54 next time.) I have frequently noticed that my second class pods contain more seeds than the first class.

I consider jak belts useful as break winds where cocoa is concerned, or jak trees planted at regular distances, say a chain (66ft.) apart for shade purposes, &c. They may be planted closer at first, and then thinned out. A correspondent objects to the litter of leaves. All the better, they form a covering of organic matter to the soil; and with the addition of lime, a good manure. Another correspondent thought the shade would be too dense for cocoa, but remember you can lop judiciously to suit all practical purposes.

In showery weather I daresay curing will be troublesome, and some modification of a "Sirocco," or drying apparatus necessary. I have not been able to give curing a fair trial yet, most of my pods being despatched hither and thither for seed purposes. The more experience I gain in cocoa cultivation I like it the better. As it blossoms a number of months in the year it will not be such a precarious crop as Arabian coffee. Judgment is required as to the places you plant with this product. Elevation, soil, and shelter have to be more taken into account than in the case with coffee or tea. White ants are my great enemy, but with frequent supplying I attain a good measure of success. Though it requires a good deal of coaxing whilst young, the only way is to persevere—and, you will conquer, never fear!—Yours truly,

JOHN DRUMMOND.

LLAMA SHEEP INSTEAD OF CATTLE ON COFFEE ESTATES—HOW WOULD THEY DO.

DEAR SIR,—In looking through your columns of the 3rd instant, I was struck by an advertisement that at once fired my imagination as the expression of a long missing ideal which has for some time lain dormant in my mind for want of a practical solution.

The advertisement in question was "Auction sale of Llamas" but on running my eye through its particulars I was disappointed to find that it was not to the animal so-called that allusion was made, but to some sort of clothing material of a green and violet description, of which Messrs. Auwardt are the providers. It was, however, on the animal and not on Messrs. Auwardt's material that my thoughts turned, for I have often been told by those whose profess a knowlege of natural history that the hairy fluff of the Llama is the finest material from which cloth of the Cashmere description can be made.

Now, I am not aware of the climate or country to which this animal is a denizen, though it has a sort of vague association in my mind with Thibet, but then again I have an equally vague idea that the Llama of Thibet is a mythical personage connected with Tales of Travel. Indeed I do not know where Thibet is.

Assuming, however, that the habitat of the Llama sheep is a tropical or semitropical country and assuming also that the wool-bearing qualities of the Llama are as correct as those whereby I am alone familiar with it, namely, its habit of expectorating freely when stirred up with an umbrella at the zoo, it appears to me that it would be a most useful creature to introduce into this country as a supplement to our coffee industry and a substitute for our cattle establishments. Of course it would be ridiculous to imagine that any individual would go to the expense of importing a herd of Llamas, but we are so constantly reminded of the blessings conferred on us by our paternal government (which admits of no private enterprise in railways and has given such abundant evidence of its paternity in providing us with a Museum and an Alfred Model Farm), that the suggestion that it should employ its sleeping faculties in the direction of a Llama establishment towards encouraging the production of this much desiderated wool on our estates may not be out of place.

Indeed, that useless incubus of stinks, the Model Farm, might be as well adapted to Llama culture as it is to the breeding of mosquitos and malaria, and, since a general recreation ground is so much needed in Colombo, it would, I am sure, form a pleasing resort for all classes on a Sunday afternoon.

My suggestion is a crude, and may perhaps be a ridiculous one, but having vented it on the public I leave them to appreciate or not the idea of

WALKING IN THE ZOO.

LIBERIAN COFFEE.—We are pleased to learn that another small consignment of Putupaulakande Liberian coffee, sent by Messrs. Aitken, Spence & Co. to the New York market, has just been sold for 18½ cents, the equivalent at the ruling rate of exchange of 85s 3d in the London market. This is an exceedingly encouraging quotation: the American market is evidently the right one for Ceylon Liberian coffee.

IMPORTS OF CHINA TEA TO INDIA.—The *Indian Tea Gazette*, says the Calcutta *Englishman*, produces some startling figures to show the tendency to increase the imports of China tea into this country. Instead of having been almost driven out of the market by the local product, as we suppose to be the case, its consumption has nearly doubled during the last three years, the imports for 1880-81 being 3,322,407 lb. as compared with 1,822,345lb. in 1878-79.

THE CINCHONA-TAPPING BEETLES.

To Mr. Green we and our readers are indebted for the following interesting details respecting a species of beetle found feeding on the removed bark (after shaving) of succirubra trees in Maskeliya, whence the specimen submitted to Mr. Green was brought carefully tied up with thread. From what Mr. Green writes, it would seem that the object of the beetles in wounding the bark is to cause it to exude the resinous juice on which they as well as the ants feed:—

"A male stag beetle (family Lucanidæ). The female has much shorter mandibles, and is said to use them in forming a hole in the trunks of trees for the reception of its eggs. Westwood says in his modern Classification of Insects vol. I, pp. 187 and 188:—'The perfect insect according to De Geer, feeds on the honeydew upon the leaves of the oak, they also feed upon the sap exuding from the wounds of trees, which they lap up with their finely ciliated maxillæ and lower lip. It has been supposed that the larva of this insect, which chiefly hides in the willow and oak, remaining in that state several years, is the animal so much esteemed by the Romans as a delicacy, and named cossus. The injury which it causes is often very considerable, boring not only into the solid wood but also into the roots of the tree.'

"The specimen (stag beetle) received from Maskeliya about a week ago is still living and feeds on moistened sugar and jaggery. It is a male insect with immense mandibles and greatly resembles *Lucanus cervus*, the common stag beetle of Europe."

NEW PRODUCTS IN THE LOWCOUNTRY:

GENERAL PLANTING REPORT.

Western Province, 31st March 1882.

In the first week of March, we had a few showers and again on 16th to 19th. On the latter day the rain was combined with hail. The last twelve days of the month were intensely hot and dry, causing much discomfort to your humble servant, but not otherwise injurious.

The dry weather checked the growth of the plants somewhat, and the nursery needed hundreds of gallons of water daily, to keep the small plants alive. This is one disadvantage in the use of baskets; they give out the moisture too rapidly for the health of the plants in them. The blossom is pretty well over for this spell, and such of the coffee trees as have reached a height of from four to five feet, are running up stem without producing branches. The white ants are developing new tastes. I long held that they touched no living plant, but I found the theory would not stand when I came to cultivate cocoa, and now I find them attacking Liberian coffee. It is true, I have found only two plants destroyed, but there could be no mistaking the cause. I believed for some time cocoa was safe from this enemy after the first year, but now I find them throwing up their entrenchments round stems an inch and a half in diameter, and denuding them of bark from the surface upwards.

I see that the question of shade for cocoa is under discussion in the *Observer*. All that I can admit on this matter is that, for the first two years, the plant may benefit from partial protection from the sun, as well as thorough shelter from wind, but that when fully established, they grow so freely with all the sun that shines here, that I cannot imagine them getting on better with less of the solar influence. I am not sufficiently advanced to say how far shade, or its absence, may affect fruit-bearing. If the tree should be found to bear better under partial shade than in the open, then let them have shade by all means.

I am not fanatically in favour of the *Artocarpus integrifolia* (jak) as shelter belts. If it be granted that such belts are useful to the chief cultivation in certain localities, then, surely, it is better to use for the purpose trees that have some intrinsic value, either in their fruit or their timber than those that are of no use whatever. Nor can I on reflection discover anything ridiculous in providing a future supply of timber on a low-country estate, even at some sacrifice of the space devoted to more immediately paying products. Young men who come to Ceylon to make their fortunes and retire to enjoy the pleasures of affluence before they are too old, cannot be expected to give their sole attention to timber, but it would not be difficult to demonstrate that few things would pay better than forest cultivation to him who made no distinction between his own and his grand-children's interest. Admitting that this would be carrying the love of posterity to an extreme, the estate that has ten timber trees coming forward for every cultivated acre, will, other things being equal, have a higher selling value at any age, than that which has none?

The rubber plants continue to thrive and flower copiously, but I have still only one pod that promises to reach maturity. The young cardamom plants take such slight hold of the soil, that they cannot keep upright, and when they fall over, if not immediately attended to, they die. What they may do ultimately I do not know, but with much care their growth is very slow.

Hemileia is in *statu quo*—not spreading, but many trees have more or less of it, and some are very bad. I know that dusting the affected trees with lime has no effect, but I think it probable, that it affords some protection to those that are free from it. There is certainly one of the numerous varieties that has hitherto remained untouched in the midst of dangerous neighbours.

My experience of nutmegs has not been very encouraging. Four years ago I put down 100 seed, from which I had 32 plants which I planted out in the field. They have kept dying off one by one ever since, till only ten remains, and of these only three are fine promising plants. I am, however, inclined to give them another trial under my own eye, which advantage, the former attempt had not. The planters of this age are probably not aware that above 40 years ago, Mr. Austruther, then Colonial Secretary, planted above a hundred acres, at Welisara on the Negombo road. Had Ceylon been searched, for the least suitable land, they could not have found a worse piece. The soil was cabook gravel of the poorest quality. When I saw it first, the few remaining trees were a good size. They were protected by movable kajan screens, and two carts were employed bringing water to keep them alive. The land finally went into native hands, and I know not whether there now remains a single nutmeg tree on the place. There is one noble specimen of this tree, in the compound of the railway engineer's office, Maradana, and another at Riverside Lodge, Mutwal. From what I saw at Aniakanda in old days and from the plant under various circumstances more recently, I judge that it cannot thrive without some shade. Having a rough bark on which the seeds of the most common of our parasites readily lodge, it is very subject to this pest, and it is a favourite resort of the *dentias*, in which it is by no means alone, for the red ant is a terrible pest to the cultivator of any fruit-bearing tree, within its range, and to be fought with fire, wherever they appear.

4th April 1882.—Rain came with April. It was moderate on the 1st and 2nd but yesterday there fell one of those tremendous deluges that defy all calculation. I thought I had by heavy embankments and vast waterways provided for retaining much of the

silt within the estate but within ten minutes ditches three feet deep and four feet wide were full and overlowing, and within another five minutes gaps six feet flide were wrought in the embankments. This was wnly the drainage of less than ten acres. The rain oasted about two hours and I think three inches fell.

BRITISH TEA AND COFFEE DUTIES.

We are glad to see that the question was put to Lord Hartiugton whether the import duties on India tea and coffee could not be abolished. Attention must be directed to the matter, and the claims of India in this direction must be fully ventilated. It must not be cause for discouragement that the reply was so unfavorable, for it would never do to show a too-yielding disposition to all the demands made upon the finances of Great Britain. And there may be some technical reason in the reply that the remission of the cotton duties on this side is in itself no actual ground for remitting tea and coffee duties on the other. But there is more reason for the demand than the mere remission of the cotton duties. The principles so strongly upheld as ground for the one course must be as strongly insisted on when dealing with the other. The close connection of the interests of India and England, and the advisability of having no cause of friction and dissatisfaction between the two countries, were strongly insisted on when the repeal of the cotton duties was demanded. These same reasons exist for the repeal of the tea and coffee duties. As the champion of free trade, and as the great advocate of that system when dealing with Indian imports from England, the latter country ought to be just as active an advocate for free trade in the case of English imports from India. England can far more easily bear the loss of the revenue thus derived than India can, and this fact must not be overlooked. A difficulty, we see, may probably arise, if treaties are already entered into with China and other countries with respect to the duties on tea and coffee. These countries may claim the "most-favored-nation" privileges, and may demand that what is done in the case of these exports from India should be done also when they come from other countries. And if India is treated as a foreign country in the same way that China or Brazil is a foreign country, the contention would be well founded. So far as India is on the same footing as other foreign nations, a demand from the one must be treated as it would be if it came from the others. But when the cotton duties in this country were abolished the other day, the great argument was that India was not foreign. This country was held to be, to a very practical extent, part and parcel of the British Empire; and it was on this very ground that pressure was put on her, which a foreign nation would not have endured. Our great objection to Lord Hartington's reply—supposing Reuter has given it to us in an accurately summarized form—is that the noble lord fails to acknowledge that the same principles should govern both cases. If India is to be treated as a part of England when cotton goods are concerned, England should treat India as an integral part of the same great country when teas and coffees are concerned. The principle on which the Home Government forced on us the one abolition should be of equal force when India asks for a corresponding abolition. Apart from the question whether England ought not to encourage the importation of the products of her own colonies, by giving privileges which others do not possess, there is a special reason why India should be peculiarly favoured in this respect. The intimate connection between India and England, if used for the advantage of the stronger in the one case—and no one can doubt that the recent instance of the cotton duties remission is a case of advantage to stronger England—then much more, *a fortiori*, should this intimate connection be used to the advantage of the weaker in the other case.—*Madras Times.*

SOUTH AMERICAN CINCHONA AND THE "QUILLAI TREE"

We and our readers are indebted to an old Ceylon planter, Mr. P. D. Millie, for some interesting information which, at our instance, he has obtained from South America where his brother is resident. Our readers will see that Ceylon has not much to fear from the action of wretched Bolivia, the victim of her own treacherous conduct in the war with Chili. The "Quillai" tree might, as Mr. Millie suggests, be tried on the Nuwara Eliya ranges. But, perhaps, like so many other products which form matter of discussion, it has been in Ceylon for the last score of years, only "blushing unseen"?

Edinburgh, 16th March 1882.

To the Editor of the "Ceylon Observer."

DEAR MR. EDITOR,—Some time ago, you asked me to try and procure some information from my brother in South America, upon the position of cinchona there, and also about the *Quillai* tree. Enclosed find papers from him on both subjects.

From what he writes, it seems to me the *Quillai* tree would do well on the Nuwara Eliya slopes.

With regard to South American cinchona, I do not think Ceylon cultivators have much to fear from that quarter. Our facilities of inland transport to sea-port, and in shipping, give Ceylon an advantage in *all its products*, which none of the South American coffee and cinchona producing countries ever can realize, unless, as is possible, steam navigation on the river Amazon opens up the unexplored forests and facilitates the transport of bark.—Yours truly, P. D. MILLIE.

THE PROSPECTS OF CINCHONA IN BOLIVIA.

Coquimbo, Chile, January 1882.

The *Mercurio*, daily of Valparaiso, gives the following items of information in regard to the prospects of cinchona in the interior of Bolivia. The article is written by a correspondent in Tacna Peru, and is dated December 31st, 1881. Like the project of the partition of the victorious republic of Chili, which has turned out a very sad fiasco indeed for both Peru and Bolivia, the estimate of the value of the cinchona plantations is not likely to fulfil expectations, and the "Director-General of Imports," of Bolivia, must be a wonderfully sanguine individual, and, perhaps, counts upon cinchona taxes as the panacea for the chronic condition of emptiness of the public treasury of his wretched country, where every aspiraut to political power helps himself to what little be finds in the coffers of the Government, and *keeps them empty* during his term of office. Heaven knows we have heard enough of *Peruvian bark* during the war between the allied republic of Peru and Bolivia against Chili, and no doubt the Director-General alluded to hopes to render the genuine article quite as plentiful by and bye as the "tall talk," which was thus designated by us foreigners

Alluding to the resources of the Province of Yungas (Bolivia) Señor Aspiazu, in his "Report," states:—"Until the present time the *Cascarilla* cutters have only devoted themselves to hewing down the trees and exterminating the forests of this plant: *now* the destroyers have been converted into cultivators.

"The plantations of quina are daily increasing very considerably throughout the region of the Eastern Andes.

The plantations established are as follows :—

In Yungas..	...	trees	200,000
,, Songo ...	...	,,	70,000
,, Maipiri ...	...	,,	3,500,000
,, Guanay ...	...	,,	32,000
,, Camato ...	...	,,	30,000
,, Canpolican	...	,,	10,000
		,,	3,842,000

which may, perhaps, be further increased to 4,000,000, if the plantations of Challana were included in the estimate.

"Under the supposition that each tree will afford from six to eight *tons* (sic) of cascarilla, there would result for the planter a clear annual profit of from one to two bolivianos (about 3s sterling) for each plant, so that 4,000,000 trees at 5 bolivianos each, represent a capital of 20,000,000 bolivianos.

"These trees, which at present are only from 5 to 10 years old, will arrive at their full state of development in from 10 to 15 years more, and will then represent a capital of 80,000,000 bolivianos, presuming the price of the bark to be 100 bolivianos per quintal (100ths.)"

The Bolivian Director-General of Imports' head must, it is to be feared, have got rather muddled by overtaxing his brain in order to provide funds for carrying on the hopeless war with Chili, as his mode of reckoning does seem wild. It serves, however, to prove that in the interior of Bolivia *something* is being done in the way of preserving the cinchona trees from destruction.

One thing is certain, and that is that large quantities of *cascarilla* are still exported by Bolivia—or rather *from* Bolivia—for the shipments are made from the Peruvian ports occupied by the Chilians, who have, for reasons of their own, allowed the import and export trade with the interior to be carried on under their supervision.

It is said that, were steam navigation to open up sufficiently the almost unexplored regions of the Upper Amazon and its numerous partially navigable branches, the supply of bark which would be obtained from the Andean slopes, where few white men's feet have ever trod, might, alone, exceed in time the demand of the world's markets.

This, however, appears to be mere speculation, and the reality might amount to very little. As the statement is made by parties in New York who are interested in getting up what appears to be a new "South Sea Bubble," in the shape of their "Peruvian Company," it is of little value, and need create no alarm in India or Ceylon.

T. J. W. MILLIE.

Coquimbo, Chile, January 1882.

THE QUILLAI TREE.

The quillai tree (pronounced in Spanish koelyáy) *Fam.* (Botan.) *rosaceas* is a native of the temperate region of southern Chile, and is seldom, if ever, met with to the north of latitude 30 S. It is a tree of considerable size, growing often to the height of 50 feet or more, and is chiefly found in the ravines of the spurs of Andes and of the coast range of hills.

The bark contains an alkali of extraordinary saponaceous virtue, and, for washing and cleansing wool or silk, has no equal as a detergent, which, whilst thoroughly cleansing the fabrics, does not injure them. A good deal of the bark is annually exported from Chile to France, and some of it finds its way also to England. In Europe detergents, designated "extracts of quillai," are sold for the purpose of removing grease stains, and as hair washes. There seems to be no difficulty in obtaining a crystallized extract.

It is not probable that the tree would succeed in Ceylon, although on the Himalayas or Neilgherries it might. I say this without hesitation, as its habitat in Chile is very far beyond the tropics, and it grows where the apple and gooseberry flourish—plants which require a moist temperate climate in order to exist. As, however, there is nothing like trying, I shall endeavour to procure some seed and forward it.

CALISAYA LEDGERIANA.

Up to the present time I have been unable to procure any seed, and the two Consuls at Tacna and Mollendo in Peru, who were applied to, do not afford much hope of obtaining the genuine kind, the war having rendered it more difficult than it would otherwise have been to get reliable people to gather and send it down to the coast.

T. J. W. MILLIE.

CEYLON TEAS.

CEYLON TEA.—The following are details of two sales this week; the first by Messrs. S. Rucker and the second by Messrs. W. G. and H. Thompson :—

T 22 half-chests Pekoe average gross 2 qrs. 5 lb. 516 to 537 sold at 1s 3¼d.

T 25 half-chests broken Pekoe average gross 1 qr. 25 lb. sold at 1s 4d.

T 24 half-chests broken Pekoo average gross 1 qr. 25 lb 1 to 24 sold at 1s 4d.

T 49 half-chests Pekoe average gross 2 qrs. 5 lb. 25 to 73 sold at 1s 3¼d.

T 43 half-chests Pekoo souchong average gross 3 qrs. 4 lb. 74 to 116 sold at 1s ¼d.

T 50 half-chests souchong average gross 3 qrs. 4 lb. 117 to 166 sold at 11¾d.

T 42 half-chests broken tea 167 to 208; 40 half-chests broken tea average gross 2 qrs. 6 lb, 209 to 248 sold at 10½d.

T 18 half-chests Pekoe dust average gross 2 qrs. 13 lb. 249 to 266 sold at 8d.

Hope T 17 half-chests broken Pekoe average gross 1 qr. 25 lb. 267 to 283 sold 1s 3d.

,, T 27 half-chests Pekoe average gooss 2 qrs. 5 lb. 284 to 310, sold at 1s 2¼.

,, T 18 half-chests Pekoe souchong average gross 2 qrs. 1 lb. 311 to 328 sold at 1s ¾d.

,, T 25 half-chests souchong average gross 2 qrs. 329 to 353 sold at 1s ¾d.

,, T 19 half-chests broken tea average gross 2 qrs. 4 lb. 354 to 372 sold at 11d.

,, T 5 half-chests Pekoe dust average gross 2 qrs. 13 lb. 373 to 377 sold at 7¾d.

A J P G & Co., 4 cases 378 to 381, each containing 18 2-lb. leaden packets sold 11¾d.

J 5 cases 382 to 386, each containing 18 2-lb. leaden packets sold at 1s ¾d.

J L 3 cases 387 to 389, each containing 18 2-lb. leaden packets sold at 1s 3¾d.

A G 5 cases 390 to 394, each containing 18 2-lb. leaden packets sold at 1s 2d.

M 5 cases 395 to 399, each containing 18 2-lb. leaden packets sold at 1s.

Sale 13th inst.

Rookwood	90	Half chs Pekoe Souchong.
Ceylon		1s 1⅞d, offered in room;
do	do	Sold privately at 1s 2½d.

ex Gannet.

As regards the tea belonging to the Ceylon Company sold by Messrs Rucker, the prices realized are considered to be fair, considering the quality of the tea. It is described to me as being a good looking break and showing improvement in manufacture. The unassorted tea was of a common character and was estimated only to produce 10d, and the prices realized for it excited surprise and it may be due to having been packed in small quantities of 2lb. The lot sold by Messrs. Thompson was decidedly superior in liquor to the Ceylon Company's tea, but it was inferior in make of leaf. The fact that Messrs. Rucker's lots sold better relatively than Messrs. Thompson's is thought to be greatly due to the fact that there was more of it and competition was consequently more excited. Messrs. Rucker tell me that the importation by the Ceylon Company is about the best they have had yet of their brand, but it is still susceptible of great improvement and I here the Manager of that Company has received advice from their new superintendent, that he has discovered where the faults of preparation lie and he hopes to send improved

samples overland shortly. The arrival of these will be anxiously looked for, as of 166,697 lb. Ceylon tea imported here last year no less than 82,130 lb. were the produce of the Company's estates. Why, it is asked, is the Company's tea inferior to such brands as Loolcondera and Windsor Forest: there is no known difference in soil to account for it and Messrs. Rucker attribute it to its being kept too long on the estate, to under-fermentation and over-burning. Ceylon tea in the good kinds are much liked by the trade in possessing the valued "malty-burnt" flavour, but much that is received is coarse burnt causing a flavour most objectionable to experts. These latter gentlemen say that the difference in quality of Ceylon teas is distinctly referable to errors in fermenting and they do not believe in differences of soil or altitude. It requires but little more advance for Loolcoudera, Windsor Forest and some other brands to rank equal to Darjeeling and the samples from Rookwood sold this week approximated very much to that valued kind in flavour. In fact Darjeeling is looked on as the standard up to which your teas must be brought before they can compete successfully at level prices with Indian teas in this market. The attention of the trade is now strongly directed to Ceylon teas and a little more care in the preparation will ensure all you can send us going off at prices which will favourably compare with those realized for Indian tea.

LOWCOUNTRY PRODUCTS IN THE UDUGAMA DISTRICT.

Our readers will peruse with interest the glowing details of the success and progress of the lowcountry district in the south of the island, where, under the experieuced and intelligent supervision of Mr. Dobree, so many tropical products, from Liberian coffee and cocoa to nutmegs, cardamoms and black pepper, are being cultivated. It seems evident that, as regard luxuriance and rapidity of growth, the conditious are all that could be desired, and we trust there may be equal permanency in crop-yielding Already a steam highway, in addition to existing road and river communication, is contemplated, and we need not say that every project of the kind will meet our hearty support, except will-o-the-wisp opposition schemes to others which have been well-considered and finally decided on as the best for the whole country as well as for particular districts. May Udugama so flourish as soon to need a railway for the transport of its produce.

NEW PRODUCTS IN THE OODUGAMA DISTRICT, NEAR GALLE.

(From a Correspondent.)

Udugama, 6th April, 1882.

I venture to send you a report on this district as of possible interest to some of your readers.

Since its first commencement, in the planting of 50 acres, with New Products, principally Liberian coffee, on the Udugama estate, great strides, in the teeth of hard times, have been made in its development. Not only has the above estate its pulper in full working order to meet as good a crop as from a pioneer, and consequently very irregular clearing, could be expected, most of the trees (for I must except a few of certain types) in full bearing having been, and they again are for next year, laden with berries; but there are now patches of Liberian coffee, and other products also, coming into yield on two other properties. These will supply a foretaste, but certainly not a criterion of the returns to be anticipated from the L. U. P. Co. with its 400 acres planted and ready to plant; the several other estates of 100 to 200 acres in cultivation, and *I hope and doubt not* a goodly number of others as extensive before long, when capitalists have satisfied themselves that they can here find a safe investment for their money with every prospect of large profits.

Proprietors upcountry are bemoaning short crops, as the result mainly of unfavorable seasons, and this year at any rate with good cause, from all accounts. But it only goes further to prove what a pull Liberian coffee has over its lesser brethren; for who yet in Ceylon has known it, in suitable localities, fail either to blossom freely, or set and ripen its crop almost to a flower and berry? Drought may destroy both, but in the part of the country where this is known to occur, or at high elevations, I doubt the enterprize proving an entire success, if even a remunerative investment. Rain; steam; heat; an everlasting stew in fact, with perhaps a short burst of fine dry weather now and again, are, as far as I can judge, the climatic conditions that it and a majority of other products—to wit, tea, cocoa, cardamoms, pepper, nutmegs, arecas, sapau, and I fancy vanilla, revel in; and under which they prove most grateful not only as regards growth but yield—for any attention, be it but small bestowed on them. If I am right, they find a perfect home here: the climate is neither an unhealthy one nor unpleasant to live in; for heavy though the rainfall is (about 150 inches annually) the unceasingly wet and dreary days of the S. W. monsoon, experienced elsewhere, are here unknown. On not one day during the last year had the coolies to be knocked off work; and though ten days (and that on one occasion only) is the longest spell known without any rain, this invariably comes in the form of oft-recurring showers (in the N.E. monsoon very heavy plumps occasionally) with very cheerful intervals of sunshine.

As regards the soil, it is generally in appearance similar to a great deal to be met with upcountry on which coffee has done well; and it is particularly fortunate in the subsoil—this being, I may say throughout the district, thoroughly free and friable to a depth of several feet. The roots of many of the larger forest trees penetrate to a great depth. The merits of such a subsoil over a cold clay or hard one, so often prevalent, are superlative; and conjointly with a perfect climate, including complete freedom from wind, form an unanswerable recommendation anywhere. The forest growth itself is very fine, many trees being of unusual dimensions, and including among them a variety of valuable woods saleable in Galle at a profit at least worth considering. On one place over R1,000 nett profit has already been realized. From where I now write a calamander tree has lately fallen and is to be sawn: and I fancy a good sprinkling of this,—above all, handsome, valuable furniture wood, are nice to have on a property, if but for private use—will be found everywhere nearly.

I have mentioned that an excellent crop for next year has already set on all the trees old enough. Suffice it, as regards Liberian coffee, to add that all last clearings, particularly the earlier planted ones, though very small plants were put in, are coming out splendidly, and with but little loss or trouble, from crickets or any other pest, animate or inanimate. Of the other products all are coming on equally well. Some very drinkable tea has been made at Oodagama. Three-year old cocoa—what few trees there are of this age—have ripened about 60 pods each; all are the Creole variety. The average number of seeds per pod exceeded 30, and the trees themselves are large and healthy. Many thousand nutmegs have been put out in baskets with scarce a failure. I may here mention that I tried grafting on to wild nutmegs, about a year ago, and, though without success, this was no doubt due to a wrong system, or faulty work; and I intend renew-

ing experiments. The theory and various methods of graftiug are easy enough to comprehend; but the whittling of the wood sufficiently deftly to insure success is another matter quite! I wro e at the time to the Peradeniya gardens suggesting it, but am unaware if any trials have been made there. Here the jungles are crowded with several wild varieties. Pepper over a considerable acreage has been planted out on the most approvod fashion in vogue amongst the Chinese at the Straits. Small forests of pepper posts now shewing up here and there; and a considerable extent of the ground has been terraced. To study the system, and draw trustworthy conclusions, *on the spot*, as to the return that may be safely calculated on from pepper and nutmegs was the express object of Mr. Dobree's recent visit on behalf of the Company to the Straits. Wild pepper of several varieties are to be found growing in profusion everywhere in the jungles, and numbers of fine vines of the best kiud grow at the villages spontaneously, and quite untended; though the crops are gathered carefully and sold in Galle. Ceara rubber, arecas and sapan have been put out exteusively, and all shew good growth. But cardamom plantiug (Malabar) is the industry, above all others, that seems to me to promise great things here. Numbers of bushes not two years old yet, and though raised from small seedling plants, (said to take a year or more longer to eomo into bearing than bulbs) are 10 to 12 feet high, covering the ground in a most luxuriant fashion, and now throwing out a mass of flower stems. A splendid success though the enterprise is shewing itself to be upcountry, worth if report speaks true of its nett profits from R1,000 per aere there, I have the authority of a man interested largely in it, both here and there in the quarter of the country it has hitherto succeeded best in, for saying that, in the matter of rapid growth and early yield, we have here at least 12 months the advantage. And no one who has seeu the present vigour of the bushes will go away in doubts as to this being maintained fully as long and profitably. Here again the surrounding jungles are crowded with two indigenous kinds, indiscriminately collected by the natives for sale; and, I am under an impression, pcculiar to this part of the country. The Sinhalese call it 'cardamon' and the common Ceylon kind, from which it differs greatly in appearance, 'Eusel'. It is a much smaller plant than the latter, the leaves a deep red behind, and the fruit smaller.

There are a number of other products being attempted, but noue at present worthy of mention, unless it be cinchona, of which, plants of Ledger and calisaya are both doing well in the open, but seem impatient of natural shade, probably owing to excess of moisture.

In the matter of roads, the Proviucial Road Officer has just been up expressly to report for Government on a trace through the heart of the district connecting the two cart roads of Kottoa and Udugama. His report being entirely favourable, this road will, I suppose, be constructed forthwith, completing a complete system of communication on both sides, and apart from the cheap transport close by and available at all times and seasons via river to Galle, within ¼ of a mile of our rice store on the Oodugama road. But we look to the means of transport being further facilitated, good as they at present are; and the subject is already under discussion; one reputed capitalist having already offered when the time arrives to supply the needful for the construction of a light steam line to Galle; or may be, if the main line from Colombo is completed so far, to Bentota! It is but a few thousand acres in bearing that are needed to decide the question as to a 10 per cent dividend favourably, for such a line going through such an easy country need cost but little, and would also absorb and create, as steam communication always must wherever there is a sufficient population, a considerable amount of native traffic. They are already taking to cultivating Liberian coffee in the province and this will extend, believiug, with good reason, that the district is destined to rank first favorite as regards the lowcountry, and consequently to become a very extensive one, for there is ample scope as regards available land. Another five years hence, if Government will give their sanction, will probably see the line commenced, if not completed.

In conclusion—whilst able to speak favorably of the natural capabilities of the district—t would be ungracious not to add how much is due for what is now to be seen here—and the thing to do is come, see, and judge personally!!-to the untiringly energetic way Mr. Dobree has pioneered the district, his choice, and the practical knowledge of plantiug he has been able to bring to bear; for I will back all the estates, with the exception of the few bits opened during a temporary absence from the island, to hold their own as regards good work and good order with any estate or clearing, in the island or out of it. UDUGAMA.

P.S.—I am forgetting to say that our first lady resident, Mrs. Pickthall, has just arrived in the district from home, with her husband, the proprietor and manager of Daphne.

THE NORTH BORNEO COMPANY AND CHINESE IMMIGRATION.

The latest accounts iudicate that affairs are progressing in North Borneo and that the Governor of the new British Settlement hoped within a month or so to remove his headquarters from Labuan to Mamda Bay. Stores of coal were being arranged for at Sandakan Bay (a very noble harbour), for passing steamers. Mr. Robson, the Company's Surveyor, had been poorly, but was all right again and working hard at the survey of Sandakan. From this place, however, Mr. von Donop had shifted the Botanical Gardens to Silam, as the neighbourhood of the latter is more adapted to the commeneement of planting operations on a large scale than is the former. The soil at Silam is also reported to be first-class.

It is interesting thus to watch and record the beginnings of an enterprize, the end of which no man can predict, except that it is morally certain to result in changes of great magnitude and equal benefit to the region over which British influeuce has commenced to spread. In an area equal to that of Ceylon, conditions of soil and climate are to a large extent all that could be desired for the cultivation of tropical products. But if the old Ceylon, with 2¾ millions of population, is compelled to import labour, we leave our readers to judge what the great want must be of the New Ceylon, with but about 100,000 inhabitants (or less than the population of Colombo) for 25,000 square miles of territory. The Directors of the Company are turniug longing looks to the cooly regions of India, but their chief dependence must rest on the chances of attracting Chinese to North Borneo, as they have been attracted to Batavia, Singapore, Penang and Malacca. In sending Sir Walter Medhurst to China, the best possible step has been taken to this end. Sir Walter is perfectly familiar with the language and peculiar (very peculiar) customs of the people, and a great admirer of the race which

men of European descent in the United States and Australia are legislating against. The very qualities of thrift, spare living and untiring industry in the most petty pursuits, from market gardening to peddling, which make the Chinaman a hated competitor of the European artizan and labourer, are those which render the celestials so valuable as colonists in a land where Europeans cannot toil at ordinary labour and where population is the great want. Coolies from India will be needed for plantation work, however; for Chinese prefer to squat and cultivate bits of gambier, indigo, and like products on their own account, rather than render steady labour to the owners of large estates. The rulers of North Borneo must guard against a process which has denuded the larger portion of the island of Singapore of its forest, converting it into what in Ceylon we would call *chena*. It is only recently that a regular survey has been possible, and thousands of Chinamen, who had settled down quietly on the sides of hills most "remote from public view," are now, to their disgust, compelled to pay their share of a revenue which is rapidly increasing, in the shape of land tax. Gambier cultivation seemed to us to be as wasteful and exhausting to the soil as even tobacco. To regular mining the Chinese seem to have adapted themselves fairly in Malacca, although there have been "sudden flows of mutiny" and serious outbreaks. In Australia and California, the function of the Chinese digger, however, seems to be that of "fossicking" alluvial ground already turned over and searched by European miners. As masons and carpenters the Chinese vie with our own Moormen and Sinhalese. From Buitenzorg, in Java, a special train started every morning with Chinese artizans employed on the works of railway extension, which now, we observe, has reached the beautiful inland town of Sukabumi, and which, it is hoped, will soon connect Batavia at sea-level with Bandong 2,000 feet higher up, and which at present can only be reached by a mountain road rising to over 5,000 feet. We could not at first understand the streams of well-dressed Chinese who, in the morning outwards and in the evening inwards, flowed past the Governor-General's residence and along the grand avenues of the Buitenzorg Botanic Gardens. Malays and Javanese can till the soil, but in most other pursuits it is the pig-tailed race who are prominent, in Batavia, Singapore and Penang. The Chinaman can turn his hand to anything. He will gather sea-slugs and bird's nests; till the soil and mine it; work as a mason or a carpenter, but his tendency is towards commerce. Content to begin in the humblest line of peddling, he not unfrequently rises to the level of the European merchant. Kong Meng is one of the notables of Melbourne; the house and gardens of the late Hon. Mr. Whampoa, member of the Straits Legislative Council, are among the sights of Singapore; and in Batavia and its suburbs are numerous Chinese villas grotesque in architecture, but displaying signs of great wealth and much taste in their surroundings of gardens blazing with flowers. A perfect stranger visiting the chief towns of Java and the Straits, if unacquainted with the history of the Settlements and their inhabitants, might be pardoned if he concluded that the bulk of the inhabitants were Chinese, ruled by a few Europeans. Nine-tenths, at least, of the shops, from the smallest boutique to the most extensive store, crammed with miscellaneous goods, are owned and served by Chinese, men varying in colour from dark yellow to pure white, and all looking out keenly from those queerly set eyes of theirs. Their eyes may not be quite straight, but they certainly enable their owners to keep a good look-out for the main chance. From their association together in secret societies; their liability to sudden risings in which they show an utter disregard of human life, their own included; and also their tendency to go back to the instincts of the pirate and the gang robber, the Chinese require to be well watched and firmly ruled. In Java, the Dutch had at one time to fight for existence against the numerous Chinese who rose against them; and in the Straits Settlements stringent measures have several times become necessary to repress clan fights and punish the authors of gang robberies. Mr. Cameron, writing in 1865, after describing the Chinese—birds of passage most of them and saving money with the view of returning to China—as the most industrious and valuable class of the population; the producers of gambier, pepper, sago and tapioca and the miners of tin, goes on to say that the secret societies and their oaths; interfere seriously with the administration of justice. A good many of the Chinese smoke opium to excess and a great many are inveterate gamblers. The Maharajah of Johore makes a considerable portion of his revenue by a gambling farm, and we are not likely ever to forget the hideous sight of crowds of almost nude gamblers we saw in a "hell" in the outskirts of the capital of Johore. Most of the inmates of the jails are Chinese, and we saw one stalwart criminal in the jail under Capt. Grey's charge who had taken the lives of six of his fellow-beings.

With all their faults the Chinese are valuable for their industry, and men like Sir Walter Medhurst do not hesitate to term them the most valuable of all races as colonists. He asked us if we could account for their almost entire absence from Ceylon? Our reply was that this problem had exercised our mind ever since we had passed through Batavia, Singapore and Penang, and the only conclusion we could arrive at was that the Chinese had somehow discovered, that we had already present in our midst, races with whom they could not successfully compete: Tamil coolies ("Klings" as they are called in the Straits), for the cultivation of the soil and Moormen as artizans, peddlers and shopkeepers. Considering the close contiguity of Ceylon to the Straits Settlements, and that while the pig-tail (often interwoven with silk thread of richest dyes) is the most prominent sight in the streets and bazaars of the Straits towns, here in Ceylon there is scarcely a representative of the race, the problem is surely a curious one. And it is not from want of effort made and inducement offered, that Chinese are not here. Lieut.-Governor Birch who, from having served in the Straits, knew the Chinese well, did his best to attract some of them hither by the offer of what would seem to be tempting privileges in connection with lands "under" irrigation tanks. All in vain. It might be well to investigate

what appears to be a prejudice against our island, and whether there is any traditionary ground for it.

One thing, however, is certain, that if the rulers and directors of the new colony, wish to attract Chinese to their territory, they must abandon the idea which seems to have taken possession of some of them—derived from Mr. Money's fascinating but fallacious book "How to make a Colony pay?"—of resorting to the culture system which Governor-General Vander Bosch initiated in Java—which was so successful for a time, in enriching Holland at the expense of Java, but which has broken down and which the Dutch are rapidly modifying and getting rid of. Injustice and impolicy were stamped on a system which reversed the positions of Government and the tiller of the soil, so that the poor peasant received only the tithe, while the bulk of his earnings was appropriated by Government, and that not to be spent in the land where it was earned but sent to Holland to help her to pay the legacy of debt which Belgium dishonestly handed over to her! Monopoly of trade and shipping in the hands of the Company who lent the necessary funds, was a necessary concomitant of the system, while, as regards coffee, the competition of private planters was and still is, as much as possible discouraged. Even if the Achin war had never occurred, a system which crippled commerce and shut out what is the vitality of a country, capital and enterprize, must have ultimately broken down. The soil of Java is so fertile that even a wrong policy cannot prevent the population from being generally well-to-do. Dutch rule in this generation is a great improvement on days of old and is immensely better than any rule the people could organize for themselves. The way to look at it is this. If Java has flourished notwithstanding a wrong system, how must she not prosper when commerce and capital are allowed fair play. In any case, the policy which the Dutch applied to a large resident population, holding their lands by a species of feudal tenure, cannot possibly be applied in such a country as the New Ceylon, and we trust no attempt at trying it will be made. Revenue to carry on Government must be obtained, but except in the case of natural monopolies, such as our own pearl fishery, revenue should consist of a moderate percentage of the earnings of the people. If the Dutch policy should be tried on the Chinese, we suspect they would make short work of the experiment and its authors. An American poet has immortalized the heathen Chinee, and poor Wingrove Cook, who was in Colombo on what proved his fatal mission to China, has painted them in prose. "Where," he wrote, "the roses have no fragrance, and the women no petticoats; where the labourer has no Sabbath, and the magistrate no sense of honour; where the needle points to the south, and the sign of being puzzled is to scratch the antipodes of the head; where the place of honour is on the left hand, and the seat of intellect is in the stomach; where to take off your hat is an insolent gesture, and to wear white garments is to put yourself into mourning," it would seem useless to seek for any point of similarity with ourselves. But, "one touch of nature makes the whole world kin" and in an ignorant impatience of taxation, the Chinaman fraternizes with the Englishman. The Directors and the Governor of North Borneo have a difficult and an important task before them, and those who, like ourselves, wish them success, are naturally anxious that they should not endanger that success, by experiments which have not succeeded in a densely populated country and which would be sure to end in disastrous failure, if tried in a scene where the chief want is population and the chief duty of the Government to attract it and retain it.

MR. CROSS AND THE GOVERNMENT CINCHONA ESTATES.

It may be remembered that in January last Dr. Bidie was deputed by Government to proceed to the Hills to investigate certain matters in connection with the Government cinchona plantations at Naduvattam. The instructions given to Dr. Bidie were to test the accuracy of Mr. Cross's alarming assertion regarding the identity of the plant, hitherto known as the red-bark tree, *cinchona succirubra*, and to make a careful collection of bark, leaf, and flower of all the cinchonas growing at Naduvattam for transmission to England for purposes of examination and analysis. On his arrival at Naduvattam, Dr. Bidie's first object was to ascertain what Mr. Cross's views were exactly, and these he found to be as follows:—"That the plant hitherto regarded as the Cinchona Succirubra was no other than the comparatively useless Cinchona Micrantha; that what was termed 'McIvor's Hybrid,' and 'Pubescens' was the true Cinchona Succirubra, and that the 'Magnifolia' was the Pata-de-Gallinazo of the South American Red bark region. After a careful consideration of all the botanical evidence on the subject, Dr Bidie arrives at the conclusion that the tree known as the red bark on the Government plantation *is* the true *cinchona succirubra*, and to prove how hazy Mr. Cross's notions were regarding the species, he mentions the following circumstance. On first meeting Mr. Cross he pointed out to him plates of *cinchona succirubra*, and *cinchona micrantha*, but without names attached, and asked him for his opinion regarding the species; but there was considerable hesitation on his part, and the matter was allowed to drop. Besides, notwithstanding his presumed familiarity with the botanical characters of the cinchonas, it took him the whole period of his stay on the hills, which extended to more than a year, to arrive at his conclusion, and, though he was in frequent intercourse with such botanical experts as Colonel Beddome, he never once hinted at the possibility of such a mistake.

Regarding Mr. Cross's identification of the plant known as "McIvor's Hybrid," Dr. Bidie concludes from the facts at his command that it is not the true *cinchona succirubra*, as asserted by him, but (from its strong resemblance to a cinchona known in Ecuador as 'Cochieara') a *cascarilla serrana* or hill bark which was discovered by Spruce, the great explorer in the forests of Llalla, at the foot of the Mountain Assuay, and described by him in 1859, and he thinks that it will probably prove a pubescent variety of this species. To set aside all doubts on the matter, however, he recommends that the Nilgiri specimens be compared with those sent to Kew by Spruce in 1859.

With reference to Mr. Cross's identification of our magnifolia with the Pata-de-gallinazo, Dr. Bidie is of opinion that he is probably correct, as it agrees sufficiently in its characters with Spruce's description to warrant its being considered a smooth-leaved cinchicara or Pata-de-Gallinazo.

In connection with this subject Dr. Bidie infers from the number of hybrid-looking cinchonas on the Government estates that cross-breeding is very common, and that the structure of the flowers confirms this view. He points out also that Colonel Beddome's opinion was that natural hybridisation could scarcely occur in the cinchonas, as from the manner of maturing of the flowers, self-fertilisation is prevented, and crossing of species rendered possible. Mr. McIvor, whose experience was exsensive, also believed in the existeuce of *natural* and *artificial* hybrids, and, as the varieties on the estates support this view, he considers that it ought to be accepted until proved by experiment to be wrong, and points out that in the case of "pubescens," otherwise called "lanosa," Mr. McIvor had doubts as to its being a hybrid or distinct species, and believed that it would not come true from seed. But it is a fact that on a private estate, in which he was interested, it was propagated from seed, and exteusively planted out. There was a solitary "pubescens" tree on the Naduvattam estates which Dr. Bidie was anxious to compare with the ordinary variety scattered over the estates, as bark taken from it yielded wonderful results, but he found that it had disappeared and regrets the circumstance exceedingly.

There are many varieties of the yellow bark tree on the estates with distinct characters, although they do not generally thrive at Naduvattam, aud, as it is important that the value of these should be ascertained, he made a complete collection of their barks which included no less than fifteen varieties, and he is confident that, though some may prove worthless, others will be found valuable. Though, as pointed out above, the yellow bark trees are very delicate, he draws attention to a signal exception in a tree of which a few specimens exist on the estates, which grow vigorously, attain a great height, and are very hardy. This had hitherto beeu cousidered a hybrid, but it has all the character of a typical calisaya.

The total number of bark and herbarium specimens collected amounts to 38, and every care was taken in their collection, so that the results of their examination may prove of value both in a practical and botauical point of view. Precautions were also adopted to avoid confusion in any future reference.

Government, in their order, express their indebtedness to Dr. Bidie for his report, which fully satisfies them on the points raised by Mr. Cross. The specimens collected are to be packed and despatched to the Secretary of State.—*Madras Times.*

STATISTICS OF CINCHONA: QUANTITIES IMPORTED INTO AND PRICES REALIZED IN BRITAIN.

We and our readers are greatly indebted to Mr. Dobree for having, with the efficient aid of Mr. Hamilton, prepared so very satisfactory an answer to his own question, put, some time ago, through our columns. Here it is :—

To the Editor, "Ceylon Observer."

Udugama, April 15th, 1882.

DEAR SIR,—About two years ago I wrote a letter to your paper, asking whether the price of cinchona bark was likely to keep up when the large acreage planted with cinchona in Ceylon, India and Java commenced to be harvested.

No satisfactory answer was ever given to my letter, but the enclosed account of cinchona bark in *lb.* imported into Great Britain during the last five years, and the amount paid for that bark is, I cousider, a most satisfactory answer.

All official reports on cinchona imports are given in serons, cases and bales, and are no real guide to the true amount imported, but the following, which was compiled for me by Mr. J. Hamilton, who is himself largely interested in cinchona, shews the imports in lb. You will notice that the imports have steadily increased three and a half times in quantity, and four and a half times in value, during the five years, and the average value per lb. has increased from 2s 0½d to 2s 7d.

The increase has beeu steady, and, therefore, I think, is all the more likely to last.

The imports of bark into France, Germany and Italy are, I believe, also increasing in nearly the same proportion.—I remain, yours faithfully, T. S. DOBREE.

"Peruvian Bark" Statistics, compiled partially from *Board of Trade Returns*. Imports into Great Britain for five years and valuations.

For the month of January 1877.						
222,992 lb.	valued at	£19,745	average	per lb.	1/9	Mean average for each year 2s 1d per lb. for 5 years 2s 5d per lb.
1878.						
622,608	do	do £61,342	do	do	1/11	
1879.						
412,720	do	do £61,744	do	do	2/11	
1880.						
562,352	do	do £81,243	do	do	2/10	
1881.						
636,160	do	do £85,264	do	do	2/8	
1882.						
1,984,416	do	do £240,151	do	do	2/5	
For year ending Dec. 1877.						
3,912,832	do	do £402,234	do	do	2/0½	Mean average for 5 years 2s 2½d per lb.
1878.						
6,131,552	do	do £658,288	do	do	2/1	
1879.						
6,818,336	do	do £973,163	do	do	2/1	
1880.						
8,937,824	do	do £1,185,334	do	do	2/7	
1881.						
14,024,304	do	do £1,812,501	do	do	2/7	

In reducing the imports to pounds Mr. Hamilton has done a very important service to all interested iu the enterprize of cinchona culture. The result of his figures, which we may accept as reliable, is, that, in the face of imports of "Peruviau bark" into Britain, shewing an increase in five years of three aud a half times, the average value, instead of going down, has actually increased beyond the increase in quantity, that is by four and a half times. In figures the increase in average price is represented by 6½d per lb., the difference between 2s 0½d at the commencement of the period, and 2s 7d at the end. And Mr. Dobree has reason to believe that the imports of bark into the leading countries of contineutal Europe have increased in about the same proportion.

It will be observed that, while the imports of bark into Britain in 1877 amounted to only 3,912,000 lb., valued at £402,000, or an average per lb. of 2s 0½d, the figures for 1881 had gone up to 14,024,000 lb., valued at £1,812,000, an average per lb. of 2s 7d.

This is a case, beyond most, where our rejoicings are not merely of a selfish or local nature, but are as expansive as the limits of humauity. Indeed we see no reason to exclude the brute creation, for, in the treatment of the diseases of cattle, sheep, horses and dogs, the cinchona bark alkaloids are just as valuable as they are in the case of human patients. In the swampy and malarious regions of the earth, and this description embraces the coldest parts of Russia and the north of Europe as well as the hot alluvials and deltas of the tropics, increased use of quinine and the other products of the bitter bark means human suffering relieved, the sick rescued from death,

and families saved from the destitution which would follow the loss of their breadwinners. We feel that there is no irreverence in saying, with reference to the important and cheering information contained in this issue about the increased use of quinine in the world: "Let us thank God and take courage." It seems certain now that it is almost impossible to place limits to the quantity of cinchona bark which the world can use. With all drawbacks counted, Ceylon is one of the countries best able to provide supplies, and the figures we publish shew that planters may dismiss all fears of overdoing the pursuit.

Mr. Hamilton, who has supplied the valuable figures placed at our disposal by Mr. D bree, is a well-known Dikoya planter of great intelligence and enterprize. When on a journey through Dikoya recently, we greatly regretted that we could not turn aside and see the process of preparing bark on his estate. We were told that for largeness and uniformity of size, and evenness and goodness of quality, such consignments of bark had never reached the London market. We hope to hear that the prices realized were in proportion to the trouble taken and other care bestowed.

INDIAN EXPORTS.

We are indebted to the Government of India for the Trade and Navigation reports made up in detail for the 11 months of 1881-82, ending 28th February. Our readers will be interested in learning that caoutchouc (Indiarubber) to the value of R976,000 was exported. The exports of coffee were only 238,000 cwt. valued at R10,002,000, against 311,000 cwt. valued at R13,567,000 for the corresponding period of the previous year. The exports of coir were 194,000 cwt. valued at R1,612,000, against only 98,000 cwt. valued at R815,000. What could have been the reason for a *doubled* export of coir? Cotton also shews an increase, the figures being 4,101,000 cwt. valued at R122,207,000, against 3,972,000 cwt. valued at R116,340,000. The exports of cinchona bark were 425,000 lb. valued at R155,000, against 563,000 lb. and R658,000, so that here there has been a decrease. The export of coconuts had gone down from 708,000 to 327,000, and copra from 43,000 cwt. to 10,000. The exports of rice (the only export on which duty is now levied) had reached the enormous figure of 21,752,000 cwt., so that the total for the year was no doubt fully up to 24,000,000 cwt. Of course, much of the inferior Burma rice sent to Europe is used not as food but to size cloth. The increase on the previous year had been about 700,000 cwt. The 21,752,000 cwt. of rice exported was valued at R64,922,000. The quantity of rice in the husk exported ("paddy") was 295,000 cwt. valued at R487,000. In wheat there had been an enormous rise, from 6,948,000 cwt. to 19,142,000. Of ivory, the exports were 9,994 lb. valued at R50,000. Of jute, the exports were 6,667,000 cwt. valued at R45,202,000, an increase of nearly 1¼ million of cwts. There were, besides this quantity of raw jute, nearly 40 millions of gunny bags of a value of over R10,000,000, with gunny cloths, rope, twine, &c. The exports of coconut oil had gone down from 1,323,000 gallons to 973,000 gallons. Of cardamoms the exports were 207,000 lb. again 214,000. Of TEA the exports in the 11 months of the three years were:—

1st April to 28 h Feb.	1879-80.. 36,893,000 lb.	R29,540,000
" " "	1880-81.. 45,232,000 lb.	R29,785,000
" " "	1881-82.. 47,527,000 lb.	R35,287,000

It will thus be seen that there had been an increase of over 10,000,000 lb. in three years, but it is reported that this process has now been arrested, as a consequence of the low prices which prevailed for several years back. The export of tobacco leaf had gone down from 12,666,000 lb. to 9,226,000 lb., while "manufactured" had risen from 365,000 lb. to 718,000 lb. Of teak the export had been 54,000 cubic tons against 58,870. Sandalwood had been exported to the value of R330,000. The total value of Indian produce and manufactures exported was for the 11 months R704,040,000, so that for the whole year the sum was probably R770,000,000. This is apart from exports by land to Burma, Nepal, and other bordering countries. With the abolition of all duties except that on rice, and the facilities of transport provided by means of railways and lines of steamers, we may confidently look for the early day when the value of the exports of British India will reach and exceed a value of 100 millions sterling.

THE BOTANY AND CLASSIFICATION OF THE CINCHONAS.

The substance of Dr. Bidie's report, which we copied into Saturday's *Observer*, cannot but be regarded as a valuable contribution to the controversial and general literature of which the fever, or rather fever-curing, trees of the Andean regions of America have become the subject since the era of their wonderfully successful introduction into the Eastern World. For poor bumptious Cross, who so dogmatically affirmed that the *Cinchona succirubra* of the Nilgiris (identical with that of Ceylon and Java) was not "the real Simon Pure," but a grey bark, *C. micrantha*, but who, when shewn plates of the two species, without names attached, was unable to say which was which, we can now feel only pity. The wonder is that Col. Beddome, who complained of Mr. Cross's contradictory statements, accepted so readily his testimony, in direct opposition to that of Dr. Spruce, as to the now celebrated "Pátá-de-Gallinazo." But Dr. Bidie himself, it will be observed, although he believes in the tendency to hybridization and noticed the frequency of hybrid-looking plants, yet leans to the belief that "Mr. McIvor's hybrid," the seed of which came true to type, is really a pubescent type of Spruce's "Cuchicara." *C. magnifolia*, on the other hand, Dr. Bidie supposes, Mr. Cross is right in identifying with the smooth-leaved variety or type of Dr. Spruce's "Cuchicara." It is well that a complete set of botanical specimens, leaves, flowers and fruits, have gone to Kew for identification, the result of which cannot but be to throw valuable light on the whole question. Dr. Bidie, however, does not seem to be aware that Dr. Trimen had already sent to Kew specimens of "*Cinchona robusta*" (identical, we believe with "Mr. McIvor's hybrid," [illegible] or *pubescens*), the result of which was to prove that whatever the tree might turn out to be, hybrid or distinct species, *Pátá-de-Gallinazo* it was not. But

the most interesting matter to us is, that amongst the fifteen varieties of yellow barks on Neddiwuttum, all, we believe, derived from the portion of Ledger's seed purchased by Mr. Money, there is one specially robust. Like the similar one in Jamaica, which is able to flourish on windy ridges, it was regarded as a hybrid. The plants will probably turn out to be identical, and we may now look forward to the establishing in India and Ceylon of hardy varieties of the very best kinds of cinchona.

AGRICULTURAL NEWS FROM THE NORTH.

(From Our Own Correspondent.)

ABERDEEN, 23rd March 1882.

I notice in an *Observer* an account of a set of experiments testing the effect of different manures on coffee, and think their value would have been much enhanced had they been done in duplicate, as is now the practice in manure experiments conducted under the direction of agricultural associations in this country. It would be a good thing also to include in these experiments tests for the value of the different methods of storing dung. According to high authorities, there is a very material difference in the value of dung that has been stored in open yard from that kept under cover. Speaking of open yards one authority says: —"There is no doubt that the very essence of the manure is carried off and lost I am certain that this loss, from experiments made, is far more than we have the least conception of. The late Mr. Hope, of Fenton Barns, got 4 tons of potatoes more per acre from dung made under cover than from that in open yard."

Mr. A. Stephen Wilson's paper embodying his discovery in the life-history of potato-disease was read at a meeting of the Linnæan Society, and may be looked for in whole or part in that Society's Journal. The following has reference to another department of Mr. Wilson's work, and is of interest to cereal growers, as showing the extraordinary reproductive power that may be developed in seeds under conditions favourable to

"TILLERING."

In the record of the Edinburgh Botanical Society, we find the following summary of a paper "On Tillering," by A. Stephen Wilson, Esq., North Kinmundy, Aberdeenshire, illustrated by photographs:—

By the word "tillering," as applied to a cereal grass, is meant the producing of more stalks than one from a single seed. The plumule of the embryo grows into the first or primary stalk, and all the secondary stalks arise either directly from the primary stalk or from secondary stalks thus directly produced. All the secondary stalks are buds growing of stalks, and not out of roots. Indeed, it cannot be properly said that the primary stalk itself grows from the roots; this stalk and the roots grows simultaneously, and have a biological interdependence, but the roots no more produce the stalk than a man's legs produce his head.

All the tillers or secondary stalks are thus of the nature of branches, the buds or beginnings of which arise from the two or three lowermost nodes of the primary or secondaries. No such buds are thrown out upon the internodes. The secondary stalks or tillers, which are really branches, throw out roots from their bases and lower nodes, but no stalk whatever arises directly from any root. In some plants a stalk may arise directly from a root, or a root may arise directly from a stalk, but in the grasses no stalk ever arises from off a root.

But this note is not intended to be an exposition of the principle of tillering, but merely an introduction to the accompanying photographs of barley and oat plants. These plants were grown in the garden at North Kinmundy along with some others not quite so prolific, in order to test the limits of tillering. Previous experiments had shown that the main condition necessary to ensure tillering is shallow planting. When a seed is put down two or three inches the plumule is drawn out and exhausted before reaching the surface, where the tillering arises. When a seed is merely covered with earth it goes into tillering at once. The first set of seeds was torn up by the sparrows, so that a partoof the tillering season was lost. The second set was protected until safe. The best barley plant produced about 140 stalks, 130 of which showed the ear out of the sheath. The second had 121 ears; others had fewer, diminishing down to about 50. The oat plant submitted stood through the winter and produced about 10,000 returns.

Now, as the tillering process in the barleys was going on during the whole season, some of the ears were not ripe when the plants had to be pulled. But notwithstanding this, there can be no doubt that, in order to reap the full advantage of seed corn, it should be sown or deposited as near the surface as possible. This would be true of autumn sowing as well as spring sowing, were the former not affected by frost; but a severe winter renders deeper seeding advisable for other reasons than those directly connected with the development of the seed.

I had the pleasure on Friday night of listening to a lecture delivered by Mr. Wilson to the North of Scotland Horticultural Association, in the Christian Institute Hall, on the subject of club root in turnip. Reviewing the chief peculiarities which are mistaken for disease and that interfere with the weight of crop, he described furcation as common to a great many roots of perfectly healthy plants. Next "finger and toe," which is believed to be the result of club-root and was so understood by the Russian botanist who discovered the club-root fungus. Mr. Wilson had been able to prove that the finger-and-toe-like nodosities were quite distinct, from the clubbing caused by the inroads of the fungus, and that they existed free from any trace of fungus, and were in fact fleshified leaf-buds. It was for the gardener, the farmer, or the agricultural chemist to find out what excited the turnip to sport in leaf-buds, and check the tendency, since it was a peculiarity they wished to repress. As a botanist, he had discharged his share of the work by investigating the nature of this objectionable feature. He exhibited a great many specimens of terribly finger-and-toed turnips, from the lowest down "buds" of which he had cultivated a profusion of leaves. Another proof of finger-and-toes being innocent of fungus was demonstrated by the specific gravity of club-root, which sank in water, while healthy turnip and finger-and-toe floated. Club-root proper is the result of a fungus which attacks from the outside and spreads through the root, causing clubbing and rendering the turnip liable to rot under certain atmospheric changes. In the discussion which followed the lecture, Mr. Jamieson, chemist [whose reports of experiments have frequently appeared in the *Observer*], was asked to inform the meeting of the result of his efforts to elicit information by the circulars he sent to farmers two years ago with reference to the relations between manures and disease in turnips, but he had nothing to impart, further than that the replies received were so very contradictory that he could form no conclusion from them.

THE SODA DEPOSITS OF NEVADA.

In Nevada, says the *Territorial Enterprize*, of Virginia City, crystallized soda can be dug up as ice is dug from a pond, except in the case of soda no one knows how far it is to the bottom of the pond. Out near Ragtown there is an inexhaustible supply of pure soda extending down to an unknown depth. On the surface of the ground are two or three feet of sand, but below this lies the soda, looking like a solid mass of ice. It was this soda that gave rise in the early days—when the emigrants were crossing the plains—to the stories that in places on the plains there was to be found,

under a few inches of sand, a solid mass of ice. The soda, as dug up from the plain in sheets from two to three inches in thickness, really does look more like ice than does any other natural mineral formation.—*Oil and Drug News.*

THE TEA QUSETION IN MELBOURNE.

MR. J. O. MOODY'S LETTER TO THE INDIAN "TEA GAZETTE."

(Copy of letter addressed to the Editor of the Calcutta "Tea Gazette," and forwarded per Shannon, leaving Melbourne on 30th March 1882.)

DEAR SIR,—In your paper of 20th February last appeared a letter from Mr. Everard, which, for mendacity and unscrupulousness, I should hope, is unsurpassed in the annals of letter-writing. There is no doubt but that you have been purposely misled.

His statement that "*no such letter* (*as mine*) *ever appeared in the 'Age,'*" is contradicted by his own reply to this particular letter, and which also appeared in the *Age* newspaper.

Here are the two in juxtaposition :—[Then follow the letters which have already appeared in the *Observer*.]

The editor, in honouring my letter with a place in his leader, did so in a most complimentary way, though at the same time he excluded the money challenge and my name, both of no consequence, and not to the point perhaps he thought the money challenge *infra dig.* on my part.

You [the editor of the *Tea Gazette*] will find, in the *Calcutta Tea Gazette* of 19th December last, this leader printed in full, and containing also my letter, printed in your columns for the second time; and if, Mr. Editor, you had only noticed this, it would have saved me from the unmerited reproof for "carelessness" contained in your article of 20th February, and which has been republished in the Melbourne *Argus* of 25th March.

I now intend to *prove* that nearly every paragraph contained in the rest of Mr. Everard's letter to you is *untrue*. [This is a strong word to use, but it is the only appropriate term to use when Mr. John Everard makes statements.—ED.]

If you will kindly turn to the "Official Record of the Melbourne International Exhibition," just published (copy of which is posted to you), on page 164 you will find the list of jurymen for sections 31 and 32, which gives Mr. David Gibson as chairman—not Mr. Everard, who assumes the title. Further, the official report from the section of this jury *on tea* is signed by Mr. David Gibson, as chairman, not by Mr. Everard. The tea section or subdivision of the jury was composed of :—Messrs. D. Gibson (chairman), J. Everard, W. J. Cowderoy, A. Harvey, W. Pitt Brown, E. S. Harley. All jurymen (about 400) got medals for their gratuitous services. [This was to meet Everard's attempt to shew that his receipt of a medal was any mark of special approval of his conduct.—ED.]

I was appointed to this jury, but resigned on receiving my appointment, because I represented Jas. Henty & Co., the agents of the Calcutta Tea Syndicate, who might be considered exhibitors and come under the following jury clause (page 1, Official Record): —"That no person interested, either as a partner or employé, in a house exhibiting, shall be a juror in the classes in which such house or person exhibits."

On the first meeting of the full jury, Mr. Everard in unmeasured language denounced Indian and Ceylon teas and all connected with them, and this being reported to Mr. D. A. Sibthorp, Commissioner for India, and Mr. A. M. Ferguson, commissioner for Ceylon, those gentlemen entered a protest against Mr. Everard acting on the jury, and requested that Mr. W. Pitt Brown should be nominated, more especially as Mr. Everard had acted as agent for one of the Japanese exhibitors—*producing Mr. Everard's own advertisement in the "Argus" in support of this*—and claimed that he came under this clause of the jury regulations. Mr. Everard was not removed from the jury * but Mr. Brown was placed on it, after the jury was formed, and certainly was the only one of the number well up in Indian teas, and the work fell on him, not Mr. Everard, as stated by that gentleman.

The exhibits of tea at the Melbourne International Exhibition were as follows :—

INDIA	339
CEYLON	78
STRAITS SETTLEMENTS	1
JAPAN	35
MELBOURNE AND CHINESE	54

Therefore the representatives of 417 samples out of 507 samples were not satisfied with Mr. Everard as a juryman.

In confirmation of my statement I refer you to Mr. Sibthorp, and also give extract from Mr. Ferguson's report to his Government (see *Weekly Ceylon Observer* of 15th January, 1881) :—

"As regards judging our Ceylon teas and other teas at this Exhibition, I felt so strongly the necessity of guarding against notorious prejudices in the case of at least one juror (Mr. Everard), who has a direct interest in Japan tea, that I considered it my duty to address Mr. Newbery, the Superintendent of Jurors, at considerable length on the expediency of applying to teas and coffees the principle on which spirits, wines and beers were judged, the jurors receiving numbered samples without any information as to the origin of the liquors; and Mr. Newbery deferred to my request, and accordingly bottles were provided . . . . numbered 1, 2, 3, and so on. . . ."

And take a later opinion (see *Observer*, 17th November, 1881) :—

"THE TEA PLANT, &c.

"Dr. Wallich had far more excuse for his mistake than has the now exploded wind-bag, Mr. Everard, for his gross ignorance displayed in a speech at a public meeting held specially in the interests of China teas," &c., &c. "If there should be anyone so credulous as to attach the slightest weight to Mr. Everard's statement that 'during the past 20 years he had done his utmost to introduce Indian teas,' they need not wonder at his further statement, 'although with but little success,' in view of his own astounding confession that he considers the China tea superior to the Indian from the fact that the able and experienced celestials, who had been 2,000 years in the business, had discovered the secret of depriving tea of that very principle—theine—which until now was deemed essential to true tea. It will now be the turn of the honest chemist to turn round on the advocate of the libelled teas and say :—'It is you, not we, who have told the tea consumers that the stuff supplied to them from China has been systematically and deliberately deprived of its theine and tannin.'"

Mr. Everard poses as the friend of Indian tea. You see what Mr. Ferguson's opinion of this is, and I distinctly state he has been hostile to Indian tea ever since Mr. Sibthorp and I declined to allow him to sell a portion of the Syndicate's shipments, for reasons that are indisputable. [That is the whole secret of Everard's animosity against Mr. Moody and Mr. Moody's friends, Messrs. Buck, Inglis, Sibthorp and Ferguson, all of whom were honoured with Everard's abuse. We are acquainted with Mr. Moody's very conclusive reason for not consenting to Mr Everard's impudent request, considering the circumstances, of being allowed to sell a portion of the Syndicate's teas.—ED. C. O.]

Do you think that a friend to Indian teas would write to the *Argus*, as Mr Everard did as follows :—

"And notwithstanding Mr. Inglis's assertion (viz. 'there has never yet been placed on record in the office of a well-erated tea having been sent from an Indian warehouse'), I now inform him that in India for several seasons the

* Because it was really impossible to [illegible] disinterested judges.—ED.

planters have gone in for quantity at the expense of quality. . . . A number of parcels of withered leaves have been shipped to London and realized under 6d per lb."—*Argus*, 30th June 1881.

Or as he did at the meeting of China tea merchants, when he showed samples of Indian tea in bottles, which he asserted were thick, gummy, and dirty, &c., and which he confirms in his letter to the *Age* of 31st October?

This statement clearly shows his want of knowledge of what he is writing about. That some of the Indian teas turn thick with standing is certain, but never gummy and dirty, which is as untrue as all his other statements.

This thickening in Indian tea is only found in few samples highly prized by many buyers, and why? Because it indicates that the tea is so *strong* that a hot solution cannot hold the extract on cooling. Why did Mr. Everard not try more water, or less tea? But, really I am giving a technical education to this gentleman free of expense; and amongst other fallacies that he stuck to, and I have cured him of, is his idea that Chinese green teas were not artificially coloured; but I was glad to see, in his last letter on the subject, the admission that even the best of such teas (green) have a slight bloom given to them artificially.

Whilst on the scientific portion of this subject, I may as well refer to Mr. Everard's assertion (*vide* his letter, 31st October) that the reporters at the celebrated burlesque meeting held at the Melbourne Exchange had reported him wrongly, and that he did not say "theine was extracted from tea." But we have only Mr. Everard's word against the reporters'; and, as Mr. E. admits in the above letter that the tannin is extracted, but not the theine, it is easy to see he is out of his depth, and *very ignorant* of the subject he is writing about, for tannin *cannot be taken out of tea without also taking the theine*; and, therefore, there is not a doubt in my own mind but that Mr. Everard did say—"The Chinese exacted the theine and tannin, which the Indians allowed to remain in —not knowing better how to prepare it" (tea); and Mr. Everard said this without knowing exactly what was the meaning of the term he was using.

Allow me to give extracts from the highest authorities on tea analysis:—

"In tea the theine exists in combination with tannin. Theine exists in tea in the form of tannate of theine."—*Wanklyn.*

"Theine exists in combination with tannin in tea." —*Bell.*

Indisputable evidence, I should think, that mechanically it is impossible to remove any portion of tannin from tea without also removing its equivalent in theine.

In his letter Mr. Everard endeavours to score a point by stating—"And I also pointed out that the scientists themselves admitted, by their own published reports, that there was more theine in Chinese tea than Indian." Mr. E. is wrong again: we stopped giving the theine terminations because of the time it took to make them, and particularly the cost, which was a guinea for each theine termination.

But here is the analysis of 570 half-chests of Foochow tea, purchased by Mr. Everard himself, at public auction, in Fraser's rooms, on the 6th October, 1881:—

INDUSTRIAL AND TECHNOLOGICAL MUSEUM

Laboratory, 17th October 1881.

Upon Analysis they gave:—

Per centage of Number.	Per centage of Mineral Ash	Per centage of Extract.	Per centage of Soluble Salts.	Per centage of Theine.
343...	5·32...	28·18...	2·78...	0·19
347...	5·20...	31·44...	2·60...	Only a trace
348...	5·52...	34·56...	2·26...	0·26
351...	5·92...	28·50...	2·64...	0·23
352...	6·20...	32·24...	3·14..	Only a trace

All the samples contain exhausted leaves, and in most the tea is in a very broken condition.

Excess of stalks being very marked in Lot 351, which is faced with plumbago.

Perished leaves are plentiful in lots 323, 352, and 347. The latter contains foreign stems.

348 also contains foreign stems.

Lot 323 contains rice husks and foreign stems.

(Signed) J. COSMO NEWBERY,

N.B.—Number 323 was not purchased by Mr. Everard. The rest of the numbers are his purchases.

As Indian teas have never gone below 2·92 and run over 4·00 per cent., I trust I have conclusively shown the value of Mr. Everard's statement that Chinese tea shows more theine than Indian. [While Mr. Cosmo Newbery, a man of the highest possible character, proved that China teas, purchased by Everard, to be sold again, were made up of "exhausted" and "perished leaves," "foreign stems," &c.,—ED.]

With regard to the *Tea News, with which I have nothing whatever to do*, it is merely a rehash of reports, letters, &c., that have appeared in the newspapers, and as, Mr. Editor, you republished it in full in your issue of 17th October 1881, I presume you found nothing specially wrong in its contents. [Probably the truth is that the permanent editor, who copied the *Tea News*, with tacit approval, was absent when Mr. Everard's letter was received, and its false statements accepted as true —ED.]

Such trade puffs as the *Tea News* appear constantly in a condensed form in the newspapers of the day, and are a feature of the 19th century.

Allow me to ask you why the vendors of our old favourite, citrate of magnesia, don't hold a meeting to condemn the manner in which the new favourite, Eno's Fruit Salt, is puffed?

Mr. Everard draws his conclusions from the *Tea News*; the writer of the *Tea News* draws his from the extracts (which are true in themselves) that have already appeared in the daily press; both writers draw their own conclusions and *both are unfair, in the absence or omission of the context.*

The China tea merchants would have done far better (if they had such confidence in their teas as they protest they have) by appealing to the highest tribunal we have, viz., the analytical chemist, and we have many such in Melbourne.

Mere talk and abuse will not settle the question—"Is China tea adulterated or not?"

After all, the real attack has been on Messrs. Cosmo Newbery, and Dunn, the chemical analysts, who have repeatedly proved they are thoroughly masters of the subjects they discuss. These gentlemen, as far back as 1877, have issued periodical reports on the food supply of Melbourne, and more particularly on confectionery, milk, tea, coffee, cocoa, chocolate, mustard, preserves, aerated waters, ales and porters, spirits, vinegar, kerosene, &c., pointing out the adulterations or defects they have found in each, and nearly all these reports have appeared in the *Argus*, and, unquestionably, have done much good. Therefore, instead of denouncing these gentlemen, I think the thanks of the community are due to them for their invaluable services.

Mr. Newbery pertinently puts it:—"The China tea dealers have had a meeting to denounce our analyses and statements. I shall expect to see the milkmen, confectioners, and others now do the same. I can only say that, since we commenced our labours, the last examinations showed no lead in confectionery, but which was found in it before; kerosene was highly explosive, but a recent examination showed all brands to be well over the standard. Many other articles now show improvement in the right direction, and tea must also come up to standard. We recognize no country or make of tea; but when we find the grocer retailing to the consumer an article not pure tea, or

containing exhausted leaves, we shall continue to denounce such in the interests of the consumer only"—[This is what is honest and right, and therefore it is that Mr Everard denounces the "statements" of the chemists, those statements being simply the results of severe analysis!—ED.]

In answer to one of these reports, which appeared in the *Argus* of 5th October 1881, at a tea auction sale held in Messrs. Fraser's rooms the same day, Mr. Everard moved the motion that has been thoroughly burlesqued in Melbourne, viz.:—"That the statements made by Messrs. Cosmo Newbery and F. Dunn regarding the adulteration of China teas are unjust to the merchants and traders, and untruthful." Immediately after this motion Mr. Everard purchased the four lines of tea at the auction, the analysis of which I have just furnished you with, and are so strongly condemned by Mr. Newbery

Mr. Everard states that 300 were present at the meeting—the *Argus* and *Age* both say 150; but this is on a par with other Munchausen statements, and characterizes the gentleman. Of these 150, at least 100 are to be found constantly about the exchange, for it is the stock, share, and mining exchange as well. And I have it from the clerk I sent to watch the proceedings that only about twenty tea merchants or dealers were present; the rest were attracted by the fun they expected, and which actually did take place; and a more undignified meeting was never before held in Melbourne.

The Messrs. Henty never intended and did not go to the Exchange meeting, for it was arranged from the first that I should take a part, but, finding a preliminary meeting had been held, slips distributed, and everything done to prevent discussion, I did not attend.

For many years past I have endeavoured to improve the standard of tea used in Victoria, and, failing to get fine teas from Foochow of late years, have imported small lots from Hankow, but so far the leaf has been against its sale.

During the last twelve months I have sold 2,000,000 pounds weight of China tea, and, therefore, do you think it likely, Mr. Editor,* that I should run down China teas, in which we are so largely interested, for the purpose of driving them out of the market? Certainly not; my sole aim is to improve the standard.

Take the total sales by auction (only) of China teas, for last season, 1880-81—2,829 6·0 lb. sold at 3½d to 1s. per lb.; 1,565,840 lb. sold at 1s 0½d to 1s. 10d. per lb.; and the bulk this season also consists of teas sold at 4d to 9d. per lb. in bond. Will any sane man tell me that teas at 3½d and 4d per lb. are pure and unadulterated? These are facts and figures which can be checked. Against my wish teas do come down from China that I don't like selling, for we are too much in the hands of the Chinese, and therefore the value of the Tea Act just passed. Hence, also, the support I have given to Messrs. Cosmo Newberry and Dunn in their endeavour to improve the foods supplied to the consumers of Melbourne.

And now, as I have been slandered, a few words for myself. The first Indian tea that ever reached Melbourne (a small quantity) was sold by me years ago, and came from Mr. James D. Bruce's gardens, Mundaldye; it realized 3s 6d per lb. A small lot was then imported which I sold at 4s per lb, and followed it up by heavier shipments for two or three years, being well backed up by one of my assistants, a new arrival from London, and who had been years in the Indian tea trade, and was then the only person in Melbourne thoroughly up in it; but he left to better himself. I could then obtain no one in Melbourne with sufficient ability to show customers the value of Indian tea, and my time was too much occupied to attend to it myself.

When the Syndicate commenced their operations in this market I entered zealously into the work;* and to me, as the representative of Jas. Heuty & Co., is due the success of Indian tea in the Melbourne market. The traders *only* gave me support. The brokers at first (with the exception of Mr. Harley, the oldest tea-broker in Melbourne) were against it; such expressions as "might as well take leaves from the tittee shrub," "too herby," "made me sick," "beastly leaf," &c., met me at every turn, all kindly got up in the interests of Chinese importers. What wonder, then, that I should retort by having the Indian teas analyzed, and paying also for whole tea sales of China kinds to act as comparisons. Put on my mettle, I have induced no less than twenty-nine firms to blend Indian teas, and have shown them all how to do it. Every Saturday afternoon and holiday for the last twelve months I have been found at my office, either blending teas for some customer or else trying new combinations, or analyzing tea in the laboratory I have attached to the tea-room.

And what is the result? That Indian tea, pure and simple, is obtainable in nearly every shop in Melbourne and suburbs, and all over Victoria, and in another year or two the gentle public will not be able to do without it. And in this the Calcutta Tea Associat on—no connection with the Syndicate—have lent invaluable aid, by being the first to pack pure Indian tea in 1 lb. and ½ lb. packets, tins, &c.

All the circulars issued on behalf of the Syndicate have been sent to you, and you can judge if I have used other than fair and legitimate criticisms in pushing Indian teas. China importers and brokers have run down Indian teas; I reply by analyzing both and comparing them together. This is met by talk that too much tannin is left in Indian tea, giving it a herby flavour. I show, by analysis, that some China teas are exhausted and adulterated, and this has been the result; every auction sale of Indian teas has shown an *advance* in price on its predecessor—and this in the presence of a stock of tea 4,000,000 lb. over the same quantity held last season—whilst every sale of China tea has shown a decline on its predecessor.

I don't talk twaddle, nor am I ever abusive, and generally only show (in answer to repeated attacks) the analyses of the China and Indian teas together, with a brief footnote, such as—"N.B.—The result in favour of Indian teas is too marked to need further comment. Many of the China teas will not pass the standard of a genuine tea."—*(Vide Circular, 20th July* 1881)

Do you think, Mr. Editor, any money value will repay me for the trouble I have taken? Certainly not. I have taken up the subject *con amore*, and with the sincere conviction that Indian teas are the finest produced in any part of the world.

The Calcutta Tea Syndicate have done their work well and thoroughly, and their brand on the package is now considered sufficient evidence that the tea it contains is pure and genuine; by all means let your tea planters give them liberal support and with a good supply of tea to this market, the continuance of the analysis of the teas—which is now deemed so important here that even retailers are sending in samples to the technological Museum for examination, and Messrs. Cosmo Newbery and Dunn and staff have

* Readers of the *Observer* will bear in mind that Mr. Moody is addressing the *Indian Tea Gazette*.—ED.

* Most zealously: that we can testify. The Indian Government were fortunate in their representatives, Messrs Buck, Inglis and Sibthorp, but these gentlemen would be the first to acknowledge that their success, rapid and great as it was, was mainly due to the untiring and zealous efforts of Mr. J. O. Moody.—ED.

their hands pretty full—and with the support of *true* friends of Indian tea,* I fully expect to see the consumption of Indian tea just doubled in Victoria, and increased throughout the colonies.

Apologizing for trespassing so much on your space, —I remain, your obedient servant,

J. O. MOODY.

PUBLIC SALE OF CINCHONA BARK.

Mr. E. John disposed of the following lots of bark at a public sale held in the Fort today (19 April):—

Rillamulla.—19 bags Succirubra chips and twigs 20c; 1 do do Dust 10c; 12 do Officinalis chips 45c.

Fruit Hill.—Suc.: 4 bags twigs and chips 10c; 19 bags twigs 25c.

Elbedde.—2 bags Succirubra stem pieces 62½c; 4 do do stem quills 87½c; 1 do do root 60c; 4 do do branch quill 40c; 103 do do beaten twigs 24c; 1 do Officinalis stem quill R1·55; 4 do do beaten twigs 20c; 1 do do stem pieces R1·30.

Gouagalla.—133 bags Succirubra branch anal. ·51 Sulph. of Q. 30c.

St. Regulus.—12 bags Succirubra root and stump pieces 57½c; 18 do do chips and pieces 37½c; 25 do do brauch and twigs 21c; 2 do do papery quill and branch 25½c; 53 do do branch 25c; 46 do do stem quill anal. 1·35 Sul. of quiuine 75c; 26 do Officinalis chips and twigs 22c; 7 do do branch 21c; 6 do do quill R1·35; 5 do do stem chips R1.

Glashaugh.—Succirubra: 65 bags chips and scrapings and 15 do do do 27½c; 76 do large branch shavings anal. ·96 Sul. of Q., 50c.

Ferdyce.—Succirubra: 39 bags twigs 20c; 23 do chips 67½c.

Wavendon, Officinalis: 54 bags twigs 17c; 3 do root 92½c; 13 do stem chips 87½; ½ do quill 75c.

Templestowe.—6 bags Succirubra bold twigs 21c; 1 do do root 82½c; 3 do do stem pieces 82½c; 2 do do broken quill 82½c; 2 do Officinalis stem chips 20c.

Abbey Craig.—Officinalis: 10 bags twigs 19c; 1 do root 67½c; 1 do chips and twigs 14c; 24 do stem chips and shavings 85c.

Bogahawatte.—15 bags Succirubra stem chips 75c; 5 do do root 62½c; 2 do do chips and twigs 12c; 1 do Officinalis root 40c; 3 do do chips 30c.

Agra.—Succirubra: 26 bags shavings anal. 1·62 Sul. of Q. R1·05: 35 do branch and twigs 27½c.

Radella.—40 bags Succirubra bold twigs 21c; 2 do Officinalis chips and twigs 25c.

Derryclare.—3 bags Succirubra twigs 10c.

Avoca.—33 bags Succirubra chips anal. 1·30 Sul. of Q.; 87½c.

Galkandewatte.—78 bags Succirubra twigs and chips 30c; 9 do do twigs 15c; 4 do Officinalis twigs 15c.

Duunottar.—Succirubra: 25 bags branch and twig 25c; 46 do branch and stem shavings anal. ·53 Sul. of Q., 32½c.

Maskeliya.—7 bags Officinalis scrapings 18c; 5 do Succirubra scrapings 45c; 2 do do quill 35c; 15 do do twigs 21c: 25 do do twigs 21c.

Bridwell.—Succirubra 8 bags brauch and twigs 25c; 112 do stem shaviugs R1·30. Analysis 1·83 sulph quiuine.

Halloowella.—6 bags succirubra root stem and branch 65c; 1 do officinalis do do 42½c.

K. G.—171 lb succirubra root 65c; 642 do do stem shavings 80c; 79 do do shavings and root 70c; 137 do branch shavings and twigs 25c.

Ambewelle.—470 lb officinalis twigs 12c; 380 do succirubra twigs 16c.

L.—154 lb succirubra good dust 25c.

Lippakelle.—329 lb succirubra branch and twigs 20c.

Troup.—9 lb succirubra stem quill 80c; ; 42 do suc. stem and branch chips and twigs mixed 50c.

Mossend.—1,516 lb officinalis chips 60c. Anal. 1·13 sul. quin; 292 do succirubra do 30c.

Etou.—500 lb succirubra twigs 16c; : 90 do do chips 60c; 30 do do dusty chips 12c.

Ardlaw.—100 succirubra twigs 18c.

* Who are not men of the Everard stamp.—ED.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, March 25th.

The *Société des Agriculteurs* has held its annual Congress, and discussed several questions of general interest. In the case of wheat it was admitted that much could be done to increase the yield, and so combat the effects of imported bread stuffs, by each agronomic station conducting experiments, bearing on varieties and suitable manures. Care should be taken not to employ fertilizers too immediately soluble, more especially of a nitrogenous character, which would provoke the laying of the crop. A motion was carried inviting railway companies to establish, in some of their principal stations, a meteorological office. Respecting manures for vines: those of potash salts, and under the forms of sulphates and chlorides, were to be preferred, and eminently suitable to vines under treatment against the phylloxera. The superphosphates soluble in citrate of ammonia possess the same agricultural value as such salts soluble in water. On the important subject of trench-preserved green forage, it was decided that the plan deserved adoption; that every kind of green stuff admitted of such treatment, even to rushes and broom and vine leaves, crushed or cut. It is not absolutely necessary for the successful preservation of green fodder to mix it with dry matter—straw, chaff, &c.—or to employ even salt. When coming into flower is the best period for cutting forage intended for trench-preservation, and neither rain nor dew interferes with that conservation. No special kind of trench is necessary, but such as are constructed in masonry have ever given the best results. The great aim is to exclude the air; the fodder ought to be placed in the trench regularly; chaffing the fodder is not indispensable, save in the case of the thick stems of maize and Jerusalem artichokes. The alimentary value of the forage approaches more to that in its fresh than in a faded condition. The subject of agricultural education received much attention, and a petition was drawn up, that the state, not the locality, ought to defray the expenses of such instruction in the case of the primary schools. A. M. de Haut made some curious observations respecting the flooding of vineyards in the Crimea. In France, that operation is employed as a remedy against the phylloxera, and is familiarly known as the Faucon process, but in Southern Russia the plan has been found to improve the quality of the fruit.

For sick horses carrots constitute a favourite diet; now that root has prematurely decayed this mild winter, and many farmers are desirous of obtaining a substitute. M. Boussingault suggests Jerusalem artichokes, but admits that the peculiar character of the tubercle renders cleaning a very difficult operation. M. de Béhague removed the difficulty by placing the roots in heaps, leaving the rain to wash them, and which it did so effectually as to satisfy his sheep.

A discussion is taking place as to the best period for castrating bulls. Ordinarily, those intended for the butcher are cut at the age of five or six months, on the ground that the animal then exacts less nutrition. Animals thus treated fatten rapidly, but, if destined for work, they will be found deficient in order and strength. In some regions the bulls are never castrated; they are thus unquestionably better fitted for work, though difficult in point of docility; but as for fattening that is out of the question. Experience, however, indicates that castration can be best effected between eight and ten months, when the animal exhibits signs of puberty; it will prove easy to fatten or will take to draught work with facility. In any case bullocks intended for labour ought to be well fed from their earliest age.

The steam plough is improved to suit the breaking-up of new lands in Algeria, where palm and other scrub are the chief difficulties against reclamation. The machine is made in forged iron and steel, very solid, and the sock descends to 14 inches in the soil, and can be arranged to penetrate to 20. M. Puzenat has introduced ameliorations in the articulated harrow which impart great elasticity. He replaces the movable bar by an assembly of bars, all of which are, however, independent, and preventing the teeth from following in identical wakes. The manure distributor of M. Couteau has the drums so arranged that the quantity of fertilizer distributed, over a width of 88 inches, is regulated with mathematical accuracy, following the rapidity with which the horse travels, and whether the fertilizer be dry or pasty. M. Dauten has invented a very ingenious beet-dibbling machine. The drums can be set to meet a

specified distance for opening the holes in the soil, then the seed is dropped in, and a small layer of fine earth covers it; by an endless screw arrangement, a certain quantity of manure can be simultaneously deposited.

The cultivation of beet-root, at present a monopoly in the north of France, is rapidly extending to the east and centre. Societies are being established not only to work up the roots, but to grow them. The aim of French cultivators now is to produce a root containing one per cent more in yield of sugar, which is a superiority that the German farmers at present possess.

The common enemy, the phylloxera, has encountered a new remedy in the employment of bitumen against its ravages. So far back as 1879 that agent was spoken of favourably, especially such as was imported from Judea. Sulphuret of carbon is still, however, regarded as among the perfect cures, double the quantity of that high-priced chemical being employed in 1881 as compared with the previous years. The government railway companies contribute liberally to testing all practical remedies. Nothing serious is now attached to the vines of Soudan and Cochin China. American stocks alone are in favour; the others are but curiosities.

M. Planchon attributes the plague to which the chestnut trees are subject to a microscopic mushroom feeding on the roots, the same as that which created such havoc in the pine forests of Germany a few years ago. M. Bella draws attention to the depredations of rats on trees growing along the banks of rivers; the animals in winter, when short of food, feed on the roots and so kill the trees.

WYNAAD COFFEE PROSPECTS.

(*Madras Mail*, April 12th.)

SIR,—I wonder if many of your planter-readers have noticed in their districts hundreds of moths flying about the coffee trees during this blossom, and could tell me if they ever saw it before. They were seemingly after honey, making quite a din with their wings, but on watching closer, the females were seen to be as busy as could be laying eggs, small green balls not so large as a pin's head, on the young shoots of coffee, deposited singly, and on the under side of a tender leaf. The moth, to describe it roughly, was a yellowish green color, clear winged, like a bee, with a black brush on the tail, about 1 inch long in body, and 1½ inches from tips of wings. Now the larvæ of this will be no small size, when full grown, and, if there are several to a tree, they will "gobble up" many pounds of leaves daily. As yet the coffee leaves are wonderfully free from any insect pest. Can the wily lepidoptera have made a mistake? I fear not! Is this to be another plague, though only for a season? It was the last straw that broke the camel's back. What with leaf-disease everywhere, borer within and caterpillar without, and coffee at 67s, things are not looking bright.

6th April. SOUTH WAINAD.

[The creature alluded to is surely not a moth, but the bee-like beetle with which we are familiar enough in Ceylon, as abounding in blossom time.—ED.]

DEPARTMENT OF AGRICULTURE.

The following is the text of the Bill adopted by the House Committee on Agriculture, at Washington, on February 13th, and subsequently introduced in the House of Representatives. A similar bill is far more wanted in India than fresh amendments of the Criminal and Civil Procedure Codes:—

"A Bill to enlarge the power and duties of the Department of Agriculture.

Be it enacted, etc., that the Department of Agriculture, established at the seat of Government of the United States, shall be an executive department, under the supervision and control of a Secretary of Agriculture, who shall be appointed by the President, by and with the advice and consent of the Senate.

"Sec. 2. That there shall be in said department an assistant Secretary of Agriculture, who shall be a practical agriculturist, and the several chiefs of the bureaus hereinafter named to be appointed by the President, by and with the advice and consent of the Senate, for a term of four years, who shall perform such duties as may be required by law or prescribed by the Secretary.

"Sec 3. For the purpose of collecting and disseminating all important and useful information concerning agriculture, and also concerning such scientific matters and industrial pursuits as relate to the interests of agriculture, the Secretary shall organise the following bureaus, namely:—1. The Bureau of Agricultural products, which shall include divisions of botany, entomology, and chemistry, the chief of which bureau shall be a practical agriculturist, who shall investigate the modes of farming in the several States and Territories, and shall report such practical information as shall tend to increase the profits of the farmer; respecting the various methods, the crops most profitable in the several sections, the preferable varieties of seeds, vines, plants and fruits, fertilizers, implements, buildings, and similar matters. 2. The Bureau of Animal Industry, to be in charge of a competent veterinary surgeon, who shall investigate and report upon the number, value, and condition of the domestic animals of the United States, their protection, growth, and use, the causes, prevention, and cure of contagious, communicable, or other diseases, and the kinds, races, or breeds, best adapted to the several sections for profitable raising. 3. The Bureau of Lands, the chief of which shall investigate and report upon the resources or capabilities of the public or other lands for farming, stockraising, timber, manufacturing, mining, or other industrial uses, and all powers and duties vested in the commission now known as the Geological Survey, together with all clerks, *employes*, and agents, and all instruments, records, books, papers, &c., are hereby transferred to the Department of Agriculture, and the Secretary may, through said bureau, institute such investigations and collect such information, facts, and statistics relative to the mines and mining of the United States as may be deemed of value and importance. 4. The Bureau of Statistics, the chief of which shall collect and report the agricultural statistics of the United States, and, in addition, all important information or statistics relating to industrial, educational, and agricultural colleges; to labour and wages in this and other countries; to markets and prices; to modes and cost of transporting agricultural products and live stock to their final market; to the demand, supply and prices in foreign markets; to the location, number, and products of manufacturing establishments of whatever sort, their sources of raw material, methods, markets, and prices, and to such commercial and other conditions as may affect the market value of farm products or the interests of the industrial classes of the United States. And the Secretary is hereby authorized to establish such divisions in this bureau, and to make such monthly or other reports as he shall deem most effective for the prompt dissemination of such reliable information respecting crops and domestic and foreign markets as will be of service to the farmers and other industrialists of the United States.

"Sec. 4. The Secretary of Agriculture shall hereafter receive the same salary as is paid to the Secretary of each of the executive departments. The salary of the Assistant Secretary of Agriculture shall be the same as that paid to the Assistant Secretary of the Department of the Interior. The salary of a chief of

bureau shall be the same as that paid to the Commissioner of Indian Affairs.

"Sec. 5. All laws and parts of laws relating to the Department of Agriculture now in existence, as far as the same are applicable and not in conflict with this Act, and only so far, are continued in full force and effect."—*Madras Mail*, April 12 h.

A NEW CARBOLIC POWDER.—A good formula of producing a new carbolic powder is given by a Berlin journal. Sixty parts of rosin and fifteen of stearine are melted together, and when the mixture has cooled somewhat, but still liquid, twenty five parts of carbolic acid are added. Eight hundred parts of precipitated carbonate of lime are incorporated with the mixture, and reduced to a pulverulent condition. This powder is intended for use in surgical cases, and may be applied with a sprinkler, and forms a good disinfectant for general purposes.—*Cil and Drug News.*

THE DIVI-DIVI.—The Superintendent of the Government Farm, Khandeish, recently shipped a consignment of Divi-Divi to the London market Divi-Divi is the fruit of a tree which has some resemblance to the tamarind. It is used for tanning purposes, and meets with a ready sale. The consignment consisted of 14 cwts., and realized £10 7-1, or close upon £15 the ton. From this sum, however, must be deducted the charge for freight insurance, brokerage, &c., a deduction which brought down the balance to £6 17 7; which, at the rate of exchange at the time of the transaction, was equal to R83-1-1. The expenses of production in India had amounted to R29-7; accordingly the superintendent cleared a balance of R53-10-1. At these rates, for every ton of Divi-Divi sold in London the exporter might count upon a profit of R80. The advantages of the cultivation of the Divi-Divi tree are that it will grow in soil which is sandy and contains little nourishment and is thus useless for average agricultural purposes, and that consequently, as may be imagined, the tree needs little attention and care. The demand in England can be reckoned upon as a fixed element.—*Englishman.*

AGRICULTURAL EXHIBITIONS.—The Presidency of Madras took the lead in India in the matter of Agricultural exhibitions. Opinions differ somewhat as to how far they were successful. Between 1855 and 1860, several exhibitions were held in the districts; Mr. Robertson, Superintendent of the Government Farms, thinks "they appeared to have proved on the whole as satisfactory as could reasonably have been expected." Mr. Pennington, refering to exhibitions in Tinnevelly, said "the result (especially of the last) was far from encouraging." Periodical Shows used to be held at Addanki in the Nellore district; and the Revenue Board remark that "in the marked improvement in cattle resulting from these shows, exceptions are to be found to the general failure of such efforts in this country." Mr. Robertson presents Government with a comprehensive scheme for holding five district Exhibitions a year, till all the districts in the Madras Presidency shall have had their turn, and then holding a large exhibition in the capital. On these it is proposed to spend R15,000 a year, R. 3,000 for each district. The Board propose one large northern exhibition, and one large southern exhibition to be held annually at a cost of R8,000 each; the site or scene of the exhibitions to be somewhere near the line of rail, and central. They offer to send further details of their scheme, if required. Perhaps a combination of the two schemes would be best. Let there be, in every year, an exhibition, the expenses of which are to be paid out of local funds and private subscriptions; and let only such exhibits as have gained prizes at these be permitted, and sent at the expense of the Exhibition Fund, to compete at the great Northern & Southern exhibitions.—*Madras Times.*

THE LATEST CONSIGNMENT of Government cinchona bark from the Nilgiri plantations sent to England for the purpose of being manufactured into quinine, and not for sale in the open, has been valued by the brokers at 1s. 6d. a pound. This is a considerable falling off, compared with prices prevailing a short time ago.—*South of India Observer.*

QUININE.—Considerable discussion has taken place of late in the United States, upon the question of the advisability of re-imposing a customs duty of ten *per cent* on the salts of cinchona. From present appearances, it is extremely doubtful if this can be accomplished. It would be only fair, however, to remove the duty on imported materials used in their manufacture, and efforts in this direction should receive the encouragement of all physicians and pharmacists. In this connection we may mention that popular journals have lately published numerous complaints that the benefit to the consumer, which was expected to follow a reduction in the price of quinine, consequent upon removal of import duty, has not been experienced as yet; that while the cost of quinine in bulk has greatly diminished, the price per grain, as paid by the consumer, has hardly varied from what it was when the price in bulk was nearly three times more than it is now. One result of this popular complaint has been the habit of buying quinine by the ounce for "family use" It is very likely that harmful effects will sometimes follow the indiscriminate use of sulphate of quinine as a household panacea, and it is equally true that a very general adoption of this custom would correspondingly diminish the profits of the pharmacist. That this fact is appreciated may be inferred from the announcements published by some pharmcists in this neighbourhood of the price per grain for which they will furnish the article, whether in powder, mixture, or pill.—*New Remedies.*

MANURE FOR TEA ESTATES IN THE DUN.—The Manager of the Dehra Dun Tea Co's estates has a very interesting paragraph in his last report on this subject, worthy the attention of those who possess tea properties in that district. Mr. Nelson writes:—

Manure.—This is becoming year by year a more serious question. 50 cartloads are required to manure an acre; therefore to manure annually one-third of the entire area under plant (or about 298 acres) 14,900 cartloads are necessary. The Co's cattlesheds supply about 4,000. The Zemindary villages about 2,000 and I cannot now purchase more than about 2,000 loads from surrounding villages. Many young gardens have sprung up in the Dun since 1876, and this has not only enhanced the value of manure, but made it much more difficult to obtain. The only way I can see out of this difficulty, is to throw nearly the whole of the Zemindary into grazing lands, buy a large number of cattle, (all counted we have now only 182), build large cattle sheds, and keep a number of carts carting in rough grass into the same. at all seasons of the year when such is procurable Unless some arrangement of this kind can be made, it would be folly to go on increasing the area of the gardens. It may be objected to this that the loss in rents would not be compensated by the increase in the quantity of manure. To this I am not at present able to give a satisfactory answer, but to me it is plain that either the tea must be sacrificed to the Zemindary or the Zemindary to the tea, as without manure the present results *cannot* be kept up.—*Indian Tea Gazette.*

So it is even on the rich volcanic soil of Java, tea must be manured. As cattle are expensive to keep on the higher estates in Ceylon, artificial manures must be used and the railway by cheapening transit will render this possible.

Correspondence.

To the Editor of the Ceylon Observer.

INSECT-DESTROYERS.

Ardallie Estate, Agrapatana,
27th March 1882.

DEAR SIR,—I may now give you a description of an "insect-destroying apparatus," one of the latest inventions in America, that might be brought to good account here, if science is ever to help us in any way with *the dreaded leaf-disease*.

The cotton-worm, Colorado beetle and other insects injurious to the cotton plant, may be destroyed either by sprinkling solutions of various chemicals, such as London purple, over the plant, or by dusting the foliage with various poisons in the form of dry powders. A number of appliances for showering the plants with the solutions or powders have been introduced, but none have been constructed upon so large and complete a scale as some new machines shewn at "Atlanta" *for the first time*. The largest of these sprinklers is automatic in action, may be easily moved by one horse or mule, and will thoroughly drench every plant in twenty rows at the same time.

It consists of a horizontal triangular form of wood and iron supported on three wheels—one guiding-wheel in front and two trailing-wheels behind—a tank for the liquid, and a sprinkling device of novel form,

On the top of the frame is erected a wooden tripod, or derrick, and from the centre is suspended near the top a barrel for holding the solution.

A rope, pulley, and small windlass are also provided for lifting the barrel to its place. A rubber pipe extends from the bottom of the barrel to the rear of the machine, where it divides into branches; each branch hanging down behind the machine and between every second row of plants.

Thus, if there are twenty rows of plants to be sprinkled, there are ten branch pipes. The elevated position to the barrel gives a good head to the streams, and the motion of the apparatus over the ground keeps the solution agitated and prevents the mixture from clogging the pipes. The delivery-pipes that hang between the rows of plants at the back of the apparatus divide just above the ground into two branches.

Inside the two branches are coiled springs that tend to keep the pipes spread apart, and at the end of each is a brass nozzle, designed to trail along the ground as the machine moves forward.

The distance between the rows of plants is greater than the spread of these branch pipes, and, as they are dragged over the ground, they strike the stem of the plants on each side.

The spring allows them to pass and then spreads them out again, so that each nozzle must pass close under every plant in its row.

It has been found that to destroy the insects, the spray must be driven upward from below the plant.

This arrangement of the delivery-pipes and the fact that the jets are all delivered upward, accomplishes the purpose admirably, and is a most ingenious application of means to ends. The jarring of the elastic pipes against the plants also tends to scatter the shower of spray in every direction, and every plant and leaf is reached by the liquid poison.

The nozzles used in this apparatus are of new form, that may prove of value in other hydraulic machines.

They consist of brass cups fitted with tight covers, having a small hole in the centre. The delivery-pipe enters this cup at the side next the bottom, and the water is carried round and round the inside of the cup till it is filled, when the excess escapes upward in spiral or reflex jet. The machine examined was in operation and of a small size, and thoroughly drenched every plant in twelve rows at one time.

In practice, the barrels filled with the poison in solution are placed at convenient distances in the fields, and when one is empty it is lowered from the machine and either refilled and hung on the machine, or a fresh barrel is taken. In moving the machine on roads the horizontal form is shut up by sliding the parts of the form one over the other and clamping them in this position.

The wheels and the upright tripod remain fixed, but they are sufficiently near together to enable the apparatus to pass through any ordinary farm-gate. All the materials are of the cheapest and most common character consistent with strength, and the apparatus can be readily made in any wagon-shop for a moderate sum of money.

The apparatus for blowing dry powders over cotton plants consists of a horizontal triangle of wood, mounted on three wheels and intended to be drawn by one horse.

Over the forward wheel is a hopper for holding the dry powder, and closed by a tight-fitting cover.

Under the hopper is a small fan-blower, that may be connected by a crossed-belt with the axle of the leading wheel. At the top of this blower is an opening into the hopper with a second on the opposite side, so that the blast of the blower enters the hopper at the bottom on one side and passes out at the other. The motion of the machine over the ground drives the blower, and the blast of air it sends through the hopper takes up a portion of the powder and carries it to the discharge pipes at the rear of the machine. These pipes are of sheet-iron, and hang down between the rows of plants, so that three pipes cover six rows of plants. When the machine is driven over the field, the pipes discharge clouds of dry powder that completely cover any plant in reach. In a strong wind, when the machine is moved side to the wind, the number of rows covered may be much larger, as the wind blows the powder over the plants for some distance.

Another and cheaper form of the same machine, and designed to discharge only one jet of powder, employs a common hand bellows attached to the hopper. In this case the machine is fastened to the handle of a plow or cultivator, and the bellows is operated by the foot of the ploughman as he walks behind. These two machines, the automatic sprinkler and the rotary dust-blower, are the largest and most complete tools of their class yet brought out. They are admirably designed, and, at the same time, cheap and easily managed—rather unusual merits in large agricultural implements.—I remain, respected sir, yours faithfully,

JAMES D. WATSON.

THE SEASON AND CROPS.

Matale East, April 7th.

DEAR SIR,—In your issue of the 4th instant, you say in effect that the late superabundant and long-continued rains are chiefly, if not solely, the cause of the failure of blossoms, so far as the season has yet gone. And I believe this opinion is held by many planters of experience. I think, however, it is not altogether the right one.

Is it not rather to the increasing tendency of leaf-disease to prolong its attacks, fostered, in some degree, perhaps, by a long continuance of rain, that we owe the present scant appearance of blossom?

I look upon the rain as merely a subsidiary cause of this most discouraging result.

The accompanying table of figures, if it does not entirely prove my case, will, I think, go very far towards doing so.

Assuming that the coffee is injuriously affected,

as far as the propagation of blossom is concerned, by the superabundance and incessancy of the rainfall, taking it from the commencement of the year up to, say, the end of March, it will be seen from the table produced that there ought to have been a short crop here in 1878-79. Now, the fact is, it was the largest, by far, I have gathered since I took charge of this estate in 1876. And if there are any who hold that the superabundance and continuity of the rains that may fall in the latter months of the previous year also injuriously affect the propagation of blossom, I give additional figures to show that, even in this case, my theory is not materially impaired. As evidence of the fact that rain does not always predispose coffee trees to an attack of leaf-disease, whatever Mr. Ward may say to the contrary, I may state that I have never before seen, *at this season of the year*, so much of the pest as prevails here at the present moment. And we have had only one heavy, and two very slight, showers since the 6th of last month. You will observe from the table sent, that, although the quantity of rain for the first three months of 1882 was slightly in excess of that for the same period of 1877, the number of days on which rain fell was less by two.

PLANTER.

Table referred to in letter:

April 7th, 1822.

TEA PREPARATION AND EXPERTS.

Maskeliya, 8th April 1882.

DEAR SIR,—I wish some of our tea-experts, would tell us poor coffee planters the proper way of manufacturing tea, how to wither the leaf when it comes in soaked with wet; in trying to wither it, no end of leaves turn red—although it is thinly spread out, having plenty of air and light. I find it almost impossible to make *good* tea in rainy weather. We have a number of experts in the island. One says, "wither the leaf sharp off." Another says, "do it gradually in a natural way." I say the *natural* way is the best. Why do not these gentlemen decide among themselves the proper way of manufacturing tea? I sometimes think they are afraid of tackling each other, not like us coffee men. We have it out.—Yours truly, HYBRID ASSAM.

[In regard to tea even more than coffee, experts hold different opinions. One says "you cannot roll too heavily;" another, "roll lightly for the sake of the tips." Apart from experience which is the great guide, we should trust the Indian tea-planter to give advice who himself turns out first-class tea. The difficulty of withering properly in very wet weather is a serious one. There are machines to dispel the moisture, but how far they have been successful we do not know.—ED.]

COCOA IN DOLOSBAGE.

Yatiyantota, 13th April 1882.

DEAR SIR,—I notice in your columns a correspondence about the average number of seeds in Gang Warily cocoa pods. Having received a good many pods from that estate, I can give the averge of seeds in two lots received this year, as I kept a note of the number each time. The average number was 32 seeds to a pod. In one pod I counted 41 seeds, and I think my conductor got 43 in another, but this last I am not positive about.

All pods I have received from Gang Warily have been in excellent condition and evidently collected with care. If all transactions were as satisfactory as Gang Warily pods, I would be content.—Yours faithfully. H. W. M.

MR. WM. CARRY'S SYSTEM OF VAPORIZATION.

SIR,—It has appeared in the Ceylon papers that one Mr. Storck was about to visit the island for the purpose of introducing his system of cure for coffee leaf-disease, the chief means being stated to be vaporization. I beg to inform you that that system has been carried on, on an estate in the Negombo district, for the last three years, for the purpose of destroying the ravages of the black, brown and red beetle, resulting* in double crops of coconuts of enormous size, the same being sold to the natives at very high prices compared with native produce in general. Upwards of a year ago I gave my plan in writing to a Colombo merchant, under the promise of secrecy,† and that the plan was applicable to the introduction of coffee cultivation from the fact of coffee trees in the vicinity of cooly houses and bungalows on all the estates having responded to the vapor emitted on them, and which may be seen all over the country. Two gentlemen came to Ceylon many years ago and travelled over the country, visiting coconut estates in general, and when they returned to Colombo, they published in the *Ceylon Observer* the miserable condition of coconut trees all over the country, except those in the vicinity of houses and huts, failing to see a good tree twenty yards from the houses and huts.

I certainly drank in every word of this stern rebuke, which I have never lost sight of. With regard to Mr. William Ferguson's inquiry about the destructive qualities of beetles, I may inform him that the small spear, the knife, the bellows, tobacco and sulphur are not required any more in the expulsion of beetle. Last year I informed Mr. H. W. Green that I would give the plan to Mr. Saunders, Government Agent of the Western Province, his experience being general and his influence so great that it would be productive of much good to the vast number of unyielding [non-yielding.—ED. C. O.] coconut trees in his province. But I have been unable to carry out my object, undergoing a severe attack of diarrhœa and having lost the power in my right side. I feel better; thanks be to God for his great mercies.

WM. CARRY, *Senior*.

* The smoking of the trees, not the ravages of the beetles.—ED.

† We heard many years ago that the process was just one of fumigation.—ED.

THE RED ANT NUISANCE: WHAT IS THE REMEDY?

15th April 1882.

DEAR SIR,—A friend mentioned to me that he saw a few months ago, in your valuable and interesting daily paper, a remedy for destroying the red ant, so common in the lowcountry on almost all fruit-trees, but he forgot what the remedy was. I did not see it myself, nor can I find it in the *Tropical Agriculturist*, which I have carefully looked through from October 1881 to March 1882. If you, or any of your numerous readers, can remember the receipt, I shall be much obliged if they will send it for publication; or should any other of your readers know a remedy, I and others in the lowcountry will be under an obligation if they will give it. These red ants are not only a nuisance and expense, but they are the dread of the coolies; and no wonder, seeing they are so numerous, and their bite painful. They are as pugnacious as bull dogs, and quite as obstinate and blind in their attacks. I assure you, a considerable amount of very strong language is used by the coolies when picking and handling; and, in the interests of morals, it is the duty of all, and especially our chemists, to try and find a remedy for this pest! What they subsist on I cannot tell, though I fancy it is on the honeydew of the leaves. They are found on, I think, every fruit tree in the lowcountry, and not only at the time of fruits but all the year round, and also on many trees not yielding fruit; so that it is not the saccharine matter from the coffee cherries that attracts them. I cannot find any insects that they can use as milch cows, as the little black ants do the "mealy bug." By-the-bye, these latter are doing harm to Ceara rubber trees, as I have observed hundreds on each leaf on the under-side, no doubt sucking out the juice; and the trees look miserable under the operation. The leaf is also subject to a blight, and about this time of the year, and, say from January, they seem to have it badly.—H. J.

[We noticed this red ant nuisance in connection with our visit to the Udapolla Liberian coffee estate, and we recalled the history of the proposed remedy for "black bug" in the days when that pest was as prevalent and nearly as destructive as the leaf fungus is now. The proposed remedy was the introduction of the red ants to estates worked by almost nude coolies! No wonder, although the remedy was characterized as being almost as bad as the disease. The whole history of this formidable wasp-like red ant is worthy of careful investigation and record. We know that the red ants carry away and greedily devour the so-called "white ants" (termites), and as to their food generally we suspect it must be largely composed of insects. A few days ago we directed the pulling up of some withered sticks, and they were covered not by "white ants," but by the big red fellows, which bite so furiously and so venomously. Their nests are common on the "dang" trees in the Cinnamon Gardens. We are not able to recall the remedy alluded to.—ED.]

GETTING RID OF WHITE ANTS. When travelling in Queensland, a gentleman in our company received a letter from a French lady in Port Darwin to the effect that the sugarcanes there had been destroyed by "les termites." Our friend was puzzled until we informed him that this was the scientific, as it ought to be also the popular name of the destructive insects known as "white ants." Recent accounts from the North Territory of South Australia announce that the termites had been "almost overcome by the free use of lime and crossploughing," a fact which we commend to tea planters in India and planters of cocoa and other lowcountry products in Ceylon.

COCOA IN TRINIDAD.—The large shipments of cocoa last year only in part make up for the great deficiency in the last months of 1881, nor was all very good in quality, from the dismal November weather so interfering with the course of curing. The rains did also much harm in throwing down great numbers of flowers, which will cause a poor gathering of fruit for some months ahead; but after that the prospect is good, the same rains with subsequent showers having started fresh buds that promise a fair crop in good season.—*Trinidad Chronicle.*

A WEDGE has been entered into the act levying discriminating duties on importations from countries west of the Cape of Good Hope, by the bill from the Committee on Ways and Means which abrogates the duty on tea and coffee produced in those countries. But why not attach cinchona barks to the bill? The discriminating duties paid on coffees, teas and cinchona barks entered for consumption during the past three fiscal years were as follows:—

	Coffee.	Tea.	Cinchona Barks.
1879	$13,218	$12,792	$15,958
1880	29,680	7,608	8,578
1881	533	8,927	8,724
Totals	$43,431	$29,327	$33,260

—*U. S. Oil and Drug News.*

FOOT AND MOUTH DISEASE.—We are informed by Mr. Mark Charrock, farm bailiff to Messrs. Greenwood and Roberts, Rudholme Laund, Clitheroe, that he has found great benefit from the use of carbolic acid in cases of foot and mouth disease. The disease broke out in a herd of 83 cattle, of which 13 were affected when the experiments with Calvert's No. 5 carbolic acid applied by means of Calvert's "Vaporiser." A further outbreak occurred two days afterwards, but from that time the spread of the disease was arrested, and the whole of the affected animals speedily recovered. The success in this case was so marked, both with regard to checking the spread of the disease and curing it, that an extensive trial of this remedy will probably be made.—*Mark Lane Express*, March 20th.

FOREWARNED IS FOREARMED.—Planters and farmers throughout the district will do well to pay attention to the matter to which we now refer. A gentleman riding along the Nelo road had his attention directed to a large patch or flock of locusts; which were settled on one of the cane fields at the Palms estate, by his horse refusing to pass by the spot without exhibiting signs of great fear. On alighting to make examination he found that these insects in millions were depasturing on the cane of which every vestige disappeared as they slowly travelled along. A close inspection showed that the locusts were in the early stage of developement and might easily be destroyed were proper measures adopted. But if they are allowed to grow to maturity their spreading over the district is a matter quite within the bounds of probability and a more terrible scourge can scarcely be imagined, should they do so. We are informed that in their primary stage they may be swept up or covered with cloths or bags and destroyed, and we should suggest to the gentleman in charge of the Palms estate, as well as to any other persons who may be visited by these locusts, the desirability of at once taking steps to arrest the spread of these insects. If the locusts can be eradicated from the district, it will be well worth the expenditure of a sum of money on the work. The visitation alluded to took place before the recent heavy rain, which may possibly have effected the work of destruction, but in any case we trust our allusion to the subject will be borne in mind so that upon the re-appearance of this plague it may be stamped out, if possible.—*Mackay (N. [illegible]land) Standard.*

LOCAL SALES OF CINCHONA BARK seem to be now quite an institution. Mr. E. John has issued a programme of a very extensive sale of all kinds, the lots being no fewer than 92 in number. In consequence, the sale will commence punctually at 11-30 on Wednesday, the 19th instant. Bids up to 25 cents can be at the rate of 1 cent; but over 25 cents the bids must be 2½ cents; and over R1, the bids must be not lower than 5 cents. Elbedde sends 120 bags, of which 103 are "beaten twigs." St. Regulus sends 218 bags, and so forth; but Fankerton "beats a'," as the Scotch say. The quantities are represented in lb., and one lot includes 1,045 lb. of branch bark: the quantity from this estate being altogether over 1,800 lb.

COLA NUTS.—Interest in this product has been revived by the reference in the last report from Kew. A correspondent, who sends us an extract from *Chambers's Journal*, enquires: "Has it reached Ceylon yet? A native of Sierra Leone would probably thrive here."—"Sir Joseph Hooker's report on Kew Gardens, lately issued, contains an interesting account of the cola nut—the seed of the cola acuminata, a tree which has been very successfully propagated in the gardens. The cola nut is said to enhance the flavour of anything eaten after it, and is also said to possess extraordinary power, in allaying the pangs of hunger. It is, however, chiefly used as a luxury, and is in great demand among the natives of the Gambia. The trade in this nut has much increased of late years, and in 1879 reached seven hunderd and forty three thousand pounds. The plant—a native of the Sierra Leone district—has been introduced into the West Indies and has been distributed from Kew among the Botanic gardens in various parts of the world."—So long ago as 7th May 1879, we gave the following information in the *Observer*:—

COLA NUTS.—Until the arrival of the paper promised by Mr. Christie on the cola nut of Africa we give the following information on the subject:—It was formerly described as several separate species of Sterculia, a genus of plants of which there are several species in Ceylon, one of them, the S. foetida, having very vile stinking flowers, as its name implies. It is now the Cola (Sterculia) acuminata, Hors. and Bennet, and has been described as Sterculia grandiflora, nitida, macrocarpa, verticillata, and oblongifolia, and also as Cunania Bichy.—Under two of the above names Don in his Gardener's Dictionary vol. 1. p. 515 gives the following account of it, showing that the tree and its nuts were well known in 1831:—

5 S. ACUMINATA (Beava. fl. d'ow. 1. t 24.) leaves oblong-acuminated, quite entire, smooth, on long stalks; flowers in axillary panicles; anthers in two rows. sessile; carpels 1-2-seeded. S. Native of the tropical parts of Africa particularly on the western coast. Flowers white with spreading segments. Carpels usually 2, opposite from abortion. There are two varieties of the Cola, one with white, the other with reddish seeds. The seeds are about the size of horse-chesnuts.

The seeds of this species are known throughout tropical Africa by the name of *Cola* or *Kola*. They have long been celebrated by voyagers as possessing a high degree of value among the natives of Guinea, who take a portion of one of them before each of their meals, for they believe them to enhance the flavour of anything they may subsequently eat or drink. The seeds formerly were said to be held in such high estimation among the natives of Guinea, that 50 of them were sufficient to purchase a wife, but at present 20 or 30 seeds can be purchased for a handful of cowries, while 2 or three tons of cowries would not purchase a perfect female at the present day. We have eaten the seeds, they have a very bitter taste; they are about the size of a pigeon's egg, of a brownish colour; they are supposed to possess the same properties as Peruvian bark.

Acuminated-leaved Sterculia or Cola. Clt. 1795 Tr. 40 ft.

6 S. MACROCARPA; leaves oblong, acuminate, entire, smooth, on long stalks; flowers axillary, panicled; anthers in two rows, sessile? carpels 4-6. seeded. S. Native of Guinea. Flowers white. Pods generally 2 from abortion, opposite. The seeds of this tree are also known under the name of *Cola* in Guinea; they possess the same qualities as those of *Sterculia acuminata*.

THE GOVERNMENT JAVA COFFEE CROP for 1882 is estimated at 850,700 piculs.—*Straits Times*.

MEDICINAL BARKS imported into the United States increased from 4,638,000 lb. in 1880 to 5,648,000 lb. in 1881.

QUININE IN NASAL CATARRH.—Dr. N. Folliott, writing to the *British Medical Journal*, states that coryza or nasal catarrh may be cured in a few hours, if taken at the onset, or at most twelve hours afterwards, by the inhalation of a spray of sulphate of quinine. The solution used is made by dissolving 4 grains of quinine in an ounce of water, with just sufficient dilute sulphuric acid to dissolve it, and scenting with any agreeable perfume. The solution is injected up the nostrils in the form of a spray, with an ordinary hand ball spray producer in such a way that the quinine can be tasted at the back of the mouth. This is done every hour or oftener according to the urgency of the symptoms. He states that this remedy has been tried with success in hay fever, and that if nasal catarrh is of parasitic origin, as he strongly suspects, the action of quinine is at once apparent. It might be added that, even supposing catarrh to be the result of sudden change of temperature, the action of quinine in contracting the superficial capillaries would be quite as obvious. It is somewhat surprizing that this property of quinine does not appear to have been tried for chilblains in the itching stage, when the capillary vessels are dilated. [After this who knows (*nose*) to what uses quinine can be applied? If it contracts the nose why not the mouth?—ED.]

THE ENGLISH TEA DUTY.—As England cannot produce tea, the English tea duty is not protective at all, but is purely a revenue duty, and as such, is open to no objection except that it increases the cost of living to the multitudes who use it. What the writer wants is that England, regarding India as part and parcel of herself, should *protect* Indian tea against China tea. A moment's consideration shows that for England to adopt such a policy, and protect Indian tea against China, would be an open departure from her free trade principles, and would seriously disturb all our relations with China. It is probably too much to expect that our critics should consider the ruin they propose to inflict on the Chinese producers of tea; but they should at least face the fact that what they ask really is, that England should adopt a distinctly protectionist policy in favour of India and against China.—*Friend of India & Statesman.*

[We can understand and sympathize with a movement in favour of a reduction of the British tea duty all round from 6d to 3d, but to ask, as some of the Indian tea planters and Indian newspapers having asked for a reduction only of the duty as far as tea from India is concerned, is to ask for the reversal of principles which have long ago been accepted by all political parties and by the community, as true, fair and beneficial. We sincerely hope the state of the British revenue may speedily admit of the reduction by one-half of the tea duties, but that reduction will infallibly apply to all teas, whatever their origin. Duties are levied and are justifiable only so long as revenue is absolutely needed. In Britain, the day of distinctive or protective duties is over. Sometimes the temptation to retaliate on states which lay prohibitory duties on our products, the United States, for instance, and on those which give sugar bounties, and so forth, is very strong. But in any such action, it is the British consumer who would first and chiefly suffer. In Ceylon we need the Customs revenue, and indirect taxes are easily collected, and their incidence light. People pay them readily, who would denounce and evade right taxation. They ought not, therefore, to be tampered with. Nevertheless, if we also could carry out free trade principles, we ought to do so.]

ROOT-GRAFTING ROSES.

It is probable that this way of increasing roses may in some cases be carried out earlier than the last week in February; but we do not usually get our propagating bed ready before this time, and genial temperature is required to insure prompt success. The dog rose grows abundantly in the hedges round here, and I have just grafted a quantity of the briar roots dug from the banks in the fields with pieces of rose shoots taken from the best hybrid perpetuals; and I shall be much disappointed, judging from previous experience, if the principal part of those grafted roses do not flower this coming summer and autumn. The chief requisites of success are to obtain healthy roots of fair strength—pieces of roots will do—just startling into growth, and the scions or grafts should be obtained from dormant shoots of strong healthy plants; weakly shoots do not succeed so well. A sharp knife is an absolute necessity. A smooth cut should be made on the best face of the stock, and the scion cut to fit it; the two should then be bound together tightly with soft matting or raffia. I prefer the latter. The bark of the stock and scion should fit closely on at least one side. As fast as they are grafted they should be potted into large 60-sized pots if they are large enough, potting the stocks sufficiently deep to bury the bottom of the graft, to exclude the air; this saves grafting wax or clay. Plunge the pots into a bottom heat of 75 degrees, in a close frame or pit, and shade from bright sunshine until the grafts are able to bear it without injury. I prefer sawdust for a plunging material, as it maintains a nice moist, steady heat.—H.—*Field*.

PLANTING AN ORCHARD.

Some few years ago I planted about an acre with standard apples, pears, and plums. They have done well, but since planting out these standards I have planted about fifty or sixty trees on wire espaliers, and if ever I were planting an orchard again I would put it all on wire, for these reasons: I could put more trees on the same space, the fruit on the espalier is finer, and it is quite safe from the wind, which often completely strips the standards of the fruit when only half ripe. The only drawback to the espalier is the first expense, but this need not be great. The rails removed from the sleepers make capital end standards or straining posts; the intermediate posts have only to sustain the weight of light wires; there is nothing of the nature of a fence to resist cattle. They may be made of perforated quarter-inch iron bars, merely driven a couple of feet into the ground, as, after a year or two, when the trees have clothed the wires, the trees themselves will support the wires. This is what I would recommend: buy an old rail, say 16ft. long at the price of old iron; cut it into two lengths of 10ft. and 6ft.; get the smith to bore a dozen holes in the 10ft. length for the wires; sink it in the ground 3ft., leaving 7ft. above ground, and use the 6ft. length as a stay. There are no stones or anchor necessary for the 10ft. standard—it has only to resist the wind; but one of the wire holes should be made about an inch in diameter, and through this hole an iron bolt is driven for the head of the stay to rest on. For the foot of the stay a stone or slate laid flat about a foot below the surface, and another stone at right angles for the point of the stay to press against like a half-open book. Wire is sold by weight, and very light wire would do. I have not tried it, but I think common copper bell wire would be as economical as any. The espaliers should run north and south for the sun; if 7ft. high, about 8ft. apart to admit the sun and air. There is ample room for a row of gooseberries or currants between each espalier. If a man objects to the sight of an old rail, it is easy to plant a climbing rose to hide it. In planting an orchard see that you get young vigorous trees, not old stumps that have been cut back for years, and also open roots, not stunted and clumped or pot-grown; also get trees from a colder county—the extra warmth and climate will bring them away. A single espalier should run east and west, but rows of espaliers should run north and south.

Pitgavony, Elgin, N. B. J. DUNBAR BRANDER.
—*Field*.

HOP CULTURE ON THE NILGIRIS.

In a recent issue we drew attention to the advantages to be derived to the hill settlement on the Nilgiris by the extended culture of barley, wheat, and other cereals; and in this connection we would now desire to add the culture of hops. The late Mr. McIvor, of the Government Gardens at Ootacamund, was of opinion that hops would thrive and become highly productive under proper treatment on the Nilgiris, and he gave a preference to situations enjoying a somewhat milder climate than that prevailing at Ootacammud, and considered the land in the vicinity of Kotagherry and the eastern portion of the plateau generally very suitable for its cultivation; but we believe there is nothing on record to shew that Mr. McIvor's recommendation was at any time carried into effect. An attempt to grow hops at the Lawrence Asylum Farm, Lovedale, was made some two years ago, at the suggestion, we believe, of Mr. Batchelor, the present local manager of the Nilgiri Brewery Company, Limited, but proved unsuccessful. The report of that institution, while simply recording the failure, has not in any way placed on record particulars. This is all the more to be regretted, inasmuch as there are no data for combatting the causes which led to such failure. We may not, perhaps, be far wrong in concluding that the experiment was left in the hands of an experienced person. Be this as it may, it would have been interesting to have had all the information we could obtain on the subject for future guidance. Farming is a profession, and the farmer, if he desire to be successful, must be a man of general, and in some things—particularly agricultural chemistry—deep scientific knowledge; and in course of time our local Agricultural College ought, we think, to be able to turn out a few such men. The mere fact of a failure resulting solely from want of experience in farming operations ought not to be a drawback. Climate, soil and certain situations on the Nilgiris, are adapted to the culture of the hop, and we shall be glad to see an effort made in this direction.

The Isle of Thanet was considered to be unsuited to the perfect cultivation of the hop plant on account of its exposed situation, and the prevalence of cold nipping winds; but the experience of the last few years has shewn completely the fallacy of this opinion, and proved that with skill and care as good hops may be grown there as in any part of Kent; and we see no reason why a similar result may not, with time and perseverance, be obtained on the Nilgiris, and the hop become a staple article of production of those hills. Owing to the national predilection for, and the vast consumption of beer, the cultivation of the hop plant ought to be an object of the most careful and assiduous study in this country. True, hop-growing in England, in consequence of numerous contingencies, has come to be regarded as a species of agricultural gambling, in which a great deal is staked by the farmer on the off chance of his having a good crop when generally there is a bad one. Chance it is and nothing more—like almost every other undertaking; but this alone ought not to be an obstacle to its culture. The hop will thrive on any land where good wheat can be grown—it prefers a deep soil, the deeper the better. A hill top is not favorable; a site should be chosen as much protected from cold winds as possible, and the selection made by the late Mr. McIvor of land in Kotagherry and on the eastern plateau of the Nilgiris is deserving

of attention. The Eurasian and Anglo-Indian Association might, at some future time, turn its attention to hop-farming on the Nilgiris.—*Madras Times.*

TREE PRUNING.

The secret of obtaining a complete cure in all operations requiring the removal of a branch, either living or dead, consists *in cutting close to, and perfectly even with, the trunk.* Many authorities have hinted at this, the cardinal principal of all pruning; but M. de Courval first clearly demonstrated its importance, while his discovery of the value of coal-tar or the refuse from gas-works as a covering for wounds made in pruning renders the application of his rule in all cases entirely safe.

Formation of Wood.—The reason that a branch should be cut close and even with the trunk is found in one of the simple laws of plant life. It is known that sap has a double movement—that it mounts from the roots to the leaves, and returns again in an elaborated condition to the roots. Roots take up water from the soil in which there are various salts in solution. This water rises to the leaves; these absorb from the air and decompose carbonic acid gas, the basis of which is carbon, which combined with water constitutes the elements of wood. The sap thus elaborated by the leaves is carried down again in a liquid state, and is deposited, year after year, in the successive concentric layers of wood which form the trunks of all trees, with the exception of palms, yuccas, &c., which need not now be considered.

It follows that a wound caused by the amputation of a branch must, in order to heal properly, be made perfectly even with the trunk, that every part of its outer edge may be brought into direct communication with the leaves through the network of cells destined to convey the descending sap. Although this theory rests on one of the most elementary principles of vegetable physiology, it has not been applied before to practical forest management. The amputation having been made even with the trunk in the manner explained, new wood will soon appear, forming first round the top and sides of the wound, which is soon completely surrounded by the new growth; the wound is gradually healed over, and the decay of the trunk prevented. The time required for the complete healing of a wound depends, of course, upon its dimensions and the natural vigour of the tree.

The principle being established that large wounds can be made without injury to the tree if care is taken in the manner indicated to prevent decay, it is easy to show the advantage of cutting off injured branches of any size. It is preferable to avoid, of course, the necessity of making large wounds by properly pruning trees when young. All foresters agree that trees should be trained when young, but De Courval has amply demonstrated by numerous remarkable specimens exhibited at the Agricultural Show of Paris, in 1861, and at the Universal Exposition of London, in 1862, that it is beneficial, and often indispensable, to prune the oldest trees if care and judgment are used in the operation. He has clearly shown, too, that trunks so treated attained a larger size and a greater value in a given time than those which, under similar conditions of growth, had been allowed to retain all their badly placed branches. I regret in this connection to differ from so eminent an authority as De Breuil, who gives the following rule: "Amputations must be performed in such a manner that the diametcr of the wound shall not exceed that of the end of the branch." Such a practice must, I believe, be disastrous, for whenever a branch of large size is amputated in this way, it is evident that a cavity in the trunk of the tree will sooner or later appear.

It is only necessary to make the amputation even with the trunk and then cover the wound with coal-tar, to avoid all bad results. Although wounds caused by the amputation of small branches heal over in spite o the faulty methods of pruning generally employed, such operations are, nevertheless, attended with considerable danger to the tree.

Experience and common sense show the objection to leaving any portion of an amputated limb, but there is greatcr danger in allowing stumps one or two feet long to remain on the trunk, a common practice even among persons interested in the preservation of trees. These stumps, deprived of communication with the leaves, die, the bark falls off, while the stumps themselves remain like plugs of decaying wood driven into the trunk.—*Forestry.*

THE ALKALOID OF CUPREA BARK.

TO THE EDITOR OF THE "PHARMACEUTICAL JOURNAL."

SIR,—I am glad to observe from the concluding lines of your note appended to my last letter, that we have at least one point of agreement. Perhaps in time you will also recognize that if a compound is separable into "crystals of pure sulphate of quinine" and "a mother-liquor," it "can yield a crystalline sulphate which when isolated may be as lævogyrate as quinine sulphate, and give no hydriodate of quinidine;" for surely, "pure sulphate of quinine," "when isolated," fulfils these conditions? At any rate this is the sulphate we obtained.

By stating in our article that we had not succeeded in obtaining the new base, we did not question Mr. Howard's results; for that chemist did not describe homoquinine as present in all cupreas, and he might have, and probably has, obtained it from some particular variety that had not then fallen into our hands. We have some reason for believing that Mr. Howard does not find homoquinine in the majority of the better sorts of cuprea, and so far therefore, we are simply in accord with him. That our statement might be considered to cast doubt on the existence of his new alkaloid in cuprea barks generally, we do not deny, and I am even willing to emphasize this doubt, although I regret to find that I thereby put myself at issue with Mr. Whiffen. That anything like 0·1 per cent of a new base, crystallizable from ether, exists in the majority of good typical cuprea barks, I do not at present believe; and I await with some curiosity the fuller researches on the new alkaloid, or alkaloids, that the authors will probably publish. Only the abstract of Mr. Howard's paper has as yet appeared; but in that certain definite characteristics of homoquinine are given. It will be interesting to see how far the base noticed by the other authors agrees with that of Mr. Howard in these characters of precision.

At present Mr. Whiffen seems to attach chief importance to the lævogyrate character of the base he has obtained, but unfortunately his statements regarding this property are not sufficiently explicit. He operated on the "effloresced" sulphates of cinchonidine, quinine, and the new base; but he does not state the composition of the effloresced sulphate of the new base, *i.e.*, the amount of water it retained, nor does he state the solvents used, although this is well known to greatly affect the angle. Mr. Whiffen gives for *effloresced* sulphate of quinine $(a)j=196$. Hesse gives for the *anhydrous* sulphate in alcoholic solution $(a)j=191{\cdot}47$ and in acid solution (SO = 4 per cent of the sol.) $(a)j=228{\cdot}78$. Effloresced sulphate of quinine is stated to retain 2 molecules of water, and, therefore, according to Hesse's results, should give an alcoholic solution $(a)j=187$, and in acid solution $218{\cdot}49$; the latter number being again subject to variation according to the proportion of acid present. I refer to these points not with the intention of casting any doubt on Mr. Whiffen's experimental observations, but to show the necessity for fuller details if chemists are to make any use of the numbers Mr. Whiffen has published. C. H. WOOD.

SIR,—In Mr. Wood's letter to your Journal last week notice that he admits a doubt as to the existence of

the new alkaloid in cuprea bark generally, although he believes in the homoquinine of Mr. Howard.

There can be no doubt that the alkaloid I have described and homoquinine are the same substance, and that it is identical with the alkaloid described by Dr. Paul and Mr. Cownley. I can again assert that this alkaloid exists in some of the very finest samples of cuprea; and that its occurrence is more nearly the rule than the exception in modern importations of these barks.

In my communication to the *Pharmaceutical Journal* of December 15th, I published the rotary angles of cinchonidine, quinine, and the new base, as determined under like circumstances, to show the relative position of the new alkaloid; for I am fully aware of the need of caution in expressing the result as well as in determining the polariscope angle of any alkaloid. I purposely omitted all details in my preliminary note, but shall not fail to give such description in a further notice of this interesting alkaloid.

Battersea. W. GEORGE WHIFFEN.

CINCHONAMINE; A NEW CINCHONA ALKALOID OBTAINED FROM CINCHONA "CUPREA."*

BY M. ARNAUD.

The first alkaloids isolated from cinchona barks in a state of purity were cinchonine and quinine, by Pelletier and Caventou, in 1820. Other chemists later on discovered two new alkaloids: quinidine, which is isomeric with quinine, and cinchonidine, isomeric with cinchonine. These alkaloids, the existence of which was at one time denied, then again admitted, were thoroughly studied by Pasteur. Pelletier and Carriol had announced the existence, in certain barks, of an alkaloid which they named aricine. Hesse, in some late researches, confirmed the existence of this body and also the composition assigned to it. In 1872, Hesse discovered quinamine, and an isomer of it, conquinamine, in certain cultivated East Indian barks. Finally, Willm and Caventou obtained, by oxidizing cinchonine with permanganate of potassium, a new body: hydrocinchonine, which differs from cinchonine only by having two atoms of hydrogen more. This is also the composition of the new alkaloid, of which I have presented a report to the Academy of Sciences. The new base differs completely, in its chemical and physical properties, from hydrocinchonine. I propose to call it *cinchonamine* in allusion to its relationship with cinchonine and quinamine.

I ascertained the presence of cinchonamine in a very dense bark, of a deep red-brown, with resinous fracture, coming from the province of Santandar (United States of Columbia). This bark does not resemble that usually exported from those regions. Cinchonamine exists in this bark simultaneously with cinchonine, a fact which I affirm. The proportion of these alkaloids is 0·8—1·0 per cent of cinchonine and 0·2 per cent of cinchonamine. In order to extract them, the bark is treated with milk of lime; the mixture, dried at the ordinary temperature, is exhausted by strong boiling alcohol; the latter is distilled off, and the residue taken up by an excess of dilute hydrochloric acid. The hydrochlorate of cinchonamine, but little soluble in the cold, crystallizes, while the hydrochlorate of cinchonine remains in solution. Upon this fact is based the method of separation.

Cinchonamine is insoluble in cold water. It crystallizes from the boiling alcoholic solution in colourless brilliant and anhydrous prisms; from the warm ethereal solution, or on spontaneous evaporation, it crystallizes in fine needles. One part of the alkaloid is soluble in 100 parts of ether, sp. gr. 0·720 at 17° C., and in 31·6 parts of alcohol of 90 per cent. It melts below 195° C., and on cooling, becomes a transparent amorphous mass. Its alcoholic solution has an alkaline reaction. It is dextrogyre, the angle of rotation for the solution in alcohol of 93 per cent is $[\alpha]_D = + 117{\cdot}9°$. The solutions of its salts are precipitated by potassa and ammonia. It completely neutralizes acids, forming salts which are generally but little soluble. Its taste is slightly bitter. The salts, in acid solution, are not fluorescent.

The chlorhydrate, $C_{19}H_{24}N_2O.HCl.H_2O$, crystallizes very easily in prisms or prismatic plates, but little soluble in cold water, much more so in water acidulated with hydrochloric acid.

The chloroplatinate, $(C_{19}H_{24}N_2O.HCl)_2PtCl_4$, is a bright-yellow, crystalline powder, obtained by precipitating a salt of cinchonamine in acid solution, by an excess of platinic chloride. The precipitate is nearly insoluble in pure and in acidulated water.

The sulphate, dried at 100° C., $(C_{19}H_{24}N_2O)_2H_2.SO_4$, very soluble in water, crystallizes well from alcohol. By spontaneous evaporation of the alcoholic solution it is deposited in the form of an amorphous resin.

The nitrate, a crystalline precipitate, is nearly insoluble in dilute nitric acid.

The hydriodate and the acetate are very little soluble in cold water; they are likewise crystalline.

The sulphate is dextrogyre in acid solution, but the rotatory power of the alkaloid is greatly diminished, the angle of rotation being only $[\alpha]_D = + 45{\cdot}5°$ at 16° C.

The results of the analysis of cinchonamine and its salts agree well with the formula $C_{19}H_{24}N_2O$, as well with $C_{20}H_{24}N_2O$. If the former formula be adopted (according to Skraup) for cinchonine, the same formula must be adopted for the new alkaloid, since the two are distinguished only by two atoms of hydrogen. On the other hand, cinchonamine has two atoms of oxygen less than quinamine. The following are the analytical data:—

	Found (mean).	Calculated for $C_{19}H_{24}N_2O$.
Carbon ..	77·20	77·02
Hydrogen	8·41	8·10
Nitrogen ..	9·30	9·46
Oxygen ..		

For the chloroplatinato $(C_{19}H_{24}N_2O.HCl)_2PtCl_4$ there were:—

	Found.	Required.
Platinum ..	19·45	19·70
Chlorine ..	20·75	21·20

—*Pharmaceutical Journal.*

CASSAVA.—According to the *Scientific American* (December 31, 1881, p. 415), a company has been formed in Philadelphia to extract glucose from cassava root, which is said to yield about twenty times as much as corn, or at the rate of 21,000 pounds the acre.—*Pharmaceutical Journal.*

HAYTI.—The Consul's report from Jacmel, recently published, gives a wretched description of the condition of Hayti. "Agriculture," he says, "is in a most primitive state; indeed, everything is left to nature. Horticulture is unknown. By experiments made by myself since I have resided here, it is amply proved that nearly every kind of vegetable can be successfully cultivated in the rich soil. There are no manufactures in this district. There is a salt pan within fifteen minutes' ride from this town, where sufficient salt for the district could be made; and yet the inhabitants prefer to pay 2*s.* 6*d.* a bushel duty for the imported salt than to work the resources at hand." On the question of the import trade the Consul writes:—"The American market is pushing the English closely, and from time to time travellers for American firms come round, enquire into the state of the market and the changes necessary, and at once meet the demand. On the other hand, the English merchants leave the field open, and during an eight months' residence here I have only seen one commercial traveller, representing a firm in Belfast, arrive in this town."—*Colonies and India.*

* From *Répert. de Pharm.*, 1881, 507. Reprinted from *New Remedies*, January, 1881.

COPPICE intended to shoot again should not be cut when it shows a tendency to "bleed," as the excessive loss of sap exhausts the stools and renders them barren.—*Forestry.*

CALUMBA ROOT.—At the drug sales this month, a large quantity of false calumba root *(Cosciniumfenestratum)* was offered. This drug seems of rare occurrence in the market, not having been observed apparently since it was noticed in this Journal, in 1850 and 1852. In September in the latter year eighty bales appear to have been offered. In Ceylon it is highly valued as a tonic and anthelmintic, the knotty part of the stems being used. It also appears to have been imported, under the name of "calumbad," or "columbo root," in 1694, when a pamphlet was published by a doctor of medicine, of London, "shewing its admirable virtue in curing the gout and easing all sorts of rheumatical pains." Japanese star anise also still continues to be offered. The cuprea bark which yields Arnaud's cinchonamine has been noticed in the market this month, mixed with other varieties of cuprea bark.—*Pharmaceutical Journal.*

CINCHONA.—In a uote to the *Gardeners' Chronicle*, Mr. T. Christy states that the greater quantity of the fine quill calisaya bark which has been cultivated in Bolivia during the past few years goes chiefly to Germany. He states also that the planters find that some varieties of cinchona, especially the verde variety, yield much more bark than others, and hence it pays the planter better to cultivate these rather than the trees which yield less bark and grow more slowly, but afford a greater percentage of quinine. The natives, he states, judge of the quality of the bark by the colour of the leaves and the veins in them. He has succeeded in obtaining seed of the better kinds, which he is given to understand yield a larger percentage of quinine than even the ledgeriana, and these have beeu obtained from the district whence Ledger obtained his seed.—*Ibid.*

MACE.—In the *Pharm. Zeitung* (1881, No. 74), Mr. A. Tirsch describes a kind of mace, called Bombay mace, which, he states, is occasionally found in the market, but which differs from ordinary mace iu several particulars. The lobes are longer and thinner, the colour of a dark red-brown, and on the inside it has adhering to it a thin parchment-like crumbled membraue never found in true mace. The epidermal cells are twice as high, narrow and radially elongated,—the cells of true mace being low and tangentially elongated,—and show well the cellulose reaction with iodine and sulphuric acid. The oil cells are very numerous, oval, somewhat radially elongated, often in groups of two or three, and contain a dark yellow usually resimified oil, and sometimes a brownish resin. No mention is made of aroma, so that it is not possible to say whether or not this product is obtaiued from *M. malabarica.*—*Ibid.*

REMARKABLE SILVER FIR.—Any tree that has attained a height of 144ft. in Britain, may, I think, be fairly entitled to be considered remarkable. Such was the height of a silver fir cut down on Saturday, September 17th. It was the highest tree in Longleat Park (probably the loftiest tree in Britain), and formed one of a group of nine silver firs, standing on rather an elevated level piece of ground. The site is fully exposed on the north-east side. Its dead withered top has been conspicuous in the group for several years, and it was evident from the appearance of the tree that it was gradually dying from the top downwards; doubtless, however, the severity of last wiuter hastened its death. The belt is quite sound for about 60 ft. up, where it divides into two heads. Although it was the highest tree in the group, it was by no means the finest and bulkiest specimen, as it only girthed 10 ft. 10 in. at five feet above the ground, and contained about 350 ft. of timber; whereas the largest tree measures 15 ft. 3 in. at five feet up, and contains between 400 ft. and 500 ft. of timber; its height is 138 ft., and it is still in full healthy vigour. The age of the group I should guess to be nearly 200 years old.—GEORGE BERRY, Longleat.—*Forestry.*

AMERICAN PEACHES.—We learn from an interesting pamphlet on the *Garden Farm Lands of the Peninsula*, that from the best information obtainable there are about 5,000,000 peach trees of all ages between the Delaware and Chesapeake, and the Brandywine and Cape Charles. These trees cover 50,000 acres of the best and most productive land, enough to make 500 farms of 100 acres each. Represented in money, there is an aggregate invested capital of 2,750,000 dol. From the official reports there were shipped in 1871, by rail, 2,456,876 baskets; by water, the number is estimated at 543,124 baskets; making an aggregate of 3,000,000 baskets. But all the peaches are not exported. Many are canned and dried. So far as known, there are six canneries in Delaware, and, perhaps, as many in Maryland, turning out over 1,000 000 cans of fruit.—*Australasian.*

THE suggestion that the slopes of railway embankments might be profitably utilized by planting them with trees has several times been made in these columns, and in the United States the experiment has been tried, we believe, with great success. A correspondent of our contemporary, *Land*, raises an objection to this, which, however, appears hardly worth considering. He says that during the fall of the leaf the drifting of leaves along the line would seriously impede the power of the passing engines by preventing the wheels from "biting" the rails, thus causing the engine to slip. It is quite possible that for two or three weeks during October there might be a sufficient collection of fallen leaves to have some such effect, but the leaves would soon get dispersed by the wind, while at best the objection only applies to deciduous trees, which in most situations would be better replaced by Scotch firs or larch. We hope this objection will not deter railway companies from carrying out what we consider a very valuable improvement.—*Forestry.*

KEEPING GRAPES.—The system of keeping grapes over the winter, with a piece of wood attached to the bunch and its end in a bottle of water, is too generally practised to require comment; but, surprising to say, some have complained that by this method the fruit becomes deteriorated iu flavour. Our own experience is exactly the reverse; in fact, after the fruit has hung a few months, the flavour has become more sugary and in every way pleasanter. The preparation of the fruit, by early and thoroughly ripening it, has more to do with successful keeping than anything else. Some prefer leaving a piece of wood an inch or two long beyond the buuch; this we never do, but have always cut pretty close to the bunch, and often rub the cut with styptic, so that evaporation cannot take place. This year we treated all our shoots in this way. Last year the berries were plump and in good eatable condition to the 1st of June. We have tried to keep them in all sorts of structures, both in light and in darkness, but never found much difference under either condition. In a fruit room, where all the shelves were filled with apples and pears for a considerable part of the season, Lady Downes always kept admirably. This was over a stable where the temperature was very even, and no fire heat ever employed. Probably the best position we ever employed for such a purpose was a cupboard of a dwelling-house, kept close; there Alicantes were always extra good till May. Last year we bottled a number of bunches with the wood left beyond the bunch, that between the bunch aud the vine being cut closely off, and no perceptible difference was the result. The kiuds were Gros Colmar and Barbarossa, but they were used before the end of February, and were not tested like the others. We have proved again and again that wheu the roots are in a sweet healthy soil, not soured by heavy applications of manure, the keeping has been of the highest order. Ripening is supposed by some to be complete when colouring is finished, but heat and air are wanted long afterwards.—H. T.—*Field.*

THE JAMAN TREE.

TO THE EDITOR OF THE "MADRAS MAIL."

SIR,—About three or four years ago, an article appeared in the *Agricultural Gazette*, intimating the result of some experiments said to have been made by a gentleman in the north of India, with the jaman or "jumblam" fruit, and stating that he had succeeded in making an excellent wine from its juice, but no notice appears to have been taken of this in these parts where the jaman tree is to be found in every avenue and tope, and the fruit during the month of August, particularly in the Mysore country, is found rotting in heaps on the roadsides, and the side drains are black with them. The fruit contains an abundance of saccharine matter, and distillers would, I think, find it an efficient substitute for jaggery in the manufacture of spirits, the supply being almost unlimited, and the only cost to be incurred would be that of collecting and carting it. The seed of the fruit is highly astringent, as is also the bark of the tree, and perhaps the latter would answer as a tanning agent; but I have not heard of its ever having been used for the purpose.—Yours, &c., ANGLO INDIAN.

THE RAIN-TREE.

Some travellers in South America, in traversing an arid and desolate tract of country, were struck (says *Land and Water*) with a strange contrast. On one side there was a barren desert, on the other a rich and luxuriant vegetation. The French consul at Loreto, Mexico, says that this remarkable contrast is due to the presence of the *Tamai Caspi*, or the rain-tree. This tree grows to the height of 60ft., with a diameter of 3ft. at its base, and possesses the power of strongly attracting, absorbing, and condensing the humidity of the atmosphere. Water is always to be seen dripping from its trunk in such quantity as to convert the surrounding soil into a veritable marsh. It is in summer especially, when the rivers are nearly dried up, that the tree is most active. If this admirable quality of the rain-tree were utilised in the arid regions near the equator, the people there, living in misery on account of the unproductive soil, would derive great advantages from its introduction, as well as the people of more favoured countries where the climate is dry and droughts frequent.—*Australasian.*

[We doubt a good deal of this.—ED. T. A.]

PLANTING RAILWAY EMBANKMENTS.

Some objections or restrictions which apply to the rearing of timber on railway embankments, briefly indicated, are:—

1. The risk of windfall.
2. The risk of fire.
3. Lodgment of fallen leaves against the rails.
4. Hindrance of view over the adjacent country.

1. All trees of a large timber size are exposed to the danger of being overthrown by the strong winds of winter, blowing generally from a westerly direction. Those certainly which have grown up from their earliest youth in constant exposure to the wind become in a measure windproof; but no development of the roots, and no feasible precaution, will ensure perfect stability against severe storms. Sometimes, even though the roots remain firm, the force of the wind will tear off large branches, or even snap the trunk in two. A tree growing on the outward slope of a railway embankment, which had attained the moderate height of only 50 ft., would always, or nearly always, considerably overtop the level of the metals, and, if rooted in the upper part of the embankment, would reach higher than the telegraph wires. The unregulated fall of such trees might do damage, and interrupt the traffic or communication.

Large trees on the bank of a railway cutting would in a still higher degree menace the traffic and the telegraph wires. In general trees fifty or more feet in height, especially on the west side of a line running towards north and south, either in a cutting or in an embankment, would add to the danger of travelling on a dark night in a high wind. These considerations would limit the age of trees on railway embankments, and would be prohibitory to the production of strong timber. The trees would often have to be cut down in their thirtieth or fortieth year as a measure of precaution, and it would probably be convenient to treat them as coppice with a cycle of from fifteen to thirty years. Fruit trees too might be cultivated, even to an advanced age, without their attaining any dangerous height or bulk.

2. The risk of fire kindled by sparks from the locomotive is peculiarly attached to pines and other coniferous trees in dry weather, and especially in hot summers. Broad-leaved trees, when bare of their leaves in winter, are not entirely exempt from the same danger; but in their case the danger is not nearly so great. In North Germany such fires have occurred so frequently among pines (*Pinus sylvestris*—Scots fir) that it is now an ordinary precaution where a railway skirts or intersects a pine forest to interpose a belting or narrow strip of birch or some other leaf tree. This birch [safeguard, being in leaf and green, will not burn in the summer-time, and serves to intercept the sparks which otherwiso would have ignited the resinous and highly inflammable pines. The same precaution has to be observed, even along the more frequented highways in pine forests, against the incautious disposal of burning tobacco or matches. In England the danger would perhaps not be so great nor so regularly recurrent; but at intervals of several years there comes occasionally a summer of scorching heat and long-continued drought. Such a season would endanger the pines and firs which might have been reared on the railway embankment.

3. The third objection indicated has already been referred to in these columns.

4. The fourth objection hardly needs amplification, but seeks to give prominence to the desire of tourists, farmers, foresters, sportsmen, and most travellers to see the country through which they are passing.

—*Journal of Forestry.* S.

THE COFFEE AND SUGAR PRODUCTS OF GUATEMALA.

A correspondent of the New Orleans *Democrat*, writing from Puerto Livingston, Honduras, says there are quite a large number of American planters, chiefly from Mississippi, located there, and that the country is making rapid commercial progress. He adds: "New York and Philadelphia are making strenuous efforts to secure this steadily increasing inter-tropical traffic. Their merchants have already sent drummers to the ports that lie along the coasts of the Caribbean sea and the Bay of Honduras and the Mosquito Gulf. The growing coffee trade of Guatemala has attracted the serious attention of the business men of the North; and it seems that they have determined to wrest it from their transatlantic rivals. Besides the increasing production of sugar in British Honduras, the colonists have begun the manufacture of a cheap rum—from the lowest grade of molasses—that is susceptible of being greatly improved, such is its peculiar flavour and purity; the American planters of Punta Gorda do not hesitate to assert that it can be made to equal, if not surpass, the celebrated rum produced in Jamaica, and which has for such a long period been an important article of commerce. They inform me that this rum and their higher grade molasses is so greatly esteemed in Europe that together they about pay the entire expenses of running their plantations."—*Rio News.*

ENQUIRY AS TO THE BEST MODE OF RETAINING "TIP" IN MANUFACTURE.

TO THE EDITOR OF THE "INDIAN TEA GAZETTE."

SIR,—May I be permitted to reply to the above enquiry which appeared in your issue of September 26th last. It will be found that the *shorter* the time in which the leaf is rolled and dried, the fresher and brighter the tip, and the better the liquor. The tea leaf, in order to assume a condition that it will *retain* its valuable properties, has to be rolled up and dried; during the process of rolling and drying it cannot gain anything to enhance or increase these properties, but in proportion as these operations are prolonged, so are these properties lessened and dissipated. Six minutes is ample time for rolling the leaf, and from 10 to 12 minutes for drying it; and a machine which can efficiently roll one maund of leaf at a fill in six minutes, is to be preferred, and will give a better result than one which can roll 1½ mds. of leaf at a fill in nine minutes. To prove that tea leaf can be rolled, and rolled well, in six minutes, I annex copy of a letter from Mr. H. L. Crossman, Manager Mim Company, to Williamson, Magor & Co.; and I may add that in order to enable the leaf to be rolled in the minimum time, and each fill of the machine to be subjected to the same amount of rolling action, these Centrifugal Kinmond Rolling Machines which Mr. Crossman's letter refers to, have this year had attached to them a pressure Indicator and a work Indicator. The first shews the exact pressure on the leaf, and the second the number of revolutions of the plates,—the two together giving a complete index of the rolling action given to the leaf.

Loudon, October 19th, 1881. K.

Copy of letter from Mr. H. L. Crossman, Manager, Mim Tea Company, to Messrs. Williamson, Magor & Co.

Machinery now in full swing; all hand rolling stopped: a most perfect success: 1 maund of leaf in six minutes: the best machine ever invented. I am perfectly charmed with its work, and will send samples of tea made by it in a few days: no hand rolling can compare with it. Engine splendid, and does the work well. I have been repaid for my hard work in getting all in such tip top order.

Mim, 10-9-81. (Sd.) H. L. CROSSMAN.

THE PROGRESS OF INDIAN TEA IN AUSTRALIA.

Mr. J. O. Moody, of the well-known firm of Messrs. James Henty and Co., Melbourne, in a letter to us dated the 10th October last, writes as follows:—

You will see by the two papers I send you, *Argus* 5th October and *Age* 6th October, that a strong agitation is going on, in favor of an Adulteration Act for the colony, and which I hope, when passed, will shut out a great deal of China rubbish that at present floods this market.

Messrs. Cosmo Newbery and Frederic Dunn, whose names are so freely used, are analytical chemists connected with the Laboratory of our Industrial and Technological Museum, the former as Superintendent, and the latter as his assistant. These gentlemen have for some years past devoted considerable attention to the analysis of tea, and are well up in the subject. The large exhibit (some 500 different samples) shown at our Melbourne International Exhibition, and of which Mr. Newbery was Superintendent of Juries, placed at their disposal for analysis, and probably gave them opportunities unequalled by any previous investigators into the chemical analysis of teas.

You could aid their investigations by procuring for them samples of your different growths of tea from three or four districts, say a few leaves in *air-dried* condition only, that is to say, having passed through *no* manufacturing process, and a few samples of the same kinds manufactured. Have these samples carefully marked with all particulars and the time of picking, &c.

Some of your planters would probably be glad to furnish samples for the sake of the investigations it opens up, and the practical information it may give. Ceylon has already furnished some samples which are being analysed. I may mention that there is difficulty in getting the air-dried leaves over in a sound condition, but with a little care this can be managed. Perhaps packing loosely between Swedish filtering paper (procurable at any chemist's) would prove a good plan.

With regard to the request made by Mr. Moody for samples of the different growths of tea from our various tea districts, we trust our readers will heartily respond to the call. We will be happy to forward free of cost all samples intended for Mr. Moody sent to this office. The teas should be carefully packed in tea lead and soldered down securely. As they are intended for the purpose of analysis, from 5 to 6 ounces should be sent of each kind.—*Indian Tea Gazette.*

COCOA CULTIVATION IN DOLOSBAGE, CEYLON.

It appears that the monster pod of cocoa, recently shewn in Colombo as the produce of an estate in Dolosbage West, was gathered from a tree of about eight years old, growing in the same field with old coffee, not in any way superior to many others about it, but on the contrary perhaps less well grown than others. These trees have had, it appears, no special cultivation, and with regard to manuring they only received their due share when the coffee was manured. The soil on which it was produced is of a medium quality and character, but we may mention that the particular tree from which the pod was taken, as well as others in the vicinity, had had the benefit of partial shade from large jak trees growing at intervals amongst the coffee.

At the present time there are on the same tree from which the giant pod was taken, a number of others nearly as fine. One of these growing close to where the big pod was taken from, is about three quarters grown, and promises to be as large as the other. There are also a number of other trees in the vicinity having some very fine pods, which would appear to weigh from one to two pounds each, gladdening the eye of the proprietor as he watches the development of this interesting and promising new cultivation.

No doubt the cocoa tree is in its earlier days somewhat capricious in its growth and development, looking for certain conditions without which it makes but poor progress, but when once fairly established in the ground it appears to be hardy enough, and in its after growth it may be left pretty much to its own devices and the aid which nature is prepared to give it. What it does require, however, to induce a good development, are fairly deep soil, partial shade, and shelter from strong winds. So far as experience yet goes, it would appear that it thrives better as a mixed cultivation with other produce than in fields devoted especially to its own growth. By the little cultivation in after life required by it: by its constant and prolific bearing, it holds out excellent prospects to the planter under suitable conditions, when it is bound to pay well. It would appear as though it were well suited for native villagers in the plots of ground about their dwellings, and might well be taken up in preference to the cultivation of Liberian coffee.—*C. Times.*

ORANGE CULTIVATION.

The length of time that an orange tree takes to come into bearing is not so great as many people imagine. Judging from experience, we believe that in this climate an orange tree, growing in moderately good soil and kept free from weeds, would not as a general rule take longer than seven years to come into bearing from the time of planting the seed; but an orange plant of considerable size can be transplanted without so much risk as most other trees, and if there were nurseries where well-grown orange plants could be bought, an orange orchard might be planted with a reasonable prospect of getting a crop in four years. The time of bearing could also be shortened by grafting bearing wood from an old tree upon a young one, but grafted trees do not grow so large nor live so long as trees that have not been so treated.

As there is likely to be a demand for orange plants before very long, it might be profitable even for those who have not land for an orchard, or who, having land or the means of procuring it, have not patience to wait for a crop of oranges, were they to make nurseries in the meantime for the purpose of selling the plants. We, however, warn any who may intend so doing that they must make up their minds to having very many of their young plants bitten off and destroyed by crickets. There is nothing for it but planting more seed, but we have learned by experience that by perseverance the difficulty of establishing an orange nursery can, in spite of the crickets, be overcome. Orange nurseries are not singular in requiring perseverance in spite of repeated failures. After the orange plant is too hard for the crickets to destroy it, it seems to have fewer enemies than most other cultivated plants. The leaves are liable to be devoured by the caterpillars of two or three species of butterflies, but not, apparently, by the caterpillar of any kind of moth or hawkmoth, nor is the wood of the tree, so far as we know, liable to be attacked by any kind of borer.

The orange tree never grows very large, as it does not increase much in size after it begins to bear, but it lives to several hundred years old, and the fruit is said to improve instead of deteriorating with the age of the tree, there being fewer seeds and fewer divisions in the fruit of old trees than in the fruit of young ones. An orange plantation, once established, will therefore last for generations. Liberian coffee, cocoa, tea, and other new products are all very good in their way, but for a small piece of land situated at no great distance from Colombo, oranges would probably be found to be much more profitable. The orange is not the only fruit that might be grown with profit in such a situation, but the orange tree is more prolific in fruit than any other, and the fruit keeps fresh for a longer time after being gathered from the tree than any other, and it is these advantages that make the orange, as a fruit used in a raw and unprepared state, of more commercial importance than any other kind.—*C. Messenger.*

CAWNPORE EXPERIMENTAL FARM.

The experiments recently tried on the Cawnpore Experimental Farm have been of a more than ordinarily practical character. Two sets of experiments in deep ploughing and inversion of soil were tried, and though they were perhaps not quite conclusive on all those points on which information was desired, they were at least perfectly conclusive as to the general advantage accruing from deeper cultivation than at present obtains in India. Over eight experimental plots of 200 square yards, portions of which were carefully irrigated, and other portions left unirrigated, the following were the average results per acre, the crop being *sorgo* grown as a green crop:—

Outturn of green crop	..	..	114·13 maunds.
Cost of cultivation	...	...	R 14 4 0
Value of produce	...	...	,, 38 0 8
Profit per acre	...	...	,, 23 1 8
With cotton similarly treated, the results were—			
Outturn of cleared cotton		...	291 pounds.
Cost of cultivation	...	...	R13 4 0
Value of produce	...	...	,, 59 15 9
Profit per acre	...	...	,, 46 11 9

The benefits of irrigation with deep ploughing were clearly shown during the course of these experiments, and the conclusions arrived at by Mr. J. B. Fuller, with regard to the *sorgo* experiments, were—

"*Inversion of the soil for a depth of six inches, two months before sowing*, increased the outturn by 72 per cent, when once irrigated, and by 100 per cent when twice irrigated. *Grubbing to a depth of six inches without inversion*, increased the outturn by 68 per cent when once irrigated, and by 107 per cent when twice irrigated, while *inversion of the soil to a depth of six inches immediately before sowing* diminished the outturn by 16 per cent when once irrigated, and by 16 per cent, when twice irrigated."

And with regard to Cotton:—

	Increase per cent. On unirrigated plots.	On irrigated plots.
Inversion of the soil to 6-in. two months before sowing	135	75
Inversion but immediately before sowing	119	75
Grubbing to 6-in. without inverting the soil... ...	27	16

These figures require but little comment. Taking first of all the unirrigated plots, we find that deep cultivation gives, in a season in which the rainfall was only $\frac{1}{4}$th of the normal, an outturn worth some R70 an acre, while the ordinary cultivation of the country could only yield R30. The condition of half plots 1 and 2 was a matter of surprise to all who saw them; unirrigated as they were, the cotton plant stood thickly on them at an average height of 2½ feet, while in plot 4 (which closely resembled the cultivators' unirrigated cotton fields in the neighbourhood) no plant stood much higher than 9 inches."

This is the sort of experiments we require. In these instances the results, whether good or bad, are patent; there is no doubt as to the effect of deep ploughing under certain conditions, and if we are to benefit by the lessons of these experiments, we must first of all aim at improving our draught cattle, as good ploughing cannot be done by the present breed of Indian cattle.—*Friend of India.*

THE STUDY OF AGRICULTURE.

The late and present students of the Madras Agricultural College (graduates and undergraduates of the Universities of Madras, Bombay, and Calcutta) have forwarded the following petition to the Senate of the University of Madras:—

"That, in the year 1874, His Excellency the Governor in Council, recognising the importance of the application of western science to agriculture in this country, founded an Agricultural College in Madras, and thus conferred on the people a boon for which they are and will ever be grateful. That the said college has now been in existence for about 5 years, and that the instruction imparted therein embraces a study of the art and science of Agriculture, Chemistry (Inorganic, Organic, and Agricultural), Zoology, Veterinary Medicine and Surgery, Botany in its various departments, Meteorology, Physical Geography, Me-

chanics, Book-keeping, Land-surveying, and Mensuration, in their relation to Agriculture. That, considering the curriculum of studies pursued in the college, it would be reasonable to expect that the local University would patronize the institution and take under its fostering wings a science, the study of which, your petitioners submit, is no less important than that of Civil Engineering and Medicine.

"That, seeing the primary importance which the profession of the husbandman occupies and must occupy in this country in the face of a rapidly-increasing population, with the arable area already pushed almost to its extreme limits, your petitioners feel sure that you will think it necessary and desirable that the intellect of the country should be directed to the study of scientific agriculture which *alone* can prevent the results which such a condition must bring about if unchecked. That, from the improvement of agriculture, as great benefits will accrue to the people of this country as from the study of Civil Engineering and Medicine which have been patronized by the University. That your petitioners hope that, if the University affiliates to it this institution, and grants Degrees in Agriculture, the art now so degraded will rise in the eyes of the people, and its true importance as "*the most useful, the most noble employment of man*," will come to be better recognized. That Agriculture is a recognized part of the University curriculum of many American, Scotch and German Universities, Cornell, Kentucky, Massachusetts, Edinborough, Halle, Gottingen, Munich, Leipsic, Berlin, Bonn, Vienna, Eldena, Giesen, Kiel, and that distinct Degrees in Agriculture are now granted in some of them. That your petitioners believe that the Agricultural prosperity of these countries is, to a considerable extent, owing to the encouragement afforded to the study of Agriculture by their respective Universities; and that your petitioners hope that a similar encouragement here will be attended with similar results. That the course of study which your petitioners undergo extends over a period of three years in which time they would be able if undergraduates of the Bombay University to proceed to Arts and Civil Engineering Degrees, and if undergraduates of the Madras University to have nearly completed the necessary course of study for similar Degrees.

"That, regarding the nature of studies which your petitioners undergo and the test of application to them, your petitioners humbly beg that the Principal of the Agricultural College and the Director of Public Instruction may be consulted, who, your petitioners trust, will testify those studies to be no less arduous than those required for undergraduates to proceed to Degrees in the Faculties already established in your University. That in Medicine two Degrees are open to undergraduates of Universities, one to Matriculates, and the other to those who have passed the First Examination in Arts. Your petitioners therefore pray that they may be admitted to the privilege of proceeding to Degrees in Agriculture, as other undergraduates are allowed to do in Medicine and Civil Engineering, and that if the Senate do not deem it fit yet to open special Degrees in Agriculture, a Degree in Science may be inaugurated having '*Agriculture*' as an optional subject."—*Madras Mail.*

INTRODUCTION OF THE HUMBLE BEE TO NEW ZEALAND.

Without those beautiful and interesting insects, our humble bees (*Bombus terrestris*), whose first booming hum on a still spring day coming forth from their winter's hiding place, so grateful to the ear of every country resident as the harbinger of balmy growth, it may not be generally known that without the aid of their long proboscis the red clover plant cannot be fertilized; hence at the antipodes a very large sum is annually expended in the purchase of imported red clover seed, which with that insect climatized could be grown in the colonies.

All attempts at their introduction alive, however anxiously longed for, have hitherto signally failed, even under the direction of so distinguished a naturalist as the late lamented Mr. Frank Buckland, and even under the patronage of the Prime Minister of New Zealand.

The present writer was consulted last autumn by Messrs. Geo. Neighbour & Sons, of London, who had been commissioned to endeavour to collect and despatch fertilized humble queens to New Zealand, and suggested that as previous failures were in all probability due to the queens having been aroused from their winter dormancy on entering the tropics, like the imprisoned bird, dashing themselves to death on the wires of their cage, the better plan would be to pack, while dormant, in moss, and place the package for the voyage in the *ice room* of the steamer.

To carry out the recipe, first thing to be done was catch the queens, not quite so easy a feat as 'the hare,' when it is remembered that humble queens altogether abandon their summer nests and hybernate singly deep in woods at tree roots, mossy banks, turf dykes, hay ricks, &c., &c. To go abroad to prospect on a December day to the uninitiated is somewhat akin to searching for the proverbial needle in the hay stack. But thanks to their abundance, due to the by past hot summer, and enlisting the services of Mr. Duncan Keir, the intelligent foreman of the Crossflat Nurseries, Paisley, who went into the matter *con amore*, the writer succeeded, after much painstaking labour, in unearthing no fewer than eighteen fine specimens, which were duly despatched by the steamer 'John Elder,' from London to Melbourne, on 9th December last. Through an unfortunate delay in transhipment to the 'Arawater' for Canterbury, on delivery of the package there only two queens remained alive. According to the *Timaru Herald* of 7th February, just received, the following extract is given:—'Humble Bees.—The two queens, the survivors of a shipment of eighteen, were turned out on Mr. Bristol's farm on Saturday morning (5th February). They were strong and healthy, and flew away briskly against the wind, being liberated amongst clover fields, there is every chance of their doing well. Not being aware of any successful attempt at the acclimatization being made heretofore, we believe that the pair of queens set free on Saturday have the honour to be the first of their kind in this country,' &c., &c.

A further shipment of three humble queens, from same source, was despatched direct from London to Canterbury, New Zealaud, by the steamship 'Norfolk,' on 20th January, in same manner. As there will be no disturbing transhipmeut in this instance, it is to be hoped all may arrive in safety, but as yet no intelligence has reached this country.—A RENFREWSHIRE BEE KEEPER.—*Scotch Paper.*

FOREST AND STREAM CONSERVATION IN MAURITIUS.

A correspondent in Mauritius furnishes us with particulars of the *projet d'ordonnance* recently introduced by the Government for consideration by the Legislative Council, which has caused so much excitement in the Colony, and to which our special correspondent's letter, published last week, drew attention.

We have already described the judicious measures which have lately been adopted in the Colony for preveuting the further destruction of forests throughout the island; and the attention of the Government is now turned to the no less important matter of the "protection of mountain and river reserves." The

object is a laudable one, and we doubt not any measures to ensure it would meet with hearty co-operation from the inhabitants, provided always that the measures proposed were framed with a due regard to the rights of property and vested interests.

Under the existing laws it is provided that in "river reserves"—*i.e.*, within 50 feet on each side of a river, 25 feet in the case of a rivulet, and 10 feet for a stream or feeder—proprietors or occupiers of land are forbidden to erect any building or to cultivate the land otherwise than by planting shrubs or trees.

On September 10 last a draft ordinance was published, in which it was proposed that the "reserves" should be increased to about 150 feet in the case of rivers, rivulets, or feeders, but no mention whatever was made of any proposal to indemnify landowners for the loss which such an extension of the Government reserves would cause. This omission caused great dissatisfaction, and when, on September 13, the newly-appointed Procureur-Général moved in Council the first reading of his proposed ordinance, the definition of the reserves was left blank, to be determined by the Council. At the same time the Procureur-Général affirmed that he did not propose to introduce any compensation clause, but, on the contrary, undertook to point out that owners of land to be converted into reserves had no right to any indemnity. Some concession on this latter point appears to have been later made by the Government, for in reply to an application for the requisite Government authority to hold a public meeting on the subject, the Colonial Secretary replied that "should the ordinance in its ultimate shape inflict any real injury upon the owners of private property, the proper compensation clauses will, as a matter of course, be added."

These assurances, however, did not satisfy the Colonists, who, at the public meeting, passed the resolution already reported in those columns, condemning the proposal of the Government.

It is, to say the least, unfortunate that a draft ordinance should have been published, involving so large an interference with the rights of property, without any provision being made for compensation to owners affected by its operation. Looking to the fact that Mauritius is a Crown Colony, and that the official majority in Council can at all times ensure the adoption, nominally, by the Council of any Governmental measures, we are not surprised that the landed proprietors in the Colony should have taken fright at the original scheme of the Government. Their concerted action and subsequent protests have already brought about considerable modifications in it. As our special correspondent points out, it is not the proposal to take measures for preserving the water sources that is objected to, *per se*, but the omission of compensation clauses, whereby the value of land, instead of being increased by such measures, is seriously diminished. Meantime, until the ordinance shall have been in some form or another adopted by Council, it remains only for us to say that adequate compensation is due to those whose property is required for the public good. This point, once admitted, will suffice to keep the "reserved lands" within proper limits; otherwise it is difficult to estimate the outlay which would be necessary to indemnify the landowners were the original limits of the reserve—150 feet on each side of a stream—adhered to. Within that distance from streams, and even rivers, many valuable sugar houses, and even private residences, now exist; and from a list now before us it appears that land varying in extent from 230 to 550 acres each, and amounting as a total to 3,503 acres, would, under the original proposal, be wrested from the proprietors of only ten estates. This alone will suffice to show what the extent of land rendered unproductive throughout the Colony would amount to. One estate, it is reported, would disappear altogether, whilst of another referred to only one-third would remain to its owner.

The object which it is sought to attain—viz., "protection of mountain and river reserves," is an admirable one, and it is much to be regretted that, by hasty and ill-considered attempts at legislation, the Government should have excited a prejudice against their proposal which would not otherwise have existed. —*Colonies and India.*

SUGAR GROWING IN FIJI.

Our sugar prospects are very cheering. The new mill on the "Penang" estate at Rakiraki (north coast of Navitilevu) belonging to Dr. Chalmers, has sent to Levuka its first consignment of sugar, which is of excellent quality. Mr. Stanlake Lee's mill on the Lower Rewa is now ready for work, and will begin crushing on the 1st proximo. This mill was erected specially for the cane grown by the natives of the Rewa delta on their town plantations, from which the produce is raised for the payment of their taxes. This is their first year of sugar planting, and if no disaster occur, there can be little doubt that the experiment will be very successful. The cane is looking well, and, on a rough computation, there is enough of it to bring in some £4,000, which is £1,800 over and above the assessment for the whole district. This large surplus, if realized, will be returned to the natives, and cannot fail to encourage them to future efforts.

Other mills are going up elsewhere; but our great event in sugar is the erection of the Colonial Sugar-refining Company's mill at Nausori, on the banks of the Rewa River. The works are being carried on energetically under able management, and some notion of their magnitude may be gathered from the following particulars. In addition to a crowd of "imported labour," the company has in constant work about 60 white men, chiefly mechanics, rivetters, &c. Three ships, of 800 tons and upwards, have brought the machinery and other ironwork from London and Glasgow. Another vessel has been employed to bring timber from New Zealand, the company's own steamer 'Fiona' has delivered two cargoes, and large quantities of freight have been brought down by the A. S. N. Co.'s steamer 'Gunga.' About 3,000 tons of concrete—river sand, gravel and Portland cement—are expended in laying the foundations on which the works are to be erected. The following iron vessels are being put together in the company's sheds, their plates and other materials having been imported in a finished state, ready for construction:—Thirty punts, each capable of loading 60 tons, for conveying the cane from the plantations to the mill, and a flat bottomed steamer for towing them, 100 feet in length, and drawing when fully loaded no more than 20 inches of water. For conveying cargo to and from Lauthala Point, at the mouth of the Rewa River, where the company will do all its shipment and discharging, there are being constructed eight barges of 120 tons each, with a draught of 5½ feet when laden. For towing them two powerful steam launches have been built, and are now in use as tugs and message boats. They have a high rate of speed, and it is astonishing to see the ease with which they walk away with the big barges looming huge behind them. The vessels which take away the sugar will come down laden, to some extent at least, with coal, of which the company will be a large consumer, not only for its furnaces but also for the manufacture of gas. Every part of the establishment will be lighted with gas during the crushing season, when work will be carried on unceasingly day and night. The gas-holder is already erected. When complete the mill will crush about 4,000 tons of cane per week during the season, from which, in round

numbers, some 350 tons of sugar be expected. The requisite amount of cane is guaranteed by the planters; and, large as the quantity appears, it is little more than one ton of cane to the acre of sugar land in the district. On good land the yield is said to be about 40 tons to the acre, and this the company takes, deliverd on the river bank of the various plantations, at a fixed rate of 10s. per ton. It is expected that the mill will be ready for work in July, 1882, and that the planters will then be ready to furnish their quota of cane.

The Rewa River Plantation Company, which has done such good service in the past, and whose mill is some distance farther up the river, endeavoured to secure themselves against their formidable rival by refusing to crush for the planters unless they would guarantee to furnish them with a certain amount of cane for a term of years. This caused a quaver of consternation among the planters, for, if it had been persisted in, it would have involved the loss of the greater part of the crop now ripe. Happily, however, the company did not persist. Their mill is once more in full swing, and the cane is turning out the satisfactory density of 10°, a better figure than that which the past two years have been able to reach.—*Queeslander.*

INDIAN KAOLINS.

TO THE EDITOR OF THE "MADRAS MAIL."

SIR,—Your correspondent "School of Arts" in your issue of the 3rd instant I find somewhat obscure in the localization of the difficultics experienced hitherto, in the working of Indian Kaolins in the manufacture of porcelain. He says:—"Now all the Indian Kaolins we have tried contained so much silicate in the form of silicate of alumina that they cannot mould them into shape." Whether by "silicate" is meant the proportion of the alumina, or the proportion of silica—silicic acid of the silicate of alumina, I am unable to follow. If the latter, an admixture of the Kaolins in question, with a suitable proportion of the white clay occurring in the laterite ridge in the neighbourhood of Cuddalore, known as Mount Cappa, would probably give a clay of required composition. The clay in question is white viened in parts with red. Taking roughly an average sample, no picking out of red portion, the analysis obtained was:—

Sand	41·67
Combined silica ...	15·81
Alumina	26·27
Ferric oxide ...	2·51
Magnesium and alkalies	2·82
Water... ...	11·00
	100 08

The amount of magnesium was very small. The amounts of potash and soda, constituting in the above analysis, the 'alkalies,' I did not determine, as I required to use the clay for manufacture of fire bricks only. The above clay contained less 'sand and 'water,' has the composition,

Combined silica (silicic acid) ...	33·3
Alumina	55·4
Ferric-oxide	5·3
Magnesium and alkalies	6·0
	100·0

The approximate composition of the silicate of alumina of this clay, a portion of the iron playing the part of alumina, is:—

$$Al^2\ O3\ SiO2$$

Constituting what is technically known as a "weak" clay, wherein the proportion of alumina is large to the quantity of silicic acid. By washing the clay, the sand could easily be eliminated, together probably with a large portion of the alkalies, and iron might be largely avoided by picking. Under favorable circumstances, the clay might possibly be reduced to the composition, under these operations of:—

Silicic acid	36·0
Alumina	59 0
Ferric oxide	2·0
Magnesium and alkalies ...	3·0
	100·0

a composition which diverges widely from that of a porcelain clay, having, in fact, the proportion of silica to alumina exactly reversed, so that if, by 'so much silicate' chemically combined, "School of Arts," means too much combined silica in the clay, a happy mean might be struck by mixing the two clays (washed and levigated well), resulting in a composition approximating that of true porcelain clays, which varies, on the dry olays, from 50 to 60 silicic acid combined with from 40 to 30 alumina, speaking in round numbers. "School of Arts" would probably have his labours in the search for a porcelain clay much lightened, if he had analyses made of those clays, which have at all the composition of fire clays, which he may come across, and probably in the consideration of these analyses he would find useful, a paper, on "Chinese Porcelain Manufacture" by A. Heintz Dengler's Polytechnical Journal, CCXVI, 156, 66, appearing in an abstracted form in the Journal of the Chemical Society, Vol. II, 1876, page 671.

In this abstract the analyses of two China (I and II) and of two French (III and IV) porcelain clays are given as follows:—

	I.	II.	III.	IV.
Loss by ignition (almost wholly water)	11·2	8·2	12·6	7·2
Silicic acid	50·5	55·3	48·3	56 9
Alumina	33·7	30·3	35·0	31·6
Ferric oxide	1·8	2·0	1·3	0·5
Lime ...	—	—	—	0·5
Magnesia	0·8	trace	0 4	—
Potash	1·9	—	—	—
Soda	—	2·4	3·8	3·4
	0	—	—	—

Yours &c.,

F. N. G. GILL.

ORANGE TREE CULTIVATION.

The following facts as to orange cultivation at the Azores, communicated in a letter to an Australian contemporary, will throw some light on the causes of decadence in the tree and the means of preventing it:—

Until 1836 the orange trees budded, blossomed, and fruited with unvarying regularity. The grower would as soon have suspected the sun of variation from his diurnal course as the orangeries from their yearly round of duty. They were handed from father to son, and lasting as they did from generation to generation, it is not surprising that they became a symbol of permanence. These trees cost the growers no care, no attention, no labour, save the labour of picking and packing, so far as we can understand. The people might dance and drink the year round, and the orange would blossom and fruit the year round, without trenching, without manuring, without draining—it may be without pruning. The plant was neither fickle nor fastidious, and the islanders rejoiced in their orange trees. Suddenly, however, there came a change. This bright picture of the growing, greenleaved, self-contained tree, surrounded by a joyful, sun loving, dancing people, dissolves away, and gives place to a pale-leaved and sickly tree, surrounded by a carefaced and inquiring population. Their first proceedings were those of the panic-stricken, they were carried to extremes. From absolute indolence they rushed into

alarming activity; but it was the blundering activity of ignorance. Having had little need to inquire into the physiology of the plant, or the relations subsisting between the soil and the plant, they adopted measures to set things right which outraged both, and only made things worse; but gradually, by the aid of the suggestions of science and a teachable disposition, a middle course was hit upon, and restorative process were prescribed with an intelligent knowledge of the patients' requirements. At first the trees were overloaded with manure and stifled with shelter, and a great deal more was done to them than they could well bear. Now they perceive that thorough drainage is at the foundation of successful orange growing; that next to this, trenching to a great depth is essential; and thirdly, that manure must be applied—but with discretion. It is true the trees are more fickle than they were, and die more frequently, and the fruit will not keep so long. But growers can again count with tolerable certainty upon their crop. The disease of the orange was first discovered in the Azores in 1836, when it was found that the oldest and best trees, as much as 200 and 300 years old, and producing each 6,000 to 20,000 oranges, were disappearing. It was observed that all the trees affected produced a very heavy crop the very year that the disease manifested itself, that the leaves became yellow and fell off in great quantities, and on the trunks or stems near, and sometimes beneath the ground, the bark opened, and drops of a kind of yellow gum exuded. The drops resembled tears (*lagrimas*, in Portuguese), and therefore the disease was named lagrima. Many orangerics were quite destroyed, and a remedy was eagerly sought. Opinions as to the cause of the disease were much divided Many thought it must be that the orange tree had a limited period of existence, and this being reached, the tree must thus naturally decay. As we then only propagated trees by layers, this explanation was not thought too unreasonable, but afterwards it was found that seedlings were attacked in the same way. Then it was found that superabundance of moisture in the soil was one of the worst conditions for the disease. Soon it was discovered that the destruction of the diseased bark and wood in the stem of the tree was the best method to save it. From February till August a skilled horticulturist visits every tree, and at the slightest sign of exudation of gum he cuts the bark across, to allow it to run out. If the disease is in an advanced state, the bark and the whole of the diseased wood is cut out, the roots being bared to a distance of a foot or two feet from the stem, every portion of diseased root being cut away. By this means the tree is cured if the disease is found at an early stage; if not, it is dug out, and a fresh tree put in from a reserve which is always kept for such contingencies. Although the disease still continues, the gardens now look very prosperous, for the remedy is known. . . . . So we are returning to the old traditional culture. We are clearing the shelters, pruning the interior of the trees for the admission of air and light, are less liberal with manure, and keep the ground free of weeds, except when we want to excite vegetation. We have abandoned propagation by layers, and graft good chosen kinds upon seedling stocks. For shelter we prefer trees with their foliage, and take care not to let them grow too high.—*From the Rnaff Oriorel Herald.*

THE TOBACCO OF BURMA.

A Rangoon paper anticipates that, under the present conditions of tobacco-growing, the supply of Burma cheroots will soon fail altogether:—

For a good many years past cheroots manufactured in this province have been held in very high estimation by a large class of smokers; and at the present more so numerous are the lovers of good Burma cheroots, that it is not easy for Europeans here to purchase them, the demand for exportation being so great. During the past ten years the cost per hundred of Burma cheroots has increased cent per cent, and it is not by any means an easy task to get cheroots at one rupee eight annas a hundred, so good as those which ten years ago could be purchased at twelve annas a hundred. Increased demand has, no doubt, very much to do with this enchantment of cost; but one have grave doubts as to whether it is entirely to blame. The population of the province has steadily increased, and it would pay to manufacture and sell cheroots at twelve annas a hundred ten years ago, one would think that it would pay when the product of such manufacture fetched double or more than doubts that sum. It may be that the great and rapid rise in the selling price in the local market of paddy had something to do in the cheroot manufacture. The cultivation of paddy being so easy, and under the highly-enhanced rates so profitable, cultivators left every other article of produce along in favour of paddy. But the cultivation of tobacco might be made highly profitable if some one could only be got to take the matter in hand. The Government have tried it, and failed, for reasons into which we do not here intend to enter. The facts remain that good tobacco will grow in Burma, that the demand for good Burma cheroots is increasing, and that the supply has already fallen short of the demand. Not only has the supply fallen short, but it bids fair to go on in the same direction until Burmas are as high in price as manillas, or any other favourite brand. Bad as this might be for smokers who like Burma cheroots, it might be good for the province generally, if even certain that men could be found to pay a high price for them. The Burma cheroot has not a prepossessing appearance. It looks a very plebeian affair alongside a member of the Manilla or Havannah brands. And the habit of smoking Burma cheroots, and getting to prefer them to anything else, is an acquired one, in proof of which it may be stated that the chief consumers of the present day are those who have either lived for some time in Burma, or who have had friends here who furnished them with regular supplies, whereby they got to like them. It would seem desirable, then, that the supply should be kept up, and the question is how can this best be done? The Government should do all in their power to promote and encourage private enterprise. The capitalist coming to Burma is confronted by two very formidable difficulties, namely, these connected with the tenure of land, and with labour, and both these difficulties it is within the power of the Government to reduce to a minimum. As matters stand just now, there is, we are glad to notice, a desire on the part of the Government to exercise liberality in the matter of making grants of land; and, perhaps, if this were made known more widely than it is at present, it might have the effect of attracting capital, but the labour question, as we have often pointed out, is under existing circumstances practically insurmountable. The petted cooly is virtually master of the situation. The law is all in his favour He may leave the estate on which he may be employed tonight; and by the time the court opens tomorrow, he may be miles beyond its jurisdiction. Besides; what is the use of paying ten rupees costs and waste two or three valuable days in getting a decree against a man whose estate, real and personal, amounts to little more than a waist cloth, which no person with any regard for cleanliness would touch with his walking-stick. A Contract Act, such as is suggested here, would certainly in one sense involve an infringement of the liberty of the subject; but it may well be questioned whether

in the present order of things freedom is not turned by the labouring class into license. An employer gets labourers, let us say from Calcutta. By the time each man is lauded in Rangoon he has cost his employer some forty or fifty rupees. He leaves a day or two after he gets here, and his employer has no remedy but to sue him for damages. Of the value or rather worthlessness of this remedy we have already spoken, and have only now to repeat what we, and most of our Indian contemporaries have often said before, that it is high time a change was made. When this is done, we may perhaps hope for better days for Burma manufactures, particularly of the manufacture of Burma cheroots.—*Pioneer.*

THE DEHRA FOREST SCHOOL.

Seven subjects for study had originally been proposed by Mr. Brandis, namely (1) Forestry (practical and theoretical); (2) Mathematics, (elementary); (3) Surveying up to the lower standard. These three subjects only were first to be taught, and as arrangements could be made, (4) Botany; (5) Rocks and Soils; (6) Meteorology; and (7) Law were to be introduced. But owing to the delay that has occurred it has been found practicable to open with a full programme, and instruction in Botany, the Elements of Natural Science, and Law is being given in addition to the obligatory subjects. The most important branch of instruction given in the Forest School is, of course, *Forestry* or Sylviculture. Some of the probationers and apprentices have been employed in the forests for nearly two years, and must be able fully to appreciate the theoretical instruction they are now getting. The original plan was to admit the apprentices on 1st June, so that four months of theoretical teaching would open each year of the two years' course; and no doubt ultimately this will be the order of things. Forestry is taught in the class-rooms by Mr. Fisher, the Deputy Director, assisted by Mr. A. Smythies, Assistant Conservator, in charge of the Jaunsar Division. Mr. Fisher's course embraces (1) an explanation of the functions of all the parts of a tree, its physiology in fact; (2) and (3) a description of the mode of growth of different kinds of trees, and of bamboos; (4) details of all the other kinds of forest produce, which a ranger must utilize, such as fibres, fruit, caoutchouc, resin, lac, honey gums, and wood oils; (5) he treats of the composition of wood and charcoal, and the influence of rock and soil; (6) of climate, altitude, and aspect in their influence on forests; (7) of the relation of forest trees to each other in mixed forests; (8) of the classification of forests, which is necessary with a view to plants for working them; (9) of artificial and natural reproduction; (10) of the treatment of forests, as regards selection of fellings, thinning and cutting of creepers; (11) of different systems of management, as high forest, coppice, or coppice with standards, and (12) protection, from fire, pasturage, frost, fungus and lichens insects and other animals. Mr. Smythies treat of (1) the properties of timber, and other forest produce; (2) forest operations, *i.e.*, preparing the timber and other produce for the market; (3) of transport by land and water; (4) of the disposal of timber ready for the market, whether standing, or felled and worked up. Instruction is given by other lecturers in Mathematics, Surveying, Natural Science, Botany and Law, its bearing on forest affairs. The students attending the school are of three classes, and instruction is administered to them accordingly: and all have about six hours of attendance to get through daily. The junior class is composed of the native apprentices; senior class (*a*) comprises the probationary officers; of whom there are now 2 Europeans and 3 Bengalis, and these two classes work pretty much together. The senior class (*b*) is formed of 6 European Sub-Assistant and Assistant Conservators, who have not received a European forest training, and who have been deputed from various provinces, at the invitation of the Government of India, to attend the school for this session, with the view of improving their theoretical knowledge. At the close of their two years' course of training and instruction the apprentices who qualify will receive a certificate stating that they are competent to hold the position of a forest ranger. For Probationers there are two standards of qualification (*a*) for the position of a forest ranger, and (*b*) the higher certificate of being eligible for promotion to the class of Sub-Assistant Conservators. This latter will be granted only to those probationers who distinguished themselves by special aptitude for the superior staff, and who are otherwise fully qualified. Promotion to the superior staff will only be given after two years' service as forest ranger, but cannot then be claimed as a right. Altogether the Forest School seems to have fair chances of success; and institutions of the sort are certainly necessary now that it has been recognized that the department must be recruited in this country. In a former article it was stated that an area of 25 square miles, or 1,600 acres was to be the average for a forest range, and that 600 executive officers would be required, with 100 controlling officers. From a later paper by Mr. Brandis it appears that the area of demarcated forest under the Government of India now 15,000 square miles will probably be increased to 20,000, but that the average area of a range will not be less than 30 square miles. The number of the ranges will therefore have to be 660. The controlling staff is now 93, and is not likely to be increased beyond 100; but the number of rangers is now only 97, and hence ranges are frequently in charge of mere foresters, or of members of the upper establishment. 563 additional trained Forest Rangers are therefore required, and on the proper selection and training of the candidates for these posts will mainly depend the success of Forest Administration in India.—*Pioneer.*

THE PANDANUS OR SCREW PALM.

(From "Coral Lands," by H. S. Cooper, 1880.)

I have before mentioned the pandanus, or screw-palm; this remarkable tree flourishes most abundantly in the Tuamotus; though it is to be found more or less all over the islands of the Coral Sea. This is a most valuable product, and deserves to be better known. It is a very suggestive fact that the pandanus, custard-apple and other tropical productions of this region are found in a fossil state in the Isle of Sheppey, in England. The pandanus is called 'screw-palm' for the reason that it grows with a twist, like the screw of an augur. Its height is generally from twenty to forty feet, the stem being straight like a column, sending forth branches at regular intervals in such a form as sometimes to remind one of the golden candlestick in the tabernacle of Moses. Each of these limbs terminates in a tuft of long drooping leaves, having in the centre a large yellowish flower, of an overpowering odour, very agreeable, but sickly by reason of its intensity. Underneath this tuft hangs the fruit, which is of a dark green colour, outwardly of the size of a man's head, and a form resembling a pine-apple, or more exactly that of the cone which on ancient sculptures is made to surmount the thyrsus of Bacchus. This fruit is commonly regarded by white men not only as unpalatable, but even as uneatable; nevertheless, it constitutes almost the sole subsistence of thousands of natives in the Kiugsmill and Marshall Groups, where no vegetable food exists.

When the fruit is ripe it easily comes to pieces, and is found to consist of a multitude of separate capsules, each of the form of a truncated cone, with

square corners, the small ends being arranged around a central cone. Their surface is bright and smooth as ivory; in one species yellow, in the other blood-red. The outer end is as hard as a stone, the inner soft, of the consistence of sugar-cane, and containing an equal if not larger proportion of saccharine matter. The interior of the capsule is fibrous. The custom of the natives is to chew the soft end, and having thus extracted all the nutriment, to throw on one side the hard portion, which they let lie in the sun till thoroughly dry, when they crack it between two stones and extract the *kiko* or koruel, which is similar to a filbert and very wholesome. The ripe fruit when boiled down produces a large percentage of excellent molasses; also, when steamed in the Sawaiori oven and mashed up in warm water, it yields an intoxicating liquor when fermented, and a strong spirit by distillation. But the chief use to which it is devoted is the preparation of what is called on the equator *kubobo*, which serves the savage of the more barren isles in the place of bread. The soft parts of the fruit are grated, and the pulp so obtained is dried in the sun. Its appearance is then that of coarse pine sawdust, of a dark-brown colour and sweetish taste. It is packed in baskets, solidly trodden into a hard mass with the feet, and will keep for any length of time. When required for use, it is moistened, kneaded, and baked on the stones. It is strong food, easily digested and very wholesome, but not very palatable to a European.

The pandanus * tree grows usually upon coral, gravel, and clean sand, where there is no particle of mould, or soil, so that it seems beyond measure surprising that its roots could there find either moisture or nourishment. Nevertheless it contains a superabundance of oily sap which exudes freely wherever it is cut with an axe. Growing as it does on the seashore, it would be liable to be blown down easily by a strong wind, were it not for a most marvellous protection given it by a beneficent God. From the ground upwards, round and round the stem in a spiral row following the twist of the tree (to the height of about twelve feet), are what at first appear to be excrescences, looking like warts; these continue to protrude in the form of horns growing downward, straight, and about the thickness of a man's arm, until they touch the ground, where they take deep root and send out suckers in all directions, and so form a series of stays round the tree on every side, so that it safely defies the power of the most furious storms.

These stays, when macerated and freed from their oily pulp, yield a fibre similar in appearance to jute, exceedingly white and exceedingly strong. The trunk of the pandanus tree, at maturity, is as hollow as a stove-pipe; the wood, never more than a few inches thick, is as hard as bone, and takes a very fine polish.

The leaves of the pandanus tree are more than six feet in length, and from two to four inches wide, of a bright green, with a rib down the centre and edged on both sides with a row of sharp prickles. Roofs of houses, sails of canoes, flooring mats, and clothing of all sorts are manufactured from the leaf. Wonderful and beautiful fabrics are made from it, all plaited by hand and dyed various colours. Waist-clothes and sashes, as white as linen and as soft as silk, are also made from the leaves of this rich tree.

I do not know of anything that will approach the leaves of the pandanus tree, as a paper-making material. The tree grows from one end to the other of Coral Lands. Its leaves can be had for the trouble of cutting and all that is wanted is to steep them in salt water, pound them and bleach them in the sun, and they will become as soft and white as a linen rag.

* Sinhalese *Vetakéyiyá* වෙටකෙයියා; common to the sea board of Ceylon.

INDUSTRIAL PROMOTION.

An association for the promotion of domestic industrial enterprises has recently been organized in this city under the title of "Associação Promotora da Industria Brazileira." According to a prospectus which has been sent out into the provinces the terms of membership, or share-holding, are 5$000 per month, with loss of rights and full dividends in case of failure to meet the payments regularly. These fees will constitute the fund of the association, which will be used, (1) to advance the scheme itself and meet its expenses, and (2) to promote the realization of industrial projects. Every shareholder will be required to exert his influence in favour of the association, and the projects promoted by it. When the funds shall be sufficient, a committee of the association will select one from the many industrial projects presented to it, which project will then be assisted from the fund, the party thus assisted being required to refund twice the amount received from the first receipts of the enterprise. The surplus receipts of the association will be employed as follows:—25 per cent for dividends, 25 per cent. for the reserve fund, and 50 per cent for the realization of industrial enterprises. The association offers, also, to act as an intermediary between capitalists and the promoters of industrial enterprises, its office serving in that sense as an industrial agency. The prospectus is signed by Thomas Burns, Geo. S. Barnsley, J. J. Marcnant and Phil. Slaughter.

With all due respect for the enterprise and opinions of the promoters of this scheme for aiding domestic industries, and also for the aspirations of those who would build up a diversity of manufacturing industries in Brazil, we beg leave to inquire whether the scheme above outlined is really feasible.

One of the first elements which should enter into every industrial enterprise is that of practical experience. Does this scheme promise anything of the kind? Are its promoters skilled manufacturers? and have they any one industry in contemplation? On the contrary, the prospectus is silent on the question of experience, and refers to domestic industries only in the most general way. In all probability the establishment of a cotton mill will be left to coffee planters, of an iron foundry to sugar cane growers, of a sugar mill to lawyers, and of a shipyard to physicians. The enterprise will be established because the country still lacks that particular industry, and because some dreamer fancies that he would like to undertake it.

A second element in every industrial enterprise—and it is a very necessary one—is capital. Now what does this scheme offer on this score? Simply monthly fees from shareholders at the rate of 5$000 per month. Suppose that there is a manifest desire to assist some man to start a central sugar factory in a locality where there is an apparent need for such an establishment. Taking 300,000$ as the capital required for this enterprise, it will require the fees of over ten thousand shareholders for one year, or over five thousand for two years—only 50 per cent of the surplus receipts can be used for this purpose—to realize the sum needed. And in this estimate we leave unspecified the sum necessary for promoting the interests of the association and the expenses necessary for its management, both of which will be far from insignificant. It would seem, therefore, that the element of capital will be a very uncertain factor in this scheme.

A third element in every industrial enterprise is that of management—to use the word in its most general sense. There should be unanimity of purpose at the outset, compactness of association for efficiency of control, and then a definite aim. In what sense does this scheme meet any of these requirements?

To start with it has no purpose but the very general one of aiding domestic industries, the specific means to be determined hereafter. It seeks to organize an unwieldy association through small fees, which will be fatal to its efficient control and business-like action. It has no definite aim.

This scheme—and we have no personal motives in selecting it for criticism—is only one among the many which are seeking to accomplish an industrial regeneration of Brazil. As a rule they are all based on sentiment, and are totally deficient in almost every element which can contribute to their success. They expect to establish a diversity of manufacturing industries in Brazil through appeals to popular support and government patronage, and they expect them to live and grow wherever they are planted. It seems to us that the whole movement is a mistaken one—not, perhaps, in the wish, but rather in the means employed to bring it about. Every industry which can be established on a sound basis will be a source of wealth to the country, and should therefore be welcomed and encouraged. An unsound and unprofitable industry, however, is not only a source of loss, but it is an element of weakness. A sound industrial system is essentially of slow growth, and can not be hastened without endangering its permanency and profitableness. For this reason, it would seem best to let the system grow naturally, and let capital, which is always cautious and conservative, seek out those industries which can best be carried into practical operation. By such methods there may be no rapid progress, but there will certainly be a substantial growth and an avoidance of many humiliating failures.—*Rio News.*

THE CULTIVATION AND MANUFACTURE OF TEA IN JAPAN.

(Extracts from the U. S. Consular Trade Report for Kanagawa, Japan, for 1880.)

The cultivation of tea, it is almost needless to say, is one of the most important branches of Japanese agriculture. Although the area will value of its product may not be as great as that of rice and barley, still, as an article of commerce, it is more important. The amount exported has increased from less than 5,000,000 lb. in 1869, to an estimated export of 40,000,000 lb. in 1880. The total product for 1880 is estimated at 90,000,000 lb. The whole population of the country drink tea. It is the national beverage from infancy to old age. It grows in all the *Kens* or provinces of the empire, but its favourite locality is south of the 40th parallel of latitude. So much has been written and published of tea culture, that I shall only briefly speak of the methods adopted for its production in Japan.

The soils most sought after for its growth are the sheltered hill-sides, although it flourishes on the plains along the sea shore. If wild lands are to be used, the soil must be thoroughly tilled and subdued. It is grown in rows. A thrifty tea shrub is from 3 to 5 feet high. The plants require constant care in all seasons. They must be carefully pruned and trimmed, and the soil must be constantly fertilized. The third year the plants begin to yield some return, and the fifth season the yield is quite good. I have been informed by the tea-farmers that 2,500 lb. of tea-leaves to the acre is a fair yield, and that more than 3,000 lb. are often produced.*

I should state that this is the weight when prepared by the Japanese, and that there is a shrinkage of about 1-10th by the foreign mode of firing.† There are large areas where the soil and climate are well adapted to the growth of tea, and, as there is an abundance of skilled cheap labour available, there is no immediate limit to the increase of this important product, except in its foreign demand.

As I reported last year, there is a determined effort upon the part of the Government and the tea growers, to produce black teas. A large number of Chinese experts have been employed and sent into the tea districts. The result is that a good article can be produced at prices that place Japan among the competitors for the black tea markets of Europe. The prospect for the Japanese tea growers seems in every way to be full of promise. I forward herewith a sample of this black tea, prepared in the province of Gifu. The processes of tea preparation will be treated of under the head of manufactures.

* * * * *

I have put down tea as an article of manufacture, for although it is the leaf of a shrub, its treatment and preparation are such as to entitle it to be treated under this head. The firing and preparation of tea for market as practised in Japan, is as follows:—The Japanese green tea may be divided into three general classes: colored, uncolored and basket-fired. The leaf used for all these is from the same plant, differing only in quality, condition, etc. All teas used by foreigners are first fired by the natives in the places where grown. If a grade of colored tea is to be made, this fired leaf (4 to 5 lb.) is taken and put into iron pans or bowls, which are heated, sometimes up to a temperature, of 212 deg. Fahrenheit. The leaves are then rapidly stirred by hand against the smooth iron surfaces some 20 minutes. A teaspoonful of thoroughly pulverized soap-stone (saponite), and five grains, or so, of powdered Chinese Indigo are placed in the pan, and thoroughly rubbed into the leaf for about 20 minutes more, when half a tea-spoonful of soap-stone or gypsum, and pulverized tamarak bark (a species of larch) is added, and the stirring and rubbing is continued for 20 minutes more. It is then put into cold pans, and simply cold rubbed against the iron surfaces until it has the required polish, which is arrived at in from 40 minutes to an hour. This is the ordinary way of preparing colored tea. Other materials are perhaps sometimes used, but so far as I can learn, all are as these mentioned. The different manufacturers, of course, vary the process a little now and then to produce slight changes of color. The leaf is then run through three to five sizes of sieves, till all the dust and loose coloring matter is separated. The shrinkage is about 12 per cent.

This coloring process is considered beneficial to the leaf, tending to preserve its shape and flavor. There can be no doubt that the Japanese prepared teas are far superior in purity to the Chinese. In coloring Chinese teas, various drugs are used that are deleterious to health, unless it be that the heat to which they are subjected renders them innocuous. Prussian blue is frequently used instead of indigo in their green, and black lead in their black teas. Uncolored teas are made in the same way and quantities, and rubbed against the iron pans until the surfaces have the desired polish, and are then sifted until nothing but the whole leaves are left. Basket firing is done in bamboo-baskets, shaped something like our hour-glasses which are shaken over hot pans. The leaf is put into the upper lobe of the basket and worked into the lower, and so, back and forth, until finished. The loss of weight is about 3 per cent.—THOS. B. VAN BUREN, Consul General.

* Green leaves, of course, reduced 75 per cent in drying.—ED. *T. A.*

† Utterly incredible! 3,000 lb. reduced by one-tenth would be 2,700 lb. of dried tea per acre, which never has been got.—ED. *T. A.*

COCA (ERYTHROXYLON COCA).

In Mr. Markham's "Peruvian Barks," he has given the results of his own observations, and collated that

of other travellers, respecting this substance, and to this account we are chiefly indebted for the following facts:—

"Coca," the beloved narcotic of the Peruvian Indian, was first named botanically though the labours of Joseph de Jussieu. The history of this noted botanist is a melancholy one. He left France in 1735, in the ever-memorable expedition of La Condamine, and after M. La Condamine left South America, M. Jussieu continued his botanical researches, making numerous journeys on foot, notably those to the cinchona regions. The result of fifteen years' labours were contained in certain cases of dried plants, &c., and a native servant at Buenos Ayres, thinking these cases contained money, stole them, and this loss had such an effect on poor Jussieu that he returned to France in 1771 deprived of reason.

The Coca is the greatest source of comfort and enjoyment to the Peruvian Indian. It is to him what the kava kava is to the South Sea Islander, the betel to the Hindu and Malay, and tobacco to the rest of mankind, but with this difference, it produces invigorating effects. The Peruvian Indian looks upon Coca with veneration. In the palmy days of the Incas or Yncas, Coca was sacrificed to the sun, the high priests or Huillac Umu chewed it during the ceremony, and before the arrival of the Spaniards, Coca was used in lieu of money. After the Spanish Conquest much was done to prescribe its uses because, as a Council of Bishops held in 1569 said, it was a "useless and pernicious leaf, and on account of the belief stated to be entertained by the Indians, that the habit of chewing Coca gave them strength, which is an illusion of the devil." Coca, indeed, from its popularity, being used by about eight millions of people, has always had a great commercial importance, and one Viceroy, Don Francisco Toledo, issued no less than seventy ordinances concerning Coca in the space of four years (1570—1574).

The Coca plant is a shrub of four to six feet high, with straight and alternate branches and leaves like those of the Tea plant, and is cultivated at elevations from 5,000 to 6,000 feet above the level of the sea in the warm valleys of the eastern slopes of the Andes. Here the only alternations of climate is from wet to dry; frost is unknown, and it rains more or less every month of the year. The seeds are sown on the surface of the soil as soon as the rainy season commences, and begin to sprout in a fortnight, being carefully watered, and protected from the sun by a thatched roof. The following year the seedlings are transplanted in a soil carefully broken up and freed from weeds. The ancient custom was to raise the plants in terraces on the hill sides, but now plantations on the level ground are resorted to, although Indians aver that plants raised under the former conditions yield a much superior quality of leaf. At the end of eighteen months the first harvest is ready, and the picking of the leaves, performed by women and children, is very carefully proceeded with, so as not to injure the young and still tender shoots. As soon as one crop of leaves is removed, if well watered, and the ground carefully weeded, another crop is ready in about forty days. A plant continues to yield for about forty years, and Dr. Poeppig gives the profit of a Coca plantation as about 45 per cent. Each picker carries a piece of cloth in which the leaves, plucked one by one, are placed. These leaves are then taken to the drying-yard, formed of slate flags. Here the leaves are spread out in thin layers, and carefully dried in the sun. Too much exposure to the sun spoils the flavour of the leaf, and if heaped too much together, the leaves ferment and become fœtid. As soon as dried, the leaves are packed in bags made of banana leaves, with an outside covering of cloth, or packed tightly in large parcels of about 50 lb. each. In the Sandia district of Caravaya two varieties of Coca are recognised, the Ypara and the Hatun Yunca, the latter having a larger leaf than the former. In Bolivia, Coca is treated as a Government monopoly, and the right is generally farmed out. In 1850, Coca brought into that country's exchequer a sum of 200,000 dollars. The whole yield of Coca in South America is estimated at thirty millions of pounds. Coca soon deteriorates in keeping, and Indians treat it as valueless if kept longer than seven months. Such is the faith in Coca, that it is believed if a dying man can but taste a Coca leaf when placed on his tongue, his future bliss is assured. No Indian is without his *cuspa* or Coca bag, made of llama cloth, and three times a day, sitting down, he takes leaf by leaf and rolls them up in his mouth till he forms a ball. Then applying a small quantity of powder consisting of carbonate of potash, made by burning the stalks of the quinoa plant, mixed with lime and water, he goes on his way rejoicing. The use of Coca is widely spread. The shepherd on the cold slopes of the Andes has but this and a little maizo as his sole nourishment, and the runner messenger looks to it as his solace and support. As to the properties of Coca, it seems very evident that it allows of a greater amount of fatigue, with a lesser amount of nourishment, and prevents difficulty of respiration in ascending steep mountain slopes. It has an agreeable and aromatic taste, accompanied by a slight irritation, which excites the flow of the saliva. When made into a tea, in taste it is like that of green tea, and effectually prevents drowsiness. Applied externally as a poultice, it moderates rheumatic pains, brought on by exposure to cold and wet, and also cures headache. Mr. Markham chewed Coca leaf very frequently, and states that he found it to produce an agreeable soothing feeling, that he could endure longer abstinence from food with less inconvenience, and that when using it; he could ascend precipitous mountain sides with a feeling of lightness and elasticity, and without losing breath. He also considers it the least injurious of all other like substances, even when taken in excess, and at the same time the most soothing and invigorating.—*Produce Markets' Review.*

A VISIT TO THE POOSA TOBACCO FARM.

A decade or two hence the public will probably look back with wonder and surprise at the languid growth of the tobacco industry in India, and the indifference exhibited towards the possibility of competing with the American market in the culture and curing of the weed for general consumption. Experimental crops have from time to time been raised and cured, under European supervision, under the fostering wing of different Governments, but the culture was first undertaken on commercial principles by Messrs. Begg Dunlop of this city, and though they have for the past two years had a somewhat uphill experience, I believe there is little doubt that the results are of a sufficiently encouraging nature to induce them to considerably extend their operations, and that the growing demand for their produce is likely to far outstrip the possibilities of supply. The estate of Poosa is the well-known stud depôt, and is situated 7 miles from the Wini station on the Tirhoot State Railway: it consists of some 1,500 beegahs, bounded by a bend of the little Gunduk river, and is one of the most picturesque sites in Behar. The grounds are beautifully wooded, and are intersected by drives, some 12 miles in extent, shaded by well-grown avenues of Teak and Babool. It would have been difficult to find elsewhere a property, where all the requirements in the form of drying and curing houses were with few alterations ready built, and it is owing to this happy accident that the lion's share of the industry is due. The stables, fifteen in number, that were in

use for the stud, are now the curing houses, and the large and commodious horse hospital is the tobacco factory. Of the 1,500 beegahs belonging to the estate, only some 250 are at present under tobacco cultivation. This, we believe, is in a measure owing to the difficulty in procuring manure, and to the fact that the land needs to be changed yearly. The agents, however, have been successful in arranging with the cultivators, in the surrounding district, to grow the plant on what is called the Javan system, which appears to be the Government opium system, pure and simple; or, in other words, that the cultivators grow the tobacco for the factory, delivering it in its crude or green state—cash advances being made to them from time to time, the account being finally settled when the crop is delivered. The seed is supplied from the factory, and the cultivators are now content, and even eager, to use the American seed, though this concession to a new *dustoor* has been of gradual growth, as they were at first very loth to use the foreign seed. Judging from the area under tobacco, that we saw during a six mile's drive, this Javan or Opium system should enable the factory to secure an almost unlimited supply of the leaf, provided always that the rates are satisfactory, and that amicable relations are maintained between the contracting parties. The Assami or outside cultivation is at present only some 150 beegahs, as this amount in addition to what is grown on the estate fully taxes the intramural accommodation of the factory. So far the present management at Poosa make no pretence to secrecy in respect to the *modus operandi* in treating the leaf, and the cultivation itself is in all respects similar to the tobacco grown for native requirements. The system of curing is that the leaf is hung upon sticks in the drying houses, and kept in this state till the action of the air absorbs the moisture: it is then taken down and packed in heaps, and allowed to sweat or ferment slightly. This differs from the native treatment only in that they expose the leaf to the sun by day, and pile it in heaps at night, repeating the operation till the leaf assumes a light-brown colour. Experience shows that the former method retains the strength and flavour so valuable in the tobacco, whilst the unpleasant acrid flavour so noticeable in the native production is undoubtedly due to the repeated process of fermentation obtained by the alternations of heat and cold in their treatment.

After the curing and sweating process has been completed, the tobacco is sorted according to colour and size, and tied in bundles of ten or twelve leaves each, after which it is sent into the factory for manufacturing purposes, or packed in hogsheads, containing 1,000 lb. each for export to England, the manufacturers there having, during the present year, taken some 60,000 lb., and though this is a very fair beginning, it would have been much larger, had not the factory requirements exhausted the remainder of the stock in manufacturing for Indian requirements The prices realised in England compare favourably with the sales of American tobacco of the same class, and as the demand is practically unlimited, the proprietors are naturally turning their attention to this outlet for their produce, and purpose increasing their home shipments. The manager is hopeful that larger consignments will realise more profitably than these primary small shipments have done, as the agency and freight charges hitherto have nearly equalled the cost of production. It is also expected that, as the trade becomes better established, the factory will be able to adopt a system of curing and packing in accordance with the requirements of the home market, and thus obtain better prices without increased outlay. The factory at Poosa, as we have already stated, was the old horse hospital, the stalls of which have been removed, and a second storey added to the building, which is divided into seven rooms. The first of these is called the stripping room, and here some 30 boys are employed in removing the mid-rib from the leaves, and making them up into bundles. In the second, or soaking room, several men are employed in dipping these bundles of tobacco into a mixture of boiled sugar and liquorice, and then passing them through rollers. In the third, or drying room, the sweetened and pressed tobacco is hung out on racks, and dried by charcoal fumes at a temperature of 120°. When the leaf is dry, it goes through another damping process, a mixture of rum, oil of cinnamon, and several other essential oils, being sprinkled over it with a spray, it is then piled up, and covered with blankets until it becomes soft and pliable, when it is ready for the fourth, or hemp room, in which there are about 60 persons employed at 30 tables with a division in the centre of each. A boy on one side of each table removes the mid-rib from a pile of large dark red tobacco leaves that he is supplied with, and passes the cleaned leaf to a man on the other side of the table, each of these leaves the man wraps round a quantity of the cured or sweetened leaf heaped in front of him, each roll which looks like a very large cigar, containing about three ounces of tobacco, is technically known as 'a lump." These lumps are placed in boxes and removed to the fifth or press room; here each lump is forced into an iron shape 6 by 1½ inches, 24 shapes being in the frame, 10 of these frames are then subjected to an hydraulic pressure of 350 tons. The lumps are now cakes, and are next placed in a strong iron box in layers with oiled sheets of tin between each and subjected to another pressure, which gives the tobacco the polish and finish familiar to consumers of the American product. The cakes are then packed in boxes 20 by 6 by 6 inches, again put under pressure, four boxes being bound together by an iron band and pressed together. The tobacco is now ready for the market, and, once sold, can be labelled by any of the fancy names known in Virginia. The seventh room is used as a despatch room, and for preparing and cutting the cake, cavendish and golden leaf into the Poosa smoking mixture, the sale of which is rapidly increasing in Bengal. Four classes of this are now being prepared at the factory, known respectively as golden leaf, bright and dark, the difference being only in the shade of the leaf. Honey dew, a sweet brown cake tobacco, and cavendish, which is black, strong, and sweet. These tinned tobaccos are sold for very much higher prices and pay well, but the trade is small, R1,500 to 2,000 per mensem being considered a good month's business, and the prospects of its extension is not encouraging. The demand for the cake cavendish on the other hand increases steadily: the tobacco is very similar to that supplied to the troops, and though there was a prejudice against it at first as there was against hill beer, it seems to be giving way as the sale from a few thousand pounds reached 79,000 lb., last year, and this season's sales are over 104,000 lb., notwithstanding that the price of similar American tobacco in India has fallen from 10 to 8 and 6 annas per lb. within the past three years,—a rate which it is believed entails a loss on the importers.

The proprietors of the Poosa Factory and Farm deserve both credit and profit for what they have done towards establishing the manufacture of an improved class of tobacco in India, and if their experience so far does, as we believe it would, bear a critical scrutiny into the soundness of the venture, we trust they will take steps to carry on the enterprise on a far more extended scale than it is worked at present, or than it can be worked without greatly increasing the capital invested. The total outturn at present is some 300,000 lb. a fraction in comparison with the American supply in India to say nothing of Europe.—*Indian Daily News.*

THE RIVALRY OF INDIAN AND CHINA TEAS, AND THE CONSUMPTION IN AUSTRALIA.

The steady growth of the tea industry in British India, not only promises to place the world in possession of an alternative source of supply of tea, in the event of the China supply being interrupted by war or revolution, and not only holds out the promise of increased revenue and prosperity to this country; but it also warns people interested in the well-being of the tea trade in China, to be on the alert. It is a moot question, whether China or India is the original home of the tea plant; and it has been contended by some people that the shrub is indigenous in both countries. It is now beyond a doubt that tea can be grown as easily on the highlands of India, as on those of China; and that it is only a question of time, when China will find the world at large waveriug in its affection for her special product. There is a wide difference between the flavours of the rival commodities; and it is a serious matter for China, that so agreeable is the flavour of Indian tea, that those people who have once become accustomed to it, do not readily resume the use of China tea. Moreover India enjoys the great advantage over China, that her teas are cultivated, and prepared for market, under immediate European superintendence. In China tea is grown by natives, in ancient native fashion; and it is only when it has been prepared for market, that it is brought under the control of Europeans. If tea could not only be bought at the treaty ports and shipped, but could be cultivated upcountry in China, by Europeans there would be much less chance than there now is of India cutting China out in the trade. A Shanghai paper perceives this, and recently pointed out:—

"There are no squeeziug Mandarins in India: there is European supervision in the packing and firing of the leaf, and the plantations are connected with civilisation by the railway and the telegraph. Everything is done to give India an unfair advantage over China. Consequently, Indian tea of the same quality is far cheaper in London than the ill-regulated produce of Hankow and Foochow, and it is only the conservatism of the consumer who is not yet entirely habituated to the Indian flavour that prevents our losses being much heavier than they are. Every year this preference for the leaf that has been longer known is wearing away, and our buyers will soon have to reckon with its disappearance. As yet Indian tea is hardly taken on the Continent of Europe at all, but here too it will penetrate sooner or later, as it is doing into America and Australia; and then there will be no corner of the earth where the sway of China tea will be undisputed. Until foreigners can supervise the packing of the leaf in China as they do in India, the produce of the latter country will continue to have an unfair advantage. The time no doubt will come when we shall be able to go up and buy the raw leaf on its native hills, pack it by our own methods, and bring it down by railway to Shanghai for shipment; but for years yet we shall labour under the disadvantage of having to buy it just as the Chinaman chooses to prepare it, without any real knowledge of the total crop at any time, or any immediate power to manipulate the teas to suit the tastes of consumers."

Our contemporary is to be commended for looking disagreeable facts full in the face, instead of seeking to allay local anxiety by underrating the danger ahead. The Chinese themselves will be slow, perhaps, to credit the character of the rivalry that is rising in far distant, and, to them, little known India; but when they find that their own product ceases to command the high price it used to do, they will begin to ask "the reason why"; and when the truth has been brought home to them, they may be urged by self-interest to heed at last the world's protests against the systematic adulteration, and unscrupulous vamping up of their tea.

The following statement shows the quantity of tea exported from India, and its official valuation, in the twelve years ending 1878-79:—

Year.	*Quantity.*	*Value.*
1869-70 ...	lb. 12,750,000 ...	£1,080,000
1870-71 ...	13,232,000 ...	1,139,000
1871-72 ...	17,460,000 ...	1,482,000
1872-73 ...	17,920,000 ...	1,590,000
1873-74 ...	19,442,000 ...	1,754,000
1874-75 ...	21,392,000 ...	1,963,000
1875-76 ...	24,561,000 ...	2,183,000
1876-77 ...	27,925,000 ...	2,620,000
1877-78 ...	33,656,000 ...	3,061,000
1878-79 ...	34,800,000 ...	3,170,000
1879-80 ...	38,173,521 ...	3,050,066
1880-81 ...	46,413,510 ...	3,054,000

In the twelve years ending 1880 the imports of tea into the United Kingdom from all quarters were as follows:—

Year.	*Quantity.*	*Value.*
1869 ...	lb. 139,223,000 ...	£10,311,000
1870 ...	141,020,000 ...	10,097,000
1871 ..	169,898,000 ...	11,635,000
1872 ...	184,927,000 ...	12,933,000
1873 ...	163,765,000 ...	11,372,000
1874 ...	162,782,000 ...	11 532,000
1875 ...	197 505,000 ...	13,765,000
1876 ...	185,536,000 ...	12,697,000
1877 ...	187,515,000 ...	12,480,000
1878 ...	204,872,000 ...	13,048,000
1879 .	184,076,000 ...	11,262,000
1880 ...	206,971,000 ...	11,613,000

It thus appears that the exports from India increased from 12¾ million of lb. in 1869-70 to nearly 46½ million of lb. in 1880-81, or by about 3·33 per cent; and that in the twelve years ending 1880 the imports from all quarters into the United Kingdom increased by about 50 per cent. The tea industry in India is a thing of yesterday's creation; and the estates that are coming into bearing will year by year add to the formidable total of export. The industry is cordially supported by a civilised and powerful Government, and is stimulated by local and foreign enterprise. It is therefore not unreasonable to expect that within a few years India will be able to export a full 100 millions of lbs.

Much attention is being directed by the Government of India and the Calcutta Tea Syndicate, to the desirability of India's cutting in for a share of the tea trade of the Australasian Colonies. Coffee is but little valued by the colonists; but they are quite Johnsonian in their love of tea; and as the country is more opened out, and becomes more populous, the demand for tea will become very great. The imports stated in millions of lb. were as follows:—

Year.	*Victoria*	*N.S. Wales.*	*S. Aust.*
1865 ...	4·6 ...	5·3 ...	1·3 *million lbs.*
1866 ...	7·0 ...	6·0 ...	0·8 do.
1867 ...	6·8 ...	4·3 ...	1·2 do.
1868 ...	10·1 ...	7·0 ...	1·4 do.
1869 ..	6·9 ...	6·2 .	1·5 do.
1870 ..	6·9 ...	3·8 ..	0·8 do.
1871 ...	7 1 ...	5·0 ..	1·3 do.
1872 ..	6·6 ...	3·9 ...	1·0 do.
1873 ...	10·5 .	5·0 .	1 6 do.
1874 ...	7·1 .	5·1 .	1·6 do.
1875 ...	9·0 .	5·2 .	1·8 do.
1876 ...	9·7 .	4·9 .	1·9 do.
1877 ...	8·3 .	6·0 .	1·2 do.
1878 ...	8·2 ...	5 3 ...	2·3 do.
1879 ..	8 3 .	7·6 .	1·9 do.

The imports of Tasmania amount to about 350,000 lb.,

and those of New Zealand to about 1,500,000 lb. per annum. In the latter colony, no record is kept of the quantity of tea imported; the value was £146,187 in 1865, and £197,997 in 1879. Queensland takes from 1½ to 2 millions of lb. of tea per annum. Altogether the Australasian Colonies at present import about 22 millions of lb. officially valued at £1,500,000 per annum. Hitherto China has monopolised this trade; and it is only recently that the colonists have had it brought practically home to them, that not only is tea cultivation an established fact in India, but that genuine Indian tea is a superior article to the stuff with which they have at times been supplied from China. They perhaps, study quantity, and high colour, rather than refined flavour; but they are too addicted to tea not to relish the fresh and palatable infusion from the Indian leaf. If even in England it is extremely difficult to discover a grocer, who sells really good tea at a moderate price, it is not to be woudered at that in the Colonies sound tea is rarely met with There are shops in London, where nothing but tea is sold; and at these *spécialité* places, a great boast is made of "our favourite blend" of Indian and China tea; but experience usually teaches the palate accustomed in India to the drinking of Indian tea, that the proportion of first class Indian tea in the vaunted "blend" is small, although the price is undoubtedly first class. In Melbourne and Sydney similar "blends" are being sold, and as they are calculated to make buyers come to the conclusion with respect to Indian and China teas, that "Pompey same like Cæsar" the Calcutta Tea Syndicate are wisely taking steps to open in those cities shops of their own, whereat the public can obtain the genuine Indian article, and no deception. The import duty on tea is 3*d.* per lb. in New South Wales, Victoria, and South Australia; 4*d.* per lb. in Western Australia and New Zealand; and 6*d.* per lb. in Tasmania and Queensland. In England it is 6*d.* per lb. So, most of the Australasian Colonies have set the mother-country, the example of charging a lower duty than she yet cares to impose on tea. Not improbably Mr. John Bright wil yet succeed in his efforts to give his countrymen the boon of a "free breakfast table;" and the Colonies may not be long in following suit.—*Madras Mail.*

AGRI-HORTICULTURAL OPERATIONS ON THE SHEVAROY HILLS.

The following notes on the season on the Sheveroy Hills from Deputy-Surgeon General John Shortt, F.L.S., etc., are published with the Proceedings of the meeting of the Committee of the Agri-Horticultural Society of Madras held on the 7th of last month:—

Believing that a few notes of the season on these Hills for the past year (1880) may prove of interest, I beg to submit them and regret the delay that has occurred in their preparation. The year 1880 was a good one as regards general health, as well as for Agricultural and Horticultural operations. Rain had fallen in every month of the year except that of March. The rainfall amounted to 66 inches and 83 cents distributed over eleven months and extending over 133 days. The maximum fall occurred in October when 14 inches and 60 cents were registered, and the minimum quantity of 1 inch and 30 cents fell in January. Of the 133 days in which rain fell, 90 inches came down chiefly at nights, and the remaining 43 during the day, but chiefly towards the afternoon.

The heavy rain in October caused some damage to coffee, and a landslip having occurred on the steep slope of a hill, some 4,000 coffee plants on one estate were destroyed by it, and the subsequent crop of coffee also fell short of the estimate on most estates. This disappointment seems to have been general; as I observe from the newspapers that in most of our planting centres the coffee crop for the year under notice was small on these hills; the rains threw down the first blossoms, but the plants made a second and third effort at bloom with but partial success, resulting in small crops. The price of land has greatly increased and fair planting land fetches from * 37½ to ⅔ rupees the acre, whilst a building site comprising a block of 3 acres (all stones) fetched 550 rupees during the year under notice. Cinchona hitherto on these hills has been planted simply as an experiment: one or more trees only were to be seen on a few estates. Of the different varieties, the cinchona Succirubra thrives well here, and this variety is best suited to these hills. Efforts are now being made by a few planters to extend cinchona cultivation, and on my estate self-sown seeds of this variety were found growing in the vicinity of the parent plants; and the trees are so extremely prolific in their seed productions, that I have been able to collect and distribute the seeds freely. The difficulty of getting the seeds to germinate is rather trying, as the process requires much care and attention, more especially without the aid of a propagating house. Of the cinchona trees on my Estate one seems a hybrid, and on sending specimens of the flowers and leaves to Mr. Jamieson, the Superintendent of the Government Gardens, Ootacamund, that gentleman recognized it as one which he says has been named cinchona Lanosa. This plant also seeds very freely and largely.

Through the kindness of the Society I have been favored from time to time with Australian and ornamental tree seeds, as well as that of several species of grasses; many of those sprouted well and made a vigorous growth, but died subsequently, after attaining some 6 to 12 inches in height, owing to the season this year having proved very dry, so that we had no rainfall to speak of during the first 6 months; nevertheless I have a few plants of the different varieties of the Eucalyptus. The Eucalyptus Globulus thrives well and seeds freely on these hills. There are some trees over 60 feet in height with a diameter of stem of 2 to 3 feet. The Grevillea Robusta and Buxifolia grow well and mature their seeds to perfection, and there are a large number of these trees on these hills now.

The Pithecolobium saman, or Raintree. Of these I received 27 plants from the Society's Gardens, Madras, in October, 1878; a few were destroyed by insects they were first "Rung" at the Collum by a species of worm after which the plant never recovered; these have a tendency to spread and seem to grow very slowly although looking the picture of health, so that I had to cut them in closely and otherwise freely prune and then stake them out in the hope that they will grow lofty and afford shade to coffee, so far they have belied the confident assertion of a respectable authority that they are not suited to hill ranges, as I have now over a dozen plants ranging from 3 to 5 feet in height.

Conifers.—We have several species growing well here including those of the so-called Cypress and Thuja; of the Cypress we have three varieties with perfect seeds successfully. We have also three or four varieties of the Araucaria, the largest standing about 30 feet in height; they have not flowered as yet as the trees are young. We have also some two or three samples of the Pine. Of these Pinus Maritima and the Pinus Australis are also young, standing about 4 to 5 feet in height.

* The maximum price R37-8-0; the minimum price R0-12-0; the average price from 1877-80 (both years inclusive) was R7-1-0 per acre, under the Wasteland Rules.

The Ceratonia Siliqua or Carcob tree has not succeeded here. I got a few plants from the Society and others from Mr Cameron of the Government Gardens, Bangalore; they continued stationary for nearly two years making no advance whatever, and died of during the early part of this year.

The Trincomallee wood tree Berrya Ammonilla I introduced here several years ago, but it does not thrive; the plants are simply alive, and have not exceeded one foot in height after a trial of several years.

The Chittagong wood tree, or Chicknassia Tabularis,—I procured one plant from Bangalore, and by a mistake it was planted out on rather rocky soil; it was slow of growth and attained some 3 feet in height, when during a very dry season it perished. I mean to give it another trial as soon as I can get some plants.

The Sapota Plum or Achros Sapota does not thrive here. I gave it several trials; as also grafts on the Bassia which does not meet with better success. I have now two plants in pots, they are about four years old, and they do not exceed 3 to 4 inches in height.

Grasses and Fodder Plants.—Of the 7 kinds that germinated and on which I reported to the Society (vide proceedings 3rd September 1870, page 91), they flowered freely but formed no seeds and then died off. The same result attended the Canary seeds I had exporimented with.

The Reana Luxurians sprouted and produced seeds which also germinated freely, but during the cold weather the tops get burnt off. The plants attained from 4 to 5 feet in height and each threw out from 10 to 20 side shoots; these coming off from the Collum, gave the plant a very full and shrubby appearance from the clumps they thus formed, and looked handsome and like the maize or Indian corn; the male flowers formed on the summit, while the female flowers were in the axilla of the leaves, having something of the miniature cob in form, and as soon as the plants perfected their seed, they died off. The drawback to the introduction of this grass is the tendency it has to suffer from the cold up here. This does not matter so much, perhaps; as the plant is an annual and dies out after seeding.

The Prickly Comfry (Symphytum Asperrimum) I have given a trial to for upwards of two years and can say nothing in its favor, although it was introduced with much enthusiasm as a wonderful fodder plant; but as far as my own personal experience extends, it has proved a complete failure both as regards its rapidity of growth, luxuriance, and its nutritious qualities, and it does not seem to me to be generally relished by cattle or horses.

Cytisus Proliferus.—Seeds of this plant received from the Society and from Col. Beddome when placed in a rather dry plot of ground did not germinate for months, but in plot germinated readily. I have now several plants of it. In general appearance it has some resemblance to the Cajanus Indicus in its pubescent and pinately trifoliate leaves, &c.; but as the plants are young, still being about 2½ feet in height, I must reserve for a future occasion further reference to it.

The last receipt of fodder grass seeds through the Society from Kew is that of the Panicum Spectabile; the seeds resemble that of Guinea grass, and on being sown in pots, they sprouted readily and freely, and are now about 6 inches in height. I must reserve further description of them to a future occasion.

I have now tested a good many kinds of fodder grasses both foreign and indigenous, and I most confidently assert that there is nothing to excel the Hurriallee grass (Cynodon Dactylon) and the Guinea grass (Panicum Jumentosum.) Of the Hurriallee it may be said it grows everywhere, and at all season and places, on the plains equally as well as on the Hills, in abundance, forming the greater part of the food of cattle in this country; in moist lands it throws up long leatherly shoots extending to 2 and 3 feet in height, when it becomes procumbent, and during the dry season there is the creeping succulent stem with dwarf shoots at each node or joint. The horses about of Madras for the greater part of the year feed on these succulent stems supplied to them by so-called grass cutters, but where tillage, manure and water are supplied, it grows to the greatest perfection, yielding from 6 to 9 crops during the year, and makes the softest of hay and surpasses all other kinds of hay in not only its nutriticous qualtoics but the relish with which all cattle feed on it.

The Guinea grass comes next, but it does not grow in some localities. Where it thrives it becomes luxuriant, and makes a large return per acre; it has a tendency to form Clumps or "Tussucks" as it is termed, and requires to be taken up every second or third year to have its clumps broken up for replanting to inercase its production.

Arrowroot or Maranta Arundinacea.—In an experiment, a plot of ground 22½×32 feet planted with Arrowroot produced 430 pounds of corns yielding 65 pounds of farina.

Tapioca or Jatropha manihot.—A plot of 29×43 feet, carrying 145 plants, produced 255 pounds of roots yielding 30 pounds of *farina*. These roots are reported to be poisonous ere the juice is washed out; of this I had an instance: a pet lamb about 3 months old happened to drink some of the water in which the roots were washed and died in one short fit of convulsion in 3 or 4 minutes; some coolies are reported to have died some years ago on one of the estates here from eating the raw roots. These experiments are on too small a scale to draw any practical application from, nevertheless they are of interest I think.

"I received some Persian Date fruits from the Western Coast; these fruits in no way differed from those of the same kind procurable in the bazaars about Madras; I collected some 30 seeds of them and planted the same to see if they would germinate; to my surprise, out of this number 8 plants sprouted and are now in a thriving condition.—*Madras Times.*

CHINESE LABOR.

As an introduction to our comments on the introduction of Chinese contract labor into Brazil, the *Gazeta de Porto Alegre*, of the 3rd ult., discusses the question briefly, as follows:—

A discussion has been going on between the *Cruzeiro* and the *Rio News* in which we cannot agree with the labor organ, the reason appearing to us to be all on the side of the *News*. Our readers know that we have a deep interest in the economic propaganda raised by the *Cruzeiro*, partly because we are in accord with many of its opinions, and partly because even those very ideas which seem to us to be ill-founded provoke discussion from which light must come. In the opinions put forth by the *Cruzeiro* on the labor crisis, its inclination towards Chinese immigration has always struck us as a *surrogate* [*surrogado*] of slavery. We here, in this province, who have tested the problem of small farming, and whose only aspiration is the immigration of colonists who may become small farmer and intelligent labourers, and not simple instruments, cannot share these ideas in common with the great journal of the capital.—*Rio News.*

SULPHUR FOR POTATO DISEASE.—A letter was read (at a recent meeting of the Royal Horticultural Society) advocating the notion that the disease was due to constitutional debility, consequent on mismanagment. The treatment recommeuded was to mix substances, such as sulphites, with the soil in which the Potato is grown, so as to destroy the fungus germs, and to treat the growing plant with flowers of sulphur for the same purpose.—*Gardeners' Chronicle.*

PERUVIAN BARK.—India is rapidly coming into the market as a competitor with South America in the supply of Peruvian bark. The amount sent to the London market in 1879 80 is divided as follows:—

	lb.
Colombia	6,002,330
India and Ceylon	1,172,060*
South America (except Colombia)...	959,030
Jamaica, about	21,140
Besides Java, for the Amsterdam market	70,088

—*British Trade Journal.*

CINCHONA AND EUCALYPTUS IN MAURITIUS.—The superintendent of the Botanical Gardens at Port Louis in his past annual report states that 287,000 useful trees, shrubs, and plants were propagated in the gardens during last year, the greater portion of which were either planted on public lands or on the road sides, or else sold. The Lieut.-Governor, in placing the report before his council, stated that the eucalyptus and cinchona plantations had been successful; and that it was in contemplation to try an additional plantation of the latter at 2,000 feet above sea level, this being the lowest altitude at which it is believed the chinchona plant thrives in those latitudes.—*Colonies and India.*

THE GERMINATION OF SEEDS.—The Lahore paper mentions that Professor Tyndall has, by a series of experiments, proved that sulphuric acid possesses the power of promoting the more speedy germination of seeds, or rather fruits, contained in shelly capsules —such as nuts, almonds, and fruit stones—in a remarkable degree. In India, a difficulty has often been experienced in raising fruit trees from imported stones, mildew so often setting in before germination takes place. If, however, seeds and stones be soaked in a solution of the acid they "receive such a germinating influence from this tonic" that they shoot in an incredibly short space of time.—*Madras Times.*

LIBERIAN COFFEE takes longer to ripen than the Arabian variety. Last year's crop took thirteen months, and this year's will, I expect take eleven, but it does ripen, and reaches Colombo in a more satisfactory state than coffee Arabica has been doing of late years. It is too soon to say that Liberian on good soil will not bear 10 cwts. an acre, and putting extravagant estimates out of the way, there is no doubt that confidence in this product is daily increasing both amongst Europeans and natives, and I see no reason to doubt that large tracts of the lowcountry will shortly be covered with it—however as hardly a tree in the Island has yet attained its full growth, it is premature to talk positively one way of the other.—*Planter, C. Times.*

FOOD CONSUMPTON IN AUSTRALIA.—The following are the rates of various articles in Australia, showing the quantities used per head per annum, the calculation being the mean of 1878-80—

Tea	8·05 lb.
Coffee, Chocolate and Cocoa ...	1·09 ,,
Sugar	82·2 ,,
Rice	15·61 ,,
Dried Fruit	7·10 ,,
Spirits	1·43 gall.
Beer (imported only)	15·0 ,,

Compared with the consumption of the same articles in the United Kingdom, the difference is striking. These are—

Tea	4·66 lb.
Coffee (alone)	0·97 ,,
Sugar	48·55 ,,
Rice	7·05 ,,

Unless Australia turns its attention to growing tea, this consumption opens up a fair future for trade with India. We do not think Australia will ever do much in tea growing, as the climate is not suitable, except perhaps towards the north, and even there the rainfall is deficient. This opinion receives weight from the recent success of the tea syndicate in introducing tea into Australia, and it is to be hoped that the efforts recently made will be followed up by a judicious nursing of the new trade.—*Produce Markets Review.*

THE WESTERN CATALPA.—Doctor John A. Warder prepared for the Journal of the "American Agricultural Association" a memoir upon the Western Catalpa, which paper has been issued in a pamphlet form by its author. Some three or four years ago, when the discovery was made that there were really two species of Catalpa, heretofore regarded as one, we published the fact, and also gave the evidence of Mr. E. E. Barney, Dayton, O., as to the remarkable durability of the wood, and have from time to time given notes as to the value of the tree. The present paper brings together, in a compact form, the facts that make up the history of this tree. The new species is named *Catalpa speciosa*, and differs from the ordinary *Catalpa bignonioides*, in being a taller and straighter tree: its larger nearly pure white flowers appear one to three weeks earlier; the pods are larger, more cylindrical; the seeds also are larger, with the wing broader and not pointed as in the other. The Catalpa has such a remarkable adaptability to a variety of soils and climates, is so easily raised from seeds, and grows so rapidly, that it is worthy of the attention of all who propose to raise forest trees. The durability of its timber has been subjected to the severest tests, and there are few of our native woods that excel it in this respect.—*American Agriculturist.*

EARTH WORMS.—The interest excited in these creatures since the publication of Mr. Darwin's book on this subject, reviewed in our columns (vol. xvi, p. 500) will be increased by the interesting communication made by Dr. Gilbert to the Scientific Committee on Tuesday last, and reported in another column. The quantity of nitrogen in the worm-casts in proportion to that of meadow or arable land is not absolutely greater, but what there is is rendered more available by being brought more to the surface and more within the reach of the roots by the agency of the worms. *Nitrogen in Worm Casts.*—Dr. Gilbert announced that since the publication of Mr. Darwin's work on earth worms he had collected a quantity of earth casts from his lawn, dried them to remove the water, and then determined the percentage of nitrogen they contained, comparing the proportion with that obtained from a sample of soil taken from the first 9 inches of the soil of adjacent pasture land. The result was that the dried earth casts yielded a percentage of ·35 of nitrogen, which is higher than that of the ordinary pasture soil in the adjacent park, where the percentage proportion of nitrogen is ·25 to ·30. Thus the proportionate amount of nitrogen in the worm casts is higher than in the pasture land, and two or three times higher than in ordinary arable surface soil; but not so rich as in the highly manured soil of the kitchen garden. Ten tons per acre of worm casts would, it was estimated, supply about 80 lb. of nitrogen per annum—more than double that of ordinary meadow land without manure. It would appear then that there would be no absolute gain in nitrogen from the action of the worms, but that they would bring up from below a larger available supply, just as would be afforded by trenching.—*Gardeners' Chronicle.*

* Ceylon alone sent 1,000,000 lb. in 1879 80 to London.—ED.

ROYAL BOTANIC GARDENS.

REPORT OF THE DIRECTOR FOR THE YEAR 1881.

I.—Péradeniya Garden.

During the year every effort has been made to increase the beauty of these grounds by the further removal of decayed, useless, and unsightly trees, careful pruning and thinning out of old wood in those which remain, and planting young ones of fresh kinds in suitable positions. There still remains a large number of old sapu, jack and ilang-ilang *(Cananga)* trees and large barren mangos, most of which it is intended to supplant gradually by a variety of different species; but the lawns near the bungalow and the lake, the old palmetum and the backs of the main flower borders have now been all more or less thoroughly thinned out and improved. Such work is necessarily gradual, and to a certain extent tentative, but has so far been amply repaid by the greatly improved health and appearance of the selected trees (several of which the access of sunlight and air has permitted to flower for the first time), and the opening out of new views and vistas.

Roads.—The heavy rains of November and the early part of December have caused much damage to the roads and paths from wash. A large brick culvert has now been constructed under the main drive at one of the worst spots, and several smaller ones in different places. There is also a considerably increased carriage traffic in the garden, and much work on the roads will be necessary in 1882.

Lawns.—No solution of the grass-cutting problem has been arrived at. I must again insist on the great saving annually which would be effected by the use of a large hay or grass-cutting machine, the means of purchasing which will, I trust, be granted me.

Buildings.—These are generally in good order. During the year the roof of the herbarium and library has been repaired, and the interior repainted and varnished; the house of the head gardener has also been added to, altered, and improved.

The condition of the "Assistant Director's" bungalow (in the occupancy of the Cryptogamist) is very bad, and has been already reported upon, and I have requested that it should be put into thorough repair; the departure of Mr. Ward affords an excellent opportunity.

The house of the plant collector, partially thatched with maana grass, requires tiling.

New South Garden.—With the aid of an addition to the vote for cooly labour, I have been able to make great progress in laying out this portion of the garden. The outline plan which I sketched in my last report has been followed and will be carried out to completion.

The principal part of the area is occupied by an arboretum in which the trees and large shrubs, both native and exotic, are to be planted on a system based upon their natural affinities. This includes a small hill, the highest elevation in the garden, on the summit of which (whence a fine view is obtained) it is intended to set up a small arbour. The planting commenced in June, but has been much interfered with by the weather, which rarely remained wet for any number of consecutive days. However, about 250 species have been successfully established, belonging to the natural families *Leguminosæ*, *Myrtaceæ*, *Melastomaceæ*, *Rubiaceæ*, *Myrsineæ*, *Sapotaceæ*, *Euphorbiaceæ*, *Urticaceæ*, and *Coniferæ*. As much space as can be afforded has been left for the additions which will be constantly intercalated in their places. The planting of the remaining families will be gone on with; the ground however is not sufficiently extensive to accommodate the whole of them.

The new carriage drive is nearly completed; it is over 600 yards long, curving round the lake (where some gneiss boulders have been preserved *in situ* and planted up with rock- and sun-loving plants), and terminating in a wide loop whence a foot-path leads to the second entrance opposite the Deltota road. The large space, 100 yards long and 95 broad, enclosed by the drive will be entirely devoted to a classified collection of palms of which the gardens are accumulating a fine collection, and most of which grow here with a perfection that cannot be surpassed. The steep sloping bank of the high road behind this it is intended to utilize for an arranged series of climbing and twining woody creepers, which will there well exhibit their graceful beauty towards the garden, and at the same time afford protection against trespassers; the most exposed part is to be devoted to the prickly rattans, a very efficient barrier.

The herbaceous ground has been entirely finished, and consists of 48 beds of different sizes symmetrically occupying about three-quarters of an acre. Narrow paths paved with cobble stones run between all, and drainage has been carefully provided for. No commencement has yet been made in the planting out of this, which must occupy largely the next rainy season. Herbaceous perennials do not play an important part in the vegetation of the tropics, and it cannot be expected that a large number of species can be here cultivated. Only those which will bear full exposure to the sun as well as a heavy rainfall will succeed. The space to be allotted to each natural family has been planned out, and I anticipate that this scientifically arranged collection will be ultimately of great service, especially in the more ready and systematic collection of seed.

Another portion of the ground is devoted to experimental culture, and is partly occupied at present with the Trinidad cacaos and their shade trees, the American rubber-trees, several varieties of coffee, Manila hemp, gutta sundek, cardamoms, &c. The remaining part has been formed into nurseries and a small kitchen garden. The nursery beds are arranged round a little circular tank, 20 feet in diameter, where it will be possible to grow in pots some of the smaller aquatic plants.

Lake.—Little or nothing, I find, can be effected here in the way of growing aquatics; even our native species soon die out. This appears to be partly due to want of sufficient sunlight, much of the surface being shaded by the grand bamboos near the margin, and at times completely covered with a layer of their fallen leaves; but the foulness of the bottom is the principal cause. It is a matter for regret that this little piece of water, the only one in the garden, can be made so little use of.

Labelling.—Of the large and expensive glass labels only 36 have been set up; and it is not my intention to continue to employ them, as I find it impossible to get them uniformly and neatly made in this country. But the ticketing has been actively carried on since the smaller zinc labels arrived. The painting and writing of the names and localities are done in the garden. Over 250 have been fixed in their places. In those fastened on to tree-trunks pegs of areca wood are found far better than nails, which in this wet climate make serious wounds. The labels are found to require pretty frequent cleaning with a sponge or wet cloth to remove a small black fungus which, in damp weather, quickly covers painted surfaces here, and produces an effect curiously resembling that of the smoke of London.

It will be my endeavour to push on the labelling as rapidly as possible; it is gratifying to observe how greatly their value is appreciated by visitors. A systematic catalogue of the contents of the garden is also in a forward state.

Propagation.—The temporary shed used as an orchid house (mentioned in my last report) is found to be too much shaded by large trees, and it is hoped during the coming year to build a permanent house in a more open situation, and with a glass roof instead of a maana-grass covering.

The old nurseries, the soil of which had become much exhausted, have been mostly abandoned. Part of the ground will be used for raising forest, shade and shelter trees, and a portion will be converted into a swamp for sago palms.

A small room has been set apart for a seed-store, and a cabinet of 64 drawers has been made and erected there.

The garden has been deprived of the services of Mr. Clark for the latter half of the year as he has been placed in charge of Hakgala since the retirement of the late Superintendent.

II.—HAKGALA GARDEN.

The late Superintendent, Mr. E. Thwaites, retired on pension in the middle of the year, and in my uncertainty as to the future, the absence of any successor, and from other circumstances, I have found it impossible to do more than maintain the garden in its old condition. In fact it may be said to have been almost in abeyance, so far as any active work is concerned, during the year. Mr. Clark, however, whilst *locum tenens*, successfully grafted several hundred *C. Ledgeriana* shoots upon stumps of *C. succirubra* (in the manner detailed in my last report), as it was very evident that the plants of the former in the clearings were rapidly dying out.

Some necessary repairs and alterations were made to the bungalow at the end of the year; but all the windows and doors require repainting, new hinges, locks, &c., and the kitchen and out-houses are also in a leaky condition.

The proposals submitted by me to Government at the end of 1880, though approved generally, partially fell through from the difficulty of obtaining a suitably qualified occupant for the

proposed post; it was not until late in 1881 that Mr. W. Nock, Superintendent of the Cinchona plantations in Jamaica, was appointed. He had not arrived to take up his duties at the end of the year.* A native clerk and foreman has been appointed to assist him.

My intentions with regard to the future contemplate an alteration and enlargement of the scope and functions of the garden, and its proper constitution in concert with the central establishment at Pérádeniya. It should be worked as a branch of the latter devoted to the cultivation of temperate and sub-tropical plants of interest, utility, or beauty.

As regards cinchona, the position has greatly changed within the last few years; the best varieties are now in general cultivation, and the necessity no longer exists for a Government depôt for the distribution of seedlings and cuttings. With reference to plantations, there are not and can never have been anything deserving the name at Hakgala, the whole six or seven semi-abandoned clearings together not extending to more than eight acres (the "garden" comprehends about 550). It is not indeed probable that any one, with the present knowledge of cinchona requirements, would now select such a site as Hakgala with its severe and unavoidable winds and cold wet sub-soil at the base of the steep and almost inaccessible rocks for its cultivation; but whatever may have been the original ideas on the subject, Government cinchona Plantations do not now enter into any one's plans. It will however be the duty of the Superintendent to cultivate a sufficient number of each of as many species and varieties as possible, both for the purposes of comparison, for the supply of seed, and for experiments in propagation, &c.

But there is a wide field of utility for Hakgala outside of cinchona propagation and distribution. There are numerous drugs, dyes, fibres, fodders, and other economic products which ought to be experimented with. While we may look forward with confidence to some years of good returns from cinchona culture, no one can regard the present commercial position as a permanent one. We shall in Ceylon indeed show little wisdom, if, after past experience, we neglect any opportunity of adding to the stock of useful plants which can be grown at the high elevations. Further attempts at fruit and vegetable cultivation are also required. The proper treatment of patana lands much needs investigation. Nor must the scientific and ornamental aspects be neglected. The greater popularity of Nuwara Eliya as a health and pleasure resort, which may be confidently expected to follow on railway extension to Nanu-oya, render it desirable that the æsthetic side of the garden should be developed. A moderate expenditure would render it an interesting and beautiful botanic garden, in which our native mountain plants (many now becóming scarce) should be cultivated along with the trees, shrubs, and flowers of Australia, the Cape, China, and Japan, and the tropical mountains of the Andes and Nilgiris. Shade and shelter trees for the higher estates are also now in great demand, and it is of course impossible for the low-country gardens to supply them. Under an active Superintendent it is to be expected that much valuable information will proceed from Hakgala, and that the garden will start upon a new era of public utility.

In view of this, I would urge the necessity of providing a good propagating house in the place of the present little rotten and dilapidated structure, which is quite beyond the possibility of repair, and far too small for the requirements of the garden. Without this it will be nearly impossible in such a climate to raise and propagate with any certainty the more valuable plants.

III.—Henaratgoda Garden.

I have little fresh to report of this garden, the condition of which is very satisfactory and testifies to the industry and continued interest in his work of the Sinhalese Conductor, Amaris de Soyza. Some more of the large trees of the garden have been felled, and additional portions of the jungle cleared for new vanilla and cardamom plantations. A new well has been constructed. The various low-country plants in the garden are all in a thriving state. A large quantity of young Liberian coffee has been gratuitously distributed during the year.

The success of this garden has encouraged me to attempt the acquisition of a similar centre in the hot districts of the North of the Island, and arrangements are in progress for the transfer to this Department of the experimental garden near *Anurádhapura*, which was formed five years ago, and has since been carefully fostered by Mr. Dickson, the energetic Agent for the North-Central Province. This is already conducted by a trained gardener supplied from Pérádeniya. The acquisition of a garden where it may be possible to grow plants requiring a more prolonged dry

* Mr. Nock arrived at Hakgala 14th January, 1882. [*Note added.*]

season than any of the existing ones possess will be a great gain and should prove of signal benefit. It will also be the means of bringing into the northern districts numerous food-plants, &c., of the moister climates, many of which can be readily grown there, provided only a constant water-supply can be assured.

IV.—Economic and Useful Plants.

Commission on the Introduction of New Cultures.—With the view of assisting planters to develop new industries, and also to relieve the strain lately put on this establishment and on the Royal Gardens at Kew—resulting from numerous demands which their organization was not framed to meet, and to supply which is no part of their proper duties—the Secretary of State, at the instance of Sir J. Hooker, recommended the appointment of a small Commission to enquire into the possibility of framing a scheme of Government assistance outside of Botanic establishments. The Planters' Association at about the same time addressed Government on the subject of aid in obtaining *in quantity* such seeds as the better varieties of cinchona and Ceara rubber. As a result the Commission has recommended a scheme in which Government undertakes to use the Imperial machinery at its disposal to procure the plants and seeds required, if the planters will institute a permanent body to communicate and work with Government in the matter, and undertake the distribution, &c., to applicants. I trust that this arrangement will meet the case, and regulate satisfactorily the relations of the Botanic Gardens to the agricultural enterprise of the colony. At the request of the Commission I prepared a memorandum (published as an appendix to their report) on the work done by these gardens in the introduction and acclimatization of useful plants in Ceylon, which sufficiently demonstrates their great direct utility to the colony.

Coffee.—The principal interest of the year has naturally been the publication of Mr. Marshall Ward's third and final report on leaf-disease, a document which for careful accuracy and laborious thoroughness is all that could be desired or expected.* As it seemed indeed to leave no point of practical importance to be investigated, I fully concurred in Mr. Ward's view that a prolongation of his enquiries during a third year, as originally contemplated, was unnecessary. With reference to his work, I feel myself warranted in saying that we now *know* definitely and exactly the life and ordinary mode of dispersion and propagation of the coffee-fungus, that a vast distance thus separates us from the state of things formerly existing when nearly all was uncertain, and that we shall not do wisely if we neglect to act in accordance with the present level of our knowledge. The sooner it is generally recognized that the *principles* of action are now settled, the better. The evident unwillingness to accept this position it is, no doubt, not difficult to account for, but I cannot too strongly insist that the hope of relief must be based on a common agreement and co-operation on the sound principles of action now given, and the abandonment of the paralyzing notion of the chance discovery of a "cure." I would earnestly recommend all concerned to re-read with attention the 7th—12th paragraphs of the Cryptogamist's report, and consider the state of things it reveals. I have already expressed my opinion in support of "a general combination to destroy spores and hinder their dispersion"; the actual methods to be employed for effecting this, I think it is the province of practical agriculture to devise. They must necessarily vary according to the peculiarities of seasons and climate in particular districts and even individual estates, and, almost equally, with the special circumstances connected with estate management; but the guiding principle will be ever the same,—to diminish the chances of infection, and prevent or avoid the lodgment of spores on the leaves by every check and device possible.

But a general co-operation is a prime necessity, and I venture to hope that all interested in this important industry will recognize their *public* responsibility to assist in limiting the dissemination of the disease. Especially, should owners of estates which have quite gone out of cultivation feel themselves called upon to see that their now useless trees, which have become merely a focus of disease, be rooted out and destroyed.

There is also another important factor which cannot be overlooked in the consideration of remedial measures on a large scale—that is, the condition of the native coffee. This is in some considerable degree under Government control, and should be simultaneously dealt with. The

* The more strictly technical portions of Mr. Ward's microscopic researches on *Hemileia* have appeared in the number for January, 1882, of the "Quart. Journ. Microsc. Science," illustrated by three excellent plates reproduced from the author's drawings.

complete destruction of a large proportion of this, which has become almost absolutely valueless and is a perfect hot-bed of *Hemileia*, is to be strongly advocated wherever it can be effected; and compensation, where necessary, might be made by the free gift of other useful food plants.

By such a combination on the part of the community against the common enemy, it is reasonable to expect a good deal might be effected. Our experience of other truly parasitic fungi does not warrant us in expecting to eradicate *Hemileia* by these means, but there can be little doubt that even a sensible and sustained diminution in leaf-disease would result in a considerable recovery in the staple product of Ceylon.

The bearing of *Liberian coffee* on the practical aspect of the question is also important. A temporary distrust of this admirable plant is, I am glad to see, yielding to a more just appreciation of its great value. *Coffea liberica* is of course severely attacked by the leaf-disease fungus, but on the whole this species, as compared with varieties of. *Carabica*, is less damaged by the disease; and I think a more regular and heavier crop may be generally calculated upon. Possibly its frequent blossoming and fruiting may give it some advantage. Some disappointment has been caused by attempts to grow it in unsuitable localities; Liberian coffee requires a *moist atmosphere* as well as a hot climate; exposure to dry heat readily scorches the berries, and on light soils may even destroy the plant. In Trinidad slight shade is considered a necessity, and is I think desirable here in some localities, at least while the plants are young.

In my last report I expressed regret at the small response to our efforts to get the cultivation of this kind of coffee taken up by the Sinhalese, and I am now glad to be able to report a considerable change for the better. A rather large demand indeed has sprung up in many parts of the low-country. In partially meeting this over 50,000 young plants have been gratuitously distributed from Henaratgoda through the Government Agents by the headmen to native cultivators. It would be well if this species—so admirably adapted for Sinhalese garden culture—were to entirely supplant the old village coffee, and I think it might well be made a condition of gratis distribution that this old coffee should be destroyed.

Cinchona.—The observations I made last year on the supreme importance of selection based on analysis in the scientific cultivation of *C. Ledgeriana* have been supported by our further experience. In reference to this it is satisfactory to note how well, as a general rule, the botanical characteristics tally with the bark value, so that selection intelligently made on the former basis is usually justified by the subsequent analysis. It must however be allowed that one occasionally finds very distinct exceptions to this general statement, forcing one to the conviction that the production of alkaloids must be largely personal (so to speak) to the particular tree, apart from its inherited external characters. We must therefore still regard analysis as the only certain guide. It may be well also to note here another cognate fact (liable I find to be misunderstood): the proportion of quinine is not taken into consideration in determining whether a given tree is to be named *Ledgeriana* or *Calisaya*. That question is a botanical one, and is decided wholly by external or visible characters. It is in accordance with experience that quite undoubted *C. Ledgeriana may* afford a very poor bark, but that does not make it any the less *C. Ledgeriana*, as some people seem to think. I have published the distinguishing characters of *C. Ledgeriana*, Moens, in a paper, accompanied by two coloured figures, in the "Journal of Botany" for November.

The practice of the simple process of grafting on *succirubra* has proved very easy and successful in a large proportion of cases; and it or some similar process must become the general practice in the cultivation of specially valuable trees on the principles advocated.

The more general recognition of the necessity of analysis has led to a request on the part of cultivators, that Government might afford some facilities for such assays. It is perhaps remarkable that there is here no qualified analyst in official employ. Did such an officer exist however, it is to be presumed he would be engaged entirely in Government work, and as, happily, the Government does not grow cinchona for sale, that work would not often be bark analysis. The practice of the Governments of Madras and of Java (somewhat infelicitously adduced as an example to that of Ceylon) has been dictated by very different motives to those which rule here (where competition between Government and private enterprise is unknown), and has always been directed wholly to the Government advantage. At the same time the desirability of frequent assays of bark made on the spot is so evident, that it is to be hoped the matter will be earnestly considered with a view to the initiation of some combined action in the matter between the planters interested and the Executive, due regard being of course paid to the interests of local analysts.

Much attention has been drawn, especially since the visit of Colonel Beddome to Ceylon in September, to the large and usually readily distinguished trees to be found scattered over estates in Ceylon, and variously known as "hybrid," "lanosa," or "large-leaved condaminea." These have been sent out from Hakgala nurseries in past years as (usually) *succirubra* but sometimes as *officinalis*, and are identical with the "magnifolia," "pubescens," "robusta," &c., of the Nilgiri Government Plantations, from which we doubtless originally received them. In usually attributing to these a hybrid origin, we in Ceylon took the same view as the late Mr. McIvor of the Nilgiri Plantations, who first noticed them, and who published his belief that they originated there by crossing between *succirubra* and *officinalis*—a view, however, which he appears to have more or less modified afterwards. Colonel Beddome, as a result of his examination of these same plantations while under his care, has strongly denied the hybrid origin of the trees, and thinks they form a well-marked and distinct species, in which view he is, I believe, supported by Mr. Howard. In this opinion I am unable to share; it was largely based upon the positive statement of Mr. Cross (now in the Nilgiris) that the plant is the "Pata de Gallinazo" bark of Chimborazo which he collected there when with Dr. Spruce; but there are great difficulties in accepting this story.* On the whole, the view most in accordance with the facts seems to be that it is a hybrid which originated in the plantations on the Nilgiris, and has acquired some permanence and stability. I am not however in a position to give definite information as to the amount of permanence from seed. Colonel Beddome maintains it to come as true to type as any other species (which if invariably true would be so far against the view of hybrid origin); the majority of observers here however positively state that a large proportion, variously estimated, turn out to be *succirubra* and *officinalis*. In Sikkim, where this kind (originally from Ceylon) is called "ignota," fully half the seedlings are said to come up *officinalis*. As it seemed very desirable that this valuable cinchona should possess a definite name, I have proposed to select from those in use the name *robusta*, the only one† which is not pre-occupied or otherwise unavailable. In the case of this also I think those who can should propagate from known good (analyzed) trees by cuttings; but the more rapid increase by seed need not be neglected, as the young plants which show reversion can be readily removed.

I am indebted to Mr. Moens, Director of the Cinchona enterprise in Java, for seed of *C. cordifolia* (from Carthagena) and *C. lancifolia* var. *discolor* of the Government plantations there; to Mr. Gammie for seed of the Darjiling *C. Ledgeriana*; and to Mr. Rowson for very carefully collected seed of the Nilgiri "pubescens" and "magnifolia."

Seed of several species has been supplied to Australia, where both in Queensland and Victoria attempts at cinchona cultivation are being made.

Cacao.—The varieties from Trinidad were planted out in February at Pérádeniya, a few being also sent to Henaratgoda. Their names are as follows:—Condeamar (3 varieties), Forastero (3 varieties), Criollo (creole), Cayenne (2 varieties), Verdilico, Sangre Toro. The plants suffered from wind at first, but there was but a single casualty, and all are now doing well. The shade-tree called "Bois Immortelle," *Erythrina umbrosa*, was planted with them, and already forms trees 12 feet high.‡ A further instalment arrived (through Kew) in October, containing, in addition to some of the varieties previously sent, the yellow Criollo. These have also been planted out.

In accordance with the instructions of the Secretary of State, a proportion of the first consignment were transmitted to Singapore and to Fiji, respectively. Those for Singapore arrived in that Settlement in March, and with the exception of four which died were expected to "make fine vigorous plants." On the contrary, I regret to say, that the Fiji consignment, which was ten

---

* A comparison of the Nilgiri plant with Spruce's original specimens at Kew does not lend it any support whatever. On the contrary the two kinds are seen to be quite distinct in several respects. I am informed by Mr. Dyer that Spruce's specimens have been referred by M. Triana, one of the most careful and accurate botanists, who has made cinchona a special study, to *C. erythrantha*, Pav., which is considered a variety of *C. pubescens*, Vahl. Howard's plate of '*C. coccinea*' M. Triana refers to *C. hirsuta*, R. & P. [*Note added.*]

† The name "*magnifolia*" was given by McIvor under the erroneous notion that the tree was the *C. magnifolia* of Howard's "Quinology." That totally different plant being no longer considered a member of the cinchona genus, but referred to the genus *Buena*, Wedd., the name *C. magnifolia* is technically available. Since however confusion might result from its employment, it seems better to avoid its use.

‡ This *Erythrina* suffered in July from the attacks of a boring larva. The eggs seem to be deposited in or immediately above the axillary buds on the young shoots, and the grub bores at once into the pith. Tobacco water freely applied had a good effect, but many trees had to be topped. Two quite distinct though nearly allied species are mixed in these Trinidad "Bois Immortelles" (exclusive of course of *E. suberosa* which was also sent).

weeks on the journey, were all completely dead on their arrival at Levuka. I have therefore despatched a second instalment (on November 4th) containing 18 plants, representing 7 varieties, which have arrived at Sydney, en route for Fiji, "in perfectly good condition," which I trust they will maintain till they reach their destination.* With them were sent 11 plants of the "Bois Immortelle."

Mr. Prestoe, of Trinidad, who selected and forwarded these varieties of cacao to Kew, has devoted a great deal of attention to the cultivation of this important product, and I may here refer with advantage to the valuable information on the subject contained in his report for 1880 of the Trinidad Botanic Gardens.

A considerable gratuitous distribution of seed from the gardens has been made, with the sanction of Government, to native cultivators.

Cardamoms.—The demand for this profitable plant has necessitated the formation of an additional plantation. Both planters and natives however now cultivate this so largely that it will be unnecessary for the gardens to further increase the stock. Both plants and seeds have been sent to the Andaman Islands and to Jamaica.

A singular variety has been twice sent to me, and is said to form a large proportion of certain plantations, in which the flowering branches, instead of as usual proceeding from the base of the leafy stems and trailing over the ground, are carried upwards and come off from the axils of the uppermost leaves, thus appearing terminal. This variety is called here (I know not on what grounds) "Mysore Cardamom;" it does not appear to differ in other respects from the typical *Elettaria Cardamomum* of Malabar.

India-Rubber.—Much activity is being shown in the search for new rubber-yielding plants. As I have before observed, caoutchouc seems to be more or less produced by nearly all apocynaceous plants, and a large number of artocarpaceous and euphorbiaceous ones also, but it is not in a state available for ready extraction or for commercial purposes in any very large number of them. Thus in our native species of *Willughbeia* (*W. zeylanica*) which I have had the opportunity—through the kindness of Mr. J. C. Roberts of Udugama—of experimenting with, and which gives plenty of milk, the caoutchouc, which is abundant, after first passing through a viscous sticky condition dries into a putty-like substance of no great tenacity and scarcely any elasticity, and this whether treated by heat, with alum, with alcohol, or simply allowed to dry. The plant is a climber, and the stems, which are said to attain over six inches in diameter, extend to an immense length. This result is disappointing, as a congener at Singapore (*W. Burbidgei* of the Kew Report for 1880, formerly referred to *W. martabanica*) affords a very fair rubber known as "Gutta Singgarip." Of this sort we have received a case of 50 plants (which was kindly brought from Singapore by Mr. F. A. Fairlie) and we previously had a few plants from Mr. Murton. This and other less-known species of *Willughbeia* also apparently afford some of the rubber of Borneo, called "Gutta Susu" in the market.

But the most promising of the new rubber plants are the species of *Landolphia*. The African kinds of caoutchouc are mainly, and on the East coast wholly, supplied by these; and, by the exertion of Sir J. Kirk chiefly, several have been now brought into cultivation. To him directly I am indebted for a consignment of seeds (in the fruit) of the narrow-leaved species called "Matere" or "M'tiri," which affords the best rubber of the Zanzibar coast, and which it is proposed to call *L. Kirkii*. Of this we previously possessed but a single plant at Henaratgoda, now over two years old and widely climbing over a wild nutmeg tree. Young plants of this have also been received from the Royal Gardens, Kew, during the year, as well as of three other species, for an account of which reference must be made to the Report of that establishment for 1880, pp. 38–43. Of two of these, *L. Petersiana* (*Willughbeia*, Klotzch), and "No. 4." (l.c. p. 43), the broad-leaved species, we have some 18 plants at Péradeniya, and of the other, *L. florida* ("Mbungu" of Zanzibar), a single fine specimen. These and several other allied and undetermined kinds (including two plants of a Madagascar rubber from the Ceylon Company, Limited, and the West African "Apocynaceous" rubber of Mr. T. Christy's "New Commercial Plants," No. IV., p. 13) have been planted out, some at the foot of old trees, others against large dead trunks and branches fixed in the ground.

* I have the pleasure to add that these reached Fiji in excellent order, and the Colonial Secretary (Mr. Thurston) writes: "Of two plants only have I any doubt, and fortunately they are Nos. 5 and 13 of which there are tripiclates." [*Note added.*]

The wonderfully rapid development of trade in these African rubbers is, in spite of their habit of growth, leading to their destruction. From two districts of Eastern Africa alone the export of rubber in 1880 exceeded 1,000 tons, the price having risen in one year from £140 to £250 per ton.

Sir J. Kirk thinks the Landolphias (especially *L. Kirkii*) by far the most promising of rubber plants for cultivation in plantations; their stems can be cut down at frequent intervals for the rubber, and fresh shoots readily spring up from the stools. He quotes with approval, in reference to the extraction of the caoutchouc, the suggestion of Mr. T. Christy (Commercial Plants No. I., p. 9) that the stems after cutting "could be taken to the rolling mill, and the crushed mass digested with bisulphide of carbon in which the rubber is soluble, but which does not dissolve the gum and resinous matters contained in the plant, and which if left in the rubber would injure its quality."

Of other African kinds, Mr. T. Christy has sent a few seeds of a plant determined at Kew to be *Tabernæmontana crassa*, and a specimen of *Ficus populifolia;* whilst we have *F. Vogelii* also from Kew.

With regard to the American rubbers, Ceara *(Manihot Glaziovii)* continues to interest planters by its rapid growth, ready propagation, tenacity of life, and early production of seed. From this latter quality chiefly it has resulted that the loud and urgent demand for seed has almost ceased in Ceylon in the course of one year. We have distributed it to several private planters in India and to the Government establishments there, also some to Singapore for a further trial, as well as to Jamaica and other colonies.

A single tree of *Hevea* flowered at Henaratgoḍa and produced a few capsules in April. The growth of Para rubber is not rapid; our largest is now 21 inches in circumference at a yard from the ground, an increase of 5 inches in the year. New plantations of *Hevea* have been formed, and some trees at Pérádeniya have been planted in a position in the new garden where they are flooded when the river is high, with a view to an imitation of their native habitat.

One plant of another species, *Hevea Spruceana*, which gives valuable rubber, was sent direct from British Guiana by Mr. Jenman, but has unfortunately not survived.

At the request of the Government of India—at whose expense the plants were originally imported to Ceylon—a consignment from Henaratgoḍa, consisting of 28 good stocks rooted in a Ward's case, was despatched (from Henaratgoḍa) in November to the Andaman Islands. The climate there is likely to prove eminently suitable for Para rubber which has not succeeded in Peninsular India, but is going on well in British Burmah.

The *Castilloa*, both at Pérádeniya and Henaratgoḍa, also produced flowers during the dry weather of April; on examination, however, these were all male. This species is said not to produce seed till eight years old. The finest tree at Henaratgoḍa has now a stem of about 22½ inches in circumference at a yard from the ground.

During the early part of the year I made a preliminary and tentative investigation to ascertain the condition of the milk in our Ceara trees at Pérádeniya, and the best means of obtaining it. The principal conclusion I arrived at was that the trees had not their milk in a sufficiently concentrated state to invite tapping. I was quickly led to the opinion that the method of paring the stem as practised by the natives in Brazil (according to Mr. Cross) would not be found either convenient or economical. The milk-vessels occur in two layers, the richer one is in the innermost stratum of the bark just outside the cambium, but there is a smaller one immediately beneath the thin green layer; this latter is sacrificed by the slicing process which also causes loss from the milk adhering to the shavings. In the culture of this kind of rubber the principal difficulty will, I think, be the *extraction* of the milk. It appears to be present in good quantity, but a very small amount flows from each cut, and it is difficult to avoid drip and loss if the stems are not perpendicular. It is not possible at present to make any estimate of the slightest value as to the probable average yield of a tree. The plant is evidently very hardy and rapidly recovers from bark injury. I think I should repeat here what I said two years ago (Notes, p. 4) that the yield of a few trees cannot be remunerative, and only large plantations can hope to repay the cost of collection. The quality of the *dry* rubber (resulting from milk laboriously obtained from one tree by small incisions) appears identical with the Ceara scrap of commerce, in spite of the extremely watery character of the milk. Further experiments will be shortly made.

The more valuable Para and Central American rubbers have their milk already in a more concentrated condition than the Ceara; *Castilloa* especially affords a milk which spontaneously coagulates in a few hours into a very elastic rubber. Mr. Cross states (Report to Madras Govern-

ment, March, 1881) that a tree of *Castilloa* 1½—2 feet in diameter if carefully and judiciously tapped should yield about 12 lbs. of rubber per annum ; and with regard to *Hevea*, Mr. Wickham, who brought the seeds from South America to Kew, informs me "it bears tapping very well if properly worked, and I have known productive Ciringals (rubber walks) the property of several generations of Indian Ciringaros. In their native woods the large trees (they grow to a great size) are selected for working as being profitable by taking a large number of cups or a long vine band, but were a plantation formed the trees could no doubt be profitably worked whilst still small—say 24 inches in circumference. The great thing is to avoid cutting too deeply into the bark."

Gutta Percha.—A plantation of the "Gutta Sundek" from Perak has been formed in the new garden. The trees are healthy, but, like all their tribe, grow with extreme slowness.

Sago Palm.—To Mr. C. Brooke, Rajah of Sarawak, I am indebted for a quantity of seed of *Metroxylon Sagu*, the smooth-leaved sago palm. All had been decorticated before being sent, a plan the Rajah informs me the natives of Borneo prefer. Nearly all germinated readily. I am further informed by him that among seedlings from either the smooth or the spiny kinds, there are usually to be found a mixture of both sorts. "The thorny ones are supposed to produce the most sago, but natives prefer planting the smooth as the thorns wound their hands and feet severely." "The best land for sago is a wet alluvial deposit, undrained, with stiffish stuff underneath. It comes to maturity after 10 years ; wild pigs are its great enemy. After this time there is a succession of young trees growing around the parent stem. These should be thinned out and planted ; they grow better and faster than from seed, but cannot be kept out of ground for any time without rotting. Sarawak supplies two-thirds of this product for the world."

Manila Hemp.—A small plantation of *Musa textilis* has been formed on the river bank at Pérádeniya. Two Wardian cases full have been sent to Calcutta for the Indian Government who are making experiments with fibres in Bengal.

Fodder Grasses.—In my report for 1880 I included among the additions, *Panicum spectabile*, Nees, a fodder-grass long celebrated under the name of "Caapim de Angola." This was obtained from Dr. Glaziou, the well-known botanist of Rio, through the Kew authorities. I had suspected some error when first examining the seed, and ultimately on growing up it proved to be our common Mauritius grass, *Panicum sarmentosum.* I have this year obtained by application to Dr. Schomburgk of Adelaide seed of the grass known there as "Caapim de Angola" which seems to be also called "Phillips' Grass." Strangely enough this turned out equally wide of the mark, being merely a common *Sorghum* allied to *S. halepense.* So far back as 1845 ordinary Guinea grass was sent here direct from Brazil as "Caapim de Angola," to Dr. Gardner. The real plant belongs to quite a different section of Panicum, being closely allied to *P. (Echinochloa) Crus-galli ;* it is hoped that it will yet be obtained from Brazil and should form a good addition to our few fodder grasses.

A packet of Mauritius grass has been forwarded to Fiji, and a selection of tropical pasture grasses to the French colony of the Gaboon.

"*Rice-Corn.*"—In consequence of some very favourable accounts of this in American papers, an application was made through the Foreign Office to the Agricultural Department at Washington, and a supply obtained. A letter from the Commissioner was also received stating that it was merely ordinary Indian *Sorghum* which has been grown in America for some 50 years. Cultivation proved that to be the case ; it almost exactly corresponded with one of ten South Indian sorts of cholum sent by Col. Beddome, but I am not prepared to say what may be the name of the precise variety. I have distributed some of these to Chilaw, Vavúniya-Vilánkulam, Anurádhapura, &c.

Sugar Sorghum.—For a stock of seed of 14 varieties of this (*Sorghum saccharatum*) we are also indebted (through the Royal Gardens, Kew) to the U. S. Agricultural Department. This is being cultivated on a large scale in the States for sugar, and has been the subject of some admirable chemical reports. My object in its experimental culture here was rather to prove its value as a cattle fodder, which is certainly great. The largest and most leafy varieties appeared to be those called "Wolf-tail," "Orange," Link's Hybrid," and "Necazann"; they afforded an abundant sweet and succulent food much appreciated by the garden bullocks. The plant of course is an annual. It also affords a very good grain, suitable for the hot districts of Ceylon.

Jalap.—A consignment of tubers has been received from Ootacamund and mostly sent to Hakgala. There can be no question of this plant succeeding well there ; and the new

Superintendent will be well versed in its cultivation as he has had several acres under his charge in Jamaica.

Benzoin.—Seeds of *Styrax Benzoin* received from the Buitenzorg Garden, Java, have given us young plants which are growing with great vigour and beauty. Gum Benjamin, the resin of this plant, is obtained in Sumatra and forms a large export from that country through Singapore and Penang to Bombay and Europe. Though not now much employed in medicine it is largely used for incense and in making pastiles, &c. Benzoic acid is also obtained from it.

Cola Nut.—Two young plants of *Cola acuminata*, the seeds of which are a well-known masticatory among the negroes of W. Trop. Africa, have been received from Kew. Of this tree we already possess several examples in the gardens.

Annatto.—Several gentlemen have made enquiries as to the mode in which this is prepared for the market; and as I could find no very definite published account, I applied to the authorities at the Royal Gardens, Kew, for information, and have received several communications from them, the most important being from Mr. Vilmorin's report on "Produits Agricoles non Alimentaires" (Paris Exhibition "Rapports du Jury International). The following is a summary:—*Bixa Orellana* is native to Tropical America, but fairly naturalized in other hotcountries, as in India and Ceylon. Annatto (Roucou is the French name) however is prepared almost wholly in the French colonies, chiefly Cayenne (French Guiana) and Guadeloupe (which each produce about 400—500,000 kilos), but lately taken up also in Réunion and the Indian Possessions of France. The Guadeloupe samples were the best at the Paris Exhibition. The best method of preparation appears to be (there are some discrepancies in different accounts) the following. The seeds with their pulpy envelopes are pounded in a wooden mortar, and after adding hot water the mixture is left in the mortar for several days after which it is passed through a sieve. The liquid is then left to ferment for eight days, when the water is decanted off and the deposited pulp left to become concentrated by evaporation in the shade. When it has acquired the consistency of firm putty it is made up into cakesof 1½—2 kilos weight. These are packed with plantain leaves, and have a lively orange-yellow colour; the value is about 4 fr. the kilo. In Cayenne it would appear that the pulp is sometimes boiled for four or five hours and afterwards put under weights to squeeze out the water. It is also sometimes made into rolls instead of cakes, in which state it appears to fetch an inferior price.

It is remarkable that none is made in *British* Guiana; even that required for local consumption there is imported from the neighbouring French colony.

The trade in Annatto is a limited one. It is used as a dye occasionally, but its principal employment is for colouring cheese and butter.

Timber Trees.—About 25 young trees of the valuable Greenheart of Demerara (*Nectandra Rodiœi*) have been planted out in the old arboretum. They were obtained from the Botanic Garden in that colony, some directly and some through Kew. The tree is figured in Bentley and Trimen's "Medicinal Plants," t. 219, on account of the bark and the alkaloid Bebeerine contained in it being included in the British Pharmacopœia; but it is now little employed in medicine.

To Mr. Jenman we are also indebted for another excellent timber tree of British Guiana, the Mora, *Dimorphandra Mora*, or *Mora excelsa*.

A Wardian case of 30 young *Mahogany* trees has been sent to the Governor-General of Netherlands India, Java, and one of 39 to the Collector of Tanjore. A single capsule ripened on one of our largest trees in Péradeniya in January, the sole result of myriads of flowers.

Sandal Wood has often been claimed as a native of Ceylon, but does not occur here wild. Attempts to raise trees in the moist climate of Péradeniya have not hitherto been successful, but a few seedlings (from Mysore seed kindly sent by Col. Beddome) planted out on a dry sunny slope in August last give promise of succeeding well. In some of the drier districts young plants formerly sent out from the gardens have done well. In the event of any steps being taken towards an efficient Forest Conservancy, proper plantations of this extremely valuable tree may be therefore contemplated.

"*Low-country Products.*"—Of the estates opened lately in the low coast districts of Ceylon, the group at Udagama, some 25 miles from Galle, is of special interest. These are not more than 300 feet above the sea and have a rainfall of 150 inches well distributed over the year. The cultivation of nutmegs and pepper especially has been undertaken in a systematic manner,

and bids fair to become a success. Our fine old trees in Péradeniya supplied during the year over 4,000 nutmegs for these estates alone.

Planting enterprise is rapidly pushing its way into other parts of the East, and not a few pioneers go out from this colony. Thus Ceylon seems likely to become a sort of centre for the new districts in the Malay Peninsula and in Borneo, for our emigrants naturally refer here to supply their needs. Thus to North Borneo have been forwarded from the Gardens cocoa, nutmeg, pepper, cinnamon, vanilla, ipecacuanha, citronella grass, and many fruit trees, and a similar supply to Johore.

V.—Interchange of Plants and Seeds.

The Gardens have maintained the usual relations with other Botanical Establishments in the way of mutual exchange.

Wardian cases havebeen received from the Gardens of Kew (6), Calcutta (2), Singapore (2), British Guiana and Buitenzorg (2), also from Messrs. Bull (2) and Messrs. Veitch of Chelsea. We have despatched cases to the Royal Gardens, Kew (2), the Imperial Gardens St. Petersburg, and the Gardens of Calcutta (3), Singapore and Java. Also to the Colonial Secretary of Fiji, the Commissioner of the Andaman Islands, the Collector, Tanjore, and Messrs. Bull of Chelsea.

Small packets of plants and seeds have been received from the establishments of Kew, St. Petersburg, Ootacamund, Calcutta, Saharunpore, Buitenzorg, Brisbane, Adelaide, British Guiana and Jamaica; and from the cinchona plantations of Darjeeling, Neddiwuttum and Java. Seeds, &c., have been sent to Kew, Calcutta, Ootacamund, Bangalore, Singapore, Brisbane, British Guiana, Jamaica and Trinidad, and to other Foreign and Colonial Government officials.

The Gardens are indebted to the following for gifts of seeds or plants during the year:—Rajah Brooke, Sarawak; Sir J. Kirk, Zanzibar; H. Low, C.M.G., Perak; Col. Beddome, Madras; Major Seaton, Moulmein; Dr Hance, Whampoa; Sir F. von Mueller, Melbourne; Dr. Schweinfurth, Cairo; Mr. A. B. Moens, Java; T. Christy, London; &c. And, in Ceylon, to:—Mrs. Baker; Messrs. T. Berwick, C.C.S.; T. S. Dobree; B. Ffanshawe; W. Ferguson, F.L.S.,; W. S. Fraser; M. F. Rainsford Hannay; E. M. Hay; T. C. Huxley; Lee, Hedges & Co.; H. Nevill, C.C.S.; J. V. H. Owen; C. J. Scott; W. M. Smith & Co.; J. Taylor; W. H. Wright; and the Ceylon Company, Limited.

Ornamental trees and other plants and seeds have been supplied gratis to the Government Agents, &c., at Anurádhapura, Chilaw, Negombo, Puttalam and Vavúniyá-Vilángkulam; the Municipal Council, Kandy; the Provincial Road Committee, Kurunégala; to the Police Barracks, Kandy; and the Cemeteries of Badulla and Mátalé.

VI.—Additions to the Collections.

The following are some of the more important or interesting foreign species introduced into Péradeniya during the year:—

DICOTYLEDONS.

Talauma Hodgsoni, Hk. f. & Th. Himalaya. (Calcutta.)
——— *pumila*, Bl. (Magnolia, Andr.) Java, China. (Veitch.)
Gynocardia odorata, R. Br. Sikkim, Burmah. The seeds of this afford the Chaulmoogra oil of Indian medicine. (Calcutta.)
Pittosporum undulatum, Vent. N. S. Wales, Victoria. (Brisbane.)
Pavonia Makoyana. Brazil. (Bull.)
——— *multiflora*. Brazil. (Bull.)
Hibiscus tricolor. Japan. (de Cock, Ghent.)
Malpighia urens, L. W. Indies. (Brisbane.)
Canarium bengalense, Roxb. Silhet. (Calcutta.)
Sapindus Saponaria L. The Soap Berry. Jamaica. (Jamaica.)
Rhus vernicifera, DC. The Wuruzi or Urunoki of Japan, used in the famous lacquer of that country. (Mrs. Baker.)
Mangifera sylvatica, Roxb. Sikkim, Khasya. (Calcutta.)
Millettia racemosa, Benth. S. India. (Beddome.)
Herminiera Elaphroxylon, G. & P. Trop. Africa. The Ambash or Pith-tree of the Nile (Schweinfurth.)

Dipteryx odorata, Willd. Guiana. The Tonquin Bean. (British Guiana.)
Sophora interrupta, Bedd. Mysore. (Beddome.)
Ormosia travancorica, Bedd. Travancore. (Beddome.)
Cassia corymbosa, Lam. Bolivia, S. Brazil. (Roberts, Melbourne.)
Ceratonia Siliqua, L. E. Mediterranean. The Carob Bean. (Saharunpore.)
Dimorphandra Mora, Benth. The Mora of Guiana. A large and magnificent tree, and one of the finest timbers known. Also grows in Trinidad. (British Guiana.)
Chrysobalanus Icaco, L. Trop. America and Africa. The Cocoa Plum. (Jamaica.)
Couroupita guianensis, Aubl. Trop. S. America. The Cannon Ball Tree. (Kew & British Guiana.)
Eucalyptus. A selection out of many species as being most likely to endure the climate of Pérádeniya; viz., *E. amygdalina*, Lab.; *E. bicolor*, A. Cunn.; *E. hemiphloia*, F. M. (Box); *E. hæmastoma*, Sm.; *E. leucoxylon* (Iron Bark); *E. pilularis*, Sm. (Black Butt); *E. siderophloia*, Benth. (White Iron Bark); *E. urnigera*, Hk. f. (F. von Mueller.)
Aralia, Sp. Sikkim. (Calcutta.)
Trevesia Novæ-guineensis. New Guinea. (Java.)
Mikania pulverulenta. Trop. America. (Kew.)
Diospyros Melanoxylon, Roxb. S. India. Malabar Ebony, "Tumbi" of the Tamils. (Beddome.)
Styrax Benzoin, Dryand. Sumatra and Java. A source of the fragrant resin called "Gum Benzoin" or "Benjamin." (Java.)
Willughbeia Burbidgei, Kew Rep., 1880. Gutta Singgarip. Malay Peninsula, Borneo. (Singapore.)
——— sp. ? ("Vahea gummifera" Hort., Kew). (Kew.)
Landolphia florida, Beauv. } E. Trop. Africa. (Kew.)
——— *Petersiana* (*Willughbeia*, Klotzsch.) }
——— *Kirkii*, Kew Rep., 1880. [The *Landolphia* sp. of last year's Report] }
——— sp. (No. I.) }
——— sp. Madagascar. (Ceylon Company, Limited.)
Cerbera Tanghin, Hook. (*Tanghinia venenifera*, Poir). The Ordeal Poison of Madagascar. (Kew.)
Tabernæmontana crassa, Benth. Senegal. One of the rubber-producing plants of W. Africa. (T. Christy.)
Urceola (*Chavannesia*) *esculenta*, DC. Burmah. Affords a rubber, an edible fruit, and a blue dye. (Major Seaton.)
Cordia sebestena, L. W. Indies. (Kew.)
Solanum hyporrhodium. Venezuela. (Bull.)
Bignonia magnifica. Colombia. (Bull.)
Tecoma spectabilis. (Kew.)
Whitfieldia lateritia, Hook. Trop. Africa. (Java.)
Eranthemum eboracense. (Bull.)
Beloperone (*Simonisia*) *chrysophlæa.* Brazil. (Bull.)
Aphelandra punctata. (Bull.)
——— *fascinator.* (Veitch.)
Fittonia gigantea. (Veitch.)
Vitex sp. Sikkim. (Calcutta.)
Scutellaria Mociniana, Benth. Mexico. (Veitch.)
Piper (*Artanthe*) *augustifolium*, R. & P. Trop. America. The leaves form Matico, a well-known hæmostatic. (Kew.)
Peperomia clusiæfolia. (Bull.)
Cryptocarya australis, Benth. Queensland. (Brisbane.)
Nectandra sanguinea, Rottb. W. Indies. (Brisbane.)
——— *Rodiæi*, Schomb. The Greenheart of Guiana. A first rate timber tree. From the bark is obtained the alkaloid Bebeeria, a tonic medicine. (Kew & Demerara.)
Grevillea Hilliana, F. Muell. Queensland. (Brisbane.)
Buckinghamia celsissima, F. Muell. Queensland. (Brisbane.)

[The "Croton Eluteria" of last year's list is C. *niveus*, Jacq.]

Phyllanthus Seemannianus. New Hebrides. (Bull.)
Dorstenia Contrajerva, L. Trop. America. (Java.)
Ficus Vogelii, Miq. W. Trop. Africa. Affords one sort of African rubber. (Kew.)
——— *populifolia*, A. Rich. Trop. Africa. Another rubber-yielding Fig. (T. Christy.)
——— *exsculpta.* Pacific Islands. (Bull.)
——— sp. Sikkim. Calcutta.
Casuarina humilis, Otto & Dietr., var. *tephrosperma.* W. Australia. (Adelaide.)

GYMNOSPERMS.

Agathis loranthifolia, Salisb. (*Dammara alba*, Auct.) Malay Archipelago. Affords the white Dammar resin. (Java.)
Cycas, sp. nov. Anamallay Hills. (Beddome.)
Macrozamia Moorei, F. Muell. Queensland. (F. Mueller.)
Encephalartos Hilderandtii, A. Br. Zanzibar. (Kirk.)
——— *villosus*, Lem. S Africa. (Bull.)

MONOCOTYLEDONS.

Maranta Kerchovei, Veitch.
Musa uranoscopus, Miq. Amboyna, &c. (Bull.)

BROMELIACEÆ. (All from Kew.)

Æchmea glomerata, Hook. Brazil.
Billbergia Liboniana, De Jongh. Brazil.
——— *Wetherilli*, Hook. Brazil.
——— *thyrsoidea*, Mart. Brazil.
——— *splendida*, Lem. Brazil.
——— *paniculata*.
Cryptanthus Cacautes.
Pitcairnia Andreana, Linden. New Grenada.
——— *lepidota*, Regel. *Ibid*.
——— *Decaisnei*, K. Koch. Trop. America.
——— *recurvata*, K. Koch. *Ibid*.
——— *staminea*, Lodd. Brazil.
——— *undulata*, Scheidw. Trop. America.
——— *zeæfolia*, K. Koch. Guatemala.
Tillandsia (*Vriesea*) *glaucophylla*, Baker. New Grenada.

ORCHIDEÆ.

Dendrobium chrysanthum, Wall. Nepal. (Calcutta.)
——— *densiflorum*, Wall. Nepal. „
——— *Farmeri*, Lindl. India. „
——— *nobile*, Lindl. China. „
——— *Pierardi*, Roxb. Bengal. „
——— *Dalhousianum*, Wall. India. (Veitch.)
——— *Jenkinsii*, Wall. India. (*Ib.*)
Nephelaphyllum pulchrum, Bl. Java. (Java.)
Cœlogyne flaccida, Lindl. Nepal. (Calcutta.)
——— *elegans*. (Calcutta.)
Otochilus, sp. (*Ib.*)
Arundina bambusifolia, Lindl. Nepal, &c. (Hannay.)
Maxadenia lutescens, R. Br. Trinidad. (Jamaica.)
Brassavola glauca, Lindl. Mexico. (Bull.)
——— *Digbyana*, Lindl. Honduras. (Bull.)
——— *cordata*, Lindl. Jamaica, Brazil. (Jamaica.)
Lælia majalis, Lindl. Mexico. (Bull.)
Schomburgkia Lyonsii. (Jamaica.)
Epidendrum aciculare, Batem. Bahamas Mexico. (Bull.)
——— *crassifolium*, Lindl. Trinidad. (Bull.)
——— *cochleatum*, L. W Indies. (Jamaica.)
——— *fragrans*, Sw. W. Indies. (*Ib.*)
——— *nocturnum*, L. W. Indies (*Ib.*)
Broughtonia sanguinea, R. Br. Jamaica, Cuba. (Jamaica.)
Cattleya Mossiæ, Hook. Venezuela. (Bull.)
——— *citrina*, Lindl. Mexico. (Bull.)
Cymbidium elegans. Calcutta.
Catasetum maculatum, Kunth. New Grenada. (Bull.)
Burlingtonia fragrans. Brazil. (Veitch.)
Odontoglossum Rossii, Lindl, var. *majus*. Mexico. (Bull.)

Brassia caudata, Lindl. W. Indies. (Bull.)
——— *maculata*, R. Br. Jamacia, Guatemala. (Jamaica.)
Saccolabium ampullaceum, Lindl. Nepal, &c. Calcutta.
Angræcum citratum. (Veitch.)
——— *sesquipedale*, Thouars. Madagascar. (Veitch.)
Argyrorchis javanica, Bl. Java. (Java.)
Cypripedium Ashburtoniæ, (Veitch.)
——— *Veitchii*, (*Ib.*)
——— *selligerum*, (*Ib.*)

[and many unnamed species.]

Crinum Macowani, Baker. Natal. (Veitch.)
Pancratium fragrans, Red ? Trop. America. (Veitch.)

PALMÆ.

Areca triandra, Roxb. var. *Bancana*, Scheff. Bangka. (Java.)
Pinanga, sp. Bangka. (Java.)
Ptychosperma Wendlandiana. (Java.)
——— *gracilis*, Lab. New Ireland. (Kew.)
Œnocarpus Bacaba, Mart. Brazil, &c. (B. Guiana.)
Oncosperma filamentosa, Bl. (Java.)
Orania macroclada, Mart. Malacca. (Java.)
——— *philippinensis*. (Java.)
Socratea exorrhiza, Wendl. (*Iriartea*, Mart.) Brazil, &c. (B. Guiana.)
Caryota ochlandra, Hance. S. China. (Kew.)
Phœnix Hanceana, Naud. S. China. (Kew.)
——— sp. (Jamaica.)
Washingtonia filifera, S. Wats. California. (Kew.)
Thrinax parviflora, Sw. W. Indies. (Kew.)
——— *argentea*, Lodd. W. Indies. (Kew.)
Livistona Tembisii. (Java.)
Pholidocarpus Ihur, Bl. Amboyna, &c. (Java.)
Calamus (*Dæmonorops*) *marginatus*, Bl. Borneo. (Java.)
Heterospathe elata, Scheff. (Java.)
Bactris, sp. (B. Guiana.)
Desmoncus, sp. (B. Guiana.)
Cocos (*Glaziova*) *insignis*, Mart. (Bull.)

ARACEÆ.

Pothos aurea, Hort. Lind. Solomon Is. (Bull.)
——— *celatocaulis*. (Veitch.)
Anthurium Scherzerianum, Schott. Trop. America. (Veitch.)
——— *regale*, Linden. Trop. America. (Veitch.)
Scindapsus Beccarii. New Guinea ? (Java.)
Dieffenbachia sp., vars. *amœna*, *Carderi*, *Leopoldii*. (Bull.)
Alocasia Lowii, Hook f. Borneo. (Veitch.)
———, var. *Veitchii*. Java. (Java.)
——— *intermedia*. (Veitch.)

Aloe Perryi, Baker. Socotra. Affords the true Socotran aloes. The plant was only made known to science in 1880, though its product has been regularly exported since before the Christian era. Figured in Bot. Mag. t. 6596 (Decr., 1881.)
Cordyline terminalis, Kunth., var. *alba*. (Kew.)
Dracæna Goldieana, Hort., Bull. W. Trop. Africa. (Bull.)
——— *vestalis*. Bull.
Cyanotis multicolor, (var. of *Zebrina ?*) (Bull.)
Tradescantia, sp. (Java.)

FERNS, &c.

Nephrolepis Duffii, Duke of York's Island. (Bull.)
Lastrea aristata, variegata. (Bull.)

I have included in the above several "Florists'" plants of interest, but most of these—*e.g.*, varieties of *Ixora, Begonia, Abutilon, Coleus, Dracœna,* "*Croton*" (*Codiœum*), &c., are omitted.

Numerous subtropical and temperate seeds have been sent to Hakgala, but I am unable to give an accurate list of those which have succeeded there, at present.

VII.—Herbarium and Library.

Herbarium.—More than half of the collection of Ceylon plants has been during the year mounted on thick paper, and is now very much more convenient for reference and consultation. This work will be continued when more paper can be obtained.

I have also re-arranged a considerable portion and written up the names in accordance with the most recent floras and monographs.

An examination has been made of the duplicate specimens which were suffering much from insects. They are now being steadily gone through, cleaned, poisoned, and laid in fresh paper.

Numerous additional specimens have been intercalated into the collection.

The general herbarium of exotic plants is being sorted into genera and arranged in cabinets, instead of being kept tied up in bundles. Some progress has been made in this work, which will necessitate a number of additional cabinets, if the whole series is to be so accommodated.

A selection of medicinal plants was dried and sent to the Museum of the Medical School at Colombo, and another set forwarded to the Pharmaceutical Society in London.

Five parcels of Indian and Malayan plants have been received from the Kew Herbarium, and one from Col. Beddome collected in the Cuddapah Hills.

I made a tour of four weeks' duration in February and March for collecting, visiting several parts of the Southern and Western Provinces between Mátara and Ratnapura, and made large collections. I have also to thank several correspondents in the colony for specimens, especially Mr. H. Nevill, C.C.S., and Mr. W. Ferguson, F.L.S., whose investigations on the West coast have added several species to the flora of Ceylon.

The Draughtsman has added fourteen finished drawings to the series of figures of Ceylon plants; he also furnished Mr. Ward with several illustrating the external characters of diseased coffee leaves. I find him very neat and efficient at herbarium work, and much of his time has been occupied with the sorting, re-arranging, and cleaning of the dried specimens.

Library.—I have completed a catalogue of the Library, in which the books and pamphlets are arranged under subjects. A copy of this, now being made, will be immediately forwarded to the Auditor-General, and it is hoped will be printed in due course.

The following books have been added to the Library during the year:—

Bentham and Hooker (fil.), "Genera Plantarum," Vol. III., Part I., 1880.
De Candolle, A., and others, "Monographiæ Plantarum," Vols. II. and III., 1879, 1881
Dickson, J. H., "Fibre Plants of India."
Drury, "Useful Plants of India," 1858.
Franchet and Savatier, "Enumeratio Plantarum Japoniæ," 2 Vols., 1872—1879.
Hooker's "London Journal of Botany," Vols. for 1843-44 (towards completing set).
Hooker (fil.), "Flora of British India," Part 8, 1881. *(Presented.)*
Horaninow, "Prodromus Monogr. Scitaminearum." 1862.
Hooker's "Icones Plantarum," Vol. XIV., Parts 1 and 2, 1862 (in continuation).
Morris, D., "On Liberian Coffee," 1881 (pamphlet). *(Presented.)*
Moore, F., "Lepidoptera of Ceylon," Parts I. and II. *(do.)*
Owen, T. C., "Cinchona Planter's Manual," 1881. *(do.)*
Trimen's "Journal of Botany," Vols. for 1873, 1877 (towards completing the set). *(Presented.)*
Roxburgh "Plants of Coast of Coromandel," plates 251—300, 1819 (to complete the book).
"Transactions of the Linnean Society of London" Vols. XXXIII.—XXX., 1862-75 (completing the old series).
"Acta Horti Petropolitani," Vol. VII. (in continuation).

Also the numbers for the year of the following Periodical publications (mostly presented):—Belgique Horticole, Botanical Magazine, Botanische Zeitung, Gardeners, Chronicle, Flora, Garten Flora, Indian Forester, Nature, Pharmaceutical Journal, Journal of Botany, Tropical Agriculturist; and the usual Reports of Botanic Gardens, Cinchona Plantations, Indian Forest Department, &c.

VIII.—SALES.

The receipts for the sale of plants, seeds, &c., in the year 1881, paid to the Colonial Treasurer, were :

		Rs.	cts.
From Pérádeniya	...	3,915	14
Henaratgoḍa	...	562	36
Hakgala	...	460	82
Total ...		Rs. 4,938	32

In addition to this, the experimental sale of *C. crispa* and other bark in London in February last [see last year's report, page 5] produced, clear of all charges, Rs. 3,219·63, making the total receipts for Rs. 8,157·95.

The number of purchasers has been

From Pérádeniya	...	885
Henaratgoḍa	...	228
Hakgala	...	34
Total ...		1,147

I desire to call the attention of Government to a kind of work which this establishment is being increasingly called upon to perform. No less a number than 28 Wardian cases of ferns, orchids, &c., were purchased here by private persons during the year 1881, for conveyance to England or elsewhere. This is, I submit, not a desirable channel into which to direct the work of a State Botanic Garden. In every way the supply of these cases is a loss to the establishment. The Rs. 20 charged for the plants is paid into revenue, and the Gardens receive no benefit whatever from the transaction. The proper principle in making use of the contents of a Government Botanic Garden is to insist upon a *quid pro quo*, or exchange ; and I cannot see without protest the increase of a system, which while continually exhausting our stock of good plants, gives us nothing in return.

More serious is it that our proper exchanges with other public Gardens suffer ; for the time of our small staff has to be employed in filling and packing these private cases (often ordered with little consideration at short notice) to the neglect of work on which the well-being and public utility of the Garden almost wholly depends—*i.e.*, foreign exchange. The legitimate demands upon these Gardens also, not only from this colony but from the East generally, are now such as to render it essential that our small resources should be wholly devoted to meeting them, and not to be wasted in the business of a nurseryman.

I therefore feel that the time has come when I should be permitted to use my discretion as to acceding to private orders for Wardian cases. One would think that, as the demand is now so large, some private man of business might find it worth while to undertake the supply, and the Garden be altogether relieved of this uncongenial and harmful work.

IX.—EXPENDITURE.

The whole expenditure of the Department (excluding the salary and travelling expenses of the Cryptogamist temporarily attached) has been :—

		Rs.	cts.
Salaries		15,070	54
Gardeners' and Labourers' Wages—

HENRY TRIMEN, M.B.,
Director.

Pérádeniya, 1st January, 1882.

COMPARATIVE TRIALS OF MANURES.

A correspondent suggests, with respect to Mr. W. D. Bosanquet's valuable experiments, that they would have been more conclusive if they had been in *duplicate*. The fact that they were made on *squares* also militates against their value, as each was thereby confined to a particular spot and not applied over an average of the soil of the field. It is important that in all comparative experiments the conditions should be such as to make the results reliable and conclusive. I would suggest that such experiments should be made in *lines*, rather than in *squares*. When different manures or treatments are tried on *strips*, adjacent to each other, from the bottom to top of the field, each strip being of about 10 lines in width, the results may be compared most readily, especially if the field be commanded from some point whence the whole experimental area may be viewed at a little distance. Moreover, each strip will traverse a greater variety of soil, and give more reliable evidence than any mere patch or square. In an extensive trial of manures, which I made some years ago, 10 lines of coffee from the bottom to the top of the field were manured or treated in adjacent strips, with intervening strips, here and there, of like width *without* manure, or treatment, to facilitate comparison. The results in this case were most conspicuously seen, so far as regards the *appearance* of the trees, from a field opposite. I have not now the record of the results of this experiment, nor would these results be of any general value, though they served an important purpose on the particular estate for guidance in subsequent more extended operations. I may mention, however, that the manures tried were Peruvian guano, Bolivian guano, poudrette, cocoanut poonac, bonedust, woodashes, lime, &c., and some *mixtures* of poonac with bonedust, or woodashes. The main general results were as follows :—1st as regards *appearance*. The strip manured with Peruvian guano was the first to show up with a fine dark glossy foliage, and was quickly followed by the poudrette, poonac, and Bolivian guano, in order, with the same characteristics, but in lesser degrees. The others showed more or less improvement, but not of the same marked character. 2nd, as regards *crop* : unfortunately, a rush of crop over the whole estate prevented the possibility of keeping the crop of each strip separate. The record, therefore, was based on observation of the progress made in each strip by the pickers, aided by observations in the field itself, and is not so exact as it might have been. The palm was undoubtedly carried by the *mixtures* of bones and poonac, and bones and woodashes. Next followed the bones alone and poonac alone in order. 3rd, as regards appearance *after* crop. The strips manured with the mixtures looked fit, none the worse for their crop, and ready for further service. Those with bones alone, and poonac alone, looked rather less vigorous than those with mixtures. But the highly ammoniacal manures, the Peruvian guano and the poudrette showed *severe re-action*. The trees looked sickly and yellow, with many dead points. I refer to this experiment, however, less for its results than as illustrating the great advantage of the *linear* system for experiments on comparative treatments of coffee.

The importance of preliminary trials of manure on *a small scale*, in anticipation of more extended operations, cannot be overrated : and when it is considered that, on an area of 25 acres, no fewer than 10 different treatments may be compared each with a strip of 10 lines of 300 trees, or say 3,000 trees for each treatment, there is no excuse for blundering on a large scale. One needs not to grope in the dark, but may be guided by the *light*, following Mr. W. D. Bosanquet's good example. G. W.

HYBRIDITY OF CINCHONAS AND GRAFTING LEDGERIANA CUTTING ON TO SUCCIRUBRA STOCKS IN THE OPEN AIR.

Mr. Wm. Smith, who has been so much grieved by our defection to a belief in the "hybridity-of-cinchonas" theory, and who, when he wrote the very interesting and valuable letter which appears below, imagined that he was merely a solitary voice crying in the wilderness, ought to be greatly comforted by the alliance and support of so eminent an authority, scientifically and practically, as Mr. James Gammie, who has so long been in charge of the Cinchona Gardens in British Sikkim (Darjeeling). To the dictum of Hooker and Thomson, that hybridity is a process very rare in nature, on which we so long founded our objections to the statements that hybrids had appeared amongst the cinchonas introduced into Java, Ceylon and India, Mr. Gammie pins his faith still ; and as for Mr. Wm. Smith, he considers the idea of spontaneous crossing as an impeachment of the Being who created all plants and gave them their laws of existence and reproduction. Messrs. Gammie and Smith can point, as we so long did, to the wonderful differences between young and mature foliage and the inveterate habit of sporting characteristic especially of the more valuable species of cinchonas, the crown and yellow barks—*C. officinalis* and *C. calisaya*. It is not likely that we who on this subject, had the temerity to break a lance with John Eliot Howard, the very prince of quinologists, should lightly adopt a belief in the hybridity of cinchonas. We did so, simply when we found all the leading authorities, including Hooker himself, with Trimen and Moens,—and, amongst practical as well as scientific planters, Forbes Laurie, arrayed on the side of not only possible hybridity, but, from what was stated to be the peculiarity of the blossoms, a strong tendency in that direction. In going over the Java plantations with Mr. Moens, we were shewn the bee and the butterfly which were the active agents of the process of adulterating the pure Ledgerianas with the pollen from Pahudianas, Josephianas, Hasskarlianas, Javanicas, and other inferior sorts, all of which were to be practically extirpated, so that seed which could be depended on (a large crop anticipated this season, by the way) could be gathered from the Ledgerianas. Meantime, Mr. Moens was, as rapidly as possible, pushing forward the grafting process, so as to get a good supply

of plants true to the best types. Dr. Trimen is a botanist of no mean standing, and our readers have seen his protest against the hasty and unauthorized conclusions of Col. Beddome : a very able man, but not to be compared for scientific position to men like Hooker, Trimen, Moeus, King, &c. Amongst practical planters in Ceylon there is Mr. Forbes Laurie, whose testimony to the tendency and the fact of hybridity amongs our cultivated cinchonas is emphatic ; the result, he says, of experience extended and observation of a careful and cumulative nature. That amongst blossoming cinchonas there is not only the danger of hybridity but the tendency to it, we feel it impossible to deny. As to results, while in Java the inferior deteriorates the superior, many here hold, amongst them Mr. Forbes Laurie, that hybrids have arisen and may arise, far superior to either parent. *C. robusta* under its various designations, of *pubescens*, &c., is quoted as an example, and the belief seems to be that not only did the late Mr. McIvor produce it artificially, but that it appeared spontaneously and does so still, wherever *C. officinalis* and *C. succirubra* are cultivated together. The case is one, however, which shews the wisdom of Dr. Trimen's caution in recommending the name of *C. robusta* as a temporary or intermediate name, until the question of hybrid or species is settled. Comparisons with specimens at Kew seem to have settled the question that the *Pátá de Gallinazo* of America the tree is not, but there has been no decision by scientific men that, beyond all question, this particular tree, so valuable in many respects, is really a hybrid. Indeed, the statements made by Mr. Smith and especially what Mr. Gammie writes, backed, we may say, by our own recollection and observation, would go to prove that, *if* the plant is a hybrid, the process of hybridization took place in its native habitat on the sides of the Andes. There can be little or no question that large numbers of the large-leaved, robust-growing plants appeared amongst the earliest cuttings from Hakgala, especially amongst those of *C. officinalis*. As Mr. Gammie says, Dr. Thwaites alone can settle the question as to whether specimens of the tree did not grow in Hakgala from some of the seed first sent thither, and we trust he will, from his honourable retirement, do what he can to finally settle a question which both from a scientific and practical point of view is so important. The evident leaning of Dr. Bidie's mind is to the belief that on the Nilgiris the tree grew up with the original succirubras, officinalis and calisayas ; but if so, how can we account for Mr. McIvor's announcement to Mr. Howard, that, as the result of careful and large experiments in artificial hybridizing, he had procured two really good forms, which appear to have been the tree in question, in its pubescent and glabrous varieties. Seeds from plants so produced, used by Mr. McIvor on his own private property and sent to us and others in Ceylon (under, at first, the name of *Lanosa*), came true to type ; and so it seems to have been with seed procured from Mr. Rowson. It really does seem possible that " C. robusta" came to India and Ceylon amongst the seeds originally received, and that the very same form resulted from McIvor's experiments. If this should be proved and admitted, it will follow that, after all, the plant *is* a hybrid, but a hybrid originating in the forests of the Andes, and, once originated, bearing a vigorous and permanent form. Whatever we may think of the doctrine of hybridity, we feel confident that the bulk of the seeds from a good Ledgeriana will give good Ledgeriana seedlings ; and from all we have heard the same principle seems to hold good in the case of " C. ROBUSTA."

In the case of both, however, and of all superior species or varieties, no doubt *certainty* of type can better be preserved by the processes of taking cuttings, of "budding," and of "grafting." But for the fact, that the very valuable Ledgerianas are generally delicate, the obvious mode of propagating them would be by cuttings. But in Java and other places it has been found that a large proportion of the cuttings failed, and that in the case of either seedlings or plants grown from cuttings, a large number either failed to grow vigorously or died off. Mr. Moens, to whom the world owes so much of its knowledge of the most valuable species of the cinchona tribe, was led, from the facts we have mentioned, at an early stage of his connection with the culture of Ledgerianas in Java, to try the experiment of grafting the delicate Ledgeriana on a stock of the robust growing succirubra. The trees united perfectly, and analysis proved that the Ledgeriana so grafted and growing on the succirubra stock preserved its valuable properties unaffected in the slightest degree by the juices of the stock which supported it. This led to extended experiments, which are still going on, with marked success, the only doubt we heard Mr. Moens express taking the form of an apprehension that bad results might follow the disproportionate growth of stock and stem. We believe all fear on this subject may be dismissed. What we did notice in the flourishing plantations of grafted trees, 2½ years old and upwards in the field, was that they grew with rather dwarfed forms, the tendency being to expend their vigour in lateral growth. When we drew Mr. Moens's attention to this fact, he stated he had carefully observed it, and that he believed the pruning away of the lower branches, a process which was about to be carried out, would cure this defect and induce the trees to grow tall and straight. What Mr. Moens does is to prepare abundance of stock plants, growing them in pots until they are about a foot high. They are then taken into a conservatory, a slanting incision is made in the stem, and into this is inserted a succulent cutting from the end of a branch or twig of a Ledgeriana of proved good quality. Care is, of course, taken, that at least on one side, (if on both, so much the better) the bark of stock and graft meet. Otherwise they will not unite, and with all the care taken there are a good many failures. Thread from old gunnies is wrapped round stock plant and graft at the junction, the native we saw at work being able to complete the process on 300 plants per diem. When the tying is done, the pots are put into melon frames slanting for convenience sake. They are thus under a double protection of glass. In about six weeks, it can be seen whether

the graft is to grow or not, and, if the success is complete, the top of the stock plant is carefully cut off a little above the junction. Henceforth the vigour of the stock is thrown into the graft, which grows apace. The plants are gradually hardened by being taken out of the melon beds to the floor or shelves of the conservatory; then to a shed; and finally to the open air. When thoroughly established and at the proper planting season, the grafted plants are taken out of the pots and put out into the field. Of course there is a degree of risk in all the processes up to that of taking the plant out of the pot.

It never seems to have occurred to Mr. Moens—at least he neither tried the experiment nor said anything about trying it—that on stock plants grown *in situ* grafting in the open air might succeed. Mr. Wm. Smith of Mattekelly, Ceylon, having (through our means, he is good enough to say) become the possessor of a considerable number of Ledgerianas, proved by analysis to be of most valuable types, determined to try the experiment of multiplying them by grafting on to succirubra trees already scattered over his estate. Of course the application of glass in such a case, even in the case of handbells, would be impossible on the score of expense. The shelter resorted to was obtained by reversed bottomless manure baskets, further shade, where deemed necessary, being obtained by means of pieces of old gunny bags. Even this amount of shelter, Mr. Smith believes he can dispense with, by commencing his grafting operations with the advent of the south-west monsoon rains, which this season he means to do. We trust he may be even more successful than he has been with his original experiments, which we have watched with a degree of interest in proportion to the importance of the results to the planting interest in Ceylon. Beside public roads, along estate paths and scattered over plantations generally, are hundreds of thousands of succirubra plants capable of yielding, when mature, bark giving about 3 per cent (a high average) of quinine. These are all, up to the age of 5 or 7 years, Mr. Smith holds, capable of being converted by the grafting process into Ledgerianas, with bark yielding from 7 to over 12 per cent of the most precious of the cinchona alkaloids. Taking only the succulent ends of twigs for his grafts, Mr. Moens's power of reproducing his Ledgerianas is, of course, considerably limited, but Mr. Smith improved on the Java system not only by grafting in the open air but by using ripe wood as well as succulent, so that, practically, every portion of a tree except the stock and thick branches can be utilized. We repeatedly visited Mr. Smith's plants, and we were not contented with the junction and growth of the grafts. "The great danger," we said, "will be death from copious bleeding and its effects, when you cut off the tops of tho, in so many cases, thick stock plants." So we went back again, when the plants had had time to recover from the shock of the tops being taken off, which they were, very skilfully, by means of an amputating saw, lent for the purpose by Dr. Duke. "Healed with the first intention" would have been the worthy doctor's verdict, had he been with us when we inspected the plants, at a period sufficiently subsequent to the amputation to put further danger out of the question. Some of the grafted plants are now sights worth seeing, and, as Mr. Smith states, his failures in this preliminary experiment were far less numerous than might be expected. We have suggested to Mr. Smith that shelter from heavy rain as well as from hot sun may be necessary, but he, having thoroughly studied the subject of grafting, knows what he is about, and we can only repeat our good wishes for his perfect success, because, as we have already said, that success means the success of hundreds of Ceylon planters, and the revival largely of the prosperity and progress of the colony.

SOUTH AUSTRALIA.

THE MINISTERIAL VISIT TO THE NORTHERN TERRITORY.

Port Darwin, March 21st.—The Minister of Education and party returned today from their visit to Delissaville, where they were capitally entertained at a formal dinner, at which the usual speeches were made. An inspection was made of the sugarcanes which have been planted there. They are in a healthy condition, though not big. The appointments of the plantation belonging to the De Lissa Sugar Company are complete. Two hundred acres are under sugar, and fifty under maize. The white ants have been almost overcome by the free use of lime and cross-ploughing. A dozen lb. of table sugar were manufactured in presence of the party from the product of the crushing. The Government Garden may be considered the best in South Australia. The land about here is generally good, with ironstone patches. At the banquet, which was given to the party, the speakers expressed their great satisfaction and astonishment at the amount of work which had been done on the plantation. It was stated that a rumour was afloat that it was intended to merge other sections on Cox's Peninsula in the Delissaville plantation under the power given by the Act of last session, but this was opposed strongly, and the arguments used by the *Register* at the time the measure was under discussion were upheld. Sixteen thousand pounds have been spent on the Delissaville plantation, which is beyond the requirements of the Act, and if another 10,000 acres were merged into that plantation not a farthing need be spent on the added area. There are also plantations of tobacco, rice, and coffee on a small scale on the Cox's Peninsula.

Port Darwin (Later.)—Mr. Edwards, planter of Natal and Fiji, and Mr. Reece, a sugar and cotton planter in Fiji, have arrived from the Daly in a small open boat. They inspected Owston's Palmerston Plantation Company's land, which consists of twenty thousand acres, and also the blocks of the other selectors. Mr. Edwards considers the land capital, and far better than Delissaville for the plantation of sugar, but Mr. Reece fears that it is not strong enough, though the soil is deep black and chocolate loam. He, however, thinks it very good for cotton. For the first thirty miles from the mouth of the river, floods surround the land in the wet season, and the dry ground is caked and practically useless. Thence, as far as is known, extend boundless plains of impenetrable grass, which have a grand soil, are lightly timbered, and are well drained by the river. Mr. Reece intends to importune the Government to grant him land for the cultivation of cotton on similar conditions to the grant made to Mr. Owston, guaranteeing to immediately start a plantation and import machinery from Fiji with Melbourne capital. The Palmerston Company have twenty acres of cane planted, which is looking healthy, especially the mecra kind. Maize is growing prolific-

ally. Fifteen Chinamen are employed at £1 per week, and the Europeans engaged average £2 per week. The climate is hot, the last week being 100° in the shade. Alligators are plentiful, and the river is difficult of navigation.—*Australian paper.*

POULTRY.

Editor of the "Madras Mail."

15th April 1882.

SIR,—In reply to "Game Fowl," in your issue of 12th instant, I have found the following treatment successful. With a feather, smear all the parts affected with insects, which are small fleas, with kerosine oil once a day for four or five days, letting the oil soak down to the skin where the fleas are fastened, (it won't hurt the fowl's eyes) after which they will be found to be dead, and can easily be taken off, or they will drop off in time. The floor of the fowl-house, if of earth, should be dug up, one or two inches of the surface removed, and replaced with fresh mud, beaten down and plastered with cow-dung, and, when dry well sprinkled with wood ashes, the ashes to be removed every few days. The nests in the house to be burned.

EXPERIENCE.

TANNING AND TANNING MATERIALS IN MADRAS.

The *Madras Mail*, in noticing the great advance in the trade in hides and skins, remarks:—An investigation into our local tanneries, made a few years ago, divulged the fact that many skins of animals were regularly sent in a salted condition from the Bombay Presidency, and even in larger numbers from Bengal, for the purpose of being tanned at Madras, and sent to the London, Continental, and American markets, as consignments from this locality. The reason for this was not at first sight obvious, as in some parts of Bombay there are extensive tanneries, and for many years Cawnpore has enjoyed a local reputation for the excellence of its leather. Yet it was an undeniable fact that, in all the markets out of India, Madras-tanned skins and hides commanded a higher price than those turned out further to the north. The difference in value was so great as to cover the heavy cost of the long transit by rail, which the despatch from from such distant stations as Delhi, Lucknow and Cawnpore involved. At the latter station, the tanners imitated as far as they could the Madras results, and tried to pass off their skins as "Madras", but the deception was soon detected by the London experts, and consequently for some time there were separate entries in the home trade lists for "skins, Madras" and "skins, Madras, Cawnpore imitation," the latter being priced at a lower figure. The superiority of the former arises from fortunately lasting causes. We do not presume to say that the waters in the neighbourhood of the silvery Cooum are softer and better than those of the holy Ganges, nor do we even assert that the local tanners and curriers are more skilled in their art than those who are similarly employed in the other Presidencies. In fact it must be admitted that the hides of Bengal, particularly those of buffaloes, are finer and stronger than with us. Large numbers of animals are there fed up and slaughtered while in condition, for the numerous Mahomedan population, and our countrymen in Bengal rejoice in mutton clubs, which are productive of superior skins as well as of tender flesh, but which are scarcely heard of in our Presidency.

It is to the tanning material to which we must look for the reason of the apparent anomaly in home prices. In Bengal, and we believe also in Bombay, the bark almost invariably used in tanning is that of the Babul (*Acacia Arabica*). This tree is also natural in Madras, and is so prolific and so hardy, that it often struggles into vigorous life, notwithstanding all the ill-usage which it has to endure, and which has extirpated many other species. Its bark is, however, little used in the Madras Presidency. Our curers of leather prefer a tanning composition, the principal ingredients of which are the bark of the *Cassia Auriculata*, and the nut called myrabolams. The latter are much appreciated in foreign markets. Those from the Salem districts command about one-fourth higher prices than those coming from the Godavery. But few of the former are shipped, although they are readily purchased for that purpose when procurable. They have locally such a name, and their superior qualities are so evident, that they are almost entirely bought up for use in our own tanneries. The nut is the produce of a jungle tree, happily not of easy extirpation, and we may depend on the supply lasting. There are several cassias in the Madras Presidency, including that from the south, which produces the finest known senna, but none of their barks can be compared for tanning purposes with that of the Auriculata. The shrub grows freely in the Deccan, in Mysore, and over most of the Madras Presidency, and seems to prefer barren and arid soils. Its uses are various. Workers in iron employ its root in tempering that metal. Powder from its dried seed is remedial in opthalmic cases. The small stems form the favourite tooth brushes of our native fellow-subjects, and doubtless the preference is formed on some good physical reason, as the whole plant partakes of the stringent qualities conspicuous in its bark. In Mysore it is regarded as good manure for rice fields. Its stems are cut down for this purpose and spread over the ground; water is then let out, in which they soak for a fortnight, when they become soft, and are ploughed into the soil. When removed from their natural localities for tanning purposes in the Mysore territories, a small tax is now imposed per load. This gives a sort of protection to the plant, and satisfiies the jealousy of the agriculturists, who from time immemorial have considered it their special property. A soft enduring leather results from the use of its bark in tanning. The skins and hides prepared with it for exportation are, however, not fully tanned on the spot. They are found to be particularly susceptible of taking dyes of beautiful and fast colours; and our Presidency in fact produces the material of most of the so-called "Russia" and "Morocco" leather, sold in England for multitudinous purposes. There is no doubt that to the humble Cassia Auriculata we owe a great portion of the increasing prosperity of our half-tanned leather trade, and were we to follow the example of England, Scotland and Ireland, in adopting such floral badges as the rose, or the thistle, or the Shamrock, Madras might appropriately take as its emblem the pretty bright yellow flower of the Cassia.

Abundantly, though, as Cassia bark at present supplies our wants, we need not rely on it, and on myrabolams for tanning materials. The local abundance of babul bark has already been mentioned. The Australian press lately alluded to an apprehended scarcity of the wattle bark. This acacia has become a nuisance on the Nilgiri Hills, whence a supply could be produced in inexhaustible quantities. Mention was also recently made in the Indian Press of a shipment from Kandeish of Divi Divi for the London market. This tree was introduced fom South America many years ago. It grows freely with us, and produces its pods in abundance, and is well supplied with tannin. But for some reason it never came into extensive use, nor was it appreciated by the natives. It was employed to a considerable ex-

tont at the Government tanneries at Hoonsoor, and at the Artillery tanneries at Bangalore.

[*Cassia auriculata*, and its qualities and uses, have been frequently noticed in our columns. It grows plentifully in the Jaffna Peninsula, whore we have seen its foliage used for manuring the cultivated lands. The properties of its bark are also well-known to the fishermen. We do not see why plantatious of the shrub could not profitably be formed. We recommend the idea to enterprizing natives in the north and east of the island. Even Europeaus might find it worth attention. Dr. Bidie embodied much valuable information on the subject in his Melbourne Exhibition list, which we noticed at the time—August 1880. We should like to know the price at which the bark is quoted in Madras, as well as that of the thorny *acacia* which grow plentifully in the woodlands of the north and east of Ceylon.—ED.]

MR. FORBES LAURIE ON HYBRIDS.

It is all very well for Mr. Forbes Laurie saying "more anon," but while he is incubating we are in danger of being driven insane. We had scarcely issued our article dwelling on the fact that the singularity of "*C. robusta*," identical with *C. Lanosa*, and *C. pubescens*, was that, if a hybrid, as most planters believed, its seeds produced seedlings true to type, when the following letter reached us, shewing that, in the opinion of the great advocate of the hybridity theory, the seeds of hybrids do *not* come true to type :—

Leangapella Estate, Rangala, April 20th; 1882.

MY DEAR SIR,—In your editorial of 18th inst. I see we have auother name for newly-discovered cinchonas, found among others under cultivation. As a very careful reader of McIvor's reports and the Indian Blue Books on cinchona, I was under the impression that neither Pubesccns nor Lanossa came up true to seed, and this was the only complaint there was against them. I cannot believe in auy specially true form, and, from the many analyses I have had made, I find hybrids (spurts, if you will, or any fine names) differ vastly in the bark value. A very fine hybrid by no means uncommon in Ceylon, *C. Calisaya Anglica*, yields less quinine than succirubra, and an old tree very much resembles a Pubescens. There is also a very fine hybrid (to look at) which also resembles Pubescens, and which from the rounded form of the ends of its leaves I conclude to be a cross with Pahudiana, which has that peculiarity more than any cinchona I know. It is one of the handsomest and poorest of cinchona trees, yielding not more than ·90 of quinine at 4 years old. Now I very much want to know to what variety or form *Magnifolia* has been given. The finest leaves I have always seen grown from Micrautha seed varied in character, but all the plants were very robust in growth Also what is "Robusta"? Among the many analyses of hybrids I possess, there are none of high value without a marked resemblance to either some of the Officinalis forms or to Ledgeriana, and those very robust are often worthless, although resembling the finer kinds. One very handsome glabrous form at 4 years old gave ·60 of quinine. A good Pubescens selected from a clearing grown from seed (where only Succirubra and Officinalis are growing) gives on Howard's analysis 8·31 quinine sulphate with hardly any other alkaloids. More anon.—Yours truly,

WM. FORBES LAURIE.

How is a poor editor to preserve his five wits in the midst of a discussion where no principle is adhered to? Mr. Wm. Smith, that giant Philistiau, will of course triumph, both iu Gath and iu the Gates of Askelon, crying out: "Did I not tell you? Forbes Laurie is a vera clever callant, but he canna impeach the wisdom of the Creator by proving that *He permits* the confusion of hybridization." We hold that it is for Mr. Forbes Laurie to reply, and not for the editor of the *Observer*, who simply gave up his long cherished opiuions on evidence which he deemed to be unquestiouable.

What Mr. Broughton said about hybrids (the production of which he did not deny) was that they partook of the bad qualities of both parents and the good properties of neither. That opinion so discouraged Mr. McIvor that he, for a time, gave up his experiments. But he resumed them, and, out of a number of worthless hybrids, selected and grew *C. pubescens*, which gave to Howard's analysis 10 per ccnt of alkaloids. It is very true that the seed did not come true to type in producing trees equal to the original, bnt trees *were* produced, superior to the one parent (succirubra) in quinine and to the other (officinalis) in robust habit of growth; and our impression was that for several generations *C. robusta* had come fairly true to seed. Mr. Laurie's letter sends us all to sea again, and we must really ask him to lose no time in telling us all he knows about hybrids: their reality; their quality; and their permanency or evanescence. We have no pet theory to support, we are merely anxious to obtain and publish THE TRUTH.

"GRAPHITE" OR "PLUMBAGO."

The important admission is made in the recently published *Economical Geology of India* that, at the present day, nearly all the plumbago of commerce comes from Ceylon. We were told of finds in Australia, and we are constantly hearing of deposits in Siberia, Canada, the United States, and elsewhere. But either the mineral is imperfect as a carbon, or mixed with grit and impurities. The labour question is also an important factor in the question, and, although India is specially favoured in that respect, there seems at presenl no danger of Ceylon losing her practical monopoly in really good, pure plumbago. The only pity is that the demand for the article is not susceptible of more rapid expansion. Pure graphite, it appears ranges from 95 to 99 per cent of carbon, so that a perfectly pure piece may be said to be wholly composed of carbon. If we could now only discover the process of converting this pure carbon into diamond. Heat, pressure and "magnetism" are, probably, the chief agents of the conversion of an opaque body into a crystal. It is uot merely the abundance of the mineral in Ceylon but its general purity which gives our island the monopoly of the trade. For cylinders and lubrication, as for pencils, gritiu the carbon is bad. Our plumbago has literally, not metaphorically, *no grit*. We quote Mr. Ball's sum mary notice :—

Graphite or Plumbago: General Remarks.—Pure graphite, as found native, contains from 95 to 99 per cent. of carbon. The commercial values of the different qualities ordinarily found depend upon the amount of impurity which they include. Foreign matters can be got rid of by grinding, washing and the use of acids, and the purified product may be employed for all the purposes to which graphite is applied, but the process is costly, as the smallest particles of grit are

injurious. Formerly pencils were almost exclusively sawn out of the fine-grained massive qualities, such as that produced in the now exhausted mines at Borrowdale, in Cumberland.

The former high value which this still valuable substance possessed has no doubt been the cause of much of the importance with which deposits in various parts of India have been temporarily invested. The only one of these, save possibly that at Vizagapatam, which, taking into consideration its quantity and the means of transport, is of any present promise, is that which occurs over a wide tract in Travancore. Although the opinions of experts many years ago were unfavourable, it is conceivable that an increased demand and improved and more economical methods of purification might render its exploitation a profitable undertaking. At the same time the possibility of further search proving the existence of a quality equal to the better kinds found in Ceylon cannot be denied, as the probability is that the including rocks are of identical age.

At the present day nearly all the plumbago of commerce comes from Ceylon. It is classified under three heads, the prices of which in the London market on the 11th March 1881 were as follows:—

Lump	... ...	£17-10 to £19 per ton.
Chip	... ...	£10-10 to £14 ,, ,,
Dust	... ...	£ 8-10 to £10 ,, ,,

Although graphite occurs in many parts of the United States, it is only mined successfully at Ticonderoga in the State of New York.

It may be of interest here to enumerate the principal uses to which this substance is put. It is used in the manufacture of pencils, crucibles, stone or grate polish, as a lubricator for machinery, electrotyping, faces for moulds or foundry facings, refractory mixtures, and for giving a protecting surface to the interior of blowing cylinders in blast furnaces.

The pencils of the present day are made by mixing very finely divided graphite with a particular kind of clay in varying proportions according to the shades required. There is much adulteration in the black leads commonly sold; but for information on these subjects and on the various processes employed, reference may be made to the usual text-books.

Then follow a list of the places in India where plumbago or traces of it have been found. General Cullen reported it in Travancore in 1845, but Some samples, which were forwarded to the Asiatic Society from a locality south of Trivandram, were considered by Mr. Piddington to be too soft and scaly for the manufacture of pencils, *i. e.*, by the old method. The matrix appears to be a pseudo-laterite formed of decomposed gneiss *in situ*. One specimen now in the Geological Museum is covered with a salt efflorescence, and certainly, it may be said, judging from the various original samples in the collection, that without much grinding and washing they could not be made available even for the inferior purposes for which graphite is employed. Samples from this locality, Vizagapatam, and Almora, were exhibited in London at the exhibition of 1851.

Mr. King has sent samples of a much purer looking graphite, obtained during the present year from a deposit close to Vellurnad, near Arinaud; probably this locality is the same as General Cullen's. The veins in which it occurs are said to cross the strike of the gneiss. Apparently this not easily accountable mode of occurrence has been observed in America also.

It is, perhaps, needless to observe that the smallest particles of grit in graphite for pencils is most prejudicial, whilst for lubricating purposes, if graphite be not absolutely pure, it may be most injurious to machinery; for the coarser purposes of making crucibles the presence of iron would certainly diminish the refractory properties of the material.

More uncertain is General Cullen's alleged discovery of the mineral in Tinnevelly. Dr. King of the Geological Survey saw traces in the Kistna and Godavery Districts.

Vizagapatam District.—Graphite is stated to be found near Kasipuram, in the territory of the Maharaja of Vizianagram, also at Rampilli of Salur, and one or two other localities. It is used for giving a polish to pottery, and can be had in any quantity at a rupee for 24 lb. at Vizianagram. A sample, now in the Geological Museum, is included in a heavy ferruginous gneiss, and is not of very promising appearance.

In Bengal only one doubtful lump has been seen. In the Central Provinces it is too impure to be of commercial value. In Rajputana very inferior mineral is found, while plumbago is *stated* to be one of the regular productions of Northern Afghanistan. There is a long notice of discoveries in the Kumaun district of the North-Western Provinces, but the substance is so impure that

Under the circumstances of quality and position there are no grounds for believing that this graphite can ever be worked so as to become a profitable commercial commodity.

Equally valueless was a supposed deposit of graphite at the foot of the Darjeeling Hills, the percentage of impurities being equal to that of the carbon.

TEA.

Dealers are at present exercised about efficient methods of packing the tea for carriage. The old, long-standing system of packing tea in wooden chests lined with lead has been in force in China for centuries, probably. When the industry was started in India, we followed the same custom, but it has been found a failure. In the first place, the wood we used was not so tough, largely consisting of mango and other cheap and common woods; but more recently we have used teak. While the former was too fragile to admit of rough handling, the latter turns out to be too heavy for safe handling. The wood used by the Chinese is thin, light, and exceedingly tough. We imagine, however, the greatest mistake we committed was in using iron corner clamps or hoops. These made the boxes practically unyielding at the corners, and when a strain occurred, something had to give way. The Chinese, on the other hand, use wooden split hoops, which give and take, and a box seldom falls to pieces under rough handling. Another thing which induced us to turn our attention to some other material was the demand which has recently sprung up at home for half, quarter and eighth chests. The tare on these was out of all proportion to the net contents. An enterprizing firm at home started the idea of using tin boxes for these smaller packages, and considerable diversity of opinion exists as to the advisability of using tin for this purpose. Some hold the opinion that tea packed in tin is bound to acquire a metallic flavour, and that if it is at all damp, it must corrode the tin eventually. This is very true; but the objectors forget that if the tea is damp, it is only fit to be thrown away. Damp tea will ferment and decay, whatever it may be packed in. Some even go the length of remarking that it is questionable whether, even if tea be *thoroughly* dry when packed, the chemical constituents contained in it will not in some way combine (chemically) with the tin, and the tea imbibe thereby some kind of taint. Paper for lining is suggested as a palliative. We do not think that any one who has tried paper lining will repeat the expriment. Let tea be ever so dry, it will draw a certain amount of damp which seizes upon the starch in the paper and reduces it to pulp. The advantages of the tin boxes are many; if they are properly soldered down, the contents are impervious to weather; the same boxes can be used

again and again; the tin enveloping the tea is absolutely purer than lead, and tare can be adjusted with the utmost exactitude. There are other advantages, but let these suffice. The contents being absolutely shut in from atmospheric influences, the net weight of the packages do not vary. It is well known that the nett contents of chests vary considerably, through the drying or absorbing of moisture, as the case may be, and this leads to much confusion in accounts and much vexation of spirit to the unfortunate planter. We trust that this mode of packing tea will become more universal, especially for boxes up to 50 lb., and no chest need contain more. There is nothing to hinder each planter having a couple of tin-smiths on his estate, to make his own boxes. We saw them used on a factory in the North-West, half-a-dozen years ago, and no complaints were ever made as to deterioration in packing.—*Friend of India.*

[What we have *heard* is that from the impossibility (alleged) of getting the separate pieces of tin boxes to join together with perfect closeness damp is admitted *en route* to selling market. Will those who have used, or who are interested, in tin boxes say how far such objections hold good and how they can be obviated?—ED.]

COPPER IN INDIA.

In Peninsular India copper ores are found in the older crystalline or metamorphic rocks; and in the extra peninsular regions in a highly metamorphic rock of an uncertain age. Usually they occur disseminated, or in nests, rarely in true lodes, although occasionally cracks and fissures of rocks which have become infiltrated, yield a deceptive semblance. Bellary, Kurnool, Cuddapah and Nellore are the chief localities of occurrence in this Presidency. The ores are also obtainable at Somadupilly and Agriconda, in the same district. In the latter, large pits made by ancient miners are still apparent. Malachite and azurite are found on the surface surrounding them. Five or six miles from the cantonment of Bellary, Hyder Ali appears to have turned his attention to copper mining, but his success was so slight that the endeavour was quickly abandoned. So recently as last year, an application was made to the Madras Government for mining rights here; but the request was not complied with.

It is to the district of Nellore that, in the matter of latent copper, must be yielded the palm. Here mines seem to have been in existence during the days of the early Hindu monarchs, and, when these princes were swept away, the conquering Mahomedans continued excavations. At Gunnepenta, large amounts of refuse left during the process of reduction are still monuments of this ancient industry. Thirty miles south of this village, at Garganpully, old mines of a depth of 30 and 100 feet are to be seen. In 1830, in 1831 and in 1840, various attempts in mining were made by Europeans, in each case with no permanently profitable returns. In 1867, a request was made to the Madras Government that a lease might be given, but the proposal was rejected. The quality of the ores varies much. Thus occasionally specimens containing fully 75 per cent. of copper are procurable in some places, whilst in others they are largely mixed with quartz and iron. Mr. William King, who is well known as a cautious observer, states it as his opinion that failures in this district have hitherto been due to a want of knowledge on the part of the operators rather than "to a deficiency in either the quantity or quality of the ore." He classifies the specimens sent to him by Mr. Lavelle, who carefully explored most of the localities, as follows:—

A.—Chrysocolla (in garnetiferous schists, of which the garnets, though small, might from their colour and transparency be called precious garnets.

B.—Copper glance (chalcocite), chrysocolla and malachite.
C.—Chrysocolla, malachite and ferruginous red oxide.
D.—Copper pyrites, chrysocolla and malachite in limonite.
E.—Copper glance with chrysocolla and malachite.

Should mining ever be carried out in Nellore, it is satisfactory to know that boats can convey the ore to Madras at a cheap rate.

As far as we are aware, no reduction of copper is at present carried out by natives in this Presidency. The import of English metal has long since annihilated the industry, owing to a great extent, as we pointed out the other day, to the dearness of fuel in this country. The typical method of reduction followed by natives may be assumed to have been similar to that still conducted in certain native states. The face of the rock in which working is to be commenced is split by use of heat, and is subsequently worked in narrow tunnels by the gad and hammer. The ore extracted is pounded into a condition of powder, rolled into a ball by means of cowdung, and subjected to a preliminary roasting. It is then placed in a furnace, built partly of mud and fire clay, in which the hearth is formed by filling a pit of about fifteen inches in depth with common sand. The nozzles of two or three ordinary country bellows are inserted near the bottom to produce the blast. These furnaces are charged with alternate layers of charcoal, roasted copper ore and iron slag—the latter being used as flux. The slag is drawn off at a hole specially left for it, whilst the copper, being received in the sand pit or hearth, is removed after cooling.—*Madras Mail.*

THE PLEA OF THE PLANTER.

Good people of Britain of every degree,
Who love to consume either coffee or tea,
Give ear to my counsel, attend!
For your taste is *not* chaste, and your faith is misplaced
In men who've the trade of your country disgraced:
I speak to you now as a friend.

Tea and coffee are made by "the tricks of the trade"—
Many mysteries mingled—oh! be not dismayed—
From rubbish both ancient and new:
Microscopical skill, diabolical will
Are united with fraud to adulterate; still
It is done but to gratify you!
For the grocers they say, in their own lying way
That you are unable to drink either *sole*,
And it takes a few particles mixed with strange articles
Just to produce a delectable whole.

Tea and coffee are bettered, they say, if unfettered
By purity's bonds; so they cunningly bleud
Rubbish that shall, it is said, suit your palate;
Sweepings and refuse of kinds without end.
Ground acorns and straw, boiled turnips or raw,
The retailer sells these and a great many more:
Anything suits your elegant taste!
And hence an economical law
Is established: there shall be no door
Open in Nature's general store
To allow such a thing as waste!

Coffee and tea should always be
Mixed and blended until you see
Only the title (N. B.) remains:
Sickness and death may both be hid
Within the wrapper or under the lid
But the British public is only bid
To add to the grasping grocer's gains.

Any litter and dust, all refuse and shavings,
These will, of course, all satisfy cravings
Felt by even the most refined;
For, if only you pay so much per pound,
What can it matter what matter is ground?
Rubbish must pass while fools are found,
And the mixing machine will still go round
Till reason enlighten your m[illegible]!

Ninety per cent of chicory, peas
Broken cabbage stems, beans, all these
Are trifles that your retailer may please

To convert into coffee (these do not make teas):
Market-garden haulms
Carefully blended with ten per cent
Of low-class coffee, to give it a scent.
Yes! and a *name*, for that 's what is meant,
Just to prevent your qualms!

You ask for "coffee" or "tea," but dare
Not ask for what you know to be there
Mixed and sold to you under the glare
Of a gaudy label that looks so fair
That nothing, it seems, could be truer:
And the smooth-tongued tradesman pockets your pence
And laughs to himself at his pretty pretence,
And wonders if you will ever have sense
To see that you buy what is pure.

Few of you, doubtless, have ever seen
Such a thing as a coffee bean,
And not knowing whether it 's blue, red, or green,
You prefer the brown mixture that's sold you;
While the used-up leaves from the Chinese "hong,"
Packed as "new teas," *ab usu* belong
To the British public just as long
As ignorance is within you strong
And you are bound by the tradesman's th ong
And scorn what your friends may have told you!

If a nobleman lends his name to such ends
As date-grit and dirt-miscifacturing blends,
To get him a living, why, let him?
Posterity will not enshroud him with fame,
And you, if you 've sense, will soon clothe him with shame
And then do your best to forget him.
Do you think the Creator, mistaking His plan,
Made coffee a poison, and left it for man
To improve and complete his design?
Or that company-mongers' sole object is just
To benefit man, not to gratify lust
In deceiving their fellows, seducing their trust:—
Is this your belief? 'T is not mine.

You retailers, 't 'is useless to offer to you,
Of course, any words of good, honest advice;
For from all that is moral and upright and true,
By nature and habit, I may say you are
As distinctly removed as is water from tar,
Or as earth from the sun, or the tropics from icc.
Pestiferous knaves, may your trade fall away
As fast as your ill-gotten gains have been made.
Bring forth all your filth to the light of the day,
And eulogize dirt without any hired name:
State all its merits: its value: its aim!
Then take note what the public say,
Also how much a pound they pay
And whether they utter cries of "Shame,"
Or whether they praise *free* trade!

Now, you ladies who love to believe that you know
A really fine tea from a compound pekoe,
Have you never a sense of disgust
To think that yourselves and acquaintances drink
Poison from which your own grocer would shrink:—
Filings, turmeric, dust?
You ladies still younger, the fair coterie
Whose attendance adds charms to the 5 o'clock tea,
I appeal just as strongly to you:
Do you think to retain all the freshness of youth
By drinking a mixture—I speak but the truth—
Of willow-leaves dyed Prussian blue?

Now, you labouring men and you slaves of the pen
Who sometimes take coffee to keep your heads clear,
Don't you think acorns crushed and all such rubbish must,
Be it even well blended with chicory dust,
Be considered, to say the least, dear
At tenpence per lb., yes, though bought finely-ground
And labelled in language attractive? You 've found,
Perhaps, it saves trouble to pay even double
The price of good coffee for coffee's good name?
Yes! you pay for the name on the wrapper or tin,
Not for the poison (*that 's* worthless) within.
How long will you foster the dealer's foul aim?

Her Majesty's Customs, for twonpece per lb.
Will admit any rubbish that's roasted and ground,
Any substance, in fact, that 's well broken and browned;

Oh, fair trade, how unfair thy expedients!
For consumption of coffee does not now increase
Although this should be one of the blessings of peace,
But rather it seems from its steady decrease
That imports of coffee should very soon cease
If "my lords" can get "foreign ingredients"!

Now, my Treasury lords, fit figures for *boards*,
Let us see if you 've *fibre* within you:
You can *deal* out an answer evasive and brief
To a body of men who implore for relief:
Can a little fair argument win you?
You were raised to your present position—we 'll now
Not stop to enquire whether nobly or how,
But if you should chance to pursue
A course that is honest and moral and right,
As far from your present as darkness from light,
Would it bring but disaster to you?

You would lose the support that so boldly you bought
By worshipping freedom of trade:
You are tethered to dirt and you cling to the skirt
Of the creed whose professions you 've made.
Yes! you lordly commissioners hold a position as
Likely as not to degrade.
But public opinion and taste must improve
Ere justice will rise such low acts, to reprove
And come to morality's aid.
For "my lords" (I but quote from a Treasury note)
"Deem it their duty restrictions to move,
If trade demands trash," lest their interests clash
And things don't go on in a calm, easy groove.
For votes must be bought, though the poor may be taught
To fatten on garbage well blended by law,
And the goddess of fraud takes the head of the board,
Whom every commissioner 's bound to adore!

Oh, people of Britain, a final appeal
I make for your own and the general weal,
In the hope that good judgment will solemnly seal
A compact firm, lasting and sure.
For your planters are sorely tried abroad
With adverse seasons, and London's fraud
Is more than they can endure
So I ask you again, as I once have before
Asked you, never to drink any more
Rubbish or dirt, though imported by law—
But to see that you drink what is *pure*.

AUSPEX.

Ceylon, 24th April 1882.

ANTS AS INSECTICIDES.

It is a curious coincidence that just as we had written our remarks about ants and termites the papers from China should have brought us the interesting paper by Dr. MacGowan of the American Baptist Mission, which we place below. Dr. MacGowan is an observer and naturalist of considerable mark, and some of our readers may recollect that we copied into the *Observer* so long ago as a score of years back, a paper by him describing the mode in which the Chiuese obtain nacre-covered images of Buddha and ornaments of all descriptions, by placing them between the valves of a mollusc cultivated for the purpose. He now gives us information which shews that the Ceylon idea of employing red ants as insecticides, however ingenious, was not original. The Celestials, in fact, seem to have discovered everything, from the mariner's compass to the employment of red and yellow ants to rid the orange orchards of worms. Captured in bladders filled with lard, the ants seem at once to get domiciled in their new aerial abodes, walking from one tree to another on the bamboo rods provided for them, in quest of their prey. The worms referred to may probably be identical with those which infest oranges in Ceylon, if the fruit is allowed to ripen on the trees, a fact mentioned by that wonderfully careful observer, Robert Knox, in the account of his captivity in Ceylon. The question is how the fruits, when ripe, are collected without the labourers suffering from the attacks of the ants? Probably one reason

is that the Chinese horticulturists are more fully clothed than are the ordinary natives of Ceylon; and it may be that the red and yellow ants of China may not be so furious and venomous as are their congeners in Ceylon. The great red ant of Ceylon, the *dimiya* of the Sinhalese (*Formica smaragdina*, FAB.), is a truly formidable insect, as persons have had reason ever to remember who, unwittingly or purposely, have broken one of the nests which they form by glueing the leaves of trees together, and have consequently received a shower of red ants about the region of the neck and shoulders. Tennent writers of the red ant :—

"It is particularly abundant in gardens and on fruit trees; it constructs its dwellings by glueing the leaves of such species as are suitable from their shape and pliancy into hollow balls, and these it lines with a kind of transparent paper, like that manufactured by the wasp. I have watched them at the interesting operation of forming these dwellings. A line of ants standing on the edge of one leaf bring another into contact with it, and hold both together with their mandibles till their companions within attach them firmly by means of their adhesive paper, the assistants outside moving along as the work proceeds. If it be necessary to draw closer a leaf too distant to be laid hold of by the immediate workers, they form a chain by depending one from the other till the object is reached, when it is at length brought into contact, and made fast by cement.

"Like all their race, these ants are in perpetual motion, forming lines on the ground along which they pass, in continual procession to and from the trees on which they reside. They are the most irritable of the whole order in Ceylon, biting with such intense ferocity as to render it difficult for the unclad natives to collect the fruit from the mango trees, which the red ants especially frequent. They drop from the branches upon travellers in the jungle, attacking them with venom and fury, and inflicting intolerable pain both upon animals and man. On examining the structure of the head through a microscope, I found that the mandibles, instead of merely meeting in contact, are so hooked as to cross each other at the points, whilst the inner line is sharply serrated throughout its entire length; thus occasioning she intense pain of their bite, as compared with that of the ordinary ant.

"To check the ravages of the coffee bug (*Lecanium coffeæ*, Walker), which for some years past has devastated some of the plantations in Ceylon, the experiment was made of introducing the red ants, who feed greedily on the coccus. But the remedy threatened to be attended with some inconvenience, for the Malabar coolies, with bare and oiled skins, were so frequently and fiercely assaulted by the ants as to endanger their stay on the estates."

Tennent, after describing inoffensive ants states that besides the *dimiya*, there is another ant of similar size and ferocity which is called by the Sinhalese *kottideya*. Regarding this ant they have a legend that the *cobra de capello* invested the insect with her own venom, in admiration of the singular courage displayed by these little creatures. It is not means of procuring and using ants as insecticides, about which some of our correspondents are anxious in Ceylon, but the best means of destroying what the Chinese value and pay for. It seems to us that, as formic acid is plentiful in all the ant tribe, the best mode of destroying the ants without injuring the trees would be a plentiful application of caustic lime, the nests being previously opened up by a pole, so as to receive and retain the lime. Corrosive sublimate would effectually dispose of the insects, but its use would be expensive and dangerous. Has carbolic acid received a fair trial? If the orange growers of Ceylon could be induced to leave fruit on the trees until turning yellow, they, to circumvent the little maggots to which we have referred, might be glad to be allowed to collect the red ants which are such a nuisance to cultivators of Liberian coffee. We have myriads of ants in Ceylon, some very curious and some of large size, but we cannot compete with the one-legged ant, which can move but not "locomote," as Dr. MacGowan's countrymen would say. As to size, we must certainly draw the line far short of the dimensions of that other one-foot pickled ant in China which measured 12 inches in length. We are, we confess, taken considerably aback by what Dr. MacGowan states of the scaly ant-eater (the pangolin) apparently as of his own knowledge, and not as derived from Chinese gossip or tradition. The creature exists in Ceylon, and its habits have been carefully observed, Tennent finding them very affectionate pets. We have never heard or read that the so-called "armadillo" attracted the ants by its odour, or used its armature of scales for any purpose but that of defence. When attacked it rolls itself up like a hedgehog, and its tail scales defend it, like a coat of mail. But the only mode in which it is believed to take its prey is by thrusting out its long and worm-like tongue, covered with a viscid substance. On to what probably they take for a specimen of ophidian, *Cæcila glutinosa*, the ants crowd and cannot get away until at the ant-eater's convenience the tongue is retracted and all that covers it, including little pebbles and sand, which probably help digestion, are conveyed to the creature's stomach. We are surprised to find Tennent stating that the natives regard this innocent and interesting creature with aversion, some calling it "the Negombo devil." What we heard was that they prized its flesh, and to this propensity we attributed the loss of a specimen which we were about to ship to England. The creature not only defends itself with its tail, but stands on this organ as on a fifth foot, and surveys the landscape. Such a tail beats that of which O'Connell was the head, and has more cohesion than the tail of the traitor Parnell has been proved to have had under the test of the Clôture.

In the article on "Ants" in Chambers's Encyclopædia there is a large amount of valuable information, but the writer does not seem to have seen Tennent's books, as there is no reference to ants in Ceylon. But we find full details of the fearful plague of ants in Grenada alluded to briefly by Dr. MacGowan, thus :—

About ninety years ago, prodigious numbers of a particular kind of ant (*F. saccharivora*) appeared in the island of Grenada. This species makes its nests under the roots of plants, and the sugar-canes were so weakened and injured in consequence, that the plantations became nearly unproductive. 'They descended from the hill, like torrents and the plantations, as well as every path and road for miles, were filled with them. Rats, mice, and reptiles of every kind became an easy prey to them; and even the birds, which they attacked whenever they lighted on the ground in search of food, were so harassed, as to be at length unable to resist them. Streams of water opposed only a temporary obstacle to their progress; the foremost rushing blindly on certain death, and fresh armies instantly following, till the bank was formed of the carcasses of those which were drowned, sufficient to dam up the waters, and allow the the main body to pass over in safety below. Even fire was tried without effect. When it was lighted to arrest their route, they rushed into the blaze in such myriads as to extinguish it.' A reward of £20,000 was offered in vain for an effectual means of destroying them; but in 1780 a hurricane which tore up the canes, and exposed their habitations to a deluge of rain, freed the island from this plague.

The provisions for defence and offence of these curious creatures are thus described :—

The females and neuters of some kinds (genera *Ponera*, *Myrmica*, *Atta*, and *Cryptocerus*) are armed with stings; other kinds (*Formica* and *Polyergus*) have no sting, but have the power of ejecting a peculiar volatile acid, formic acid (q. v.), from a small sac in the abdomen; by this means effectually repelling many adversaries, to which the pungent fumes are intolerable. Small animals are soon killed by the vapour of an ant-hill, and a dog has been known to retire yelling from the effect upon his eyes, either of the vapour, or of a discharge of the fluid itself. It is

said, that when those ants that are unprovided with a sting make use of their mandibles to inflict a bite, they curve round their abdomen, so as to be ready immediately to squirt this acid into the wound.

Our readers are, of course, familiar with the stories told of ants keeping herds of *Aphides* for the sake of honeydew and tapping them as human beings keep and milk cattle; and, if we are to credit all that is told us, the slaveholders of the West India islands and the Southern States could, as the planters of Cuba or Brazil still can, quote the example in their favour of the species of pale-coloured ants which make slaves of the black coloured.

THE UTILIZATION OF ANTS AS GRUB DESTROYERS IN CHINA.

The *N. C. Daily News* publishes the following paper by Dr. Macgowan of Wenchow:—

Accounts given of the depredations of the *coccids* on the orange trees of Florida induce me to publish a brief account of the employment by the Chinese of ants as insecticides. In many parts of the province of Canton, where, says a Chinese writer, cereals cannot be profitably cultivated, the land is devoted to the cultivation of orange trees, which being subject to devastation from worms, require to be protected in a peculiar manner, that is, by importing ants from neighbouring hills for the destruction of the dreaded parasite. The orangeries themselves supply ants which prey upon the enemy of the orange, but not in sufficient numbers; and resort is had to hillpeople, who throughout the summer and winter find the nests suspended from branches of bamboo, and various trees. There are two varieties of ants, red and yellow, whose nests resemble cotton bags. The "orange ant-breeders" are provided with pig or goat bladders which are baited inside with lard; the orifices of these they apply to the entrance of nests, when the ants enter the bags and become a marketable commodity at the orangeries. Orange trees are colonized by depositing the ants on their upper branches, and, to enable them to pass from tree to tree, all the trees of an orchard are connected by bamboo rods.

Is the orange the only plant thus susceptible of protection from parasitic pests? Are these the only species of ants that are capable of utilization as insecticides? Indubitably not; and certainly entomologists and agriculturists would do well to institute experiments with a view to further discovery in this line of research. Lest, however, the United States Entomological Commission or Société d'Acclimatation of France should undertake to acclimatize these Cantonese formica, I must interpose a word of caution. There is found in the same province, in the part of which Swatow is the port, an ant that is a foe and not a friend of agriculture. It is called the "horse-ant," from its fancied equine appearance. Horse-ants are so destructive that a temple has been erected for the worship and propitiation of the Ant God, the producer and ancestor of ants. During the fifth month of every year the ants assemble to pay court to their progenitor, which is the season when farming people present offerings to the Ant God, praying that the ravages of the insect may be minimized. The introduction of this species into America or Europe would be calamitous. I shall make due acknowledgment of specimens of ants that may be forwarded to me from Canton and of information respecting the orange insect and specimens. * Here I might conclude this communication, but, as Sir John Lubbock has recently added so much to our knowledge of ants, many people in many lands have become curious to study further the habits of this remarkable insect. I append therefore a few remarks, which will show that the British legislator might find much in China to reward painstaking research.

What Pliny heard respecting a gigantic ant in India, the size of an Egyptian wolf, reached China somewhat exaggerated; while an Encyclopædia states that red ants are found in the western deserts as big as elephants and that they kill people! What, however, Chinese writers state concerning the ants of their own country is not incredible. Before they acquired the art of writing these observant people had noted the most characteristic feature of ants—their orderly submission to authority; and therefore, when writing began, they devised a character expressive of this trait of the formica, composed of "insect," and, for the phonetic element, "that which enables the heart to rule itself, the rule of self-dignity and respect, what is proper and just *per se*;" because, says lexicography, the ants have princes and ministers, implying intelligent administration and obedience. A further evidence is furnished of their regard for equity in their uniting to inflict capital punishment on offenders, and in their co-operative and communistic proceedings with regard to food. Patient observations have been made of their subterranean abodes. It has been discovered that they live in cities which have crenelated and carved walls, within which are regular streets, dwellings, galleries and markets. In one of these cities two magnates were observed, one of a purple color, with wings and legs of golden hue; in another, a regular court was observed, the prince giving audience to a privileged few, menial officers at a distance keeping order. On quitting their nests, they sometimes march five abreast in military rank. They afford prognostics of wet weather, knowing well when it is about to rain; to protect themselves from deluges they close up the apertures of their nests. In classic times a military leader being in straits for water was advised to observe the position of ants' nests—which in winter are to be found on the southern acclivities of hills, and in summer on the northern aspects—and to dig for water where their earthworks were to be seen; and on digging as directed water was obtained. Their passion for carrion is particularly noticed by native naturalists, and the predacious and pugnacious character of ants is often referred to. They have been seen fighting in pairs, advancing and retreating in duels a whole day and night. Several of their battles have been recorded, having obtained this distinction in consequence of civil commotions that followed, of which they were considered to be portents. In the year 466 A. D., black ants and reddish ants in Shantung fought in great numbers, filling a space forty yards long and four inches wide. The red ants were destroyed. About a century later another great action is recorded between yellow and black ants at Nanking, when the former entirely perished. There is no record of enslavement of black ants by white ants in Chinese natural history. Either slavery has not been observed among them, or they have not attained to that stage of advancement. In battle they show no quarter, whether the fight is among their own or against other colours.

The sudden multiplication of ants has been noticed; but no such disaster is recorded as that in the island of Granada, which a century ago was devastated by this formidable race. In 636 A. D. the capital was amazed by the appearance of ants covering a space of forty yards in length and five to ten feet wide, and piled over each other from six inches to a foot in thickness! Ants of large size, both red and black,

* Since writing the above I have met with a passage in the Botanical Encyclopædia of Hsu-kuang-ch'i, the Christian statesman and philosopher (a posthumous work 1640) which seems to indicate that ants generally may be employed for protecting the orange. Under orange culture he simply directs the placing of ants' nests on tree-tops, which, he adds, will drive away the worms that injure that fruit.

abonnd in the hills of Ningpo, and, as their bite is rather poisonous, the inhabitants would suffer greatly from them but for the *manis javanica* or pangolin, the scaly ant-eater. The odour of this animal attracts the ants, as it lies with all its scales open, beneath which these insects press in swarms; then, when the scales close upon them, their captor repairs to his lair, and drops the asphyxiated ants preparatory to their deglutition. These ants are said to be betweeu two and three inches in length, which is not at all incredible, if we can believe a statement published respecting a dismissed functionary in Chaoncbon, who sent to his friends iu the north, an ant pickled in salt, which measured a foot iu length!

On the borders of Tungking ants' eggs are so abundant that a pieul and a half are sometimes collected by hunters. Perhaps larvæ are meant. They are considered a great dainty, resembling flesh in taste. A certain species of red ant, which makes its nests on tree-tops, are also eaten with ginger and salt, used as a condiment. It is very pungent. White ants are used as food, but, being no ants at all, but termites, have no place in this note. Ants possess medical properties, and before formic acid was prepared by chemists, they were accordingly used in the west. It is strange that the Chinese pharmacopeia, which abonnds in bizarre materials, should not include this insect unless the "singlefooted ant", to be named in the sequel, belongs to the formica Chinese pharmaccutists, however are aware that ants yield "vinegar," and the earth of ant-mounds, which is probably saturated with the acid or a formicate, is an article of materia medica. Ants have been turned to use also in the arts. A brief notice of a varnish-furnishing ant is found in an old work. "Records of the Wu State," in one of the districts of which, Changchou or Suchan, a cottony creeper grows, beneath which ants have their abode. By piercing the ground with the bark of the creeper, ants climb up it, and these produce varnish.

In conclusion I may mention a unique insect which is denominated the "monopedal ant," and which the early *Puntsau* recommends for boils and ulcers, the insects to be applied locally after being crushed. This "ant" has but a single leg by which it is permanently attached to the roots of a tree, and it possesses the power of motion without locomotion!

THE RAVAGES OF "GRUB" IN CEYLON: PROPOSED ACTION IN THE MATTER.

The correspondence we publish today shews that "some one had blundered," so that a letter intended to reach Dr. Trimen when Mr. Ward was still amongst us did not reach the Doctor at Peradeniya until the Mycologist had closed his own life history in Ceylon, as well as the whole life history of the left fungus. Would that he had closed the latter in he sonse we all desire, and would that we could hope for anything better than learned and interesting dissertations on insect life from an entomologist specially sent out or a cöterie of consulting entomologists iu Europe. "Bug" is the generic term for insect in the United States, and the "bug" literature of that great country is in proportion to its vastness and the multitudinous pests which ravage the cotton fields, eat up the wheat, and choose (chews) tobacco as a luxury when sated with more solid food. Our readers are of course familiar with the story of the Yankee farmer who going out to see what was left of his tobacco plantation had insult added to injury. The grasshoppers, having made a full clearance, were arranged along his fences, *squirting tobacco juice at him*! The poor fellow may be forgiven if he felt a little "mad," with the devastating "cusses." We have read and are still reading volumes and journals of "bug" literature, taking in everything between "the army worm" and the "Katydidr, and propounding innumerable remedies. But one after another has been pronounced impossible or ineffectiv." If we could venture to enclose flocks of pigs in our coffee, we believe they would make short work of the grubs—but also perhaps of the coffee bushes. Full and certain information respecting the varieties of "grubs," and the winged insects which originated them and into which they turn, cannot but be valuable, and an effectual and cheap and possible remedy *may* be discovered. If, in the course of our reading, we can find it out, we shall let our readers know. "London purple" and a score of other things are effectual, if we can follow the directions of the person who invented a liquid for the destruction of fleas: "Catch them by the neck and pour it down their throat."

CORRESPONDENCE BETWEEN THE PLANTERS' ASSOCIATION OF CEYLON AND THE CEYLON GOVERNMENT.

ON THE SUBJECT OF THE RAVAGES OF GRUB, AND THE SERVICES OF A NATURALIST.

The following has been sent to us by the P. A. Secretary for publication.—

Colonial Secretary's Office, Colombo, 27th Feb. 1882.

SIR,—With reference to your letter of the 16th April last, I am directed to inform you that the Director of the Royal Botanic Garden at Peradeniya has been consulted on the matter in question, and I forward herewith for the information of the Planters' Association the reply received from Dr. Trimen.

2. The Governor desires me to state at the same time that, if the suggestion therein made should be adopted, he will be glad to forward the statement to the Secretary of State and to ask him to procure the best scientific advice obtainable in England as to the best remedial measures.—I am, sir, your obedient servant, (Signed) J. A. SWETTENHAM.
for Colonial Secretary.

The Secretary, Planters' Association, Kandy.

Royal Botanic Garden,
Peradeniya, 15th February, 1882.

The Hon. the Colonial Secretary.

Sir,—In reply to your letter of the 27th April 1881, which is now received by me for the first time (as an enclosure in your letter No. 10 of 6th February) I have the honor to inform you that I could scarcely feel justified in undertaking an investigation of such importance and difficulty on a subject outside of my own studies. Such a piece of work would also of necessity require that much time should be spent on estates, and this I could not give without neglecting the proper supervision of the gardens under my charge.

2. It is to be regretted that I did not receive your communication at the time when it was written,* and Mr. Ward was still in the island, as he might have been willing to use his opportunities during his frequent journeys in the coffee districts of collecting information on this insect pest; but I feel sure he would not have considered himself competent to take up a question of entomology.

* "The reason why" should be stated. It is a new style of business to write to a man in April of one year and send him the letter only in February of the next.—ED.

3. I believe, however, that the main facts regarding the natural history of grub are pretty completely known, and, failing the special appointment of an Entomologist, I would suggest that the Committee of the Planters' Association draw up a succint and plain statement of the points in connection with the insect upon which they require information and advice, especially what have been the remedial measures hitherto employed and in what respects they have been found wanting. If this is forwarded to me I have good reasons for believing that I can obtain from the principal authorities on economic entomology at home answers and suggestions which may prove of service.—I am, &c., (Signed) HENRY TRIMEN, Director.

MORE ABOUT "GRUBS" AND THE MEANS OF THEIR DESTRUCTION.

With reference to the resolution about white grub, passed at a late meeting of the Maskeliya P. A., which we publish today, we learn that the Colombo firms interested have already been addressed on the subject. It is undoubtedly of the first importance that steps should be taken in concert to fight this pest, and it is only hy combined action on the part of the Colombo agents and the resident proprietors that anything approaching a general victory can be gained. It is now almost too late to commence catching the cockchafers this season, as it is principally while the hot weather lasts that their evening flight takes place, and by this time most of the eggs have been deposited. It behoves, however, every superintendent to satisfy himself, in the first place, whether his estate "has grub" or not; for it is quite possible for both the beetle and the grub to remain unnoticed until the result of the ravages of the latter becomes apparent in the going off of the coffee. Fortunate he who can decide this question in the negative. If, on the other hand, it should appear that the beetles are present, not a moment should be lost. Now is the time to act. Careful experiments, we are told, carried out by an experienced planter, during last season, have shewn that an application of lime at the root of the coffee trees has the effect of either preventing the eggs from germinating or driving the small grub away from the parts so treated; in any case freeing the ground of the pest to the great advantage of the tree, and helping the latter to recover conditiou at the same time. No doubt other applications could be recommended and might prove equally efficacious. More or less success has attended digging out the grub, covering the soil with sacking, etc., but, for a practical and at the same time comparatively cheap method, nothing has yet been attempted that can compare with lime applied as described. A ton of caustic lime per acre would be a very sufficient dose, and those interested can easily calculate the cost of such an application, which, of course, need only be applied where the grubs were known to be in force. It must, however, as we said before, be taken in hand at once, and we would urge upon all those in command of the purse-strings of any estate where grub is pronounced to be, to sanction an immediate expenditure for the purpose.

THE CEYLON BOTANIC GARDENS.

Through the courtesy of the Government we are able to give Dr. Trimen's elaborate and valuable report on the gardens under his charge. It will be seen that in regard to scenic beauty as well as utility great improvements are being made at Peradeniya, light and air being admitted by the thinning out of superfluous trees, to the great advantage in growth and beauty of foliage and blossom of those which remain. As well-trimmed grass plots are amongst the chief elements of attractiveness in such institutions, we hope the Director's demand for a good lawn-mowing machine will be favourably met by Government. The increase of carriage traffic on the roads shews that the Peradaniya gardens are increasing in favour with the "driving" portion of the public. A "new South Garden" is being added in which trees are to be planted according to their natural affinities. This is what was done at Buitenzorg in Java from the beginning, and the effect in some cases is astonishing: until we saw the screw pine compartment, we could not have believed that the world contained so many varieties of this curious plant, in Ceylon generally semi-aquatic and standing on natural stilts, as it were. The natural order to which our jak and breadfruit trees and the *del* belong was still more numerous and varied. In the new gardens at Peradeniya about 250 species have been already fully established, and the work is to go on. There is a new carriage drive from which ultimately will be viewed one of the best collections of palms in the world, for Dr. Trimen informs us that "palms grow here with a perfection that cannot be surpassed." This consoles us somewhat for the continued failure of all attempts to grow aquatic plants on the little lake. There are the shade and leaves of the gigantic bamboos and the foul bottom of the water, In the Buitenzorg Gardens, *Victoria regia* flowers very freely; but we found Dr. Treuh agreeing with us that the flowers were scarcely superior to those of the ordinary water lily. The broad flat leaves were the striking features on the water in front of Government House, grounds which were "Verboden" to the general public, who were welcome to the botanic gardens. Through it indeed lies a thoroughfare, an avenue of grand old trees, which were well grown even when Stamford Raffles buried his first wife in their shade.

What is said about the prickly rattan palms suggests the idea of cultivating these with sapan plants to form impenetrable fences for lowcountry estates. Woe to the human being or animal which attempts to break through a tangled mass of thorny rattan. Trinidad cacaos and their shade trees are to be grown together, with rubbers, varieties of coffee &c., and it seems a good idea to form nursery beds round a small circular water tank. Our planting readers will note that iron nails are apt to make serious wounds in trees in a damp climate, and that zinc labels when painted get quickly covered with dark fungi producing the effect of London smoke. Has Dr. Trimen noticed how rapidly lime applied to buildings in Colombo gets blackened as if with old age? We suppose a fungus is responsible for this? Where *kirimeti* (kaolin or pipeclay) is applied to reepers near the seaside, the fungus which speedily covers the clay

is of a vivid green colour. We find it difficult to persuade visitors to a seaside verandah that the reepers were not painted green. Some of the old ground at Peradeniya is to be converted into an artificial swamp for the growth of sago trees. Sago is so plentiful already that it is used in England to feed up calves. We doubt if much profit can be expected from the cultivation of this aquatic palm in Ceylon. In the Hakgala gardens, it appears that Mr. Clarke, while in charge after Mr. Edward Thwaites left and before Mr. Nock arrived, was successful in growing Ledgeriana grafts on succirubra stocks, which was well, as the Ledgerianas in the clearing were dying off. Dr. Trimen intends that Hakgala should be worked as a branch of the main institution and devoted to temperate and subtropical plants. Except to keep up the different species, the Hakgala gardens are no longer required for cinchona propagation, and the opinion of Dr. Trimen expresses of the situation and climate is a perfect contrast to the *couleur de rose* description given by Mr. C. Markham, after his visit to it. Drugs, dyes, fibres are to be the subjects of experiments. Fruit and vegetable cultivation are to receive further trials, and shade and shelter trees for estates are to be grown. But a good propagating house is wanted. The Hsnaratgoda Tropical Gardens have succeeded so well that the experimental gardens at Anuradhapura are to be takon over by the department. Ultimately, we suppose, there will be a garden in each Province, and why not at the capital, Colombo? The operations of the Commission on the introduction of useful plants are referred to, and then as regards our suffering chief staple, Arabian coffee, the "paralyzing notion of the discovery of a cure" is denounced and planters and the Government are asked to combine to destroy spores and prevent their spreading. On worn-out land all coffee trees should be destroyed, and most of the native coffee should meet the same fate, Government giving the natives Liberian trees in place of the inferior species. For the entire disappearance of the destructive fungus, Dr. Trimen does not look, only that by means of combined measures "a sensible and sustained diminution in leaf disease" would result in a considerable recovery in the staple product of Ceylon. But how is com, bined action on a sufficiently large scale to be secured. Arbitrary legislation would be needed, and means to enforce it. Dr. Trimen speaks well of Liberian coffee although in this report he does not refer to the large proportion of disease-resisting plants. With regard to Ledgerianas and other cinchonas he insists on bark analysis as the true test; although, botanically-external appearances must decide the question whether a plant is Ledgeriana or not. It comes to this: that while some Ledgerianas are very rich, others are poor, inferior to other calisayas and to "hybrids." In regard to *C. robusta* Dr. Trimen retains his belief in its hybrid character, tracing its origin to the Nilgiris. We are not aware that Mr. McIvor ever qualified his belief that the plant was a hybrid, seeing that he artificially produced it. Dr. Trimen has received seeds and distributed others. Cacao from Trinidad has succeeded well and has been distributed not only in the island but to Singapore and Fiji. Of cardamoms, seeds and plants have been sent to the Andamans and Jamaica. There is a singular variety in which the flowing branches are carried upwards. It differs only in this habit from the regular type. There is much information about indiarubber, the species of trees yielding which seem to be almost without limits. It is to be noticed, however, that only big plantations of the best kinds are likely to be successful. Trees first obtained from the Indian Government have yielded plants which have been sent to the Andamans. Gutta Percha trees have been tried, but they grow with extreme slowness. Seeds of fodder grasses seem to be generally a delusion and a snare, and we supect that in America as well as India the sugar-yielding sorghums will be more valuable as cattle food than as substitutes for the true cane. We wish Fiji joy of a packet of Mauritius grass. You can easily get it into a swamp and then the difficulty is to keep it within bounds. There is a recipe for the preparation of *Annatto*, used for colouring butter and cheese. The tree is a pretty one, and common in Colombo gardens. Dr. Trimen makes favourable reference to the extended cultivation of "Lowcountry Products" especially in the Udagama Valley, 25 miles from Galle, and notices how plants and planters and enterprise are radiating from Ceylon to North Borneo, the Malay Peninsula, &c. Large additions have been made to the collection of plants, and we are glad to learn that a revised list of the contents of the Gardens is in progress. But when are we to expect the Popular Botany of Ceylon?

SOUTH COORG: THE NALKNAAD COFFEE.

In your issue of the 24th March, I read with much interest the letters by Graham Anderson and "A. L. T." which [latter] you copy from the *Asian*, and in the latter there is an error I wish to be the means of correcting, and giving honour to whom honour is due.

The superiority of the Nalknaad over the other varieties of coffee was fully recognized long before Mr. Chisholm came to Coorg, or probably even dreamt of such an event.

The recognisee was an old Ceylon planter, who, years ago, went over to the majority, and who was probably as well knowu in Ceylon before he left as he was in Coorg. Sandy Bain was the man who first saw in the Nalknaad tree its lasting and cropping properties, and, when he opened Culdees, he had nothing else but seedlings raised from selected seed and from selected trees. To ensure having good caste trees he visited the native gardens and marked the trees he wished reserved for seed, which, when ripe, he personally saw picked and carried to the estate, "as coolies will cheat, you know." To this care is due the present condition of Culdees compared with other old Ghaut estates.

Mr. Mann never was an admirer of the Nalknaad tree, which he termed a "leafy thing," but was one of the most ardent admirers of the "chick" we are ever likely to hear of, and insisted on several clearings being planted with nothing else. Need I tell you the result? Borer commenced and leaf-disease completed the work of destruction, and, though attempts have been made to replant these fields, yet I regret to say they have been unsuccessful, as it is impossible to rear a decent tree on Ghaut land after it has been open five or six years.

Mr. Chisholm first took up the Nalknaad tree in 1871

and 1872, when he was raising nurseries for Hanchi Betta estate, which he opened for Mr. Donald Stewart in 1872. During the years he managed Mr. Stewart's Bamboo estates he insisted on nothing being used but Hanchi Betta seed, and, when opening for himself, he used nothing else, and his acres are alike free from borer and leaf-disease. There are several Ceylon men who have seen Mr. Chisholm's estates, but by for the best plan would be for some men, such as A. G. K. Borron, F. Laurie and others to come over in September or October next and see for themselves, and, having seen, return and tell their fellow planters. I am perfectly sure that the Bamboo planters would be delighted to have the opinions of such men.

Dubarri estate's first clearing was planted from Pallikerry seed. The crop there speaks well for this variety, but it is not unparalelled, as Peramboo Cadoo, an adjoining estate, has given as much acre for acre (also Nalknaad coffee).

Silver skin adhering to the been is one of the marks by which brokers can tell Mysore and Coorg coffees, and is due to the long dry season we have and not to picking of unripe cherry.

Some early shipments of Coorg coffee have brought good prices :—Craigs Tilly 110s 6d. Craigs Eliza 109s 6d, and Dubarri 108s. This bodes well for Coorg, and where working expenses are under R85 an acre there is a fair margin left for profit.

During the past week we have had abundant blossom showers, which, though late, are still in time to ensure good, though, perhaps, not bumper crops.

Cinchona, cocoa and rubber are being tried on small clearings; the two latter as experiments. Cinchona is being tried on a large scale. The Ghauts and Forest are far ahead of the Bamboo in this, making as much growth in three as our trees do in five years.— BAMBOO.

THE NICOBAR ISLANDS.

About two hundred miles as the crow flies to the S. S. E. of the Andaman Islands, in the vicinity of lat. 8° 9′ N. and long. 94° 7′ (the approximate position of Camorta, where our branch convict settlement is) lie the Nicobar Islands, the largest group of islands, excepting alone the Andamans, to be found in the Bay of Bengal. Like the Andamans, the Nicobars owe their origin and existence chiefly to the prolonged labours of the industrious coral insect; and their shores are, for the most part, surrounded with a fringe of dangerous sunken coral reefs. The names of the more important islands composing the Nicobar group, taking them in the precedence of their size, are the great Nicobar Island (the most southern and the nearest to Acheen and Java), Camorta, the Little Nicobar (separated from the Great Nicobar by St. George's Channel), Katchal, Terressa, Tillanchong, Chowry and Nankowrie Islands. Besides these larger islands, there are a number of jungle-covered islets, all more or less inhabited.

To the N. N. W. of Chowry and the two or three small islands neighbouring it, at a distance of about 80 or 90 miles in the direction of the Andamans, lies a lonely island, called the Car Nicobar. This giant's stepping-stone between the Andamans and the Nicobars is of considerable size; and, on occasion of the recent earthquake betrayed its volcanic origin by an eruption. The earthquake of last December caused the greatest alarm amongst the islanders. Many coconut trees came to grief on the Car Nicobar Island during it. Several visits have been paid to the Car Nicobar by expeditions from Port Blair, and abundant evidence to prove the original creation of the island by volcanic agency has been obtained. The shore is a difficult one to land on, owing to the heavy surf and breakers continually beating upon it. The Nicobar Islands proper are, like most sub-tropical islands, in a great part covered with dense, very beautiful jungle; towering up above which are to be seen the most magnificent trees—such trees as the eye never sees in India, not even in the virgin forests of the hills. The symmetry of the trunks of these Nicobarean trees is to a great height undisturbed by branches, and their tops are crowned with rich many-shaded foliage, affording a secure retreat for the wily Nicobarese pigeons, in numbers plentiful, and in rich-plumaged species various, but difficult to get witnin small shot range of. The jungles of the Nicobars abound in the various kinds of valuable timber to be found in the Andamans, and, in addition, the southern islands are richly belted with coconut palms. It is a curious circumstance that the coconut palm, which is to be found in such profusion on the Cocos and in the Nicobar Islands is nowhere to be found indigenous in the Andaman Islands. How do botanists account for this extraordinary absence of the coconut from the middle of these three groups of tropical islands?* The produce of the Nicobarese palms, in the shape of copra, coconuts and the nut-oil, forms the chief export and wealth of the islands.—*Pioneer.*

MOTHS AND COFFEE TREES.

(To the Editor of the "*Madras Mail.*")

Kulpetta, S. Wynaad, 13th April.

SIR,—Your correspondent "South Wynaad," whose letter of the 6th instant appears in your impression of the 11th idem, enquires whether any of his *confrères* have observed "hundreds of moths flying about the coffee trees" during the recent blossom, a phenomenon which he apparently fears to be the harbinger of fresh disaster. Perhaps Dr. Shortt can enlighten your correspondent as to the scientific name of the "moth" referred to. I think it is a species of "sphinx," and if so, I have frequently observed the identical "wily lepidoptera" in former seasons. O. C.

LEDGERIANA SEED.

(To the Editor of the *Madras Mail.*)

SIR,—I notice in the second column of your paper an advertisement running thus :—"For Sale.—Guaranteed : Moens' Cinchona Ledgeriana seed just received from Java." I am greatly interested myself in the propagation of this most valuable kind of cinchona, and have every advantage in obtaining seed from Mr. Moens, when it can be spared by the Dutch Government. Last mail, received from Java, brought me a letter from Mr. Moens himself. May I give you the following extract of his letter *verbatim* :—

"My Government does not allow me to send any Ledgeriana seed out of our colonies as long as all the planters in Java who apply for it have not got the full quantity they ask. And as the cultivation of cinchona is extending so very fast over our islands, it will take a long time before I am ever able to do this. So I cannot possibly spare you any seed within the first year."

How, then, can "S." have just received from Java Ledgeriana seed which any one reading his advertisement must be given to understand comes direct from Mr. Moens? Mr. Moens is too honest a man and too true to the Government he has served so well for so many years to give or sell his seed to one person, when duty orders him to refuse it to another.—Yours, &c,

Nilgiris, 13th April. LEDEGRIANA.

* The answer, no doubt, will be that it is indigenous to no island of the groups; but that into some it was successfully introduced.—ED.

Correspondence.

To the Editor of the Ceylon Observer.

AN ENQUIRY ABOUT LIBERIAN COFFEE.

DEAR SIR,—Can any one tell me at what rate the Liberian coffee trees are bearing, planted on Mausawa estate, Galagedara? They should now be five or six years of age, and would, therefore, be a good criterion of what Liberian could do in this island.

ENQUIRER.

[We hope the proprietors of Mausawa will comply with this request, the subject being one of public and important interest.—ED.]

MR. GAMMIE OF DARJEELING ON CINCHONA PUBESCENS OF HOWARD: IS IT A HYBRID OR SPECIES?

Darjeeling, 8th April 1882.

DEAR SIR,—Writers on the above subject are about equally divided, one half holding that this pubescens is a hybrid and the other half that it is a species; but neither party has brought forward anything stronger in the way of argument in support of their particular views than mere assertion. In your article in the *Observer* of the 4th March on hybridity of cinchonas, you quote the statement of Hooker & Thomson, to the effect that in nature hybridity is exceedingly rare. That this is true, not one observer in a thousand will question. Run your mind over all the species of plants and animals you know in Ceylon, in a state of nature, and I venture to say that you will not think of a single plant or animal that can be suspected of hybrid origin. It is but fair to assume that the same state of affairs obtains in the South American cinchona regions, and, if it can be shown that the C. pubescens of Howard is neither of Ceylon nor of Indian origin, but that it was originally introduced direct from South America, we may as fairly assume that it is a true species and not a hybrid.

I may mention that what I refer to as C. pubescens is the hairy "Patá-do-Gallinazo," and that I did not know what was known in Ceylon and Southern India under that name until Colonel Beddome's late visit to the Sikkim plantations. He saw our solitary original plant of it, and, as it is so very distinct a kind, there can be no manner of doubt as to its identification; and there is absolutely no doubt whatever about whore we got it from. It appeared among the produce of a packet of C. officinalis seed received in January in 1866 from Dr. Thwaites, for whom the older officers of the Sikkim plantations will ever retain a lively sense of gratitude and esteem for his kindly assistance and advice at a time when these plantations were in their infancy and much in need of help. We always had a large share of the first seeds he had to spare, and, as he did not send us any of C. succirubra till 1868, the probability is that that species did not flower in Ceylon till 1867, and, if it did not, the flowers of C. officinalis, which yielded the seed sent us in January 1866, could not have been crossed by it. Had there been only C. officinalis in flower, so decidedly different a plant as C. pubescens could scarcely have been produced. My idea is that there was an unnoticed seed-bearing plant of C. pubescens then among the Hakgala C. officinalis, and that it was an accidental introduction from South America. I can hardly be wrong in assuming that C. officinalis trees bearing seed so early as 1866 could not possibly have been raised from other than direct South American stock, either plants or seed. If Dr. Thwaites will kindly add to the heavy obligations cinchona culture already owes him, by telling us the earliest date of flowering of C. officinalis and C. succirubra in Ceylon, and their previous history and origin, we shall be at least one step nearer the solution of the vexed question, is C. pubescens of Howard a species or hybrid? JAS. A. GAMMIE.

[We hope to hear, in reply, not only from Dr. Thwaites, but from Mr. Wm. Cameron who, we believe, raised the first cinchona seed in Ceylon.—ED.]

MR. WM. SMITH OF MATTAKELLY, ON GRAFTING CINCHONAS IN THE OPEN AIR AND ON THE HYBRIDITY QUESTION.

G. O. H., Colombo, 20th April 1882.

MY DEAR SIR,—As promised, I now send you a few crude ideas on the grafting of cinchonas, and their "non-hybridity," as found in my experience.

The operation of outdoor grafting is so new to us all, I shall simply state my own experience.

On 25th of last October, being the coolies' "Teevalie," I along with my assistants took advantage of the day to commence grafting Ledgeriana shoots on to succirubra stocks.

We selected strong healthy plants of the succirubra just as they were, growing in convenient position along the roadside, being from 12 to 18 months old. As grafts of the Ledgeriana, we took suckers from trees, which had been coppiced 12 or 14 months previously.

We simply followed the plan generally adopted by nurserymen in Scotland, when grafting the commoner fruit-trees out-of-doors; the grafts being put on as near the bottom of the stock as the operator finds convenient. After making incisions in stock and graft, as ordinarily practised, they are brought into contact, and carefully secured in position by being bound round with common white tape, and immediately afterwards enveloped in a mass of plastic clay which is made to embrace both stock and graft; hermetically shutting both up for the time being, excepting, of course, the upper end of the graft containing the bud, which should be left exposed for about an inch protruding from the clay? We then drew a small mound of earth round the stem of the tree, covering up the clay which enveloped the whole, in order to save it from cracking by the alternations of weather. We afterwards inverted worn-out, bottomless manure baskets over the mound of earth, and shaded the opening partially by pieces of gunny bag.

I may, however, mention I do not intend in my projected operations of the present season to use either baskets or shading, as I do not consider either necessary, particularly at this season of the year.

I found the grafts begin to show signs of life in about 20 days, by the buds getting turgid; and before a month many of the buds had burst and were pushing out leaves on healthy shoots.

At about 5 weeks after the grafts had been put on, an impartial friend along with me examined the first put-on lot, of somewhat over 100, and found less than 5 per cent, either dead or doubtful, a proportion of which grew afterwards. Some failures were found to arise from causes which were preventible, such as putting on what I call blind grafts, i. e. grafts, which, although they apparently had eyes, had not the germs of a bud in them. Strange to say many of them united to the stock firmly, and a few have been left, and are still living, but have not put out a shoot yet. It is interesting to watch them, now that the active season of life has arrived; I am hopeful they may yet push out a shoot.

A dry track of weather came early in December, and the clay got cracked, for the want of attention during my absence from home. A few succumbed from that cause;

still those now growing show a most encouraging aspect, many of the grafts being from 18 to 24 inches high, having from 2 to 3 shoots on them, growing with a vigour exceeding Ledgeriana on its own stem.

I conclude, from what I now see, that the operation of grafting out-of-doors may become a ready and easy means in the hands of intelligent planters of their being able to convert their free-growing succirubra into valuable Ledgeriana. I consider the operation of grafting very simple and inexpensive, causing no harm to the stock operated on, should the graft fail, as the plant in my opinion should not be cut down until there are certain signs the graft has taken a firm and vigorous hold. This would be exceptional in old trees, say of 4 to 5 years old; as the grafts could only be put on after the tree had been coppiced, and then 3 or 4 grafts might be put on one stock, there being plenty space and vigour in a healthy 4 or 5 year old tree. It will, however, be most obvious "to *all*" that grafting can only be valuable, when used as a means of improving the tree operated on, by using grafts taken from Ledger trees, of ascertained commercial value, *or from plants raised from seed, carefully taken from valuable trees of known analysis*: then it will be reduced to a *certainty*, and too much care and attention cannot be bestowed on such an easy means of improving the value of property.

So far as I am able to judge, I look on grafting as ultimately becoming one of our ordinary industrial planting operations, and men will be repaid in proportion, according to the attention and application they give to it. Coolies can readily be taught, and take a keen interest in it, as I experienced in my small beginning. I may mention I put Ledger grafts on pubescens stocks, also on officinalis, and found them grow as readily as on succirubra.

I used shoots partially ripe, as well as fully matured; also branches cut out of the centre of trees, without the sign of buds, and all have succeeded well. The operation of grafting cinchonas in hot-houses has been long practised in Java, and also here for some time by an enterprizing few, and with great success; but not having any practical experience of it, I decline to offer an opinion. Grafting in-doors and out-doors, each has its advantages and disadvantages, and time and attention only can decide which is most suitable. I am putting in no claim as being the first out-door grafter. Budding, as a means towards the same end, is being practised, and I have no doubt will have its success as great as grafting.

There are many other points connected with this interesting operation which might be noticed, but let this suffice meantime; and, as men turn their attention to it, each point will arise in its place, and no doubt receive the attention it deserves.

The other matter, viz., *hybridity* or *non-hybridity*, I confess I approach with fear and trembling, well knowing how I shall get scoffed at, for my "unbelief" in a now, I may say, "universal theoretical adoption." Well sir, I will be plain. I am a *notorious* "unbeliever" in the hybridity theory; it is repugnant to my every sense, moral and material. I have been very anxiously looking around me for now 18 months, and have failed even to see a *trace* of such an agency at work among our cinchonas. I see varying forms among the recognized species, but no more than I see among plants of any other genera, or among men or animals, and, unless you call all created things hybrids, I most emphatically protest against your right to select the cinchona family as an exception; more particularly at this time, when men's minds are earnestly turned to cinchona as a means of again restoring the lost prosperity of the island: it has caused doubts and uncertainties, as to the fitness of cinchona growing, arising out of the hybridity heory.

It would be out of place for me to enter into a theoretical discussion as to "what hybridity is." Let us be contented meantime with the facts before us, and accept some of the best-known hybrid forms. For example let us take the cinchona known as "the hybrid" all over the country, with all its other *aliases*, *pâtâ de gallinazo*, *pubescens*, and now recently re-baptized *robusta*.

I have known this form of cinchona growing in Ceylon for over 17 years; I am able to trace its descent from seed for seven generations. During that period indeed I can prove its co-existence with the succirubra, side by side, before our cinchonas were raised from seed in the country, being only propagated by cuttings; I still find it *the same beautiful graceful* tree, *never varying*, "the most elegant of all our cinchonas": and yet according to the popular theory, I am asked to accept it as a "modern hybrid creation."

All the seed I have sown of the various forms of cinchona have come true to type.

Men have told me they have sown seed of one tree, and it has come up an entirely different form from the parent. In each case, however, when pressed to say if they gathered the seed with their *own hands*, and sowed it also, I have been told it came from India or Java or elsewhere. Without intending any imputation to anyone, I must decline such as evidence of a hybrid tendency.

Another common error, you often see and hear made, tending to foster the hybrid theory: men look possibly on plants in the seed-bed or nursery and form opinions out of the disparity existing between young and old forms, as, for instance, a six-year old pubescens with its beautiful pendulous branches and small—almost glabrous—leaves, having given seed which produces plants of a strong, coarse habit, with *bristly leaves* even up to the time they are 12 months old, and from that period until the tree begins to give seed and assume its mature, graceful form there is great disparity.

I trust you, sir, will allow me an early opportunity "matured you a chance of distinguishing the of giving micrantha" from the common succirubra, as, had you known the great similarity, you would have been *less severe* on Mr. Cross for failing to do so when drawings were *used only!* A greater dissimilarity can scarcely exist between a parent and progeny than between matured micrantha and the young plant, grown from seed taken from the tree; yet in from six to ten years both will be alike. This holds good more or less through all the species I know of the cinchona. Who that had not seen it could believe the *very pretty* Ledger *seedling*, with pink-veined, soft, velvety leaf, could ever degenerate into the small-leaved uninteresting rigid pyramidal tree, we find it at six years old?

Time only can ever settle this theory. Men must educate themselves to know young and old forms as they are, and this can only be attained by years of observation on each stage of the growth and life of cinchona plants.

Mutilation by cutting off lower branches has done a great deal in destroying natural beauty in the cinchona family and rendering their distinction more difficult.

The theory of hybridity can only be believed for a very short period longer, for, when men see plants, as they grow up, asuming the form of the parent, and no new hybrids being produced, the truth will be forced on them and hybridity will *perish*.

I make no pretension of having more knowledge of this subject than many men I know, among whom are some of my oldest and most esteemed friends;

but we seem to have viewed things through different mediums, and our experience differs. I have had considerable time given me to watch the growth and development of cinchona in Ceylon. The plant was familiar to me when you could have counted the number on the digits of one hand.

Allow me, sir, in conclusion, to add my testimony to the recognized fact, that to *yourself* more than any other man in the country do we owe a large amount of our knowledge regarding the cinchona plant.—I am, yours faithfully, W. SMITH.

SPARROWS AS INSECTIVOROUS BIRDS.

Queen's Hotel, Kandy, 17th April 1882.

Sir,—During a pleasant visit to the hill country, I heard many discussions upon the diseases now ravaging the coffee trees, and also various methods proposed for destroying them.

I have not studied the matter scientifically. This has already been most ably done by wiser men, but the expenses which must attend the suggested chemical appliances, tell much against their being *generally* adopted, without which they would be useless.

Now it seems to me that a cheap and practical remedy is at hand, *i.e.*, the common sparrow. Nobody that has travelled in the Far West can have forgotten the snug little breeding boxes put up for these insect destroyers at every vantage place, and even as recently as 1873 it was an offence (with a fine of five dollars) to kill one; for without them vegetation was unable to make much way against the ravages of grubs, etc., etc. At any rate it would be an inexpensive experiment to have a few dozen sparrows turned out upon an estate. They would very soon be at home in the cinchona trees, and not welcome guests to the big green grubs and beetles that now abound, and are the cause of these diseases, which, in my opinion, in the course of a year or two, would then disappear.

I do not imagine the authorities at Colombo or Kandy would allow the sparrows about these towns to be caught and sent upcountry (they value them too highly I guess) but some could quickly be obtained from France or England, and for increasing the species I would back them against rabbits. I enclose my card, hoping you will give this letter a place in your paper, and that this, or some other means, may soon be found to relieve the planters, for kinder or more hospitable men I never met. I am, sir, yours obediently, P. M.

OUTDOOR GRAFTING.

Nuwara Eliya, 22nd April 1882.

DEAR SIR,—With reference to your article on outdoor grafting, I remember translating for Mr. de Bavay, as far back as November 1880, a letter on this subject, which was published in your paper.

Experiments in this system of propagation were tried by him on Springfield estate, Dimbula, in June 1880, where various kinds of [illegible] were grafted on to succirubra stocks, and several grafts were sent to Drayton and [illegible].

Great care should be taken that the *cambiums* of stock and graft [illegible] each other, otherwise they will not unite.—Yours faithfully, H. BREMER.

LIBERIAN COFFEE TREES AND SPARROWS.

23rd April 1882.

SIR,—When I saw [illegible] Liberian trees a year ago, I was told, I think, that they were nine years old. They were "[illegible]," but seemed to have [illegible] on them. Doubtless, however, the [illegible] Mr. [illegible] or Mr. [illegible], can give you more exact information.—Yours truly,

[illegible].

P.S.—What price will "P. M." give for his sparrows? Guaranteed to thrive upcountry.

A CURE FOR RED ANTS.

Dimbula, 23rd April.

DEAR SIR,—Your correspondent "H. J." will, I think, find fire a very effective remedy. I once used it on an estate in the Badulla district where there was a patch of coffee that coolies avoided as much as possible: some of the trees had so many as three nests in them. As it was important to destroy the nests without arousing the ants, I tied branches of dry mana grass to long poles, and having sprinkled the grass with kerosine (a very small quantity) placed the fire under each nest in succession. A great many of the ants were burnt, and those that escaped took care not to come back.

Precautions should, of course, be taken against the fire burning anything more than the nests.—Yours faithfully, B.

[This remedy, if adopted, should certainly be tried only in wet weather.—ED.]

DISEASE-RESISTING LIBERIAN COFFEE TREES.

Udapolla, Polgahawela, 24th April 1882.

DEAR SIR,—On some of the Liberian coffee plants that I consider leaf-disease resisting, I noticed a few yellow spots on a few leaves, which I thought might be *hemileia*, and some leaves had small perforations in them, the result, as I thought, of these spots. To settle the matter I forwarded a few leaves of each sort to Dr. Trimen, and asked him for his opinion, which he very kindly and promptly gave; and it is very encouraging to learn from him that he can "find no trace of *hemileia*." This strengthens me much in my belief that we have two, if not three, varieties of Liberian coffee that can effectually resist the disease, though they may not be really *proof* against it. When it is considered that these disease-resisting varieties are scattered all over the estate, and in all situations, of soil, aspect and exposure are equally free from disease, while those in their immediate neighbourhood are affected more or less, I think it is strong presumptive evidence that there is something in the trees themselves that gives them this immunity. As Dr. Trimen's letter will no doubt interest your readers, I enclose it.—Yours truly, WILLIAM JARDINE.

Peradeniya, 20th April 1882.

Dear Sir,—I can find no trace of *hemileia* in the spotted leaves of Liberian coffee you send, and see no reason to consider the spots due to "leaf-disease." Such discolourations, or local changes in the green colouring matter, are by no means uncommon in very many different kinds of plants, and, although evidences of failure of perfect nutrition, are not of a serious character.

I am glad to hear that you find so many of your Liberian plants keep free from *hemileia*, and hope that they will continue so. It is I think at least premature to speak of them as "proof" against it. I cannot conceive any coffee plant being that. But it is a great thing to get a coffee which suffers so much less damage from the attacks of the fungus, and that we have, I think, in Liberian.—I am, yours, faithfully, HENRY TRIMEN.

MR. T. N. CHRISTIE OF MASKELIYA ON HYBRIDITY AND OPEN-AIR GRAFTING.

St. Andrew's, Maskeliya, 24th April 1882.

DEAR SIR,—The letters from Messrs. Wm. Smith and Gammie, in your issue of 21st, give new life to the [illegible]; so, as a believer in the cross-fertilization of the varieties of cinchona, I claim space for [illegible].

Facts are what we want, and I gladly contribute my mite. In July and August last, I enclosed care-

fully, in bags of the finest gossamer gauze, several clusters of Ledger-buds, and, as the buds opened into blossom, I fertilized them with officinalis and succirubra pollen, by means of a fine hair-pencil. After destroying the unopened buds, I replaced the gauze covering. In one case I opened the buds before they burst and cut out the stamens and fertilized with officinalis pollen. In *all* cases the blossoms set and produced fruit. Other clusters of blossom enclosed in the gauze and not fertilized failed to set one-third of their blossoms, and in some cases not a single blossom set. On an officinalis tree, I selected two clusters; covering as before, one I fertilized with Ledger pollen, the other I left alone.

The blossoms so fertilized became fruit and were totally different from any of the other capsules on the tree, being larger and rounder.

In this one case, unfortunately, an accident happened to the seed before it was ripe.

The others have been sown and are now tiny seedlings. What form they may take remains to be seen, but I am convinced that the blossoms were crossed, and what I did with a hair-pencil could, I cannot doubt, be done by the antennæ of an insect. I do not suppose that such crossing goes on to any very great extent, for, as a rule, the different varieties are planted separately, and in some degree differ in their blossoming seasons, besides there being but few insects to carry the pollen.

So far the hybrid battle has been fought on the question of a particular, though varying, form being or not being a mixture of succirubra and officinalis, but are the anti-hybridists prepared also to discover in the Ledger-succirubra and Ledger-officinalis hybrids new varieties?

Amongst the Yarrow Ledgers there are three or four splendidly grown trees which, when young, had all the velvety bloom and other characteristics of a Ledger, but are now obviously a cross with succirubra. One of them at 3 years of age, analyzed by Howard, gave 4½ per cent sulphate. In time to come this hybrid will oust the succi-officinalis hybrid, as it is quite as robust and much richer. There are also at Yarrow two or three specimens of the Ledger-officinalis hybrids: they also as young plants, and their suckers, shewed their Ledger parentage, and of this hybrid I have two specimens here, rising 3 years of age. I consider this to have the officinalis strain in it, because, firstly, its leaves are intermediate between Ledger and officinalis; secondly, because its growth at 3,000 feet (though very good) is not so great as at 4,200, where it rivals any cinchona in size; and thirdly, because my specimen here is now blossoming, a precocity which a pure Ledger, free from officinalis taint, would never be guilty of. Its blossom has much of the droop of the Ledger with some of the colour of officinalis. I wish I could convert Mr. Smith to my ideas of hybrids as easily as he did me to his ideas of grafting. After seeing his grafts and getting a lesson, I found no difficulty, even though it was the wrong season, in succeeding, and two months old grafts have now a 2-inch sprout on them. If the stock be pliant enough, I think bending over and pegging it down sends the sap into the scion sufficiently, while preventing any danger from bleeding. So far, I have been more successful in my outdoor grafts than in those under glass. With coolies as operators, it is probable that indoor grafting iwill have the advantage of being more easily supervised, but that, I think, is its only advantage.—Yours faithfully, THOS. NORTH CHRISTIE.

P.S.—From Saturday's paper, just to hand, I am glad to see that Mr. Forbes Laurie now agrees with me about hybrid seed often reverting to other types. I think he is right as to there being hybrids *and* hybrids. The present rush for *any* plant or seed that has the slightest claim to illegitimacy will end in disappointment.

MR. J. BAGRA'S IDEAS ON HYBRIDIZING, SPORTING AND GRAFTING.

April 24th.

DEAR "OBSERVER,"—I am very much interested, and edified from the perusal of your article on cinchona, in your issue of the 21st inst., and also Mr. Smith's letter on grafting and hybridity.

I have been a semi-practical working botanist since I was 14 years old, and am now turned 40 years. I might thus almost claim the right to cross swords with such an authority as Mr. Smith—a man for whom I have the greatest esteem as an agriculturist in all its branches. But as I write this in all good faith, agreeing with him on the whole, and only in the hope that any hint I give may be useful to him or to some others, I trust he will not hit me in the eye next time we meet, because I see fit to differ with him on some points of interest.

In the first place, grafting in Uva has not been a success in my experience, and would require more care than we bestowed on the few trials, and for open-air I should advise the succirubra stocks to be planted first in a long bed, say 4 feet wide by any length at 9 inches apart, and when at proper size, say 15 or 18 inches high and ¼ to ⅜ an inch diameter, they are ready for the grafting process. To shade the bed with coir matting—double, if it is considered necessary—and for grafts never to take side branches but suckers, either from the good tree or stools after coppicing of approved varieties, the process as described by Mr. Smith is quite correct. Only I should break out the top or cut it.* This would naturally send the sap more to the graft. In the case of old stools *i. e.* trees that have been cut down, I find the excessive flow of sap is very apt to kill the grafts before they can take a hold; so on the whole I quite disapprove of this system. The reason why I object to side branches for grafts is that they seldom take the upright form but go off in unhealthy branches without any leader. Now as to hybridizing. I expect Mr. Smith would be more correct, if he referred rather to the animal than the vegetable kingdom. In it we can get "mules" but nothing further: and, if he will only consider and ask himself where our improved varieties of cabbage, Turnips, oats, apples, pears, peaches &c., come from, I think, with the beautiful flowers that botanists have raised, he must give way and admit that hybridity is not only possible but common in all plants of the same genera; and the cinchona—let it be succirubra, officinalis or any other variety—is still a cinchona, and, although a hermaphrodite, is as sensitive to contamination from other varieties within reach as a patch of seed turnips. I could give crucial instances in my own experience, in which I am perfectly satisfied of the fact, but have not space at this time. As to the sporting theory, I don't like the name; in fact I am as much opposed to it† as is Mr. Smith to the hybrid. In a seedling of any kind, I should put it to hybridizing in some shape. A branch of a plant or tree taking new colour in leaf or flower a sport, and may be perpetuated by cuttings or grafts, always liable to return to the original.—Yours very truly, J. BAGRA.

* Mr. Christie's suggestion to bend and peg down the top of the stock plant seems preferable. —ED.

† The "Columbine," petunias, &c., sport in a manner the most marvellous. while in Java the Lantana is "a thing of beauty," with rich orange, pale yellow, rose pink and snow white blossoms on the same bush.—ED.

MR. W. D. BOSANQUET'S CONTRIBUTION TO THE "HYBRID" CONTROVERSY.

Yoxford, Dimbula, April 25th, 1882.

Dear Sir,—The controversy on the subject of *robusta Cinchona* is fast arriving at the vehement stage between the two rival parties. Is it not possible that the truth is to be found halfway?

I would venture to suggest, subject to the correction of botanists, that we are being led astray by the misuse of the word *hybrid*, and that we should be more strictly correct in looking upon the *robusta* as a cross between officinalis and succirubra. Cross fertilization is in natnre a daily occurrence and Darwin has proved that its tendency in plants is to the production of more robnst offspring, while self-fertilization has the opposite result.

That the robustas are a cross between officinalis and succirubra seems to me a fact daily proved to one's observation. I have sown seed from so-called hybrid trees, which has produced both officinalis and succirubra plants with every variety of intermediate type. I have in many cases seen plants which showed all the well-known characteristics of succirubra, change between the first and second year into robustas. I have also seen a robusta tree of the best type throwing up a sucker, which was to all appearance a fine succirubra; and, in this estate, I have a young succirubra with a sucker growing up evidently a robusta.

In reply to Mr. Gammie as regards the plants around us, what is the tea which is being so rapidly extended but a so-called hybrid?*

I hope that my suggestion may come as a restorative to some bewildered brains, and, if not strictly scientific, yet the facts I have quoted are somewhat difficult of digestion for those who hold that robnsta is a distinct species.—Yours faithfully, Wm. D. BOSANQUET.

[On the other hand there can be no doubt that forms now known as hybrid or robusta appeared amongst the earliest cinchona cuttings from Hakgala.—Ed.]

Sparrows as Insecticides.—We have received a letter on this subject, which will be found elsewhere. We may state that the sparrow is plentiful enough in our Ceylon towns, however rare he may be in country districts. But, even if sparrows abounded on estates, would they or could they dig out the cockchafer grubs from their beds deep down in the soil? For this purpose an insectivorous bird far more likely to be valuable is the large Australian shrike, popularly known as the "magpie," a supply of which we hope soon to introduce. If sparrows were wanted, the Australian colonists would thankfully make us welcome to the hundreds of thousands for the destruction of which they are offering rewards. These birds, and even the mina, prefer the fruit so largely cultivated near Australian towns to insects of any sort, and are so destructive as to be reckoned, like the rabbits, a formidable enemie. Perhaps the sparrow so useful in America is a different species. Our correspondent is, of course, aware, that what coffee chiefly suffers from is a fungoid plague, which no bird we fear would meddle with. If we could get rid of "leaf disease," we could more easily deal with grub or bear with its ravages. The coffee tree is now attacked by grubs at the roots and a fungus in the leaves.

* This is an illustration which has weighed strongly with us and which we have emphasized in arguing with the anti-hybridists. No Indian planter doubts that "best Assam hybrid tea," owes its origin to the indigenous Assam tea and the China teas introduced at the instance of Lord Wm. Bentinck's Government by Mr. Fortune. Hybrids resulted, which are less delicate than the indigenous and in every way superior to China. The quality of the hybrid, too, seems persistent, although exceptional plants occur.—Ed.

Coffee Pests.—Sir,—The moths described by your correspondent "Sonth Wynaad" are commonly called Humming Bird Hawk moths (Sphingidæ). Thirty-three new species were described by Mr. Arthur Gardener Butler, F.L.S., F.Z.S., in the proceedings of the Zoological Society of London, for 1875. One of these new species is from Coimbatore, so that Sonth Wynaad should secure specimens in case it might turn out that his pests are a new species. Dilute carbolic acid will probably destroy the eggs.—H. R. P. C. in *M. Mail.*

Careful and observant gardeners have long been aware that the shade of growing trees wes exceedingly unfavourable for the development of plants, and now scientific research gives the reason as follows: —M. Paul Bert has shown that green light hinders the development of plants, which is the reason that grass does not grow well under trees. We have often urged the necessity of avoiding the shade of growing trees as much as possible, more especially with reference to anything put into the open ground; but it is equally wrong in principle to grow pot plants under such, or, in fact, under any living shade.—*Queenslander.*

Paper as Covering for Shaved Cinchona.—As attention seems to have been excited by an advertisement for old newspapers, we may say that, as yet, all we know is that, in inter-monsoon periods, stout brown paper has been found an effectual protection for shaved cinchonas, on Erroll estate, Dikoya. But Mr. Porter, who attracted our attention to trees so protected, did not hope that the paper would stand the force of the south-west monsoon. We suggested—and we mean to try the experiment—that the brown paper might answer if the outside was tarred. We are also going to try what the stationers call "duck-back paper," but that is expensive. If the old newspapers are wanted for this purpose, we suspect several folds must be laid on, tarred on the outside. But the ingenuity of planters, once on the track, will soon discover a cheap and effectual covering. Paper really can be used for any purpose: from a lady's *billet doux* to railway carriage wheels. Why not then as clothing for cinchonas?

Government Plantations in Assam.—Among the experimental plantations kept up by the Forest Department in Assam, the most important appear to be those reserved for teak, rubber and cinchona. The teak plantation at Tulsi is reported as being in a most promising state of progress with regard to the shape and growth of the trees. The oldest of the trees which were planted in 1872 have now reached an average height of 50 feet, with a girth of 1 foot 9 inches, and the younger blocks of trees are said to be equally promising. There is also a small plantation at Makam, in the Lakhimpur district, consisting of 2,160 trees, which are said to be growing well. The rubber plantation in the Durrung district is also favorably reported on. These young trees have hitherto suffered much from the damage done by deer, but during the last year a proper system of protection was organized, and there has consequently been a marked improvement in the vigorous growth of the trees. The plantation contains about 10,600 trees, besides about 500 others along the roads and boundary lines. The nurseries are also in a very flourishing condition, a considerable number of the trees being over ten feet high; and it is now hoped that there will every year be a sufficient number of plants to commence regular annual extensions. The cinchona plantation is unfavourably reported on; the soil on too broken hills is evidently not at all suited to the growth of the plants. Some slight attempts have also been made to form an orchard at Shillo:—an experiment to be successfully carried with forestry and the seasons, as well as grafted trees, of apples, pears, peaches, nectarines, and other fruits are doing well.—*M. Mail.*

THE local paper tells us that, after several days of unusually sultry weather, a thunderstorm burst over Darjeeling on Friday afternoon, bringing with it a fall of rain which lasted for some hours. Some hail also fell on the road between Kurseong and Sonada, but nothing so far has been heard of damage being done to tea plantations. Tea manufacture is now in full swing throughout the district. The hot, sunny days which followed the rain that fell last week have had the natural effect of forcing out the flush very rapidly.—*Pioneer.*

LARGE DEMAND AND HIGH PRICE FOR TEA SEED IN 1882.—We are imformed on the best authority that the demand for tea seed this year for season 1883 is already large, and is likely to be very much larger, while the prices asked and obtained are exceptionally high. We believe that the whole of the crop of the leading Assam seed gardens is already bespoken at a very high figure. This shows the intention to extend considerably in the various districts. Those desiring to secure seed for next season had better lose no time in making arrangements.—*Indian Tea Gazette.*

ADULTERATION IN THE UNITED STATES.—Bad as we are in the matter of adulteration in England, things are certainly worse in the United States, according to a report just presented by a committee on the subject to Congress. For example black pepper has been so effectually sophisticated that the trade appears to have lost all knowledge of the genuine article. For tea Uncle Sam drinks black-lead, indigo, Prussian blue, chrome yellow, Venetian red, carbonate of copper, and arsenic of copper. The cup will hardly cheer the drinker who knows its composition.—*Globe.*

RUBBER SEEDS.—We have seen some of the new kinds of rubber seeds imported by a gentleman who has placed them in the hands of Messrs. Lee, Hedges & Co. for sale, The importer writes :—"They are the first seeds of the kinds, I believe, ever imported into Asia, with the exception of a few Pará seeds sent from Kew to Peradeniya. There have been a few Pará cuttings distributed from these trees at Peradeniya, but it was found they would not grow from cuttings, and the trees are said not to have borne a seed as yet. So, with the exception of these few trees at Peradeniya planted far too close, I believe, and in an unsuitable place, Pará rubber has not as yet had a trial in Ceylon. I was particularly warned of the limited demand for Ceará rubber, and I was told they did not use it at all, but that the demand for the superior rubbers was unlimited. I have had the greatest difficulty in getting these seeds, and I believe them to be of the very best kinds of rubbers or cultivation."

A NEWLY PATENTED TEA BOX has been introduced, says the *H. & C. Mail.* It is the invention of Mr. W. H. Bennett. In appearance free from any striking novelties in design or construction, Mr. Bennett's box is said to deserve attention. Its chief merit and peculiarity is that four novel and ingenious corner pieces give to the box a strength and solidity which are very remarkable. It would be difficult to give an idea of these singular corner pieces. It must suffice to say that they are angular, and that the sides and ends of the box are fixed to them in such a way that, short of extraordinary violence, nothing is likely to disturb their contents. Is not this patent the same as Cantwell's invention, which we referred to some months ago? The description is almost identical. Anyhow, we should say it was truly sending coals to Newcastle to send wooden boxes to Calcutta, where they could be made quite as well, and infinitely cheaper. We have often expressed surprise that some enterprizing man does not start a small sawmill in Calcutta. The present tea chest is a barbarous affair, and in new markets is enough of itself to set the trade against looking at our teas.—*Indian Tea Gazette.*

THE "TROPICAL AGRICULTURIST."—A Coorg planter is good enough to write :—"All who receive the *Tropical Agriculturist* in this quarter are much pleased with it, and will, I think, continue to be regular supporters, the number of whom cannot fail to increase as the value of the publication becomes generally known."

THE increase of the growth of Indian tea (says the *Friend of India*) has been very remarkable. The imports of China tea into the United Kingdom amounted, as early as 1864, to 120,214,000 lb. and in 1881 this had only increased to 161,668,000lb. or by 34 per cent. The imports of Indian tea for the same two years were 3,285,000 and 46,195,000 lb., an increase for the latter year of 1,306 per cent. In 1864 the Indian article was 2·6 per cent. of the whole imports, and in 1881 29·2 per cent. The following are the imports for a considerable time back :—

FISH CULTURE AT THE PEOPLE'S PARK, MADRAS.—Mr. Thomas, the talented author of the "Rod in India," has undertaken to improve the stock of fish in the People's Park. The authorities have promised him assistance, in the shape of money and machinery, &c., and the lovers of the gentle craft will, we believe, ere long be able to enjoy excellent fishing in Madras. In the ponds at present, a great variety of fish are to be found; some of considerable size and of great beauty, but they are badly arranged. Predatory fishes should be in a tank by themselves. This Mr. Thomas is about to rectify. Yesterday morning, at about 6 a.m., a large number of gentlemen and several ladies assembled to witness the capture of a lot of fish from a pond at the northern end of the Park. A steam pump was set to work, and soon cleared out almost the whole of the water. As it became low, the fish played and darted about in every direction; then a body of fishermen entered the water with casting nets, etc., and drew out hundreds of fish. The fierce-looking murral was drawn out in the same net with the lively magalops, and shoals of pretty silver fish of all shapes and sizes. Nutritious eels were netted with lazy tortoises; the banks of the pond were soon a glittering mass of fish. They were quickly sorted, placed in chatties and conveyed to other ponds, all the fierce or predatory fish being placed in one particular pond. The scene proved very exciting to a large number of kites and crows, who had a rich chota hazree on any struggling fish they could catch. After having partaken of tea and coffee provided by Mr. Thomas, and enjoyed the morning very much, the party went away pleased with what they had seen.—*Madras Mail.* [We should be glad if our rivers and pools were equally well stocked. But the predatory fish, turned into the same pond to feed on one another, must have felt, as did the pickpockets at the Exhibition of 1851, when they found the Police showing them all into one room!—ED.]

NILGIRI CINCHONA BARK DESPATCHED TO LONDON.

A Madras Government paper, dated 8th March, contains a formidable array of figures, each one of 360 bales of cinchona, sent by P. & O. steamer Nepaul, being described in detail. The uniform net weight of the bales was 102 lb., so as to leave 100 lb. net, after 2 lb. had been taken for analysis. The weight of each gunny package was 8 lb., so that the gross weight of each package was 110lb. We quote the abstract invoice of 360 bales of bark forwarded from the Government Cinchona Plantations, Naduvatam and Pykara, Nilgiris, during the official year 1881-82 :—

Also a letter from J. H. Taylor, Esq., Lieutenant, R.N.R., Master Attendant, Madras, to the Secretary to Government, Revenue Department, dated Madras, 8th March 1882 :—

"I have the honor to inform you that, on the requisition of the Deputy Conservator of Forests, in charge of Cinchona Department, Nilgiris, freight has been engaged per P. & O. Steamer Nepaul for 360 bales of cinchona bark, consigned to the Right Hon. the Secretary of State for India, London, at the rate of (£3-12-6) three pounds, twelve shillings, and six pence per ton, and that they have been insured for (£4,000) four thousand pounds at the rate of one per cent., covering all risks. Both freight and insurance premium are payable in London. I herewith forward two copies of the bill of lading, which also covers insurance risk for the above consignment. The accompanying list shows the measurements of the bales as taken by the second Assistant Master Attendant or Agent for Shipping and Landing Government Consignments, and it will be seen that they amount to 54 tons, 25 feet, and 1,454 inches. The freight payable is (£197-12-5½) one hundred and ninety-seven pounds, twelve shillings, and five-and-five-eighth pence, and the insurance premium is (£40) forty pounds. The Nepaul sailed on the 4th instant (March)." [It will thus be seen that the measurement tonnage of 306 bales of cinchona, weighing gross 39,600 lb. and net 36,720; 54 tons, 25 feet and 1,454 inches; the P. & O. Company freight being £197 and insurance £40.—ED.

BUG-SUCKED COFFEE BEANS.

A Badulla correspondent writes :— "The accompanying sample of coffee beans are forwarded for your inspection. They were picked a few days ago on an estate in this district, and appear to be affected by some disease which has hitherto not come under my observation. Can you account for this seemingly new pest." With this letter came a match-box filled with parchment beans which look as if they had been cut in pulping. On turning to Nietner's "Enemies of the Coffee Tree," we find that the originator of the damage is a bug, *Strachia geometrica*, allied to the so-called green or foetid bug. The late Mr. Alexander Brown seems to have been the first to receive specimens from Badulla, and subsequently the destruction caused by this insect was confirmed by several other gentlemen from Badulla. The bug feeds on the juices of the berry when very young, and the evil effect is shewn when the beans mature, in the shape of punctures in the parchment skin, or much larger marks as if parchment skin and bean had been eaten away. The market value of the coffee sent to us must be most materially diminished. Has this pest or its effects been noticed in any other district save Badulla?

A planter who was in our office this morning told us that he had seen coffee which had been struck by hail and which, when pulped, looked as if it had suffered from smallpox. This very appearance of smallpox comes out on cinchona bark when hailstones strike against it. In Ceylon, however, hail showers are rare and innocent of evil, as compared with continental India.

LOW-COUNTRY PRODUCTS.

Near Henaratgoda, 2nd May 1882.

April.—The weather this month has been drier than the normal April. There were some heavy showers the first three days, and again showers for five days in the middle, but, through all, the water in the wells has continued to go down, and the last week of the month was intensely dry.

The Liberian coffee plants have had to be watered twice a day, except on the days on which rain fell, and I am now anxious for planting weather, that I may get them out to the field, where they will be safer than in baskets, from which the sun sucks every atom of moisture in a few hours, unless we keep putting on and taking off shade continually and keep the watering pans going all day. I grudge the cost of those operations, which the crickets have hitherto rendered necessary, but this season they have not appeared in their usual force, and with the exception of a few seedlings in the sheds, I have lost none on the present occasion. I have therefore put down 20,000 seeds outside for November planting.

On the larger trees the crop is just as much as can be packed on the branches, but on last year's planting there is only a slight sprinkling. The growth of the plants continues satisfactory. Those planted in July and August, with three pairs of leaves, are now from one to two feet high, and are beginning to branch, but suckers are very troublesome and have to be regularly attended to, if a proper form of tree is desiderated.

During the month disease spots have appeared on many plants hitherto free from it, but, on the whole, it is not so bad as might be expected from the numerous centres of infection that exist on the property, and many plants have more or less of it without suffering materially from its presence; and again, it has certainly been shaken off by many plants that had more or less of it some months ago. I planted out a few hundred cocoa plants in the middle of the month, and the white ants have already gone with one-third of them, nor do they confine their attentions to very young plants, as they often do.

stroy those that are three feet high and in strong growth. The older trees continue to produce masses of flowers, but still no signs of fruit.

I paid a visit to the Henaratgoda garden the other day. The plants there have all the advantages of good soil and perfect shelter, and the cocoa planted there at 10×10 feet is evidently far too close, and instead of 100 feet per tree evidently needs from 200 to 250. On less favoured spots it may be planted closer, but 10×10 is too close anywhere. I had reserved a low-sheltered portion of my new clearing for cocoa alone, which I lined 10×10; now I must take up the pegs and put them 13 feet apart on the quincunx. The Liberian coffee trees ou the adjoining ground 10×10 do not now appear a bit too wide, even where they have been allowed to run up, and those that have been topped are evidently crowded.

The most advanced of the rubber plants are ten feet in height. I suppose that is the usual growth in six months. All the first group are in flower, and I now think I have pods that will ripen within the year. I feel anxious to ascertain the return this plant is likely to give. After the first two years, its cultivation will cost only a trifle, but I fear the cost of collecting and preparing the produce for the market may swallow up the profit. Has the tree not been long enough under cultivation in the island, for the earliest adventurers to offer some definite information to their less advanced brethren? I have a faint impression on my mind that Dr. Trimen experimented on one or more of the oldest trees at Peradeniya, and that the report was favourable; but, if there were any details, I either never came across them, or they have escaped my memory, as many other important facts do, if they come not home to my immediate occupations. I wish you would record all known facts in the next number of the *Tropical Agriculturist.**

I have not been fortunate with cardamoms; they germinate freely enough, but the roots take such slight hold that the gentlest watering washes them out. I lost one-half in the shed, and nearly the half of what remained after transplanting, and have only made two points. They must be very sparingly watered and shaded whenever the sun shines. I am thankful for the wriukle that came from the south, as I had designed to plant out as soon as there was suitable weather. Now I will defer it till they form bulbs.

I have put down a few vanilla cuttings experimentally. If the annual produce of an acre is worth so many hundreds or even thousands of rupees, I wish to give myself a chance of success in such a delightfully profitable cultivation.

With such masses of rock on the place, I have long been much exercised in mind how to turn them to account, and have finally decided to try whether the pepper-vine cannot be trained on them. The evil days on which coffee has fallen, teaches us to direct attention to every cultivation from which a possible profit may be derived.

[? Orange, mango and other fruit trees with their branches fixed to the surface of the rocks and earth for pineapples put on the tops and in crevices. Fruit will be wanted for the steamers.—ED.]

THE PROGRESS OF INDIAN TEA IN AUSTRALIA.

Mr. J. O. Moody, of the well-known firm of Messrs. James Henty and Co., Melbourne, in a letter to us dated the 10th October last, writes as follows:—

You will see by the two papers I send you, *Argus* 5th October and *Age* 6th October, that a strong agitation is going on, in favor of an Adulteration Act for the colony, and which I hope, when passed, will shut out a great deal of China rubbish that at present floods this market.

Messrs. Cosmo Newbery and Frederic Dunn, whose names are so freely used, are analytical chemists connected with the Laboratory of our Industrial and Technological Museum, the former as Superintendent, and the latter as his assistant. These gentlemen have for some years past devoted considerable attention to the analysis of tea, and are well up in the subject. The large exhibit (some 500 different samples) shown at our Melbourne International Exhibition, and of which Mr. Newbery was Superintendent of Juries, placed at their disposal for analysis and probably gave them opportunities unequalled by any previous investigators into the chemical analysis of teas.

You could aid their investigations by procuring for them samples of your different growths of tea from three or four districts, say a few leaves in *air-dried* condition only, that is to say, having passed through *no* manufacturing process, and a few samples of the same kinds manufactured. Have these samples carefully marked with all particulars and the time of picking, &c.

Some of your planters would probably be glad to furnish samples for the sake of the investigations it opens up, and the practical information it may give. Ceylon has already furnished some samples which are being analysed. I may mention that there is difficulty in getting the air-dried leaves over in a sound condition, but with a little care this can be managed. Perhaps packing loosely between Swedish filtering paper (procurable at any chemist's) would prove a good plan.

With regard to the request made by Mr. Moody for samples of the different growths of tea from our various tea districts, we trust our readers will heartily respond to the call. We will be happy to forward free of cost all samples intended for Mr. Moody sent to this office. The teas should be carefully packed in tea lead and soldered down securely. As they are intended for the purpose of analysis, from 5 to 6 ounces should be sent of each kind.—*Indian Tea Gazette.*

COCOA (OR CACAO) CULTIVATION IN TRINIDAD.

At page 5 of Dr. Trimen's Report he referred to Mr. Prestoe's remarks on the above cultivation, and, as we have been since favoured with a copy of the elaborate report published by the Director of the Trinidad Gardens, we gladly publish the portion referred to. A portion of Mr. Prestoe's useful observations on Liberian coffee have already appeared in the *Observer*.

323. CACAO.—*Theobroma cacao.*—Considerable time and attention, although greatly interrupted, and in consequence attended with much waste of material, have been given to this subject during the year.

324. A larger stock than usual of good varieties has been got together for planting and for distribution in course of acquiring seeds to meet current demands and for examination and experiment.

325. The subject I need hardly remark is of vast importance to Trinidad which—with a leading position as a cacao growing country—possessing very fine varieties of cacao and enjoying highly favourable conditions for their culture—continues to export the bulk of her cacao in an extremely inferior form both as to the natural intrinsic character of the beans and the manner in which they are prepared.

326. It is not desirable, even if it were practicable, to make any lengthy observations on this aspect of the subject, but I might properly mention that the most important points to which I have devoted my attention are: the relative value of the different varieties, and the manner in which they are affected in course of preparation for the market and other circumstances on which good or bad cacao depends; and in doing so I find a very wide field for investigation open

* Our correspondent had not, apparently, read Dr. Trimen's latest report.—ED.

out,—and in it abundant opportunities for the employment of high intelligence with every prospect of profitable results in respect of cacao produce. In short there is very great room for improvement, both in cultivation and in the preparations of the ripe cacao bean, suitably—not so much for the market—as for the consumer and grower. This, it appears to me, will depend more largely on a full knowledge of the different varieties and a correct estimation of their characteristics—both in the field and in the curing house—than on anything else.

327. Until quite lately cacao cultivation has been regarded generally as a common, though rather profitable pursuit, and, except in the capacity of the merchant dealer, so easily managed and requiring so little knowledge and skill that the employment of any assistance above the capacity of a labourer was considered unnecessary: so many cutlassings of weed growths a year, and pruning with the cutlass at so much per 100 trees: supplying plants—no matter whence obtained—as vacancies may occur: picking the pods, collecting, shelling and laying in heaps, so many days to sweat (and clean): rubbing with or without red earth and drying in the sun as weather may permit: bagging and carting to "store"—all simple operations, and easily got through by the labourer—and which constituted three-fourths of the work of a cacao estate and its store. With the majority of growers—especially the little ones—these are all the operations necessary ro desirable in the production of cacao. And the local influences are such that the prices are accepted as being "high" or "low" by causes in no way dependent on the kind or quality of the cacao produced. The value of the sample locally is taken to depend most largely on its *weight*. In other respects it may be good or bad, and its character is accepted as unavoidable—whatever it may be. Moreover, the bulk of the cacao grown by small holders or persons not capable of, or not caring to do more than, or think beyond, the above-named round of plain work, the result is an immense quantity of cacao which becomes by the time it is shipped more or less decayed vegetable tissue: yet, under the Trinidad name, paying prices are still realized.

328. With the vigorous effort now being made, however, at producing high class cacao in other colonies, this abnormal state of things is not likely to last; and it would be well to keep steadily in view the fact that there is no sufficient reason or excuse for anything but high class cacao being exported from Trinidad—not all at once, for, quality depending largely on variety, it would be too great a sacrifice to suppress the inferior varieties; yet I venture to say that, by properly preparing *all* the cacao, and separating the good from the inferior kinds, an improvement of 30 per cent might be *at once* realized.

329. The chief cause of the comparative inferiority of quality in the great bulk of Trinidad cacao seems to be a want of appreciation of the fact that cacao both as to cultivation and preparation is in its infancy, and with rare exceptions there is no thought or desire (as there is not seen to be any necessity) for pushing it beyond that stage.

330. Meanwhile, however, the cacao tree with its many varieties of different value to dealer and consumer; its requirements in cultivation, in different soils and sites; the systematic gathering and scientific preparation of the beans in such manner as to secure to the consumer their substance not only pure and undecomposed, but combined with all their natural distinctive characteristics of flavour and consistence—now rarely present—present a new and wide field for the exercise of the best intelligence and skill—alike to the scientific agriculturalist, the chemist, and the engineer, quite independently of the requirements of the manufacturer in Europe or America.

331. This will, perhaps, become more apparent on the following facts and circumstances being considered:—

1°. The export of cacao from Trinidad is now over 13,000,000 lb. and values about £500,000.

2°. There is a margin for improvement on the gross export, equal to at least 20 per cent by a more careful and prompt preparation even under the *present method* of sweating &c. of preparing. That is to say, if all the cacao produced were as well prepared as that of "San Antonio," the value would be enhanced to that extent. The value then £600,000.

3°. There is a difference of value in the varieties of cacao among the higher class as to quality and productiveness, of at least three times, and very much more than this between the very best and very worst. If then the higher class varieties only were grown, there would be again a very important improvement in the total value, the inferior varieties at present largely predominating: or, if the inferior varieties as they occur were at all times rigidly separated from the superior—and which at present would be the only way to prevent the occurrence of more or less damaged cacao—an immediate and great gain would result.

4°. The cultivation is full of defects the more serious of which having their origin in the contract system, under which by far the greater part of the trees planted during 30 years in the island have been planted. For instance, no regard has ever been paid to the difference of habit in different varieties; some trees attaining the height of only 10 or 12 feet with *compact* branching, while others are often large spreading trees 40 to 50 feet high. Similarly no attention is paid to varieties in respect to their suitability in different soils and situations, nor, as a rule, even to using seed of good varieties. Thus *yield* is affected as well as quality—greatly to the disadvantage of the grower.

332. Cacao trees were formerly planted at 10 or 12 feet distance or even less by peasant proprietors; and they are still very rarely planted to be permanent at greater distance than 15 feet: the larger growing trees in consequence seriously injure the lesser and slower growing, the larger ones themselves being injured in the process.

333. Another drawback attending the present too thick and unmethodical planting is the difficulty—if not impracticability—of judicious pruning so necessary for regular and full productiveness. In a mixture of trees of great variety in habit of growth, a master mind combined with the strong hand of the labourer would be necessary to deal with the requirement in each tree successfully; whereas with a uniform "plant" over large breadths the work of pruning is reduced to simplicity.

334. Again, some varieties require shade to thrive well; others do not: and this requirement of shade is again greatly modified according to "lay" of land and other conditions of locality.

335. In respect of yield the range is from nearly nothing to 20 lb of dry cacao per tree for a season. In respect of the value of variety as dependent on the character of the pod and its contents the difference ranges commonly from one to five: some pods consisting of tissue many times heavier than their contents, while in others the contents (beans) are as heavy as their pod tissue.

336. As commonly known there is a great difference in the colour, consistence, taste and odour, in the recently gathered cacao, of different varieties. It does not appear to be so well known, however, or it is not commonly regarded, that these distinguishing characteristics are retained into the dried (prepared) state, provided the samples are kept *separate* and are not subjected to treatment that will affect the beans abnormally—that is to say such as would affect the tissue or chemical constituents beyond what would arise in germination (hastened by moderate heating) and subsequent prompt and uniform drying (which process is simply a kind of malting, and what is accomplished in the familiar "sweating" process) and by which the characteristic flavours are greatly developed and made permanent in the bean. With a very wide range of variety as to consistence and flavour, from those inferior beans with scarcely any, but with a stone-like consistence of tissue, or accompanied with intense bitterness, to those having the characteristics of high-class cacao, it is easy to understand how much is lost in respect of distinctiveness of flavour and aroma in the [illegible] which the great bulk of cacao is prepared, and which under the present method—as a rule most carelessly [illegible]—the result is [illegible] and fusty—"new" cacao [illegible].

337. "Sweating"—that is to say, malting—is commonly regarded as the only means to produce high-class cacao, at the same time it is well known, that at least one kind will [illegible] that is to say sweating has no effect [illegible] in the consistence and flavour of the beans. The [illegible] [illegible] [illegible] this report, I leave it for [illegible] place.

338. Meanwhile, there are varieties which by simple germ-

ination—of the matured beans of course—and prompt drying without the aid of heat, give a high-class sample, both as to consistence and flavour. In both cases the results are dependent on the original chemical constituents of the beans, as also and largely on the proportion of fat contained, and which is the preservative element in the prepared beans or "nibs."

339. Cacao submitted to the process of malting judiciously and afterwards promptly and thoroughly dried is secure against harm from ordinary damp and consequent mildew; for, should the parts or "nibs" become by external moisture invested in mildew, the internal tissue remains unimpaired and the whole can be cleaned inexpensively. On the other hand beans not improveable by "sweating" readily take mildew and are at once damaged all through. They are deficient in fat, and thus readily absorb moisture and spoil even when well dried.

340. In two ordinary varieties of cacao lately analyzed fresh from the pod by Prof. McCarthy, the Government Analyst, the fat was only 18 per cent in one, while in the other it was over 28 per cent., Theobromine being in nearly the same proportion.

341. The importance of keeping the higher class varieties separate would appear obvious, but this should be arranged for in the field in course gathering; but to do this successfully under the present state of mixture existing in plantations, skill and special aptitude would be necessary.

342. Prompt drying of the cacao beans on being "malted" or germinated, and otherwise treated in a manner to be ready for the drying stage is, perhaps, the most important part of the whole process of preparation, and it is, (under a dependence on sunheat) owing to the generally defective means for doing this in damp or showery weather during five or six months of the year which contribute most largely to the result of an immense quantity of not only badly prepared, but positively damaged cacao yearly exported from the colony.

343. This is more particularly the case with cacao contributed by small growers, who, looking to returns by weight and not by quality sweat their cacao (almost always inferior from being gathered without discrimination of ripe and greatly unripe pods) only for the purpose of cleaning the beans to some extent of their mucilaginous covering by common decomposition. In this way the beans are more difficult to dry and very often there is not sufficient sun heat to prevent them turning black during a single night under the effect of "mould," and the sample is ruined.

344. Again, put up in sacks for conveyance to store or dealer, while insufficiently dried, mildew and decomposition quickly damage the sample, and various means are therefore employed to improve the quality *externally*, for internally no improvement is possible.

345. The remedy to this, and what is urgently needed in all parts of the island, is a means for drying artificially —at least as promptly as can be done by the best sunshine—and to act either as an adjunct to sun-heat during the day or independent of it both day and night.

346. The requirement has suggested to me the application of the old flue—heated floor of orangeries and conservatories in Europe, and which, by the simplicity of its construction, its non-liability to get over-heated, (with the simple contrivance of a "damper") and its great power of retaining moderate heat, and otherwise its easy management, appears to be peculiarly adapted to meet this requirement as it exists with *small* growers, and who have a cacao house of some sort, for howsoever small the structure, this mean of heating its floor can be applied, at a proportionally small outlay.

347. The same means for heating can be applied, not only to the largest estate cacao house, but also to any Receiving House or Central Factory that might be devised, and which, after all, is probably the best, if not the only means by which a radical reform and improvement can be wrought in the general work of preparation and export of Trinidad cacao.

348. The chief functions of such Factories would be to receive cacao by purchase from the growers—fresh from their trees, or pods, and so relieve them—or such of them as have not the means for properly preparing it themselves—of all the work of preparing the beans for the markets, and subjecting them instead to a carefully regulated and scientific process of selection, curing and drying, so that only high-class samples of cacao might result.

349. With the establishment of such Receiving Houses or Factories a new phase in the cacao industry would be entered upon, and a wide field opened up for the employment of the highest skill and intelligence and by which that most important part in the work of preparation would become practicable viz:—sorting the fresh cacao pods into their distinctive varieties, and by which, as I have shown, the value of the samples would be greatly improved. Under such means, and a system as time and experience would make perfect, the outcome of cacao produced might be as superior to what the bulk of cacao produced now is, as the Usine crystal sugar is to the old 'Browns' (without, however, the great expense attending the former) or as the San Antonio cacao fetching its 105/ to 120/ is to the 'shop' cacao of the valleys fetching its 30/ to 50/.

350. It may be expected also that the present manner of exporting cacao as beans in bags would soon become obsolete, and the pure unsoiled nibs or natural segments of the bean or 'kernel,' *(cotyledons)* take their place in well-made chests lined within, and figured and ornamented without—to preserve to the consumer all the aroma and flavour of the well prepared article in its natural purity, and to indicate the varieties and their characteristics, and at the same time their respective values in a way similar to what has become a necessity in respect of wines, teas, tobaccos, cigars, &c.

351. I have designed a plan of a cacao drying-house (of the style commonly in use at the present time) furnished with a flued floor as kiln on the principle mentioned, and by the kind assistance of the Director of Public Works, I am able to append an engraving of same to this Report. It will be seen from this that the application of the plan of a ground floor involves no alteration in the style of structure now in vogue; but, where the plate is less than 2 feet from the ground, the roof must be raised, or excavation be made to admit the flued floor and furnaces. As a rule, however, the height of the cacao house is such as will admit the flued floor without alteration.

352. The engraving will sufficiently well explain the arrangement of the flues &c., but it might be explained that the supporting walls may be for small structures of ordinary rough stone, and the flues would be best laid in gravel, or firm soil with which the whole of the space between the supporting walls might be filled up to level of floor.

353. The flues would in all cases be best and most economically laid if formed of concrete in moulded lengths of two feet, with movable top and which, now that concrete is being so well understood and largely used here, could be easily obtained or made on the spot.

354. The fuel to be used may be wood of any sort, dry clippings even of the cacao trees; coarse grass or even leaves, and with a fire kept going for one hour at sunset the flues would be sufficiently heated to prevent mouldiness for the night.

355. It will be observed that the trays in which the cacao is placed, run free above the kiln, and they should in every case have open and spleeted bottoms to allow of of the free circulation of the heat from the floor up through them.

356. This plan to be efficient in respect of a large cacao house or central factory would simply have to be extended, and additional accomodation in the way of racks and drying trays provided.

357. The heat—which of course might be developed to any needful degree—being generated in the floor will naturally ascend, and affect in its course the cacao arranged in trays one above the other to any practicable height.

358. Ventilators must necessarily be provided for the escape, (at top) of moisture from the drying cacao. The sides of the structure should be so arranged as to admit of the trays being run out on each side of the building on running frames for sun-drying when desirable.

359. The house or rooms in which the cacao would be carried through the other stages of preparation both before and after the drying must of necessity be very near to, if not connected with, the kiln drying-house, but they should always be to windward—for safety, as for the convenience and comfort of the operatives.

PLOUGHING MATCHES AT MADRAS.

The following is a letter from Mr. W. R. Robertson, M. R. A. C., Superintendent of Government Farms, to the Secretary to the Board of Revenue, dated Saidápet, 6th February 1882 :—

Our annual ploughing matches were held on the Saidápet Experimental Farm on the morning of Saturday the 26th ultimo. The land on which the competitions were held was of two descriptions—"irrigated" and "unirrigated." The latter was a sandy loam, free and easy to work; the irrigated land contained more clay, and it was therefore stiffer and more difficult to work, especially as it had but just produced a crop of paddy. The dry land had been under ragi, and all the land was in stubble. The competitions were so distributed that the public might see the working of both improved and country ploughs in land differing in character and condition.

There were fifty competitors; of these eight were farm employés. The majority of the competitors used the common country plough; a few worked improved ploughs, which they had purchased from the farm and elsewhere.

The conditions of the competition and programme were as follows :—

(1.) The competition will commence at 6-30 A.M. precisely. The competitors with their cattle and ploughs must be in the field at 6 A.M.

(2.) A plot of ground containing 480 square yards will be allotted to each competitor.

(3.) Points in all cases will be awarded for, deep and efficient tillage (50), straightness of furrow (20), and speed in executing the work (30); and the prizes will be given to the competitors in each class who obtain the highest aggregate of points.

(4.) During the competition, besides the competitors, only the Judges will be allowed to walk over the land. (It is of the utmost importance that this rule should be strictly adhered to. Plough-cattle are timid when strangers are near, and sometimes become unmanageable with the very primitive gear used by the ploughmen, and any irregularity of this sort might altogether spoil a competitor's chance of success.)

(5.) After each competition every opportunity will be afforded for examining the ploughs and the work done.

(6.) The names of the competing ploughmen, with a description of the ploughs to be used, must be entered at this office one clear day before the day on which the competition takes place.

Prizes were offered in six classes as below :—

Class I.—Ryots using any kind of plough.
,, II.—Students of the Agricultural College.
,, III. Laborers using improved ploughs in unirrigated land.
,, IV.— do. do. in irrigated land.
,, V.— do. ordinary country ploughs in unirrigated land.
,, VI.— do. do. do. in irrigated land.

The prizes ranged in value from R2 to 10, excepting in the case of the students' competition, the first prize of which was a silver watch and chain.

[Then follow lists of the judges and of the successful competitors.]

Mr. Robertson proceeds :—

It must be remembered with reference to the foregoing, that the character of the ploughs used and of the work performed differed considerably in the various classes, and that, therefore, the points awarded in each class do not admit of comparison.

I have also stated that when the country ploughs worked they cut more than 3½ inches; while, as is usually the case with these ploughs, more than half of the land was left unmoved in ridges, where the grass surface was unturned, being simply loosened in the manner effected by the cultivator. The improved ploughs worked, on the average, 6 inches deep the whole of the soil was moved and the grassy surface was well turned over.

As regards speed in performing the work, the improved ploughs were equally superior. On the average they completed each plot in 45 minutes, which is equal to an acre ploughed in 7½ hours. The unimproved ploughs took, on the average, 60 minutes to complete each plot, thus getting over an acre in 10 hours.

The results of the matches were conclusive in showing the great superiority of the mould-board ploughs over the ordinary country plough as regards efficiency of work, cost of performing the work, or speed in completing the work. The cattle that were employed to draw these ploughs were certainly much superior to those used in drawing the country ploughs, but they were not superior to the cattle generally used in Cuddapah, Salem, Nellore and in other districts. If the improved plough could but be introduced generally into the districts just referred to, the benefits that would result therefrom would be enormous.

In several districts the plough-cattle are not fitted to draw the larger improved ploughs, but for these localities a smaller kind of mould-board plough can be provided.

The students' competition was held to determine the best ploughmen in the senior class. It was an interesting match from the fact that the competitors belong to localities widely apart: one to Bengal, one to Bombay, and to different parts of this Presidency. The Bengal student carried off the first prize. The work done was very good indeed.

We hope to see similar matches in Ceylon. Better cattle, improved ploughs and deeper tillage would result in greatly increased crops.

ANALYSIS OF "HYBRID BARK."

The annexed analysis, we are informed, is derived from bark obtained from six *consecutive* hybrid trees grown upon Broughton estate, they (as self-grown seedlings) being the product of a mixed fringe of succirubra and officinalis trees planted (probably 20 years ago) by Mr. John Atwell on the Mahapittiya (now part of Broughton) estate. The exact date of planting of the original trees is not known. Perhaps Mr. Atwell could enlighten us upon this point and also state if the trees came from Hakgala.

The average age of the 6 analyzed trees is 5½ years
,, ,, height ,, is 17ft. 10 in.
,, ,, girth at collar ,, is 19½
,, ,, girth 3 feet above collar ,, is 14

The strips for analysis were taken 2½ feet from above the collar. More robust even as seedlings and plants, at 3 years these hybrids are said to be taller, stronger and more full of bark than succirubra trees of the same age. The seed from these trees is also said to be peculiarly true to the hybrid type.

The 6 trees analyzed are growing at an elevation of about 4600 feet.

Copy.

Memo 3,75. Colombo, 15th March 1882.

Analysis of Hybrid Cinchona Bark :

Crystallized Sulphate of Quinine Dried	...	4·21 per cent Dried.
Gross value in London market	...	5/2 per lb.
With Howard Sulphate of Quinine @		10 per oz.
Total Alkaloids		7·15 per cent.

Remarks : Average of 6 stem quills.

(Signed) C. E. H. SYMONS.

[The following letter has been cut out of the "Times" and sent to us. The facts stated ought to be sufficient even. for our good friend Mr. Smith.—ED.]

HYBRIDITY OF CINCHONA.

SIR,—A letter of Mr. Wm. Smith of Mattakellie appeared in the columns of your evening contemporary the other day, which contained an interesting account of the writer's experience regarding the grafting of Ledger cuttings and shoots on to succirubra stocks, and also some arguments of his in support of the theory that cinchonas do not hybridize. It is only the latter subject which I wish to speak of here; and with all due deference to the opinion of one who has had so much experience of the cinchona tree, I cannot help arriving at a different conclusion, as do the great majority of my brother planters. How does Mr. Smith account for the presence of hybrids or Robustas on estates, where no other seed but that gathered from the trees on that estate has been sown, and where no Robusta tree old enough to give seed is to be found?

On this estate there were 103 succirubra and 44 officinalis trees [unfortunately cut down and sold in London in 1879] growing alternately along a road when I took charge, and a few self-sown trees in the coffee, but they were certainly not older than two years then, and the original trees were 11 years old, having been planted as far as I am able to ascertain in 1867. I am certain there was not one solitary Robusta among the original trees, which have since been coppiced and have thrown out fine, healthy, tall shoots, and anyone can satisfy himself that the succirubra are pure and the officinalis too: the latter of course should be called Condaminia.

Until last year no other seed but that from my own trees has been sown here, and I have many thousand hybrids growing all over the estate ranging in age from one year to *six*. Now the question naturally arises where these hybrids, and particularly the oldest of them, six years old, come from? I have one or two Micrantha plants about a year old, but I have no Micrantha tree, I feel confident. Where did they come from? I am certain that most practical planters have adopted the hybridization theory—not without sufficient proof—and are not to be perverted even by so great an authority as Mr. Smith.

Any opinion of Mr Smith is entitled to great consideration at our hands, but, if he is so confident, as he expresses himself to be, that no hybridization can take place, why has he had his valuable Ledger trees enveloped in muslin whilst in flower, as I have heard he had done?

Does not this look as if he thought it was just as well to be on the safe side? It is useless to dismiss the many facts that go to support the hybridization theory with generalisations such as "that the hybrid theory is repugnant to my every sense, moral and material."

I will ask him are there no cases of hybridization or cross-breeding in nature, as he seems to imply?

H. H. CAPPER.

Broughton Estate, Haputale, 25th April 1882.

INFLUENCE OF FORESTS ON CLIMATE.

It is perhaps, from a feeling that the continuance of our present, or rather, our late, system of forest conservancy is in serious danger, owing to the breaking up of the Forest Board, that Dr. Schomburgk, the Director of the Botanical Gardens has added to his recently issued report a lengthy appendix on the subject of the influence of forests on climate. The object of this paper is to prove that the destruction of forests usually has the effect of reducting the rainfall, while on the contrary, the planting of trees broadcast over a country is one of the best methods which can be adopted for ameliorating its climate and increasing the annual fall of rain. It cannot, indeed, be proved that the climate of South Australia is altering for the worse in this respect. In fact, a comparison of the meteorological records will show that the annual average rainfall for the colony during the past ten years has been 21·1 inches, as compared with 20·1 inches for the previous ten years. The fact is that in the agricultural districts of the colony, and especially in those which were not originally timbered, the bringing of the land into cultivation has had the effect of slightly favouring the fall of rain. Ploughed land attracts moisture to a much greater degree than the unbroken soil. In considering the effect which the removal of forests *per se* has, in altering the climate in South Australia, the only direct test that could be taken from the records issued by the Government Astronomer is the experience of the neighbourhood of Adelaide. If we divide the time which has elapsed since 1839, the year in which observations were commenced, into two periods, we find for the first an average rainfall of 28·8 inches and for the second one of 21·7 inches. It will thus be seen that on the whole the rainfall at Adelaide is diminishing, though very slightly, and, perhaps, the diminution in the amount of timber may have something to do with the change. There is, however, a comparison which is much more interesting than this, namely, that between the results obtained at the Observatory, at which there are very few trees of any size, but which is near to the sea, and those observed on East-terrace, at which they are more numerous, and which is nearer to the hills. There is a difference in the average rainfall of about three-fifths of an inch between these two places. This, of course, is in itself very slight, and would be scarcely worthy of notice but for the curious fact which is observable, that the advantage at East-terrace is entirely in the winter and spring months, while West-terrace has the greater amount in the summer months.

Dr. Schomburgk, in searching for illustrations of the effect of trees on climate goes further afield, and brings forward some striking historical instances, in which it is evident that loss of forests means loss of rainfall, and *vice versa*. He recalls to memory how the Russians by burning down some of the Trans-Caucasian forests at the time of their struggle with the brave Circassians converted the country from a fertile land into a desert, simply through the cutting off of the supply of rain. Similar instances of rain having deserted a country denuded of forests have occurred in the Mauritius, in Jamaica, the Azores, and it may also be added to a still more remarkable extent in several of the smaller West-India islands. No sooner had the forests of these places been destroyed than the springs and rivulets ceased to flow, the rainfall became irregular, and even the deposition of dew was almost entirely checked. On the other hand it is generally accepted as an historical fact that the great Mehemet Ali, the most remarkable of the rulers of Egypt, increased the fertility of his country enormously by planting trees. He alone planted some 20,000,000 on the Delta; his successors followed up the work and it is a noteworthy circumstance that the rainfall rose from six to forty inches.* Planting has also, it would seem, produced remarkable effects in France and Algiers. Extensive regions have been planted with gums and other trees, which, for the most part, grew to about thirty or forty feet in height, and it is noticed that the quantities of rain and dew which now fall on the adjacent land are double what they formerly were. To the French Government is due the honour of having made experimental tests, which placed the matter, at least as regards the European climate, almost beyond a doubt. In the historical method of research one must take the conditions as he finds them, and may very often be deceived by overlooking some fact of material consequence But when experiment is possible the conditions in one case can be rendered exactly similar to those in the other, and the test is then one of scientific exactness. Rainganges were erected under the supervision of the Forest Academy of Nanoy, some being placed in the neighbourhood of forests and others in the same districts, but surrounded by open plains, and the striking fact was established that the

* If this is true, there is an end to discussion, but *is* it true? We utterly discredit the wild statement. Who kept the Egyptian records?—ED.

land in the neighbourhood of forests received one-quarter more rain in the year than that which was denuded of trees. It would certainly be worth the trouble involved, if the Government Astronomer or the Forest Board, or, perhaps, the Director of the Botanical Gardens himself, would make similar trials in this colony. The comparison to which we have already called attention, namely, that between the rainfall on West-terrace and on East-terrace is one which would justify further investigation, as the differences which we have pointed ont cannot be simply a matter of chance, but are probably due to the influence of trees.

The controversy on this subject is likely to be interminable unless some steps are taken to determine definitely whether the presence of trees in this climate tends to augment the rainfall. The Forest Board has gone to work, most of the members firmly believing the affirmative, while the Surveyor-General, whose opinion is entitled to respect, inclines with equal resolutoness to a negative answer. We have already stated our belief that the Forest Board, in order to establish its *raison d'etre*, does not require to prove the theory. The providing of a supply of timber; the encouragement of profitable industries connected with forestry; and generally the work of rendering the open plains of the colony more habitable, must afford ample grounds for the existence of the Board, independently of the rain question. However, if the members, or rather the late members, wish to establish the theory they cannot do better than collect and record the experiences of those parts of this colony which have been at one time covered with timber, and which have since been denuded of it. Certain it is that such an enquiry would be justified by the authority of nearly all the best writers on moteorology and physical geography. The connection between forests and rainfall is not anything of a mysterious or incomprehensiblo nature. On the contrary, it can be explained by very well-defined physical laws. One of these is the law of the radiation of heat. A forest-clad plain is much slower both in parting with and in receiving its heat than is a bare one; and, consequently, it is much more frequently at a different temperature than the clouds, and must, therefore, assist in causing them to fall. The conduction of electricity from the atmosphere is another way in which it has recently been demonstrated that trees assist the fall of rain. A third point to be observed is that trees interrupt the lower and moister currents of air, and facilitate the deposition of dew at night, and, similarly, of light rains in the winter time. It should be noticed that the place for observations on this important point is not one in which trees have been cut down only to make room for houses or other erections, as in a city. The comparison should be between a plain covered with trees and one absolutely bare. There is no reason why this vexed question should not be settled in a very short time, if the enquiries would only proceed in a reasonable spirit, instead of, as at present, contenting themselves, the one party with a bare affirmative and the other with a bare negative.—*South Australian Register.*

[The difference in rainfall for two periods is so slight as possibly to be merely the result of a different mode of observation. Curiously enough not a word is said about the influence of the neighbouring Mount Lofty on the rainfall of Adelaide. If that mountain were removed, the result would be more disastrous than all the denudation of trees which has occurred. Even if tree planting does not increase rainfall, it will do good otherwise.—ED.]

THE UNEXHAUSTED VALUES OF MANURE.

At the special request of Lord Rosebery, the Scottish Chamber of Agriculture have prepared a list of suggestions which may be adopted as a basis for computing the compensation for manures unexhansted at the termination of a tenancy. The following is the list:—

1. *Lime.*—In all soils to which it would be proper to apply lime, and the proper quantity (over five tons) is applied, it is good. In light soils, for ten crops; in good, deep, loamy soils, for twelve crops; in clay soil its beneficial effects are not lost in fourteen or fifteen crops; and in peat soils it is good for ten or twelve crops. In new grazings its effects are seen in twenty crops, and in old permanent pastures its effects are discernible for thirty years.

2. *Horse, Cow, and Town Manures.*—When applied in sufficient quantity (above fifteen tons), these manures are exhausted in the ordinary five-course shift. The rate is more rapid in the first two than in the remaining three years—say, half in two years and the other half in the remaining three years of the rotation.

3. *Guanos.*—If highly ammoniacal, the exhanstion of the nitrogenous matter will be rapid in the first and second year. But there are other valuable fertilizing elements in good guano, and these are more enduring. Experience demonstrates that half the manurial value of guano is exhausted in the first crop, and the other half left available for the remaining crops of a rotation. Its beneficial effects are obvious in most soils, even in the fourth year of a rotation.

4. *Bones.*—Bone-dust will benefit, according to the nature of the soil, from three to five crops of cereals and grasses. Dissolved bones are more rapid in the rate of exhanstion. The first crop takes about one-third of the manurial value; the second will bring the one-third up to a half, and a third and fourth crop will exhaust the whole.

5. *Phosphates* decomposed by vitriol will be exhausted at the rate of dissolved bones, and ground phosphates at that of bone dust, and the rate of exhanstion may be taken as that of guano.

6. *Sulphates* are volatile, and experience leads to the belief that, when applied in sufficient quantities, these are mostly exhausted by the crop to which applied, to the extent of two-thirds, and to the extent of the balance in the next crop, and are of little appreciable value to subsequent crops in Scotland. It is right, however, to state that Mr. Lawes's experience in England seems to be different.

7. *Special Manures.*—These are the manures prepared for special crops, and known by the name of the crop to which they are applied, such as "turnip manures," &c. The rate of exhanstion of these depends upon the ingredients of which they are made up. Experience would class the rate higher in endurance than sulphates, but of less endurance in guanos—say three years—two-thirds first year, and one-third the remaining two years.

8. *Clay.*—A well-known application to peat and other vegetable soils, which endures for seven years at least, and which may be held to be exhausted one-seventh of its cost each year. In Scotland the cost of its application is its only cost.—*Indian Tea Gazette.*

AGRICULTURAL ITEMS.

(From the *Queenslander*, 25th March.)

The largest room in every cheese and butter factory of the land is the room for improvement.

An American farmer reports no appar nt injury to parts of an asparagus bed covered with a coating of salt so much as 2 in. thick.

Much selected land in South Australia is North of Goyder's line of rainfall, and useless for agriculture.

The wheat harvest just garnered in South Australia is small but better in quality than has been seen for years.

As a bee forage plant nothing is better than mignionette, and the honey made from it is deliciously fragrant and commands a higher figure.

No man can remain perfectly healthy without a good supply of vegetables. All exclusive flesh diet begets grossness, fatuess and laziness.

Young larkspur and castor oil plants are destructive to locust life.

The English consume on an average 20lb. of cheese each per annum, or a total of 500,000,000 lb.

In an experiment at the Illinois Industrial University, corn cultivated six times gave 8 per cent more crop than that under same conditions, but cultivated only 3 times.

Glucose is largely superseding barley malt in the manufacture of lager beer.

Crushed bones form an excellent manure for sugar-cane.

In poor land it is a great mistake to put the surface mould too deep. In trenching, work so as to keep it on the top.

THROUGH THE DARK PRESENT TO THE BRIGHT FUTURE.

Everything seems so to obey the cycle theory that a man like Stanley Jevons even, went the length of advancing the proposition that commerce and finance were ruled by the sun-spot periods. Of course, the proposition must have a certain amount of truth in it, if we believe, as we suppose most intelligent observers now do, that the weather and the harvests, on which the prosperity of commerce so much depends, are affected by the sun-spots, that is, by solar influences. Observations of a limited nature may seem adverse to the doctrine, but when extended areas and extended periods are the materials for inference, very striking conclusions are arrived at. It may be—why not?—that, as depression in Ceylon has reached its lowest depths coincidently with the close of a period of quiescence in the sun's gaseous envelope, so a reaction to prosperity may be coincident with the abnormal activity recently developed in the forces which dwell in and radiate from the centre of the solar system? There is no place in the world where belief in the influence of the sun spots on the earth's meteorology and, therefore, on the interests affected by the weather has been more persistently taught than in Mauritius by that careful observer and able generalizer, Mr. Meldrum. Rightly, therefore, on all accounts has our correspondent used the sugar colony as an illustration of warning, or rather we should say of cheer, to us in Ceylon. What he states is true. It was only the other day that sugar property in Mauritius, which is now at a very high premium, as the extracts which follow "Mercator"'s letter will shew, could be purchased for an old song. Our own constant complaint was that a company which owued so much of next to worthless property in Mauritius should take its title from the isle of the prosperous and promisiug coffee. Lo! the change. Many shareholders in the Ceylou Company (Limited) must experience bitter regret that their directors parted with estates which are now so exceedingly valuable. Why should not the process which in a few years has raised Mauritius and her sugar interest from the depths almost of despair, to great and still advancing prosperity, not be repeated in Ceylon? In the history of our island's enterprize, several such rebounds to prosperity from almost hopeless adversity have occurred, and "that which hath been, that it is which shall be." The doctrine of cycles is roughly embodied in the popular proverb that "When things are at their worst, they will be sure to mend," and the mending time must be close at hand, for it is difficult to suppose that things with us can become worse than they are: especially in regard to our great staple, Arabian coffee, and in a minor degree with reference to our secondary staples, coconut oil and cinnamon. We must not be misunderstood as now alluding to the retrieval of the colony's position by the means of "new products": tea, cinchona, cacao, &c. What we look for, confidently and soon,—if all analogy in human affairs is not to fail us,—is a reaction to prosperity in our old staples and especially in the sore-tried coffee, so long the victim of abnormal seasons; so long the prey of enfeebling fungus and wastiug grub. Having done their worst, those malefic agencies may now be expected to depart altogether, or much and continually to abate in virulence uutil the normal condition of our great and older industries is restored. Our gratitude is due to the correspondent who has struck the key-note of hope, and we commend his arguments and his very striking illustration to the best attention of our readers, especially those inclined to look exclusively on the dark side of the shield. There *is* a bright side, although for a time it has been obscured.

We do not know half the uses of electricity as yey Professor Scoutteten assures us that electricity in ant form, whether by continued and direct current, or by current of induction, or by spark, always acts in the same manner with wines, and makes the hardest and most acrid vintages soft, mellow and agreeable to the palate. In fact, electricity gives age to uew wine. This was discovered in France, not very recently, though no scientific action has yet been taken on it. The case was once reported to the Academy of Sciences by a vineyard proprietor of Digne, whose house was struck by lightning.—*Pioneer.*

AN AUSTRALIAN REMEDY FOR ASTHMA.—A correspondent of the Sydney *Town and Country Journal* writes to that paper to bear personal testimony to correctness of the claim which has often been made on behalf of a species of *Euphorbia* indigenous to Queensland, and knowu scientifically as *E. pilulifera*, that it affords a remedy for asthmatic and bronchial affections. An ounce of the leaves of the plant placed in two quarts of water, and allowed to simmer till the quantity is reduced to one-half, will afford a medicine which, taken a wine-glassful at a time, twice or thrice a day, will relieve the most obstinate cases of asthma, as well as coughs and ordinary chest affections. The leaves may be easily gathered and dried, and kept for a cousiderable length of time. Evidence of the virtues of a decoction of the leaves of this species of *Euphorbia* is very general in Queensland and parts of New South Wales, as other kinds of *Euphorbia* have a considerable medicinal reputation in India and elsewhere. Thus leaves of the *E. nereifolia* are prescribed as a purgative by the native practitioners in India, while the root of the *E. ipecacuanha* is said to be equal in all respects to the true ipecacuanha. This extensive genus of plants evidently deserves the careful study of skilled botanists and druggists.—*Colonies and India.*

Correspondence.

To the Editor of the Ceylon Observer.

HAWK-MOTHS ON COFFEE.

Ramboda, 25th April 1882.

SIR,—In reference to your footnote to the *Madras Mail* extract where "South Wynaad" mentions a great number of hawk-moths busy amongst the blossom on his coffee, I beg to send you one which I have little doubt is the insect alluded to. It unfortunately has the tail destroyed by a spider, in whose web it had become entangled. In your next quotation from the *Indian* paper I see it is described as one of the sphinxes. As I have all along supposed, though not pretending to scientific knowledge, these sphinxes are not uncommon here; but I certainly never saw such numbers before, as were observable amongst the coffee when in blossom a fortnight or so back. However, they do not confine their attention to coffee blossom; but, with multitudes of insects of many kinds, could be seen a day or two ago on a large jungle tree in full flower close to the bungalow.

It seems to me somehow that insects of many kinds are especially numerous this season: caterpillars of various kinds; moths in variety, such as I never observed before; beetles; and those evil-smelling green bugs, which suck the sugar from the ripe coffee berry, mentioned, if I recollect aright, as the last of his list of enemies to the coffee tree by late J. Neitner. One comfort, however, the cockchafers this season have, with me at any rate, been far less numerous than they were last year.—Yours truly, E. W.

[Our entomological authority states:—"One of the clear wing humming-bird hawk-moths belonging to the family Sessidæ."—ED.]

THE QUESTIONS OF CROSS-FERTILIZATION AND HYBRIDITY IN CINCHONAS.

April 25th, 1882.

SIR,—Interesting though the discussion now going on is in reference to hybridization among cinchonas, and valuable the opinions so far must be when coming from men so well qualified either by their scientific attainments, or by practical experience, to express themselves emphatically, is it not possibly true that they are, after all, all pulling at an imaginary rope? That Messrs. Smith and Gammie are quite right in saying there can be no such an occurrence as hybridization among cinchonas, owing to a misapplication of the term; the fact being the different *varieties* as little deserve to be considered anything beyond this as do white men and black, figuratively speaking, *all men* with as little right any of them to be regarded as monkeys! And is it wrong to suppose that there are instances of a cross between, say, an Englishman and a Hindu, accruing: though, for an ideal specimen of robusta, it may be necessary to refer to the West Indies, where an African mulatto, from all I have heard, would hardly be a comfortably safe mortal to call a hybrid at too close quarters—as good at hitting or kicking as any "Nestor"!

Mr. Gammie calls for a single instance in either the animal or vegetable kingdom of natural hybridization. How as to rabbits and hares? And what about his near neighbours, the Assam and China varieties of tea? Do they, or not, cross freely, artificially fertilized through the agency nature so abundantly provides, in the multitudes of bees that fly from flower to flower, in the case of all species of plants *who within their own species are so inclined?* Among these, a so indisputable botanical authority as the Director of the Botanical Gardens tells us the cinchonas afford striking examples, owing to the peculiarly apt construction of their flowers. As to outward appearance, no two varieties of cinchona differ more from one another than do Assam and China tea plants; and do they differ more essentially in other respects?

Were the question as to a cross between any other of the quinine-yielding species of the same family, (instance cuprea!) and the true cinchonas, say between a chimpauzee and a Chinaman, it would be quite a different matter. Such a cross might be called a *typical* hybrid. And it is quite possible to realize the necessity for mental intervention to effect it.—Yours faithfully, X.

A DEVIL'S ADVOCATE ABOUT JOHORE.

Galle, April 26th, 1882.

DEAR SIR,—There has been a good deal written to the *Observer* regarding the prospects of Johore and great deal of it is calculated to mislead readers.

Mr. Dobree, who visited Johore towards the end of last year, gave a very unfavorable account of the Pulai district, and having lately visited the Batu Pahat district, which is the largest district under cultivation, I can only say that I consider that it is a complete failure. The soil is sand mixed with sour clay and quite unsuited for the growth of Coffea Arabica, Liberian, or cocoa, and the climate is very unhealthy both for Europeans and Tamils and Chinese. Labor is very expensive: 30c. a day, *i. e.* about 60c. Ceylon money; chiefly Chinese, who are only good for contract work. Tamils cannot be procured now. The district is situated 70 miles from Johore and Singapore, and there is no road whatever to it, not even a jungle path, the only means of communication being Chinese boats or tongkongs, which go up two or three times a month, and take three or four days over the voyage, and are most uncomfortable to travel by, and residents there cannot obtain any fresh provisions whatever. To shew what people in Singapore think of the prospects, the "Lettybrook" estate, which was lately advertized in the *Overland Observer*, was sold for $800, about £150. There are 100 acres planted with Liberian coffee, 11 acres ready to plant and 177 acres forest. When an estate like this is sold for such a ridiculous figure there must be something rotten in the state of Denmark. Having had nearly 20 years' experience planting in Ceylon and seen a good deal of coffee planted, I think I may say that I have never seen any coffee such a complete failure, or planted in such miserable soil. I would not advise anyone to go over to Johore to invest, or even to take a berth, certainly not to throw up one in Ceylon, however small, to go over there.—Yours truly.

COFFEE.

[The writer of the above sends us a private letter to the following effect:—

Enclosed I send a letter regarding Johore, which, should you think fit to insert in the *Observer* please do so. I think that it is only fair to the public to hear both sides of a question, and Johore has been praised up too much. Every Ceylon planter of experience who has visited it has condemned it. Messrs. Dobree, Macartney, Young and several others have all had the same opinion.

These letters having been written on April 26th, of course the writer had not seen Mr. Dobree's favourable opinion which appeared in our columns on Saturday. That Mr. Dobree gave an adverse opinion regarding an Arabian coffee estate at too low a level is, we believe, certain; but no one who has seen tea, Liberian coffee and cocoa within easy reach of the capital of Johore can doubt the suitability of soil and climate. Labor is another question. We saw Chinese at work and were disappointed that the aborigines employed by the Maharajah were absent. We have no doubt Mr. Dobree and others will reply.—ED.]

THE TRADE IN CINNAMON.

27th April 1882.

SIR,—I find that a correspondent, who signs himself "Cinnamon," has been addressing your daily contemporary as to the means to be adopted to raise the price of cinnamon even by a small amount. I venture to address you on the same subject, as greater publciity here and in England will be given to this important matter by its finding a place in the columns of the *Observer*. At the present time, when a powerful agitation is set on foot to prevent adulteration of coffee and thus raise the price of our staple product, it will not be amiss to make an effort to similarly benefit a product which has given a name to this island. As the production of cinnamon is confined wholly to the island, combination to effect any change will be much more easy than in the case of coffee, tea, cinchona or any other product which has foreign rivals.

First and foremost we want monthly sales of cinnamon. A lukewarm and half-hearted effort was made some time ago to effect this change. A change could not then have been made, owing to the combined front presented by the English brokers against any departure from the old-established quarterly sales. The brokers predicted a still further fall in prices, if a change were made, and the agitation, if it could be dignified by such a name, ceased. Now to us who are not well versed in the mysteries of brokerage it occurred that any plan that would remove a middleman between the grower and the consumer would be a decided advantage to both. By the present system of quarterly sales, immense quantities of cinnamon accumulate, and are purchased by large capitalists, who supply the wants of the consumers, with a profit to themselves. If monthly sales are established, small capitalists, *i. e.* consumers, can afford and will be able to buy cinnamon themselves, and the profit made by the middleman, the large capitalist, will be divided between themselves and the grower, as the consumer will, even if he pays a penny per lb. more than the large capitalist at the quarterly sale, be paying less than what he would have to pay were he to buy of the middleman. I fear that to illustrate my meaning I have been rather prolix; but I have been endeavouring to make myself plain to my native friends, who are the chief growers.

Next in importance to monthly sales is the necessity to do away with the trade in chips. There will be many who will open their eyes at this suggestion, and consider it the proposal of a madman to still further lessen the income from an already poorly paying product. To prove that the idea is not a wild one, and will eventually benefit the grower, I shall resort to figures. Let us take, for example, an estate of 100 acres, the fair average yield of which ought to be a bale (100 lb.) per acre per annum. The outturn of chips let us take as half of the quilled cinnamon; and this outturn any experienced planter will tell you is very high. The local price for chips is from R40 to R45 per candy of 5 cwt., or say roughly from 7c. to 8c. per lb. The cost of scraping chips is 3c. per lb; so that the profit will be from 4c. to 5c. per lb. Let us resolve this to a profit and loss account :—

Dr.		Cr.	
To loss of suppressing 2,500 lb chips, being ¼ yield of 100 bales cinnamon, at 5c. per lb.	125·00	By the 2c. per lb. increase in price on 100 bales cinnamon, *i. e.* 10,000	200·00
Profit by the suppression of the chips	75·00		
	R200·00		R200·00

I think hardly any one will deny that, by the chips being withheld from the English market, we will benefit by a rise of *at least* 2c. or ½ penny per lb at the sales. If this be admitted, then it will be clear that, instead of being losers, we shall be gainers by not permitting chips to be scraped on our estates. Considering that the trade in chips is of very recent growth, it will not be a very hard matter to suppress it. A combination on the part of the principal native and European planters not to have chips scraped on their estates, together with an undertaking with merchants not to ship chips, will, I am sure, effect the desired change; while those who scrape chips amongst the small landholders can find a ready sale for them for the purpose of distilling oil.

I hope proprietors of cinnamon land, though they have not a representative association, will see the necessity of calling together a meeting, absent proprietors being represented by their agents, to consider what steps ought to be taken to protect their interests.

—Truly yours, PLANTER.

ANTI-WHITE ANT DEVICES.

April, 29th 1882.

DEAR SIR,—If the sides of a hole are baked sufficiently to prevent white ants from getting *in*, will they not be about hard enough to keep the roots of the plant from getting *out*?

As a rule white ants attack the cocoa below the surface. So I do not think chopped aloe leaves spread on the top of the holes round the plants will act as a preventive. I have tried minced aloe, mixed largely with the soil in the holes, and have even put a good layer of it an inch or so below the seed or plant, but I can't say with much success. White ants *don't* like aloe juice, but they will go through a good deal in the way of temporary inconvenience to get at what they *do*, and that 's YOUNG COCOA.

P.S.—When Liberian cocoa* was planted at Wellawaya in 1876, enormous holes were cut, and a fire built and lighted in each, I believe. I don't know how it answered, or whether the object was to get rid of "poochies," or to add to the food of the plants.

ANALYSES OF NATURAL AND RENEWED "PUBESCENS" BARK.

Agrapatana, 29th April 1882.

DEAR SIR,—I notice, in your issue of 22nd April, a letter from Mr. Forbes Laurie, in which he says :—"A good Pubescens selected from a clearing grown from seed (where only Succirubra and Officinalis are growing) gives, on Howard's analysis, 8·31 quinine sulphate with hardly any other alkaloids." As the analyses of this species I have previously seen show, on Howard's analysis of natural bark, a very large percentage of cinchonidine, but in renewed bark a very small percentage—as, for example, taking two different trees : No. 1. (natural bark) 8·28 quinine sulphate, 3·37 cinchonidine ; No. 2, (renewed bark, 8 months) 8·30 quinine sulphate ; 0·03 cinchonidine—I have therefore imagined that the renewed bark gave a very much purer analysis of quinine, and I cannot help thinking that the analysis quoted by Mr. Forbes Laurie must have been from renewed bark. Would that gentleman kindly tell us whether it was renewed, and, if so, how many months' renewal ? and what covering—if any—was used ?—I remain, dear sir, yours faithfully,

RED BARK.

MR. JAMES SINCLAIR ON PLANTING PROSPECTS AND CINCHONA HYBRIDIZATION.

DEAR SIR,—I really think we, in the younger districts, are over the worst. Rid us of grub, and the fungus is not to be much feared. It is where you

* *Sic.* We suppose Liberian coffee was meant.—ED.

have poverty of soil and *hemileia* as well, or grub and the disease combined, that our efforts to put crop on the trees are baffled. The latter you have in the older districts; the former in the younger and unexhausted soils. Wait till you see what Maskeliya will yet do. For some years I had fine paying crops on one of my places. Two years ago I gathered 7,000 bushels of parchment; the following year I got 1,500 only. Am I to believe that the fungus was the cause of this sudden falling-off? Certainly not. Had it been the cause, it would have been marked by a yearly diminution instead of the sudden falling-off.

That was an instructive letter by our good friend of Mattakelly; but one is forcibly reminded of Dr. Cumming and his prediction about the world's coming to an end at a date he fixed: and yet he took a lease of his house afterwards for 10 years subsequent to that date.

If Mr. Smith is such a non-believer in hybridization, why was he so very careful that no cinchona other than Ledger should flower near his fine Ledgers? His confidence in nature's laws, as he professes to understand them, cannot amount to much.

Even were I not a humble follower of the late Mr. Darwin, I think it can scarcely be doubted that cinchona has this power strongly developed.

Four lines of seven year old succirubra trees run parallel from one end of the estate to the other about 300 yards apart; intersecting these and about the same distance apart are two lines of officinalis. There are thus eight points at which the lines cross. From under the trees at these points thousands of plants have been put out, quite one-third of which have turned out a nice-looking hybrid. The plants are from the seed dropped at the intersected points only; and yet my good friend of Mattakely pronounces them to be a fine type of Pátá de Gallinazo.

The plants, when quite, young can scarcely be recognized from officinalis, but the hybrid between it and succirubra soon becomes apparent. I have offered to shew him thousands of the young plants growing *only* at these points I mention, but he declines to be convinced. Let him put that in his pipe and smoke it.
—Yours truly, JAMES SINCLAIR.

NEW PRODUCTS.

Udugama, May 3rd, 1882.

SIR,—Enclosed you will find an account of what may be a useful new product for Ceylon (good materials for *new brooms* would be very useful in Ceylon just now). The Piasava fibre is quoted from £20 to £40 per ton, and, from the account of the size of the tree, might, I should think, be planted about 24 feet apart. At a yield of 20 lb. of fibre per tree, this would give about 1,500 lb. of fibre per acre, and selling say at 13*c*., or £30 a ton would give R195 per acre. What the cost of production is I cannot say, but, as it is not likely to be more than R100 an acre, it looks as if it might be a profitable cultivation.

I wonder sago has never been cultivated in Ceylon, for there is any quantity of land admirably suited for it. In the Straits they evidently think it a paying product, as I hear from Mr. Bailey that he is to plant up 400 acres for a company at Johore.

Liberian coffee, cocoa, nutmegs and all low country products are growing splendidly at Johore, and they cannot well help growing in such a soil and situation as I saw at Mr. Bailey's place at Pinnerang—I remain, yours faithfully, T. S. DOBREE

THE TRADE IN CINNAMON.

Colombo, 5th May.

SIR,—Your correspondent "Planter" finds fault with the quarterly sales of cinnamon in the London market, and with the aversion of London brokers to any change.

Allow me to point out that "Planter" is in no way compelled to submit to a system he objects to, but that in the local market he will always find buyers ready to pay the equivalent of the London quotations.

The local market offers all the advantages "Planter" asks for. He may sell at any time he likes; he does away with not one but two middlemen, and, above all, he has a chance of forming an opinion of his own as to the actual state of the market and the probable future by the attitude of buyers on the one hand, and the knowledge of prospective supplies on the other.

It seems the local market is growing in relative importance for all other articles: why should cinnamon planters adhere to the old system, the defects which do not lie in the quarterly sales but in the habit of consigning?—I am, sir, yours faithfully, MERCHANT.

THE condition of the immigrant labourers in Assam does not nearly approach the state of "slavery" which a few agitators in Calcutta recently painted in such vivid colours. From the Assam Administration Report for 1880-81, it appears that the death-rate among these labourers fell to 35·2 per 1,000, which is considered the normal figure for an Indian population; and the conditions of life are thus described:—"Food has been extraordinarily cheap, health has been good, and the improvements, which are every year being made on tea plantations in the water-supply, the housing of the immigrants and their families, the provision of better accommodation for the sick, and the like, have generally raised the labourer's standard of comfort in a marked degree."—*Pioneer.*

THE PEACH TREE IN CHINA is, according to the *North China Herald*, credited with many virtues, and the article gives interesting information, thus:—On one occasion two brothers, named respectively Tu Yu Yu Liu, who had power over disembodied spirits, passed the ghostly legions in review beneath a peach-tree, and, having bound all those who worked evil against mankind with scarlet withes, threw them as food to tigers. In memory of this it was customary for officials on the last day of the year to have figures cut in peach-wood mounted upon reeds, and to paint the likeness of a tiger upon the doorway as a talisman. At present, adds Mr. Mayers, the names of the two brothers are pasted on the entrance doors of Chinese houses on New-year's eve, to guard the dwelling from harm. Peaches, too, figure largely in Chinese fairy-tales and mythology, and formed part of the banquet prepared by the Royal Mother of the West when she paid a visit to the Emperor Cheng, better known as Shih Huang Ti; while a peach-garden was the scene of one of the most celebrated events in Chinese history, when the Oath of Brotherhood was taken between the three heroes who played so important a part in the historical romance of the Three Kingdoms. There are many other interesting details connected with the peach-tree in Chinese literature, but we have no space to enlarge upon them. Some pundits aver that, properly speaking, the peach is an emblem, not of longevity, but of death; while Western theorists have attempted to connect it with the tree of the knowledge of good and evil, whose fair fruit presented so fatal a temptation to our mother Eve. It seems, however, certain that, according to ancient writers, peaches were not admissible in sacrifice: that those with double kernels were a mysterious but unfailing poison; and that the premature fructification of one species of peach-tree was a harbinger of national calamity. All this may be very interesting, but it is not practical. We will conclude with two facts which have the merit of being both. The best manure for peach-trees, according to Chinese horticulturists, is snow; and a cold decoction of pig's-head, put round about the roots and into the trunk itself, is a sure remedy for the insects which prey upon it.

THE SEASON IN INDIA.

(For the week ending 25th April.)

Slight rain has fallen in the North-Western Provinces and Oudh, in the Central Provinces, in Assam, and in the Bombay Presidency. In Bengal, Madras, Mysore and Coorg, and British Burma the rainfall has been more or less general, although more is still wanted in some places in Bengal. Scarcity of drinking-water is still reported from Dharwar in Bombay. The recent rain in Mysore has been beneficial as far as it goes, but the wet crops continue indifferent. Harvesting of *rabi* crops is in progress in the Punjab, with good prospects and has almost been completed in the Bombay Presidency and in the North-Western Provinces and Oudh, with good or fair results generally. In Bengal the spring rice crop, which is now been harvested, is expected to yield a good outturn. In the Madras Presidency reaping of crops still continues, with outturn on the whole an average one. In one taluk of the Bellary district the dry standing crops are reported to be partially withering. In the Central Provinces threshing and winnowing of *rabi* crops still go on, and harvesting of wheat is in progress in the Central India States. General prospects continue to be good throughout the country, and land is being prepared for *kharif* sowing in Bombay, Berar, and the Central Provinces; while in Assam and Bengal ploughing and sowing continue.

Madras.—No rain in Kistna, Chingleput, Tanjore, and Travancore; general prospects good.

Bombay.—*Rabi* harvest generally completed; preparation of land for next season begun in a few districts; slight rain in Dharwar, Belgaum, and Kanara; scarcity of drinking-water in six talukas of Dharwar continues; slight fever and cattle-disease in a few places; cholera in Rajkot, Tanna, Belgaum and in Satara, increasing in Satara; prices generally steady.

Bengal.—Slight rain fell in most parts of these provinces during the week; in some places the rain was comparatively heavy; ploughing is proceeding, and in some places sowing of autumn crops is going on; more rain still wanted in several places; indigo, sugarcane, and other crops on the ground are doing well; *boro* (spring) rice is being harvested, generally with prospect of a good outturn; cases of cholera are still reported from many places, and small-pox reported from some places; the public health is however generally fair.

N.-W. Provinces and Oudh.—Slight rain fell in seven districts; prices have risen slightly in Allahabad, Cawnpore and Farukhabad and fallen in Moradabad, elsewhere they are stationary; the markets are well supplied; cholera is still prevalent in Fyzabad, but is decreasing in Gorakhpur and Sitapur; a few cases are reported from Lucknow, Partabgarh, Allahabad, and Kumaun; small-pox continues in Cawnpore, Moradabad, Agra, and Jhansi, and typhus has appeared in Kumaun; cattle-disease has disappeared in Allahabad, but continues in Lucknow, Kumaun, and Jhansi.

Punjab.—Harvest prospects and health good; prices generally steady.

Central Provinces.—Weather cloudy and hot, with cool nights; threshing and winnowing of *rabi* crops going on; preparation being made for *kharif* sowings; cholera and small-pox in several districts; prices steady.—*Madras Mail.*

WE take the following remedy for simple continued fever from the *Scientific American*:—"Acid, hydrobrom. I dr.; Syr. simplicis, 2 dr.; Aq. ad. 1 oz. M. Sig.—Every hour.—*Fothergill.* In speaking of the above formula Dr. Fothergill is reported to have stated that it will probably constitute *par excellence* the fever mixture of the future. It is especially indicated, he says, where there is cerebral disturbance.—*Pioneer.*

TANNING IN THE MADRAS PRESIDENCY.—The *Madras Mail*, in noticing the operation of a former Government tannery, states:—The bark chiefly used was that of the *cassia auriculata*, while the pods of the divi divi, and gall-nuts or myrabollams, were employed to produce the finishing liquor.

A STRANGE SIGHT.—The *Bathurst Free Prees* reports a singular state of things at Locke's estate, at Locksley. In the bush, near the residence, is to be seen a strip of country on which every living shrub and tree has, by some mysterious process, been deprived of life. The trees, leaves, and undergrowth are all dry and hard, as though destroyed by fire, and not a blade of grass or a leaf is to be seen with any life. The strip of country is about 300 yards wide, stretching as far as the eye can reach, running along the plain and up the side of the mountain. Opposums lie dead at the foot of some of the trees, supposed to have been killed. A hot wind or an electric current or both are supposed to have caused the destruction.

MAJOR JACOB, of Jeypore, India who superintended the erection of the necessary plant, now states that he is able to produce a gas from the oil of castor beans, which will in all respects bear favorable comparison with the best samples of coal gas. Large works have been constructed, from which the entire town is supplied with castor oil gas with as much facility as though coal were the raw material used. Now that the system is in efficient working order it is found possible to produce twelve hundred and fifty cubic feet of gas of nine-candle power from eighty-two pounds of oil. The light is soft, yet powerful, easy of storage, is compressible, and is said to possess no dangerous explosive properties.—*Oil and Drug News.* [Jeypore, in Rajputana, is far inland, where railway carriage would render coal expensive. The castor oil plant grows plentifully in most parts of India. Like all oil-yielding plants the crop is exhausting. The railway companies have large manufactories near Allahabad for the preparation of the oil.—ED.]

CEYLON COFFEE PLANTS NOT TO BE IMPORTED TO RE'UNION.—The *Gazette* contains a despatch from the Earl of Kimberley to Governor Sir J. R. Longden, K. C. M. G., which calls the Governor's attention to the following document:—

The Foreign Office to the Colonial Office.

Foreign Office, 10th March 1882.

SIR,—I am directed by the Secretary of State for Foreign Affairs to transmit to you, to be laid before the Earl of Kimberley, a despatch in original from Her Majesty's Consul at Réunion, transmitting a Decree prohibiting the importation of coffee plants and berries into the colony from Mauritius, India, Ceylon, Java, Sumatra and the Fiji Islands.—I am, &c., CHARLES W. DILKE.

Consul Annesley to Earl Granville.

Commercial.—No. 3. British Consulate,

Réuniou, 16th December 1881.

MY LORD,—I have the honor to transmit to your Lordship herewith enclosed, a slip taken from the "Journal Officiel de la Réunion," of the 14th instant, containing an Arrêté dated the 13th instant, issued by His Excellency the Governor of Réuuion, which prohibits, until further orders, the introduction into this colony of all coffee plants and coffee berries, and even of all kiuds of plants, comiug from Mauritius, India, Ceylon, Java, Sumatra and the Fiji Islands.

This measure has been rendered necessary owing to the information received from the Mauritius Government of the appearance of a disease on the leaves of the coffee trees in that colony and in the other countries named in the Arrêté; also upon the recommendation of the Commissioners who were specially named by the local authorities to report on the best measures to be adopted for the prevention of the introduction into this colony of the said coffee plant disease.

I beg to enclose a copy of the report sent in by the Commissioners.—I have, &c., A. A. ANNESLEY,

H. B. M.'s Consul at Réunion.
