"THE HYGIENIC AND AGRICULTURAL VALUE OF PHOSPHORUS."—This is the title of a lecture delivered before the Bethune Society in Calcutta by Mr. J. L. Macmillan, F. C. S., on 30th December 1880, and the first part of which, published in pamphlet form, has been sent us by the author. This part treats of phosphorus from a hygienic point of view only, the agricultural question being left for the second part. Mr. Macmillan shows how important an element phosphates are in the human system, and the necessity for supplying the daily loss, an entirely vegetable diet being a mistake, even in hot climates. The discovery of phosphorus is related, and the relative values of different articles of diet are set forth. A table is given showing the amount of phosphates in 100 grains of the brain of the calf, and the brain and spinal marrow of the ox, respectively. Mr. Macmillan then says :—"Sideby side with these facts the much lauded oyster, as a phosphorus-yielding food, fades into comparative insignificance. The oyster yields under one per cent of phosphates : whereas from the figures above given, the brain of the calf furnishes over five per cent, and that of the ox, nearly three. With the exception of *salmon-roe*, which contains 50 per cent of a highly phophorized albuminoid body called nuclein, there is no food stuff of modern times that approaches the brain of the calf and the ox, as a source of available *organised* phosphates. Trout yields over two per cent of phosphates and therefore ranks higher than the oyster. The flesh of oxen, swine, and that of the roe, pigeon, and chicken, contain fractional percentages as compared with the results from brain just mentioned." The value of phosphorus as a brain-food and an enricher of the blood is then shown, and Mr. Macmillan then gives the following formula of a preparation devised by him at the request of the Drug Committee of the Victoria hospital for children, London, to take the place of the well-known "chemical food" in which sugar forms an ingredient which is sometimes objectionable :—

		Grains in 100 minims.
Ferrous Hypophosphite	$Fe_2 P H_2 O_3 + 6 H_2 O$	2·77
Calcium do	$...Ca_2 P H_2 O_2$	3·5
Sodium do	$...Na\ H_2 Po_2 + H_2 O$	3 5
Magnesium do	$...Mg\ P H_2 O_2 + 6 H_2 O$	1·99
Hypophosphorus Acid	$...H_3 Po_2$	1·66
Water		86·58
		100·00

One fluid drachm being equal to :—

Ferrous Hypophosphite	...1·6	} 6·7 grains of the mixed salts.	
Calcium	do	...2·	
Sodium	do	...2·	
Magnesium	do	...1·1	

This preparation is now largely used by London physicians, the vehicle for its administration being Hungarian Carlowitz or British raisin wine, the former of which contains 2 per mille of iron phosphate and both having very little alcohol.

HORÆ HORTULANÆ:—ON SOILS.

(*Gardeners' Chronicle*, 24th September 1881.)

(*Continued from page* 476.)

The fundamental difference between live and dead soils, as alluded to in the last article, entails many other secondary differences, and of these perhaps the most important are what we may speak of as physical differences. I do not overlook the influence of pronounced chemical characters of soil, such as those which distinguish clay from sand or chalk, but I feel sure that many results attributed to the chemical nature of a soil are in reality due to physical features, induced, it may be, or favoured by this or that particular chemical constitution, and not the direct consequence of the presence of this or that chemical substance. But over and above chemical constitution, to which I will return presently, every gardener will admit that the physical characters of a soil are of prime importance. These may be roughly classed under three heads—cohesion, which determines whether the soil be stiff, or friable and loose; moisture; and behaviour towards radiant heat, according to which the soil is spoken of as warm or cold.

In respect of cohesion, extremes are seen in the stiff clay which the mattock can cut out in almost perfect cubes, and the light sand which is in danger of being blown away by every gale of wind. Each of these, viewed from the simple physical point of view, has its advantages: the stiff clay affords anchorage for stout and long thong-like roots, the loose sand favours the wanderings of tiny thread-like rootlets. And though it cannot be denied that the nature of some plants leads them to flourish best in a stiff soil, while others refuse to grow in other than a loose one, the soil which is most satisfactory for the gardener, the one which he can clothe most abundantly with the choicest and most varied flowers, is a "mean" soil, one which is neither stiff nor loose, or, to speak more truly, which is at the same time both stiff and loose. This indeed is recognised in the usual directions of gardening books, where we are told to lighten the stiff soils, and to give body to the light ones; but—and this is the point to which I wish to call attention—it does not seem always kept in sight, that the most suitable degree of cohesion, the condition of soil which is tenacious without being lumpy and caked, which is porous, and yet lies undisturbed by the fiercest winds, is one of the most precious attributes of "live" soil, is one of the results of the ferment actions of which I have spoken.

Many of us, I suppose, have taken in hand a patch of dead stiff uncompromising clay. Sticky, buttery, clammy all the winter, baked to a hard, rough, brick-like cake in the summer drought, it was at first our despair. As, however, season after season we dug into it a good body of rich farmyard manure and turned it over and over, it changed its nature, and mellowed into a rich "live" loam. That change was not merely the result of a mingling of the particles of decayed straw and dung with the particles of the merely divided but otherwise unaltered clay—was not merely due to the addition of ammonia, potash, phosphates, sulphates, and the like, to the alumina basis of the clay—was not wrought alone by the burrowing rodent action of the numberless rootlets of the plants we from time to time grew in it—it was not solely brought about by the cleaving might of winter's frost, which split the ragged lumps into crumbling powder; it was not the work of each of these, of all these alone, though every one in turn helped. More potent than any of them, though working with and through each of them, was the action of the ferments, of which the stable-yard manure was at once the source and seed bed. These attacked the stiffness of the clay at its very source, altering the chemical combinations on which the molecular stiffness hung deep; these not only mixed but united the salts and carbon compounds of the manure with the aluminic base, and thus digested at first the incongruous factors into a uniform whole. And their work was a lasting one, whereas the crumbling powder which the winter's frost leaves, if it be the work of frost alone, is soon battered back again by the rains of spring into a cakey lump; the clay once worked up into "live" soil can never go back to its native stiffness.

The case of sand is somewhat different, since the silica of sand does not lend itself so readily as the alumina of clay to chemical transformation; to convert pure sand into a wholesome soil some distinct "body" must be added in mass. But here, too, the subtle influence of ferments may be seen. If you mix pure sand with pure clay, even though you pour into it abundantly solutions of ammonia and all necessary salts, the result will be simply an indescribable medley fit for no man's land—a muddle, which after a while will resolve itself back again into clay and sand. Work into the same mixture an adequate supply of organic stuff, either itself holding ferments or serving as material with which ferments can work, be it stable manure, peat, or leaf-mould, and in a short time clay and sand will be blended into a profitable nutritious mould.

Everywhere, indeed, we may see the same thing, the hidden slow subterranean work of fermentative organic matters, aided by rain, sun, and frost, converting the too tenacious, or the too fugitive native sterile dead earth into porous and yet consistent fertile live soil. And this medium soil is assuredly the best for most, if not for all plants. I do not pretend to understand the mystery why some plants love a light and others a heavy soil, but there are reasons for thinking that the long stretching roots, which are almost characteristic of the latter class, serve rather for anchorage or for the gathering in of adequate moisture than for the seizure of actual food. At all events, these long, bare, whip-like roots are accompanied by masses of matted fibrous rootlets, which, running into the generous superficial mould, seem specially adapted for assisting the plant to obtain more copious nourishment. And whenever such rootlets are present, access to a rich, friable, lively earth is sure to bring healthy foliage and an abundant bloom.

Important as is this attribute of live earth, whereby its spongy yet firm nature affords the best bed for the continual spreading of the tender, tiny rootlets, still more important perhaps are the relations of the same thoroughly digested soil to moisture. If there be one thing which is above all others the gardener's one anxious care, it is to see that the plants shall have enough, and not more than enough, water. Out-of-doors we are lifted with hope or tilled with despair according as the rain falls at the right time and in proper measure. In the greenhouse the one question which repeats itself in worrying fashion day after day is—"Shall I give this plant more water or no?" The ignorant, clumsy gardener is known at once by his manner of watering, and where mistakes in soil, or pots, or pruning have killed their thousands, mistakes with the watering-can have killed their tens of thousands. "Let me have day by day just as much water as I need, so that I am never dry and never water-logged!" cries nearly every growing plant, and in hundreds of glasshouses throughout the land many a wretched flower is being baked when it should be moist, and drenched when it should be barely damp. One feature of "live" earth is that it does its best to remedy the pitifulness of outdoor weather and the errors of indoor ignorance. This is very clearly shown by a valuable experiment of Lawes and Gilbert. These gentlemen laid down a series of parallel deep drains in a long sloping field, at the bottom of which each drain opened into a reservoir, so that the amount of water passing along each drain could be measured. Part of the field was either left alone or treated with saline matters only; part was well dressed

with rich farmyard manure. When the outflow of the several drains came to be measured, it was found that though the same rain had fallen over the whole field, far less water escaped by the pipes which drained the thoroughly manured plot than by the others. That is to say, the manured land, the live soil, absorbed and retained within itself, for the benefit of the plants which grew on it, far more water than did the more dead soil. This, indeed, is perhaps after all the chief and the most valuable characteristic of cultivated live soil; by virtue of the changes of which I have spoken taking place in it, it acquires the property of retaining—of holding in some sort of combination—a large amount of water. Of the exact nature of that combination—of the exact manner in which the water is held—we cannot at present say anything very definite, but the combination is of such a kind that while the plants can take up the water as they need it, the soil itself cannot be said to be wet. When heavy showers fall on dead soil, the water which does not roll off the hard solid surface rapidly soaks through, carrying, dissolved in it, as much precious soluble matter as it can take up, and in a short time, under a hot summer sun, the earth is once more baked and dry. When the same showers fall on cultivated, ferment-holding, spongy live soil, at first almost every drop is taken up and stored away amid the manifold compounds present; it is only when its sponginess is satiated, when more water would become injurious to the plants, that it trickles away below. And live soil thus adequately wet remains for a long time moist, giving up with great unwillingness apparently to evaporating forces that which is easily wrung from it by the action of the roots. Naturally the thicker such a layer of fertile live soil the greater is the reservoir of available water, and the wise gardener who desires to grow flowers whose demands for water are imperious will plant them in ground in which the depth of cultivated live soil is measured, not by a few inches, but by 2 or even more feet. In such a bed, secure of their water supply, plants will gather benefit only from the warm rays of a summer sun, which would soon scorch them to death in shallower soil.

Lastly, it is worthy of note that just as all ferment-wrought decompositions tend to generate blackness, all the particoloured objects of Nature being reduced by decay to a dull dark mass, so all soil darkens as it becomes cultivated and live—the red loam, the bluish clay or the whitey chalk, all in time become changed into blackened mould. And this very change of colour is in itself no mean advantage. When we remember that a black surface absorbs more heat than a light one this becomes evident. In those happy days when a bright summer sun shines upon us we ourselves throw aside the black hat, or hide its blackness with a white puggaree; but what we fear, the plant delights in, and to it the presence of black earth round its roots is a wholesome stimulus to more luxuriant growth. A dark soil is a warm soil; it takes up and gives to the plant the rays of heat which a lighter surface wastes, reflecting back into the air. So potent is this influence of absorbed warmth that a white barren patch of cold chalky ground may be made at once in a measure fertile by the mere admixture of some black material of little or no manurial value. And it is an incidental advantage of proper cultivation that while aiming at other things it tends to make the land of darker hue, and thus to increase its power of absorbing warmth. Such, then, are in outline some of the beneficial physical changes which are wrought in the ground, as by means of subtle transformations crude dead earth is converted into active live soil.

But over and above, indeed causative of, these physical features, are countless changes which we may speak of as chemical. The subject is full of intricate problems, to solve which we need, as in so many other cases, not so much empiric trials—for of these the gaps in our gardens show we have almost enough—but definite experimental inquiries. In the presence of so much difficulty and doubt I dare not trust myself to do more than touch on a few general aspects of the matter.—DIETES.

(To be continued.)

CINCHONA CULTIVATION ON THE GOVERNMENT PLANTATIONS, NILGIRIS.

The Government have passed the following order on Colonel Beddome's Report (which we shall give hereafter) and other papers containing valuable information on several points relating to cinchona cultivation:—

"The papers recorded above contain valuable information on the several points discussed relative to cinchona cultivation. The series commences with the inspection report on the Government Plantations, which Colonel Beddome was directed to prepare on assuming charge of the Plantations. Next in order come the Conservator's remarks upon Mr. Cross's recent interesting account of his impressions on visiting the different locations on the hills where cinchona is grown under Government superintendence. This is followed by Mr. Cross's remarks on the most appropriate elevation for the cultivation of the Cinchona Calisaya var. Ledgeriana, and his observations upon Mr. Howard's analysis of samples of bark selected and sent home by him during the spring. Finally, though not latest in point of date, come Colonel Beddome's remarks upon the results of recent cinchona sales. The Governor in Council proceeds to remark briefly on some of the more salient points brought to notice. He observes that, on the whole, the Conservator's report is favourable as regards the progress made since Captain Campbell Walker's detailed examination in 1878. The appendices to Colonel Beddome's report furnish particulars of the number and variety of trees existing in 1878 and at the present date. Taking the plantations in the order in which they are dealt with, it is observed that, while the bulk of plants at Naduvatam are of the succirubra variety, it is the Conservator's opinion that all of this kind, which have been planted on grass land, should be uprooted and replaced by Officinalis or Pubescens. He states that, though the elevation of Naduvatam is too high for succirubras, still it pays well to grow it on shola soil there. Mr. Cross, it is noted, bears testimony to the quality of the soil in the Naduvatam ravine which appeared equal "in fertility to the lower slopes of Chimborazo, the native habitat of the red bark" and he remarks upon the growth and development of the plants which excelled even those he had seen growing in South America. With reference, however, to the inferiority of the red bark for the purposes of the quinine manufacturer, he appears to deprecate any extension of its cultivation. Colonel Beddome points, however, to other reasons why this variety may be expected to hold its own. On the whole, it seems to Government that it is unnecessary to devote much further attention to this species and that the proposals advocated by the Conservator for replacing it in certain localities may be carried out. The information furnished as to the mistake made in attempting to propagate the calisaya varieties anywhere on the Nilgiri plateau leads the Government to consider favourably the recommendation in which Colonel Beddome and Mr. Cross concur, as to the opening up, at an elevation of from 3,000 to 4,000 feet, of a small plantation where these "yellow barks" as well as "grey barks" may be tried with fair prospect of success. The proposal is that the Forest Department at Nilambur should clear part of a shola in the "Silent Valley" for this purpose and for experiments with rubber trees and the ipecacuanha. The Conservator will prepare an estimate of probable cost and will take the necessary preliminary steps to carry out his suggestions.

Adverting to the great number of casualties in the Hooker estate, and the suggestion to abandon the lower portion of the Wood plantation, the Conservator will report separately and in detail on the question of retaining these estates after consulting the correspondence which has already taken place on the subject. The state of the Dodabetta plantation is pronounced promising by the Conservator and Mr. Cross, though they do not agree on the question of terracing, which Mr. Cross thinks unnecessary. The eradication of the bracken fern, which is stated to be robbing the soil of its goodness, will doubtless be taken in hand without delay. Mr. Cross noticed the fact that in this locality especially the plants at the beginning were placed far too wide apart. From Colonel Beddome's report it appears that the same mistake has been made elsewhere. The subject will doubtless receive attention in the full memorandum of instructions which the Conservator intends to prepare for the use of the officers in charge of the plantations: a copy of this should be furnished for the information of Government. The Government are not prepared at present to express any decided opinion on the merits of barking as contrasted with the coppicing system. The latter has had but small trial as yet, and the present report shows that the coppicing carried out in 1879 resulted in failure to a large extent in consequence of the lateness of the season. There is no necessity at present to coppice any more blocks, but the Conservator will, of course, take care to coppice isolated trees which may show signs of decay. As to the method to be observed in coppicing, it is observed that, while Colonel Beddome does not agree with Mr. Cross, he alludes to suggestions for trying three different systems of coppicing, one of which appears identical with that advocated by Mr. Cross. However, the plan finally adopted under the instructions of Government is now stated to be on the whole the best.

Some information is given as to the results, so far as the trees are concerned, of the plan of harvesting the bark by scraping, reported to have been carried out on a small scale in 1879-80. A large proportion of some 5,000 succirubras at Naduvatam failed to renew, and Colonel Beddome is inclined to think that the system is likely to be more trying to trees generally than partial barking in alternate strips. No losses occured at Dodabetta, where a similar experiment was made. The question requires more study, and experiments should be carefully prosecuted. The Conservator will report when the first consignment of scraped bark was despatched to England. The result of the sale should noted, as already directed in G. O. 4th March 1881, No. 398, paragraph 7. The Conservator enters at considerable length into the history of the "Pubescens" variety, which has, until lately, been looked upon as a hybrid. It is clearly shown, however, to be a distinct plant known in South-America as the "Pata de Gallinaz," and is a narrow leaved variety of the red bark. There appears every probability of this species proving hardy and valuable. The first specimens sent home (in December last) have lately been sold, and the prices realized were 7s 1d per lb for natural Pubescens and 5s for renewed ditto. The Conservator is anxious for more information as to these particular bales; but it seems hardly likely that they can be followed at this date, and the only way will be to draw special attention to the next consignment. The Conservator will, in due course, specify the information which he requires to be obtained.

In forwarding to the Secretary of State the dried specimens referred to in paragraph 110 of the Conservator's Report, for the purpose of comparison with the various species in the Kew Herbarium, attention will be solicited to Colonel Beddome's request that the "Magnifolia" and "Pubescens" may be specially examined. The Government agree with the Conservator that it is unnecessary at present to attempt hybridization in the plantations. Colonel Beddome's proposal to proceed to Darjeeling to see the Cinchona Plantations there commends itself to the Governor in Council. The Government of Bengal will be addressed on the subject. The remarks which Mr. Cross and the Conservator of Forests have recorded upon Mr. Howard's recent analysis of samples of cinchona bark collected by Mr. Cross will be forwarded to the Secretary of State with reference to his recent despatch.

The first point to be noticed here is the extraordinary difference of opinion as to the extent to which the *Uritusinga* species of *cinchona condaminea* has been propagated. Colonel Beddome re-iterates the statement, which will be found at paragraph 46 of his detailed report, that there are but a thousand of this kind in the Dodabetta plantation and a few only at Naduvatam. Mr. Howard must therefore have been misinformed, and, as it is clear, that all the samples of Crown bark sent home by Mr. Cross were of the ordinary Officinalis, it is important that Mr. Howard should be made aware of this fact and "Uritusinga" was *not sent at all*. No trace of the trees said to have been planted by Mr. McIvor prior to 1875 can be found in the Government Plantations. The analysis made by Dr. Paul of this species in 1879 shows the following results:—

Samples.	Percentage amount of					
	Quinine.	Quinidine.	Cinchonidine.	Cinchonine.	Amorphous Alkaloid.	Chrystallized Quinine Sulphate.
Natural . .	1·20	..	1·50	0·18	0·10	1·62
Mossed . .	2·13	..	2·00	0·47	0·20	3·00
Renewed . .	3·40	..	1·48	0·14	0·20	4·58

It is desirable that further specimens of this species should be forwarded for analysis and the Conservator will issue the necessary instructions. The difference which he notices in the analysis of the Pitayo bark in 1879 and 1881 renders it probable that the yield of alkaloids in the Uritusinga will also be greater now the trees are older. Samples of the Pubescens and Magnifolia (Mr. Cross's Pata de Gallinaz) should also be transmitted to England for analysis, as well as specimens of bark of different sorts harvested by the scraping process—as suggested by Mr. Cross. The Government agree with Colonel Beddome that the extended propagation of Pitayo is desirable. The necessary steps should be taken to this end. The Conservator will report further on the calisaya specimen transmitted by Mr. Cross. The Conservator's suggestion to employ a competent Chemical Analyzer at Ootacamund will be referred to the Secretary of State for decision. By paragraph 27, G. O., 24th February 1879, No. 463, it was settled that reference could be made, if necessary, to "an European Chemist of repute." The proposal to dry bark by the heat of the sun as an experiment is approved and should be reported upon in due course. It is observed that, when the attempt was made in 1878 to dry bark by natural heat, Dr. Ogg, who carried out the trial at Coimbatore suggested that a short exposure daily to the morning sun would probably ensure the perfect desiccation of the bark.

The Conservator's remarks in paragraphs 14 and 15 of his letter, No. 498 A., will be brought to the notice of the Secretary of State and the thanks of the Governor in Council will at the same time be tendered to the Messrs. Howard for their careful analysis and interesting report.

SILK IN CHINA.

(*North-China Herald*, 16th Sept. 1881.)

The publication in one year of the reports of silk culture and manufactures in China, and the report on opium consumption, by the Inspector-General of Customs, merit

the thanks of all who are interested in this part of the world. We quite believe that the former gave all the information procurable by the various Commissioners, and that every care was taken in the preparation of the papers. Perhaps it is doubtful if such an amount of actual knowledge of their famous silks was ever before placed within the attainment of the Chinese themselves. It is certain that nothing so complete was ever before offered to foreigners. And though the report on opium is of less importance, it is valuable as giving trustworthy estimates, which may help fair-minded people to sober conclusions on a subject, in the discussion of which much heat is evolved by those who attack, and those who defend, the use of and trade in opium. To those who are not connected with the trade of China, and whose interest in the country and the people springs from higher motives than commerce can supply, these two reports are very valuable. They give accurate information in two important matters; one closely connected with the industry of a large part of the Empire, and the other, the indulgence, or it may be the vice, of a large portion of its inhabitants. And it is a great thing in these times to get information on which one may thoroughly rely. It too often happens that the works of authors and compilers offer everything to the public except perfectly trustworthy information. In certain cases, this is not to be wondered at, for there are many things in all countries which lie beyond the observation of the shrewdest travellers or strangers, and which can only be supplied by having the special knowledge afforded by official life. Anyone, therefore, in the position of the Inspector-General of Customs, who makes public the veritable facts regarding any parts of the lives of the people, and their affairs, confers a boon upon all who take an interest in them. We hope that further reports will follow those that have been published this year. There are a sufficiency of subjects connected with the Chinese with which we wish to be made acquainted. And, as we believe in the progress of the Empire and the people, we are sure that, when those subjects which are in existence at present have been exhausted, others will be ready for treatment by the general staff of the Customs. If we compare those parts of China with which we are familiar, with the same parts twenty years since, we must own that great improvements as well as great changes have taken place in the mental attitude towards foreign ways of the inhabitants. The advance has been slow, but it has been steady and considerable. And the next twenty years are likely to show a great increase in the speed of this nation's progress, with, we hope, proportionably beneficial results to the country, and to the world. If any old resident who went home, say a quarter of a century ago, were to publish a faithful description of the Chinese with whom he came in contact, we should find that the portion of the race whom we met in business, have advanced beyond those immediately before them as much as we have advanced beyond those who lived in England three-quarters of a century ago, when steamships, railways, and telegraphs were not. And as the Chinese are just beginning to run their race of improvement, the next twenty years may bring them almost abreast of many Western nations. We hope that the Customs department will, by the publication of such special reports as those which have lately been given, distribute full information as to the effects of the changes, and the development of the resources of the people and the country, which they bring about. These will be invaluable, not only at the time, but long afterwards, and the Inspector-General may feel sure, that, if he engages in the work, he will be heartily thanked by all who desire the extension of knowledge.

We understand that Mr. Hart is now getting a series of science primers translated into Chinese. These will doubtless be distributed over the Empire, and we are certain will be in great request. This is a ready and excellent way of making the Chinese acquainted with the process and results of Western science and thought. Some attempts of the same kind have already been made with fair success, but the opportunities of introducing his series to the notice of the people, possessed by the Inspector-General, gives him extraordinary advantages. That they will be fully used, and a great extension of knowledge among the Chinese follow, is certain. Much of the credit for this will be due and given to Mr. Hart, who among the pressing claims of his offices has found time to initiate works which will have a very great effect for good on the Chinese character. We suppose it must be taken for granted that Westerns know more of the Chinese than the Chinese know of them. But at the same time, we should confess, honestly, that our knowledge of the deeper and best parts of the native character is very superficial. Even in judging of their ordinary traits we believe we are often mistaken, and that the real Chinaman who deals with us, or transacts our business, is quite different from the idea that we have formed of them. Some, at least, of these mistakes on our part, will disappear with increased knowledge of the people. Whatever errors in judging the Chinese we may have made, we may be sure are light compared to the blunders they have fallen into, or adopted, about us and our works. The task of enlightening their minds will be made easier by its being undertaken by a branch of the administration of their country, and it was a wise thought of the Inspector-General to commence the work. We trust, and indeed we may say we believe, that the result will be in the highest degree satisfactory to himself and all whom he may associate with him in the labur.

INDIAN DYES.

(*Pioneer*, 14th September 1881.)

The vivid colouring imparted to fabrics of various kinds by the natives of India, has probably been remarked by every European visitor to the country since the days of Alexander the Great. The partiality of the native mind for bright colours has been made the basis of many pictures in the style of Mr. Val. Prinsep, and the text of many verbal descriptions after the manner of Thomas Moore. But a really practical view of the subject was not taken until so late as the year 1875, when Mr. Thomas Wardle, an experienced English silk dyer, wrote to the then Secretary of State for India, suggesting that the properties of Indian dye-stuffs should be investigated, and the resulting information thrown open to the public. He pointed out that—India being probably the largest dye-stuff-producing country in the world—our natural superiority in this respect only needed cultivation to distance all commercial competition by other less favoured nations. Government acted on the hint, and steps were quickly taken to collect the requisite information. Great delay and some incompleteness has been naturally caused by want of time and knowledge on the part of the reporting officers. Such particulars, however, as have come to hand have been duly collated and worked up into a Memorandum of some hundred and fifty pages by Mr. L. Liotard, of the Agricultural Department. This Memorandum is valuable and interesting, not only from the commercial importance of the subject-matter and the hitherto inaccessible nature of the information it furnishes, but as a substantive contribution to a most sensible series in course of publication on the natural industrial products of the Empire. There are two points to be considered in the *modus operandi* of the dyer. First comes the preparation of the dye-stuff itself; secondly, that of the mordant. The majority of the colours yielded by Indian dye-stuffs are produced from plants and extracted either from the root, stem, bark, flower, or fruit. Insect formations such as those created by the two species of the Coccus insect, Coccus lacca (lac) and Coccus cacti (cochineal) also furnish dye-stuffs; and thirdly, there are various dyes of mineral origin. Of aniline dyes produced in Europe,

and largely imported into this country, we shall speak separately. As to *mordants*, perhaps, it will be as well before going further to explain this simple, but most important, term. A mordant is, strictly speaking, a substance used by dyers to fix their dyes, and render them immovable by washing. But by rather an unhappy looseness of expression, the term is also applied to substances which, when used in connection with a dye-stuff, have the property of brightening the colour, or of altering its shade. For example, cream of tartar is called a mordant, because it is used to brighten the red communicated to silk and wool by chloride of tin. It seems a pity that the suggestion of Berthollet to distinguish this latter class of mordants by the name of *alterants* is not generally adopted. The principal mordants, in the strict sense of the word, that are used in England, are alum and metallic oxides, particularly of tin. The natives of India, Mr. Liotard tells us, use catechu—which is the juice of trees of the acacia tribe—galls formed on the pistachio-nut tree, the rind of the pomegranate, tamarisk galls, and myrobolams or the nuts of a genus of trees known as *Termenalia*.

Mr. Liotard divides that part of his Memorandum which relates to actual process of dyeing, under two heads, namely, simple or single colours, such as red, yellow, blue, and black; and compound colours, such as purple, green, and orange. Brown, it may be mentioned, may be considered as either a simple or compound colour, being producible by a single dye-stuff or by a mixture varying according to the shade required. The first of the simple colours treated by Mr. Liotard is red. There are twelve sources mentioned in the Memorandum as yielding dye-stuffs for red and its various shades. Of those the *Carthamus tinctorius*, the *Coccus lacca*, and *Coccus cacti* seem to be the most important. The first is sometimes known as the bastard saffron, and yields safflower or carthamin, used both as a dye and as the basis of *rouge*. The second is an insect which forms round the bark of various trees a resinous incrustation called lac. From this lac is obtainable both shell-lac and lac-dye. The *Coccus cacti* is the cochineal insect, the dried body of which produces splendid and well-known red, crimson, and scarlet dyes. It has been calculated that 70,000 insects go to a pound weight. Over 1,100 tons were imported into Great Britain in 1850, which argues an extensive mortality amongst cochineals. Of yellow dyes, arnotta and turmeric appear the best known. Arnotta is made from the pulp enveloping the seeds of a small evergreen. It is imported into England, and is used to colour butter and cheese. The Chinese also used to employ it to dye the original nankeen. Turmeric is the rhizome, root-stock, bulb, or tuber of another small plant; and is well-known not only as a dye-stuff, but as a bitter and tonic, and a condiment in curries. Blue dye is, of course, produced from indigo. Black dye can be obtained from the juice of the cashew-nut without any addition, but is more often derived from a combination such as myrabolams (one part), alum (two parts), *al* (four parts), and sulphate of iron (five parts). Pomegranate rind, with iron filings, is also used to produce a black dye.

In connection with each of his notices of the simple colour dyes, Mr. Liotard gives collated descriptions of the methods practised in various localities for applying the dyes firstly to silk, then to cotton threads and cotton cloths, lastly to wool and woollen fabrics. The same plan is adopted in treating of compound colours, which are, as already mentioned, produced by combining the dye stuff above described as yielding simple colours. A final section of the chapter on compound colours is devoted to colours such as brown, grey, drab, dove-grey, &c., obtained from a mixture of black and other colours. But the practical information given on this head, particularly as regards silk dyeing, is scanty. In reference to the modern Indian practice of calico printing, Mr. Liotard quotes a lengthy and exhaustive report by Mr. Buck, on the method adopted in the North-West Provinces. Mr. Buck, it may be mentioned, evidently prosecuted the enquiry into the nature of dye-stuffs, and the methods of applying them, with characteristic energy and thoroughness; and his correspondence on the subject is, perhaps, the most valuable portion of Mr. Liotard's Memorandum. But as his description of calico-printing in the North-West-Provinces is rather long, we may quote a simpler example of the preparation of material used for holiday petticoats, especially in marriage festivities. It is called *kartika*, and shows white prints on a blue ground. The material, being English longcloth cut into pieces of six yards each, is first given over to the washerman, who deprives it of the starch by washing it in clear water. The next step is to prepare a resist-paste of lime, gum, pulse, flour, and water. This is is stamped on the cloth by means of a mould, the impression while still wet being sprinkled over with wheat flour, to increase the resistance to the subsequently applied blue dye. The cloth now passes into the hand of a *rangrez* or dyer in plain colours, who dips it in indigo, thus dyeing it blue except in those places previously printed with resist-paste. Washing, and beating smooth with clubs, complete the process. The cost of dyeing 20 pieces, that is to say, 120 yards of longcloth, is R3-7.

We now come to the influence exercised in India by the importation of aniline or phenylamine dyes, derived by distillation from coal-tar. This subject is of the utmost importance in connection with Indian dyes, as it involves to a serious extent the possibility, that the use of the latter may become actually extinct. As far as one can gather from the reports collected by Mr. Liotard, the aniline dyes seem almost everywhere ousting dyes of local production. As Mr. Hutchins writes, reporting for Mysore, "supposing, for instance, a man wants a handful of scarlet yarn to continue his design, it is produced in three minutes; a pinch of the cheap glittering powder and a little hot water in a brass saucer is all that is required. By the old method it would have taken him three days and involved dirt and a tedious process." The statistics relating to the use of aniline dyes in India during the last five years, show an average annual importation to the value of about R4,00,000. The actual figures for 1879-80 are R5,90,791. As regards the sources of importation, the United Kingdom is credited with having sent to India aniline dyes to the value of R1,51,394. Italy, France, and Austria come next. The Straits Settlements and Turkey in Asia export to the value of about R1,000 between them; while a small quantity comes from other countries not named. Of the whole amount, very roughly speaking, Bombay takes three-fifths, Bengal one-fifth, the remaining fifth being divided between British Burmah, Madras, and Sind; British Burmah taking about fifteen times as much as the two last put together.

But in spite of the popularity of aniline dyes, their employment—setting aside all questions of taste—is open to one very radical objection, namely, that of great instability. Looking at the superiority, on this point, of Indian dyes, as well as at the necessity for protecting the commercial interests connected with them, Government have not only acted in a politic, but also in a most natural, manner by remitting the export duties on Indian dyes, and allowing aniline dyes to remain under an import duty of 5 per cent. Mr. Liotard thinks that all it seems absolutely desirable for Government, to do, further, for the present, is to continue the careful production of lac and extend the systematic collection of myrabolams. The rest must be left to private enterprise. Government, by calling for reports from numerous quarters, has done what it would take an individual a lifetime to do—in a few years. It has produced a work of reference showing the existence of many dye-stuffs of which, probably, English dyers have hitherto been completely ignorant. By describing the processes adopted in various parts of the country, it has shown what are

the failings of Indian dyers, and how, particularly as regards mordants and improved fabrics, these failings may be met and overcome. Private knowledge, private energy, private captial, and, let us hope, private profit should complete the work which Government has begun. It will surely be a good day for Indian trade when fabrics steeped in fugitive aniline dyes shall cease to

"Mock the air with colours idly spread,"

and the beautiful bright hues imparted by turmeric, safflower, and the rest shall be blended by European taste, and rendered really permanent by the application of scientific principles under the auspices of European art.

TOBACCO PRODUCTION IN THE UNITED STATES.

THE preliminary report of the Census Department on this branch of industry shows an apparent increase in production of 80 per cent, which exaggerates the real advance in tobacco cultivation, as the preceding census crop was a small one, and the fear of taxation may have operated to prevent a full census of tobacco in 1870. The crop in 1880 was one of medium production, not in excess of the present requirements of home consumption and exportation. Fifteen of the States produce more than 99 per cent of the tobacco of the United States, though it is grown, more or less, in 22 other States and six territories. The following is the yield of the seven leading States in tobacco cultivation:—

State.	Acreage.	Pounds.	Pounds per acre.
Kentucky ..	226,127 ..	171,121,134 ..	756
Virginia ..	139,423 ..	80,099,838 ..	573
Pennsylvania.	27,567 ..	36,957,772 ..	1,340
Ohio	34,679 ..	34,725,405 ..	1,001
Tennessee ..	41,532 ..	29,365,052 ..	707
North Carolina	57,215 ..	29,936,448 ..	471
Maryland ..	38,174 ..	26,082,147 ..	683

While these States, together with Wisconsin, Connecticut, and New York, have all increased their cultivation, some of them, such as Pennsylvania, to a market degree, others, such as Massachusetts, West Virginia, Indiana, Missouri, Illinois, and Tennessee, have retrograded. The average yield per acre is 731 lb. The variation in rate of yield, from 1,599 lb. in Massachusetts to 471 lbs. in North Carolina, is due in differing degree to the use or neglect of fertilisers, the habit of growth of different varieties, and the vicissitudes of the season. In Massachusetts, Connecticut, New York, Pennsylvania, and Wisconsin, the seed-leaf varieties are mainly grown and high fertilisation practised, always resulting in heavy crops. In Ohio, the yield is above the average, the Ohio seed-leaf being extensively cultivated in the Miami valley, while the Burley, a vigorous grower of less productive character, is almost exclusively cultivated in the Ohio river counties. Kentucky, producing many grades of cutting and shipping tobaccos upon an exhausted soil of original fertility, makes an average yield. The low yield in North Carolina is due to the production of the fashionable yellow "bright" grade used for plug wrappers, grown on a poor soil with low fertilisation, sufficient to stimulate early growth, but not enough to prevent early maturing.—*British Mail.*

TAHITI AND SAN FRANCISCO TRADE.

In an article on Tahiti and the Society Islands, by J. Pinet, and translated for the San Francisco *Journal of Commerce*, he dwells particularly on the trade with San Francisco. He says:—

The greater part of the merchandise consumed in the country comes from San Francisco. Of a great number of vessels engaged in the transportation of this merchandise, there are three carrying about 350 tons each subsidized by the local government for carrying the mails between Papeete and San Francisco, which depart alternately from San Francisco for Tahiti on the 1st, and from Papeete for San Francisco on the 12th of each month. Those which leave San Francisco touch at the marquesas, those that clear from Papecte sail directly to San Francisco. The cargoes carried by these vessels from San Francisco, consist of a great variety of articles—flour, bread, rice, wine, provisions of all descriptions, furniture, carriages, Amcrican stuffs, lumber, etc. The return cargoes are made up principally of oranges, coconuts, lime juice and vanilla, for the markets of San Francisco, and cotton, pearl shells and pearls, in transit for the markets of Europe.

The soil of Tahiti is of great fertility—its principal productions are cotton; equalling "Sea Island cotton"—sugar, to the production of which the climate is exceptionally favourable, and which is noted for its fine appearance and its great similarity to New Orleans sugar, and the coconut, which dried is, under the name coprah, despatched to the great European markets. There is obtained from it an abundant oil, excellent for the manufacture of various qualities of soap. It is to be regretted that coprah, which Tahiti and most of the islands of the Archipelago produce in great quantity, should not find a regular market in San Francisco, as it would be a very convenient means of exchange, and there is no doubt that if it could be utilized with profit in California, this alone would give rise to a considerable trade between Papeete and San Francisco. This would render profitable the establishment of a line of steamers—so desirable—between Tahiti and San Francisco. If, as we all hope, the idea of this line of steamers is about to become an accomplished fact, not only would the two points of arrival and departure secure great commercial advantages, but Tahiti would, without doubt, become one of the favorite places of resort for a great number of the people of the Pacific Coast, who would travel over an ocean, which is almost always magnificent in its aspect, in less than 20 days. The climate of Tahiti is one of the healthiest and most agreeable in the whole world. The soil, traversed by a great number of living streams of an extreme purity, produces in abundance, and without cultivation, the orange, the citron, a great variety of bananas, ananas, bread fruit, besides a large number of other delicious fruits. The Isle of Tahiti, which was rightly named by the first European who touched there as the new Cythera, is a veritable terrestrial paradise.

There is no doubt, adds the editor, that a great trade will grow up in the future between San Francisco and these Islands, and it is our belief that San Francisco merchants should cultivate and foster this trade, and that they should take an interest in the development of the Islands. The area is given at 450 square miles, or 288,000 acres; small, it is true, but under a tropical sun capable of producing out of all proportion to its extent.—*American Exporter.*

PERIODICITY OF RAINY AND DRY YEARS.

M. de Parville has published in the *Journal des Débats* a paper on the temperature of the present year, which at Paris has risen to a height exceeding all previous authentic records. On July 5th, at the Observatory in the Park of St. Maur, the Centigrade thermometer registered 35·6 degrees, and on July 15th, 37·8 degrees. The highest temperature previously recorded during the present century was 36·75 degrees on July 31st, 1803. Higher temperatures have been recorded, but their authenticity has been questioned. Thus, Cassini has recorded 40 degrees for August 17th, 1701; but it is believed that the true temperature was only 36·85 degrees. So, also, the temperatures set down by Messier of 39 degrees in 1763, and 40 degrees in 1765, are attributed to errors of observation, and should be corrected to 36·6 and 37·5 degrees respectively. M. de Parville passes on to ask whether the dryness of the present summer could

have been foreseen, and he answers in the affirmative. Having referred to the influence of solar action on the atmosphere, he says:—"A very long series of observations has also shown that the moon, which passes every month from one hemisphere to the other, influences the direction of the great atmospheric currents. The changes in those currents, in consequence of the prevailing moisture or dryness, are intimately connected with the relative position for the time being of the sun and moon. The distance of the moon from the equator—that is, the inclination of the moon's path to the plane of the equator—varies every year, passing from a *maximum* to a *minimum* limit; and the meteorological character of a series of years appears to be mainly dependent upon the change of inclination when those extreme limits have been touched. Observations prove that the rainy years, the cold winters, and hot summers return periodically, and coincide with certain declinations of the moon. In our latitudes the rainy years occur when the moon's declination has touched its extreme limits of 28, 26, or 18 degrees respectively. They are separated from each other usually by periods of about three years and then six years. The following table traces backwards this connection between the rainy years and the moon's declination:—

Rainy year.	Greatest declination of moon. Deg.	Rainy year.	Greatest declination of moon. Deg.
1879	26	1819	28
1876	28	1816	26
1872	26	1810	18
1866	18	1804	26
1859	26	1800	28
1856	28	1798	26
1853	26	1792	18
1848	18	1787	26
1836	26	1785	28
1828	18	1783	26
1821	26		

The severe winters as a rule coincide, at least within a year, with the same declinations:—1879, 1875, 1871, 1867, 1859, 1857, 1853, 1846, 1837, 1835, 1830, 1829, 1822, 1819, 1818, 1815, 1812, 1809, 1804, 1801, 1798, 1792, 1788, 1785, 1782. The dry summers come naturally in the middle of the period which divides two wet years, thus—1874, 1869, 1863, 1857, 1854, 1849, 1842, 1832, 1825. Applying the rule which this experience suggests to the summer of 1881 we find that the next wet year ought to coincide with the declination of 18 degrees, therefore, with the year 1884, as the last was 1879 with the declination of 26 degrees. Consequently the dry summers should come about the middle of the intervening period between those two years—that is, they should be 1881 and 1882. It might therefore have been foreseen that, beginning with 1880, we were proceeding towards a *maximum* of dryness."—*British Mail.*

THE SOY BEAN, A NEW FEEDING STUFF.

Mr. Wamford Lock has drawn attention to the soy bean of China and Japan, *Glycine soja (Soja hispida)*, sufficiently familiar as the source of the eastern sauce of that name, and affording a valuable oil (bean oil), which is the subject of an article in the new "Industrial Encyclopedia." It is attracting considerable attention among Continental agriculturists, and has recently been experimented on with regard to its value as a food for milch cows and fat cattle. As a forcing food for milch cows, the soy bean is superior to grains; for fat cattle, it is less adapted, and ranks second to grains.

The plant can be cultivated in Central and Eastern Europe, and similar localities, especially in unfavourable years, when other crops are backward. For growth as a field crop it is recommended to be sown in rows 18 in. apart in the middle of May.

The qualities of the beans grown in diluvial and alluvial soils are shown by the following analyses:—

	Diluvial.	Alluvial.
Water	15·20	19·50
Fat	16·21	17·94
Protein	28·63	25·94
Non-nitrogenous extractive matter..	30·84	33·16
Fibre	4·38	4·45
Mineral matter	4·74	8·82

The straw or haulm of the plant is practically worthless for neat cattle, but the husks and leaves, mixed with mashed food, or even alone, are readily eaten. It has also been found that the chopped beans, soaked for 12 hours in water containing a little salt, are greedily taken by cattle, and that few pass through undigested.

According to M. Roman, a French savant, the cultivation of the soja or soya, has of late years been largely developed in Austria-Hungary, Italy, and parts of France. This plant is extensively cultivated by the Chinese, who make a cheese and various dishes from its fruit. When roasted the seeds form an excellent substitute for coffee, and altogether M. Roman thinks that the plant will pay better than the potato. At present the retail price of the soja beans is sixpence per pound, but as the plant becomes more extensively cultivated, they will no doubt be reduced in price.—*British Mail.*

ENEMIES OF CEARA' RUBBER SEED.—A Matale East planter writes:—"I have just had my attention drawn to the fact that *lizards* eat up Ceará rubber seeds; and this notwithstanding the fact that they had been dipped in kerosine oil before planting. The seeds were most neatly dug out of their restingplaces and apparently not devoured on the spot. It seems to be the common green lizard that does the damage."

CULTIVATION OF THE DIVI DIVI PLANT.—A correspondent writes:—This plant, which grows in many of the outlying villages of Madras, and has been up to date uncared for, is now found to be a valuable article for tanning purposes. Large quantities of the pods these plants yield are being shipped to Europe, and in fact many persons have begun to pay some attention to the cultivation of this plant. A consignment of 88 bags of dried fruits from this plant was shipped to England by the "Duke of Buckingham," 173 trees of the Divi Divi in full bearing which would take an acre of land is supposed to yield fifty cwt of pods, which are valued in London at £37·10; and as the cultivation and care costs literally nothing after the trees are once in bearing, it is found to be a most profitable crop.—*Madras Mail.*

TEA AS IT OUGHT TO BE DRUNK.—During the present season there is a public want of a really wholesome temperance drink. What do our readers say to a teacocktail? The following is given, in an exchange as an extract from the "Diary of a Hunter" by the late Col. Irly, one of the first Englishmen who ever visited the Karakorum Pass:—"Now took place a very curious and important operation—the brewing the real tea—not the "make-believe" as the Marchioness styled the choice liquors she concocted for Dick Swiveller. The tea being immersed, a ladle of ghee is put in, and four or five table-spoons of salt added: then much stirring and mixing takes place, a curious implement being used to froth the beverage, like what in the navy in my younger days—perhaps, the very name now forgotten—was called a "swizzle-stick," which, by rapid revolution between the hands, aerated the grog in the tumbler, giving it a pleasant sparkling appearance and freshness of flavour. Many a time I applied it in my first voyage from England to Hobart Town, via Canada, instructed by the veteran purser, Tucker; and a by no means contemptible beverage it made in tropical latitudes at eight bells. Well, the tea well mixed, and frothed, and repeatedly tasted, was ladled out to the anxious party, and much relished."—*China Mail*

PROGRESS AT THE STRAITS.

"The present Governor of the Straits Settlements (Sir Frederick Weld)"—writes an ex-Ceylon planter—"appears to be a very enterprizing and progressive officer, and he has the interests of this colony most decidedly at heart." The present mail-news from Singapore confirms this opinion in a very practical way. Sir Frederick Weld has just started on a tour of inspection intending to explore portions of the British Settlements at Malacca and Klang, which had never before been visited by British officers. He is well seconded at Perak by Mr. Low, to whom (with his chief) will now belong the honour of getting the Secretary of State to alter a decision twice expressed against Cooly Immigration into these semi-British Settlements.

INDIAN IMMIGRATION.

From the dispatch of Governor Weld to the Secretary of State.

Singapore, 5th May 1881.

Mr. Low has set out in clear language how essential it is, in opening out the excellent agricultural lands of Perak, that Indian labour should be introduced, and he points out that, unless such labour is procurable, that State must rely on its tin deposits for any development that must take place. He states that the Indian Immigrants can be as effectually protected in Perak as in Province Wellesley or Ceylon, and he explains that for the administration of justice, there are British Magistrates at eight stations, and that Police are quartered in twenty-five different localities. He reports that the Government has power to carry out all necessary regulations, and he adds that it may be fully trusted, under the supervision of the Governor of these Settlements, to enforce any regulations that may be made. The statements in the Resident's letter will, I feel confident, have great weight with H. M.'s Government. They come from a very experienced and trustworthy official, who has proved himself to be a most competent administrator, and I have not the slightest hesitation—personally acquainted as I am with the country and its administration—in supporting those statements, and confirming them in the most authentic manner possible.

There is, too, abundance of British capital forthcoming, so far as I can learn to open up these fertile states, but on every occasion of an application for a grant of land being made, the experienced planter points out the necessity of obtaining Indian labourers before any real work can be done with the view of making any considerable investment. Certain grants of land have been taken up in each of the Protected States, and in Johore, still but comparatively little progress has been made owing especially to the existing uncertainty of the action of H. M.'s Government on this question. And I think that there can be very little doubt, but that if the final decision is adverse to the course which I am advocating, those who are now prepared to embark to a large extent in planting in the Native States will be driven elsewhere and that the attempts made by this Government to introduce a large system of agricultural undertakings in the Native States, which would tend to the direct advantage of those States and to British interests, will receive a great blow and heavy discouragement, and the solid improvement of the country be indefinitely postponed.

On every ground, therefore, I am of opinion, that it would be advisable and expedient that Indian Immigration should be permitted, under regulation, to the Native States and also to Johore. In the first place, there would be the advantage of opening up magnificent country, already proved to be eminently suited or plantations of almost all kinds; in the second, there would be the direct advantage to both British and Native interests, by increasing trade, and ensuring that the resources of the country are not solely as at present, dependent upon its mineral wealth; in the third, there would result the abolition of the growing practice of introducing such labour under no recognised regulations or authority: and in the fourth, there would be thrown open large remunerative employment and room for settlement, in a field every way eminently suited to their habits and constitutions, to numbers of the labourers of a country already greatly overstocked, and which is periodically visited by famine to a most lamentable extent.

From the Resident of Perak to the Colonial Secretary, S. S.

In 1879, the disease which has been so injurious to the coffee plant in Ceylon, caused almost a panic amongst the planters of that Colony: many of them visited Perak and other parts of the Malayan Peninsula, and applications were made to this Government for about 35,000 acres of forest land, on which it was proposed to commence the cultivation of coffee, cinchona, &c.

All the skilled gentlemen who examined the country declared that Perak, from the extent and elevations of its mountain ranges which reach to 8,000 feet; from the quality of its soil; from the facilities of access by its very numerous rivers and creeks; from its absence of destructive winds; and from its neighbourhood to a British Colony; had every facility which could be required for the successful cultivation of all tropical agricultural products.

Having some knowledge myself of such matters, I am able confidently to assure His Excellency that none of these advantages were over-estimated, and the gentlemen from Ceylon, who saw the padi crops at Krian, were astonished at the productiveness of the soil, which gives, year after year, without manure and with little cultivation, an average of 800 to 1,000 gantangs per orlong, and reaches, in good seasons, to as much as 1,900, being an increase of 250 to 300 fold on the seed sown.

The only drawbacks to Perak, as a field of investment for British enterprise, were that it was not British territory, and that free immigration of coolies from India was not permitted.

The planters from Ceylon did not seem to think so much of the first of these difficulties as the British merchants of the Straits Settlements, and I do not think it would have deterred them from the adventure, but the question of labour was of far more gravity, and all concerned were sanguine that, considering the rapid progress of this State towards complete security and settlement, Her Majesty's Government would assist in the solution of this difficulty.

I have no special knowledge of the present condition of the other States of the Peninsula, but I fear that, in this matter, the interests of Perak may have suffered from having been considered in connection with Johore, the circumstances of which are very different and by no means so favourable to the health of the labourer, and the attainment of the object in view.

At the present moment, two gentlemen of enterprise and capital have settled from Ceylon in the Slim river, and have cleared about 150 acres of land; another from Province Wellesley has commenced an estate in the Throng district; above 120 acres have been cleared by two gentlemen on the eastern face of the range of mountains, half way between the port of Matang and Kwala Kangsa, and the Government experimental plantation is in the same neighbourhood with nurseries at Kwala Kangsa.

In the Krian district four or five thousand acres of land have been taken up, and sugar cultivation commenced by influential members of the Chinese

Community of Penang, and, at the Dindings river, an agreement has recently been entered into for re-opening a portion of the sugar estate commenced by Mr. Tooth.

Other gentlemen are only waiting the solution of the labour difficulty at once to commence similar undertakings on an extensive scale.

For a tropical climate, Perak is far more healthy than either Borneo or Ceylon, the low lands in both of which extensive islands are everywhere subject to fevers of more or less severity.

In Perak, where good proof of the climate is accessible from the Chinese population scattered over the entire country, fever and other sickness were almost unknown, until the recent attack of Beriberi broke out amongst the miners, whose numbers had largely increased in 1880.

Two spots only are recorded in which fever was proved to be endemic, the one being the neighbourhood of the Pass through the hills on the road to Kwala Kangsa, and the other having been detected on opening the estates at Slim, which was done on land of about the same elevation as that of the Pass, namely from 400 to 500 feet. The plantation of Messrs. Schulize and Wray, situated 1,500 feet above the Pass, and that of the Government at 3,250 and of another of the same elevation, have been entirely free from sickness, although about one hundred and fifty men have been employed on each of them during several months past.

The Malay population, which in all, numbers about 56,632, has never been accustomed to regular labour, or to work for wages. A marked improvement in them is visible, and by bringing to bear upon them, through their chiefs and in accordance with the usages of the country, gentle pressure in the way of requiring, for their own good, a certain amount of cultivation, I have no doubt that time will turn them into an agricultural race similar to the Javanese, but they are not sufficiently numerous, nor can we hope sufficiently to change their habits to calculate on them as regular labourers to supply the steady industry necessary for an area of cultivation such as it has been my hope might be established in Perak under the auspices of Her Majesty's Government.

Every range of mountains, and these run nearly all parallel to each other and the sea coast, contains valuable veins of the ore, which, having for ages been acted upon by atmospheric influences, have formed rich and easily accessible deposits at their bases. Each valley is traversed by a river sufficient, when cleared out, for all purposes of transport, so that with diminished cost of production, I have no fear that Perak will be able to compete in the market with any country in the world at whatever price for many years to come, but it will be with the greatest sorrow that I shall receive from His Excellency a conclusive intimation that this beautiful and fertile country, with a Government and people ready to sacrifice its prejudices and even its interests to support Her Majesty's Colony, and anxious to invite the influx of British enterprise and capital and to do its duty by them, is prevented, by fears which, I believe, to rest on insufficient information, from increasing its resources, improving the circumstances of its immigrants, and adding to the wealth, industry and commerce of its own and of Her Majesty's subjects.

I have, &c.,
HUGH LOW,
Resident.

Lord Kimberley gave way after this, saying on the 12th August last :—

Mr. Low's arguments have convinced me that the experiment may be safely tried on a limited scale. I will therefore, if the consent of the Indian Government can be obtained, no longer withhold my sanction to it.

Immigration into the Native State must be subject to the same regulations and conditions as those which are in force in the Straits Settlements.

It would be desirable that the Immigrants should, in the first instance, be employed near the station of a Magistrate, if that be practicable, so that the system may be started under close supervision.

There can be no doubt that Tamil coolies will be employed to great advantage on the Perak mountain ranges.

We are sorry to receive bad news from Johore: the large clearing of the Company of that name, opened under Mr. Watson's auspices, at an elevation of about 700 feet above sea-level has been condemned for Coffea Arabiea, although it is deemed suitable for Liberian coffee, cocoa and, perhaps, tea. Mr. Dobree's report was so adverse that the Directors decided to plant no more ordinary coffee at this elevation if, indeed, they do not abandon what has already been put out. A planting correspondent writes to us as follows about the future prospects :—

"Planting progresses fairly. Labor is now plentiful, but, as compared with Ceylon, John Chinaman requires rather too much (Untong) *gain* to expect planting to pay handsomely—unless in such a matter as cocoa or Liberian coffee, where a fourth or one-eighth of the abor is sufficient, compared with *Coffea Arabica*. I find in "Cocoa as Grown in Trinidad and How to Plant in Ceylon," 20 men might work a plantation of 200 acres, whereas the same acreage of Coffea Arabica would require from 160 to 200 coolies per day. I guess our elevation is rather unsuited to *Coffea Arabica*, unless one were accustomed to find it growing luxuriantly in the Binteuna country, from the foot of the Haputale range to that of Gongala. Our soil, from 600 feet down to sea level, is perfection in most cases : of course, there are parts with a clay subsoil, but that is by no means frequently found. I fully believe that Ceylon cannot fully compete with it. However, we have our chenas in the form of abandoned Gambier clearings over a great part of the lowcountry. These are not quite so washed out as the most of Ceylon chenas; as they are much fatter and the grass is allowed to grow, being only cut down twice or three times a year, and allowed to decay on the ground, which tends to enrich the soil considerably in my opinion. I believe these clearings would pay handsomely yet in tea or even Liberian coffee, although virgin soil might be more profitable in the end. If a steamy atmosphere is suited to cocoa, I say Johore is the place to try : we have a constant rainfall, scarcely ever exceeding four days dry on end; hence our steamy atmosphere. These rains are not thunder showers of great violence as in Ceylon; frequently gentle showers for hours on end in the lowcountry; heavy dew every night. Liberian coffee must, I think, find a suitable home here, and its success is already almost certain. "It is only necessary to visit the plantation of His Highness the Maharajah, to find that the new products we hear of so often are receiving attention in Johore. This Liberian coffee referred to, planted by His Highness, is a perfect picture of excellence ; it is now a little over two years planted; the trees are from 6 to 8 feet in height, bearing heavily and giving excellent blossoms all the while, and the beautiful dark green foliage seems unfading under any circumstances, even though considerable pickings are being got every few days. There are, I believe, several other patches doing equally well in the vicinity of Johore. Tea! Who has not read that several well-prepared samples by a pro-

fessional fetched the tip-top prices of the London market, in January last? Who will then be surprised to know that already there are thousands of acres being taken up for tea, and men on the spot to commence operations. Any one who will have tasted a cupful of Johore tea before it comes in contact with spurious imitations, will surely never forget to take care of his dollars until he has got in his own few acres. Land is cheap and every encouragement is held out to intending investors. I understand His Highness has ordered a steam plough from England to facilitate planting in the lowcountry.

"Pepper must not be unnoticed—a most profitable and sure investment, proved to be a great success here. It is a beautiful sight, a pepper plantation, each vine clinging to the upright stem. They are beautifully cultivated in every case; they are allowed to grow to 9 and 10 feet high. On entering any of these, John Chinaman meets you, and if he knows enough Malay, he says: 'Tabby Tuan' as a Tamil would give his salaam to durai. If you go into further conversation, John is found generally wanting, and goes off with 'Qua Quvah' or such unintelligible language only known to himself: yet withal, he's a very good fellow, an energetic workman, perfectly honest if you look well after him, civil if you don't giv him occasion to be otherwise. What do you think of cardamoms down here? I have seen them in a wild state in Ceylon at 4,000 feet: how do they do at 400 or less?"

The Johore pioneers cannot do better than give a fair trial to all new, as well as old products.

COFFEE LEAF DISEASE IN CEYLON.

We feel that injustice is likely to be done to the Government Cryptogamist by criticism based on isolated extracts from his recent Report. Mr. Marshall Ward will no doubt desire that it ought to be read and commented on as a whole. There are important facts which are apt to escape the attention on a first and cursory perusal. For instance, the immunity of the Uva principality as compared with the districts on this side of Nuwara Eliya from the same number of attacks, and the often rapid repetition of attacks of the fungus. This immunity Mr. Ward shows is owing to the comparatively dry Uva climate. Haputale, for instance, has pre-eminently the rich soil and fine cover of leaf in which *Hemileia vastatrix* is ready to revel, and when continuously wet weather sets in there—rarely enough—the conditions are all fulfilled for a bumper (virulent) crop of the fungus, such as has often been noticed. But the rainy weather is soon over and the succeeding crop or sporess, blown hither and thither, fall upon evil times. In the normally dry weather they are unable to enter the stomata of the leaves, or to fructify in the absence of the moisture which is their very life and consequently they perish by thousands and millions miserably, in many cases through the operations of other and lower fungi; so true it is that

> Big fleas have little fleas upon their backs to bite 'em,
> And little fleas have lesser fleas, and so ad infinitum.

So long as moist rainy weather prevails, the *Hemileia vastatrix* rules supreme, passing through its life-history in three weeks and luxriating wherever there is a coffee leaf to feed on, but let dry weather set in persistently and the spores not only are not active, but they run the risk of destruction through a variety of agencies, not the least being a series of *fungoid* enemies! Hence the great advantage of the the Uva districts right along from Namunakulikele to Idulgasheua and from Lunugala to within hail of Pedrotalagala; for, be it noted that at least 24 hours' soaking rain is, according to Mr. Ward's observations, required to give the leaf fungus a fair start. A mere passing shower will not do it; isolated thunder-showers, from which so many parts of Uva derive great benefit, are not sufficient, and as for the night dews on which the coffee in the Principality is often dependent for weeks and months together, it is of the smallest possible consequence to the ubiquitous spores, which want good heavy showers to enable them to spring into maturity and and absolute virulence. Here then is consolation as well as most valuable information from the "Scientist" for the planters in Uva, and indeed in other comparatively dry districts, and they must henceforward remember that the rain they often long for is not the unmitigated blessing they have been wont to regard it. But perhaps even more important is it to recall the fact which Mr. Ward and Dr. Trimen repeat and emphasize with all the assurance of matured conviction that the *hemileia* in no way affects the vitality or healthfulness of the coffee tree save throgh the leaves. The absence of the same display of feeding rootless as in days of old, the dying back of wood, the non-ripening of crop, have all been regarded as indubitable signs that the coffee-tree was dying beyond recovery—that the disease had entered the sap and marrow of the tree and that the periodical dropping of leaves was merely a further and external indication of its ravages. Now Mr. Ward will not admit this for one moment. The disease is confined entirely to the yellow pin-spots on the leaves and it is quite compatible with, indeed the fungus prefers, healthy and luxuriant trees, and it is only as repeated and persistent attacks, fostered by continuously wet weather, denude the tree of its leafage that it begins to suffer and manifest indications which have been accepted as independent evidence of internal disease. There is encouragement in this to continue the battle with the pest with the additional light which this investigation has thrown on its mode of working. In gathering and burying fallen leaves, in the judicious use of caustic lime, in timely pruning and careful manuring, the planter may be able to do much to combat and cheat his great enemy even in districts where the rainfall will continue to bring forward successive crops of fungus-spores.

"THE TROPICAL AGRICULTURIST!": COFFEE PLANTING IN THE PHILIPPINES.

The *Agriculturist* is likely, as a London correspondent hinted in our Saturday's issue, to bring Ceylon planting (and publishing) enterprise into wider notice than it has ever yet obtained. We have received complimentary letters and support from places so far apart as Jamaica and Borneo or still farther to the South-east, Queensland, and from Calcutta to Natal. A felt want by

colonists scattered far and wide has been met and it must be our endeavour to make the publication worthy of the steadily increasing support which we may fairly anticipate it will win not only from residents within the tropical belt, but from the large number who, though non-residents, are personally interested in "Tropical Agriculture." Today's mail brings us letters from India, Java and China on the subject. Mr. Kimball of Bantam writes :—"I have been so much pleased with the specimen copy that I cannot resist the temptation to become a subscriber;" while from "Pakhoi, China," a similar request comes from a gentleman who adds the following rather singular postscript :—"I would be very grateful for a hint as to where one may find the best land for coffee culture. I am about to purchase a tract in the Philippines, but think that soil is not adapted to the growth of coffee." We cannot doubt that soil of volcanic origin is to be found in the Philippines well suited for coffee, and if our correspondent can make his selection at a suitable elevation say from 2,500 to 3,500 feet above sea-level, provided the rainfall is well distributed with an average of about 100 inches per annum, we do not doubt that, so far as soil and climate are concerned, coffee in the Philippines should do as well as in any other part of the world.

SALE OF TEA IN MELBOURNE.

(From our Correspondent.)

Thursday, 6th October, 1881 :—Ex S. S. "Cathay," from Calcutta, choice Indian Teas, 1,3/4 half-chests from the celebrated districts of Assam, Cachar, Darjeeling, Chittagong and Kangra Valley. Greig and Murray will sell by auction, at their rooms on Thursday 6th October, at half-past two o'clock. Under instruction from Messrs. James Henty & Co., agents for the Calcutta Tea Syndicate, in connection with the Government of India.

INDIAN TEA.

Ex S. S. "Cathay," from Calcutta. Per lb. in bond.

6 half-chests Assam pekoe souchong 44lb. (each 2 tins.) Greyish black bold even curled leaf few ends rasping pungent heavy infusion 1s 5d.

20 half-chests Cachar pekoe 44lb. (each 2 tins) Evenly curled and twisted greyish black leaf high burnt brisk and very flavory 1s 4½d.

9 half-chests Darjeeling souchong 45lb. rather large boldish black even leaf rich fragrant delicate malty flavor 1s 3d.

30 half-chests Assam broken souchong 39lb. Blackish brown rather open and loosely twisted leaf pungent and strong full ripe pekoe flavor Fine Mixer. 1s 0½d.

16 half-chests Darjeeling pekoe 45lb. Choicest neat wiry even black perfect leaf full of tips a grand tea drawing a pleasant fragrant telling infusion The finest Darjeeling of the season. 2s 5½d.

50 half-chests Kangra Valley pekoe 40lb. Black boldish fairly curled leaf pekoe tips very flavory richly fired ripe pekoe flavor. Pleasant tea. 1s 1d.

50 half-chests Cachar pekoe 40lb Handsome wiry very even blackish leaf pekoe tips choice rich telling liquor very strong heavy flavor. Finest Cachar. 1s 7d.

23 half-chests Assam broken souchong 50lb. Neat small very even greyish black leaf Namuna kind much strength pungency and grip Powerful mixer. 1s 0½d.

50 half-chests Darjeeling pekoe souchong 40lb. Boldish greyish fairly curled and twisted leaf fragrant delicate rich pleasant flavored tea Fine tea to drink alone. 1s 1½d.

8 half-chests Darjeeling Terai pekoe 50lb.

11 do do do 38lb.

Choicest wiry neat perfect leaf full orange tips rich ripe brisk full pekoe flavored delicious tea. 1s 11d

70 half-chests Assam pekoe souchong 35lb Handsome well made evenish black leaf pekoe tips great strength and character with rich heavy infusion Fine mixer. 1 3½d

19 half-chests Cachar pekoe 50lb. Rather hard some small wiry greyish leaf pekoe tips little malty brisk ripe pekoe flavor. Pleasant tea. 1s 4½d.

25 half-chests Assam pekoe souchong 45lb. Extra fine greyish well twisted leaf few tips pungent and strong brisk tolling infusion. Strong tea. 1s 1d.

18 half-chests Darjeeling broken tea 44lb. Small neat blackish open leaf rich ripe full brisk flavory Fine mixer. 1s 0¾d

20 half-chests Darjeeling pekoe souchong 40lb. Well made wiry blackish grey even leaf full bodied brisk ripe malty pekoe flavor Fine tea to drink alone. 1s 2½d

18 half-chests Darjeeling souchong 45lb. Evenly curled greyish black well made leaf delicate rich full infusion with great strength Fine tea to drink alone. 1s 3½d

20 half-chests Assam pekoe souchong 45lb. Extra fine even twisted black leaf pekoe tips pungent and strong rich very full brisk flavor. Powerful tea. 1s 3d.

50 half-chests Cachar pekoe souchong 45lb. Greyish black neat well twisted leaf telling infusion strong and pungent with great body Rich mixer. 1s 3d.

9 half-chests Darjeeling broken tea 44lb. Brownish black open and loosely twisted leaf rich delicate ripe brisk pekoe flavor. Fine mixer. 1s 1½d.

22 half-chests Darjeeling Terai pekoe souchong 39lb. Well made greyish black evenish leaf full flavored thick heavy rich infusion Delicious tea. 1s 2d.

28 half-chests Assam souchong 45lb. Neat closely curled blackish crisp leaf strong rather pungent thick heavy liquor 1s 1¾d.

25 half chests Assam broken pekoe souchong 40lb. Very neat greyish black small leaf strong rasping brisk pungent liquor Fine mixer. 1s 1½d.

50 half-chests Darjeeling pekoe souchong 40lb. Bold brownish even curled crisp leaf rich full malty delicate pekoe flavor. Delicious tea. 1s 2¼d.

89 half-chests Assam pekoe souchong 40lb. Extra fine well curled and twisted leaf with pekoe end rich heavy very fruity malty flavor Heavy liquor. 1s 2d.

36 half-chests Darjeeling pekoe 45lb. Choicest well made perfect leaf full orange tips drawn a magnificent infusion rich fragrant and delicate Most delicious tea 2s 2d.

50 half-chests Cachar pekoe souchong 45lb. Extra fine well curled greyish black leaf rasping telling liquor very pungent and strong. Rich mixer. 1s 3d.

55 half-chests Cachar broken pekoe souchong 44lb. Greyish black even curled crisp leaf namuna kind pungent rasping telling choice infusion Powerful mixer. 1s 1d.

20 half-chests Assam broken souchong 45lb. Small neat greyish black open leaf briskly fired deep rich flavory. Thick liquor. 1s 0½d.

54 half-chests Darjeeling pekoe souchong 45 lb. Evenly curled greyish black hard crisp leaf Fragrant delicate rich full telling liquor. Delicious tea. 1s 1½d.

30 half-chests Assam pekoe 40lb. Very handsome even wiry greyish leaf full of pekoe tips a perfect liquor wonderful strength with great body and delicacy. Most powerful mixer. 1s 9d.

50 half-chests Cachar pekoe 45lb. Closely twisted greyish black even leaf few tips strong full rich ripe pekoe flavor. Fine liquor. 1s 3½d.

12 half-chests Assam pekoe souchong 44lb. Rather large but closely twisted greyish black leaf pekoe tips little pungent and strong full brisk flavor Rich mixer 1s 1½d.

50 half-chests Cachar pekoe souchong 44lb. Greyish black well twisted and curled strong full ripe brisk pekoe kind. Useful tea. 1s 1½d.

50 half-chests Cachar pekoe souchong 42lb. Even blackish round and tidily curled leaf strong full flavor pekoe kind Thick liquor. 1s 1d.

20 half-chests Chittagong pekoe souchong 60lb. Superior well made greyish leaf few tips namuna kind pungent rasping liquor with fine character and flavor. Powerful tea. 1s 3d.

50 half-chests Cachar pekoe souchong 40lb. Greyish black well curled crisp leaf strong full ripe rich flavory. Good tea to drink alone. 1s 2d.

40 half-chests Cachar pekoe souchong 39lb. Rather large boldish black even leaf pungent and full brisk pekoe kind. Strong tea. 1s 1½d.

50 half-chests Cachar pekoe souchong 35lb. Greyish black even wiry leaf rich ripe full strong pekoe flavor. Fine mixer. 1s 1½d.

A CEYLON PLANTER IN MANITOBA.

A correspondent writes:—"I send herewith copy of a portion of a letter received this morning from a friend of mine, formerly a Ceylon planter, lately settled in Manitoba, as the publication of it may prove interesting to some of your readers."

Portion of letter referred to :—

"I arrived by rail at Emerson on the 5th of August, and am living with my brother here. He has a good two-storied house, and a farm of six hundred and forty acres—about 120 in crop, and 60 head of cattle. Altogether he is doing well, but farming does not pay very well here as yet, as there is so much public work going on, in the way of railways &c., that labour keeps very dear—8s. 4d. a day and board, in harvest time! My own land is about three miles from here, and I expect to be able to work it from here, if I can get a good man as overseer. I have 640 acres at present, 100 acres ploughed, and will be cropped next year. I am in treaty to buy another 640 acres adjoining it.

"I believe that one cannot well go wrong in buying country-land here, as it is now worth 15s. to £1 per acre, and, as far as I can see, must be worth £5, at least, in a few years; so that, if one can make a living off it meantime, he is not doing badly. We are twelve miles from Emerson, which is situated where the Red River crosses the State's boundary, and our nearest railway station is only six miles from my land.

"The life here is one of ease compared to Ceylon, but there are occasional spurts of hard manual work, as, when threshing, for instance. The general living is less comfortable than in Ceylon, as servants are expensive."

NEW CINCHONA PLANTATIONS.

About five and thirty years ago little was known of Darjeeling beyond the fact that it was a pleasant hill station, romantically situated and highly favorable to the renovation of health. At the period we quote, the man would have been suspected as a monomaniac who spoke of its capabilities for the cultivation of tea and cinchona, but it was not till that prince of utilitarian botanists, Dr. Royle, suggested the possibility of naturalising the most useful varieties of the cinchonas of British India, that Darjeeling came to occupy the position it does now as a tea and cinchona-producing district. Knowing so much of the South American cinchona forests, he was led by an exhaustive comparison of the flora and climates of the Darjeeling, Cossiah and Neilgherry Hills to come to the conclusion that, with the usual precautions, they could be got to produce the bark now so eagerly looked for and prized everywhere. It is now upwards of thirty years since Dr. Royle gave expression to his belief of the capabilities of Darjeeling as a cinchona-producing field, but the question was subsequently taken up by other experienced botanists, Doctor Anderson among the rest, with the happy effect of inducing the Government to undertake experiments on a scale commensurate with the importance of the undertaking. It is not to relate how and through what several stages cinchona-cultivation passed as an experiment that we make our present obervations, but to ask whether other localities besides those we had already entered upon might not be selected for similar experiments, and it would be worth while, we think, for Government to invite opinion as to other promising spots. Gigantic difficulties, no doubt, will have to be encountered and overcome, just as was the case at Darjeeling, but unflagging perseverance, and botanical knowledge will be equal to the attempt. British Sikkim seemed at one time to be a very discouraging field, but that opinion has since been reversed by the successful naturalisation of the C. Succirubra, C. Officinalis and C. Calisaya. These are by far the most valuable of all the cinchonas, and if they can be got to flourish at suitable heights in Northern India, we see no reason why they should not be equally successful on certain other equally favored spots in other parts of India. It is almost impossible to estimate aright the universal benefits which will be conferred upon the inhabitants of marshy and malarial districts, when quinine and its allied alkaloids are brought within easy reach of the poorest in the land. *Quiniaina* is in no whit inferior to quinine itself, as most of your readers are aware, and being less costly it could be brought within every one's reach. The extension of the growth of so valuable a febrifuge ought to commend itself to Government, and I trust to hear that a commission is appointed to report upon the eligibility of other spots besides those that are already known as cinchona-yielding districts.—CINCHONA.—*Madras Times.*

SALE OF CINCHONA BARK.

Messrs. Robinson & Dunlop put up for public sale, at their offices to-day Nov. 4th the undermentioned lots of cinchona bark :—

	lb.		R.	c.
East Holyrood—42S	succirubra twigs sold for ...		0	30
275	,,	stem quill ...	0	80
606	,,	,, broken	0	90
55	,,	,, renewed	1	05
660	,,	,, ,,		

From 5 to 6 year old trees, elevation 4,000 feet, Dimbula district.

Analysis dated 31st October, by Mr. M. Cochran, of the parcel of 660 lb. renewed: stem quill shews :—

total alkaloids	4·80	
sulphate quiuine...	2·21	
driage ...	12·38	R. c.

Waverley—1,000 lb. officinalis stem shavings 1 60

From trees 5 year old, elevation 5,000 feet, Agrapatana. Analysis, dated 2nd November, by Mr. M. Cochran, shews :—

total alkaloids ...	4·86
sulphate quinine ...	3·03
driage	12·88

Though the quantity offered was small, the attendance of regular buyers was good, and biddings spirited, especially for the renewed succirubra and officinalis shavings, shewing that, for good sized lots of really good quality, there is a locally a good sale.

OSTRICH FEATHERS.—The French Consul at Tripoli notices the remarkable increase in the quantity of ostrich feathers despatched thence to France last year. The total value is estimated at nearly 5,500,000f., against less than 3,500,000f. in the previous year. This increase is mainly attributed to the fall in the price, consequent upon the arrival in England of great quantities of feathers from the Cape of Good Hope. In England it is remarked that the Cape specimens are preferred, as being perfectly white and full feathered, and lending themselves easily to those harmonious tints of colour in vogue nowadays. In Paris, North African feathers seem to be held in less disfavour and hence strenuous efforts are being made to acclimatise ostriches from Tripoli in Algeria.—*British Trade Journal.*

THE AGRICULTURAL INTEREST OF THE UNITED KINGDOM, AND A WORD FOR THAT OF CEYLON.

"Ships, colonies and commerce," and especially commerce, have contributed so largely to the wealth and the greatness of the British Isles, that a vague but very general idea has obtained possession of large numbers that home agriculture occupies but a very minor comparative position. Those who have studied the question know how fallacious this idea is. It is very true that neither England nor Scotland is so exclusively dependent on the land and its products as, unfortunately, the inhabitants of the sister isle are. On the other hand, more capital, more science and more of steady, well-directed labour have been devoted by the English and Scotch in doing "justice to the land" than has ever been the case in unhappy and, until in recent years, misgoverned Ireland. The fact that, under the feudal or rather the patriarchal system which prevailed amongst the Celts of Ireland as well as those of the Highlands of Scotland, the land was never considered the absolute property of an individual —the Chief or Head of the Clan merely held it in trust for the whole body—must never be forgotten. The possession of land, too, however acquired, involves duties and responsibilities, as well as privileges. These principles, as well as lessons drawn from the traditional land laws of the Indian branch of the great Aryan family, no doubt guided Messrs. Gladstone, Bright and their associates in making concessions to Irish tenants which, in the estimation of many, have approached the verge of confiscation. Having made all the concessions which are possible, with due regard to justice to the landholders, those who rule the nation will be fully sustained in the position they have now assumed towards a conspiracy which had for its object nothing short of spoliation and anarchy. But it was inevitable, especially in view of the disastrous consequences of a succession of abnormally wet years on the agricultural interest of Britain, that the question should be raised of applying to farming in England and Scotland the main principles which are deemed just and beneficial in the case of Ireland. Accordingly movements have taken place both in Scotland and England for a reform of the land laws which will surely bear fruit. Abolition of those laws of entail and primogeniture which in too many cases have converted the nominal holders of land into mere genteel paupers, utterly destitute of capital necessary to improve or keep up the condition of their estates, in the case of land held directly by themselves or rented as farms, is but a question of time. So with the game laws, except in cases where game alone can render vast tracts of barren moorland productive. Such tracts there are in the Highlands of Scotland, but even there public opinion will demand that the welfare of human beings, when at stake, should be preferred to the existence of herds of deer or flocks of ptarmigan or grouse. Justice to tenants as well as justice to landlords, which are quite compatible, will be insisted on; every obstacle being removed and every inducement offered for the expenditure of more and more capital on the soil, the pasture and the flocks and herds, so as largely to increase production which even now is enormous. A falling-off in the export trade of Britain excites universal attention and concern, but few take account of the market for manufactures and products of all kinds which has been lost or diminished by the evil times which have affected home agriculture since the culminating point of prosperity in 1874. As more and more foreign corn was introduced, it would naturally be expected that British farmers would more and more turn their attention to the breeding of animals. But just as the Ceylon planters have been compelled to restrict the use of fertilizers at the very moment when such substances were most required, so the farmers of the United Kingdom have been unable not only to increase their stock of animals but to prevent a serious diminution of their own and their country's wealth. Figures given by a farmer, writing to the London *Times*, shew that the loss by decrease in the seven years has been 377,000 cattle (out of 10,281,000), valued at 4½ millions sterling; 6,937,000 sheep (out of 34,837,000), valued at £13,875,000; and 387,000 swine (out of 3,537,000), valued at £581,000. The total decrease is equal to a loss of little short of nineteen millions sterling. That this loss will be recovered we cannot doubt, but this is only one direction in which agriculturists have been adversely affected. Of course the legislature cannot provide against abnormal seasons, in the British Isle any more than in this eastern isle, but it is the duty of Government here as there to mitigate the disastrous effects of providential visitations of an adverse character, not by the imposition but the removal of burdens, restrictions and disadvantages. Numerically the agricultural classes in the United Kingdom, with those dependent on them, are equal to 8½ millions or one-fourth of the total population. Their capital, it is affirmed, is in exactly the same proportion to the realized wealth of the nation. How enormous the aggregate is, becomes apparent when it is necessary to represent it by figures which stand for *nine thousand millions* of pounds sterling! The share of the agricultural classes is stated at 2,281millions. Here we must quote:—

The agricultural capital is thus apportioned:—The gross yearly rental assessed for income-tax—namely, £62,000,000—consists of about £16,000,000 of rent for the land and about £16,000,000 interest of sums laid out for inclosure, buildings, drainage, roads, fences, and water supply; and capitalizing the former amount at 30 years and the latter at 25 years' purchase, we have the landlords' property of £1,380,000,000 in the soil and £400,000,000 in improvements, or £1,780,000,000 together. The lay and clerical tithe-owners take revenues from the soil amounting to about £5,000,000 a year; which, capitalized at 25 years' purchase, represent £125,000,000 more, or a gross aggregate value of agricultural land and what is upon it of £1,905,000,000. Tenants' capital, Major Craigie takes at £8 per acre on 47,000,000 acres; giving a sum of £376,000,000. The whole capital of the proprietors and occupiers of the agricultural land of the United Kingdom is thus estimated at £2,281,000,000.

The capital wealth of Britain being represented by thousands of millions; and her people, even with the Irish element counted, being enterprising and industrious to a degree, we are, perhaps, somewhat prepared to learn that the *annual income* of the 34 millions who

inhabit the British isles is no less than *one thousand millions sterling*: of which £370,000,000 are the result of capital, while £630,000,000 are derived from earnings. To shew the importance of the agricultural interest, we must quote again :—

Of the £1,000,000,000 total, about £158,000,000 is the income of the agricultural classes, made up as follows:—£62,000,000 income of landowners, £5,000,000 income of tithe-owners, £33,000,000 income of farmers (which is 9 per cent on their capital), and £58,000,000 earnings of labourers (which averages about 24s. per cultivated acre and 14s. per week for each worker.)

From such important facts, the farmer draws correct deductions, thus :—

Now, the community can ill spare any portion of this great income derived from the cultivation and stocking of land. The trading, manufacturing, mining, brewing, ship-owning, carrying, professional, and various other classes must be concerned not to lose from their books any of that great share of the £100,000,000 annually which land and tithe-owners and farmers have expended in the purchase of home manufactures and commodities. And the urban population, including both the industrial and retired classes, are also deeply interested in the question whether the £58,000,000 of agricultural labourers' wages shall be cut down by turning large areas of plough-land into grass and sending surplus hands more thickly than ever to the towns, or whether the wages fund shall be increased and rustic workmen kept at home by augmenting the bulk of that farm-produce which requires manipulation and by planting more families in occupation of the land. A time has arrived when the business of agriculture no longer yields the amount of income to landlords and tenants which has hitherto totalled up so largely; and hence, the public have, not only a serious commercial interest at stake, but for mere self-preservation, they are bound to aid if they can, in restoring the agricultural classes into a solvent and profit-making position.

The bearing of all this on Ceylon is obvious. Our island resembles Ireland, not only in area but in the fact that, having neither mineral wealth nor manufacturing industries of consequence to fall back upon, the very life of the population as well as the sustentation of all that constitutes Government is directly dependent on the land and the success of those who have devoted their lives, their energies, their skill and their capital to the cultivation of the soil. If in the manufacturing and commercial mother country the agricultural interest is important and deserving of all the possible relief and encouragement which a wise and just Government can afford, how much more is similar action demanded from the ruling authorities of a dependency of the empire, the very existence of which depends on the land and its products?

With all the adverse influences which have operated to depress the agricultural interest in the United Kingdom, the annual value of salable produce in the shape of crops, animals, wool, &c., is reckoned at £300,000,000, while the total value of the year's export trade was only £223,000,000. But, after all, agriculture is only *relatively* important in the United Kingdom. In this Colony its importance, and especially of that branch of it conducted by Britons with British skill and British capital, is supreme and overshadowing. Blot out the enterprise referred to, and Ceylon sinks back into a mere historical name—a country interesting for its *ruins*. If therefore, the revival of agriculture in Britain is urged as one of the highest duties of statesmanship, is this a time in Ceylon for increasing, instead of diminishing burdens on an enterprise which is already suffering the extreme of depression from causes beyond human control and apparently beyond human cure? "Time the healer" will bring relief; but meantime those on whom the hand of a mysterious providence has fallen heavily have a right to expect that their rulers will do all that is possible to lighten their burdens, instead of assuming the attitude and carrying out the policy with which the name of "Rehoboam" is associated in a manner the reverse of favourable, or famous, or worthy of imitation.

THE "TROPICAL AGRICULTURIST."

(Communicated.)

The "Tropical Agriculturist" has now reached the age of half a year. The last three numbers show a marked improvement in the way of selection of useful articles relating to our old products, as well as to those of later time, and hints respecting those that might be cultivated. A great many useful extracts occur which point out to us the state of affairs relating to such products in other parts of the world

It must be admitted by every one interested in Agriculture, directly or indirectly, that this is one of the best Agricultural Records in the East, pointing out to us the success and failures of the different modes of treatment in various localities of this island.

With the steady growth of this magazine, we note that there have been rapid strides in the yield of our cinchona trees, the last recorded in the journal being 9·6 of quinine from a 5½ year old tree in Dimbula. This has been outdone by trees on Yarrow. However, with the increased yield of quinine and increased planting, we have to note that Howard now quotes his quinine at 8s per ounce, and though this may be only a temporary depression, giving rise, perhaps, to a greater consumption; yet the time must come when the price will fall far below 8s. There is now still greater need for us to manufacture the quinine in Ceylon, and so save the charges of transport, as well as the heavy agency charges at home.

A very useful paper on "Lime and Manure" appears in the October issue, and an interesting article on lime or the ashes of the kumbuk tree.

Coffee leaf disease has its share of literature, and Mr. Ward's final report is promised us in the next issue. We doubt whether much good will spring from all this enquiry, save the fact that certain proposed remedies are of *no* avail. *Hemileia vastatrix* is of a deeper stamp and more mysterious than it looks, and all outward treatment will be futile. Such treatment may, however, afford a passing relief.

Tea and rubber show a gradual progression. With respect to the latter, however, the one thing required is: will the yield be sufficient to enable the European to pronounce it a remunerative crop?

Two valuable papers referring to scientific agricultnre and agricultural education appear in the last number. We only hope that we may have some agricultural education here, accompanied with some practical work, to divert the ever-abounding and continually increasing thirst for the youth of Ceylon to enter the legal or medical professions, or to rest content with a clerkship. If only such a diversion could be effected, what a different race we should have in time to come! How much they themselves would be benefited and the island in general!

Papers on gardening from the *Asian* and Sutton's *Guide* will be much appreciated by those who have leisure to spend on such a useful and healthy occupation

AMERICAN TRADE WITH LIBERIA.

Consul-General Smith, in transmitting the statement of the direct trade between Liberia and the United States, notes that there are, each year, "additions to the farming class of the country from among Liberians, recent emigrants, and a few aboriginal Africans. There is an impression spreading, and happily influencing the common people, that the hope for bread, for comfort, for respectable manhood is in the soil.

The increase of coffee is in like proportion to the quantity reported, perhaps a little in excess of last year. Camwood has not appreciably decreased in quantity nor quality. The Consul-General reports having been shown some very fine specimens of gum copal from the Kroo country between Grand Bassa and Cape Palmas. But the Liberians have done nothing toward securing and shipping this valuable article. The Consul-General having given the necessary information concerning this new article of gum copal to some American dealers, he believes that it will soon be found in the New York and London markets. —*American Exporter.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special letter.*)

PARIS, 8th October.

With the view to develop the use of steam ploughs in France, a native manufacturer will lend that implement gratis, in order that intending purchasers may test its utility. The combination system, for the general purchase of farm machinery, the subscribers employing the implements by a rotation determined by lot, is also making satisfactory progress. At the Electricity Exhibition, the plough ordinarily worked by steam has for motor electricity, which drags the machine in inverse directions, as do the locomobiles. In the case of the electric motive power, it is not necessary to transport the generating machine to the grounds, the current can be sent along by wires, at a distance of one or two miles from the farmstead, where the generator can be turned by the stationary steam engine. It does seem, that the only difficulty connected with the use of electricity is to be able to produce it on a large and cheap scale. In the case of extensive illumination, electricity can be profitably employed, but not otherwise up to the present. There is no doubt electricity, as a source of power and heat, as well as of light, will be made commercially cheap. For example, the power of the fluid is marvellous; in the Electric Exhibition the one current supplies the light, and drives the several machines, while never displaying any diminution in power, despite the several and varied demands made upon its services.

Salicylic acid, after remaining for a long time a laboratory curiosity, has developed into a modern industry. The new product was accepted by some enthusiasts as the philosopher's stone: it was boasted that it cured every disease, no matter whether of long or short standing, like a patent medicine. Then came the inevitable reaction. The French Government excommunicated it in the interest of the public health, while other countries, that dispense with Government tutelage, had no complaints to record on sanitary grounds. In Germany the acid has been found by veterinary surgeons efficacious against several diseases; horses with sore mouths were cured in five days by merely allowing them to bathe their lips in a weak solution, renewed thrice daily. In 1874 in Hungary, when the poultry epidemic broke out—eruption about the eyes, head, feet, &c.—a cure was effected by touching the affected parts with a brush dipped in a solution; adding the acid to a tub in which ducks and geese could bathe, and mixing it with sand or ashes wherein fowls liked to roll. Of late, in Germany, salicylic acid has been successfully and generally employed, not as a remedial so much so as a preventive agent. For horses, bulls, cows, &c., these receive one-thirtieth of an ounce daily; smaller stock in proposition: about three ounces of the acid dissolved in a bucket of warm water, and the solution proportionably distributed. As an antiseptic the acid is excellent. An objection has been made, that it lessens the reproductive powers of stock, but M. Ludloff, who has employed the acid daily for five years, finds that 100 cows produced 89 calves, while the average was 88 for the preceding five years. The generative functions are thus unaffected. The cost of the acid, per head of cattle, per week, is only one penny.

The cultivation of the parsnip is taking extensive proportions in France as a forage plant: its natural home appears to be Brittany, where it continues to grow till the close of December. M. Le Bian has made the culture of this root a speciality, and is in a fair way to substitute it extensively for oats for horse feeding. It goes capitally with maize, and hogs accept it as a dainty dish

The seat and centre of the *charbon* disease, or "mountain malady," is in Auvergne: the Pasteur process of vaccination has been tried in several of the mountainous districts, and with the fullest success. M. Pasteur announces that he is occupied in the arrangement of a little laboratory for the commercial preparation of vaccine: he will not be ready to execute orders till next spring; no loss will be incurred in the interim, as the disease is limited during winter. He will prepare 44 gallons of the "pock," sufficient to vacciuate one million of animals; it will be forwarded in special glass tubes, and the cost will be one-halfpenny per head of stock. Up to the present, 50,000 animals, sheep, oxen, cows, horses, &c., have been vaccinated, and with success, in the sense that they have been saved, while others at their side have succumbed.

The two most successful means for destroying the phylloxera are, autumnal inundations followed in spring by rich manurings, and, next, the use of sulphuret of carbon, in the proportion of three-quarters of an ounce per square yard, dibbled around the roots. The sulphuret has the disadvantage of being dear, and the drawback of killing the patient occasionally. Where the latter occurs, the cause will be found to reside in an excess of humidity in the soil, and the lowness of surrounding temperature. On well-drained lands, having a silicious or calcareous subsoil, the sulphuret may be employed with safety: treat only vines not too gravely attacked by the bug, and select winter for the work; when the soil is tenacious and the disease long standing, multiply the holes in the square yard and reduce the doses. In spring, apply farmyard manure, with the addition of potash salts, in the chloride form for example, but never employ oil-cake.

Petroleum cures cutaneous affections; M. Desbois finds, if it does not kill ants, it drives them away, as he knows from experience in his conservatory.

It has been decided by several of the Councils General that for the future highroads and the byways shall be planted with fruit trees, instead of elms, poplars, acacias, ash, &c., that merely exhaust the soil.

The vintage is excellent this year in point of quality. The beet crop will not be heavy, but the juice will be very rich.

NEW PRODUCTS: LOWCOUNTRY REPORT.

LIBERIAN COFFEE; COCOA; CEARA' RUBBER; CRICKETS; LEAF-DISEASE; TALIPOTS; PALMS IN FLOWER.

WESTERN PROVINCE, 4th Nov. 1881.

October has maintained the character of 1881 as the most perfect for the lowcouutry planter that he could have made, had he himself been clerk of the weather. It has rained almost daily, and, towards the end of the month there were several heavy thunder storms.

I have planted up the piece of new clearing and have since been supplying the vacancies caused by the crickets in the July and August planting. The havoc has extended to a very large percentage of the young plants, and it is a question now if I have sufficient plants to fill all the empty spaces immediately. The crickets have not entirely disappeared up to date, but they are less mischievous than they were up to the middle of the month, and I can now put out plants with some confidence. I have now accepted the cricket as a fact of the situation, to be provided for by larger nurseries, letting the plants be more advanced before putting them out, and planting just at the time when the enemy disappears for three months. The plants put down now will have three months to establish themselves and gain strength, before the next generation are ready to take the field. That Liberian coffee is to be got up in this batali land at all is due to the one fact, that the crickets do not attack the young plants in baskets to any serious extent.

The year old plants continue to grow in the most satisfactory way and the older trees are elaborating a heavy blossom, which will open towards the end of this, or early next month.

I sowed the Ceará rubber seed in a shed, and the first of it came up on the fifth day and was six inches high in a fortnight. The shed, I find, is a mistake, as the plants all lean towards the light, at an angle of 45 with the surface. I have therefore put down the second supply of seed in the open ground. I have already lost several plants, not by cricket, which only works at night—these were cut at midday—but probably by a species of fly; but I did not see it.

Much of the cacao that appeared dying some months ago has taken a start, and now grows tolerably, but shows a tendency to throw the growth into suckers from the stem, which I am trying hard to counteract, by stripping and pruning. I have recently supplied the vacancies on the ground, where the older plants looked most promising, and, in planting, have used a good deal of quicklime for the benefit of the whiteants: time will try its effects. The older trees continue to flower copiously, but have never yet formed a pod.

The teak, bambu, jak, mango, beli, are all flourishing in a very satisfactory manner; only the cinchona is a complete failure. The lime and orauge do very well after they get a foot high, but out of many hundred plants I have not half-a-dozen fully established.

I lost one coffee plant, about three feet high, from a white grub, about an inch and a half long, which entered below ground, and ate its way up the centre of the stem, and some dozen young plants have lost their tops, from a small brown grub that enters a few joints below the top and eats out the pith upwards.

Where the leaf-disease happens on the older trees, it never leaves them: some get spots on every leaf, but neither drop leaves nor crop; while others, on which the look is not so bad, have a bare beggarly appearance, with the fruit remaining, but never growing bigger. Some of the year old plants get a very virulent attack, and, for some time past, I have stumped all that I found so affected: but I find them very slow in throwing out fresh shoots and, at the end of two months, some of them have not made the attempt.

I suppose every one who has had to deal with Liberian coffee during three or four years past has been forced to accept the fact, that *upwards* of twelve months elapses between the flower and the ripe fruit. If the fruit sets on a healthy tree, it will ripen in its season, and those who are not content with the nature of the plant will do well not to meddle with its cultivation. If the crop dries on the tree, before ripening, it indicates a bad plant, or a poor soil, or a specially bad season, but not an incapacity in the plant to ripen its fruit in a climate that closely resembles that of its habitat. If well treated throughout and planted in good soil, the Liberian coffee plant will flower at two years from seed, and may or may not, according to the season, continue to blossom every month for the next twelve, but its true blossoming seasons are January and July. When the tree has a crop it will not grow much young wood, while bringing forward its fruit, and the next blossom will be a comparative small one. Thus there will be two crops in the year, and one of them will be larger than the other. If the season is a moist one, the streugth of the tree will go into the production of wood; if it is dry the wood will ripen sooner, and there will probably be several small blossoms in the iutervals of the larger ones. It is claimed that the plant bears crop on the old bare wood, but I would not put much trust in what crop may be so obained. I have no trees more than four years old, so that my experience is not very extensive, but I see clearly that the struggling blossom on young trees will cease, and they will settle down into bi-annual flowering, in ordinary seasons, in this portion of the lowcountry.

Colombo residents who have never seen the most stupendous flowering apparatus in nature should take the opportunity, which half-a-life time in the island may not again bring round. The talipots are in flower, all over the Siyane and Hapitigam Korales. There is one close to the Governmeut garden at Henaratgoda, and they are to be seen along the railway as far as Ambepussa. I can see above twenty from the top of this estate, and they are still more numerous about Muguragampola. Perhaps some botanical authority will explain why they all flower together.

"KEGELIA PINNATA."

In your notice of the fruit of this plant brought to Ceylon from Java by Mr. A.M. Ferguson, you forgot to mention that it was a case of bringing coals to Newcastle. There is a fine specimen of this tree in the garden behind the public offices in the Fort, close to the end of the Government Printing Office, which is always in flower and fruit, the latter hanging on stalks often 8 to 10 feet in length, and in this respect, being one of the most remarkable plants in the vegetable kingdom. I saw a fine specimen of this tree in the triangular bit of ground opposite the main entrance to the Royal Botanic Gardens at Peradeniya forty years ago, and even then it was conspicuous from the Kandy roadside by its singular flowers and fruits, the latter hanging down on long rope-like peduncles, but so concealed otherwise by a mahogany tree, the so-called star-apple of the Peradeniya Gardens, but really the *Chrysophyllum olivaeforme*, with a small elongated fruit, and other trees, that Dr. Thwaites did not notice it until I pointed it out to him about 25 to 30 years ago. The tree has been freely distributed from this one by Mr. Thwaites, but our Colombo one would have shared the fate of other rare or valuable foreign trees in the Fort garden which were said to impede the free circulation of air, had I not on more

than one occasion used my influence to save this remarkable tree.

The calabash plant of the West Indies, *Crescentia Cujete*, which was introduced to Ceylon more than 20 years ago, and is now quite common about Colombo, is a close ally of the Kegelia: indeed they were formerly included in a separate family, *Crescentiaceae* so named from the former genus, but they are now included in *Bignoniaceae*. (See notice of *Crescentia Cujete* in note *f* at bottom of p. 208 of "Ferguson's Directory" for 1863.)

Mr. A. M. Ferguson when travelling in Ceylon or elsewhere, never lost the chance of collecting specimens in flower or fruit of any plants which struck him as being remarkable or ornamental, with notes on them, and his long residence in Ceylon has enabled him to learn a considerable number of the names of plants; but without a list of the plants, introduced and naturalized in Ceylon, and an idea of what they are, he and others are likely to bring specimens of plants we already possess.

Mr. Morris's catalogue was the first attempt made to enumerate the foreign plants growing in Ceylon, but a second edition or catalogue on another plan is much wanted, to enable parties deeply interested in the introduction of useful and ornamental plants to avoid the useless expense of introducing plants already in the island, many of them here since the times of the Portuguese, Dutch and English, viz., 1505 to 1656, 1656 to 1795, and 1795 to 1881. It is perhaps adding a few straws to Dr. Trimen's burthen to ask him to make such a catalogue in the midst of his multifarious duties, but I feel sure such a catalogue would be very valuable, and much appreciated by a large number of people resident in Ceylon and elsewhere interested in the island and its productions introduced and indigenous. I believe nearly every other colony except Ceylon has issued such a catalogue.—W. F.

MR. DARWIN ON EARTH-WORMS.*

At first sight, the subject of Mr. Darwin's new book seems to promise less of interest to the general reader than almost any among the series of minute and patient monographs which have followed up the epoch-making publication of the "Origin of Species." But the fact is, Mr. Darwin's skill lies most of all in just such surprises as that which he gives us in this delightful little volume. He takes up some unpromising and seemingly dull study—the growth of coral reefs, the slow movements of climbing plants, the effects of cross-fertilization—and in his wonder-working hands the mass of dry detail becomes quickened as if by magic into a living romance, full of vivid reality and instinct with evolutionary plot-interest of the most fascinating sort. Something of the same kind he has now done with the common earthworm. In the eyes of most men—nay, even of most naturalists—the earthworm is a mere blind, dumb, senseless, and unpleasantly slimy annelid. Mr. Darwin undertakes to rehabilitate his character, and the earthworm steps forth at once as an intelligent and beneficent persouage, a worker of vast geological changes, a planer down of mountain sides, a creator of fertile alluvial corulands, a friend of man in his agricultural operations, and an archæological, though unconscious, ally of the Society for the Preservation of Ancient Monuments.

The surface of the earth in all moderately humid countries is covered to a depth of some inches by a rich layer of blackish vegetable mould, composed of uniformly fine and small particles. The part which earthworms have borne in producing and renewing this all-important coat of fruitful soil forms the main subject of Mr. Darwin's investigation. As long ago as 1837 his attention had been called to the matter in hand by Mr. Wedgwood, who suggested to him that the tendency of marl, cinders, or pebbles strewn over meadows to "work themselves downwards," as the farmers phrase it, was really due to the large quantity of fine earth brought to the surface by worms in the form of castings. Mr. Darwin has followed up his inquiries with his usual minute experimental care, the result being the little work now before us. But as the world at large has not kept and watched tame worms with the same assiduity as our great naturalist himself, he is kind enough to preface his remarks with a full account of the habits and manners of the animals which makes up by no means the least interesting part of his book. Earthworms belong to a few genera, externally closely resembling one another, and distributed apparently over the whole world. They abound on bare chalk downs and in London parks; they inhabit the most isolated islands, and they have by some mysterious means found their way even to Kerguelen Land in the Antarctic Ocean. In their habits they are nocturnal, remaining in their burrows during the day, and only coming out to feed at nightfall. They lie, however, close to the mouth of the burrows, apparently for the sake of warmth, and are thus devoured in large numbers by birds. The most interesting point in their internal structure is their possession of gizzards, in which they triturate their food with the aid of small stones, a function which has important bearings on the production of mould. On their senses and intelligence Mr. Darwin made several curious and careful experiments. He found that, though they had no eyes the front part of the body, containing the cerebral ganglia, was slightly sensitive to light (a point of much lateral importance as bearing upon the evolution of special organs of sight), and that when the rays from a candle were concentrated with a lens upon what we may by courtesy call their heads, they "dashed like rabbits into their burrows." If, however, the heads were shaded and light cast on other parts of the body, they took no notice of it. This ability to distinguish between day and night doubtless serves to protect them from diurnal animals which prey upon them. On the other hand, worms are absolutely deaf, and when Mr. Darwin played the piano to them, they obstinately refused to listen to the music; nor were they moved even by the strains of a metal whistle. By way of compensation they are actuely sensitive to jars, and retreated at once when their pot was actually placed on the piano and a note struck. Smell seems to be present, though feeble; for while they took no notice of perfumes or of acetic acid, they quickly discovered bits of cabbage and onion buried in the ground. Taste they clearly possessed, as they shewed a marked preference for green over red cabbage, and for celery over either; and they distinguished in like manner between the leaves of different trees. But they are as omnivorous as man himself, greedily devouring meat; and when Mr. Darwin fixed several pieces by long pins in their pots, they might be seen night after night half out of their burrows tugging at the bits of this rare delicacy. Indeed, so closely do they approach the level of humanity that they are actually cannibals as well.

The evidence of intelligence in worms is slight; but Mr. Darwin thinks sufficient. They drag leaves into their burrows (which are regularly constructed nests, with a chamber at the bottom) partly as food, and partly to plug up the mouth; and Mr. Darwin noticed that the way in which they pulled down even unfamiliar or foreign leaves and triangles of paper so as to avoid mechanical difficulties was indicative

* "The Formation of Vegetable Mould through the Action of Worms; with observations on their habits." By Charles Darwin, L.L.D., F.R.S. (London: John Murray. 1881.)

of some intelligence. They always plug the entrance, sometimes with leaves and sometimes with small stones. This may be as a protection from their great enemy, the scolopender, but it is more likely for the sake of warmth; as Mr. Darwin noticed that when kept in a room with a fire the performed the work "in a slovenly manner." They also often coat the upper part of their burrows with leaves, to prevent their bodies from coming into contact with the cold ground. Besides eating vegetable and animal food, worms seem to some extent to swallow earth for the sake of the organic matter it contains; and their castings are composed of such earth, as well as of that which has been voided for the excavation of their homes. Even in England these castings often attain a considerable size, but in India and Ceylon they sometimes reach a height of six inches and weigh as much as a quarter of a pound.

Passing on to his more special subject, Mr. Darwin shows that the amount of mould thus brought up to the surface by worms may be measured in two ways, both of which he followed. The first method is by ascertaining the rate at which objects left upon the ground are buried: the second and more accurate method is by weighing the quantity brought up within a given time on a given space. At Maer Hall, in Staffordshire, quicklime was spread upon a meadow, which was not disturbed for ten years. At the end of that time square holes were dug in the field, and a lime was found in a layer at a depth of three inches from the surface, covered by dark-coloured, fine mould, and underlaid by a coarse gravelly or sandy soil. In many other instances similar results were obtained with cinders or marl on chalky or peaty ground. A field at Down was so thickly covered with flints that it used to be called "the stony field;" but thirty years after the worms had worked so vigorously that a horse could gallop from one end to the other over compact sward, without ever striking a stone. A path on the lawn at the same place was paved with small flags, set edgewise, through which the worms threw up castings; for a while it was swept and weeded, but at last it was left alone; and after several years the flags were found buried beneath an inch thickness of fine mould. In the same way worms slowly bury even big stones; for when such a stone is left on the surface it rests at first, of course on its more protuberant parts; but worms soon fill up with their castings the hollows on the lower side, for they like the shelter of stones. When the hollows are filled, they eject their castings beside the stone; and as the empty burrows collapse the stone slowly sinks. Thus builders are almost always slightly embedded in the soil. The fallen monoliths at Stonehenge have in this manner been partially buried, as Mr. Darwin elaborately proves. But the second method gives even more certain results. Mr. Darwin shows (after Hensen, that there must be no less than 53,767 worms living in a single acre of land; and in one case the burrows numbered nine in two square feet. Some barrels of bad vinegar (poisonous to worms) being spilt on a small piece of land, the heaps of dead worms found piled on the spot were so amazing as to be almost incredible. Mr. Darwin collected and weighed the castings thrown up at various times in various times in various places, and comes to the conclusion that they would amount on the average, in many cases, to a uniform layer of mould one-fifth of an inch thick every year. The chief work of worms in the economy of nature is thus to sift the finer from the coarser particles of the soil, to mingle the whole with vegetable debris, to saturate it with their intestinal secretions, and so finally to form that upper layer of rich mould which alone man employs in his agricultural operations.

Finally, Mr. Darwin considers the part played by worms in the disintegration of rocks and denudation of the land. It is known that the disintegration of rocks is largely due to the acids in the humus; and Mr. Darwin shows that such acids are apparently generated within the bodies of worms. Moreover, the constant interchange of particles between top and bottom layers effected by worms brings these acids to work more often upon the subjacent rock. Again, the small stones swallowed to aid trituration in the gizzard are themselves slowly ground down, as was proved by their rounded edges under a lens, and this must produce no inconsiderable amount of fine earth, when we remember the vast numbers of worms always at work. Not only are the castings composed of very fine matter, but the small fragments of brick or pebble found among them are well rounded. The castings thus turned out on sloping hillsides are washed away in part by the rain towards the valleys, and finally carried by streams and rivers to the sea. So that in the end the insignificant little earthworm turns out to be a geological agent of vast importance, to whose actions the denudation and sculpture of the earth's surface are largely due. And if we doubt the possibility of so small and humble an animal performing such wonders in the history of our planet, Mr. Darwin opportunely reminds us that the coral-polyps of tropical seas have played almost as large a part in the ocean as he believes worms are at present playing on the dry land. It is of interest in this connection to note the fact, unmentioned by Mr. Darwin, that the burrows of annelids are among the very earliest fossil indications of the presence of life upon the earth.—*Pall Mall Budget.*

BRAZILIAN PRODUCTIONS.

It is creditable to Brazil that, in the great struggle for supremacy in the consuming markets of the world, no effort is being spared to maintain it by improving the quality of coffee and sugar, her chief articles of export, the coffee exhibition about to be held in Rio de Janeiro being with a view to this laudable object. It would appear that Brazilian coffee has been made a kind of stalking horse for inferior qualities of coffee to ride upon, and the result of the exhibition must show how far this statement is correct. The question is of importance to Brazil and the result will be watched with much interest. The large and increasing production has brought down the price of coffee to a very low ebb, from which it does not appear likely to rise for some time to come, the speculative movement, which so long kept prices at a fictitious value in the States, and in some European markets, having entirely collapsed.

The next great staple of sugar is improving in quality by the assistance of great central factories in the provinces, to which the canes can be sent for grinding, with all the appliances of modern machinery, and it would appear that this facility is being largely availed of by small farmers, who are without adequate means of dealing with their canes. We lately published a statement from the "Times" as to the large production of crystalised sugar in Demerara, calling the attention of Brazilian sugar growers to this improved system, by which we hoped they might profit. Both the articles of coffee and sugar are capable of being rendered more useful to consumers by a careful manipulation of them in the process of manufacture, and it is satisfactory to notice that the Government is fully alive to this necessity. We hear of a Brazilian capitalist who has subscribed 100,000 francs towards the establishment of a grand cafe in Paris, where Brazilian coffee will have fair play, and we heartily wish it success. By recent advices from Rio, the crop is

going to be a very large one, the facilities of railways bringing it early to market, and this is likely to become more a feature in the future. In New York we see that prices remain steady, the quotation of Santos being about ½ a cent below that of Rio.—*South American Journal.*

ARTESIAN WELLS.

The third part of the *Records* of the Geological Survey of India has recently been received, and contains a very able paper on Artesian Wells, which, of late years, has received prominent notice in India, at first, with but little to encourage, but of late with great success. We quote from Mr. Medlicott's paper on the nature of Artesian Wells:—

"*The Artesian Wells.*—The simple phenomenon to which artesian wells are due is of very common occurence in ordinary wells sunk below the sub-soil wtaer: whenever, as frequently happens, the water rises at once to a higher level than that at which it was struck. When the ascensional power is sufficient to bring the water up to or about surface, the well is called artesian, from the province of Artois, in France, where such wells have been used from remote times. Where such a source can be found, it is manifestly sufficient to tap it by a boring, the dimensions being regulated according to the discharge required,

"*The popular explanation: two classes of conditions.*—The familiar explanation of this action, and indeed the only one mentioned in many books,* is somewhat *misleading*, as being but a special case of the required conditions. If an elastic tube be filled with water and allowed to hang in a loop or curve; if then the tube be punctured on its upper side, the water will spout up from the hole with force proportional to the position of the puncture below the level at which the water stands in the tube. This illustrates the example usually given of artesian conditions; where the water-bearing stratum lies in a basin, whether from the original conformation of the area of deposition, or as induced by disturbance of the depo its. Such features are, however, of the rarest, in any vernacular sense of the word basin. Most of the so called basins have one or more sides wanting, and are, in fact, compound inclined planes. This popular view of artesian borings would not even *primâ facie* apply to the majority of cases, nor to any trials that have been made in India. The fiction and its misnomer may, however, be retained to denote the important class of cases where the artesian conditions have been largely produced by disturbance, causing partial upheaval and visible bending of the strata, in contradistinction to the other great class in which the simple inclined (flatly curved) plane of original deposition is the prevailing condition, although the only examples of complete 'basins' would be found in this latter class, in the case of filled-up and dried-up basin.

"*The primary conditions: as produced in nature.*—The essential conditions of the phenomenon are fulfilled whenever a body of water confined in an inclined channel, of whatever dimensions, is arrested or retarded by a total or partial obstruction in its progress to its point of discharge, so as to be pressed back above that level: a state of permanence being attained when the increase of pressure so produced causes a discharge equal to the supply of water at the upper end, or when overflow takes place there. These conditions are produced continually in nature by the ordinary process of formation of sedimentary rocks, independently of any turning up of the strata either from the original form of the floor of deposition or by subsequent disturbance. Even in an open water basin the formation of strictly horizontal deposits is a very exceptional occurence, for there is always greater deposition on the side from which the sediment is derived. It is similar in the case of depo-its formed above water level by the action of rain and rivers, of which we have such extensive instances in India; accumulation takes place most rapidly in the border zone where the denuding action of these agencies changes into one deposition; and thus do alluvial plains present a constantly increasing slope from the sea-margin to the foot of the uplands whence their materials are derived. In this way the first condition of artesian springs is established originally in all sedimentary rocks, in the prevailing slope of deposition; subsequent disturbance would generally increase this condition of slope or 'fall.' The other conditions are also often aboriginally provided for in stratified rock: in the distribution of coarse and fine deposits by alteration, or by the latter covering the former, the confined water channel is produced; and the usually greater accumulation of the coarser materials at and near the higher marginal zone of the so-called basin ensures the retarded discharge and the consequent accumulation of water at a higher level, which is the active factor in artesian springs."

In 1864, anxious enquiries were made by the Government of Madras as to the prospect of artesian borings in districts liable to drought, but, in the places pointed out, the proposals were not adopted from want of funds.

In two out of the three places, the hill district, as well as the ground beneath, consisted of crystalline metamorphosed rock similar met with in Ceylon, and in the third place of slate and quartzite.

Mons. Poulian, the enterprising manager of the Savana factory, undertook experiments at Pondicherry with entire confidence, and was rewarded with success. There are now three artesian wells in continuous operation, within a circle of 600 yards' radius and close to the sea:—

"*Special condition of their success.*—It is important to call attention to a secondary condition of success in these Pondicherry borings, namely the continuous prolongation of the deposits to a considerable distance under the sea, whereby the water of these springs at the shore line has still to force its way for many miles before finding an escape. It is, I think, evident from the experiments described in paragraph 5, that, all else, remaining as now, the springs at Pondicherry would cease to deliver water at the surface if the sea were to excavate a moderately deep channel near the shore,

"*Altered condition of the shores.*—The frequent mention of vegetable matter, and 'decayed wood' at all depths in these borings is certainly suggestive of shallow waters or even of terrestrial conditions, and therefore os continuous subsidence of the ground; yet it would not be safe to insist on this, for it is scarcely known to what extent water-logged vegetable débris may form an ingredient of free deposition in the immediate vicinity of land densely covered with forest, as no doubt was the condition of the Coromandel until comparatively recent times. Nothing of the kind could occur now; but changes of the surface conformation, effected by the destruction of forest, are no doubt as marked here as in the upland alluvial areas already described: the line between land water was probably then far less marked than now: instead of the mud flats that form the present shore at many places, there would have been everywhere an impenetrable passage through swamp vegetation into the actual sea.

We have our dry and thirsty part in Ceylon districts, at any rate where artesian wells would be a great boon, viz., the northern and eastern parts of the island.

We have no natural basins of any extent, but numerous inclined planes. These two sources of artesian

* As in the latest edition of the Encyclopædia Britannica.

wells are called *basins of disturbance*, geologically, such as the noted ones of Paris and London; and the other, *basins of original deposition*. Of the latter, we have several in Ceylon. In such cases, we see only the topmost beds and have no idea of what lies below except by trial.

Such an inclined plane of deposition has recently been proved to exist, by the sinking of the cylinders, in the construction of the railway bridge not far from the Colombo and Kandy line, and still later by the cylinders put down for the new Kelani bridge. That there is an actual dip, and that it is continuous between the two there is not the slightest doubt, and from analogy and other borings and wells, there is reason to believe that such a basin of original deposition extends to a considerable distance on our western shore.

It is very remarkable that nearly all our good wells in Colombo are close to the sea, *e.g.*, the large one in Kollupitiya in front of Steuart Place. One would naturally expect these waters to be distinctly brackish, but it is not so. We have no doubt one of the conditions of an artesian supply is the prevailing store of deposition, and if such be the case, might we not have been better served and at much less cost than by bringing our water-supply for Colombo so many miles?

Other papers follow on Oligoclase granite and on Palaeontology. Mr. Bose gives a very able reply to Mr. Lydekker's criticism on "undescribed fossil carnivora by P. N. Bose, B. Sc. London," which appeared a former *Record*. Mr. Bose is the first native gentleman in India who has passed on to the Survey Staff. He gained high honors at the University, and promises o do good and useful work.

t

"ARBORICULTURE."*

A REVIEW.

Mr. John Grigor, a well-known Scottish Forester and writer, has just published a work on Arboriculture dealing in a most exhaustive manner with the raising and managing of forest trees in Great Britain. Much that he has written cannot fail to be of considerable interest to planters in the tropics, cultivating, as they chiefly do, trees and shrubs of ligneous growth. In his chapter on acclimation, the author gives many remarkable instances of the effect of climate on the foliage and habit of trees, which render what has been found to occur in this respect in the case of the cinchonas all the more interesting and noteworthy. To quote briefly:—

There is no tribe of plants with which I am acquainted that is so susceptible of climatic influence as the Coniferæ. In the celebrated native pine forests in the Highlands of Morayshire any variety among the trees can hardly be distinguished. But I have taken seeds from these, and after raising them, have planted them on the warm sands only a little above the level of the sea, where a variety foliage and habit became perceptible; when these had yielded cones, and another generation of plants had been reared near the sea level, I have found many of them so far removed from the ordinary type, that some individual plants could scarcely be recognized as belonging to the species. This tree is found to accommodate itself to circumstances, producing long or short yearly growths in proportion to the ripening influence of the climate which it inhabits. A few generations of the tree existing in a high temperature would no doubt render its progeny nearly as tender as our greenhouse plants.

The necessity for procuring seeds from acclimatized trees is forcibly shewn, and the worthlessness of the plants of *Pinus sylvestris* or Scotch fir, grown from Continental seed, when planted in the north of Scotland, is instanced. Mr. Grigor's remarks on the necessity for selecting nursery plants, a matter in which it is to be feared we are not sufficiently careful in Ceylon, are well worth quoting:—

It is but reasonable to suppose that with the view of laying down a crop destined to stand for generations—it may be for upwards of a century—every precaution would be taken to secure its vigour and success, by selecting plants of the most approved varieties of the species; in many instances, however, this is not done. Indifference, in this respect, with the trade, or with plant merchants, who pass the commodity from hand to hand in course of a few weeks, is not so surprising; but with those who are to own the plants in their final destination, the selection is surely worthy of the exercise of thoughtfulness and care. Seldom, however, is this care taken, seldom is the same vigilance exercised here, which the agriculturist displays in laying down a crop destined to last only a few months. In arboriculture the result stands far away in the future, whereas with the farmer it is close at hand—the character and quality of his crops are readily ascertained, and the difference between good and bad is realized in a few months in a tangible form. In the formation of plantations, great or small, the work is generally proceeded with as if every tree or plant of its name were equally good, without regard to variety, pedigree, or climatic influence.

On moorland, "notch planting" that is, the mere insertion of the plant into a notch made with a spade, appears the most successful method, 3,000 and more plants per acre being put out at a total cost of 10s in some cases. Pit planting and trenching appear to be the most usual methods, but the low cost of forming a plantation by whatever method is certainly striking. Mr. Grigor's remarks on the necessity for thinning plantations are noteworthy:—

Considerable loss is frequently sustained by producing through confinement tall trunks without a proportionate diameter; and unless the soil is very congenial, and the trees of great vigour, they are often slow to become stout or shapely when ample space has at last been afforded to them. In plantations formed with plants at a distance of four feet, the thinning should commence when the plants attain to the height of from twelve to fifteen feet, by removing the more worthless kinds, which press too closely on the others, and fully half the number of plants inserted per acre should be removed by the time that the most valuable portion is twenty feet high. When they attain the height of thirty feet, they should stand on an average fully seven feet asunder, or about 800 per acre. At the height of forty feet, which is generally that number of years' growth,* the trunks are formed to a con-

*"Arboriculture, or a Practical Treatise on Raising and Managing Forest Trees and on the Profitable Extension of the Woods and Forests of Great Britain. By John Grigor, the Nurseries, Forres, N. B., author of the Highland and Agricultural Society's prize essays 'on raising forest plants,' 'on forest planting, and on trees adapted to various soils and situations,' 'on raising and managing hedges,' 'on forest pruning,' 'on the native pine forests of Scotland,' 'on planting within the influence of the sea,' 'on the deodar,' 'on the varieties of the larch cultivated in great Britain,' 'on the larch plantations of Scotland,' and on various other subjects connected with arboriculture.—*Second Edition.*"

* While in Southern India and Ceylon *Eucalyptus globulus* shoots up at an average rate of ten feet per annum, attaining a height of 100 feet in 10 years, and 150 feet in the 15th year.—ED.

siderable height; and at this stage of their progress it becomes necessary to furnish considerable space for the development of the leaves of the trees which are to occupy the ground, in order that their trunks may possess a girth corresponding to their height; therefore, generally speaking, they should stand from eleven to twelve feet asunder, or at the rate of from 300 to 350 trees per acre.

In coppicing, the necessity for a clean coppice is shewn, as trees left standing diminish the quantity and quality of the shoots. Superfluous shoots are mentioned as being removed only in the second year. In harvesting bark for tanning purposes the only process mentioned is that of felling the tree: coppicing in fact. Considering the slow growth of the oak, the bark of which is most esteemed by the tanner, it seems strange that no reference is made to the possibility or otherwise of some less destructive mode of procedure. From this chapter we will quote at length:—

The season begins as early as the sap of the tree circulates so freely as to admit the bark to rise from the timber which varies considerably in different trees, and is also regulated by the nature of the soil and situation, and by the earliness or lateness of the season. That first removed is found to be the strongest in the tannin principle, and consequently the most valuable. When the tree expands into full leaf and produces young shoots, the bark has deteriorated one half; nor is this the only disadvantage of late barking, for the future growths from stools, which form the following crop, rise but feebly compared to those where the timber has been removed in April or in May.

In detailing the process of barking it is necessary to remark that, on old trees, and particularly on the birch, a rough exterior bark or *epidermis* commonly exists, which is of no value; this is removed by an axe, or more readily by an implement termed a scraper, which is shaped like a common draw-hoe, but is more powerful, and much sharper. It is found that this rough outside bark does not easily part with the inner bark so early in the season as the inner bark rises from the wood; but later, when the sap flows more copiously, it is readily removed.

Before the trees are felled, a person advances with a barking-iron or bill, and forms a circular incision, cutting through the bark of the tree close to the surface of the ground, and making a similar incision at the height of two feet; between these the bark is removed. A woodsman follows and notches the tree about two inches deep all round the surface, which prepares it for being cut through by the common cross-cut saw. Immediately on the tree being felled, the smaller branches are cut with an axe or bill, into pieces about two feet long, from which, when tapped over a stone with a wooden mallet, the bark loosens, and is readily removed. The barking-iron is applied in cutting through the bark around the trunk and main branches, at places about two feet apart, and with the aid of the mallet and barking-chisel the main timbers are peeled. The tools used in the various operations no doubt vary in form in different districts; a heavy axe and cross-cut saw for felling the timber; a light axe and a hedger's short bill for cutting through the bark—the former also for use as a mallet; and barking irons of various sizes, which are blunt duck-bill shaped chisels, flat on one side and rounded on the other, are the tools commonly used in England. Women, in some districts, and boys, are employed, six or eight being superintended by a man, who lops the branches, and assists in turning the trees as the work proceeds. As the bark is raised from the tree it is classed into two sizes, the smaller into heaps, and the larger covering them, placed with the outside uppermost.

We now come to the most important part, the process of drying, which in a great measure regulates the value of the produce, and in wet weather becomes very precarious. A bark drying-shed should occupy the most airy situation in the forest or in its vicinity. It should consist of a roof, which may be formed of deal, and supported on pillars ten feet high. Across the house, at the distance of every eight feet, splits of wood should be erected, four tiers in depth, forming shelves to dry the bark. The bark, on its removal from the timber, is immediately collected and spread three or four inches deep; the smallest should occupy the lower ranges, and the large bark the upper, with the outsides of the large bark uppermost. Around this drying-shed an open space should be reserved, capable of containing several ranges of shelves, which, when supports and rails are formed, may be set up in a few minutes, and should be taken advantage of in favourable weather. Where no drying shed is used, the bark is harvested in the open ground, and commonly at or near to the spot where it was produced. This is indeed the more common practice. A set of straight limbs are supported on forked sticks along the surface of the land, and about three feet from it; against these, first the small pieces, then the larger are piled, and over all, forming a roof, the trunk bark is placed, sheltering the whole from the effects of the weather. If the bark be of small size, and showery weather occur while it is exposed, damage must ensue; but if a considerable proportion has been yielded by stout timber, it may, if put up thus with care, be preserved with safety even during unfavourable weather. Of course the most open and airy convenient situation should be preferred.

Another method may be described thus:—A few of the forked branches are inserted into the ground, with the prongs uppermost, to support rails or splits of wood from twelve to eighteen inches asunder, similar to the shelves described for the drying-house; with this difference, that in the open ground the rail on the one side should be placed a few inches lower than the other, so that the surface of the bark, when exposed on the rail, may form a declivity sufficient to discharge water. It is found that rain on bark during the operation of peeling, or immediately thereafter, while it possesses its own sap, does it little or no injury, though afterwards, when but partially dry, it infuses or extracts its virtues. Having erected the timber the small bark is laid first on the rails to the depth of about three or four inches, above which a cover of large pieces is then placed with their outsides uppermost, which forms a shade and protection for the small. During the preparation of bark, the forester should bear in mind that the influence of sunshine on its inner side causes a large decrease of its weight, by the evaporation of its most valued juices, which do not escape while the outside is kept uppermost in drying. After the bark has stood on the rails in the shed, or in the open ground for a day, it is apt to get compact and mouldy; it should therefore be shifted and disturbed in a similar manner every twenty-four hours, for three or four days. That in the drying-shed, when crowded, should be removed to the outside rails every favourable morning, and placed under the roof every night, and during rain. In unfavourable weather, two or three weeks are sometimes necessary to dry it in the open ground, but under more favourable circumstances it becomes quite dry in eight days. It is then removed into a house and chopped to the size of about two inches, an operation which is commonly performed by contract, at six shillings per ton; this fits the bark for the tanner. The cost of preserving bark must be always regulated by the price of labour in the district, and the size of the timber which yields it. One person will trip from stout timber about five or six cwt. per day; from small timber only about one cwt.

On pruning forest trees, Mr. Grigor has much to say which must interest cinchona planters:

The utility of pruning hardwood trees is generally admitted by experienced and practical men. It is sometimes denied by those who have witnessed the bad effects of an improper system, such as carpenters, and mechanics, who readily discover the evil resulting from the "lopping and boughing" of a bad system, while they are unacquainted with the advantages of early and judicious pruning, which leaves no mark on the future bole, but directs it early into the figure most valuable as timber, and in some cases its effect on the individual tree may be compared to that of the judicious thinning of a plantation, as it directs the energies of the soil to the growth of one trunk instead of a number of smaller ones. Theorists also sometimes deny the use of pruning, overlooking the frequent necessity of directing the growth of the trunk in the way most suitable for mechanical purposes, and they contend, on physiological principles, for bulk, through the agency of leaves. Although pruning does not in ordinary cases ultimately increase the bulk or weight of wood, yet trees which are *early* and *judiciously* pruned will be improved in quality, increased in their useful dimensions, and ultimate value, and will grow in greater numbers on a given space.* * *

With respect to hardwood trees generally, in some situations the necessity of pruning may be in a great measure obviated by close planting and timely thinning. These means are generally most effectual in producing straight and well-grown timber of every species. Where young trees stand moderately close, their leading shoot, which is to form the future bole of the tree, is guided upwards by its own natural efforts, and as the lateral branches of the one press gently on those of the others all round, they are prevented from acquiring an undue strength, and ultimately disappear, leaving straight and clean trunks, which are always of most value, except in the case of oak timber for shipbuilding, which should form an exception from the ordinary mode of treatment, as will be noticed in the sequel.

All experienced foresters agree that the most beneficial pruning is that which begins early, doing little at a time, but repeating the operation frequently, and directing the ascendancy of the leading shoot till the stem of the tree has acquired a proper form. When trees in a young plantation have produced three, or, very thriving, two years' growth, pruning should be commenced. The pruning-knife is the most suitable implement, and where the work is early and frequently attended to no other implement is required during the whole progress of forest pruning.

The top is the principal part of the plant that requires attention, in order that only one shoot may be allowed to remain as a leader, the others next in size, if not very inferior, should be headed down to about one-half their length, and all the stoutest lateral branches shortened in the same manner. None of these branches need be cut close to the stem, and if the plantation is moderately close this will be all that they require, as they will get enfeebled and fall away; but in more open and airy situations those lateral branches which were shortened may be in four or five years removed close to the stem, before they are beyond the size of being cut off by the pruning-knife. Young plantations should be gone over every second year, until the stems of the trees have acquired a proper form, having an eye to a sufficient girth in proportion to the height, which girth is promoted chiefly by side branches, at the same time bearing in mind that next in importance to keeping the tree in a proper figure should be the preservation of the greatest quantity of its foliage. It is the general rule to shorten the branch likely to gain an ascendancy over the leading shoot; but if the leading shoot is weak, stunted, or unhealthy, it is sometimes of advantage to remove it, and prefer the more vigorous one, which through the flow of sap will readily become straight and in proper form. A few years after hardwood plants are planted, it sometimes happens that some of them are found stunted and making no progress; and in the case of oak, elm, or ash, young shoots frequently appear at the surface of the ground. This is sometimes occasioned by the roots being too bare, or destitute of a sufficient supply of young fibres, or from their exposure to the weather in planting, or subsequent drought, etc. In such cases the plant should be lopped over at the surface, or just above the most vigorous shoot, which should be retained for the future tree, and the other suckers should be pruned off. The lopping of such plants should be performed with a sharp knife by a practised hand, so that the operation may be made without disturbing or straining the root of the plant. It is a common error in the management of plantations to clear the stems of all side-branches to a certain height at the first pruning, and afterwards to operate only on the under branches of the tree. This tends to produce a small trunk, an irregular top, and side branches more vigorous than the leader. When this is practised in exposed places, not one in a hundred ever becomes a large or valuable tree. Were pruning altogether abandoned, trees of fifty years' standing would generally be of more value, rough, knotty, and forked as a great part of the timber would be, than those subjected to such an injurious method.

It is in hedgerows and other open situations, where trees are apt to ramify into an unprofitable figure, that pruning is of the greatest value; but even in such situations it is not necessary to shorten all the branches previously to their being removed from the trunk, though it is to be recommended in dealing with all luxuriant branches, particularly near the top shoot, and in checking such throughout the tree; the progress of such being impeded in a greater or less degree in proportion to the distance from their extremities at which they are cut. When trees have advanced from ten to fourteen feet, the oldest and stoutest branches (previously shortened) may then be removed from the stem. Sometimes the small pruning saw is employed as the most efficient implement, observing that at the junction of each branch to the stem there is a swell or bulge, and the branch should be removed close to the outside of it, at which point the diameter is not so great as at the very bottom, consequently a much smaller wound is occasioned, and sooner healed. When plantations are closely attended to, however, the pruning-saw is seldom required. The knife is the safest implement; its wounds heal most readily, and where the branches are sufficiently checked by being shortened they do not acquire a diameter beyond its power. When trees are from fourteen to twenty-five feet in height, or from twelve to twenty years of age, they generally advance very rapidly, and if not standing close in a plantation, admit of more pruning than at any other period; but under any circumstances trees are much injured by being severely pruned; for, as already stated, pruning is only of much advantage when performed early in those side branches which are apt to bear too great a proportion to the leading branch, thereby modifying the tree and directing its energies gradually to the top, preserving at the same time a sufficient quantity of foliage. All young hardwood trees should have tops long in proportion to their height. A good proportion in a tree of thirty feet in height is twenty feet of top to ten feet of bare trunk; but no given rule in this respect can be exacted for all sorts, as a longer top is requisite in a rough exposure and in poor soil than

where the ground is well sheltered and fertile. The skilful forester observes at a glance whether the tree is possessed of a trunk stout in proportion to its height, and, as in thinning, regulates the pruning accordingly. Where height is required he subdues the side branches; where girth of trunk is necessary; he preserves them as the speedy means of obtaining girth.

On grafting the author says:—

The simplest and most successful method of grafting such is to saw off the top where it is only an inch or two in diameter, make a slit about an inch and a half long in the bark of the stock, raise the bark with an ivory handle, to make a space for the graft or shoot to be inserted, which may only be six or seven inches long; prepare it by a smooth slanting cut on one side, slip in the prepared scion with the cut side next to the wood to the length of the cut of one inch and a half; tie round with mat, and cover closely with grafting clay all over the wound on the stock. After the clay is dry, and all fissures filled up, the ball may be covered over with moss or meadow hay, and tied over to insure safety and exclude severe drought. When the stock at the point of grafting is older and of several inches in diameter; another, and the easiest mode, is, after sawing off the top, to tie the stock round tightly for a few inches beneath the point of amputation, and force down a peg of hard wood, or any hard substance, between the wood and the bark, in the shape of the prepared scion, then withdraw the peg and insert the scion, pressing it tightly into the incision; by this method two or three grafts or scions may be inserted around the edge of the same stock, then clay as recommended. The month of March is the ordinary season for the operation, or just as the buds are beginning to swell. When the graft has grown a few inches the clay should be removed, and the bandage retied, adding a stalk to support the scion from being broken off by wind.

The remainder of the book treats of the various British forest trees in detail, and must be of great value and interest to those engaged in forestry. In every case there appears to be some insect enemy which attacks the tree, and in some cases a disease of more obscure origin.

NETHERLANDS INDIAN NEWS.

(*Straits Times*, Nov. 6.)

The prospects of the coffee crop are favourable, generally speaking, at Pasuruan this being especially the case. At that port there had been delivered up to the 7th instant, 330,000 piculs, of which 175,000 piculs had been shipped. The tobacco culture, however, continually gives a rise to complaint and dissatisfaction all over Java. From Kediri, a correspondent wrote to a Samarang paper recently that all the tobacco planters there were on the road to ruin. Even should this prove to be exaggeration, it is certain that the condition of this branch of cultivation, formerly so flourishing and so profitable to both planters and people, is far from being satisfactory, and that the subject demands the serious attention of the Government.—*Java Bode.*

BRITISH COLUMBIA.—The Villard party have visited Victoria, and returned to Puget Sound. Mr. Villard has obtained much valuable information concerning the coal and mineral lands of Vancouver Island. Heavy continuous rains have quite destroyed the hopes of the farmers in the interior, their crops being utterly ruined. The crops of the island and lower mainland, however, were safely housed before the rain commenced, and all the live stock were looking well.—*Colonies and India.*

WHAT IS THE ANALYTICAL STANDARD FOR LEDGERIANA CINCHONAS?

A Lindula correspondent enquires:—

"Don't you think it a mistake to call any Calisaya 'a Ledger,' which has got less than 8 per cent of sulphate of quinine in it? *Vide* Annfield analysis in your issue of the 11th instant."

The writer of the above thinks "the line should be drawn somewhere," but it would be impossible to decide the indentity of Ledgerianas, with reference simply to analytical results, unless all the circumstances were carefully taken into account. For instance the age of the trees. Our correspondent would have the standard fixed at 6 per cent of quinine (= to 8 per cent sulphate); but in Mr. Moens' last quarterly report published by us, will be found included a series of analyses of the bark of Ledgeriana trees which range from 11·20 down to 2·94 per cent of quinine. Of course the trees yielding the lower amounts will be noted as of inferior types and treated accordingly. Mr. Moens, some time ago, was inclined to think that true Ledgerianas rarely flowered before the eighth year (and he selected no seed from trees flowering at an earlier age), but it would never do to condemn the Ledgers which have flowered in Ceylon in their 5th and 6th years, the bark having giving a most gratifying result on analysis. Perhaps the most satisfactory and convenient plan will be to confine the term "good type" Ledgerianas to trees yielding 5 to 6 per cent and over of pure quinine when not more than 6 years old. Every year's growth after that period ought to make a very appreciable addition to the alkaloids secreted, chiefly if not entirely quinine.

INDIAN AND CEYLON TEA.

Melbourne, 24th October 1881.

Dear Sir,—We intend to offer at Messrs. Greig and Murray's Auction Rooms, about the 13th November, on account of the Calcutta Tea Syndicate, in conjunction with the Government of India, their entire shipments of Indian Tea, now on the water, and amounting to about 4,000 half-chests of Darjeeling's, Assam's, Cachar's, &c., &c., when we hope, with your support, to sell the entire parcel.

The following significant facts from Messrs. W. J. & H. Thompson's well-known London Tea Circular, Dated 1st September, 1881, are worth your attention:—

LONDON DELIVERIES FOR 7 MONTHS:
1st January to 30th July.

	1881.	1880.	1879.
INDIAN TEA	28,657,000	22,501,000	20,722,000.
CHINA TEA, &C.	85,565,000	89,041,000	96,561,000.

The INCREASED deliveries of nearly 8 MILLION pounds weight of Indian Tea for the first 7 months of 1881 as against the same period of 1879, and compared with the DECREASED deliveries of 11 MILLION pounds' weight of China Tea for the same period, is the eloquence of figures in favour of Indian Teas

We remain, your obedient servants,
JAS. HENTY & Co.

CINCHONA IN CEYLON.

Colonel Beddome has submitted to the Government a short report of the visit he paid to Ceylon to inspect and report on the progress which Cinchona cultivation is making there with a view to it be forward the plantations maintained by the Government on the Nilgiris. Some of the plantations visited by Colonel Beddome showed that the planters recognized the different species and the uniform and rapid growth have induced many to give attention to it. The analysis conducted was most interesting, showing what a large percentage of quinine was to be found and the value of the yield

Colonel Beddome says that he had not the good fortune of seeing any good officinalis plantations which are situated at Haputale and Uva; but at o her places some large plantations inspected looked exceedingly well. On one estate at Upper Ramboda, called Frotoft, 45 acres of officinalis had been uprooted at 4½ years of age and the trees yielded 25 tons of dry bark which was sold for £11,200. Many of the estates are considerably below 5,000 feet and consequently at an elevation much below that on which the local Government grow officinalis on the Nilgiris. On another estate the owner with a view to protect the cinchona, put down Eucalyptus which acted as a sort of breakwind for the plants and the growth was very fair. Colonel Beddome thinks that this plan may be adopted with success on the plantations at Dodabettah Neddiwuttum and Pykara. The more valuable species of cinchona, the Lidgeriana succes fully grown in Java by Mr. Moens who visited Ceylon, induced many of the planters to grow the species. Mr. Moens obtained 13 per cent of pure quinine from a tree of this species —in Ceylon no analysis of the bark could be compared with the results obtained in Java. Colonel Beddome suggests the appointment of a competent analyser to the Nilgiri plantations and he thinks that a subject of such importance should not be allowed to be postponed on the score of expense. At the suggestion of the Conservator of Forests, one hundred copies of Mr. T. C. Owen's cinchona planters' manual will be procured from Ceylon and distributed among the officers in charge of the Government plantations on the Nilgiris. Colonel Beddome considers it a carefully compiled publication full of useful and interesting information about cinchona. It is probable that the Government will address the Secretary of State on the appointment of a qualified Chemical Analyser for the Nilgiris.—*Madras Standard.*

THE TEA HARVEST IN DARJEELING.

The Darjeeling Tea Harvest extends throughout the greater part of the year. Leaf is plucked from March to November, but the midsummer months are the most productive. The tea-plants are trimmed down to a broad, almost flat top. When there is a "flush," the new bright-green shoots rise above the level of the bush, and are quickly noticed. Flush is the planter's name for the new tender shoot of three or four leaves which the tea tree sends out at intervals through the year. When there is no flush, the planter can make no tea—the old leaves are worthless—and when there is a flush, it must be plucked at the right time, or it will be lost. I know of no crop, unless it be the peach or strawberry, which so imperatively requires to be plucked at the right time. Good growing weather is, of course, most productive of flush. Drought or extreme rain or cold keeps back the trees. It thus happens that for weeks the factory will be idle, and then a season of fine weather will bring a large part of the garden into flush at the same time, and the tea-makers must work night and day to take care of the maunds of green leaf that daily pour in upon them When the flush is about four inches long,* and has two or three leaves besides the terminal unopened one, it is ready for plucking. The pickers rarely take a single leaf, but nip off the shoot just above the axil of the lowest leaf, so that the uninjured bud will sooner produce another shoot.

The bright yellow-green termiual leaf of the flush is the most delicate and fragrant part. It retains its brighter colour during the process of manufacture, and becomes that small whitish leaf in tea which is called 'tip.'

* Leaves four inches long are certainly not picked for tea making.—ED.

Tip is the planter's idol. Its bright face in his tea-bins promises golden returns. Tip is the broker's delight; for it is in demand by merchants. Tip is the drinker's joy; its delicate aroma is the distilled sweetness of fragrant flowers."

There are five operations in tea-making as carried on in Darjeeling—wilting, rolling, fermenting, firing, and sorting. The green leaf, as it comes in from the garden, is spread out in the drying-loft to be wilted. This loft is usually over the firing-room, and the heat from below, coming up through the open wooded and matted floor, soon wilts the leaves. The wilting process requires careful watching by experienced teamakers, who stir it about on the mats until it is ready to be rolled.

In small factories the rolling is done by hand. The wilted leaf is piled on a large table, usually covered with bamboo matting. The roller takes a double handful of wilted leaf, rolls and kneads it into a ball, pressing and bruising it all he can until his ball becomes a wet, cohesive mass. When his ball of bruised leaves will retain its shape, it is supposed to be sufficiently rolled, and is then set aside for fermentation.

The fermenting process is one of the most delicate and important parts of tea-making. Let the balls of bruised leaf be either too much or too little fermented, and the quality of the tea suffers. An hour's delay in getting the fermenting tea to the fire, we say, lessens the value of the tea 50 per cent. Experience, intelligence, and carefulness are absolutely requisite; and it is surprising to see the instinct with which these tea-makers in Darjeeling manage this part of their work. But they are sometimes caught napping; and I remember a pile of over-fermented tea on the floor of a certain factory which led me to pity the owner, and express the hope that none of that tea would find its way to my grocer.

When sufficiently fermented, the balls of tea are broken up, the leaf is spread out on large sieves of wire or cane, and set over a charcoal fire for roasting or firing. The charcoal lies at the bottom of a square, funuel-shaped furnace, a yard square, and two and a half feet deep. The sieve with the tea is placed over the fire a few minutes, then taken off, stirred about with the hands, and replaced. This process is repeated several times, changing the sieve to furnaces of greater or less heat, as the need may be, until at last it is thoroughly dried, and thrown into the bin for sorting. The firing process is the most difficult part of the tea-making. *It is so easy to get the fire a little too hot and burn the tea, or leave it a moment too long, when that one moment may change what was fragrant tea into tasteless, priceless, chips.*

The proper manufacture of tea ends with the firing. The tea is made. It is just as the consumer gets it. The sorting and sifting simply separate the coarse from the fine varieties. A new machine—a sort of tea crusher—has lately been introduced, which grinds up the coarse leaves into beautiful fiue Pekoe. But it cannot make "tip," and my opinion is that the crusher is a mistake. Makers will not take extra pains to produce fine tea when the crusher makes all so much alike. The sifter is like a common grain winnowing-mill. The different varieties of tea, which ordinary mortals suppose are grown at different seasons and separately plucked, are but one promiscuous mass in the hopper of the machine. The sieve does the sorting, and though all did grow on one bush, and was plucked at one time, and made in one batch, yet it is true that a finer flavour is in the fine leaf; and the tea factory fanning mills but confirms the old proverb, that valuable goods are put up in small parcels. The sorting process completes the manufacture of the tea. It is then packed in boxes, containing from 80 to 100 lb. of tea, and stout Bhootia

porters carry it to the various stations on the "Eastward," whence it is shipped to agents in Calcutta, who generally dispose of it at public auction, although some of the larger companies send their tea direct to London. *Pure Darjeeling or Assam tea seldom reaches the table of the consumer in Europe. The great London China tea merchants have discovered that the adulterated teas from China cannot fairly compete with the stronger and purer Indian teas. The waning reputation of the China article is, therefore, bolstered up by fine admixture with Indian tea.*

The Darjeeling planters confidently await the day when the superiority of their tea shall no longer be a trade secret, and their brands shall command the price their purity and strength deserve.

MANITOBA: A FERTILE FARM FOR FOUR SHILLINGS AN ACRE.

The following description of a farm in Manitoba, located in that part of the province lying from 100 to 150 miles west of Winnipeg, where the land alternates curiously between sand and loam, bog and wood, and which a few years ago was described as hopelessly barren, is given by the correspondent of the London *Times*:—

"Mr. Brackett pointed out a tract of land on either side of the road, extending over about 1,000 acres, and covered with splendid crops. It is owned by four brothers, who find it so good that they have actually deserted that 'flour-garden of Manitoba,' Portage la Prairie, leasing the land they own there. They prefer this soil, as less heavy than that at Portage la Prairie, and bringing quicker returns for their labour. In May they put in the crop, and by the middle of August have the wheat stacked. We drove through a very fine field quite ready for the sickle. It is said to average 30 bushels to the acre; and one man, a keen farmer, with au exceptionally good piece of land, has for ten years averaged 35 bushels. Of this land, be it remembered, 160 acres were 'homesteaded'—that is, got gratis, except a fee of $10. Another 160 would be 'pre-empted' by the same man for a fee of $10, which secures him his previous right of purchase against auy other would-be purchaser, and then bought for $1 the acre, the payment being extended over ten years, with interest at 6 per cent. Thus the four brothers would got between them 1,280 acres of splendid land for a little over $1,280, or, say, from 26 *l.* to 270*l.* They probably would not take $10 au acre for it now. I may mention that the soil is also well suited for oats, barley, and such vegetables as potatoes and turnips."

Such land is even now to be had in the virgin districts of the North-West, but, as was to be expected, the approach of the Canada Pacific Railway is driving up the price of land in the near neighbourhood of the route to be taken by it. Near Portago la Prairie, for instauce, land is now valued at $30 per acre. Whether or not it is worth that price may be judged from the foregoing description and from the following figures, which apply to the land in the neighbourhood of Portage la Prairie. There wheat averages 30 bushels per acre; barley, 35 bushels; and oats, 60 bushels per acre. As to vegetables, it is difficult to find any soil that can produce better and heavier crops.

As to the future of this town and district, the past affords a pretty good indication. Four years ago the whole town consisted of a little log-house, calling itself in prophetic spirit an hotel, a smithy, and a few shanties; now the population numbers 1,500, with a floating population of some 400 or 500 more. Some notion of the rapidity of increase may be got from the fact that it has actually doubled since last January. But then Portago la Prairie is just now, like Winnipeg, enjoying an exceptional "boom," due to the Pacific line, though, as the worth of the soil all about it is genuine beyond all question, there is no reason why the influences of the "boom" should not last. Good settlers are welcomed, especially if they are "good" in the commercial sense of the term. Sound morals form a welcome addition, but the essential point is that a man should bring out 200*l.* if possible, but certainly not less than from 80*l.* to 100*l.* As for labourers, they need bring out only their thews and sinews, with the will to use them, and in summer they would get readily $2 a day. Labour is sorely needed about Portage la Prairie, the farmers for want of it having to use more expensive machinery than they can well afford, to say nothing of the capital sent out of the country into the States, whence most of the machines have to be brought.—*Colonies and India.*

BRAZIL: IMMIGRANT LABORERS.

The "Club da Lavoura" of Taubaté, province of São Paulo, has been studying the question of employing immigrants in the place of slave laborers, and has arrived at the sage conclusion that the effort has thus far resulted in failure, that it is a grievous burden upon the public treasury, and that it does not meet the exigencies of the present phase of the labor question. A committee appointed by the club to study the question concludes that "The substitution of slave labor by foreign immigrants is thrown completely into confusion, and that 20 years of painful experience has made us recognize that foreign emigration to Brazil has been an abyss for public moneys because the heaviest and perhaps the most unfruitful item in our budgets has been "immigration and colonization." And for this there have been imposed the heaviest imposts upon agriculture and commerce, whose only results have been the scandalous waste of the public moneys and the most bare-faced patronage for displaying abroad a vitality which we do not possess, although nature has bestowed upon us riches of unqualified value."

With so just a cause for complaint it is a matter for deep regret that the planters of Taubaté have gone so far astray both in their determination of the cause, and in their conclusions. They are perfectly right in condemning the excessive appropriations of public money in behalf of "immigration and colonization," and they are equally right in denouncing the many questionable uses to which that money has been put. But does that warrant the conclusion that there is something inherently wrong in immigration, and that the substitution of the slave by the free immigrant is a mistaken quest? Can any logical conclusion against foreign immigration be drawn from any one colonization enterprise which has thus far been attempted in Brazil, outside of the three southern provinces? On the contrary, may we not conclude from the misuse of appropriations, and the vicious policy pursued both in the acquirement of colonists and in their after treatment, that all the evils and burdens are owing rather to the system employed than to the legitimate enterprise itself?

Our Taubaté friends should not deceive themselves in this matter; for it is only through a just appreciation of this question that the evils which afflict it can be eradicated. They should understand that new legislation without a radical reform in the old will not afford a remedy; and they should then understand that all these measures must be supplemented by still another change in the unwritten laws of Society itself. There must be no degradation attached to manual labor, and no restrictions upon the laborer. There must be perfect equality before the law, and a just estimate of every man's worth independent of his avocation.—*Rio News.*

COFFEE PROPAGANDA.

In our last review we pointed out the fitness of a competent representation of our province at the Rio coffee exposition where the representatives should ventilate not only the restricted coffee question but also all those referring to the prosperity of this culture, such as the question of railway tariffs, of export duties of the substitution of agricultural labor and the measures necessary for the practical amplification of the rural credit system.

Let us now, in a few rough sketches and as far as is in our power, examine some points of these questions.

The question of railway tariffs has been much discussed lately in the press, and though at times partiality has been transparent yet the proofs furnished demonstrate the necessity of reform. A railway tariff which is to satisfy all legitimate exigencies, must be not only clear and convenient for the public but also moderate and, principally, well proportioned or equitable.

To accomplish a work of this kind it is, therefore, necessary that all the interested elements assist in its organization. If, as has been done until now, it is left to some fiscal employees, conjointly with the administration of the railways, to manufacture the tariffs, it will infallibly happen that the former, disinterested and badly versed in the matter, will leave its organization to the latter who will always make it according to their liking and convenience; the result will be certain excentricities like those pointed out some days ago by one of the principal papers of our province, when for the transport on 272 kilometers of railway, from Santos to Piracicaba, 729$920 was paid on 1627 kilos of nitric acid, whose prime cost and transport by land and water from Germany to this port amounted to only 484$040. The same disproportion exists with reference to a great number of other articles, chiefly salt, an article of prime necessity.

It must also be considered that a tariff should not remain permanent; the rates on the various articles should be periodically revised so that it may not happen, as it has done until now, that coffee and cotton pay always the same freight although the intrinsic value varies from 6$000 to 14$000 per arroba for the former and from 5$000 to 30$000 for the latter. To establish a rational tariff it seems to us necessary that all the interested parties, which are the fiscal, the administration of the railways, and the public, should co-operate, represented by delegates from commerce, industry and agriculture.

The fiscal, conjointly with the respective administrations, must state approximately the amount necessary for the dividend to the shareholders and for the expenses. The delegate, conjointly with the administrators, basing their calculation on the statistics of the previous traffic, must organize the tariff in which each category of merchandise is taxed according to its intrinsic value and the conveniences or necessities of consumption. In the adjustment of the sums necessary for the dividends the Government must take into consideration that when the railways had not yet a safe future the shareholder had a right to a high dividend; to-day when the capital of the same is perfectly guaranteed, the interest must be more moderate; and we are certain that in the face of these considerations in favor of our agriculture, the S. Paulo shareholders will not shrink from the necessary sacrifices. From the capital required for expenses there must be eliminated what is not called for by necessity. In the adjustment of the tariff, for the transport of merchandise as well as passengers, the administrations of the railways should avail of their observations with reference to the expenses of locomotion and transfer this combined with the indications, from the delegates of the public, respecting the transport of passengers as well as the position of passengers as well as the position of each class of merchandise of import and export in the goods tariff will unite in itself all the elements for the production of a work which will be practical and satisfactory to all. In the list of the competition which will be established during the next ten years between the various coffee-producing countries, our position will be definitely strengthened under the condition of all the elements with the fate of which the prosperity of coffee-culture is interwoven, if every one in his sphere would help to diminish the cost of production.

The tariffs, the origin of which dates from the epoch when the general prosperity admitted of certain liberty, are susceptible of reform, in essence as well as in application, reductions having to be made which are ture.—absolutely necessary for the upholding of agricul *Rio News.*

MANILA NEWS.

(*Straits Times.*)

"*Agricultural Bank.*—We have been informed that in one of the shortly expected steamers of the Marquis de Campo's line, there is to arrive at Manila, the agents of an Agricultural Bank about to be established in these island for which an influential company has been formed at Madrid, provided the necessary capital for such an important undertaking."—*Comercio* 21st Oct.

TOBACCO IN DELI.

(*Straits Times*, Nov. 12th.)

The Java *Courant* of the 14th October reports that the prospects of this year's tobacco crop in Deli are good as to quantity, and unusually favourable as to quality. Matters are otherwise in the tobacco growing districts in Java, the situation there being thus described in the *Sourabaya Caurant* of the 14th October:—

"Most saddening is the impression made when travelling from Kedirie to Blitar, on viewing the present condition of the tobacco establishments, formerly so flourishing, most of which are now no longer the seats of busy industrial activity, but on the contrary are uninhabited and forsaken. From Nujang to Bendo no signs of former prosperity are perceptible other than overseers' dwellings falling to ruins, and drying sheds partially fallen in. Tobacco cultivation, which heretofore put hundreds of thousands of guilders into circulation among the population, is now expiring. Over competing may have contributed greatly to ruin it, but no less is its decadence attributable to the means by which Javanese tobacco growers turned to account, as much as possible, the foolish rivalry among European buyers. They began by failing to plant the tobacco at the requisite distances from each other to enable the plants to develope properly, their object being to obtain greater produce. Quantity was aimed at, not quality. Often the whole crop was cut without leaving a single plant for bearing seed. Hence a frightful deterioration in Blitar tobacco formerly so much in demand in the European market. In short the thoughtless native tobacco growers have killed the "goose that laid the golden eggs."

A great many tobacco estates in Buitar are now for sale, only a few energetic European planters still persevering in tobacco cultivation, but, however, most of them have betaken themselves to coffee growing instead.

A CURE FOR PHYLLOXERA.—Messrs. W. & A. Gilbey, writing to the London *Times* on the subject of the French vintage, say with regard to Phylloxera:—"We may add here, in conclusion, that the latest remedy suggested is sulpho-carbonate, which is applied to the roots of the vines, with a considerable quantity of water, and which it is stated has not only the effect of killing the insect, but as a manure serves to fertilize and strengthen the vine. Suffice it to say that, during a visit this morning to a very beautiful and well-managed estate at St. Estèphe, we were shown vines which, only 12 months ago, had all the appearance of being shortly dead now fresh and verdant, and apparently in a fair way to recover all their vigour and fertility."

Correspondence.

To the Editor of the Ceylon Observer.

CALISAYA LEDGERIANA ON ANNFIELD ESTATE, DIKOYA.

[Mr. Anderson sends us the following report and analyses from Mr Howard for publication: with trees giving 3·68 and 4·55 of quinine, Mr. Anderson should be well satisfied. —ED.]

Lord's Meade, Tottenham, 14th Oct. 1881.

T. C. Anderson, Esq., Annfield, Dikoya.

DEAR SIR,—In reply to yours of the 5th August, I now send you the analysis of the bark sent, which I hope will afford you useful information. No. 1 and No. 3 seem useful barks to cultivate, and No. 6 will no doubt improve by age: but the Calisaya Anglica agree with my published information and can scarcely be made profitable. No. 2 may also turn out good, unless the cinchouidine in this (as in No. 6) should become developed at the expense of the quinine.

I have pleasure in sending you the enclosed, as it is very important that the best kinds only should be cultivated. This is desirable for the manufacturer as well as the cultivator.

You have probably seen the analyses of 30 specimens sent by Mr. Cross which, I hear, is published (as I requested) by the Government.—I beg to remain &c.,

(Sgd.) JOHN ELIOT HOWARD.

Analysis of bark sent by Mr. T. C. Anderson, Annfield Estate, September 1881:—

	Quinine Sulph.	Quinine.	Cinchonidine.	Cinchonine.	Quinidine.
No. 1 ...	6·07	4·55	0·28	1·04	0·50
No. 2 ...	3·11	2·33	1·97	0·13	trace.
No. 3 Ledg. or Cal. Vera.	4·91	3·68	0·27	0·15	0·05
No. 4 Ca. Angl. (burned.)	0 61	0·46	0·00	0·56	0·26
No. 5 Cal. Anglica ...	1·37	1·03	trace	2 72	0·84
No. 6 Ledgeriana ...	2·03	2·21	0·00	0·04	0·28

[No. 4 was accidentally burned in the drying, which accounts for the analysis being so poor a one.]

CEYLON TEA IN THE LONDON MARKET.

4 Guildhall Chambers, London.

DEAR SIR,—In further conversation with the same gentleman whose views upon Ceylon tea we sent you a mail or two back, he told us that it is desirable, in sending tea for public sale to this country, that it should be sent in large "breaks." The trade will not take the trouble to draw samples from small lots, and anything under 15 chests does not meet with proper attention. He urged the advisability of shipping in as large quantities of the same sort as possible. Further he pointed out that *chests and half chests* are much preferred to boxes, except in finest sorts.

We had, on Tuesday last, a consignment of Ceylon tea up in public sale, and it would have infused fresh life and determination to persevere into the planters, to have heard the shower of bids when the first lot was put up. The bidding was continued briskly until the end, contrasting most encouragingly with the earlier reception of Ceylon teas in the London market, when a few bids were given with growls of "more of that Ceylon rubbish." If good tea is sent, it may not at first fetch its full value, but it will win its way in time, and after all what will best pay the planters in the long run is that their tea should have its place esteemed in the London public sales. At the same time, it is desirable that the private sale should be pushed, and no efforts should be spared by those interested (*all* ought to be) to induce people at home to use it and inquire for it at the local grocers' shops, thus creating a demand, starting the sale, and getting the tea known. One grocer's shop in the West-end is selling a certain quantity, but passing it the other day, we saw only a small written placard with "Ceylon Tea" upon it in the window. A good show-card with, for instance, a well-executed picture of a Tamil girl bearing a basket upon her head, marked "Ceylon Tea," is what is required. Grocers never object to placing a taking show-card in their windows, and in these days of showy, brilliant, advertisements, it is necessary to rival other articles to catch the public eye. These show-cards cost money, however, and your northern correspondent has already shown your readers that pioneers are those who do not reap great advantages. Let the Chamber of Commerce, or the Planters' Association, look to this, and vote a small sum out of their funds to advertise in this manner.

In conclusion, we are glad to report that the later consignments of tea have shown a marked improvement in tip, liquor, and infusion. With increased care given to the manufacture, satisfactory prices can be obtained here without doubt.—Yours faithfully,

HUTCHISON & CO.

[The interest taken by our correspondents in the promotion of a trade in Ceylon tea will be appreciated by the planters: we have received through a gentleman, who lately returned to the island, a series of samples of Indian and Java Teas made up by Messrs. Hutchison & Co. from breaks sold in the market, which are of interest and good service in comparing with Ceylon teas. They consist of Indian Pekoe sold at 2s 8d per lb; ditto broken Pekoe at 2s 10d to 2s 11d; ditto broken orange Pekoe (Nowrea Nuddy Tea Company) at 2s 10d to 3s per lb; ditto Pekoe (N. T. M.) at 3s; ditto orange pekoe at 3s to 3s 1d; and Panchauor broken Pekoe, well-made leaf 3s 4d per lb; and a sample of Java tea sold at 2s 8d per lb. We shall be glad to shew these samples to merchants and planters interested.—ED.]

COFFEE LEAF-DISEASE.

Kent, 19th October 1881.

DEAR SIR,—I enclose a cutting from the Loudon *Times* of the 17th instant which, no doubt, you have seen and, perhaps, have remarked upon in connection with *Hemileia vastatrix* and the manuring question.

What I wish to call attention to, for the consideration of Ceylon planters, is the opinion expressed by General Showers that the methods pursued for the cure of phylloxera are utterly useless, and that what the vine requires is a rest. The writer founds his opinion upon the experience gained by him, while conducting experimental cultivation in India. It does not seem quite clear how the rest is to be given, but, I presume, by stripping the fourth part of the trees of the fruit, as it forms, and not allowing it to come to maturity. It may, perhaps, occur to the planter's mind that, if rest be required in Ceylon, to recruit the strength of the coffee tree, the remedy has been taken in hand by the tree itself, in only yielding about one-third of what it was formerly capable of doing. General Showers says nothing about manuring, and evidently think that forcing the trees in any way is injurious. Is this an argument in favor of those who do not or cannot manure? My own experience points to the contrary, and I intend to manure as long as I find it pays to do so.

The late gale was very severe in this part of Kent. Oaks and elms have been hurled to the ground and several corn-ricks blown down. J. P. G.

The letter in the London *Times* is as follows:—

"SIR,—In reference to the Phylloxera Congress at

Bordeaux, will you allow me to submit, through your columns, for the consideration of all interested, my view of the origin of the pest and of the means for its extinction? In a matter where such vast interests are at stake, and which has accordingly exercised the minds of the most experienced wine-growers of the day to discover its origin and remedy, I should naturally have felt insuperable diffidence in venturing to obtrude my views upon the attention of the public but for the opportunities I have enjoyed in India, while conducting experimental cultivation for the improvement of the indigenous products of the country, of observing the attacks of similar vegetable parasites, and what proved the best means for their extinction, the success which has attended my operations, as attested by the reports of professional experts on the produce of my farm, obtained through the Agricultural Department of the Government of India, encouraging me.

"In the table appended at the foot of *The Times*' notice of the assembling of the Congress six Departments are named as having been subjected to remedial treatment, and the vineyard acreage respectively experimented upon in these Departments is detailed. The methods pursued were submersion and the application of sulphurate of carbon and sulpho-carbonates —all designed to operate directly as insecticides. Other chemical preparations of the same class and character have been tried by M. Fichet, of Versailles and others. Further, the methods described by the Duchesse de Fitz James, in last June's number of the *Revue des Deux Mondes*, comprising the grafting of American vines on French vine stems, French vines on American stems, the planting out on sandy soil, &c.—all these several remedies would seem to be open to the reproach to which all empiric treatment of disease is obnoxious—viz., the attacking of a symptom instead of the essential root of the disease, and thus betraying a want of right apprehension of its true origin. This, in my humbie view, is to be attributed to exhaustion of the vitality of the plant, induced by unduly and unnaturally overtasking its productive powers. In this respect, the phylloxera of the French vineyards bears a close analogy to the red spider of the Indian tea garden, to the leaf worm of the Indian American, and other cotton fields, and in short, to parasitic growth wherever proving fatally destructive throughout the vegetable kingdom. The mode in which this law of nature, as it may be termed operates may be understood by reference to the physiological paradox, 'Life dies; death lives.' Wherever the vitality of a plant is abnormally diminished by over-plucking, overpruning, and unceasing inexorable demands to produce more, more, when nature demands rest and repose to recruit exhaustion, the sap, the plant's life blood, becomes poor, sluggish, and enfeebled. Parasitic life is then evolved and preys upon the little remaining life that injudicious culture has left the plant.

"If the above view in regard to the origin of phylloxera be accepted as an approximation to the truth, the remedy would seem to be self-indicated—repose. Give the vineyards rest. I passed through the wine-producing districts of France last year on my return homewards from India *via* Marseilles. Most picturesque was the landscape, with the neat villages and detached farmhouses nestling among the slopes of the hills bounding the Côte d'Or on the west and throughout the undulating plains in other parts. But the vineyards! A vast wilderness of stunted sticks, showing barely a leaf left, through the injudicious over-pruning, to imbibe the fertilizing elements from the favouring atmosphere and carry the much-needed nourishment down to revive the dried up, sapless stem and roots. If I might venture to formulate the remedy above referred to as self-indicated, it would be in the terms of my article in the December 1878, number of the Journal of the Agricultural and Horticultural Society of India on 'Indian Famines: an inquiry into the causes, with suggestions,' pp. 188-9. Adapting the principle therein propounded to the circumstances of the French vineyards, I would suggest to each proprietor to divide his estate into four equal parts, not by fences, but certain well-recognized land marks. Then proceed by allowing to each portion in rotation its year of rest, or Sabbath year. In any portion where the vines might appear to be exhausted past retrieval there would be nothing for it but to plough up and renovate the soil by planting deep-rooted green crops, such as lucerne, turnips, carrots, &c., and plough in at or a little before maturity, and in the succeeding year plant with vines afresh. For the future let the Sabbath year of rest for one quarter of the estate in rotation be rigidly observed. The apparent sacrifice by the proprietor of one quarter's fallaciously computed revenue may be contemplated without misgiving in view of the wholesale ruin which has overtaken the important wine industry of France from 'killing the goose that laid the golden eggs,' and would be amply compensated by his estate being maintained permanently in undiminished fertility all round.—I am, sir, yours obediently,

C. L. SHOWERS, Major-General."

[General Showers' explanation cannot be the correct one, for our coffee leaf fungus attacks young coffee, and coffee trees grown from introduced seed, just as readily as the oldest trees in the country. For instance, Capt. Bayley's Liberian coffee trees at Galle, 100 miles distant from the coffee districts, shewed the fungus as soon as they had leaves.—ED.]

CEYLON TEA IN AUSTRALIA.

November 4th, 1881.

SIR,—We tea planters have to thank you for publishing the sales of Indian and Ceylon teas in Australia. The last sales shew, *on the surface*, fair prices. But it should be borne in mind that the little words "in bond" take a good deal of "gilt off the gingerbread." It means taking the first lot as a guide that, though *purchaser* pays 1s 5d per lb., SELLER has to pay 3d per lb. duty before delivery; that broker's commission is charged on the 1s 5d per lb. and not on 1s 2d; ditto also for agent. So that the seller of this tea sells his tea for 1s 2d, but he pays broker's and agent's commission on 1s 5d per lb. *and* discount to buyer on 1s 5d. Other charges are also high, and, I think, it is a question if as good or better prices could not be got in England for really good teas.

It seems unnecessary confusion for seller to pay the duty and it all leads to the loss of the producer and consumer. For in the latter case, consumers read the price tea is sold for in the papers and think the duty has still to be added. I think tea planters should take this matter in hand and specially Melbourne charges. It seems ridiculous that commissions to selling broker and agent, and also a discount to the buyer should be allowed on the Government duty, as well as on price paid for the tea.—Yours truly,

PEKOE TIP.

P. S.—As at the time of the "anniversary of a centenary" or a centennial anniversary, Yankees are given to blowing a good deal, it should be remembered that Cornwallis surrendered to a combined force of Americans and disciplined French, the latter about one-third of the entire force and that a French fleet blockaded Yorktown.

COFFEE CULTIVATION IN THE PANWILA DISTRICT.

4th Nov. 1881.

DEAR SIR,—In reply to your Kelebokka correspondent's letter, in your issue of 28th October, I am glad to say that the owner of Maria estate has no Colombo or visiting agent to consult as regards the management of his estate, and is both able and willing to keep it in good order. I must, however, correct a report going about that it is the *large* amount of manure applied to this estate which gives such good results. I can prove that, as a rule, the coffee is only manured once in two years. When coffee is attacked with leaf-disease, it gets a dressing of wood-ash and country-lime. If very bad, a small dose of manure also. Coffee suffering on account of heavy crop or other causes is at once attended to by digging in some manure.

As regards crop, I am glad to say I am able to raise my estimate this year to 7 cwt. per acre, and the trees, as they get relieved of crop, are making plenty of new wood. There will be sufficient wood to give a good crop next year on parts of the estate, and a fair one on the rest.

There was one estate, "Longford," last year in the market. The late proprietor was so anxious to sell out and go home that he sold his estate at half its value, and I must congratulate the present proprietor on his purchase. Who would not accept a large profit now on his bargain? Where was Kelebokka then?

To prove that I was not at sea as regards *Hemileia* leaving coffee and settling on jak trees or in the jungle, let your correspondent read and digest Mr. Ward's report:—"There can be little room for doubt that the former (*Hemileia vastatrix*) passed to the coffee from the jungle, as I have long suspected to be the truth." Now, if leaf-disease came from the jungle, where it was staying and feeding, for goodness knows how long, what is more natural than that it should find its way back again from coffee trees which had been disinfected to its old habitat? Mix sulphur and lime, or wood-ash and lime, or carbolized powder, with the fallen leaves, and leave it exposed for 14 days. Then fork or bury in manure holes. This will check the spread of spores and be good manure to the coffee.

I am glad to inform your Kotmale correspondent, whose letters I value, that I consider our climate next to Uva, and we have a good sub-soil. I would undertake to guarantee to give crops similar to Maria from all (6) estates in our group. Zululand, which has similar treatment to Maria, and is carefully worked, will show splendid results next year. I cannot speak of Dimbula and Dikoya, having had no experience there. I invite inspection: one and all are welcome.
—Yours,

J. HOLLOWAY.

A CARDAMOM NURSERY.

DEAR SIR,—In reply to your correspondent who wishes to know how to make a cardamom nursery, I am glad to be able to inform him, having successfully raised plants from seed itself, that he should not buy pods for seed, unless he knows they were cured under shade—by the air passing through and daily turned; the seed is very sensitive and too much sun kills the germ. Make your nursery bed with fair mould; at the top put two parts of soil to one of sand well mixed, about one inch thick; press the soil down, slightly; put your seed which should be steeped in water for half an hour over the surface, and cover a little with the mixed soil; shade and water same as cucheens.—
Yours truly,

J. HOLLOWAY.

148

LIBERIAN COFFEE.

Lindula, November 9th, 1881.

DEAR SIR,—Many people think it the thing now-a-days to run down Liberian coffee. I think what I now have to say on the subject may make proprietors of the same feel easier. I send you only an extract from a letter:—"I should say that *Liberian* coffee is a decided success. Mr.—— sent us 2 lb., and every body who has tasted it declares it to be the best they have ever met with! I do not like coffee, but I tasted this and thought it first rate for coffee and the aroma wonderful."—Yours faithfully,

DE BARDONNEL.

HEMILEIA VASTATRIX.

DEAR SIR,—I doubt if Mr. Marshall Ward is altogether correct in stating that the mycelinm is *perfectly safe*, when once it has penetrated the leaf through the stomata. I found a drop or two of the juice of a lime squeezed on to the affected leaf entirely destroy the disease without in an any way injuring the healthy parts of the leaf.

E. F. F.

P. S.—The application of lime juice as a cure would not of course be practicable. The above is written with a view to show that the germ may be reached after it has entered the tissue of the leaf.

CARDAMOMS AND "GRAINS OF PARADISE."—A correspondent writes:—"Nawalapitiya, 25th October.—In your issue of the 21st, I notice you say that 'cardamoms are far famed as grains of Paradise,' and, as I have not seen it corrected, I write to let you know that, although they are of the same order (ginger) the true cardamoms (Malabar) are seeds from *Elettaria cardomom* and grains of Paradise from the *Amomum grona Paradisi*, or Malagetta pepper, sometimes called Guinea grains (Guinea), the seeds of which are extremely aromatic, hot, and *acrid*. *Elettaria major* is the Ceylon or wild cardamom. The value of grains of Paradise in England is only about 1s a pound." Our correspondent is correct as to the distinction between the *true* cardamom and "grains of Paradise" so-called.

UPPER LINDULA, 7th November.—A journey up from Colombo, after an absence of two or three weeks, has many very encouraging features in it. *Coffee*, which a short time ago looked almost snuffed out with leaf-disease, is now, in spite of crop, green with young wood. All the way through Kotmale and Dimbula it was most cheering to see the signs of vigorous life manifested by what, I think, I am justified in still calling our staple product. Up at this end of the district, a little leaf-disease is battling with crop-laden trees, but there is not the slightest doubt that the fungus will have the worst of it in the end. *Cinchonas* in some places, from contact with a cold subsoil I expect, are turning yellow, but the majority are growing well, having made from 4 feet to 7 feet in a year at an elevation of 5,600 above sea level. *Tea* pruned a month ago is loaded with flush, and perfectly free so far from disease of any kind. There was a tremendous down-pour of rain here on the 26th ult. but unfortunately no record was kept of the amount. I see the amount on Shewlands for the same day was 7·29. The register for yesterday the 6th, shows, 30 inch, max: temp: 72, min: temp: 58. To-day is showery with long intervals of sun. Having travelled four times up and down by the Dimbula coach, I feel it only just to mention that it is most punctual in its times of departure and arrival, very comfortable, and above all very cheap, being at the rate of 37 cents per mile, while private traps are Rl per mile plus R3 for tolls. Intending travellers will also be glad to hear that the Nawalapitiya rest-house is equally clean, comfortable, and *quiet at night*. Wonders will never cease,

JAFFNA IRRIGATION : SETTING A GOOD EXAMPLE.—While so many of the Jaffna farmers are bewailing their need of improved methods of irrigation, and calling ou "a paternal government" to furnish the means and do all the work, one, more enterprising, has undertaken to solve the difficulty for himself. Notary Cathiravalupillai of Valvetty, has ordered from England a large double pump, which has already reached Colombo, and is expected to arrive in Jaffna in a few days. The pumps are capable of raising 3,000 to 4,000 gallons per hour. They are accompanied by a windmill, of the European style, with four arms, each 10 feet in length, bearing sails. When the wind fails, the pumps will be operated by two or four coolies. The two flywheels weigh 3 cwt. each, which will give great steadiuess of motion. The whole will cost over Rs00. The well is expected to furnish all the water wanted for 150 lachams of land. This is a bold experiment, and we heartily wish it success, both for the sake of the one who has put his money iuto it, and more for the sake of Jaffna as a wholc. For this experiment can determine whether expensive irrigatiou works will pay, and also whether windmills will work satisfactorily here. We believe the American style of windmill is more economical. That has, instead of four arms, a solid wheel, *i. e.* small slats fastened all over the surface of a wheel. Some however prefer the other style. We hope to see many introduced before many years pass. All the work which the wind can be made to do is clear gain, but we are not very sanguine that manual power alone can in ordinary cases raise water more cheaply with a pump than with a *tula*.—*Morning Star*.

LIBERIAN COFFEE CULTIVATION.—We have to acknowledge the receipt of a copy of a copy of Mr. J. P. William's pamphlet in Sinhalese on Liberian coffee cultivation. In thepre face the author says :—"It is to be deeply regretted that the natives of Ceylon do not posses any Sinhalese books, which treat of the subject of cultivation. The circulation of books bearing on this subject, amongst the natives of tho island will, doubtless enable many, who are ignorant of the importance of cultivation, to acquire such a practical knowledge thereof as may prove of material advantage to them. It has occured to me, that the time is not far distant when our Government should, with a view to encourage cultivatiou amongst the natives, undertake the publication of books in the Vernacular, relative to the art of cultivation, and circulate them in various parts of the island—a course, which if adopted, will tend greatly to enlightened the natives, and increase the public revenue. The cultivation of Liberian coffee ranks high in the list of many useful and profitable cultivations recently commence ind the island ; but no work in Sinhalese relative to its cultivation, and its development, has yet made its appearance. For the accomplishment of this desideratum, I have prepared and published, for the first time, this book iutended as an incentive to new planting enterprise amongst natives. I trust this little work, though not free from imperfections, will prove useful to the majority of the natives. I have thankfully to state that the publications of Messrs. A. M. & J. Ferguson, the Proprietors and Editors of the *Ceylon Observer* have been of service to me in compiling this little book." Mr. William deserves great credit for his energy and public spirit. The following letter has been sent to him from Queeu's House :—"Queen's House, Colombo, 28th October 1881. J. P. William, Esq. Sir,—The Governor desires me to thank you for your kindness in sending him your valuable pamphlet on Liberiau coffee cultivation. I have also to thank you for the copy you were kind enough to send me.—I am, sir faithfully yours, (Signed) A. NEVILL HAYNE, *Capt., A.D.C.*" We are glad to learu that Mr. William's free distribution has been largely patronized from all parts of the island, and one application even came from Travaucore!

CINCHONA.—The *Darjeeling News* says:—The Java process of shaving the bark of cinchona trees, which was introduced into Darjeeling by Dr. King, has proved a decided success. The bark renews itself perfectly, within about a year, and the trees do not appear to have suffered the least check.—*Pioneer*.

IMPORTANT DISCOVERY OF RUBBER AND CINCHONA FORESTS IN BOLIVIA.—Dr. Heath's discovery of vast rubber Forests in the unexplored tracts bordering the river Beni, in the interior of Bolivia, bids fair to be productive of important practical results not only for that State, but for the world at large. This year the export of rubber is estimated at 750,000, and next year it is expected to exceed six million pounds. Cinchona forests have also been discovered in the region traversed. Dr. Heath proposes next year to extend his explorations to the larger and equally unknown river Madre de Dios, commencing from the ancient Inca capital of Cuzco.—Calcutta *Englishman*.

BEES AND COFFEE BLOSSOM.—A correspondent writes :—"Regarding bees, &c., old Palliser writes :—'In the old days, anything under 10 cwt was looked upon as bad. Is it not a very curious fact that the coffee crops have fallen off from what they used to be, even in good soil, aud when free of leaf disease ? I can only attribute it to deterioration of seed from constantly using the same for such numbers of years, the almost total absence of bees from the destruction of the forests (in the olden times, during blossoms, they were in millions), and over-draining and over-pruning.' Such are the words of one of the pioneers of coffee planting, and you can make what use you like of them. I myself put little or no faith in the theory of deterioration of seed. I don't believe that 10 per cent of the coffee in Ceylon is grown from seed more than four generations in Ceylon. No man in his senses ever used seed from young trees, and if he did they must have been 3 or 4 years old at least from seed, so that the whole term of Ceylon planting is covered by some possible 10 generations. I doubt if a tree on my places is in the 4th generation. About the bees I fully agree with Palliser. A coffee blossom is perfect in itself for fertilization. Darwin has pretty well proved that cross-fertilization by insects or otherwise is preferable, and if you get rid of insects you probably won't set your crop as well as if they were about. On over-draining and pruning, I don't agree with him."

THE FORTHCOMING BRAZILIAN COFFEE CROP.—Accounts of the crops continue good from all quarters but trade is very dull, especially in the coffee provinces, wherein the low rates and doubtful prospects of coffee have created a general depression, though large amounts of produce remain to forward. The promonotion of the projected coffee exhibition in Rio November 10th, is actively attended to by the Comercio e Lavoura Compauy, which has undertaken the labour, but the proposed municipal exhibition of native manufactures here seems likely to be still-born, the municipality having no power to divert funds to that object. A second meeting of coffee planters and consignees took place on July 15th, at the Secretariat of Agriculture, with attendance of the Minister of Agriculture, to treat of the coffee exhibition, towards which the Barao da Apparecida has promised to give £6,600. Senhor Ramalho Ortigao presented the committee's report, and various opinious were emitted as to the best means of promoting the consumption of Brazilian coffee. The Minister of Agriculture said that three Rio capitalists had forwarded by the last packet a credit of 100,000 francs to open a café in Paris. He also said that he coiucided with the views of the Committee's report, and he promised the building, transport, &c., and would ask necessary vote for the purpose, aud for practical schools of agriculture, from the next parliament. He hoped the first exhibition could open in November.—*Anglo-Brazilian Times*.

THE THOMAS' TRANSPLANTER (says a Haputale planter) is by far the best I have tried, and I regret I did not provide myself with more tins when ordering the transplanter. No estate should be without one.

TIN TEA BOXES.—The *Indian Daily News* tells us that "orders have been received from home by the managers of a large tea concern in the Darjeeling district, prohibiting the packing of tea in tin-boxes for the future."

CEYLON LIBERIAN COFFEE IN NEW YORK.—We are glad to learn that Messrs. G. & W. Leechman have received a telegram saying that their first shipment of Liberian coffee to New York has sold at 18 cents a pound. This, at current rates of exchange, is equal to about 84s per cwt. in London.

MINERAL PHOSPHATE OF LIME is wanted, and present prices are remunerative to proprietors and likely to continue so for some time. Some few years since we directed the attention of the bold and adventurous section of the American readers of this *Circular* to the development of the deposits in Canada. Shipments thence are now weekly received. The quality is very superior. We have inspected one sample, which tested 95 per cent.—*Samuel Downs & Co.'s Quarterly Circular.*

CARDAMOM SEED (GERMINATED).—The instructions for planters of germinated seed are as follows :—"We find the seed does best when not planted deep, but just covered with a thin film of earth, say a sixteenth of an inch thick. The nursery should be covered with a roof, and be kept well watered and protected from the sun. Plant close at first, say 2 inches apart; when 6 inches or so high, remove them to another bed, or thin them out to 4 or 5 inches apart: then they can remain until fit to plant in the field."

CALISAYA LEDGERIANA SEED.—The auction sale of pure Calisaya Ledgeriana seed by Mr. C. E. H. Symons today resulted as follows :—

15	boxes, each containing	2	grammes at	R39	R585
30	do	do	2	do	40	1,200
32	do	do	2	do	41	1,312
5	do	do	2	do	42	210
1	box	do	2	do	44	44
83	boxes					R3,351

Average per box of 2 grammes R40·37.

"CINCHONA PLANTERS' MANUAL."—The following list of *Errata*, made up by Mr. Owen, should be cut out and pasted inside this book by all who have already obtained copies: it will be added to all "Manuals" issued from our office after this :—

Errata.

Page 1.—Lines 29 and 30, for "which all consist of" read "which consist of all or some of the elements."

Page 11—Line 34, for "then cinchonidine; quinidine and cinchonine" read "then quinidine; cinchonidine and cinchonine."

Page 15.—Line 35, for "CH_{24}, N_2O_2," read "$C_{20}H_{24}N_2O_2$."

Page 17.—Line 37, omit "officinalis."

Page 22.—Line 11, for "officinalis" read "officinales."

Page 25.—Line 2, for "Cuco" read "Cusco."

Page 27.—Line 37, for "tomentose, pubescent" read "tomentose or pubescent."

do.—Line 38, dele "——" after "fruit."

Page 28.—Line 7, after "there" insert "or to the next species."

Page 36.—Line 34, for "15,000 lb." read "1,500 lb."

Page 54.—Line 16, for "500" read "5,000."

Page 90.—Line 20 for "1 lb. of guano" read "½ lb. ammonic sulphate"

Page do—Line 22, for "½ lb. ammonic sulphate" read "1 lb of guano."

Page 111.—Line 7, for "sulphate" read "alkaloid."

Page 113.—Line 11, for "quinine" read "sulphate of quinine."

BRAZIL COFFEE.—We are informed that the telegraphed average daily receipts at Rio and Santos are less by 1,000 bags than at this time last year, whilst stocks at those ports now only show an excess of 20,000 bags as compared with the same period last year.

AN ENEMY OF THE CINCHONA.—"Enquirer" writes :—"I send by this tappal a borer found in the heart of the stem of a succirubra 18 months old. It had entered at the surface of the ground and bored up over a foot and hard at work when I came across it yesterday. Can you give me any information about its pedigree." It is the *red borer*, described in Nietner's "Coffee Tree and Its Enemies," No. 13, page 14, second edition.

JAVA.—From a letter dated Bandong, 29th October, we quote as follows :—"We had some showers, but after those dry weather again. Cholera though does not make many victims, at least not amongst the Europeaus. At Buitenzorg it rains every day, and that will prevent it coming hither. In fact there are no cases but in the low country. At Mr. Kerkhoven's you saw one of our best cultivated teagardens, though tea-making will have been stopped by the prolonged drought. The fire only killed 23 of our grafts at Tirtasari, far less than I feared the number would be."

WYNAAD PLANTING AND MINING ASSOCIATION.—At a committee meeting, held on the 5th October, the first business taken up was the Coffee Stealing Prevention Act. A letter to the Collector of Malabar from the Hon. Secretary was read, noting the fact of the extension of Act VIII 1878 to the lowland tracts traversed by the coffee in transit to the coast, and the Government opinion that it will be sufficient to apply the Act to the main roads from Wynaad to the Coast, but calling for a report from the Collector to say, if this is not enough, what roads should be specified in the notification. The letter points out that it is absolutely necessary for the proper working of the Act that its provisions should be extended to the whole district, and depreeates most earnestly the proposal to confine its operation to the main line of roads. The letter also suggested the advisability of having one recognized form of Coffee Pass issued by the Government. Those passes should bear a one anna Revenue stamp, and their use made obligatory, and should be procurable at all kachcheries and post offices. This letter was approved of. The remaining business related to telegraph extension, taxing of gold Companies for road upkeep, and lastly a letter on Government sales of cinchona, from the Ceylon Planters' Association, asking the co-operation of the Association in endeavouring to prevent a continuance of Government competition with private enterprise. It was resolved that the Government be addressed on the subject. The annual report was then considered and the meeting separated. At the annual meeting held the same day the annual report was read, which stated that there were 52 members on the list, as against 55 at the commencement of the year. The report dealt with the following subjects :—Labor Law and Registration of Maistries; Madras Forest Act; Beypore-Mysore railway roads; The Mysore Government; Coffee Stealing Prevention Act; Telegraphic Communication; Local officials; and Mining Industry. The report having been adopted and the accounts passed, the following committee was appointed for the coming year:—Messrs. Batty, Bussey, Dawson, Fetherstonhaugh, Griffin, Hockin, Jowitt, C. A. Mackenzie, Malcolm, Moon, Miller, Punnett, Romilly, A. Trollop, J. Vanleeesima, Walker, Winterbotham and G. L. Yonge. A discussion then took place regarding roads and railway. Mr. Young was re-elected Honorary Secretary, and the meeting concluded.

COFFEE LEAF DISEASE: THREE "RICHMONDS" IN THE FIELD!—The following paragraph is from the Batavia *Handelsblad*:—"A Sourabaya paper asserts that Mr. Jacob F. Storck, coffee planter in the Fiji islands, intends to visit Ceylon via Java for the purpose of diffusing an invention of his. The said gentlemen has discovered a remedy for the *Hemileia vastatrix*, consisting in charging the atmosphere with an element which is fatal to the *Hemileia*, and may be produced by women and children. All this is very mysterious, but we must wait for Mr. Storck's arrival before we can say more about it." Mr. Stork has alrcady sent one or two letters to the *Observer* expressive of the utmost confidence in his remedy for coffee leaf disease. His journey hither all the way from Fiji will afford very practical evidence of his good faith, and so it behoves the Planters' Association to consider betimes what is to be done with their visitor. Would it not be advisable to select 150 to 200 acres of typical coffee, and, dividing it into three equal portions representing the same conditions as far as possible, to hand one over to Mr. Stock to experiment on for 6 months; another to be treated with carbolized vapour under Mr. Schrottky's care; and a third with sulphur and lime according to Mr. Marsball Ward's suggestions? Half-a-dozen Visiting Agents—say, Messrs. W. D. Gibbon, Bosanquet, W. Mackenzie, Young, Grigson, Ballardie and Irvine—representing varied interests and experience, should then be constituted a Board of Inspection, with the Planting Member of Council, and the Chairman and Secretary of the Association, to report definitely on the result.

MERCARA, 31ST OCT.—The S. W. monsoon closed about the first week in October, and will be reckoned as one of the very lightest that has happened in the annals of the country. The weather was similar to what was in by-gone years, but the rains were neither so persistent nor fierce, there were no terrific downpours of twelve or thirteen inches in a day and there happened occasional breaks during the day-time, when the gloom was relieved by glimpses of the sun, and patches of the blue sky in July and August. The rain-fall registered by me from the beginning of the monsoon to its close on October 3rd was 149 5 inches against 246 inches for similar dates in 1880, and 242·5 in 1879. Cardamom picking, which commenced a fortnight ago, is well forward: the out-turn will be a little below the average, but they are of an excellent quality, the pods being of a more uniform size, and of a good chrome-yellow color, whilst the seed are well pronounced in flavor and scent. There is an active demand for them in Mercara, by the native buyers, and prices keep high; the fine weather of late has given them every facility for being dried quickly and well, which so much improves the quality. The partial failure in the crop is owing to a shortness of showers, neccessary for bringing out the blossom, which should fall in April or march, being this year, both uncertain and late. Cardamoms have hitherto been in the hands of the Coorgs, who combine together in a district and rent large tracts of forest from Government. there is little more excitement or expectation of making a large profit in this way thou in being the lessee of a toll-gate. The plant is indigenous in the forests, as persistent of life as the *Petris Aquilina*, our common fern, requires no cultivation, little attention, self-germinating, and dies only from etiolation. Until quite recently it was a Government monopoly, like sandalwood and tamarind fruit to-day—and was a large source of income to the old Rajahs who held the country. The yield has grown less year by year: Europeans have never regarded cardamoms as a special culture until this year; there was some forest land that has been paid tax for above twenty years, and has literally produced nothing. Well, under the spirited energy of a new manager, attempts have been made to grow them. About forty acres are planted up, some six feet apart, with young seedlings The forest trees are left standing, an occasional tree being felled to let the light in—there will be a small crop next year.—*Madras Standard*.

THE NILGIRI COFFEE.—The coffee crop is expected to be late this year. The late spring rains brought the blossom out a little after time and the dry weather generally that succeeded did not contribute to develop the berry. In some localities it is abnormally small, but the bean shows compact and firm. The crop will probably be characterised as light and small. Most estates are short and even this limited outturn was menaced during the year. If prices rise, working expenses may be recovered, if not the outturn will leave many of the estates with an increasing debit balance. The gold industry has thrown coffee back considerably, but beyond a temporary depression this product will assert its superiority and remunerative character before long.—*Indian paper*.

SLAVERY IN BRAZIL.—In its issue of October 1st, the *Anglo-Brazilian Times* hasan interesting article on the Free Birth Act of Sept. 28th, 1871, "when the light of freedom first dawned upon the dark horizon of Brazilian slavery, and it was proclaimed that from that glorious day—glorious alike to Visconde do Rio Branco, Brazil, and humanity—not a slave could be born within the wide expanse of the Brazilian Empire." Our contemporary proceeds to remark as follows:—"Happily, the experience of the last ten years has served to dispel in great measure the doubts and fears which at first clouded the future. The generally cheerful and even benevolent co-operation of the slave-owners has smoothed away many of the inherent difficulties of the law and has extended its benefits far beyond anticipation. It is, indeed, most honourable to them that they have discharged their duty towards the children of their slaves with humanity and kindness, and that, instead of viewing the continuance of the charge as irksome, and to be rejected at the earliest opportunity, the right of option has not been availed of in more than two cases in a thousand. It is also most honourable to them that their private emancipations have been upon a scale of unexpected magnitude that proves the force of emancipatory sentiment in their midst and has thrown the official emancipations completely into the shade. As regards the solution of the labour question created by death among the slaves and a progress of emancipation which it is the desire of many in the nation to hurry to the goal, the mists of uncertainty, unfortunately, still, envelop it and render it obscured. The attitude of the native freeman, the freedman and the ingenuo in face of it, is still a problem. Immigration, partially repelled by the existence of slavery, by the defects of the land system, and by the sanitary perils of our maritime cities, has not yet become an agricultural power, and Chinese labour, even as a temporary assistance, is still of small promise of attainment. Nevertheless, some progress towards the solution is apparent; immigrant labour is superseding that of the slaves in many employments within the cities, the central sugar factories experience no difficulty in obtaining the free labour the law imposes on them, and yearly the influence of free native labour is becoming more sensible in the production of our staples, so that we seem gradually to be approaching the point when a proper adjustment of wages and the personal relations of the labourer and employer, relations still hampered by mischievous attempts to retain from the slave system intolerable restraints upon personal independence, may suffice, if not, what cannot be hoped, to avoid great difficulties and perhaps a revolution in the plantation system, and to at least tide the country over a labour crisis without great danger to the interests of agriculture.

COLONEL BEDDOME ON CINCHONA PLANTING IN CEYLON.

The report furnished by Colonel Beddome to the Madras Government on the result of his short visit to this island will be read with considerable interest. He identifies our strong-growing large-leaved "hybrid," hitherto reckoned a cross between Officinalis and Succirubra, as the "Pata de Gallinazo" a variety of red bark. But there are some contradictions in Mr. Cross's and Colonel Beddome's Reports to the Madras Government, that must be cleared up before we can be quite sure what these gentlemen mean by the new species. Mr. Cross more especially gave the name "Pata de Gallinazo" to the Pubescens, and he speaks of it as a narrow-leaved variety of red bark. Colonel Beddome classes the glabrous and pubescens (hairy) kind together, and says some of them have hitherto been spoken of as *Magnifolia*. Here is the extract bearing on the subject from Col. Beddome's Report on the Nilgiri plantations:—

"*Pubescens*."—No one can visit the Naduvatam plantation or the "Hooker" at Pykara without being struck by the splendid growth on grass land of the species known as "Pubescens"; whilst "Succirubra" is always very stunted and with the leaves very much crimpled and unhealthy looking in this soil, this species or variety is of sturdy fine growth far outtopping the Red barks and with very healthy darker green leaves; the difference in the growth, however, is not so marked in the shola soil, as the "Succirubra" grows there equally or nearly equally robust. This "Pubescens" has generally been supposed to be an accidental hybrid of Nilgiri origin and is often known as Mr. McIvor's hybrid; it is, however, no hybrid* whatever, nor has it any of the characteristics of one, and it has evidently been in the Nilgiri plantations since their commencement, though not recognized as distinct from "Succirubra" in its young growth and before flowering. It differs from "Succirubra" (besides in its more robust growth at a higher elevation and in poorer soil) in its leaves being more pointed, more coriaceous, of a much darker green, and more shining, and in the primary veins being less at right angles with the midrib. Mr. Rowson pointed me out what he called two distinct varieties; one he said called "Pubescens" by Mr. McIvor and the other called "Magnifolia"† On careful examination, however, the only difference appeared to be a certain amount of pubescence on the young shoots and under surface of the leaves in the former, whereas typical specimens of the latter are quite glabrous on the under surface of the leaves, and the young shoots are very slightly pubescent; and I found that Mr. Rowson could not tell one from the other except by very close inspection, and that the difference in Pubescens, though sometimes much marked, was in other cases not apparent. The pubescent variety has also been called "Lanosa" and growing in shola soil with "Succirubra" might be passed by as that species by the uninitiated; the leaf however is never so rounded at the apex and it has a flatter surface, and never the crimpled look that "Succirubra" always assumes more or less. I found a good many of "Magnifolia" and a few "Pubescens" in the Dodabetta plantations, and there are some fine old trees of "Magnifolia" in the 1865 plantation which are certainly not supplies (which alone would prove that they could not be hybrids), but here I found them both known to the superintendent (Narrainsawmy) as "Pubescens," the name "Magnifolia" not being known.

Mr. Rowson informed me that he considered them hybrids, as they had not appeared before the 1869 planting (it will be seen elsewhere that Mr. Cross detected them in the oldest planting); that they both generally came up true from seed, but that he had known many sown as these hybrids come up true "succirubra" which, he however, attributed to careless gathering. He also stated that he had largely propagated "Pubescens" and not "Magnifolia" on the supposition that the bark of the former was much more valuable; the bark he also said both of "Pubescens" and "Magnifolia" had not been sent to market except from a few trees taken carelessly by coolies and mixed with other barks, but samples had been collected from one or two trees and sent home for analysis, and this analysis is given in G. O., No, 1,336, of 23rd June 1879, under "hybrid Pubescens" and is most favorable, though I am not inclined, as I have said elsewhere, to give too much reliance on the analysis from single individuals, perhaps, grown under very favorable circumstances. These specimens were taken from the glabrous "Magnifolia" and not from "Pubescens."

Narrainsawmy, the Dodabetta Superintendent, informed me that he did not consider "Pubescens" a hybrid, as there were large trees in the 1865 plantation which he had always been familiar with since he took charge in 1868; he also stated that if sown they sometimes come up true, but they often come up "Officinalis" (this must of course be due to careless gathering). I subsequently got Mr. Cross to make a careful examination of this species or variety both at Naduvatam and on Dodabetta. He informs me that "Magnifolia" and "Pubescens" are one and the same species, and scarcely distinguishable, that he is quite familiar with the tree which he found himself in the red bark region on the slopes of Chimborazo, but always at a higher elevation than "Succirubra," and that the Cascarilleros or bark collectors always distinguished it as the "Pàtà de Gallinazo" (or turkey buzzard's foot), while they called the "Succirubra" "teja" (or tile bark), but that the bark was not put up separately by these collectors. He also states that he believes this tree has never been figured or described although Weddell (Notes sur les Quinquinas) refers to no less than four species as the source of Pàtà de Gallinazo, whilst Mr. Spruce in his report includes the Pàtà do Gallinazo as bark collector's lore, evidently regarding it as an *alias* of "Succirubra," though he could never have seen the trees. Mr. Cross also states that he examined the very tree at Naduvatam, that the bark was taken from for analysis, and that it is typical "Pàtà do Gallinazo" (or the glabrous "Magnifolia" of Mr. Rowson), and that there can be no mistaking the strong growing varieties of both sorts on the grassland; but that in some cases true "Succirubra" has been pointed out to him as "Pubescens" in the Naduvatam plantations and the same mistake

* Note.—Hybrids between distinct species could scarcely occur without isolation, or without removing the anthers (of the flowers to be impregnated) at a very early stage, as I find the anthers burst before the valvate lobes of the corolla are fairly open. I find the flowers of Officinalis (and all the other species as far as I have observed) dimorphic; some trees have all the flowers with short included anthers and long exserted style, others with long anthers and short included style [this dimorphism occurs also commonly in species of Hedyotis—Anotis and other genera of this tribe (Rubiaceæ) indigenous on the Nilgiris.] Seeds of hybrids would be sterile except under certain conditions.

† Nothing to do with the "Chin. Magnifolia" Rz and Pavon, which is now placed in a another genus "Cascarilla" differing from Cinchona in having a papillose instead of a hairy corolla and in the dehiscence of the capsules.

he says seems to have occurred at Darjeeling. There is evidently some confusion about the pubescent variety, and I fear that the officials do not always distinguish between some forms of "Succirubra" and "Pubescens" when growing in shola soil, and that awkward mistakes are liable to occur both in the supply of seed and collection of bark. Mr. Cross also informs me that he found trees of this "Pàtà de Gallinazo" in the oldest plantations at Naduvatam and that he has no doubt it was introduced here from the commencement, but that it was not distinguished from "Succirubra" till it grew up and flowered or till its robuster growth became apparent.

I forward with this report carefully dried and mounted specimens of both "Magnifolia" and "Pubescens," so I trust that they may be compared with typical specimens of the various species in the Kew Herbarium. I also forward specimens of all other species referred to in this report for comparison, &c.

I examined the two trees in Dodabetta from which Narrainsawmy tells me the analysis of hybrid "Pubescens" is given in G.O., No. 1,336, dated 23rd June 1879 (Nos. 10, 11 and 12); they are both the glabrous variety that Mr. Rowson calls "Magnifolia" and Mr. Cross styles "Pàtà de Gallinazo." The results from the three specimens sent vary much in the precentage of the different alkaloids, and also the variations with the samples sent from Naduvatam are considerable; this is not satisfactory, though there is proof that we have in this plant a very valuable species.

The Dodabetta Superintendent informs me that this tree suffers less from frost than the "officinalis."

Mr. Howard calls this tree "officinalis" var. "Pubescens." It is in my opinion nearer "succirubra" than "Pubescens" [Officinalis?—ED.] and it will be seen from some specimens that I forward that the leaves from shoots and suckers are nearly as large as those of "succirubra," though more lanceolate in shape and more pointed. No varieties of "officinalis," not even its largest leaved from "Uritusinga," ever produce leaves nearly as large as this.

I much fear that in some cases seed of true "Succirubra" may have been forwarded from Naduvatam to Ceylon, Darjeeling or elsewhere instead of true "Pubescens," and that unfortunate mistakes may thereby arise.

I have had long talks with Mr. Cross about this tree, and we have examined many together, and he now writes me: "The circumstance that this prolific and hardy sort has so long escaped notice, and the uncertainty that still exists as to which of the two sorts ('Succirubra' or the so-called 'Pubescens') is the richest in alkaloids is much to be wondered at." It is I now think all important that the doubts about it should be cleared up and that we should have a careful analysis from a considerable number of both the glabrous and pubescens varieties.*

This species is very strong growing, and will certainly yield far more bark in a given time than any other; it will also, I think, prove to be longer lived.

*NOTE.—There is still some doubt as to "Magnifolia" and "Pubescens" being one and the same species or rather slight variations of the same species, though I myself feel fully convinced that they are. I trust, however, that the fact may be established from the dried specimens now forwarded. It is a fact that it is Magnifolia (true) which gave the favourable analysis in G. O., No. 1,336, of 23rd June 1879, as far as Dodabetta is concerned, whilst it is "Pubescens" that is being largely propagated at Naduvatam. The Naduvatam analysis was from trees growing in Ossington which I have not seen, but Mr. Cross states they are "Magnifolia."

It is of course, of comparatively little importance whether the so-called hybrid belongs to the red or crown bark species, so long as its growth and yield of quinine are so exceptionally good as is now reported. Colonel Beddome after going over the Nilgiri and Ceylon plantations speaks of it as the "Cinchona of the future," and certainly if 7 per cent of quinine is attainable as in the case of the Agrakanda tree, and the trees prove hardier and of more rapid growth than the Calisayas, the precious Ledgeriana itself may find no mean rival in Pata de Gallinazo. The highest price secured for "Pubescens" bark of this species from the Nilgiris was 7s 6d per lb, It must not be forgotten, however, that the growth of Calisayas in several districts in Ceylon has been eminently satisfactory, as was shewn by Mr. J. A. Roberts of Pussellawa some time ago. The very successful experience of belts of blue gums on "Lover's Leap" cinchona estate near Nuwara Eliya (noticed by Colonel Beddome) ought to be decisive. There are no failures and no canker visible on this favoured property, we believe, and yet the soil was far from favourable to begin with. Messrs. Taylor and Scott—to whom the credit of the careful planting and the happy plan of belts one chain apart, trees 6 or 8? feet distant in the row, belongs—are inclined to think that the gums have not only sheltered the cinchonas, but have benefited the soil, more especially in withdrawing superfluous moisture. We believe their experience points to the wisdom of even closer planting of the gums, say four feet apart in the rows. In reference to Mr. Cross's "Pata de Gillinazo" we may mention that in a private letter received from Madras, from a reliable quarter, it is stated that the latest analysis of the "natural" bark of "Pubescens" gives nearly 13 per cent of alkaloids, of which 7·07 is "sulphate of quinine," but this is not so good as 6·77 pure quinine from the tree on Agrakanda. It will be observed that Colonel Beddome's visit to Ceylon has opened his eyes to the value of chemical analyses, and so the Madras Government (on his recommendation) will no doubt at once engage a successor to Mr. Broughton, while the Ceylon authorities without any reference to analyses, are getting out a trained cinchona cultivator in Mr. Nock, to take charge of the wretched neglected piece of waste ground and the petty nurseries known as "Hakgala Gardens." Our next visitor in connection with cinchona cultivation will probably be Mr. Gammie of Sikhim. Writing on the 4th instant this gentleman says:—

"I cannot yet fix the date of my visit to Ceylon but hope to get away soon. We have just got our bark boiling apparatus erected, and begin boiling at once, and until everything is shown to be in fair working order I cannot think of applying for leave."

Mr. Gammie will deserve a hearty welcome here not only for his intelligent and successful management of the Northern Gardens, but also for his indefatigable efforts to manufacture on the spot a febrifuge suitable for use in India.

COLONEL BEDDOME'S REPORT ON THE CEYLON CINCHONA PLANTATIONS.

Colonel R. H. Beddome, Conservator of Forests, has reported to the Government, that he lately paid a short visit to Ceylon in connection with Cinchona. He says:—

Route Pursued.—I was only able to spare a fortnight,

so that my visit was rather hurried ; but I was able to see a good many estates at different elevations and with different soils. I also obtained much information from Dr. Trimen, who accompanied me from Peradeniya through some of the estates in Kotmale and Dimbula as far as Nuwara Eliya, whence he was obliged to return. I afterwards visited the Government plantation and nursery at Hakgala, estates about Nuwara Eliya, Kaudapolla and Uda Pussellawa and returned to Peradeniya through some of the estates in the Ramboda and Pussellawa districts.

The Pata.—I was much interested to find the "Pata de gallinazo" of Mr. Cross, the species hitherto known here as "Magnifolia," about which I have written so much, widely distributed in the island, chiefly amongst the "Succirubra" trees, between 3,000 and 5,000 feet elevation and maintaining its uniform character and strong rapid growth. This species is in Ceylon generally known as "Hybrid" though it has other names, and is sometimes called "Condaminea." Most planters appeared easily to recognize all their different individuals of it as one and the same plant, and always spoke of them as their "hybrids," but were delighted at a reaction against the hybrid theory, and to think it a distinct species which could be propagated from seed, as many of them think with me that it is probably within certain elevations, the chinchona of the future. Some planters were inclined to look upon each individual tree of this as a separate hybrid, and all distinct one from the other, though almost uniform in appearance. In one estate in Lindula, known as Agrakanda, I found that the analysis of the bark of three different trees of this "Pata" had been reported on by Mr. Howard. It was as follows :—

No.	Quinine.	Chinchonidine.	Quinidine.	Chinchonine.
IV.	6·77	1·84	trace	trace.
V.	3·66	4·06	do.	do,
VII.	4·08	2·84	do.	do.

These were all large, strong, healthy trees. No. VII. the largest, was a little over 29 feet high and 2 feet in girth, breast high. I do not think correct data as to age was available, but they appeared to be not less than 10 years. This analysis is most interesting, as showing what a very large percentage in quinine some of this species can give, and also as showing how variable the yield is from different individuals ; which is, as far as I can see, equally the case with all the other species of the genus. I found Dr. Trimen exceedingly interested in this species, and he had been cautioning the planters against the hybrid theory. I believe that he is now fully convinced that it is a perfectly distinct species and an undescribed one ; and he intends, I believe, to discribe and figure it in his Journal of Botany.

Pubescens.—I also saw trees of our "Pubescens" (or the downy variety of the "Pata") particularly in Pussellawa, but they do not appear so abundant as the glabrous species.

Red Bark.—The growth of "succirubra" is exceedingly good in many parts that I visited, and I often saw it growing well in deserted coffee where the soil must have terribly deteriorated. If all old deserted coffee plantations can be planted up with "succirubra" it will be a great thing for both India and Ceylon ; except at the lower elevations, however, the "Pata" grows even better than the "succirubra," and is the tree to plant at any rate anywhere above 4,000 feet.

Crown Bark.—I was not fortunate in seeing any good "officinalis" plantations of any age or size. I was not however able to go to Hapntale or Uva, the two best districts, I believe, as far as soils and climate go. I saw both at Nuwara Eliya and in Kaudapolla, and elsewhere large plantations of "officinalis" of very young growth looking exceedingly healthy (when sufficiently protected by an eastern exposure) but the soil everywhere is much inferior to what we have on the Nilgiris, often very shallow or with a clayey sub-soil which induces early decay, chiefly from canker, and the planters do not look to longevity for "officinalis" in these soils, but they uproot at 4 or 5 years of age and replant. We have nothing of this sort in India, and I trust it may never be necessary, but the whole conditions of soil and climate are different. We have not planted any tracts with a sub-soil of impervious clay, and we have a period of drought which, I think, will turn out to be beneficial to "officinalis" (though probably not for some other species) and antagonistic to canker; whilst in Ceylon, in addition to a very heavy monsoon with often no sunshine for very long periods, they have rain all the year round, which induces early maturity and the too early flowering of the trees. So profitable is the crown bark at present prices that, even in face of this early maturity and early decay, the planters are making large profits. On one estate which I visited on upper Ramboda, called Frotoft, 45 acres of "officinalis" had been uprooted at 4½ years of age, and the trees had yielded 25 tons of dry bark which was sold at 4s. per lb. (=£11,200), and it was said that 1s. per lb. would even have paid. There is, of course, much doubt how often soils like this can be replanted ; but uprooting in this case was imperative, as the trees were all beginning to go out even at this early age from canker, and this is said to be generally the case, and that coppicing even cannot be resorted to, as it is generally the root canker. I was even told in several estates that whole nurseries had gone out from this cause. This must, I think, be simply the damping or rotting off of the roots of the seedlings from the use of too rich or damp soil in the beds and the want of silver sand. On another estate called Lool Condura (in the same vicinity), which I did not visit, I heard that two crops had already been taken off by the same method of uprooting, with very favourable results financially, and that the estate had been planted up a third time. All these estates are considerably below 5,000 feet and consequently at an elevation much below what we grow "officinalis" at, and this early decay may possibly be averted at the higher elevations about Nuwara Eliya, &c ; the growth there is all very young at present. On one estate called, I think, Thallipody* not far from Nuwara Eliya, I found that all the "officinalis" trees had been shaved (Java method) before they were barely three years old ! The proceeds were said to have cleared the estate of all expenditure, and the trees, small as they were, were certainly nearly all renewing their bark ! In another estate in this locality I saw "officinalis" which had been put down as close as $2\frac{1}{2} \times 2\frac{1}{2}$, growing very well. However, there is an opinion amongst some of the planters that close planting can be overdone and so cause unhealthy growth from an early age that may not be easily rectified by subsequent thinning ; it is a question on which actual experience is much required.

Belts of Trees as Break winds.—Near Nuwara Eliya, I saw an "Officinalis" plantation in a high bleak-exposed situation, which was exceedingly interesting on account of the systematic way in which belts of *Eucalyptus globulus* had been planted as a break-wind. At a chain apart, throughout the plantations, single rows of the e trees, each tree at 6 feet apart, had been put down at the same time as the chinchonas ; they had been topped when young, and grown out with a bushy habit, and the Cinchona was growing, comparatively, exceedingly well, where there could have been nothing but most wretchedly-stunted growth without this protection. I think this plan can with great advantage be introduced into several portions of our plantation on Dodabetta and at Naduvatam and

* Tullibody ?—ED.

Pykara, and I would draw the attention of chinchona planters generally to the great importance and value of these or similar break-winds, and I know of no tree that would answer better than the Bluegums at high elevations.

Calisaya.—I had no opportunity of seeing any good plantations of calisaya such as, I believe, exist in Maskeliya and other parts of the island which I had not time to visit However, I saw some fine trees mixed with other chinchonas and coffee in different estates at low elevations. Considering the fine appearance and growth of one that I saw growing on the estate called Agrakanda in Lindula (about 4,000 feet), I think it probable that finer calisaya will be grown in Ceylon than in India, and that with this species the moist climate of the island has the advantage against our droughts ; but I have had very little experience with calisaya. The analysis of this tree by Mr. Howard had given 5·65 per cent of quinine, 1 22 of chinchonidine, 44 of chinchonine and only a trace of quinidine. Two miles from Nuwara Eliya, at the head of the Rambada pass, I saw a most remarkable plantation of what were called "hybrid calisaya." The elevation is too high, I should think for the species being about 6,000 feet, and the trees are all quite shrubs, 4 to 6 feet high, densely branched from the base. The plantation is, however, looked upon as one of great value by some experienced planters. I recognized our var. Javanica, but there were quite a crowd of other forms that I have not seen in our plantations (we probably had some of them and they have died out) and which would completely puzzle any botanist. It is quite possible that we have here only a single species, a very protean one, producing all these varieties from the same seed, but it is, I think, more likely that there are many really different species mixed, species which have not as yet been worked out by a botanist ; either of these views are, I think, preferable to the hybrid theory. On the subject of classification Dr. Trimen has written the following valuable remarks (*vide* Mr. Owen's "Chinchona Planter's Manual"):—

"The genus cinchona presents us with a very well-marked and striking instance of a clearly defined natural group, in which the individuals composing it, instead of as usual being with more or less facility thrown into different sets marked out by clear distinctive characters, (and thus forming the 'species' of the naturalist) offer themselves as a crowd of forms closely connected in different directions, but showing only trifling modifications of structure of a sort usually regarded as of but little systematic value. Such general are not very uncommon and the botanist of Europe is but too familiar with cases in *Salix* (willows), *Rubus* (blackberries) and *Rosa* (wild roses).

"This state of thiugs is natural and has not arisen under cultivation. In 'chinchona,' the great majority of the described forms have been found in the Andes themselves, where the genus has a range of over 2,000 miles from north to south, and at altitudes from 2,000—11,000 feet, but chiefly between 5,000 and 8,000 feet. It would appear that every district of this extensive area has its own peculiar chinchonas, and very few species are known to range widely through it ; none to occur throughout. A very similar statement might be made with regard to the fruticose *Rubi* in Europe."

Really careful experiments with the seed of each marked variety or species would be exceedingly interesting and would probably clear up the doubt whether they are distinct species or all forms of one very protean species ; but if the latter be proved to be the case, the botanist will have a most difficult task in the classification of the genus. Analysis is all important in a plantation of this sort, if profit is to be looked to, and the same may be said of the ordinary form of Calisaya or of Javanica or any other of its forms, as it has been proved that forms apparently quite similar in every way may in some individuals be very rich in quinine and in others have no trace of it. The planter has therefore to be cautioned against any indiscriminate growth of "Yellow barks" at this stage of our knowledge, as not only is this an established fact, but we at present know little about the elevation or climate adapted for these species.

Ledgeriana.—Dr. Trimen informs me that both he and Mr. Moens of Java consider this species as quite a distinct one and not as hitherto supposed only a variety of "calisaya" and that he has lately described it as such in his "Journal of Botany." He also pointed out to me that the flower pedicels always have a drooping habit not seen in "calisaya," and that the flower buds want the knob-like apex characteristic of "calisaya."

The enormous profits of the Ledgerian plantation in Java under Mr. Moens, and the visit last year of that gentleman to Ceylon, have given a great impetus to the planting of this species in Ceylon. I had not an opportunity of seeing the best or oldest grown in Ceylon, but I saw some large trees many of young growth, and also experiments with Mr. Moens' system of grafting this species on "succirubra." I, however, learnt that no analysis of this bark in Ceylon could in any way be compared with that in Java, and it is probable that the deep, rich, volcanic soil in the latter place is the real cause of the wonderful results. Mr. Moens has obtained as much as 13 per cent. of pure quinine from one tree of this species, and Dr. Trimen tells me that he (Mr. Moens) destroys all trees which on analysis do not give a very high yield, and that he grafts from the richest on to "succirubra," and that he has a small area of these grafts which are giving most surprizing results and astonishing every one. Dr. Trimen also informed me that this grafting on "succirubra" was resorted to, owing to the great difficulty of propagating this species by cuttings ; but Mr. Grant in the Ouchterlony Valley (I was over his establishment lately) has been most successful with cuttings under glass with bottom heat, scarcely having a failure, so I cannot, I confess, see the advantage of the grafting, if cuttings can be grown easily in India, and I believe not only Mr. Grant but also Captaiu Cox has had no difficulty ; the grafting process besides could hardly be resorted to for large areas. It is, however, important I think that we should have some experiments on this plan, when we open ground for "calisaya" and "Ledgers" at a lower elevation. Mr. Moens' plan is described as follows in the Chinchona Mauual above referred to :—

"This system has been largely pursued by Mr. Moens in Java for the multiplication of Ledgerianas, with great success. For a description of the method we are indebted to 'Viator' and Mr. Kay-Shuttleworth who visited Java and there saw the operation performed. Succirubra being the commonest and most rapid growing cinchona is chosen for the stock succirubra plants about a year old are chosen, and to economise space are stumped at a point six or eight inches above the soil. This is done just above a joint. A flat cut is then made in the stem under the bark which is not removed sufficiently deep to make a surface large enough to allow a ledgeriana shoot (cut through diagonally, the cut being one to one and-a-half inches long) to fit cambium to cambium to the succirubra, the bark of the succirubra overlying the cut being left intact. The ledgeriana shoot must be cut just where the hard mature wood ends and where the branch begins to be tender and succulent from the newness of its growth. It is then fitted carefully into the cut in the succirubra stem, the flap of bark put over it and the whole bound firmly with Berlin wool. String pulled out of an ordinary sack will

do almost equally well. The operation is simpler, if the succirubra has a double stem, one of which is then cut off diagonally at the fork, leaving a flap of bark at the upper end of the cut. The ledgeriana shoot is then cut, so that it shall correspond in shape and size with the cut surface of the succirubra, but a flap of bark is left hanging from its lower end. The two cut surfaces are then fitted together, the flap of ledger bark overlying the succirubra stem and the flap in the succirubra overlying the Ledger cutting, and thus giving a better hold to the binding. The pots which contain the grafted plants are then laid on their sides graft uppermost, in propagating frames and kept until the bark begins to unite and new leaves to show, when they are placed upright. The succirubra is cut off just above the graft as soon as the plants are fairly united and there is no fear of this further mutilation of the tree injuring the young graft the bandage being removed at the same time. Four weeks is the time that generally elapses before this can be done. It has been proved that a good graft grows faster than an original Ledgeriana tree, and that the qualities of the stock never in the slightest degree affect the tree it bears. A skilled laborer can graft from 200 to 250 Ledger cuttings on succirubra stems every day and the operation is therefore evidently not a very expensive one. There can be no dout as to its advisability in all cases where individual trees of special value are to be propagated from."

Crispa.—I saw abundance of what Dr. Trimen calls the "Crispa variety of officinalis," and it is the same as we have abundantly represented in the Dodabetta plantations not differing from ordinary "officinalis" except in its rather smaller leaves and often running into the ordinary form so as not to be distinguishable.

Urituninga.—I saw no "Urituninga" in Ceylon amongst the older Crown barks, and I am unable to distinguish this variety from "Officinalis" when they are young.

Hackgalle Government Gardens.—As a cinchona plantation these have been utterly neglected. The older trees have almost all died out, or been cut down and the coppice not attended to; they were scarcely worth a visit; there were, however, numerous nurseries for seedlings of various kinds.

Grass Land.—I saw scarcely any grass land planting. Unlike the Nilgiris, where nearly all the grass land rejoices in an open and gravelly soil, the grass land (or patanas, as they are called) in the Central Provinces have generally a black peaty soil quite unfit for the growth of chinchona, and similar to what we have in swampy ravines only. I daresay there may be suitable grass-land soils in parts that I did not visit, but I only saw some small patches; but in these "officinalis" was growing well where planted, but it was quite young.

Importance of Analysis.—My visit to Ceylon and the advantages I have had of discussing matters with Dr. Trimen, and also of hearing Mr. Moens' views through Dr. Trimen, has made me alter my opinions very much with reference to the value of analysis, and I think it now all-important that very great attention should be paid to this subject in our plantations, particularly with reference to "officinalis" and the "Pata" (Magnifolia), individuals of which have been proved to differ so one from another in their yield of quinine. We should find out the individuals which give the richest yield and propagate largely from these, and these only, both as to seed and cuttings, continuing the experiment through several generations. Though the experiments might not be altogether satisfactory at first, and though we might find that the seed and even the cuttings of the richest yielders might often give very varied results when planted out over large areas, I feel sure experiments of this sort must be in the right direction, and if persevered in, would ultimately give very good or even startling results, as with Mr. Moens, and we should then be able to distribute the very best (and only the very best) seed and rooted cuttings to the public. This, however, can never be carried out satisfactorily unless we have a qualified Chemical Analyser for our plantations as well as a thoroughly practical gardener, but surely in a question of such importance the expense should not be considered or allowed to interfere.

Chinchona Planter's Manual.—A most excellent little Manual has just been published in Ceylon at the *Observer* Office by Mr. T. C. Owen. It treats most fully upon all subjects connected with chinchona planting planting, and has evidently been most carefully compiled from all the books, pamphlets and reports on the subject in this and other countries, and from much personal observation. It is just the book required by the officers in charge of our plantations, and not knowing that anything of the sort was likely to be published, I had intended, as already reported, drawing up a somewhat similar though much briefer pamphlet, after I had had the advantage of some further experience outside our own limited area; this, however, will now be unnecessary. I hope that Government will take a certain number of copies of this Manual, and that the Nilgiri Cinchona office may be supplied with 25 copies.

THE FUTURE OF QUININE.

(*Communicated.*)

Quinine is not so low as quoted by you the other day, but it is true that one contract was entered into as low as at 7s 6d per oz. Immediately after, however, the price rose again to 8s.

The present low price though injurious to the few who may have bark cut and ready for the market, is undoubtedly to the advantage of everyone interested in cinchona, and who can wait for a year before cutting, as by that time the market will have doubtless recovered, and, as most of the cinchona in Ceylon is at a stage which will not admit of its being cut for the next year or two, the present fall may be considered for the general good.

Those who know the trade best are very confident of the great increase in consumption which the present prices will bring about, and that the use of quinine once taken up becomes a necessity and is never abandoned; so that consumption becomes permanently increased, even though prices should return to the old level. It was at about 5s 6d per oz. that quinine came into general use, and none of the ground gained at that low figure was lost when it reached 12s 6d per oz.

These are reasons why the fall is particularly opportune at the present time, checking, as it will, if not entirely stopping, the shipments of Cuprean bark which are now flooding the London market, and may be considered the primary cause of the depression. This Cuprean bark is brought to port at great cost and it was questionable whether even at late prices it would prove profitable to exporters. Besides checking the development of this new bark, all the inferior qualities of South American will now cease to be shipped and another gain will be the check which the manufacture and use of quinetum and other mixtures of the lower alkaloids will receive, which, it was feared, might in time becomes serious opponents of quinine.

It is interesting to notice, in connection with this question, that barks have not fallen proportionately with quinine vide the prices obtained for the parcels of Abbotsford bark at the last sales, and this may be accounted for by the fact that a large quantity of bark now goes direct to the continent, being bought in Colombo and elsewhere by the agents of the continental manufacturers, and thereby a great saving in freight

charges &c. is effected by the latter. The plan they were formerly obliged to follow in buying in the London market did not give them a chance to compete with the English manufaturer, and the result is a reduction in the price of quinine, and profit of the English maker without a fully corresponding reduction bark in the value of bark.

It is not, perhaps, generally known that, when Messrs. Howard & Sons enter into contracts to deliver quinine at a certain rate, they reduce the rate at time of delivery, if in the meantime the market has favored them, but should the market have gone against them, they promptly deliver at the contract rate. It is evident that such a magnanimous system of business could only be carried out where profits were very large, and this again accounts for the price of bark not falling proportionately with quinine.

It is evident that low prices mean increased consumption, which will not only be a remedy to their cause, but, by making the present manufacturer increase and improve his plant to meet the additional business, and by bringing new makers into the field, it will tend to reduce the cost of manufacture and increase competition to the manifest advantage of the raw material.

At first sight, it would appear that all cinchona property is reduced in value relatively with the fall in value of bark, but it must be borne in mind that this fall was anticipated, and has been calculated for in valuations and estimates made in connection with plantations and we suppose in no valuation has the full late market value been calculated upon. Taking this view of the case, cinchona planters have rather to rejoice at the expected fall having come in time to increase consumption and improve the general stability of the market, before the vast bulk of the Ceylon bark is ready to be placed upon it. Our aim should be the cultivation of barks containing upwards of 2 per cent of quinine *i.e.* officinalis and calisaya as these will suffer least from low prices. With succirubra we should recommend renewing under moss &c., to raise the percentage of quinine.

"FROM ADAM'S PEAK TO MINNESOTA."

Extracts from the letter of an ex-planter to a friend in Ceylon :—

Heron Lake, Jackson County, Minnesota, U.S.A., September 27th.

I was awfully glad to receive the *Observer*, which I knew came from you by the well-known handwriting. I thought of sending the copy of the *Observer* to our local paper anonymously, but do not dare, as they would recognize it. They had an article a short time ago against me for writing against their roads which we have to put in a day's work at, with a team, as poll-tax. Their method is rotten and you just "hitch up" and plough a burrow anywhere it suits you best, and nobody thinks of doing anything. I wrote and told them I should work my tax out on such a day and proposed bringing a pack of cards with me and requested the pleasure of all true lovers of euchre to join me, as it was so horribly dull having to pass all day there doing *nothing*. They termed the whole letter as "unfriendly, maliciously satirical and a production of trenchant wit," much to my own amusement. Since writing to you I have cut —— & Co.'s establishment and taken a section of land (640 acres) about ½ mile out of town, with 230 in grain, a nice house, barn, and granary ; the wheat, of which I had 75 acres, was as usual a signal failure, on account of wet weather. My flax, however, of which there is about 120 acres, paid me well, and I was luckier than my neighbours with regard to my oats, and notwithstanding rain for five months, almost without intermission, I shall get 10 per cent on the capital invested, and experience that grain-raising alone in this locality is not so paying as "mixed farming." I have been joined by a very nice fellow from home, and we intend buying sheep *extensively*, and also raising stock, colts, and hogs. A business which pays hand over fist here is *hay pressing*. A machine costs about £300, you buy hay (prairie grass) for $2 per ton, press it, and ship to St. Paul's, Minneapolis and Chicago, and make a clear profit of from $5·75 to $6 per ton. This line is at present monopolized by an American in this village, who has mortgages on pretty well everything belonging to the small farmers, and so has the whip-hand, but I am feeling my way around, and, as the country gets settled up with *Englishmen*, I shall probably go in for it myself. Upland grass averages from 1½ to 2 tons per acre, while bottom land hay varies from 3½ to 5. With hired labor it costs about 80 cents to 85 cents to put up. Sheep cost about $2 in the fall (autumn). They live on hay and in winter on ½ pint of Indian corn per day. You then have the dips of 6 lb. per head at 25 c. per lb. and sell as fattened stock for $5·50 and may allow 75 per cent of lambs. I think you will allow that this is a pretty paying investment. The tip for stock is to buy calves (six months old) in fall for $5, keep them through the winter and spring, and in summer you get $15 as fatteued cattle. Hog-raising is a very paying speculation, but I have no *reliable* estimate to quote. I should advise fellows with £1,000 or so, to buy half section, put in enough corn and oats for sheep and horses, 10 acres wheat for home consumption, and the rest of their funds into sheep, which give a quicker return than cattle, for which you must wait till you can get them into a favourable market, whereas the sheep give you an income from their clips, and you can also afford to wait until you think proper to sell. Raising colts requires great experience, and I only do it in the smallest way, such as having eight mares instead of horses, which are requisite for cultivation. Down south in Kansas, there is a lot of money to be made in stock, but you have to live in a "dugout" (a hole in a river bank), and are sure to die of fever, so I prefer making a little less in these healthy and more civilized parts.

I often think of the old days in Ceylon, and have a heap of your old letters with me, which I often look over, and pick up some good tips in buildings. I have had a lot of shooting lately. Duck, geese, prairie chickens (partridge) and snipe swarm, and you can feed yourself from them, but one gets to hate the sight of a bird, especially as cooking is not their forte in this land, the great object apparently being to cook the meal in ten minutes and to eat in five.

THE LANKA (CEYLON) COFFEE COMPANY.

We have been favoured with the Report and Balance-sheet of this Company for the half-year ending 30th June last, and we think the perusal of these documents is calculated to re-assure a good many who are inclined to criticise rather harshly the local planting enterprise. If it had not been for the expenses incidental to the starting of a new enterprise, the profit available for division would have been a good deal larger than it is, for we observe that the *gross* grain on the three estates Rappahanock, Ampitiyakande and Arnhall amounts to £10,255, the properties having cost £67,500, a sufficient proof surely to any unprejudiced mind, that coffee can still be profitably cultivated in Ceylon. We think the Report and Balance-sheet give a clear statement of the actual position,

shewing the net profit realized from each estate separately, so that no one can accuse the Lanka Directors of paying dividends out of capital. The Report is as follows :—

THE LANKA PLANTATIONS COMPANY, LIMITED.—Report to be presented at the first ordinary general meeting of the Lanka Plantations Company, Limited, to be held at the offices of the Company, on Thursday, the 10th day of November 1881 :—The directors beg to submit their report for the fifteen months from the formation of the Company to the 30th June last, together with the balance sheet, as audited, showing the financial position of the Company, the profit and loss account, and a crop account or statement of the working of the three estates, which during that period were in the possession of the Company. The balance of the profit and loss account is £6,692 10s 4d, out of which sum there was paid, prior to 30th June, £1,994 8s 11d for two interim dividends at the rate of 8 per cent per annum, and for interest on monies paid in anticipation of calls, reducing the £6,692 10s 4d to £4,698 15s 0d. Since the 30th June, £364 0s 2d has been paid for 6 months' interest to that date on monies received in anticipation and advance of calls, and £2,848 17s 6d has been distributed in a third interim dividend at the rate of 8 per cent per annum on the capital called up and paid, leaving the sum of £1,485 3s 9d, which the directors propose to carry forward to the new profit and loss account. The average price obtained for the coffee has been below the average of previous years, and the small quantity of cinchona which came forward was sent only to test its market value nevertheless the net profits have been equal to 10½ per cent. The Company is now in possession of seven well selected estates, and it is believed that as these properties are in different districts, a good average yearly profit for working operations will be attained, which the directors do not doubt will prove sufficient to ensure the payment of regular, and satisfactory dividends.

Name.	District.	Acr. of coffee in full bearing.	Partly in Bearing.	Forest and Grass.	Total Acreage.	Cost.
						£ s. d.
Rappahannock	Udapussellawa	360	86	14	460	22,802 7 3
Arnhall ...	Haputale ...	408	50½	15	473½	18,521 6 9
Rillamalle ...	Maturata ...	199	14	347	560	8,408 14 8
Ampitiyakande	Haputale ...	327	3	38	368	26,225 5 0
Gonagalla ...	Dikoya ...	183	3	—	186	28,561 12 8
Fordyce ...	do ...	450	—	20	454	
Thotulagala ...	Haputale ...	405	137	—	540	33,000 0 0
Fruit Hill ...	Dikoya ...	227	—	—	227	10,000 0 0
		2541	293½	434	3,268½	147,579 6 4

In addition to the foregoing, the purchase of a small property (155 acres) is contemplated, as it adjoins one of the estates belonging to the Company. The reports recently received relative to the condition of the estates are generally satisfactory, and the manager has been authorised to bring them into as high a state of cultivation as is consistent with true economy, and so to maintain them. The expenditure during the next two years may thereby be somewhat above the average, but in the opinion of experienced advisers such an outlay will be judicious, and, with favorable seasons, will certainly be productive of commensurate returns. It will be seen by the preceding statement of estates purchased, that the total cost of properties acquired has been nearly equal to the nominal capital of the Company. In some instances the purchases were made subject to existing mortgages, and to the amount of £25,666 13s 4d the mortgages have not been discharged. In two cases the mortgagees have consented to accept 6 per cent interest from the Company, and it is not proposed to pay those mortgages off. The other charges, which amount to £10,666 13s 4d, will, unless 6 per cent interest be also accepted, be paid off at their due rate, and to provide the requisite amount a call will be made.

From the Balance-sheet, we take the crop account which shews the profit on each estate :—

CROP ACCOUNT, 1880-81.

	Rappahannock.	Ampittiakande.	Arnhall.	Total.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.

Value of coffee (crop 1880-81) not yet realised	244 10 0	5,114 7 6	93 7 6	5,452 5 0
	11,922 13 3	9,518 14 10	3,932 1 0	25,403 9 1

We may, therefore, well congratulate the shareholders of this Company on the good business done for them in Ceylon by their Directors, Agents and Manager.

COFFEE PLANTERS AND THEIR CRITICS.

With reference to the letter of "Post Tenebras Lux" on page 605 we may remind the writer that Dr. Trimen and Mr. Marshall Ward have said their "say," and we doubt if they have "more last words" to utter conveying knowledge beyond the existing ken of intelligent and experienced planters. A special question has been dealt with by specialists—Thwaites, Morris, Ward, Trimen, and others. The disease has been diagnosed and pronounced not to be constitutional, but due to an insidious external agency, as difficult to destroy as the mythical personage who derived fresh strength from every fall on mother earth. For long-continued years the coffee trees were forced into heavy bearing by sharp pruning, but retribution did not take the form of a leaf fungus. *Hemileia vastatrix* resembles the wind: its effects we know; but the laws which govern its coming and going, we, as yet, know not. We have seen its coming, watched its existence with an interest the reverse of benevolent, and, with Irish vision, we hope to see it go out of sight. Meantime, it seems that crying further to Hercules for help will be of little use. Planters must put their own shoulders to the wheel. Many of them are or ought to be men of science, know-

ing thoroughly the main principles of the pursuit to which they have devoted their lives. If the external affection could be killed or kept from their trees, they know that health would be restored to the latter. But if the fungus can neither be killed nor kept away, then practical science as well as theoretical dictates such treatment as will best support the trees under debilitating attacks. Judicious and discriminating manuring and pruning are the planter's chief remedies, and science has no others to offer. Except in the covering of large spaces with one product, and, in some cases, planting up inferior soil, we cannot feel that planters have shewn ignorance or deserve blame.

CINCHONA ROBUSTA OR McIVOR'S "HYBRID."

We lose no time in giving a place to Dr. Trimen's comments on Colonel Beddome's Report, and it is with a feeling of relief that we find our experienced Director and Botanist denying "the soft impeachment" that he had, equally with the Colonel, condemned the application of "hybrid" to the fast-growing, large-leaved and robust cinchona so long associated with McIvor's name. After the explicit statements made by that veteran horticulturist as to hybridizing and the result in this plant which combined the good qualities of both *officinalis* and *succirubra*, it was with considerable surprize we read the following remarks in Colonel Beddome's Report on the Nilgiris plantations in addition to those we printed the other day:—

Hybrids—I am inclined to disbelieve in any hybrid of Nilgiri origin; it has been stated that there are many hybrids amongst the "Officinalis" and "Calisaya" trees, but after most careful examination I can see no indication of such, nor have any of our trees the characteristics of hybrids, which I am sure would not seed so prolifically; individual twigs may be gathered from many "Officinalis" trees and also from "Calisaya" showing great difference in the shape and size of the leaves, but the same difference may be found on one and the same tree, and often on the same bough. We have varieties or sports of species, such as "Undusinga" and "Angustifolia," varieties or sports of "Officinalis," sometimes looking very distinct but at other times running into the type and not to be distinguished; but of hybrids between distinct species I do not think we have any.

Hybridizing experiments.—Though I do not believe in accidental hybrids between different species on the Nilgiris, I have no doubt that the different species could be crossed. I am not inclined, however, to recommend any experiments of this nature, as it would be useless to attempt it without the services of a scientific gardener, thoroughly trained in the art of hybridizing, such as Mr. Dominey or Mr. Seden on the establishments of Messrs. Bull and Veitch, and such a man could only be procured on a very high salary, and other expenses connected with any experiments of this nature would be very costly. The experiments would be exceedingly interesting and of great scientific value, but practically perhaps of no value. We have now in cultivation all the finest-known species of the genus, and it is not likely that hybridizing would improve the bark, or give us anything better than, or as good as, we now possesss; so that we might be spending large sums to get some variations in leaf and flower, or perhaps in some cases sturdier growth.

From a Wallaha correspondent we first received the news that Dr. Trimen agreed with Col. Beddome that there were no hybrids, and since then we have had no light until the Director's letter came to hand today. After its persual, we think few of our readers will have any doubt that Trimen, McIvor and Howard are right, and Beddome and Cross mistaken, in the view they have taken of both the pubescens and smooth-leaved, robust cinchona trees—the "cinchona of the future" as some think—which are to be found freely scattered throughout the Ceylon and Nilgiris plantations.

COFFEE CULTURE.

We call attention to the letter of Mr. John Hamilton on page 607. On the supposition, which we suspect many will deny, that General Maitland Showers' premises are correct, the important question arises whether *ageratum*, is left to its own sweet will for months, at certain seasons of the year, would not flower and seed, and so infect not only the adjoining coffee on the same estate but that on neighbouring estates. Looking at the mode of culture pursued in India and Java, many a Ceylon planter might feel inclined to let weeds grow. But he has to consult the wishes of neighbours who may not agree with him. How is the difficulty to be got over? On Kandanuwara estate, the sweeping of leaves and weeding were combined. Is it so still, and what are the results?

BOTANICAL GARDENS IN INDIA.

The *Times of India* has a very good article on Botanical Gardens in India, and their functions, from which we quote as follows:—

A botanical garden ought not to be a mere pleasure-ground—it ought not to be a mere living museum of the various forms of vegetation; but it should be the model for all private establishments; it should aid them in everything that is useful in the vegetable kingdom. A Government botanical garden ought to grow every plant which is to known to have any useful application, and these ought to be distributed at a small charge to those who want them. We do not want our superintendents of botanic gardens to be mere market-gardeners, for, we believe that the truest and surest foundation of economic botany lies in pure botany, and that the vegetable products of a country can never be to their fullest extent utilised without the aid of scientific knowledge as a guide. But we think the principle needs enforcement that our Government gardens ought not to sacrifice economic botany for pure botany, but it also contains objects of purely scientific interest. Kew attempts to give an illustration of every possible use to which vegetable products can be applied. The gardens at Kew have done a grand work in plant distribution in all parts of the world.

Our readers will agree with the sentiment while they sympathize with the writer of the article in being made by the printers to say:—

What it has done in such matters as cinchona, caoutcheric, Siberian coffee is well known.

Coffee has a pretty wide range on each side of the equator, and in favoured positions it flourishes even somewhat outside the tropics. But certainly the latitude of Siberia would not suit it, although Liberian coffee seems destined to be printed "Siberian." "Caon" might be mistaken for cacao, but for the immediate sequence of the remarkable word *tcheric*, which resolves the mystery and shows that from "caoutchouc" or indiarubber two new and hitherto unknown products have been evolved by this compositorial genius. The concluding paragraph is as follows:—

We wish to know what the botanic gardens of this Presidency have done towards their improvement. The climate of Poona is superior to that of Lucknow, the soil

is richer, and Poona possesses a canal which could irrigate any number of acres. The parties, we consider, have a right to have the question answered—What are the gardens at Poona doing for horticulture and agriculture?

What is here printed "parties" was no doubt written "public." But, reverting to what is said of Kew Gardens, we again quote:—

Sir William Hooker in one of his reports writes;—"Upon the Royal Gardens devolved the duties of receiving and transmitting the seeds and plants to India, of raising a large crop of seedlings, of nursing the young stock lest those sent on should perish, or the seeds loses their vitality, and of recommending competent gardeners to take charge of the living plants from their native forests to the hill country of India and to have the care of the plantations there. Further, with the sanction of the Indian and Colonial Governments, it was arranged that our West Indian Colonies and Ceylon should be supplied with a portion of the seeds." The success of cinchona in India is now an undoubted fact, and this country owes to Kew a debt of gratitude.

Then comes an equally well-merited tribute to the Saharanpore Gardens in North-Western India and to Dr. Jameson as the introducer of tea cultivation on the lower ranges of the northern Himalayas. Among heaps of papers which we intended to publish, but never found a convenient season to do so, is a very interesting and valuable letter on which Dr. Jameson reassured us as to the cultivation of tea at high elevations, his opinions having since been fully sustained by the high quality of Kangra Valley and Darjeeling teas. Saharanpore is on the route to Roorkee, the Dehrah Doon, Mussoorie, and Landour—the two latter real "abodes of snow," and the degree of cold secured at Mussoorie and even at Lucknow accounts for the flourishing of strawberries, apples and other European fruits, as noticed in the following extract:—

To the gardens at Kew, then, India is indebted for the introduction of cinchona, which promises to be one of her most valuable products, and to the fine garden at Saharumpore she owes the development of the cultivation of tea. Mr. Buck, the director of Agriculture and Commerce, writing about the condition of the garden on the retirement of Dr. Jameson, who has won for himself a European reputation, states:—"Through his position in charge of the gardens, Dr. Jameson was enabled to develop what has proved to be the most successful and remunerative enterprise which has been carried out in India under the British Government, *viz.*, the cultivation of tea. The wealth acquired by India through Dr. Jameson's efforts in the development of the tea industry has repaid Government over and over again for any outlay which has been expended on these botanical gardens. Dr. Jameson proved that in an Indian botanical garden science can be combined with utility. He not only developed an important industry, but he also founded and maintained a museum, one of the finest views* to be met with in Upper India, and he accumulated an important herbarium."

The report on the progress and condition of the Government Botanical Gardens at Saharumpur for the year ending 31st March, 1881, proves that the gardens have not suffered either in economic or scientific point of view under Mr. Duthie, the able botanist, who succeeded Dr. Jameson. The grant sanctioned by Government for expenditure on the Saharumpur and its two affiliated gardens (at Mussoorie and Dhaugair) during the year amounted to R30,000 and the actual expenditure amounted to R21,521, so that there was a saving of R5,000. But this saving was not gained at the cost of efficiency. There was a considerable increase in the distribution of plants and seeds. Almost any kind of fruit trees can be raised at the Saharanpur Gardens. And there are to be seen there "rows of plum trees bearing magnificent crops of fruit, though they had received but little special treatment." Mr. Duthie informs us that a large number of young fruit trees have been permanently transplanted throughout the garden during the year. In the piece of ground known as the farm over 500 of different kinds have been planted out. They all promise to do well, and in the course of four or five years their yield of fruit should bring in an income almost equal to our present "annual receipts for fruit." The Superintendent adds:—"Very great progress has been made, both in Europe and America, in the improvement of different kinds of fruit, and a good deal could, no doubt, be done in this country." The Portuguese showed us how much could be done in the improvement of mangoes, and a great deal, no doubt, could be done in the improvement of the peaches of Panchgunny, the strawberries of Mahableshwar, and the grapes of the Deccan. With regard to vegetable cultures we are told that, with the exception of *artichoke, lettuce, beans, peas, mustard, and cress*, it was useless ever to think of raising vegetable seed in this country which could at all compete with home-grown seed." However, in order to be supplied with cauliflower during all the cold season "both English and acclimatized seed is required." If the acclimatized seeds is sown in June, July, and August, fine heads can be cut in November, December, and January. The same seed, if sown later than the end of August, runs into flower without forming a head. English seed, on the other hand, when sown in June, sometimes does not germinate, and when it does successfully germinate the plants are often killed by the damp heat during the rains. "When sown in August, September, and beginning of October fine heads can be cut from January until the middle of April." At the Saharanpur Gardens success was obtained in the cultivation of *Taraxacum* and preparation of the extract. We agree with the North-West Government in the remark that "there is no field where there is more room for doing good service in the gardens than the production of indigenous drugs. At present dispensaries and medical practitioners are dependent for the supply of these drugs on the dealers in the native bazaars; and it is often impossible to be sure that the article supplied is genuine and of good quality, or that from long keeping it has not lost its peculiar value." This distrust of bazaar medicines is well warranted by facts. In many cases bazaar medicines are simply trash. Not only bazaar medicines, but many now imported at great expense from Europe for the use of the army, jails, and dispensaries might be grown in the country. We see no reason why ipecacuanha, belladonna, aloes, jalap, digitalis, podophyllum, quassia, dandelion, and others should not be grown in India. Dandelion and senna used to be supplied to the Medical Department from the gardens at Saharanpur, and we see by the last report that hyoscyamus is supplied still to Calcutta, Madras, and Bombay.

The report on the Horticultural Gardens, Lucknow, for the year is as satisfactory as those on the Saharanpur Gardens. In fruit culture Lucknow almost carries away the palm from Saharanpur. Experiments were made in cultivating the Malta oranges in good soil, and oranges were grown at a net profit of R88 per acre. Peaches were cultivated at a profit of R30 per acre, and plants of six kinds of peaches were added to the gardens. There are two established plants of Black Hamburg. "The superiority of this vine over what are known as Bombay Red and Country White in such important points as regularity of bearing and flavour is well established." Strawberries are grown at Lucknow, and are larger than those grown on the hills. Two kinds of loquats are grown in the garden, and plants of the Avocado pear and the apricot have been planted out and doing well. Numerous experiments were tried in early sowing in vegetable culture, and the produce of different seeds was compared. The silver-skin onion was introduced from Italy with success. The efforts to acclimatize vegetable seeds have not at Lucknow as well as Saharanpur been successful. However, the Blue-books prove, in spite of certain failures, that excellent work has been done in Indian horticulture by the botanic gardens at Lucknow and Saharanpur. From both the distribution of all kinds of trees and smaller plants besides—some for a small sum, others gratuitous—has for some years been extensive. These gardens and the agri-horticultural associations in other parts of India have done a great deal of good in the way of disseminating seeds of English flowers and vegetables. Much, however, remains to be done, even for the gardens of Europeans, and almost everything for those of natives, the poorer class of whom are too ignor-

* "Views" (?) is another misprint which defies us.—ED.

ant to profit by any efforts that are not particularly directed to them. The necessity for improving Indian horticulture and agriculture is a point that requires no discussion. Now that Mr. Buck has been afforded larger scope for his efforts on behalf of Indian agriculture and horticulture, we look for many and great improvements.

CHEMICALS AND LEAF DISEASE.

Mr. Schrottky writes :—

"In what I said about the sulphur and lime treatment establishing sour and therefore congenial conditions for the development of the fungus, I referred only to that portion of sulphurous acid gas which would be absorbed by the foliage without being neutralized by lime or other soil ingredients. I have a very high opinion of the manurial value of sulphate of lime (gypsum). Having regard only to what degree manures can affect leaf disease, my inoculation experiments led me to believe that chlorides, nitrates, bisulphates, superphosphates and all acids and sour organic manures are apt to increase the susceptibility of the tree to the disease. Sulphates, phosphates, or generally speaking neutral salts that can combine with another atomic weight of acid, all alkalies and antiseptic chemicals (other than chlorides and such as do not owe their antiseptic character exclusively to their oxidizing or deoxidising power) decrease the susceptibility of the tree to fall a victim to the disease. Oilcake, for instance, ought to be well rotted in pits with thrice its volume of soil for about three months before it is put in the ground."

We need scarcely dwell on the importance of this statement regarding oilcake. If accepted by planters, it means a considerable additional expenditure in manuring. There is first three months' loss of the use of capital and the interest of the money paid for oilcake. Added to this will be the cost of forming pits (which ought, we suppose, to be protected from sun and rain, or at least rain?) and of placing the oilcake in the pits, treatment to induce the rotting process, and finally removing the mass from the pits for application to the trees.

CHINCHONA.—Mr. Cross who was sent out to India some time back to assist the Madras Government in the propagation of Cinchona Santa Fe plants on the Nilgiris, returns to England early in December next. The plants are reported by the Officer in charge of the Nilgiri plantations to have been sufficiently well established, and their safety secured, so that the further retention of Mr. Cross in this Presidency has been found unnecessary, and he has, therefore, been provided with a return passage to England at the expense of the State. The Government have also placed on record their recognition of the valuable advice and assistance received from Mr. Cross during the comparatively short period of one year.—*S. I. Post.*

COFFEE LEAF DISEASE AND ITS CURE.—A scientific arthority, who is equally sceptical of the value of carbolic acid vapour as he was of sulphur in Mr. Morris's mixture, is inclined to believe that further experiments will shew that the benefit derived by the coffee in each case will be found to be due entirely to the *lime* in the mixture applied. It would be a curious coincidence if it were found that to the action of the lime should be attributed the good done in all the experiments of Mr. D. Morris, Mr. Ward, Mr. Schrottky, and perhaps of Mr. J. P. Storck! But that is not likely.

TEA IN YAKDESSA.—This moist region is regarded as capable of producing as abundant crops of tea as any district in Ceylon. Quantity there is in abundance; the only doubt has been about quality. But, to judge by the sample we have had of Sembawatte tea, we should say its leaf, if as well prepared as this, promises to yield as good tea as any in the island. The flavour is full and fine and the leaf well rolled and fired, and we congratulate the proprietors and Mr. Ross Wright, the manager, on the result.

INDIA *vs.* CHINA TEA.—We have received some circulars issued by Mr. Goodricke, grower and importer of Indian tea, who has offices in Mark Lane and Cannon Street, London. One of these circulars shows the excellence and purity of Indian tea, while the other is headed "China Tea—what it is! Maloo Mixture!!!" and gives an extract from the *Home and Colonial Mail*, regarding some abomination imported under that name. We are glad to see that India tea is gradually winning its way and ousting its Chinese rival in Britain.

COFFEE SACKS.—In response to various complaints, the São Paulo Railway Company published a circular on the 22nd ult., in which were the following instructions relative to carrying empty coffee sacks:—The sacks should be made into packages and legibly marked with the name and address of the consignee; the empty sacks will be transported free; the shipping bill should specify the number of packages and weights; the packages will receive the same care as regular freight. This certainly ought to satisfy all the parties concerned.—*Rio News.*

A COMBINATION COTTON-PICKER, with fingers of iron, is working a revolution in cotton-growing in the United States. It will, it is thought, reduce the price of cotton two cents a pound. The machine, by means of beaters and fans, takes the fibre from the boll, removes the seeds and all impurities, finally delivering it straightened, ready for the bale. Efforts are making to develop the invention in season for exhibition at Atlanta.—*Ibid.* [This reminds us of Nelson's finger and thumb machine, intended to pulp coffee beans as they were gathered. It produced only amusement.—ED.]

AN AMERICAN ENTOMOLOGIST advocates the use of arsenic for the destruction of cotton worms, and says it will cost only a cent and a quarter per acre to exterminate the worm with that poison. The method of employing it, which he recommends, is a solution made by adding to five gallons of water five pounds of arsenic and one pound of soda, and boiling until the arsenic is dissolved. In using, one measure of the solution is added to 160 measures of water, and sprinkled upon the plants infested by worms.—*Ibid.* [Query? Application of this solution, for the destruction of grub. It might kill them without injuring the roots.—ED.]

MERCARA, 11th Nov.—Regarding coffee, it is impossible to say what immense good has been done by the rain that has fallen since the 2nd of November. Over six inches have been registered, and the sky is still overcast. The young saplings have renewed life in them and are now firmly established, whilst the coffee berries that were, by the intense heat being prematurely ripened, have obtained a reprieve, and will will now increase in stamina and size, and less exhaust the tree—in fact, save it from dying. It is reckoned that hundreds of tons will be thus saved, that otherwise would have either dropped from the trees, or turned into light beans. As an example, an estate that would without these rains have barely yielded 35 tons, is now assumed to promise 45 tons. A flying picking has commenced on a few estates in South Coorg, but it will not be general until the 1st of December. Leaf-disease is gaining ground over the whole of the country.—*Madras Standard.*

Correspondence.

To the Editor of the Ceylon Observer.

NO BEES: NO BERRIES.

DEAR SIR,—The enclosed cutting from a home paper may (if you can find room for it in the *Observer*) be of interest to some of your readers.—Yours truly,

JOHN PATERSON.

NO BEES, NO BERRIES!—The common flowering currant is much frequented by bees as well as by other species of insects, and usually produces abundance of berries. The writer, last summer, carefully covered with muslin several of the newly-opened blossoms of this bush. This had the effect of preventing any insect gaining access to these flowers, and it was observed that they continued fresh and bright long after all their unprotected neighbours had withered, and that, whilst an abundant crop of berries was produced on all the exposed branches which had been visited by bees, not a single berry appeared on any of those from which insects had been excluded by the muslin.—*Professor Wilson in "Good Words."*

COFFEE LEAF FUNGUS ON OTHER TREES.

DEAR SIR,—I now send you some kitul, cinnamon, suriya, and other jungle leaves, even creeper, ferns, and grass, taken from a native man's garden (which all show the pin-spots), in proof of my former statement—that leaf disease having left the coffee has taken up its quarters in a native man's garden. I may call it jungle, as it is full of large trees as well as underwood and abandoned coffee.—Yours faithfully,

J. H.

[The leaves sent to us shew no signs of *hemileia* when scientifically examined: the spots are due to other causes.—ED.]

PLANTING ENTERPRIZE IN BORNEO:

A CEYLON PLANTER'S EARLY EXPERIENCE.

Sandaken, North Borneo (via Labuan), October 23rd.

DEAR SIR,—I promised, when leaving Ceylon, to let you know from time to time how planting matters progressed in this part of Borneo, but I am afraid I have nothing of much interest to tell you at present.

I had a very pleasant voyage here, stopping a fortnight at Singapore, at which place I had the pleasure of meeting several old Ceylon planters, namely, Messrs. Parry, W. W. Bailey, E. A. Watson, W. J. Garland and C. H. Bagot, all of whom, I am glad to say, appeared in a flourishing condition, and were most kind in assisting me to see what I could of the country while there. During my stay, I visited the Johore plantations; as well as the tapioca, gambier, pepper, citronella estates around Singapore, all of which were most interesting. I was sorry to miss seeing the sugar estates at Province Wellesley, but our stay at Penang was too short.

Since my arrival here I have been, and still am, travelling about the country, but I hope to settle down in the course of another month. I have selected a piece of land for my experimental garden about 25 miles from here and on the banks of one of the many rivers that flow into this fine harbour. All these rivers are navigable for many miles and will be most useful for transport. In my travels, I came across some old cocoa trees, bearing well, though in a much neglected condition. My garden will consist of coffee *Arabica*, Liberian coffee, cocoa, citronella grass, pepper, vanilla, tea, jute, tapioca, tobacco, sugar, cinnamon, ipecacuanha, nutmegs, cinchona, cardamoms, India-rubber, Manila hemp, and several useful shade trees; so that I hope to be able to supply the wants of my planters who may come here.

I had a very pleasant trip to Sulu, a small island two days' journey from here, and belonging half to the Sulus and half to the Spaniards, and which is, as regards soil, a regular little gold mine, but unfortunately has a very unsettled Government. I was told there was one European there who grew coffee, cocoa, tapioca etc., and whose plantation I was very anxious to see. It is only one hundred feet above the level of the sea, but nevertheless what few coffee (*Arabica*) and cocoa trees he had were bearing a heavy crop. I sought anxiously for leaf-disease but could find no signs of it, though plants at Singapore, which came from this island, had as bad an attack as I have seen anywhere.

I am getting all my coffee and cocoa from Sulu, and thought of sending some of the former to Ceylon, but I remembered the fate of the Blue Mountain coffee at Peradeniya and did not get any. If, however, any planter would like a very little seed, *as an experiment*, I shall be happy to do my best to procure some.

Our natives here prefer carning a living by the rich produce of the jungle, to agriculture, but Chinese labour can be procured easily and cheaply; so that their services will not be required. I hope to finish my low-country garden about September, and then steer for the north of the island and start one "on the hills."

The *Tropical Agriculturist* (or "Enquire Within") is much appreciated, as also is the *Ceylon Observer*. Mr. Pryor, the resident here, who has had great experience in China, pronounced the Ceylon tea, which I brought with me, as being of a most excellent quality, and does not wonder that "John Chinaman" has got to shut up shop in Ceylon. Has any one ever tried importing Ceylon tea into that country (China)? I anticipate a good deal will be grown here some day. Our climate and soil ought to suit its growth, the rainfall last year being 157 inches evenly distributed throughout the year. I append rainfall, as it may be of interest to your readers:—

I am glad to see the old P. A. has had a very successful meeting and that the Haputale wound has been healed.

Mr. Schrottky's experiments on leaf-disease appear not to be thought successful, but I hope they will nevertheless throw some further light on the subject. Messrs. Whittall & Co. certainly deserve the thanks of the P. A. for the plucky manner in which they gave up an entire property for Mr. Schrottky's experiments; not to mention the heavy outlay they have incurred. I see the Secretary of State for the Colonies has at last consented to allow the introduction of Indian cooly labour into the *Native* States, provided the consent of the Indian Government is obtained. This is, I think, a step in the right direction, and I hope before long to see some boat loads of them *here*, where they will get a good climate, good wages, cheap rice, and every protection from an *English* Government.

Trusting you are all busy with crop,—I remain, dear sir, yours faithfully, L. B. VON DONOP.

P. S.—I hear an application for land (the first) has just been received from a gentleman in China.

"NEW PRODUCTS":—CHANGE IN THE MODE OF TANNING LEATHER.

London E.C., 24th Oct. 1881.

SIR,—So many of your subscribers ask me to keep them informed of the natural products which are likely to turn to a profitable account, that I think I cannot do better than to give you the opportunity of publishing a change that is sure to take place in the mode of *tanning* leather in this and other countries.

It is known to most of your readers that the old process has been to place the hides in pits, and, after the hair has been taken off by lime, purge out the lime by glucose: they are then placed in pits and exposed to the action of bark, the tanning of which is extracted generally by cold water. To obtain perfectly tanned butts, it has been thought necessary to wait twelve months for the tannin to enter the hide.

The Americans have shewn that by using extracts, prepared with hot water and carefully sent to this country in casks, the process has been greatly accelerated. Other compounds have been found which assist in turning out the leather rapidly, and tanning it effectually and sufficiently. Some of the advanced tanners now go so far as to say: "We admit the great difficulty there is in collecting and drying the bark of trees, also the costliness of the freight, owing to the unsatisfactory nature of the packages, and, at the same time, we admit that we can with much greater effect employ extracts."

Since they have had the small "tannometer" or "tann-tester," which only costs £4 complete with glasses and test tubes, they are enabled to gauge exactly the value in tanning matter of anything that they may use, or that may be offered to them, and it is only this week that I have had sent me, by one of the most advanced tanners who thoroughly understands chemistry, two barks, which are said to come from India, which yield 15 per cent of tanning. The extract from this wood can be easily made on the spot, and shipped home in casks, or cases. One is "Acacia Arabica" babao bark; the other material we have not yet found out the name of for certain, but it is one of the varieties of the "mimosa."

Another great point gained is that, in India, extracts are so easily made in large pans, and the sun so helps in evaporating the last portion of the moisture, so that extracts actually come from hot climates in *better* order than they can be prepared in the cold damp climates. In South America, where there is a large quantity of fine tanning material, such as the red Quebracho ('Quebracho Colorado"), they can make the extracts, but they are not so well off for coopers to turn out the casks at a low price; but there is room for all. I need hardly add that I shall be delighted to render your subscribers any further information in my power, and also put them in the way of testing the value of the trees and plants that may be growing around them.—Yours truly,

THOS. CHRISTY.

[The Government of India have published numerous and elaborate reports on tanning barks, but there is room for further experiments in the direction of preparing extracts.—ED.]

POTASH VERSUS SUPERPHOSPHATE OF LIME AS MANURE FOR COFFEE.

32, Great St. Helens, London, 28th Oct. 1881.

DEAR SIR,—It is a long time since I inflicted a letter on you, and I will not allow another number of the *Tropical Agriculturist* to reach me, without complimenting you on the idea and its execution. I observed in No. 1 that Mr. Hughes had fired a parting shot at me, to which I turned my other cheek, having passed the age when an accusation of wasting anything is likely to apply. In this case, the expression "expensive fertilisers of an exceedingly soluble nature" is singularly infelicitous, since the mixture I use costs just about half as much as that recommended by himself, and should be worth about one-third more according to the valuation. So much for the expense. Now for the solubility: I do not use superphosphate at all, because, unless I am very much misinformed, it is *too soluble* for soils containing a large proportion of iron, which has a greater affinity for it and turns it into phosphate of iron instead of phosphate of lime. Moreover, the Aberdeenshire experiments shew that a finely ground bone-dust or natural phosphate is for us coffee planters quite as soluble (practically speaking) as superphosphate, and much more lasting. I maintain my opinion as to the necessity of a larger proportion of potash than Mr. Hughes recommends, and I have another year's results to confirm it. Before entering upon them, however, I will mention that, conversing with Mr. Dyer some time ago on the subject of potash, he remarked that most probably our soils had a much greater affinity for it than was generally supposed, from the heavy rainfall they had to endure. He said he would test the idea, and afterwards most kindly sent me the results in an interesting paper, too long to give *in extenso*. I may summarize them as follows:—

The soil experimented on contained			
Oxide of iron about...	...	...	10·7
Alumina	,,	...	10·7
Potash	,,	...	·275

Two columns of soil 16 inches deep had a top-dressing of muriate of potash = 2½ tons per acre (of course an excessive dose); 81 inches of rainfall percolated through the soil without potash extracted = ·0029 or about 1·100th of the natural potash. The same water extracted only 1-12th of the added potash, so that 11-12ths were fixed by the soil. With nitrate of potash (saltpeter) 81 inches water removed 1-10th and a further 81 inches 2-10th; so that 162 inches rainfall removed less than 3·10ths—which does not look like "exceeding solubility."

I have steadily persevered in the same plan for the last 3 years, and have but one uniform report of marked improvement in results. In Wynaad a new head-superintendent, a gentleman fresh from Ceylon, appears astonished to find estates so free from leaf-disease and with a good crop on them. From two or three Ceylon friends who have followed my advice, and from Coorg, Mysore, and the Neilgherries, I have the same encouraging results, and by the last mail only I learned something I have been anxious to know. On estates poor in phosphates but rich in potash, I applied bone-dust alone, and the mixed manure. The superintendent reports:—"There seems to be little difference between the parts manured with bone-dust and those done with the mixture, so far as leaf is concerned, but crop is heavier where the latter manure was applied." An estate I mentioned in a previous letter as richer in potash than any I had heard of (·418) where I intended trying the mixture, notwithstanding Mr. Hughes' objections, gives the same result, and the report is:—"The half of the northern bank done with the mixture, when I took charge in April 1880, has a splendid crop and abundance of new wood." The previous year it did not pay expenses; in fact, had, I believe, never been manured at all.

I write this mainly because I have many friends interested in Ceylon, and I observe there a sort of reckless rushing after every quack of whatever nationality who rattles off a lot of glib nonsense, and after any product you can mention except the good old staple coffee, which I believe and have found, only

requires fair treatment to give a generous return. The British grocer is, I consider, our worst enemy, so long as he is allowed to sell any infernal mixture that can be put into a tin with a showy label, and call it coffee. We sadly want some organization at home to look after our interests, free from any local prejudices and action against common enemies. Even a few pounds spent in analysing and exposing the mixtures palmed upon a credulous public would be productive of some good.—Yours faithfully, H. TOLPUTT.

COFFEE CULTURE: TAKING REST IN SLEEP" OR——?

Kotmale, 18th November 1881.

"It may perhaps occur to the planters' mind that, if *rest* be required in Ceylon to recruit the strength of the coffee tree, the remedy has been taken in hand by the tree itself, in only yielding about one-third of what it was formerly capable of doing."—*J. P. G.'s letter of 19th October* 1881.

"Some estates hold forth promise of even large crops, and the general aspect is decidedly better than it was last year at a corresponding period. There can be little doubt that this improvement is largely due to the more favorable season of the current year, and the condition of the trees after the *rest* of last year." —*Concluding paras of the Prologue to Mr. Marshall Ward's Third Report on Leaf-Disease.*

DEAR SIR,—What is this 'rest' that is talked of? Is it the repose of the tomb which appears to be already closing over the life's work of coffee in Ceylon; or is it *really* rest, *i. e.* a season of refreshment? We know that, chemically speaking, there is no such thing as rest: whatever the organism may be, there is *always* some change in progress, be it of composition, or decomposition. If our coffee is not being resuscitated, then, *a fortiori*, there is decay in process, and such a change we can hardly call remedial 'rest.'

We may safely assume that what was meant in both the writings cited above was a state of preparation for further work, rather than an entire ceasing from work. And, if I read these writers aright, surely, they would not intentionally speak of 'torpor,' "nor any want-begotten rest," as likely in any way to benefit our coffee!

Coffee is no free agent to be fruitful or barren as the humour leads her. If rest is wanted—and who can doubt that it *is* wanted after the years we have been forcing, and more lately trying to force abnormally large crops from our trees? and it should be noted that it is these years alone "wherein we have sufferred adversity"—then we must keep our knives off the live branches and our mamoties and forks from the roots.

It is not in this country as in old England, where you can, by heavily pruning, force a large or extraordinarily good crop of fruit to be borne by trees for which a bountiful providence has assigned an unmistakable season of apparent rest. Assuredly we have no reasonable grounds to look for a good "next year" sort of crop and also a supply of wood for the coming season, as the results of our annual heavy prunings. It seems on the surface to be against all laws of arboriculture!

No doubt both Dr. Trimen and Mr. Marshall Ward have observed many most flagrant violations of laws agri-and arbori-cultural in the management (?) of our coffee estates. One can only respect their silence, remembering the old Greek saying, "Nothing is more" disgraceful than meddling with other people's affairs. But if you, Mr. Editor, would ask one of these gentleman to give us planters a few plain hints on such matters as the use and abuse of pruning, manuring, and weeding, I feel sure that, apart from his ex-officio duty to furnish such, he would be glad of the opportunity of rendering us such a politico-economic boon. The P. A. might make a collection of planters' doubts on the utility or futility of the work's above mentioned, and from them extract a catechismal set of questions. This would simplify the work of our instruction. Or if in the face of our favorable seasons, and their concomitant leaf-disease, those gentlemen think that much may yet be done for our staple at a cost within the means of most, and that all our toil and cultivation is not absolutely *stone boiling*, let them, while there is yet time, bring to our rescue the wisdom of their years of scientific research and learning, that it may not be said, a few years hence, as the last sad planter waits, watching for the last cherry to ripen, ere he quits this land for ever:—

"Science moves, but slowly, slowly,, creeping on from point to point:

"Knowledge comes, but wisdom lingers, and I linger on the shore;

"And the individual withers, and the world is more and more.

"Knowledge comes, but wisdom lingers, and he bears a laden breast

"Full of sad experience, moving toward the stillness of his *rest*."

Faithfully yours,
POST TENEBRAS LUX.

CINCHONA CULTIVATION: FROTOFTS' FORTY-FIVE ACRES OF OFFICINALIS.

21st November 1881.

DEAR SIR,—In your issue of the 19th instant, mention is made of 45 acres 4½ yr. officinalis in Rambodа yielding 25 tons dry bark when uprooted, and that this was sold for £11,200.

Could not the particulars of this very remunerative transaction be obtained and made public? I refer more especially to the number of trees to the acre, their height and girth.—Yours truly, PLANTER.

[See paragraph on page 609.—ED.]

THE ROBUST CINCHONA OF CEYLON.

Royal Botanical Gardens, Peradeniya, 25th Nov. 1881.

SIR,—I have read with much interest, in your columns, Col. Beddome's account of his short visit to Ceylon and his impressions of cinchona cultivation as carried on here. Taken in connection with his previous able report on the Nilgiri plantations, we possess his "views" in a very clear and definite form.

I purpose to make at once a few observations upon the robust and quick-growing cinchona of Ceylon and Southern India, with which it seems likely Col. Beddome's name will henceforth be connected, since he considers it in all respects *the* kind to cultivate. And first, I wish most distinctly to disavow the conviction attributed to me in this report, that I am "fully convinced that it is a perfectly distinct species." Such is far from being the fact, and I am at a loss to understand how my friend the Colonel could have deduced such a view on my part from our frequent discussions on the subject. Ever since I have known the plant, I have avoided any dogmatism as to its origin. In Mr. Owen's little "Manual" I say of the smooth-leaved form that it "may be another variety [of officinalis] or not improbably a permanent hybrid of officinalis with succirubra," and of the pubescent form that it "approaches C. succirubra" (pp. 23, 24). It *may* turn out a distinct species, but I think that data are wanting still to settle the question, and that Col. Beddome's report does not supply them. In our view of the plant being a "hybrid," we, in Ceylon, have, of course, followed

Mc Ivor, who, on many occasions since 1872, had stated such to be the case. Col. Beddome throws over the late Superintendent without hesitation as untrustworthy, and pins his faith to the recollections of Mr. Cross. Apart from the latter's story of the collection of the plants (which will be found in a letter printed at p. 32 of Col. Beddome's report*), the only direct evidence against McIvor's view brought forward is that trees are found "in the oldest plantations [1862] at Nedivatam;" but it appears that this is not Col. Beddome's own observation. The earliest plantation in which he has seen trees of the kind is one of the 1865 planting, and no satisfactory evidence is given that the plants here were not supplies. The acknowledged fact that sowings of the seed always show a proportion of succirubra and officinalis in the progeny is readily disposed of by the observation that it is "of course" due to careless gathering. Careful experiment alone can decide this point—in a practical planter's view, the most important one of all: it will not be settled by dogmatic statements one way or the other. As regards the characters of the plants, they are in all respects intermediate between officinalis and succirubra, and in every point and degree in which a given specimen differs from one of these species it approaches the other. The intermediate character is also carried out on the whole in the proportions of the alkaloids in the bark, variable and uncertain as is the analysis of these trees.

No doubt Col. Beddome may prove to be perfectly right in his opinion as to the autonomy of this cinchona: I merely wish to point out that in my opinion the evidence he brings forward is by no means conclusive.

But indeed on this matter the Colonel's opinion possesses less weight than it might have from the singular position he has taken up with reference to hybridity in cinchona in general. This is, of course, not the place to enter into any discussion. It is scarcely necessary even to point out that the dimorphic arrangements of the flower which Col. Beddome cites as conclusive against natural crossing are precisely those which have been shown over and over again to be those specially adapted to ensure cross-fertilization by insect agency. The production of hybrids in nature is by no means an uncommon thing. In some genera they are frequent; and whether our "hybrid" cinchona turn out to be one really or not, that cross-fertilization and hybridity occur in our mixed plantations by the visits of insects to consider almost certain. Mr. Moens is now engaged in an elaborate series of experiments in artificial cross-fertilization with the object of comparing his results fwith the naturally-produced sports and varieties in the plantations. This is a long business, but in due time we may hope to have some direct evidence on this perplexing matter.

I also desire to say a few words as to the name which this cinchona should bear. It is I think much to be regretted that the name "Pata de Gallinazo" should have been brought out of its obscurity by Mr. Cross and adopted (even provisionally) by Col. Beddome. This is a mere bark-collector's name and is used in different parts of the Andean chain for at least 6 different kinds of bark. That which has the best claim to it (as having been first published and more often used) is the best sort of grey bark collected by Pritchett in Huanuco and referred to *C. peruviana* or *C. micrantha*. This "Pata de Gallinazo" was one of the first cinchonas sent to Hakgala from the Nilgiris. (See Dr. Thwaites' Report for 1860-61.) It is, of course, the case that the name is also used for the "Cascarilla serrana" or Hill red bark, which Dr. Spruce obtained on Chimborazo at 8,500 to 9,000 feet, and with which Mr. Cross (who accompanied Dr. Spruce as gardener) now identifies the plant under discussion.* But Dr. Spruce himself, with Mr. J. E. Howard, long ago determined his "Pata de Gallinazo" to be *C. coccinea* Pav. (see his letter quoted in Weddell, notes, page 30 (1869)), and it is no doubt in accordance with this determination that Howard now refers Cross's "Pata" bark from the Nilgiris to that species (see Beddome's report, page 30. The plate, however, of *C. coccinea*, (taken from authentic specimens) in the "Illust. Nuev. Quinol." is totally unlike our plant.

All this is, perhaps, scarcely in place in your columns, but it will show how far the matter is from final solution. It is to be hoped that the copious dried specimens sent home by Col. Beddome for comparison with types in the London Herbaria may clear up the matter; but this cannot be very confidently expected. Meanwhile, I would recommend the suppression of the Spanish name of "Pata de Gallinazo" for our "hybrid." If the tree has been duly described and named we shall, of course, give the proper appellation in time; if not or till then—since the names "pubescens," "magnifolia," "villora," and others are all for various reasons unavailable—we cannot, I think, do better than adopt that already coming into use in Southern India, *robusta*, which is a very appropriate one. By using this we do not commit ourselves to any views as to the origin of the plant, whether in the plantations of the Nilgiris, or the higher slopes of Chimborazo.—I am, your obedient servant,

HENRY TRIMEN.

* In conversation, Col. Beddome told me that Mr. Cross declared he had sent *seed* of this to India, but nothing is said of this in the report.

* Col. Beddome's Report (p. 8.) contains the extraordinary assertion (derived from Mr. Cross?) that Dr. Spruce "could never have seen the trees." But the latter describes their appearance, bark and leaves—the flower and fruit he did not get—in his paper in the "Journal of the Linnean Society" iv. p. 185. Indeed it is Mr. Cross's share in this matter that is the novelty.

A PHILOSOPHICAL CURE FOR THE COFFEE GRUB: "GIVING THEM THE SACK."

Agrapatana, November 25th, 1881.

DEAR SIR,—Perhaps the following method I have invented for the destruction of grub may be of interest to you, and, now that the discovery is being conducted on more estates than one, it would be impolitic for all to consider the invention any longer a secret. Decided proof as to the remedy can be obtained, on reference to those gentlemen who have seen the experiments here, and who have tried and are now trying it themselves, and further information as to the success attendant upon their efforts will I am sure be gladly accorded. The discovery would have, doubtless, been made known before this had it been already tried elsewhere by anyone, excepting those to whom the process has been explained and through whom the facts of the case have been, inadvertently, somewhat widely disseminated. Owing to the rapid and terrible depredations of grub I was induced to make repeated attempts as to a cure early in July last; at a time when the attack was becoming dangerous, and having tried every available means with little if any success I thought of suffocation, and determined to spread old and useless bags between the lines of coffee; thinking the grub would be smothered or probably that the bags would attract them: the plan was successful. All grub under the covered area rose to the surface, and on rolling back the bags were discovered in large numbers. They were not be found at a greater depth than three or four inches, and if allowed to remain long under the bags 20 per cent are attacked by the "white fungus"; the insects do not again descend deep to the ground.

I wish, however, to particularly draw attention to

the fact that from four to eight or ten days after the covering has been put down, every grub below it will come to the surface and can be picked out; or destroyed there and then with a thin sprinkling of purpuline, which I have found efficacious in no other manner; this process doing away with the necessity of constantly disturbing the soil and damaging and loosening the roots of the coffee tree. It must also be borne in mind that the same covering can be used repeatedly, for when the grub have been eradicated from one part of an estate the bags can be moved on elsewhere. A few grub will appear the fourth day, if the weather is favourable, but not till the eighth or tenth day after the bags have been put down can we be positive of their having all come to the surface. The simple spreading out of bags is not sufficient, but I shall be pleased to give full instructions to those purposing carrying out the remedy, and answering any questions that may be raised. The remedy is simple, when we consider the habits of grub and the manner in which they congregate under logs, planks, etc., and will be found to be cheaper and more thorough than any method yet known. The process will have been carried out on a large scale shortly, and, if successful, I can then speak with even greater confidence. In conclusion, I trust you will excuse the length of this letter, and will feel with me that it may be the means of assisting many in their destruction of one of the worst enemies we have to contend against, and, if, as I hope, further information as to a cure for grub will be the outcome of this letter, I shall consider it has done some good.—I am, dear sir, yours faithfully,

H. G. P.

[The plan is at once philosophical and very easily tried. The only fear we have is that a considerable number of grub would be too far down in the earth to be affected?—ED.]

THE "FALLOW FIELD" SYSTEM.

DEAR SIR,—I was rather struck by an article I read some weeks ago—I think it was in the *Field*—by a General Strachey,* on the vine pests in France, giving it, as his opinion, that the incompetency of the vines to withstand the attacks, both of fungi and insects, was brought about by overforcing the plants with a cultivation too artificial, such as excessive pruning and manuring every year, leaving the operations of nature entirely out of the question. The main remedial suggestion of his letter was that it would be advantageous in every way each season to allow a portion of the vineyard to be fallow: the acreage to be so treated be put at one quarter of the property in regular rotation every year.

Now how could General Strachey's idea be carried out in Ceylon, even in a small way, on our estates? Let us take a plantation of 240 acres for example. Let 60 acres of this which has given the heaviest crop be selected as the first "fallow field." Let it be weeded (and suckered at the same time) six times a year. Let nature have its own way with it otherwise. This field will, I anticipate, recover itself in due course, without the artificial process we so constantly follow, with a heavy bearing piece, after crop, by manuring and pruning it. No field in old coffee nowadays gives a bumper crop more than once in three years, except on the Hapútale side of the country.

The advantage, I think, to the rest of the estate would be palpable. The manure that would otherwise be used to pull round this field can be used elsewhere. The saving of expenditure on 60 acres, taking R12·50 an acre, on pruning and handling, would amount to R750, and on six weedings, taking R1·25 per acre per month, would be R450, making a total of R1,200.

The chief attention of the superintendent could then be concentrated on the remainder of the estate, which would be, after deducting 20% of the land as inferior to the rest, including grass ravines, roads, ridges planted with cinchona, and grass fields, one hundred and forty-two acres.

It stands to reason, if 142 acres are worked up with pruning (this work could then, perhaps, be finished by the end of March, instead of the end of May) and manuring (say two-thirds, if funds will not permit manuring the whole of it) and shall we say sweeping, the chances are that the crop would be more in this part of the estate, and so cheaper and easier to pick; and in the event of a bumper crop again, there would not be the necessity for such a large resident gang of coolies, and the strain on the superintendent would be considerably lightened.

It is very evident that we should now find it almost impossible to keep a large force going, whilst crop was hanging back, which is too frequently the case. Formerly it was different. We generally had clearing work to complete, roads and drains to cut, ravine composts to fill up, cinchonas and grass to plant, and especially money to spend. Luckily these works are mostly done, for many of us could not afford to do them now, and we all know what an expensive business it is making work for coolies.

Mr. Marshall Ward tells us we must first of all sweep up the leaves, if we ever mean to make headway against leaf-disease. To do this once we must spend R4·50 an acre. So that, to sweep 142 acres, we should have to spend R639. Now I would humbly suggest that the savings off the "fallow field" could be devoted to that purpose. The 142 acres must be cultivated extra highly, and, with the sum of R1,200 we certainly could sweep twice, and nearly three times in a year; for after the first outlay it would not be nearly so expensive, and R4·50 an acre is an outside figure even for the first sweeping. Of course it will be urged that the fallow field would suffer from the weeds (but we must let nature have plenty to do) from want of handling, and from severe attacks of leaf-disease: surely these are all matters for further discussion. We must continue to face and overcome our difficulties, if, in the future, we expect to do as well with our properties as in the times past.

I cannot help being struck with the paucity of letters nowadays on the cultivation of our staple, in comparison with the multiplicity of correspondence that used to be written formerly on every conceivable subject in connection with it. Perhaps the attention of your correspondents is turned more to cinchona, tea and lowcountry products; so that even if this letter promotes in any way plans for future campaigns against evils we are suffering from and yet may suffer from, it will bring, I trust, more hope than the mournful prognostications of "Wm. McK."

The former idea (which arose I think from always wishing to have our estates in tip-top order for saleable purposes, in the event of any one offering a fancy price for them) we used to have of keeping up an even appearance all over the estate has somewhat changed, and men are more ready to look to the results of crops, than the appearance of the estate. Putting manure only into the best and sheltered land (for good land is always grateful), planting up the ridges and poor soil with cinchona is now the order of the day, and rightly so.

A great deal has been done in lowering the cost of upkeep, but I do not think men have gone far enough yet, nor have they sufficiently altered their plan of work.

If we examine how it is men are now working for

* General Maitland Showers, whose letter we quoted the other day.—ED.

about half what they used to do, we shall find the savings have been made more or less on the following items: superintendence, contingencies, roads and drains, cleaning up ravines and making composts, crop expenses owing to the shortness of production, and last of all by stopping manuring and economizing in all it-lateral branches, such as the keeping of stock, planting up grass fields &c., and it is on this head particularly that the real results have been obtained.

To recapitulate: as I am of opinion that eventually we shall have to alter somewhat our present system of working our coffee estates, I will mention the following causes as likely to bring this about: possible fall in prices, the necessity for judicious economy, the want of credit compared to other times, the urgent need for following Mr. Ward's suggestions regarding leaf-disease, and the scarcity of work for a large supply of labour, and the scarcity of labour for a large crop.

By adopting the foregoing plan, we might expect to make some headway against leaf-disease, recuperate our estates, and dispense with some of our labour. We should certainly be concentrating our manure, our money and our energies, and may be adopting a plan economical and suitable for the new order of things.—I remain, yours faithfully,

JOHN HAMILTON.

HOW TO GERMINATE AND GROW LEDGERIANA SEED.

Agrapatana, 29th Nov. 1881.

DEAR SIR,—Now that the valuable pill-boxes of Ledgeriana seed are being sent to nearly every coffee estate in Ceylon, where the climate is at all suitable to the cultivation of the richest species of the cinchona family, I think it desirable that planters, who have already made Ledgeriana nurseries, should publish the results of their experience for the benefit of those now about to form them for the first time.

Those who have been successful would do good service by telling us by what method that success was obtained, while those who have wholly or partially failed might help equally by indicating the causes to which they attribute their failure. I venture to set the ball rolling, hoping that others will not be wanting to kick it along.

Failure as well as success has not been wanting in my own experience of nurseries, but I flatter myself that, taught by experience, the next Ledgeriana nursery I attempt will turn out a real good one.

I have planted Ledger seed in pure jungle soil, just as it came from the jungle. I have also used jungle soil after having thoroughly destroyed all the germs of poochie life by heating it well on a flat tin over a fierce fire. I have tried surface soil and river sand in equal proportions. I have used flower-pots, chatties, and wooden boxes to sow the seed in. I have tried beds made on the flat and on the slope, with roofs over them, of thatch, talipots and shingles, the latter in one case with window-frames taken bodily out of the bungalow and let into the roof.

My seeds have been sown an inch apart in regular rows, and also broadcast and thickly; they have been watered by absorption through porous chatties, and by spray.

When the small seedlings have refused to come on, but seemed inclined to remain for ever *in statu quo*, with their single pair of little leaves, they have been treated with tepid water, with soap-suds, with a weak solution of liquid cattle manure.

I have also tried placing manure deep down, a foot under the bed, to warm them, and draw the roots down in the same way that the window-frame above would keep their heads straight up.

The result of all this is that, I think, the best site for a nursery is one with an eastern aspect. The land should be gently sloping, the beds should be well raised and should be made of jungle soil, and river sand mixed in equal parts; the jungle soil having been scraped from the surface, then well sifted and thoroughly baked. No manure of any kind to be added.

The roofs to be thick mana-grass thatch fastened securely on large hurdles which can be attached to the posts of the nursery by temporary fastenings, and, when the seed has well germinated, these roofs can be lifted bodily off during the early morning and again in the evening. The seedlings will grow stout and hardy and will neither be sappy nor be leaning all on one side.

Sow the seed pretty thickly: seedlings seem to grow better at first close together, and to support one another. Perhaps this may be my fancy, but, if you sow the seed far apart, the nursery will always look thin, wretched and disappointing. I began with Ledgers two inches and more apart, and have been getting closer ever since.

Keep the nursery very dark and moist till all the seeds have germinated, and then gradually accustom them to much light and little water. If the weather is cold and wet, the water used may be just warmed.

These simple instructions will do well for a cinchona nursery, but a rough nursery of this kind is fit only for ordinary calisaya, succirubra, and officinalis, of which the seed is plentiful and the seedlings are hardy.

It is a remarkable fact that the young seedlings of officinalis should be so hardy and the maturer plant so delicate and difficult to grow.

Ledgeriana is just the reverse. It requires great care to get real Ledgeriana seed to germinate, and more difficult still to get the small seedlings to come on. But once established, and the delicate period of infancy once past, no cinchona is more hardy or grows faster. Much disappointed at some of my Ledger nurseries having taken long to germinate and having stuck fast as seedlings, I wrote to a friend in Boga-wantalawa, who had been among the very first in Ceylon to raise a quantity of Ledgers successfully, and told him of my anxiety. He reassured me by telling me that I could not have a better sign of the purity of my seed. I therefore took patience, and many of these seedlings are now turning into fine plants.

The common calisayas grow like weeds from the beginning.

On the largest private plantation in Java, Soekawanna, where more than four hundred acres of young Ledgers of the purest strain are growing magnificently, they economize their seed by planting every grain under glass. If they take these precautions in the Preanger, surely we in Ceylon, where the seed is so scarce and so valuable, may well do likewise. This is what the head inspector or visiting agent of Soekawanna, Mr. Von Wenning, writes to me on the subject, or, to speak more accurately, a free translation of what he writes:—

"My experience leads me also to think that the species Ledgeriana presents a great contrast to the species officinalis.

"The latter germinates easily and grows apace while yet a seedling in the nurseries, but no sooner out in the open clearing than the delicacy of its constitution manifests itself and its growth and development are slower than the growth and development of any other kind of cinchona.

"A Ledger seed, however, germinates only under favorable circumstances and requires fostering care as a seedling, but once over the critical period of its infancy, it becomes a robust tree of rapid and vigorous growth.

"This difference in the constitution of the two species has been impressed the more strongly on my mind, inasmuch as during the last three months my

officinalis clearings have suffered extremely from the drought. Many of the one year old have died for want of rain, and still more are in a very critical state. More than three months without a drop of rain is, of course quite out of the ordinary course of weather vagaries, and may well account for a considerable mortality among the plants in young clearings. This makes it the more remarkable that the Ledgers (even those quite lately planted out) should have borne this trying period most bravely, and that they should hardly have suffered at all, as is the case.

"But, for the first development, I recommend you to take every possible care. I sow the seed of my fine Ledgers in pots, placed under a two-fold covering of glass; that is, I put the pots in glass-covered frames, the frames themselves being in the conservatories. Under this double glass they remain till the seeds have germinated, and I now think that I have minimized the percentage of seeds which fail, and have given to each individual germ a fair chance of development."

To sum up, therefore I shall now describe the method I should recommend planters here to follow with their Ledger seed. Procure a melon frame: three feet of wood at the back, eighteen inches in front. Let the width be five or six feet, and the length about nine feet. This will admit of three slides of glass planes, each of three feet wide, to draw up and down; these slides, being almost entirely composed of glass with only a slight woodwork to hold the glass together, and for the necessary grooves. As the sun here is so hot, the glass should be painted green and the woodwork white or *vice versa*. Green, however, I prefer, as green not only is best for the human eye, but is nature's own favorite colour, and seedlings in their natural state have the rays of the sun broken for them by a green canopy of sheltering foliage above them.* Place the frame on a gentle slope to the east, level the ground carefully, and make a flooring of well burnt bricks closely fitted together; then put a covering, about two or three inches deep, of well-dried forest leaves, and then fill up, with a mixture of washed sand and surface soil from the jungle, to a reasonable distance from the top of the lower side of your frame. Mix your seed well with a handful of sand and then sprinkle it pretty thickly on the surface.

Have other frames ready to prick out into. This time, however, let the mixture, to be placed on the top of the layer of dead leaves, be composed, half of surface virgin soil, and half of well-burnt bricks reduced to a fine powder.

I have ordered some frames from Messrs. Bull of Chelsea, but I should think they might be made to order in Colombo or by Messrs. Walker & Co. in Kandy. Till they can be procured, one might plant in brandy cases, being careful to drill nine good holes in the bottom, to cover each hole with what gardeners call a crock, and before the layer of dead leaves to place a layer of pebbles or small stones.

The shingled roof of the bath room might be taken off and a couple of the bungalow window-frames let in instead, the glass, of course, being painted. The *seed boxes* could then be placed on shelves round the room, in company with a few traps, but not those cruel contrivances which close their iron teeth on the poor rat and keep him painfully straining at a broken leg for many hours, till his torture is ended in the morning by the last *coup de grace*.—I remain, dear sir, yours, &c.,

E. H. C.

ANALYSIS OF WYNAAD CINCHONA.

Colombo, 24th Nov. 1881.

SIR,—I send you analysis of a sample of hybrid cinchona bark, received on the 31st ultimo., from South East Wynaad, and grown at an elevation of 5,000 feet. On receipt of the analysis, the sender was good enough to furnish the following particulars:—"The tree I sent you the bark from is amongst our condaminea (not manured) and very much resembles the C. pubescens, or magnifolia in the Government Neivatam plantations. The analysis also corresponds with that of the bark from one of the Government trees of that variety. It is a very free-growing tree, size of succirubra: but the leaves are not quite so large and exactly the color of condaminea leaves."

The analysis of the bark was as follows:—

	per cent.
Moisture...	11·76
Total alkaloids	8·32
Crystallized quinine sulphate ...	4·69

CINCHONA CULTURE IN CEYLON: THE ROBUST HYBRID *vs. Magnifolia*.—A correspondent writes:—"I have been reading your cinchona news with much interest lately. I believe *C. magnifolia* to be quite distinct from the robust growing trees we are accustomed to call hybrids, many of which approach to the former in appearance of foliage. I hope to experiment with seed this year from what I believe to be the only *C. magnifolia* I possess. It would be interesting to know what the experience has been generally with so-called hybrid seed. Has it come up like its immediate parent or gone back to the original *succirubra*?"

CINCHONA IN CEYLON.—Anent Colonel Beddome's very interesting report, it would be well, if mortgagees and others at home interested in our island, would take it to heart, equally with the editor of the *Field*, who has given the advantage of his world-wide circulation to disseminate gloomy ideas of our industrial prospects. In reference to this we have been favored with the copy of a letter addressed by Mr. Duncan Skrine to the editor of the above paper in which he states the actual facts connected with the "Frotofts" Cinchona yield, not precisely as given in Colonel Beddome's report, but so as cannot fail to convince any impartial mind of the excellent prospects in Ceylon for that new products. The letter in question says that in this year forty acres of Frotofts cinchona estate have been grubbed up and the bark, including that from the roots, brought on the London market. The nett proceeds of this consignment were £6,500 or more than £162 per acre. The proprietors have besides this harvested bark from dead and dying trees on this property to the nett value of £2,000, giving a total yield of £8,500. The estate was four and a half years old when the forty acres were grubbed up, and this land will now be replanted with cinchona. The writer of the letter in question goes on to say: "Rash speculation on borrowed money, leaf-disease, and seasons out of joint have crippled Ceylon for the moment, but we are working through our troubles, and I am convinced that at this moment there are more good bargains to be had in Ceylon than in any other of our colonies. The gamblers have been crushed out, and the faint-hearted have gone or are going, but those who have the back-bone to stay on will be amply rewarded. Coffee is looking magnificent and our cinchona enterprize is an assured success."—"C. Times."

TRANSPLANTING FRUIT TREES.

(*Field*, 29th October 1881.)

In a general way, the transplanting of fruit trees is left much too late for them to succeed properly, as, unlike evergreens, which may be moved almost at any season, deciduous trees only do really well when taken in hand early in the autumn, or directly the leaves fall, as then, the earth being warm, they emit roots at once, and the buds continue to be well fed, instead of starved, as they are if the trees are disturbed after the turn of the year. This being the case, those who contemplate replanting should order their trees at once; and, that they may not be out of the ground longer than is absolutely necessary, when they arrive, provision should be made for their reception by digging holes and being prepared with soil suitable for them to grow in, as, however good that of a garden may be, there is nothing like having a little fresh soil to place over and about the roots, to give them a fair start, on which so much of their future welfare depends. To use a lot of manure, as some do, is a great mistake, as, instead of being of service, it is a positive injury when brought in immediate contact with the roots, which it causes to canker. Used as a mulching, however, the case is different, as then it acts favourably by keeping the frost out and the ground uniform in temperature; and when rain falls the juices are washed down by degrees, and gradually enrich the soil over which the manure is spread.

The best kind of soil for young fruit trees is fresh-cut turf from an old pasture that grows good grass and has been closely fed; and for peaches, nectarines, apricots, and plums such as may often be got from waste places by the roadside answers well, on account of having more grit in it; but for pears and apples the less sandy it is the better, as they like it rather inclined to be heavy than light, and, if stiff soil cannot be got, a little fine crumbly clay may be added. This will give the necessary weight and texture to the whole body of turfy loam if properly mixed with it, and when so used is a great aid to the trees during dry summer, as clay buried in that way among lighter soil is very retentive of moisture: and I have seen roots, when trees have been taken up, clinging to it with the greatest tenacity, thus showing how well it agreed with them. In getting the turfy loam, it should simply be chopped up roughly, and, if the clay is added, turned over to mix; but I would warn all against using leaf mould, which is most dangerous, as it always has a tendency to breed fungus, a parasite which is most destructive to the roots of all plants, and is often the cause of disease and death by getting on and into the bark, where it stops up the pores and poisons the sap. The soil being all prepared, the next thing is to turn attention to the trees, which should be closely examined, and have any injured roots trimmed by cutting away the points with a sharp knife, as they heal over a smooth wound much more readily and quickly than they do over a rough, jogged one.

SHORTENING THE BRANCHES.—It is the practice with some to prune back the branches, but it is a very rough and barbarous one, as it mutilates the plant so operated on, and throws it back at least a year, as after a season's growth the head will be little if any bigger than when purchased; and the object in planting a tree is, or ought to be, to get it up to a fruit-bearing size as quickly as possible. It often happens that shoots are misplaced and require thinning out; but that is a very different thing from hacking them back, as some do, thinking to make them break lower. If a tree is properly planted and cared for in the way touched on, all buds will start free enough. The plan of procedure in planting should be to partly fill the holes made for each tree with a barrow-load or so of the chopped loam, keeping the same highest in the middle where the tree goes, that the points of the roots may slope gently down; and before covering them with the same kind of soil as that placed under, it is important that they be spread well and regularly out, so that they do not cross or interfere with each other. In filling in, the soil should be made firm by gentle treading: and when this is done, the next thing is to mulch around the stems with manure, covering a surface of two feet or more. As the wind interferes much with trees rooting if allowed to sway about, the stems should be supported by stakes and ties, or, in the case of those against walls, by the aid of nails and shreds loosely applied, so as to allow the plant liberty to go down a little as the soil settles, instead of being hung up and strained.

J. D.

MR. MORRIS ON CINCHONA CULTURE IN JAMAICA.

HINTS AND SUGGESTIONS FOR RAISING CINCHONA PLANTS FROM SEED AND ESTABLISHING CINCHONA PLANTATIONS.*

I.—*Raising Seedlings in Boxes.*

Boxes.—For raising small quantities of plants—say from 30 to 80,000—it is desirable to sow the seed in small shallow boxes under cover, where they can be conveniently attended to.

The boxes may be of any size as regards length and breadth, but should not be more than about 3 or 4 inches deep. Ordinary brandy or wine cases reduced to the above depth answer well.

To promote drainage, holes about ⅜ inch in diameter should be made in the bottom of the boxes at distances of about 6 inches apart. The inside of the boxes should be treated with white wash, or thoroughly dusted with quick lime to prevent mouldiness of the soil and subsequent injury to the young seedlings. Over the holes in the bottom of the boxes place pieces of broken pots or brick, and cover the surface to the depth of one inch with rubble or broken stones.

Soil.—The soil for the boxes should consist of one-third of leaf mould, or that kind of soil of a black peaty character which is often to be found under large trees in the forest: one-third of good ordinary garden soil and one-third of sharp sand or fine river gravel. These should be mixed thoroughly together and passed through a quarter inch sieve.

The boxes may then be filled within one quarter inch of the top, with the sifted soil placed over the broken stones, &c., and slightly pressed so as to present an even unbroken surface.

Sowing the Seed.—After slightly watering the soil in the boxes the cinchona seed, which is very light and small, should be sprinkled rather thickly over the surface, so as to cover nearly every part with a rich brown tint. When this has been done, take a small quantity of the fine sifted soil, mentioned above, and sprinkle it over the seeds, *barely covering them.*

Watering and Shading.—The boxes should then be placed in the shade, sheltered from sun, wind and rain, and kept regularly watered, daily, with the finest poss-

* With the view of promoting the general culture of cinchona in the island, seeds of the valuable *C. Officinalis*, producing the Crown Bark of Commerce, and suitable for cultivation at elevations above 4,000 feet, will be supplied, free of postage, at the rate of 5/ per ounce.

Seeds of the Red Bark, *C. Succirubra*, suitable for cultivation at elevations between 2,500 and 4,000 feet, will shortly be available and supplied, by post, at the rate of 3/ per ounce.

An ounce of cinchona seed is sufficient to produce 20,000 seedlings, which, if carefully raised, will plant up five acres of land.

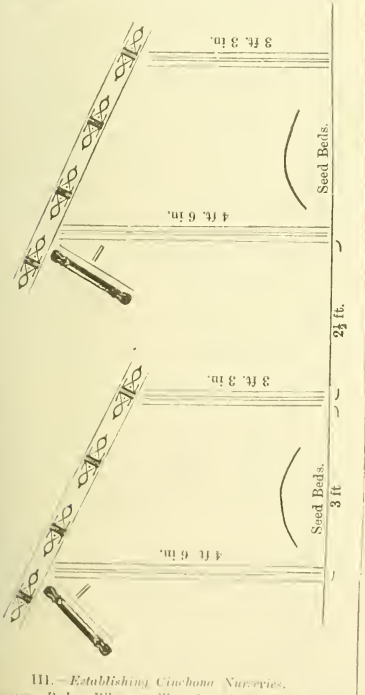
Applications for seed, accompanied by a remittance in postage stamps, or order on the Parochial Treasury, Kingston, should be addressed to the Director of Public Gardens and Plantations, Gordou Town.

ible spray from a watering can. Under the conditions above mentioned, the seeds will begin to germinate in about 3 or 4 weeks. They will require regular watering, however, till they are 1½ or 2 inches high, when they are ready for the nurseries.

II.—*Raising Seedlings in Beds.*

Where seedlings are required to be raised on a large scale it is advisable to grow them in beds protected by a roof of shingles or good thatch. The roof sloping South and supported on posts 4 feet 6 inches high on the North and 3 feet 3 inches on the South side, should completely cover the beds and keep off both sun and rain. It is also advisable to shelter the sides of the sheds by grass or wattle fence, so as to keep off the slanting rays of the sun and strong winds.

The beds should run in parallel rows due East and West; be about 3 feet wide and with a path between each bed about 2½ feet wide. After the beds are laid out, the surface should be covered to the depth of 2 or 3 inches with the same mixture of soil as recommended above for the boxes. The seeds may then be sown and kept regularly watered night and morning. The following is an approximate representation of the seed sheds :—



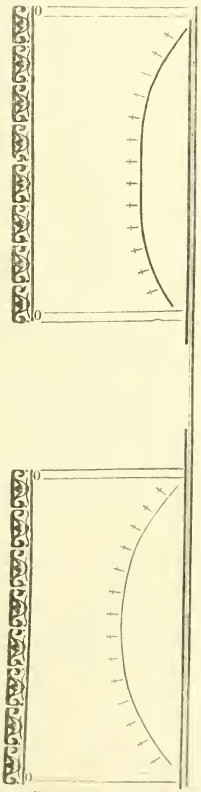
III.—*Establishing Cinchona Nurseries.*

Nursery Beds.—When seedlings have been raised either in boxes or beds and are about 1½ or 2 inches high, the next step is to transplant them into the nurseries. In selecting situations for seed beds and nurseries it should be borne in mind that a sheltered situation, with a plentiful supply of water, are no less important considerations than nearness to the land intended to be planted.

The beds for the nurseries should be laid out in every respect as for seed beds, *i.e.*, about 3 feet wide, with paths 2½ feet wide, treated on the surface with a mixture of good soil, and placed in rows due East and West.

Before the seedlings are transferred to these beds it would be well to prepare, before-hand, the necessary materials for shading them.

These may consist of long straight wattles, supported on forked sticks and covered with grass, ferns or paha leaves. Side shading is also advisable especially on the South side. The shading for nurseries would appear somewhat as follows :—



Pricking out seedlings into nurseries is a work requiring great care; but with a little experience it can be done very successfully and expeditiously.*

* At the Cinchona Plantation, pricking out seedlings is done by contract at the rate of 9d. per thousand. A man or woman after a little experience can prick out about 2,000 per diem.

The seedlings being about 1½ or 2 inches high may be carried in the boxes or raised from the seed beds in lots of 200 or 300 and brought into the nursery. The beds already prepared for them should receive a good watering and be pressed evenly by gentle tapping with a piece of board. The person about to prick out should be provided with a small wooden peg about 4 or 5 inches long and ¾ inch in diameter at one end, tapering to a dull rounded point at the other. Taking up a seedling carefully by the leaves, with the left hand, a small hole should be made with the peg in the right hand, just deep enough to take the tender roots of the seedling without bending or crushing them. When placed in the hole, the soil should be pressed closely to the rootlets by means of the peg and the seedling left firmly fixed with its leaves and stem well above ground. The seedlings should be placed in rows at regular distances apart so as to allow about two inches between each plant.

As soon as an appreciable number of seedlings have been pricked out, the shading, as shewn above, should be immediately placed over them to prevent injury from sun or rain.

The nursery beds will require regular watering for some time, but when the plants are about 4 or 5 inches high it would be well to remove the shading, little by little, in order that the plants may become gradually hardened and ultimately fit for transplanting to their permanent places in the field.

IV.—*Establishing Cinchona Plantations.*

Climate.—It may be generally accepted for Jamaica (between 17° and 19°* latitude North, and 75° and 79° longitude West) that, at all elevations from about 2,500 feet to the Blue Mountain Peak, 7,335 feet, the climatic conditions are all favourable for the successful cultivation of one or other of the various species of Cinchona. For comparison, it may be mentioned that *Cinchona Succirubra* flourishes in the Parish of Manchester, according to information supplied by Mr. Swaby, at an elevation of 2,700 feet, with a rainfall of about 120 inches, and a mean annual temperature of 70° Fahrenheit. This elevation may be taken as nearly the lowest at which the more valuable Cinchonas may be remuneratively grown in Jamaica.

At the Government Cinchona Plantations *Cinchona Succirubra* flourishes at 5,000 feet.† The records here show a mean annual rainfall of 136 inches and a mean annual temperature of 60° Fahrenheit. The trees at this elevation do not seed freely, and are apparently so slow in maturing, that this elevation may be taken as the highest, at which it would be advisable to cultivate Red Bark in Jamaica.

For the valuable Crown Bark, *Cinchona Officinalis*, as it flourishes at 4,500 feet near Whitfield Hall, and at 4,800 feet at the Cinchona Plantation, possibly it may grow as low as 4,000 feet. Its range of cultivation, so far, in Jamaica is between 4,500 and 6,300 feet; a few plants of this species planted by Mr. Nock, on Blue Mountain Peak, in 1878, though they have suffered from their exposed position, would indicate that the conditions, even at this elevation, are not unfavourable to the growth of small leaved and hardy Cinchonas.

Soil.—All species of Cinchonas are most impatient of stagnant moisture at their roots, and therefore require an open subsoil, a sloping exposure, and other conditions of perfect drainage. They naturally prefer a rich soil, and do better in newly cleared forest than in grass lands, *Cinchona Officinalis* is, however, more tolerant than *C. Succirubra* of a soil poor in vegetable humus, and grows on grass land, as well as on exhausted coffee soils.

The freer and more friable the surface soil the better, but the ultimate success of the Cinchona plant depends essentially on the character of the subsoil. An open well drained subsoil is above all things indispensable to Cinchona cultivation.

"As soon as the roots of a Cinchona tree get down into subsoil, in which there is any tendency for moisture to collect, the plant most certainly begins to sicken and die."

The best trees at the Government Cinchona Plantations grow in a good friable surface soil, overlying a porous stony subsoil produced by decomposed rock of the metamorphosed series of Jamaica Geology. This subsoil is found generally distributed throughout the Parishes of St. Andrew, St. Thomas and Portland. In limestone districts of the island eastward the soil generally must be very favourable to Cinchona cultivation, the only qualifying conditions being the elevation and mean annual rainfall.

Sites for Plantations.—In selecting sites for Cinchona Plantations, it is important to bear in mind the points above mentioned, as regards climate and soil, and the species of Cinchona naturally adapted for them.

Where Cinchona is cultivated concurrently with Coffee, it is recommended to attempt to grow the valuable Crown Bark, *C. Officinalis*, at all elevations above 4,000 feet. On rather bare patches, by road sides and indeed anywhere where plants can be placed, this hardy and valuable plant should be abundantly grown.

On Coffee Plantations below 4,000 feet, the most suitable kinds are the Red Bark, *C. Succirubra*, and a hybrid variety which has passed here as *C. Calisaya*. These may be planted on coffee estates as suggested above for *C. Officinalis*.

In selecting sites for permanent Cinchona Plantations as distinct from Coffee Plantations, the nature of the soil, the direction of prevailing winds, the aspect, the mean annual temperature and annual rainfall, are all matters for serious consideration. Speaking generally, however, no sheltered situation, with good soil, can be said to be unsuitable for Cinchona anywhere on the Blue Mountain range. The northern aspect has a more equable temperature than the southern, but the latter appears to be generally preferred for coffee. As Cinchonas delight in a moist equable temperature, it is very probable that vast tracts of land lying hitherto uncultivated on the northern slopes of the Blue Mountain range will ultimately prove suitable for Cinchona.

Clearing Land.—When it is intended to establish a Cinchona Plantation, on uncleared land, the first consideration after the site has been carefully selected, is to establish the seed beds and nurseries. Full particulars respecting these are given in the foregoing paragraphs. While the plants are being thus prepared, the land intended for the plantation should be properly cleared as for coffee cultivation.

It may be well, however, to point out that it is very advisable in Jamaica to leave moderately wide belts of forest standing on the ridges, for the purpose of affording shelter from strong winds. In addition to this, it is recommended on very steep places, rocky hollows and any patches of land unsuitable for Cinchona, that the original forest be left standing in order to ensure adequate shelter for the Cinchonas as well as save needless expense in cutting down, weeding, &c.

In India, the methods pursued for clearing forest for Cinchona cultivation are described as follows:—"The best time for beginning to clear forest land for Cinchonas is obviously when the dry season has sufficiently advanced to make a second growth of grass improbable. When the felled forest, whether grass or timber, is sufficiently dry it may be fired. Stumps and logs remaining unburnt after the fire may be rolled into spots unsuitable for planting, or heaped together and burnt. A better way is to lay them between the lines of plants, and allow them to rot and thus to profit by the humus formed by their decay. The large fibrous roots of tall grasses and other weeds likely to overpower the young trees about to be planted, should be dug out and killed either by exposure or burning. The land being thus cleared, any necessary roads may be lined off and made. The sites in which the plants are to be put must then be marked off. This may conveniently be done by means

* With 10° further north I should think succirubras ought to flourish at 1,000 ft. in Jamaica.—ED.

† 5,000 Jamaica equivalent to nearly 6,000 in Ceylon.—ED.

of a cord, about 100 feet long, on which marks are tied at the intervals at which it is wished to plant the trees. This cord is stretched on the ground, and opposite each of the marks on it, a piece of split bamboo or a peg is struck into the soil. The cord is then moved, another line is staked off at a proper distance from the last, and so on. Coolies follow, whose duty it is to dig pits, about a foot to fifteen inches in depth and eighteen inches wide, of which the stakes already put in should be the centres. The earth (freed from roots and stones) which has been taken out of each hole *should be returned to it*, so as to form a free mass in which the roots of the plant about to be planted can freely work. A cooly in Sikkim makes 100 to 130 of such pits per day according to the nature of the ground."

Planting.—When the ground has been prepared, as mentioned above, the plants already established in the nurseries after being gradually hardened will be fit for planting out. The night before the plants are taken out of the nursery beds, they should be well deluged with water, in order that a good ball of soil may adhere to their roots in the process of transplanting. The plants should be carried from the nurseries to the fields, in shallow boxes or baskets, well shaded from the sun and with a plentiful supply of wet moss, grass or ferns round the roots. The best season for planting in Jamaica is evidently after the October rains, and the most favourable conditions are obtained during a prevalence of damp, cloudy, or foggy weather, with only slight rain or occasional showers. It is unadvisable to plant during heavy rains as most soils get clogged and heavy, and become in this state prejudicial to the tender rootlets of the plants. In placing the plants in the holes it is only necessary to make an opening with the hand or a trowel in the fresh loose soil already prepared for them, sufficiently deep to receive the roots without doubling them. When thus deposited, the soil should be filled in round the plant, and well pressed as it is thrown in to cover the roots. No plant should be buried deeper in the ground than the collar or union of stem and roots. "When a portion of the stem is buried in transplanting, the growth of the plant is much retarded, and it does not, as some suppose, give a firmer hold of the ground but the reverse."

Too much attention cannot be given to the modes of putting out cinchona plants. "It is too important an operation to be done badly: it is not wise to try to economise on it, and it is always unadvisable to do it by contract." A good planter should be able to put in from five hundred to a thousand plants per day according to the nature of the soil.

Planting Distances.—In the early days of cinchona planting, the trees were put out at distances of twelve feet apart, but it was soon found out that, even for the strong and free growing Red Bark, *C. Succirubra*, this distance was too great for remunerative results. "It appears that the Red Bark, even in South America, is never a large tree: *C. Officinalis* is but a big shrub, and it is doubtful whether any of the species become much larger."

In the Government Plantations of India, at Sikkim, the Nilgiris and Darjeeling, even the large-leaved *Cinchona Succirubra*, are now planted at distances of 4 feet by 4 feet, giving 2,722 trees per acre, whereas when planted at 12 feet by 12 feet, as hitherto followed in Jamaica, the number of trees is only 303 per acre. Dr. King, in his "Manual of Cinchona Cultivation in India," remarks that "wide planting is obviously an error." All the cinchonas have the habit of throwing out a quantity of superficial rootlets, and young cinchona plantations do not thrive until the soil between the trees is sufficiently protected from the sun to allow these superficial rootlets to perform their functions freely. The growth of weeds, which is a very important factor in tropical cultivation, is also checked by shade. By close planting, therefore, two desirable objects are speedily obtained, and, moreover, the trees are encouraged to produce straight clear stems yielding a larger proportion of trunk bark and less branch bark. On this well known habit of forest trees is founded the practice of close planting in forest plantations in Europe, the object being to produce long straight unbranching stems from which to cut timber of long scantling.

As the trees begin to press upon each other, they can be thinned out and a quantity of bark may thus be got at a comparatively early period, with positive advantage to the plants that are allowed to remain on the ground. It is true that the cost of close planting is greater than that of sparse planting, but on the other hand the reduction in the cost of cleaning and the manifest greater yield of the plantation will more than compensate for this.

It may, therefore, be safely assumed that the Red Bark, *C. Succirubra*, should be planted at distances not greater than 4 feet by 4 feet, and the Crown Bark, *C. Officinalis*, at not greater than 3 feet by 3 feet.

The latter may however very conveniently be put out at distances of three feet between the rows and only two feet between each plant.

Shading.—It is very advisable to give the newly planted plants some shade for a short time after they are put out. The best and cheapest mode for any particular locality must of course depend on local conditions. At the Government Cinchona Plantations it is found very convenient to place two or three sprays of the common bracken *Pteris Aquilina* on the sunny side of the plant with the stalks well fixed in the ground. Should the weather prove wet with high gales of wind the fern leaves should be slightly moved on one side, so as not to touch or rub the plant when moved by the action of the wind.

Staking.—In windy localities, it is often necessary when plants have attained the height of two or three feet, to give them support by stakes. The great danger to be avoided in staking the plants is the chafing caused by the swaying of the plant. If the material used for tying is of a soft nature, and the stakes are placed in a sloping direction so as only to touch the plants at one point, much of the evils of chafing may be avoided.

Weeding.—Sooner or later a newly planted clearing will begin to show signs of the numerous tropical weeds which everywhere infest the land. It is hopeless to think of entirely freeing the ground from such unwelcome visitors, and, indeed, in the case of a cinchona plantation, it is quite unnecessary to do so. No special rule can be laid down as to the number of clearings actually required during the first and second years, but it would be advisable to keep down by cutting most weeds till the young plants are sufficiently grown to overtop them. Hoe-weeding as a *general* treatment should never be permitted as thereby the valuable surface soil is loosened and washed away.

"Where the majority of the weeds are annuals, and the soil is soft and friable, it may be advisable occasionally to substitute hand weeding for cutting.

"The disturbance of the surface of the soil caused in pulling the weeds up by the roots, affords a rough kind of cultivation which is advantageous; moreover the superficial roots of the cinchonas are less damaged than by hoeing. It need scarcely be stated that, in proportion as the Cinchona trees grow and their leafy heads cover the ground, the undergrowth of weeds becomes less luxuriant. A slight superficial hoeing of the soil immediately round the plants should, however, be given once a year if possible. The space to be cleared need not exceed one and a half to two feet in diameter, having the tree stem as its centre. To young plants especially this is very beneficial, and it is found that the oldest trees in the Sikkim plantation are much benefitted by the operation.

"In all cultural operations it ought to be borne in mind that the roots of cinchonas are comparatively superficial, and that any very deep hoeing is therefore more likely to do harm than good." D. MORRIS.

Director of Public Gardens and Plantations.

USE OF SMALL BIRDS IN DESTROYING INSECTS.

A correspondent writes:—In sending you the accompanying cutting from a very old number of the *Saturday Magazine*, I wish to mention that a magpie (the common Ceylon species)* has made a nest under the eaves of my office room, and I observed that in 30 minutes the parent birds have fed the young ones seventeen times, and all the food(grubs and caterpillars I believe)have been got from my flower garden, chiefly from the rose trees.

We would say a word or two respecting the benefits and injuries imputed to Sparrows, Linnets, and other small birds. That they are occasionally mischievous cannot be denied, though its but fair to add, that they also, like the Rooks before mentioned, repay us by a considerable balance of good. That the Bullfinch feeds on the buds aud seeds of trees, there can be no doubt, and that the Chaffinch, though by many considered as a pure feeder on insects, does the same, particularly in early Spring, when he inflicts ruinous injury on the sprouting crops of several plants, is equally true. Sparrows, too, burrow in our stacks, and consume a certain quantity of corn; not, indeed, in the same serious quantities that another bird does, called the Snow-Bunting: these birds, in hard Winters, come from the north in prodigious flocks, and, where they take up their quarters, become quite a nuisance; not so much by what they consume, as by what they destroy; which they do thus. In search of grain they frequent the stack, and then seizing the end of a straw, deliberately draw it out. To such a degree has this been done by them, that the base of a rick has been found entirely surrounded by the straw, one end resting on the ground, the other against the stack, as it slid down from the top, and as regularly placed as if by hand, aud so completely was the thatching pulled oft, that it was found necessary to remove the corn.

That some guess may be formed of the possible extent of good or evil occasioned by small birds, we annex the result of our own observations, on the precise quantity of food consumed by certain birds, either for their own support or that of their young, remarking at the same time, that the difference observed in the instances, may be partly accounted for by the different quantity of food required by young birds, at different periods of their growth.

Sparrows feed their young 36 times in an hour, which, calculating at the rate of 14 hours a day, in the long days of Spring and Summer, gives 3,500 times per week; a number corroborated on the authority of another writer, who calculated the number of Caterpillars destroyed in a week to be about 3,400.—Redstarts were observed to feed their young with little green grubs from gooseberry-trees, 23 times in an hour, which, at the same calculation, amounts to 2,254 times in a week; but more grubs than one were usually imported each time.—Chaffinches at the rate of about 35 times an hour, for five or six times together, when they would pause and not return for intervals of eight or ten minutes: the food was green Caterpillars.—The Titmouse 16 times in an hour.

The comparative weight consumed was as follows:—a Greenfinch provided with 80 grains, by weight, of wheat, in 24 hours consumed 70, but of a thick paste, made of flour, egg, &c., it consumed upwards of 100 grains.—A Goldfinch consumed about 90 grains of Canary-seed in 24 hours.—Sixteen Canaries consumed at the average rate of 100 grains each in 24 hours.

The consumptiou of food by these birds compared with the weights of their bodies, was about one-sixth, which, supposing a man to consume food in the same proportion to his weight, would amount to about 25 pounds for every 24 hours!

* Which is not a magpie at all, but our chief Ceylon songster, with a voice like that of Annie Lawrie, "low and sweet." "Spotted robin" seems more appropriate than "magpie" applied by Europeans to this the "dayal bird" of the Sinhalese, the *Copsychus saularis*, Linn., of ornithologists.—ED.

INCREASING FARM PRODUCTIVENESS BY ARTIFICIAL MANURES.

(*Field*, 15th October 1881.)

Probably there is no book of recent publication which deserves more attentive study from British farmers than that of the French chemist, M. Ville, on artificial manures; inasmuch as he attempts to show that by their employment in larger quantities than ordinary farmers have usually applied them, and according to the formulæ which he prescribes, the occupiers of high-rented, heavily-taxed lands in Europe would be able to face American competition, and, if not securing large profits from their business, at least escape from being submerged by that wave of ruin, against which the husbandry of the old world cannot have too many breakwaters. The argument of M. Ville in enforcing his theory is lucid and logical throughout, and no one can deny that he fortifies it very strongly with figures and facts; still, the question which he lays open for inquiry is too vast and momentous for a ready solution to be arrived at, capable of satisfying the general public, without experiments being tried over and over again under a variety of circumstances as regards soil and climate especially. For this reason the book cannot be too much read, as it seems peculiarly desirable that practical tests should be extensively applied, to prove how far its teaching can be vindicated.

The point is worthy of profound consideration that we have already in England one of the grandest tests for the system advocated by M. Ville, in the peculiar method of corn growing which has been pursued for so many years by Mr. Prout, of Sawbridgeworth. To many also the success of the latter gentleman amounts to the best possible confirmation of the truth of M. Ville's principles which they could have. Mr. Prout employs artificial manures on an extensive scale indeed, being to the extent of 50s. an acre on an average per annum for his entire farm of 450 acres. He has written a book, in which he claims that by making this outlay he has been enabled to grow grain crops year after year on the same land, and secure a far better profit in so doing than the best and most fortunate of English farmers are accustomed to realise; so that M. Ville's case may be considered proved so far, that under the circumstances of soil and climate which Mr. Prout has at Sawbridgeworth corn growing may be made remunerative, even against the pressure of American competition, through the employment of artificial manures in larger quantities than they are usually bestowed.

So far as root crops are concerned, they have been habitually increasing these to a turly enormous extent during the past forty years—ever since the importation of Peruvian guano commenced, and the great Liebig made known his discovery which led to the uprise of the superphosphate manufacture. The cheapness of mineral phosphates also has rendered great facilities to be available in raising roots, and especially turnips, more economically and largely for stock-feeding, whereby more and better farmyard manure has been made, to nourish the succeeding corn crops. To such an extent has this been done that it is a very popular belief, entertained by a considerable section of British farmers who occupy light soils, that their lands can be kept in sufficiently high condition without the aid of auy other artificial manures than the phosphatic ones employed for roots aud green crops. Still, such farmers usually are heavy purchasers of artificial foods for stock, under cover of which a great deal of nitrogen is purchased in the form of oilcakes, &c., which, after passing through the bodies of the animals, finds its way to the soil.

If by ordinary management and reliance on home made manures the value of the crops be only from £5 to £7 per acre, whereas by the employment of one pound's worth of artificial manure per acre they can be

raised to £10, there must of necessity be a great gain. But, unfortunately, farmers not unfrequently expend the pound without receiving much benefit—no doubt from the injudicious application of manures. Nitrate of soda is a favorite top-dressing for wheat, and, if the growing plant of that crop looks weakly and of a bad colour, nine English farmers out of ten, if they can afford it, rush off to the manure merchant for nitrate of soda. But frequently, after being applied, the results are very far from being commensurate with expectations; for, although the plant speedily turns to a darker hue, and may tiller out more abundantly, when the ripening period comes it gets blighted, causing the increase of produce to be more in straw than in grain. Hundreds of farmers get disgusted with nitrato of soda in consequence; and I have heard many express the opinion, after being disappointed, that its application to plants is very much akin to dram drinking—the effect is very powerful at first, but, so far from being lasting, is afterwards positively injurious. M. Ville will inform such persons that the cause of the evil is, not that the crop did not require the nitrogen contained in the nitrate of soda, but that it wanted something else also. Where lands top-dressed with this fertiliser have within themselves phosphoric acid, potash and lime, in sufficient soluble condition for the wants of the crop, the ill results would not be experienced; and it is just here that the French chemist offers material aid to the practical agriculturist in furnishing formulæ for manures, and rules for their application.

M. Ville affirms that plants are divided into three categories—those in which nitrogenous matter is the dominant constituent, to which cereals belong; those in which calcic phosphate is the predominating ingredient, such as turnips, maize, the sugar cane, &c.; and leguminous plants, comprising clover, sainfoin, lucerne, and potatoes. But he does not, like some of the older chemists, advise persons to act exclusively on the recommendation "nitrogen for corn, phosphates for turnips," because this is so, but, on the contrary, says: "This first point being established, we have next to pick the most suitable quantities both of the dominant and subordinate constituents." In fact, he divides the manures he recommends into no less than five different kinds, which he terms normal, homologous, stimulating, incomplete manure, and lastly, manure with special functions. Those who desire to study his views thoroughly had better, of course, procure the book and examine into his deductions in minutiæ: but perhaps it will be sufficient for others to explain that M. Ville prescribes, as a doctor would, for each case, giving very full formulæ in which each plant would have its dominant principle chiefly catered for; the artificial manure recommended for it would also contain the other leading elements which are required to nourish plant life, although in smaller proportions. The "incomplete manures" alone have some element absent which, in most cases, would be highly necessary. They do not contain nitrogen, and are used for leguminous crops, which, according to M. Ville, can supply themselves sufficiently with the nitrogen they need from the atmosphere by means of their leaves.

By injudicious application almost every blessing is liable to be converted into a curse; and if the work of M. Ville produces no other beneficial result, should it cause more care and dexterity to be employed in the application of artificial manures, farmers will be sure to benefit very considerably. Nitrate of soda mixed with superphosphates, so as to form a nitro-phosphate, would no doubt very often succeed far better as a top-dressing for grain crops than nitrate of soda; and in not a few other instances the careful study of the wants of the plant and the nature and properties of the soil would be sure to be useful before manures were applied in any form.

AGRICOLA.

COFFEE PROPAGANDA IN BRAZIL.

The following memorial was presented to the minister of agriculture on the 15th inst. by the commission appointed by the "Centro da Lavoura e Commercio," with reference to the projected coffee expositions:—

"*Mr. Minister:*—Constituted as a commission of the *Centro da Lavoura e Commercio* for the purpose of studying the project presented at the great meeting of coffee merchants for the improvement of the actual conditions of Brazilian coffee, an object of patriotic solicitude to the government, to the nation and especially to the classes we represent, we now report to your excellency the result of our labors.

Among the numerous economical facts which surround the great question of Brazilian coffee, its production and consumption, it is fit to distinguish those which, in the category of difficulties to overcome, belong, more or less nearly, to the direct action of the interested parties, and those which by their nature depend upon more complicated processes by their connexion with and affinity to the general economical organization.

If the production presents to us, in the complexity of the difficult problems which surround it, the gigantic work of great united efforts, organized and incessantly consecrated to this the best part of the public wealth, it is certain that the question of consumption is not only of essential interest to the economical state of the country, but also dominates the preceding and very grave question of production.

Considering the first fact separately, we find that a progressive agricultural development has considerably increased the Brazilian production, whereas at the same time the competition of other countries has considerably distanced Brazil from her former proportion in the total production of the world.

Now, if the increase in the production of Brazil, accompanied by the identical phenomenon on a still larger scale in other producing countries, had constituted an evil, we would have felt it progressively and in proportion to its manifestations. But, far from this, a great demand raised the prices, bringing a larger amount into consumption, notwithstanding the grave obstacles resulting from the fiscal regimen of many consuming countries. In this relation the coffee question offers, therefore, a favorable aspect as long as the demand tends to be maintained, even if not in the indicated progression, at least in proportion to the new and expected increase of production.

To direct in this sense all the forces which our mercantile aptitude affords, seems, therefore, the safest means to give firmness, in the present and in the future, to this great source of wealth in our national agriculture.

Such are, briefly stated, the reasons which determined us to commence our labors upon this point, without prejudice to what may be urgently necessary to be done in the interest of production.

Without enumerating for the present all the causes which are disquieting our great national market (which will form the subject of special considerations which we shall opportunely submit to the wise judgment of the imperial government) we must declare that we are yet very far from having established the approaches and associations which are so advantageous in the international relations of commerce.

To establish and encourage those communications would be the most direct means to improve and steady our position amidst the universal interests agitated in the great industrial competition, and it is under the influence of this conviction that we submit to your excellency the general outlines of the plan which, under existing circumstances, seem to us to be of the earliest and easiest execution, and of equal interest to the cause of our relations abroad and to that of our studies, observations and improvements at home.

In the month of October or November of each year

there will be held in the city of Rio de Janeiro a general exposition of Brazilian coffee produced in the provinces of Rio, Minas, S. Paulo and Espirito Santo, and also in such other provinces as may wish to take part in it.

This exposition will comprise, as far as practicable, every variety of types of the respective production, so as to give an idea not only of the good but of all the diverse qualities and is to be ceded unconditionally to the "Centro da Lavoura e do Commercio," the organizer and director of the said expositions.

The imperial government will concede gratuitous transport on its railroads to products destined for the expositions, and will provide through its dependencies every assistance which may facilitate this enterprise, such as exemption from duties and others, as well as the pecuniary subventions which may be necessary.

Within the exposition building there will be admitted the designs and models of the machines and agricultural implements which the respective manufacturers and their representatives may wish to exhibit.

On days previously designated public conferences will be held on the various questions of rural, agricultural and commercial economy, with reference to Brazilian coffee.

During the time of the expositions the government railroads will issue tickets at reduced prices.

The classification of the exhibited products will remain in charge of the coffee merchants and brokers of this city and the awards will be made by a jury named from among the various classes comprised in the commerce of this article.

The prizes will be offered by the imperial government and the diplomas will be countersigned by the minister of agriculture, commerce and public works. Special prizes will be conferred upon municipalities according to the merit and standing of their respective exhibitors.

After the close of the exposition in Rio de Janeiro it will be transferred to the various markets of America and Europe, the samples being sub-divided as may be judged most convenient, and preference in choice of markets each year being given according as it may appear most opportune in the judgment of the interested classes.

The "Centro da Lavoura e do Commercio" will endeavour to obtain, with the assistance of the local press, a complete collection of the labors realized, which should form a beginning of the library of the coffee-growers.

The expositions in the foreign markets will be organized according to a special plan which will be opportunely elaborated under consultation with leading commercial men, foreign consuls and the Commercial Association of Rio de Janeiro, so as to realize, as fully as possible, the idea of generalizing the knowledge and consumption of Brazilian coffee in its present markets and in those where it is not as yet known.

In the definite organization of these labors the economical question will be considered so as to render as small as possible the pecuniary contribution by the state, principally and directly interested in this great experiment.

The imperial government, besides giving the direct aid in the terms already specified, will recommend to all its diplomatic and consular agents to consider it their first and most patriotic duty to help and co-operate in those labours of the agricultural industry of Brazil, not only by their personal action and influence, but also by means of their prestige with the press and any other corporations of the countries where they may reside.

Such is, in its principal outlines, the plan which seems to us at once practicable and safe in its results, if the comprehension of their own interests will lead our planters, as it is to be hoped it will, to make the necessary effort.

We might offer to your excellency still other developments of the question submitted to our examination, chiefly with reference to the indispensable knowledge of the actual state of coffee culture in all producing countries; we lack, however, the necessary certainty in order to propose the best means to obtain the desired information, and this will yet form the subject of our particular attention.

We rely on the awakening of the many interests already now represented in our agriculture, menaced in its actual constitution and economy; and we are convinced that the commercial class will not withhold its assistance and support of the attempts toward improvement and progress which we so much and so urgently need.

The imperial government in its wisdom will not fail to consecrate the most constant solicitude to these great subjects of public wealth; and so many united pledges will certainly result in restoring confidence and tranquility to labor, and to the country the abundance and prosperity which we all cordially and sincerely desire." —*Jornal do Commercio.*

HORÆ HORTULANÆ:—ON SOILS.

(Gardeners' Chronicle, 8th October 1881.)

(Continued from page 561.)

Reverting to the chemical changes in the soil, adverted to at the close of my last article, I may say that in the first place, if I have at all carried my readers with me thus far, they will be prepared to admit that when we venture on questions connected with the chemistry of the soil, we have to deal not only—indeed, not so much—with the mere presence of this or that chemical substance, as with the existence and prevalence of chemical activities. As I said before, the elements which the plant builds up into its tissues are not quietly stored up in the earth like drugs in a chemist's shop, and the plant does not simply pick out the particles it needs from their quiet resting-places just as the druggist takes from bottle and drawer the materials which he compounds into a healing draught. On the contrary, if there be any truth in what I have urged, the soil is crammed with hidden laboratories, and all the earth around and even far away from the recipient rootlets of the plants is, through the ceaseless action and reaction of the compounds which make it up, engaged in continual slow but potent molecular tumult. But if this be admitted, there follows as a deduction an important truth, not always, I imagine, borne in mind, that when we add any substance to the soil, what we have to consider is, not the mere addition to the composition of the ground, but the influence which the new substance will exert on the activities which were previously at work. The substances, it is true, which I mentioned a little while back as being the constituent elements of all living things must be present in the soil at the disposal of the plant; hence, when they are absent or scanty, they must be supplied. So far the rule of mere addition holds good: but when we attempt to pass beyond this simple instruction, we are at once plunged into uncertainties. When chemistry was first applied to vegetable life, the path seemed easy enough. Since plants differ in composition, the right way appeared to be to analyse each plant, and to add to the soil the elements which predominate in the plant, giving here potash, there phosphates, according as one or the other abounded in the ashes. But a little experience showed that this leading was fallacious. Just as the potash-gathering kelp thrives in the salt-laden sea, so many a plant does best amid an abundance of substances of which it takes but a scant quantity into itself.

Nor is that guide much more trustworthy which bids us add to the ground the constituents predominant in the native soil in which the plant delights to grow—which tells us, for instance, to add lime or chalk to the bed or nook in which we wish to grow plants

gathered from limestone rocks or calcareous hills, for in such native soils the nature and proportion of the elements present determine many other conditions besides mere chemical composition. Chalk, for instance, and limestone are, broadly speaking, both calcic carbonate; they are identical in the chemist's eye, and yet to the tender touch of the living rootlet they are all the world unlike. The detritus which fills the crannies and corners of a limestone rock—and it is in such places that the so-called limestone flowers love to dwell—differs from the detritus which fills similar crannies in granitic rocks, not in chemical composition only, but in physical features as well; the bare surface of the one rock has a wholly different touch from that of the other, the difference being perceptible even to our gross sense, much more so to the exquisitely tender filaments of the young spreading roots; and these things influence the vegetation as much, or probably even more than the mere abundance or scantiness of this or that special chemical element. And every grower of alpines has been in turn disappointed and surprised at finding that often his favourites refused to grow in soil prepared in careful imitation of their native beds, but flourished grandly in quite other stuff.

There is apparently sufficient evidence that some plants, as, for instance, Rhododendrons, will not grow in soil containing an excess of lime; but we are in the present quite in the dark as to the exact nature of this antipathy. It has been suggested that the cause lies in the fact that a calcareous soil always is or always tends to be alkaline to an extent no other soil can be, since no other alkali exists in cultivated soils in such abundance as does lime. And I have heard of an ingenious gardener, who affirmed that he had made Rhododendrons flourish in a chalky soil, by continually administering adequate doses of acids; I mention this, not because I think the case fairly made out, but because it illustrates what I said just now about the complexity of questions relating to the chemistry of the soil. And in the same connection, I may call attention to the statements which have been made more than once, to the effect that sulphate of ammonia is by far the best nitrogen manure for these same calcareous soils. The explanation given is that the ammonia becomes dissociated from the sulphuric acid (the two being previously combined in the sulphate of ammonia) and oxidised into nitric acid; thus the manure added to the soil provides at once two acids to work upon and neutralise the alkaline constituents already present, whereas if instead of sulphate of ammonia the other common nitrogenous manure, nitrate of soda, be given, more alkali in the form of the soda is thrust upon the already alkaline ground. I might quote many other illustrations, showing that in all these matters we have to consider first of all the effects of the substances which we add as manure on the manifold changes which are continually going on in cultivated soil; but I think I have said enough.

So far I may seem to have been arguing against the use of adding special elements or particular substances to the soil; but in reality I have simply been striving to guard against too rash expectations and the inconsiderate use of chemical means. For that special chemical bodies added to the soil, whether by acting on the soil wholly outside the plant, or being absorbed into the plant, and working changes in its tissues, do affect the growth and vigour of particular plants, is a fact which cannot be denied. In proof of this we have over and above the rough experience of the farmer, which has taught him to use one manure for one crop and another for another, the valuable elaborate experiments of Lawes and Gilbert at Rothamsted. In their experimental farm is to be seen a portion of old pasture land divided into a number of plots. For some twenty years or more each plot has been, with some change, manured with a particular manure—this with ammonia, that with phosphates, and so on—and each year in each plot the proportion of plants forming the crop of hay is accurately determined. The result shows beyond question that particular substances favour, on the same basis of soil, under the same general conditions, particular plants. In this plot the leguminous plants, common in ordinary pasture, have been driven out of existence; in that they have flourished and almost driven away the proper grass, and so on. Every gardener who studies the record of these experimental plots can see in it the beginning of the gardening of the future. He can see that hereafter, by diligent study, he will acquire the power of giving to the soil of his favourites just the things they need in their struggle for existence. But it is only the beginning he sees, and long years of diligent study must intervene between present ignorance and future fruition.

The plots of Messrs. Lawes and Gilbert are all either of pasture land or bearing ordinary agricultural crops. What from a gardening point of view is wanted, is a similar series of experiments with our garden plants; put the experiments, to be of real use, must be carefully and systematically carried out, and, that lurking fallacies may be escaped, must be continued through a long series of years. Hasty and slovenly hap-hazard trials lead chiefly to mistakes. Until some such systematic researches are undertaken, I fear that a knowledge of chemistry cannot be of very great use to the gardener. He must continue to do what he does now—to dig into or pour into the soil a mixed manure containing in abundance all that his favourites need, but containing also in abundance things which they do not need, or which even do them actually harm. The wastefulness of such a plan is clear to every one who thinks for a minute over the matter; and the drains and subsoil of our gardens could tell many a tale of the manurial waste going on wherever flowers are grown. I have been into gardens where for many years past heavy dressings of farmyard manure have been dug into the ground year after year, and that for the growth, not of coarse vegetables, but of delicate flowering plants. The result has, I am free to confess, often been good; but I have almost held my breath when I have thought of the awful waste which in such cases must be always going on. And sometimes the result has not been good; rampant disease has made its appearance, and played havoc with the beauty before it bloomed. Nor is this to be wondered at. Every one knows that in the early stages of the comparatively simple fermentation of an ordinary compost heap, the material is a deadly poison to the plants, for which, when thoroughly ripened and rotten, its violent effervescences all over, it will serve as most nutritious invigorating food. So it is also with the slower quieter fermentations going on beneath the surface of the soil; of the multitudinous changes going on there, while many, especially the final ones, are beneficial, some, especially the initial and grosser ones, are directly harmful to the plant; and if these latter, as in heavy frequent manuring is likely to occur, be in excess, they may poison the organism which it was intended simply to feed. Happily, as in the human race—though many if not most people eat more than they need—starvation works more harm, on the whole, than does over-eating, so among plants, far more blooms fail through want of adequate food than are cut off by a too liberal diet; but the waste, both in the one case and the other, is an evil which the stern demands of economy must sooner or later make us take firmly in hand. There can, I think, be no doubt that, did we possess the requisite knowledge, both the waste and the attendant disease might be avoided. PILLEUS.

(To be continued.)

THE ROYAL GARDENS IN SIAM.—We learn from Mr. H. J. Murton, late Superintendent of the Botanic Gardens at Singapore, that by the time these lines are in print he will have left Singapore, and taken charge of the Royal Gardens in Siam. Letters and Catalogues should therefore now be addressed to him at Bangkok. *Gardeners' Chronicle.*

TEA CULTURE IN MINAS (BRAZIL).

(*Rio News*, 24th August 1881.)

In travelling over the central line of the Dom Pedro II railway and along its prolongation through the interior of the province of Minas Geraes to the Rio das Velhas, the thoughtful traveller has constantly suggested to his mind the question: What can this region, which is still almost virgin as regards regular agriculture, produce that can bear the high price of transportation to the sea board and leave a reasonable profit to the producer? Beyond Juis de Fóra the country is considered to be sterile and almost unfit for cultivation, because the climate, or soil, or both, are not well adapted to the cultivation of the great Brazilian staple, coffee. This idea that the *campo* lands are only fit for grazing is so deeply rooted that a long time will be required to eradicate it, notwithstanding that the people have constantly before their eyes proofs to the contrary in the beautiful *chacaras* and gardens of Barbacena and other places, established on typical *campo* lands, in which a little care and attention in the cultivation have given results which, if not as brilliant as in the wooded regions, are at least very satisfactory. It is the old idea of the Mexican population of the Pacific slope of the United States whose immense and so-called sterile cattle ranches now constitute the celebrated wheat and fruit-growing districts of California. It is certain that the *campo* lands of Brazil are inferior to the wooded lands, and that in many places the soil is poor and thin, but for the most part those of the centre of Minas Geraes would be considered very desirable by many farmers of the eastern United States and of many other prosperous agricultural regions. The fact is, as will be proved whenever a thorough and rational system of agriculture is put in practice, that nearly all of Central Minas is capable of sustaining a large and active agricultural population. The principal question at present is that of the kinds of cultivation which, with the actual high rates of transportation, can be followed with advantage until such time as the increase in population and wealth shall make the traffic sufficiently important as to permit such a reduction in the freight rates as will render possible the cultivation and exportation of all the products that the region is capable of producing, including even the bulky products of least value.

It is hardly necessary to speak of coffee and tobacco, as these are already cultivated on a greater or less scale throughout the region, and it is evident that their cultivation might be indefinitely extended. Except in the highest and coldest parts, coffee produces well, though it is only seen in gardens and not in regular plantations. There is a general complaint that it ripens irregularly, though this perhaps is not so great an obstacle to its general cultivation as it is often represented to be. As an article of export, however, for a great part of Central Minas, coffee is out of the question on account of the high freight rates, which will probably limit its cultivation to the zone below the Serra da Mantaqueira. Further in the interior it can only be produced for local consumption, or for the supply of more remote districts.

Many other products might be mentioned for which the climate and soil of Central Minas are fitted, and which present the all essential requisite, in the present condition of the province, of combining a high value in a small bulk, but these remarks have perhaps already extended too far for the purpose for which they were intended, viz., an introduction to some observations on the cultivation of tea. As is well known, tea culture was introduced into Brazil many years ago as an experiment, and tea plants are now found in many gardens as objects of curiosity, and tea even comes to the market from a few localities in the provinces of Rio de Janeiro, São Paulo, and Minas Geraes. This species of cultivation, however, seems to have attracted but little attention, and the question as to whether or not the cultivation might not with advantage be greatly extended, at least, to the point of supplying the home market, seems never to have been seriously considered. Among the many new or nascent industries that merit careful attention and study, that of tea culture deserves to take a prominent place not only on account of its adaptability to the conditions of the country, but also on account of the fact that the product is always certain to find a good market at a high price. This opinion is based on observations made on a small plantation of tea on a *fazenda* near Ouro Preto, belonging to the family of the late Barão de Camargos, and on information kindly furnished by the son of the late Barão, Dr. Antonio Teixeira de Souza Magalhães.

The *Fazenda do Thesoureiro* is situated on the road from Ouro Preto to Diamantina, at a distance of four leagues from the former place, and about half a league distant from the eastern base of the Serra da Caraça. The *fazenda*, which in its appointments is one of the best in this part of the province, owes its importance primarily to a rich series of auriferous rocks that traverse the property and gave origin to very extensive and lucrative gold washings, and, secondly, to a small tea plantation made some forty years ago and carefully preserved to the present time. The tea is planted on a hill-side with an eastern exposure, occupying an area of about five English acres. The plants are about four feet apart, and are kept pruned to a height of about two feet. The soil is a red sandy clay resulting from the decomposition of the greasy alkaline schists so abundant in Central Minas, and is full of quartz and ironstone pebbles and rich in iron. The ground is full of that Brazilian pest, the Sauva ant, but this is far from being so great a disadvantage as in other branches of agriculture, because, although the ants cut off some of the new leaves fit for tea-making, if they are not promptly gathered, their ravages are mainly confined to the older and tougher leaves, so that by a natural process of pruning the formation of new leaves is increased. A marked increase in growth and vigour is also noticed in those plants situated over the ant hills, due to the loosening of the soil about their roots.

The process of manufacture is briefly this. Throughout the rainy season of five or six months, the new and tender leaves that appear shortly after each rain are picked and carried to the drying-house. This consists of a large room with several tables and a low furnace of masonry fed from the outside and supporting shallow iron pans about 2½ feet in diameter set in holes in the top of the furnace directly over the fire. Each panman fills his pan with green leaves and stirs them rapidly for about half an hour over a hot fire with a peculiar motion to wilt them. In this process he has to remove the leaves every few minutes and scour the pan to remove the gummy matter which exudes from the hot leaves, and which if left adhering to the pan would cause scorching. When properly wilted the leaves are taken to the rolling table on which is a movable screen of coarse wicker-work made of bamboo, on which the leaves are rubbed with a strong pressure of the hand, which extracts from them a considerable quantity of vegetable extracts rich in tannin which oozes through the screen, and, at the same time, the leaves curl or roll up into various forms according to their degree of tenderness. They are then ready for the final drying which requires several hours in the pan. This is the most delicate part of the process, great practice and skill being required to produce the best tea by a proper management of the fire and of the stirring. After this drying the tea is assorted either immediately, or after a delay of weeks or months, according to the urgency of other work. The assorting is done by fanning the dried leaves in bamboo sieves with holes of various sizes and shapes, the number of varieties being dependent on the number of sieves employed and the care and patience expended on this somewhat tedious process. Some of the

finer varieties must be separated by picking out by hand, but this is seldom worth while, and they are left mixed with the others. After the sorting, the tea is again thoroughly dried and stored in tin-lined boxes, or sent to market in tin canisters. The varieties usually separated, with their prices, are as follows:—

Familia (unrolled leaves)	..	3$200 per kilo
Hyson (cartouche-shaped, coarse)		5 200 ,,
Ochin (do. do. fine	..	8 000 ,,
Aljofar (round, fine)	.. ..	8 000 ,,
Perola (round, coarse)	.. ..	8 000 ,,

It will be seen that the process of manufacture is very simple, requiring only inexpensive apparatus and no great amount of skill in the workmen, since this work has been done by the ordinary slaves of the *fazenda*, producing teas that even at the high prices given above, have almost excluded the foreign teas from the Ouro Preto market. The best evidence of their superior quality is the fact that it has been found of advantage to imitate the mark of the Thesoureiro factory in the market of Rio de Janeiro, and that the proprietors have first-class medals not only from all the national expositions, but also from the international expositions of London, Vienna, and Philadelphia.

Let us now examine the question of the cost of production. The leaves lose in drying about 75% of their weight. A good panman will wilt, roll and dry half an aroba of tea per day, and an active picker will gather the same quantity of green leaves. Four pickers and one panman can therefore prepare half an aroba per day at an expense (counting wages at 2$000 per day, a very liberal estimate) of 10$000. An equal sum should cover the expenses of weeding and cultivating the ground (very light work) and those of sorting and of the final preparation for the market, which is work that can be done when other work is slack. This gives a total expense of 20$000 per each half aroba (7½ kilos) which at the lowest price is worth 24$000. The mean price is, however, much greater (owing to the mixture of varieties), and practice has demonstrated that it is about 45$000. Supposing even that by the eventualities of bad weather or bad management the expenses were doubled, there would still be left a handsome profit of about 12½ per cent on the cost of production.

It is not pretended that so favourable results have been attained at Thesoureiro where the unsystematic employment of slave labour makes it impossible to arrive at any reliable estimate of the actual cost of production. The *fazenda* has about fifty slaves, including many women, children, and old men, who have been employed in tea-making, mining, and general work. The annual production has varied from fifty to eighty arobas.

The advantages of this species of cultivation, aside from that already mentioned of combining a high value with a small volume, so that the product can bear a high rate of transportation, are intuitive from the above description, and only need to be enumerated. They are:

1st. The adaptability of this cultivation to lands of difficult cultivation, on which the planting of annual plants would be very expensive or impossible.

2nd. The long life of the plantation which after the first planting only requires a slight amount of work in cleaning the ground of weeds and loosening the soil. The Thesoureiro plantation is, as already stated, forty years old and is still good.

3rd. The freedom from injury from ants.

4th. The small cost of the buildings and appliances for the manufacture, making this a very desirable branch of industry for small proprietors, especially as the most pressing work of the harvest, that of gathering the leaves, is such light work that it may be done by women and children. Even this small expense may be avoided by the establishment of central factories since, as the leaves may be kept for twenty-four hours or more before going to the fire, a factory could draw its supply of green leaves from an area of several miles.

5th. The absence of risk of loss from bad weather because the new and tender leaves fit for tea-making only appear after rains which do not prevent the picking, and, when once gathered, all the rest of the process is under cover. Coffee planters who pass anxious weeks during the drying season will appreciate this advantage.

In view of the favourable results obtained in this one experimental establishment, the farmers of Minas and other parts of Brazil will do well to carefully examine this question of tea culture, and many will doubtless find it to their advantage to embark in it. It seems particularly well adapted for the *pequena lavoura*, and the *grande lavoura* with free labour since the harvest is very light work which can be done by hands too weak for other work, and being extended over a considerable season requires a less number of hands than those crops that must be gathered in a few days or a few weeks. The empire itself offers a very extensive and ever-increasing market for the product, which even if produced on a very large scale would for many years at least be almost absolutely independent of the fluctuations of foreign markets. ORVILLE A. DERBY.

FRUIT JOTTINGS FROM SINGAPORE.

(*Gardeners' Chronicle*, 8th October 1881.)

We have just got through our fruit season in Singapore, only a few scattered fruits of Rambutan (Nephelium lappaceum), Pulasan (Nephelium mutabile), Mata kuching (Nephelium eriopetalum), Rambeh (Pierardia dulcis), and Mangosteens, now remaining on the trees. The crop in Singapore of nearly all kinds has been a very heavy one; in fact "everybody" says the heaviest ever known here. The regal Durian, as Mr. Burbidge justly styles it (*Gardeners' Chronicle*, May 31, 1879), has been particularly plentiful; and as Mr. Burbidge has sounded its praises so loudly and ably, he may be pleased to know that they have been selling here at the rate of twenty for a dollar, and fine fruit too.

The quantity of imported fruit has also been very great, especially of such kinds as do not succeed well in Singapore; notable among these being the Langsat (Lansium domesticum), and the Mango. The Langsat does well in Malacca, whence the fruits are exported to Singapore and other places; but, strangely enough it has not, so far as I am aware, ever done well in Singapore. Mangoes come to us from Siam, and delicious fruits they are; but those grown in Singapore have mostly an inteusely terebinthine flavour, and the trees are very subject to the attacks of boring larvæ which tunnel their way for long distances through the central pith of the medium-sized branches before emerging, and it is not uncommon to see almost the whole heads of large trees killed by this pest. A close ally, the Beenjai (Mangifera cæsia), does well in Singapore, but its fruits are only used for making a sort of "sumball," a name applied to numerous kinds of preparations eaten with curry and rice. To appreciate it, however, even in this style, one has to be educated to it, as with the Durian, but when once a taste for it is acquired, the pleasant sub-acid and peculiar flavour is missed with regret when it goes out of season.

The Rumaniyahs (Bonea microphylla and B. macrophylla) are professedly relished by some Europeans, but I must confess that my taste has not yet been educated enough to appreciate them, which is also the case with Jack-fruit (Artocarpus integrifolia), although it is much relished by many people. By-the-bye, while staying with some friends in Singapore last week, I was treated to some very delicious home-made Sour Sop (Anona muricata) jam and jelly, which obliges me to acknowledge that they were simply perfection. What a pity it is we cannot grow enough Sour Sops to render us independent of Crosse & Blackwell's and Morton's preparations in this line.—H. F. MURTON, August 30.

THE EDIBLE FUNGUS OF NEW ZEALAND.

(*Gardeners' Chronicle*, 8th October 1881.)

A fungus, the export value of which has reached to over £6,000 in one year and over £11,000 in another, must be deemed a matter of sufficient importance to be worthy a note. A New Zealand correspondent kindly furnishes us with samples of the fungus, Hirneola polytricha, a near relative of the common Jew's-ear fungus of this country, together with some notes of Mr. Griffin, the American Consul at Auckland, from which we extract the following:—

"The New Zealand fungus known to commerce is found upon various kinds of decayed timber in the North Island, in what are called new bush settlements. It favours damp localities, and is very plentiful on the East Coast, south of the East Cape. It exists, however, in the greatest abundance in the province of Taranaki. This province is about 80 miles long and 70 broad. It is bounded on the north by the river Mokau, on the west and south by the sea, and on the east by a straight line from the mouth of the Patea river to a bend in the Wanganui river, and by another straight line connecting the latter river with the source of the Mokau river. Within this region are the vast forests: indeed, not more than one-tenth of the entire province is composed of open land. The process of clearing the ground is very slow. The settlers often find their task so difficult that they abandon their work in one place and begin again in another. They lop off the branches of the trees and burn them, leaving the logs upon the ground, and as they are not removed soon begin to decay. The trees are well supplied with spurs, and fall in such a way as to partially rest upon them within a few feet of the ground. Sometimes the workmen erect scaffolds for the trees to fall upon. It is supposed that the growth of fungus is favored by the trees being left in this way; it is more probable, however, that some peculiarity of the climate has more to do with its growth than anything else. It requires very little trouble and no expense to prepare this valuable article of commerce for the market; indeed, the only thing necessary to do is to gather it, and spread it out on the ground in the open air, or under sheds to dry. I know a number of children who keep themselves in pocket-money by collecting it, and they have no difficulty in telling it from obnoxious and poisonous plants of similar growth. Very few men except those of idle and dissipated habits engage in the employment of collecting fungus, unless I except the Maoris (or native inhabitants), who do not consider that occupation beneath their dignity. The fungus collected by the natives is generally dried in smoky huts, and is, on that account, nothing like as valuable as that prepared by the children of Europeans. As soon as it is dried it is put in flax baskets or jute bags, and sold to the dealer for what it will bring. It is then packed in bales and shipped to China by way of Sydney or San Francisco. Some of it goes direct to San Francisco, where it is either transhipped to Hongkong, or consumed by the Chinese population of our Pacific coast. At one time the profit upon fungus was something enormous, and it could be bought from the collectors at little more than 1 cent per pound, and sold in San Francisco at 15 cents per pound, and 23 cents in Hongkong; the prices, however, are fluctuating. Now that its market value has become better known, it is difficult to purchase it here, even in small lots, from the collectors for less than 8 to 10 cents per pound. It loses rapidly in weight by shrinkage.

"THE USES IN CHINA.

"In 1873 the Government of New Zealand caused an inquiry to be made as to the purpose for which fungus is used in China, and some correspondence was had between the Colonial Secretary of New Zealand and the Colonial Secretary at Hongkong. The latter stated in one of his communications that the article was much prized by the Chinese community as a medicine, administered in the shape of a decoction to purify the blood, and was also used on fast days with a mixture of vermicelli and bean curd, instead of animal food. It is also said to be used in China and Japan for making a valuable dye for silks. Since this correspondence it has been discovered that it is used by the Chinese principally as an article of food. It forms the chief ingredient of their favourite soup, for which dish it is much prized on account of its gelatinous properties and its rich and delicious flavour. I send by this mail to the Department of State a small package of samples of fungus marked H., kindly furnished me by H. B. Morton, Esq., of this city, for examination and experiment. Mr. T. F. Cheeseman, the curator of the Auckland Museum, is of the opinion that the fragments of wood attached to one of the specimens is from a tree known to the Maories as Whau-whau-paku, or to botanists as Panax arboreum. The other specimens were doubtless found on the Karaka tree (Corynocarpus lævigatus), or the Mahoe (Melicytus ramiflorus), Kaiwhiria (Hedycarya dentata), Pubapuka (Brachyglottis repanda), and the Panax arboreum already mentioned, as well as on several other soft-wooded trees. Fungus appears to me to have a slightly pungent taste, although it is generally said to be tasteless. A few days ago I made soup out of some of the samples furnished me, but did not partake of it in sufficient quantities to be able to judge of its excellence as an article of food for civilised people; but one of my Chinese neighbours, who happened to be passing my door while the soup was boiling, caught the aroma of it, and very kindly relieved me of any further trouble in trying to cultivate a taste for one of his favourite national dishes.

The following table shows the quantity and value of fungus exported from New Zealand for each year since 1872:—

Year.	Tons.	Value.	Year.	Tons.	Value.
1872 ..	58	£1,927	1877 ..	220	£11,318
1873 ..	95	1,195	1878 ..	173	8,652
1874 ..	118	6,226	1879 ..	59	2,142
1875 ..	112	5,740	1880 ..	165	6,227
1876 ..	132	6,224			

THE PRIZE CACAO POD OF THE CEYLON SEASON is certainly the magnificent specimen sent to us by Mr. John Drummond of Gang-Warily, Western Dolosbage. It measures 10 inches in length, 14 inches in circumference, and weighs 2lb. 5 ounces exactly. Mr. Drummond writes about it as follows:—By this post, I send you a large cacao pod to shew you what we can do in this corner of the world. You see we are improving. The pod which I sent you last year, and attracted attention, was under 2 lb. weight. I make out this one to be 2¼ lb., but you had better test it.

LEDGERIANA SEED: MASKELIYA, CEYLON: 30TH NOV.—Very hot mornings and cloudy, showery evenings are the order of the day. The consequence is a general ripening up of crop, and most of the estates in the centre valley have got in more than half their estimates. Surely your correspondent "E. H. C." is a little "out of it" in advising *green*, of all colours, as the one to be applied to the glass on seed frames to moderate the heat. I thought it was the very colour to avoid as, while it keeps out the desirable light rays, it freely transmits all the heat rays. I think a common bamboo tat, on a light frame-work a foot or two above the glass, is the best, as it can be removed during the many monsoon days, when one is not troubled with too much heat or light. I do not think slowness in *germinating* any sign of purity in Ledger seed. I would interpret it as a sign of age—not desirable—equally with succirubra or officinalis, slowness in *growth* might mean freedom from any cross-fertilization.

CHERRY *VERSUS* PARCHMENT COFFEE.

A coffee planter in Southern India writes to us that he is very anxious to obtain answers to the following questions:—

"Does a box, in which picking is brought home of cherries, equal 1¼ bushel? And will three such boxes yield 2 bushels of parchment? This would be 3¾ bushels cherries equal to 2 bushels parchment."

Everything depends on the size of the box: in Ceylon, estate boxes for picking have been known to vary from the capacity of 1¼ to 2 bushels! We know that from 65,000 to 70,000 parchment beans of Arabian coffee go to the bushel, and that 166,000 cherries are equal to about 1 cwt. of clean coffee. Further, one cherry is supposed to occupy as much space as five parchment beans. Consequently, we should say, it would take 2½ bushels of cherries to turn out one bushel of clean parchment. The ratio between Arabian coffee cherries and parchment is 100 to 40, that is 40 per cent of parchment in quantity results from a bushel of cherry. That would mean 2½ bushels of cherry to one of parchment, and, say, 12½ bushels cherry to 1 cwt. clean coffee. From this, again, we infer, that about 13,000 cherries go to a bushel against 65,000 parchment beans. The result we get differs widely from that mentioned by our correspondent, and we should like to know if the proportion between boxes and bushels of cherry and parchment has ever been clearly established in Ceylon? In the case of Liberian coffee the outturn of parchment in proportion to cherry is considerably smaller, so great is the quantity of mucilaginous matter, but it is not so small as some people think; 123,000 Liberian coffee cherries (against 166,000 Arabian) give 1 cwt. clean coffee; 45,000 parchment beans fill a bushel, and the clean parchment is equal to from 22 to 24 per cent of the cherry. Consequently, between 4 and 5 bushels of cherry are required to give one of parchment, so that from 5,000 to 6,000 cherries of Liberian coffee should fill a bushel.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special letter.*)

PARIS, November 5th.

Among the most prominent events to record is the Phylloxera Congress at Bordeaux. It did not lead to the revelation of anything new, so much as to the official ratification of certain remedies. The origin of the disease was left in abeyance. The habits of the bug were relegated to the entomologists, and the latter declared that, were the winter egg of the bug discovered and extirpated, the enemy would be conquered. Three remedies or preventives were discussed in committee, and by the most competent authorities. Take the plan of autumnal irrigations known as the Faucon process, so named after that distinguished proprietor of Graveson, near Marseilles. After the vintage, he floods his vines for two months, and, in spring, literally doses the land with farm yard manure. He thus saved his vines, while his neighbours, who declined to follow his example, were ruined. In the Medoc districts, this process is at present general. It implies, however, the command of a supply of water, either natural or artificial: hence the Government is doing all in its power to extend canals and arterial drains, &c. Insecticides, or chemical preparations, follow next in order: they are limited to two: sulphocarbonate, and sulphuret of carbon. Both have drawbacks, and have not given uniform results. The first is very expensive to prepare, and, in addition, necessitates a large supply of water to be distributed in the state of solution. Its use is hence limited to vines, either very prolific, or possessing qualities of known reputation; in any case, of a nature calculated to pay the great outlay. The second, sulphuret of carbon, is cheap, but it requires much caution in being applied, or the remedy may be worse than the disease. Its effects vary with the depth and porosity of the soil, to permit of the diffusion of the salt. The temperature also influences the action. Excessive cold or excessive moisture can do more harm than good, if these follow the use of the sulphuret. As France is estimated to have lost five milliards by the invasion of the phylloxera, and the ravages still continue, besides preventing the march of the enemy, it is a necessity to replant where the devastation has been effected. Here there is really less room for dispute: the grafting of French vines on American stocks is the sole plan known. The roots of the American vine resist the attacks of the bug. American vines flourish side by side where French vines perish: ten years of successful grafting confirm the remedy. The Riparia is the variety of American vine which is in general favor. In Portugal, sulphuret of carbon and irrigation are the measures adopted: in Switzerland and Italy, extirpating the sick vines finds most advocates. In Sicily, the peasants rose against the decree for eradicating infected vines, and the inspector fortunately escaped from being blown up, with his house, by dynamite.

At the present moment, when the relations between landlord and tenant are the order of the day, the practice of the *métayage* system, which is making such rapid strides in France, merits to be discussed. In the fewest words, and freed from complications sometimes introduced, *métayage* farming means the landlord supplying the capital in live and dead stock, the *métayeur* and his family the labor, and the two contracting parties divide the produce. In the most successful working of this plan, no money transactions take place, save what goes to the state to pay taxes. Many farmers, who cannot pay a fixed rent, adopt *métayage*, and prosper: many laborers find in the system the road to comfort and independence. There is nothing new in the plan. Pliny the younger adopted it on his estates and with success, when his tenants were five years in arrears of rent, and became reckless. As a general remark, lauded proprietors in the east of France cultivate their own estates; in the north and north-west, there are tenants; in the centre and south, the *métayage* exists.

The plan ameliorates not only the tenant but the soil, and secures a dividend certain for the owner. One-half of the population of France live by agriculture, the one-third, of both sexes, by the actual tillage of the soil: one-fourth of the cultivated land is worked on the *métayage* principle, and every department of the country has farms so managed. In many cases, the partners, for the contract is practically that, divide 7½ to 20 per cent net profits in a good year: the mean is 4½, and proprietors are ever content, if they only realize 3½ on their capitals: these comprised that locked up in buildings, machinery, and improvements. The *métayeur* and his family are well-fed. They have a like stake with the proprietor in the results, and, at the end of a year, a labourer who would have remained a labourer still, has in addition to comforts, a cash dividend of 2,000 frs. The principal item of expense in farm management is wages under the *métayage* plan, where the whole family labours, it becomes a minimum. It is evid-

ent, therefore, that the more farm wages rise, the more the métayage solution imposes itself.

Salicylic acid, as a disinfectant and a preservative, still excites attention. No hygienic reasons exist, according to Pasteur, why, in certain quantities, the acid ought not to be tolerated in food and drink: the French Government has prohibited its use in beer and wine, as that use was abused. In the case of cattle disease—foot and mouth, lung, and *charbon*—salicylic acid is employed by vets with great advantage: if it does not prevent the virus to produce in the organism of the animal, it undoubtedly stops its march: one-tenth of an ounce dissolved in a quart of warm water, and sprinkled over the litte will immediately sweeten a stable; half a quart of the solution mixed with the ordinary drink suffices for an diseased animal: the acid, too, can be dusted over the sore feet, or the mouth and nostrils washed with a solution. If poultry be attacked with cholera, add a little in their drinking vessels, and mix some up in bread pills and honey.

A gentleman, alluding to the prevalence of typhus fever in horses, says his have completely escaped, and this exemption he attributes to adding a little salt and chopped garlic—the latter in small quantities at first—to their oats: further, above their backs he places movable boards, which receive a fresh coat of tar weekly. In the case of severe bronchitis, French doctors prescribe the spreading of Norwegian tar on a plate in the sick chamber, the balsamic odour effecting good.

Some prizes were awarded to agricultural industries at the Electricity Exhibition. The subject, however, is not yet ripe for practical consideration. The problem to solve is: not the application of electricity as a motive power, but of the cheap production of electricity as that power.

Owing to the destruction of the vines, and the great damage done to orchards by the severe frost of 1879-80, the production of alcohol has diminished: to remedy this state of things, farmers are being actively urged to embark in the distillation of beet—why not potatoes, as in Germany, by the ordinary alembics? Prizes are offered to encourage the new industry.

There was a milk or dairy show held at Ghent last July, when the milk of cows of the Durham, Dutch, and Flemish breeds was exhaustively examined as to density and quality: it has been demonstrated that the difference in richness can vary as 1 to 3, that is, from 4½ to 15 per cent; the yield of milk per day can vary as 1 to 5: in the great majority of cases, the first milkings are superior in density to the others in a day, and that density oscillates between 1026 and 1033. Upon 168 samples of milk, 29 were inferior in density to 1029; hence, after the expertists, they ought to be suspected of being dosed with water. In addition to density as a test for the purity of milk, must be included the percentage of cream: now at Ghent, milk unquestionably pure yielded 5 per cent of cream. Practical conclusion—difficult to decide when milk is pure.

INDIA: SEASON FOR WEEK ENDING 15TH NOVEMBER.

Rain has again fallen copiously throughout the Mysore State and in Coorg, and crops are now everywhere in good condition; the harvesting of ragi and other minor crops has commenced in Mysore, and rice and coffee will now ripen better in Coorg. In the Madras Presidency there has been further rainfall, more or less heavy, in all districts except one; and general prospects are good, although a few districts still need more rain. In British Burma and Assam crop prospects are favourable everywhere; the harvesting of rice has commenced in the latter province.

On the whole, it may be said that recent rains have materially improved crop prospects in Southern and Western India; that in the Central tracts of the country the weather is seasonable, and agricultural condition satisfactory; and that in the greater part of Northern India, general showers would be beneficial.

Madras.—No rain in Ganjam; general prospects good.

Bombay.—Good rain in Southern Maharatta Country; rain also in Kanara, Ratnagiri, Satara, Sholapur, and parts of Ahmednagar: urgently wanted in parts of last-named district and of Nasik; locusts in Nasik and parts of Broach and Surat; fever and cattle-disease continue in a few districts; prices falling in Dharwar; elsewhere generally steady.

Bengal.—Slight rain in parts of Central and Eastern Bengal during the week.—*Madras Mail.*

COFFEE LEAF DISEASE.

With reference to Mr. G. A. Talbot's letter, it is right that planters should fully and freely discuss Mr. Marshall Ward's Report, and no one has a better right to be heard than Mr. Talbot who took such an active part with Mr. Morris in the early investigations into the life history of the fungus and experiments directed against the existence of the pest. It seems to us, however, that the Mycologist and the planter are quite at one in the belief that certain conditions of vigorous and mature foliage or the reverse enable coffee trees to resist attack or render them specially liable to it. What we understand Mr. Marshall Ward to contend for is, that no coffee trees posses *inherently* any qualities enabling them to resist or rendering them specially liable to attack.

MR. KARSLAKE'S MODE OF STRIPPING CINCHONA BARK AND "E. H. C." ON CINCHONA NURSERIES.

Supposing cinchona trees can be saved from that premature decay which has necessitated the uprooting of so many thousands, the importance of Mr. Karslake's mode of bark-stripping, if finally successful, can scarcely be exaggerated. The heavy—in a large proportion of cases, the prohibitory—expense of collecting moss or other substance, and tying it round the trees, is saved. So is much of the risk which attends the stripping and shaving process. To rightly understand Mr. Karslake's process, an obvious misprint in his letter ought to be corrected. Paragraph third of his letter (the introductory matter) should read:—"Itis, I find, necessary to make only the two vertical cuts at first. There is no fear of the bark adhering after it has once been loosened, and the top and bottom cuts will be made when it is intended to remove the old bark." How does Mr. Karslake4 "remove" (properly *loosen*) the strip of bark so as not to injure the cambium—an essential condition? By McIvor's method each strip, when cut across, at the top, was drawn down, and, the process being conducted when the trees were full of sap, came easily away, without the necessity of inserting any instrument between the bark and the tree. But, as by Mr. Karslake's method the bark is left adhering to the tree at the bottom, as well as the top, we should be4 glad to lear nor

to be reminded of the mode in which the bark is "removed," without injury to the cambium, and yet so thoroughly as to justify such language as "Replace the strip of bark thus *removed* in its original position without delay." "Thus loosened" would surely be a better description, and we should be glad to know what is the "suitable instrument" which Mr. Karslake's experience has led him to decide on? A tortoiseshell paper-cutter suggests itself to our minds; or a bone or ivory spatula? An ordinary knife used by an ordinary cooly would, we fear, result in injury to the cambium? With the bark simply *loosened* and at once replaced—kept in position by string and the edges filled up with cowdung or clay—we should havo feared a process of readherence but for the result of Mr. Karslake's experience. The next great question is the effect of the atmosphere, and, especially, of battering rain on the loosened bark and its alkaloids? Has Mr. Karslake satisfied himself that bad consequences will not ensue during the period (considerably longer than Mr. Karslake's minimum of ten days in most cases, we suspect) during which the loosened bark remains on the tree? No doubt, the adhesion of the strip at bottom and top is a safeguard, but does this entirely prevent deleterious changes in the alkaloids? Mr. Karslake recommends the removal of the loosened strips only "after the renewed bark has appeared over the whole surface and is of sufficient vitality to be able to withstand the heat" &c. To ascertain the state of the renewed bark will necessitate probably several movements of the old bark from its position, and each such process would, apparently, increase the risk of chemical change in the alkaloid cells of the bark? Mr. Karslake, having given the public the benefit of the main principles of his discovery, will not, we feel certain, object to answer our queries as far his experience enables him.

A correspondent writing from Maskeliya has pointed out the one objection we felt and meant to express in regard to "E. H. C."'s valuable letter on cinchona nurseries. How he, otherwise so well informed, came to recommend the painting green of conservatory glass, we cannot conceive. Sure we are, from recent personal observation, that he could not have seen green glass, or glass painted green, used in Java. Not certainly in the conservatories of the property in which Mr. Von Winning is interested any more than in those under Mr. Moens' charge on the Government cinchona plantation. The best conservatory glass is treated like tho "moon glasses" of lamps, and white paint or whitewash can produce much the same effect with plain transparent glass. We took special note of the fact that in the case of the conservatories where Mr. Moens' grafted Ledgerianas are grown, the very device of shading with bamboo tats suggested by our Maskeliya correspondent was resorted to. When the sun shone fiercely on either side of the conservatory, the effects were modified by coverings of plaited bamboos being put over the sloping glazed roof. Indeed, much can be done for the protection of plants by the use of plaited bamboo, without glass. We may also say at once that while Mr. Moens used the porous chatties for germinating seed and growing seedlings, he had also large and flourishing nurseries of Ledgerianas in long beds of mould, protected simply by grass-covered roofs facing each other, but with an open space between to admit light and air. Right beneath the open space was the path between the two beds. The watering was performed by means of a syringe, which, inclined upwards, produced a spray that fell gently on the plants.

COFFEE IN SOUTHERN INDIA

We give prominence to the following:—

To the Editor of the "Ceylon Observer."

Tellicherry, 19th Nov. 1881.

DEAR SIR,—We have the pleasure to enclose statement of exports of Coffee and Pepper from the Malabar coast for the year ending 30th June 1881.

The present Coffee crop promises to be considerably larger than last. There seems to be considerable uncertainty as to the Pepper crop, but so far as our information goes, it points to only a moderate one.—

We are, dear sir, yours faithfully,

ALSTONS & Co.

This table is of considerable interest as shewing, among other things, the relative importance of the coast ports. On the whole Tellicherry seems to have the largest share of coffee shipments, although in respect of plantation coffee especially Mangalore is a close rival. In fact the trade of the Wynaad and Mysore districts seems pretty equally divided between Mangalore, Tellicherry, Calicut and Beypore. Farther South, Cochin has the shipping of the produce from the Peermade Hills, which during the past season shewed a falling-off for coffee of nearly one-half on the previous year, while the Pepper crop had largely increased. Travancore, through its port Colachel, was steady for the two seasons with a crop of a little over 11,000 cwt., a poor outturn for so large an acreage—in fact not much more than 1 cwt. per acre. Altogether the shipments of coffee (plantation and native), which equalled 392,583 cwt. in season June 30th, 1879 to June 30th, 1880, fell off to 257,745 cwt. for the year ending June 30th last; while the crop of pepper showed more than a corresponding increase.

Messrs. Alstons & Co. would greatly oblige us by sending the export return for a series of years: for as many indeed as reliable records are available.

CEYLON TEA IN THE LONDON MARKET.

Undoubtedly, there is a great difference in this preparation and value of different Ceylon teas as evidenced by the infallible index, the result of open sales in Mincing Lane. An experienced tea-broker, who had been consulted in October last by a Ceylon merchant as to the value of our teas, gave a very unfavourable report, remarking on the need for special improvement before much attention could be paid to them by the trade. He pointed to the miserable prices paid for some lots sold a few weeks previously.

A few days after, the following note reached the merchant from the same broker, an entirely disinterested party:—

DEAR SIR,—As an exception to what I said the other day regarding Ceylon teas, a capital little invoice, some 99½ hf-ch. were sold yesterday ex "Hankow" from the "Loolecondura" tea plantation. The teas were really good and I should say fetched remunerative prices. I enclose you three samples.

Prices realized for Loolecondura tea on Oct. 25th:—

39	half-chests	Souchong	at	1/6¾
6	„	Pekoe dust	„	/9
2	„	Dust ...	„	/6½
15	„	Broken Pekoe	„	2/
29	„	Fine Broken Tea	„	1/8¾
2	„	Pekoe Souchong	„	1/7
6	„	Red Leaf ...	„	/11
99	ex "Hankow."			

By way of contrast we have the result of a sale on the 2nd November of a quantity of Ceylon tea which was described by the same broker:—"Value as Javas; burnt and sour; very badly cured." The sale was as follows:—

CEYLON TEA.

At Cutler Street warehouse. Per "Compta," at Colombo, reported October 1881.

BULKED.

WES Season 1881.—16 half-chests broken tea 255 at 270 Av. gross 2 qr. 9 lb.	9¼d.
37 chests broken tea 271 at 307.	9¾d.
37 half-chests broken Pekoe 308 at 344 Av. gross 2 qr. 12 lb.	1s 0d.
30 half-chest broken Pekoe 345 at 374, 30 do. do.	
375 at 404 Av. gross 2 qr. 11 lb.	11¾d.
29 chest Souchong 405 at 433.	11¾d.
23 chests Pekoe Souchong 434 at 456.	1s 0¼d.

S. R. & Co., November 2nd, 1881

Ceylon tea, per "Compta" (C S) without reserve, on account of the importers.

WES Season 1881.—12 chests Congou 457 at 468.	10d.
15 half-chests Pekoe dust 469 at 483.	6¾d.
15 half-chests Pekoe dust 484 at 498.	6¾d.
24 half-chests broken Pekoe 499 at 522 Av. gross 2 qr. 15 lb.	11¾d.

PLANTING IN NETHERLANDS INDIA.

(From the *Straits Times*, 16th November.)

In the official report on the Government Cinchona culture in Java for the 3rd quarter of 1881, it is stated that on the 30th September last, the number of cinchona plants in the nurseries was 635,400 and that in prepared ground 2,072,070. During the said quarter the collection of bark was vigorously proceeded with, this year's crop being estimated at 150,000 Amsterdam pounds. The crop for 1880 was sold at Amsterdam on the 12th July at an average of 136 cents per half kilo, the highest rate being 586 cents per half kilo for Ledgeriana bark. Owing to a decline in the Cinchona market at the time of the auction, the amount realized was less than at the sale in 1880, when the average brought was 216 cents per half kilo In August last, the cinchona plants on elevated and exposed situations suffered greatly from frost at night, the temperature having fallen to very near freezing point sometimes.

The *Java Bode*, in a series of articles calls attention to the Bachan or Batchian islands in the Moluccas as a more promising field for commercial enterprise than Java, the condition of which is thus set forth:—

"In Java, which was formerly termed both by Netherlanders and foreigners the "pearl" of our possessions, and which, very untairly, as demonstrated by experienced men, had for a long time attracted to itself almost exclusively the attention of Government and capitalists, the prosperity of former times has greatly diminished. The supply of European labour is overabundant but the demand for it is small. Wages are falling. Great numbers of overseers, managers, and mercantile employés are rambling about without employment. Tobacco cultivation, which formerly gave work to so many hands and yielded such profits, is dying out. The tobacco growing provinces of Kedirie and Kadu are but ruins of vanished greatness. Whole estates have been abandoned or sold for an old song. Trade also has seen its best days. Though at present there is noticeable a welcome and unusual manifestation of enterprising spirit in tramway construction, and though many banks have increased their capital greatly, and a new bank has even been established, this does not do away with the fact that *the impression* made by Java when viewed from an industrial point of view, is anything but encouraging."

The consequence of the foregoing state of affairs is increasing attention to the other long neglected islands of Netherlands India. One result is, the formation of a company in Holland by Messrs Elout, Giebert, and Hope with a capital of 2,400,000 guilders, to turn to account the vegetable, mineral, and maritime resources of the Bachan islands, on a long lease granted them by the Sultan of the same and sanctioned by the N. I. Government. Bachan, the main island of the group, is in 0° 13' to 0° 55. S., and from 127° 22" to 128° E., and is extremely productive. Immense areas are covered with sago trees, and nutmegs superior to the Banda variety grow wild. Dammar also abounds, its collection being inexpensive. The land has been found extremely suitable for coffee, cocoa, pepper, and cloves. Immense tracts of level land watered by un-

failing streams afford facilities for rice cultnre by the Company for the benefit of Indian and Chinese coolies. The forests in Bachan abound in good timber of different descriptions. Its minerals are of importance. Copper exists, and gold has long been profitably worked. Coal, too, has been found of a quality equivalent to first class Welsh. Other products are pearl shell. The Company intend to set to work gradually, and commence operations by sago manufacture at the rate of 200 to 400 piculs of flour per day, their estimate of its value at Singapore being 3 to 4 dollars per picul. Dammar will then be collected and goods imported from Europe for sale or barter, and cattle raising undertaken. Coffee, cocoa, pepper, and clove cultivation, mining for gold and coal, and pearl fishing, will be taken in hand afterwards. The Bachanners, owing to their few wants being readily supplied by bountiful Nature, being unavailable as labourers, the Company propose to rely mainly on imported Chinese labour. The trade of Bachan is at present insignificant, but is expected to increase by better management and the exertions of the Company. The islands are favourably situated for trade, and have, moreover, the advantage of being exempt from import and export duties, lying as they do beyond the custom's line of Netherlands India. The Company intend to send their produce to Singapore for sale and also shipment by the numerous steam lines converging from and on that port. Several capitalists in France have agreed to take up large areas of land in Bachannas soon as the Company have fairly commenced operations.

THE TRADE OF WESTERN INDIA IN COFFEE AND PEPPER.

On the fair assumption that during the year ended 30th June 1881 there was no special diversion of produce from shipment at the ports of Western India, the figures furnished by Messrs. Alstons & Co., and which we published on Monday, represent deficiencies in the staple of Malabar (the Wynaad), Travancore and Cochin comparable to that shewn in our own great staple for the season ended 30th September. Only 257,745 cwts. of coffee exported from Western India ports in 1880-81 against 392,588 in 1879-80. The decrease on the previous season is no less than 135,000 cwts., or over 33 per cent. Of course leaf disease, and probably grub and abnormal weather, affected the coffee of the Wynaad and Travancore as adversely as like causes operated to reduce our Ceylon out-turn. But pepper has risen from 36,955 to 60,634 cwts., the increase being 23,679 cwts., or equal to 65 per cent. There has evidently been no diminution of demand for the fine pepper of Western India, and Achin certainly has not yet recovered from the effects of the war which, while it desolated the best cultivated portion of Sumatra, has exhausted the resources of Java and embarassed the finances of Holland.

THE MADRAS TEA TRADE.—The tea trade in Madras continues steady and the shipments made to Great Britain Melbourne and other parts show that great attention continues to be given to the manufacture of tea on the Nilgiris. From the published returns of the Sea Custom House we learn that 11,568 lb., of tea were shipped from this port last month valued at R12,316. The steamer "Duke of Devonshire," which left this port on the 5th instant, took away 211 cases of tea, the produce of the Prospect and Seaforth estates, the property, we believe, of Mr. W. R Arbuthnot, ate of the firm of Arbuthnot and Co.—*Madras Athenæum.*

157

MULBERRIES.—We seldom see fruit in the market and it is not often that anything new is exposed. Last market day, however, some mulberries were for sale for the first time. We believe the fruit was brought from the Billicul farm. It was in good form and color, but entirely wanting in flavour, being insipid and sickly. Cultivation will doubtless supply this defect.—*South of India Observer.*

RAIN AND LEAF DISEASE IN THE DUMBARA VALLEY.—For a couple of years at least, there has not been such rain in this "happy valley" as during the present week: 3½ inches fell in one day. There are good prospects therefore for proprietors; and the result of a visit by some planting authorities to the scene of Mr. Schrottky's operations on Gangapitia is reported to be very satisfactory.

CARDAMOM CULTIVATION IN CEYLON.—A planter writes:—"That Indian information about cardamoms the other day was misleading. It spoke of one picking of ripe fruit, and then cutting off the racemes! Why, one has 12 or 15 pickings at the very least each crop, which lasts for 8 to 9 months." The fact is that Ceylon planters of cardamoms will be able to instruct their Indian brethren how properly and systematically to deal with the plants.

THE "ROBUST" CINCHONA.—A cultivator of cinchona on the Nilgiris, writing on the 9th instant, reports:—"Pubescens seems likely to turn up a trump card, although Col. Beddome has condemned it. The last analysis of *natural* bark gives nearly 13 % of alkaloids, of which 7·70 per cent is *sul.* of quinine. Mr. Cross is still here with his new pets, Cahisaya de Santa Fé; I do not hear very promising accounts of them.

SULPHATE OF QUININE is reported to have fallen from 8s to 7s per ounce and there is even a report current that the price is now quoted at 6s. That will send the supply of "Cuprea" and other South American bark out of the market, for a time at least, and will also we trust tend to the opening of new means and channels for consumption—so that although Ceylon bark may fall in price for a time, in the end there may be a distinct gain to our planters.

A CURE FOR PHYLLOXERA.—Messrs. W. & A. Gilbey writing to the London *Times* on the subject of the French vintage, say with regard to Phylloxera:—"We may add here, in conclusion, that the latest remedy suggested is sulpho-carbonate, which is applied to the roots of the vines, which a considerable quantity of water, and which it is stated has not only the effect of killing the insect, but as a manure serves to fertilize and strengthen the vine. Suffice it to say that during a visit this morning to a very beautiful and well-managed estate at St. Estephe, we were shown vines which, only 12 months ago, had all the appearance of being shortly dead now fresh and verdant, and apparently in a fair way to recover all their vigour and fertility."

PLOUGHS AND HARROWS FOR THE CHILAW DISTRICT.—A correspondent writes:—"What did you do when you were a member of the Agricultural Society in respect to the introduction of ploughs and harrows for such plots as those near Kaduwella, and especially for the thousands of acres of tobacco and other land at Chilaw and other places? I am convinced that ploughs and harrows of a kind suitable for the country bullocks would be a great success. The land could be bridged and fallowed—a thing never done apparently in Ceylon." The "Agricultural Society" discussed the subject of improved implements, over a paper contributed by us, but never got further. The ploughs and harrows that came out for the Alfred Model Farm could be utilized. They have been lying idle long enough.

Correspondence.

To the Editor of the Ceylon Observer.

LIMESTONE AND GEMS IN THE RAKWANA DISTRICT: MR. A. C. DIXON'S VISIT.

DEAR SIR,—A paragraph in your valuable book on "Gold, Gems, and Pearls," on p. 72, refers to the Rangwelletenne limestone and gem district around. It states what I could have seen, had circumstances been favourable. I beg to state that I *did* find limestone of similar quality to that analyzed by Mr. Hughes, but when I stated that the Rangwelletenne limestone was poor, I referred to the limestone *in general*, and not to *selected* boulders in particular. I got off at the girder bridge on the main road near the estate and went up the ravine. I found the *bed* which is referred to on native property, specimens from which I took as well as from boulders in the stream. Lastly, it states, that had my visit to the district been known, my attention would have been directed to the rich gemming district on Everton and Batakanda. These I also visited, taking note of the pits and collecting rough and cut gems as well as their associated minerals. I saw other districts not far away yet unworked, which, I have reason to believe, will prove richer than the Everton deposit.—Yours sincerely.

A. C. DIXON.

COTTON SEED: AN INQUIRY.

Kandy, 14th November 1881.

DEAR SIR,—Can you or one of your correspondents say whether any experiments have ever been made with the seed of the Ceylon cotton, to ascertain whether it has anything in common with the cotton-seed of commerce, so highly spoken of as food for cattle, and the meal of which is said to be a fertilizer equal to guano? The seed of the cotton tree, I refer to, with bright green stem and branches in threes at right angle to it, is black, with a white kernel full of a milky juice.—Yours truly, IGNORAMUS.

[Our correspondent will find a full description of the tree, and the uses to which it is put in Ceylon, in our issue of 7th March: we shall republish this in the *T. Agriculturist*. The tree has various names and synonyms, viz. *Eriodendron anfractuosum* and *E. Orientale*, *Bombax pentandrum* and *B. orientale*, and *Ceiba pentandra*. "W. F." says:—"I think cotton seed oil is extracted in some parts of India, but I have never heard of its *oil-cake* nor of its being used as a manure. Your correspondent refers to the real cotton seed, gossypium, and to that of the silk cotton tree. The seed of the former is a universal food for milch cows in India and Ceylon, and is no doubt the cotton seed of commerce referred to by your correspondent. In talking or writing about the cotton and silk cotton care should be taken not to confound them."—ED.]

CLEARING LANTANA LAND.

Kadugannawa, 25th Nov. 1881.

DEAR SIR,—Your correspondent, "Never Too Old to Learn," wishes to know the cost and mode of clearing lantana. The usual way is to fell, as in forest land, and, after a week, set fire to it. Then dig out the roots, heap, and set fire. In getting out the roots, great care must be taken that large sized roots are not left underground, as these grow up again.

I have tried felling by estate labor, but have found it cost a good deal. If given out on contract, the land could be felled, burned, and cleared of all roots for between R10 and R12. The land I cleared was in lantana for between 12 and 15 years.—Yours truly,

PLANTER.

COCOA PODS IN THE PANWILA DISTRICT.

Gonambil Estate, November 26th.

DEAR SIR,—I am not so far behind Mr. Drummond as to the weight of cocoa pods. Last Wednesday I cut two pods off one tree (imported plants from Trinidad, and their maiden crop). The largest was 2 lb. exactly and the other 1 lb. 10 ounces, and, when opened, contained 43 and 41 seeds respectively.—Yours faithfully, H. A. GILLIAT.

[The number of seeds reported is extraordinary and quite unprecedented, we believe. 24 is the normal number, and Mr. Drummond's "champion" contained 28 large seeds weighing over 3 ounces.—ED.]

HOW TO TRANSMIT COCOA PODS OR SEEDS TO ANOTHER COUNTRY?

Nov. 29th, 1881.

DEAR SIR,—Can you, or any of your readers, inform me of the best method for sending cocoa seed to a distance, say for instance Borneo, so as to insure its arriving in good condition. Should the seeds be extracted from the pod, and, if so, how should they be packed? If not, how should the pods be treated? Any information as regards the above will greatly oblige.—Yours, CACAO.

INDIGO IN CEYLON.

Colombo, 29th November 1881.

SIR,—A correspondent of yours wishes to know where he could get indigo seeds. Having read it history that one of the Kandian Kings—I forgen which—contracted to give indigo to the Dutch, I made inquiries if this plant was growing in the island. I understand it is growing wild in Matale. I enclose a few seeds which were sent to me from Matale. I tried to grow them at Colombo, but they do not germinate at all.—I remain, sir, yours faithfully,

W. P. RANASINHA.

[The seeds shall be sent on. As stated in our Agricultural Review:—"The cultivation of Indigo in the Seven Korales, begun by the Dutch in 1646, was unsuccessful, and Governor Barnes, in 1826, lost money over this article. Mr. Henley, a Bengal planter, tried indigo also in the Southern Province, but failed in his attempt to grow it properly."—ED.]

MR. MARSHALL WARD'S REPORT ON LEAF-DISEASE.

Wallaha, 29th November 1881.

DEAR SIR,—I have read Mr. Marshall Ward's third report on leaf-disease, and, though I agree with him in what he says about the seasons of infection and the effect that rain and moisture in the atmosphere have on the growth of the disease, I must say that I think some of his inferences are erroneous, and, with a view to pointing out what I think are errors, I write this letter which I hope you will be able to find room for in your columns. I trust also that, by raising a discussion on the subject, practical planters, who have given the "disease" thought and attention, may be induced to give their opinions on the report.

The inferences that I take exception to are those expressed in paragraph 5 of the "summary and conclusions," in these words: "No special predisposition on the part of coffee is required for its infection," and in paragraph 8: "Manure can in no sense be properly looked upon as a cure for the disease." These inferences are quite opposed to my experience of coffee generally.

Before going further, it will be as well to say what I take the meaning of "predisposition" to be: it means that all coffee, whatever its age, condition, or vigour, if exposed to infection, is liable to take it

in the same degree. With this I cannot agree. I consider, on the other hand, that the condition of the tree, and consequently of the leaves, at the time of infection, has a great deal to do with the degree in which it is affected by *Hemileia*.

In support of this view, I will try and describe three fields on this estate and leave it to my readers to judge if my inference is correct or not :—

(1.) A field facing the north-east—it is not therefore much blown—was not pruned this year, and, though it looked well in June, the disease attacked it in a virulent form in July and has not left it since.

(2.) A field of 4 year old coffee that has a crop of about 5 cwt. an acre on it, was pruned in June : up to the 15th November there was no disease apparent on it.

(3.) A field of 3 year old coffee, which was planted with coffee raised from seed selected from strong and healthy trees : this is a very fine field for its age. It had a particularly good crop last year and is bearing 9 cwt. to 6½ cwt. an acre this year, and until October this year there has been no disease at all on it.

In the case of No. 1, there was too much "wood" on the tree. The individual branches, therefore, were not vigorous and the leaves were not strong enough to withstand the disease. In the case of No. 2 on the other hand, none but the strong branches were left on when the trees were pruned before the attack ; the vigor of these branches was increased in the pruning off of others : so when leaf-disease came, the leaves were hard and strong, and the disease passed from them without being able to injure them. Case No. 3 shows, I think that, if the coffee is sufficiently strong, it can withstand *hemileia* for two years and more : this field certainly has leaf-disease now but this is accounted for by the fact that in some parts it is bearing a crop of 10 cwt. an acre and the effort of ripening this crop has weakened the trees, and thus rendered it possible for leaf-disease to injure it.

The conclusion that I draw from these instances is that, if the leaves are dark and shiny and stiff to the touch, the infection does not take place, or, if it does, it is powerless to do harm. It may be that from the shiny leaves the spores slip off, or that the strong tissue of the leaf is able to stop the tubes that Mr. Ward describes from entering the stomata.

But to return to Mr. Ward's report, I think I can show, by quoting from this, that there is "something in what I say," and that all coffee is not affected alike by *hemileia*. On the first page of the report and near the bottom we find this expression :—"Careful cultivation and natural advantages of soil, climate &c. enable certain estates to stand forth prominently as though leaf-disease did not affect them or only to a slight extent, while poor nutrition ; the ravages of insects, &c., have in other cases that effect as well as leaf-disease." I read this as going far to prove that there are certain conditions of coffee which render it easy for and liable to attacks, and that there are others which enable it to withstand these attacks. On page six, it is said:—"a succulent young leaf with thin cellules sometimes develops a spot more rapidly, probably because the cells are more closely emptied by the mycelium than are those of an adult leathery leaf." Now it is admitted that the disease is developed in different degrees on leaves of different textures.

On page 13 we find :—"High and exposed ridges and places are commonly badly diseased." This is not on account of moisture ; it must be, therefore, because the trees are weak and more prone to disease.

On page 15 :—"The reasons why this district suffered from such a bad attack of leaf disease in July have already been detailed, and it will be noticed that when the winds commenced, a large surface of *young* and *succulent leaves* was ready to receive the spores of *Hemileia*." Again, on the same page :—"It is clear that leaves are formed more slowly from January to March than from April to June, for instance (in the districts referred to), but the advantage gained by either having fewer leaves on the trees in May and June, or *many hardened ones* would probably be a decided one."

These phrases seem to me to say clearly that young and succulent leaves take the disease more readily than hardened ones, and, if this is the case, as I maintain it is, I do not think it can be said that there is "no special predisposition for infection," or, in other words, that all coffee, whatever its condition, takes the disease in the same degree.

In conclusion, I will say that I consider, on the whole, Mr. Ward's report an exhaustive and able treatment of the subject, and capable of rendering planters much assistance. We have now, however, all that can be taught us by scientific men about *Hemileia*, and it is for practical planters, in working their coffee, to study the disease. I must say, I think there is a good deal to be found out yet as to the best time to prune and manure with a view to dodging the disease in July and August, and having healthy wood ready to blossom in January.

—I remain, dear sir, yours faithfully,

G. A. TALBOT.

CINCHONA COCCINEA.

Badulla, 30th November 1881.

DEAR SIR,—In Doctor Trimen's remarks on Colonel Beddome's Report, he tells us that Dr. Spruce with Mr. J. E. Howard has long ago determined his "Pata de Gallinazo" to be Coccinea Pav. Having some time ago come across some large trees which answer exactly to the drawing of this species in the "Illust. Nucv. Quinol.," I should very much like to learn if this *Coccinea* bark is of much value. The trees grow quite as large as succirubra, but the leaves are smaller and round with pink veins. The fruit is very much shorter than that of succirubra and almost round.—Yours truly,

B. G.

[Perhaps Dr. Trimen will answer this question. Personally we have no knowledge of the species referred to. The important question, however, is what is the quality of the bark of our correspondent's tree; and this analysis will at once decide. The only reference to the red bark, "Pata de Gallinazo," we can find in Markham's book, is as follows :—

Dr. Spruce, from his observations in the Pumachaca forest, came to the conclusion that the "red bark" trees grow best on stony declivities, where there is, however, a good depth of humus, at an elevation of from 3000 to 5000 feet above the sea. The temperature was very like that of a summer day in London, but with cold mists towards evening, and from January to May unceasing rain. He found the cinchona trees, in this part of the country, almost entirely extirpated, and, after a short stay at Lucmas, he proceeded to examine the region of the "hill barks," or *cascarillas serranas*, which is at an elevation of 8,500 to 9,000 feet, on both sides of the river Chanchan. In the forest of Llalla, at the foot of the mountain of Asnay, he found two kinds, called by the natives *cuchi-cara* (pig skin) and *pata de gallinazo* ;* and on a stony hill side there were twenty large trees of the former, from 40 to 50 feet high.

Dr. Trimen has said that *C. coccinea* as illustrated from authentic specimens, is quite unlike our Ceylon "rob ta" (hybrid). If our correspondent would send specimens of the leaves (and flower) of his trees to Peradeniya, we have no doubt they would be examined with interest. Can he trace the history of his trees?—ED.]

THE SACK CURE FOR GRUB.

Moruington, Nov. 30th, 1881.

DEAR SIR,—I have tried Mr. Parsons' plan of using sacking on two estates, on a small scale, and have found it succeed perfectly in bringing all grub to the surface.—Yours truly, C. B. LUTYENS.

MR. SCHROTTKY'S EXPERIMENTS ON AN ESTATE IN MATALE.

Colombo, 30th November 1881.

DEAR SIR,—Mr. Borron invites me to come to Matale and study some facts connected with my experiments. There is one thing Mr. B. can make quite sure of, viz, that while I am in the Island I do not fail to keep myself acquainted with the results of my experiments as they, from time to time, become apparent. I am cognisant of all Mr. B. says regarding the estate he refers to *and of more*, for while he (Mr. B.) has, as far I can judge from his letter, seen only 5 to 10 acres of the estate. I have during the last three weeks gone twice over and through the whole of it (20 acres). The time has not come yet for closing the results there.—Yours faithfully, EUGENE C. SCHROTTKY.

TO BRING OUT THE COLOUR OF TEAK WOOD?

DEAR SIR,—Would any of your readers kindly mention what is the best plan for treating teak wood, so as to bring out the colour, and graining more clearly, after the varnish has been laid on? Would it be necessary to apply a wood stain, and of what kind?—Faithfully yours, Q.

COST OF CLEARING LANTANA LAND.

Maria, 3rd December 1881.

DEAR SIR,—"Never Too Old to Learn" should pay fifteen rupees for felling and clearing and ten rupees for taking out roots and burning same per acre. He should road, drain, hole, and plant up the land as soon as possible after the burn, say fell in February, burn, clear and hole in March and plant in April. Do not heap lantana roots for burning except on roads, as no plants will come on on the spot where lantana roots were heaped and burnt.—Yours faithfully, J. HOLLOWAY.

P. S.—I am glad to be able to send some indigo seed herewith. Will you forward same to your correspondent. If they can export croton seed and indigo from India why not from Ceylon, I shall try to do so.

Your Kadugannawa correspondent certainly could not have had lantana as we have it here of twelve years' growth. I had lantana cleared where a man had to creep underneath and first cut it with a knife or cattie a foot above ground, then others had to beat it down and cut down the sides, and ten men could not do more than a quarter acre properly. It took three weeks after it was cut down before I could burn it. It is necessary you should have a good burn throughout, as it is less expensive and better for the plants with the ashes nicely over the whole ground than to be obliged to roll or heap it and burn. There is some lantana which could be done for R12 per acre; but if it is of twelve years' growth the soil must be poor to be able to get a contractor to fell, clear, take out and burn the roots of lantana at that price. J. H.

DAMAGED TEA IN MELBOURNE.—One of the best answers to Mr. Evcrard's bluster indefence of China tea is to be found in paragraphs like that which follows, extracted from the *Age* of October 25th:—"The Customs officers were engaged yesterday in destroying a large quantity of damaged tea recently imported into this colony."

TEA IN AUSTRALIA.—A great deal of excitement has lately been caused in Adelaide by the announcement that tea had been discovered in the Northern Territory. It is said that during the Adelaide Parliamentary recess, the Minister for the Northern Territory will visit that part of the Province, in order to satisfy himself as to the character of these discoveries' —*Pioneer.*

PLANTING INFORMATION: THE "TROPICAL AGRICULTURIST."—We had a request the other day from a mercantile Firm to procure for them copies of the Mr. Moens' Java Reports on Cinchona Culture. Our reply was that all these Reports, which are in Dutch, are translated and re-published in our columns, more especially in the *Tropical Agriculturist*, in which also are given the Indian Reports by Dr. King, Colonel Beddome, Mr. Gammie, &c., as well as Dr. Trimen's and Mr. Howard's papers. There can be no doubt that all proprietors, cultivating cinchona or other "new products," should direct a file of the *Tropical Agriculturist* to be kept on their plantations (and bound up once a year) for reference. The proper value of the publication will probably not be realized until it is too late to get back copies. Mercantile agents for estates and for absent proprietors should not overlook the hint.

COFFEE PLANTING NEAR MAURITIUS.—A gentleman living upon an island near Mauritius wrote to a Ceylon friend and fellow-passenger to Aden as follows:—

Pomong Johanná, Comoro Islands, Oct. 17th, 1881.

Just a line. How did you reach and find things on your return? We stayed 14 days at Mauritius and I got here on 16th August. I think I shall start coffee here. It grows well, but does not last more than 9 years. If I start, I shall plant at an elevation of 1,000 or 800 feet. I have some 27 plants of Liberian coffee—young plants. How does it do in Ceylon? Will you in a letter send me some cardamom seed to plant here. Also tell me how it is cultivated, and if it pays you to grow it in Ceylon? I think next year I shall pay Ceylon a visit also, for information. Will you write as soon as you can and give the information about cardamom and its cultivation? Does it yield in a year, and what is the produce worth? Also let me know about Liberian coffee and give me any news, like a good fellow. The four engineers, our fellow-passengers in the steamer, did not like Mauritius.

HOME APPRECIATION OF INDIAN TEAS.—The Calcutta *Englishman*, writing of a late tea sale there, and the prices realized, says:—"We have no hesitation in pronouncing the sale a remarkable one, as it marks the beginning of an era of prosperity for those engaged in the industry." Our contemporary further adds:—"In the face of one of the cheapest China crops on record and a market for Indian tea ranging fully 3d over 1880, the consumption of our tea has increased by over 7 million lb., the deliveries in London will certainly reach 50 million lb. this year, while the total outturn cannot approach that figure, and the increasing Colonial and American demand will appreciably reduce the supply available for the London market. The fact that the grocer at home has this year paid 3d per lb. over last year for Indian tea at a time when China teas were available at unusually low prices, and that the consumption at the enhanced price has increased to such an extent, proves that the demand for Indian teas is established, and that they will be bought whatever may be the price of the inferior China article." Now the Ceylon teas are not a whit behind the Indian, and the "era of prosperity," which the home demand is opening up for the Assam tea-planters, will without doubt also reach ourselves.

FORESTRY, AND HOW IT PAYS IN BRITAIN.

(*Gardeners' Chronicle*, 8th October 1881.)

GROWING OUR OWN TIMBER.—It is at all times desirable, but specially so at present, to grow sufficient wood upon every extensive estate for all its requirements. From a report by the Board of Trade for the year ending December 31, 1873, I find the following statement, amongst others, of great significance and interest to proprietors of woodlands, namely, £18,654,982, the money paid by this country to foreign countries for the article wood alone. That was probably an exceptional return; but even with ample allowance there is still a broad margin worthy of the attention of those interested in the growing and disposal of wood. We cannot grow all kinds of wood and timber in this country more than we can all kinds of grain, but there are some kinds which can be grown at home vastly superior in many respects to what are grown abroad, such, for example, as the Scots Pine, Larch, and some kinds of hard woods. If any one is at all sceptical in regard of this, I would advise them to visit the Pine forests of Deeside, Strathspey, and some of the woody districts in Ross-shire and Inverness-shire, such as Novar, Balnagowan, Beanfort, and many others, where both natural and planted timber trees can be seen in all their splendour and magnificence. Or where the Larch is wished to be seen in perfection, a visit to the woods and forests of Blair, in Athole, on the Tay; on the banks of the Don, at Monymusk; at Ballingdalloch, on the Spey; and Novar, Balnagowan, &c., in Ross-shire. If at these favoured places the trees, as such, are pleasant to the eye and gladdening to the heart of any admirer of sylvan grandeur and magnificence, it is equally certain that in point of quality and utility they will be found unsurpassable, if not unequalled in the known world. The justly celebrated Scots Pine of the Dee and Spey side districts have proved their durability again and again by endurance as fence and gate-posts, in which positions—the most trying possible—they have been and are still known as standing from forty to fifty years. Of Larch, again, I have in my possession some samples in excellent condition after having stood as fence-posts over thirty-five years.

There are, no doubt, well-defined and limited conditions under which any species of tree grows to perfection, and the Larch and Scots Pine are no exceptions. The first condition is to plant the trees only upon such ground as is suitable to them. The second condition is to thin them, so that at any stage of growth the trees may grow with a freedom and vigour adapted to their nature, constitution, and habit; and the third condition is to cut them at the proper stage of ripeness, and at the proper season of the year. Beyond proper planting, which includes selection of the soil, situation, &c., the next most important thing to attend to is the thinning of the trees. It is much to be deplored that vast areas of plantations are rendered less than half as valuable as they would otherwise be for want of timely thinning. In a large plantation of Scots Pine (over 1,500 acres, and fifty years old) I had once an excellent opportunity of observing the effects of thinning in all its forms, and may state the value of the trees thus:—Part not thinned at all, trees valued at 3d. each. Part thinned when something over twenty years old, worth 6d. each. Part thinned once and sparingly when young, say twelve to fifteen years old, worth 1s. each. And part thinned once at proper age, say twelve years planted and at proper distances, 4s. each. Now if we look at the value of the acre at fifty years old, at the above rates, we find it stands thus:—

1,500 small trees, drawn up like poles, at 3d. each	£18	15	0
1,000 small and branchless trees, at 6d. each ..	25	0	0
800 fine clean pole like trees, at 1s. each .	40	0	0
500 fine clean and fair-sized trees, at 4s. each ..	60	0	0

It is not to be inferred that all the plantation would have been worth £60 at fifty years old, even if properly thinned, but it may be concluded that it would have been worth £80 per acre at 100 years growth, or even more, including the whole area, which implies that some of it would have been probably over one-third more money value than above represented. The soil was thin and poor, but such as produces fine quality of wood when at maturity at, say, 100 to 120 years.—C. Y. MICHIE, Cullen House, Cullen, Banffshire, October 3.

THE COFFEE AND SUGAR PRODUCING COUNTRIES.

VENEZUELA.

Venezuela is, after Brazil, the country in South America producing most coffee; at the same time the best cocoa is grown there, and a variety of other tropical produce, prominent among which tonqua beans, a substitute for vanilla for making essence and a flavoring substance for tobacco, and furthermore, balsam copaiva. Venezuela is lavishly favored by nature. Toward the south it is watered by the Orinoco, the largest river in South America next to the Amazon, thence immense plains or "llanos" stretch across the country, and on them innumerable herds of cattle are grazing. Toward the north these plains are limited by the Cordillera and the fine mountain plateaus on which the coffee grows. Coffee planting is the all absorbing interest, and the actual President, General Guzman Blanco, is himself an owner of extensive coffee estates. President Blanco is a dictator, and his enemies blame him for the egotistical manner in which he rules the country—they say, with a rod of iron—making money out of everything and thus becoming prodigiously rich. His admirers, on the contrary, insist that he is probably the only Venezuelan living who can develop the resources of the country while preserving peace, and that his dictatorial proceedings and even his vanities are redeemed by his many excellent qualities. However this may be, it is certain that for the past thirty years Venezuela has been most of the time in a semi-anarchical state, one revolution succeeding another, and that the republic requires peace above everything else, even at the expense of some of its liberties.

Venezuela covers an area of 438,130 square miles, and has a native population of 1,784,197 souls and some 24,000 foreigners. The chief cities are Caracas, the capital, with 48,897 inhabitants; Valencia, 28,594; Barquisimento, 25,664; Maracaibo, 21,954; Maturin, 12,914; San Carlos, 10,120: Merida, 9,727; Cumana, 9,427; Ciudad Bolivar, 8,486; Coro, 8,172; Barcelona, 7,674; and La Guayra, 6,763.

The income of the republic is $4,680,000, and the expenditure $4,448,000. The internal debt is $12,962,172, and the foreign one $54,347,818. The import is $15,043,000, and the export $16,113,000, the latter including gold dust, there being valuable gold mines in the state of Guayana, not far from the Orinoco. The country also possesses copper mines. The leading ports are La Guayra, being the port of Caracas, Puerto Cabello and Maracaibo. The maritime movement is:—arrivals, 8,862 vessels, with 615,806 tons, and sailings, 9,028, with a tonnage of 627,128. Thirteen steamship lines keep up communication with Europe and America, and there are 340 miles of telegraph, but only 70 miles of railway. Venezuela stands very much in need of railroads. Their possession would impart a great impulse to coffee production, as has been the case in all coffee growing countries. Unfortunately, the unsettled condition of the country hitherto has frightened away European and American capitalists. Some of the latter have during the past few years again come forward, but so far without any tangible results. Should President Guzman Blanco during coming years succeed in weaning the country from revolution entirely, may take courage and endow the republic with better means of communication in the interior.

In 1839 Venezuela produced 13,000 tons of coffee, in 1869, 17,500, and at present it turns out 30,000 tons.

This includes all coffee received from the interior at Maracaibo, although much of it comes from Colombia. Although the species of Venezuelan coffee coming to us from La Guayra and Puerto Cabello are quite popular in the United States, Maracaibo is still more so, inasmuch as in point of outward appearance, size of bean and flavor it approaches Java, and is extensively consumed by the well-to-do middle classes in the United States in the place of the latter and Padang.

The best cocoa is the celebrated Caracas, which is in such demand in the country of its growth, in Spanish America and France, that it commands a very high price compared with all other sorts produced anywhere, and this is the reason why so little of it gets to this country. The cocoa from Carupano and other points on the coast is considerably cheaper, and goes to Mexico, Spain, France, etc.

From what precedes it will be seen that there are few American countries producing coffee and cocoa so admirably fitted to expand the production thereof almost indefinitely. That crops hardly ever fail there in either product, the trees being less exposed and less subject to disease of any kind than elsewhere. But for the curse of revolution which has rendered capital shy, Venezuela would at the present day probably produce three times as much coffee and cocoa as it does at present. It shows that in some of the countries south of us the less respectable portion of the ruling classes, in whose hands the mass of the people are mere tools, are the worst enemies of the commonwealth.—*American Grocer.*

NILGIRI CINCHONA BARK.

TO THE EDITOR OF THE "SOUTH OF INDIA OBSERVER."

SIR,—Cinchona planters on the Nilgiris must, I think, have read with much interest Mr. Howard's analysis made in May last, of thirty samples of bark sent home at the close of last year from the Dodabetta and Neddiwuttum Government Plantations by Mr. Cross, the Botanist employed by the Secretary of State for India to bring out to this country from Santa Fee, at great labour and expense, the single plant now to be seen in the first mentioned plantation—a tiny little plant about a foot and a half high, and as carefully guarded and tended as the future progenitor of a higher race, Israelites of the family, deserves to be. It is a pity, however, that a more careful description of the samples was not attempted when so important a measure was undertaken, as there is no question more momentous to the private planter of this medicinal exotic, than the difference or advantages, commercially considered, between what is known as McIvor's mossing system and coppicing, for while the words "renewed bark under moss" points unmistakeably to the former, the description "original bark" may not, in all the instances mean what would be the yield of bark harvested under the latter. The "original bark" cut and exported from the two Government Plantations annually for the home market is mostly, if not all, that which has had the benefit (?) of the covering of moss during the years it was applied for promoting the renewal of bark on trees from which two or three or four strips had been cut—the "mossing" thus serving the double purpose, as it is believed, of protecting the cambium on the parts cut on its formative efforts, against the effects of atmospheric exposure, and of promoting in the bark left untouched on the stem of the same tree a more favourable development as to thickness and alkaloid formation, the moss carrying the stem *all round*, from the ground, to five or six feet above, or where the tree branches out. It would be a difficult and hazardous feat to go all over the Dodabetta plantation, but there are few trees to be seen in the accessible parts which are not swathed in moss. "Original bark" may therefore mean that nursed under moss as above described, or that stripped from trees whose stems, as in Nature, have been exposed to the ill effects (?) of the atmosphere. Applied to bark from South America, from where Mr. Cross had just arrived, the term would involve no doubt of this kind, as cut in the forests the bark would be just that which would be harvested in an orgauized plan of coppicing. McIvor's system of mossing is, it must be remembered, a very expensive one, amounting to about one-fourth the total annual expenditure of the plantation, and while botanically admittedly effectual, it is of vital importance to the future of Cinchona cultivation on these Hills, that it should be proved to be commercially equally so; and the position it would stand in compared with a well considered plan of coppicing. Mr. Cross's description in a few places may, however, be taken to refer to unprotected trees as in Nature, as in the samples marked Nos. 1, 6, 9 and 27, and the yield of Quinine and Quinidine in these may perhaps safely be compared with the yield from renewed bark in the samples of the same species, *viz.*, Crown Condaminea, marked Nos. 10, 11, 12, 13, 14, as contributing somewhat to the solution of the *vexata quæstio* above referred to:—

	Unmossed bark.		
	Quinine °/₀	Quinine °/₀	Total
No. 1	4·51	0·67	5·18
,, 6	4·63	1·19	5·82
,, 9	4·04	0·35	4·39
,, 27	4·78	1·12	5·90
Average	4·49	0·83	5·32

	Mossed bark.		
	Quinine °/₀	Quinidine °/₀	Total
No.10	4·79	0·48	5·27
,, 11	7·69	0·16	7·85
,, 12	6·60	0·22	6·82
,, 13	4·01	0·76	4·77
,, 14	4·69	0·38	5·07
Average	5·55	0·40	5·95

The difference in favor of the much vaunted aud expensive mossing system is, by this comparison, not so great as one might suppose, the four samples of natural bark yielding say, in round numbers, 5½ per cent of the two most valuable alkaloids, against 6 per cent in the five samples of mossed bark. The Department now in charge of the Government plantations might be able to calculate whether the extra expenditure incurred in the mossing system of propagatiou aud harvesting the bark is compensated for by this 0·63 per cent of extra yield in the useful alkaloids. I have, perhaps not been altogether fair to the despised natural or unmossed bark in omitting the analysis of the sample marked No. 4 in that category, aud should enquiry show that the tree had not enjoyed any advautage from mossing, the comparison would stand then:—

	Quinine °/₀	Quinidine °/₀	Total.
Mossed bark average of five samples	5·55	0·40	5·95
Original bark average of five samples	5·50	1·11	6·61

or something rather in favor of the latter. Quinidine, Mr. Howard says, sells at more than half the price of Quinine so that to the chemist the one description of bark is on an average as good as the other. Is it the same to the planter? The talented head of the Forest Department has his attention directed to the solution of the problem, no doubt; but it is a pity that no systematic attempt in this direction was made by the officers in charge of the plantations during the last twenty years of their existence.—G. B.

COCOPALMS AND THE INSECTPEST IN FIJI.

(*Gardeners' Chronicle*, 8th October 1881.)

I regret to state that the insect pest has made the greatest havoc amoug my coconut trees; I am led to infer that they must have suffered peculiarly from the

fact that the many Europeans, old residents in the Colony and coconut planters, and also natives, who have seen my trees have one and all expressed the greatest astonishment and declared they never saw anything like it before. I have seen no coconut trees on neighbouring estates attacked in the same way as unfortunately mine are. The insect is a Phasma, the Lopaphus cocophagus, or coconut-eating Lopaphus, called by the natives Mi mi mata; when touched it ejects a foul smelling white fluid, which the natives have assured me will, when ejected into the eyes, produce blindness: is is essentially a surface (foliage) feeder; it feeds only upon the leaves of the coconut tree; it does not attack the roots in any stage; is not a borer, and does not penetrate the wood or the soft head-pith.

During the day the insects lie dormant, generally in couples, shaded from the sun, stretched out at full length under the rib of the coconut leaf, the male on the back of the female. The female is much larger than the male, she varies in colour, being sometimes a bright green, sometimes a reddish-brown; the male invariably I have found to be of a reddish-brown colour.

They do not feed at all during the day, they seem to dislike the glare of the sun, for upon being shifted to the upper side of the leaf they get back as quickly as they can to the under side. Soon after sunset, when it becomes cool, the couples separate and commence to crawl about and feed, eating the leaf in the same way as a caterpillar does, in the form of a semi-circle. Both male and female are furnished with small semi-circular pink wings about the size of a sixpence, which are of little use except to steady their flight downwards. The eggs are to be found in two rows, one on each side the intestines of the female. I have counted as many as twenty in one female in various stages of development. On examining the tail part of the female, I have noticed extending between the two tail points a piece of skin; on lifting this, and underneath at the upper and broader end of this flap you will see the ovary passage, and immediately below it a small flexible bag-like receptacle protected by two pieces of skin or scales which meet but do not overlap: these the insect can open or shut at will. In this flexible bag you will invariably find an egg encased in a hard rough brown skin with a cap-like point at one end, which comes off at a touch and discloses the egg; you can, if you wish, without difficulty remove the whole of this skin. The idea I formed is that the female retains the egg in this bag until it hatches the young insect; upon this being done another egg drops down into this receptacle to be hatched, and so on; the young insect is almost as fine as a hair. The destruction of a coconut tree by these insects is wonderfully rapid. Towards the end of last January six of my trees first showed signs of being attacked; towards the end of May two were killed outright. The trees that have been attacked by the insects are all young trees in their very prime, and before this insect plague appeared were all of them magnificently healthy trees in full bearing.

The lower leaves are attacked first; these are quickly eaten bare, nothing but the stalks and ribs being left, which soon drop off whilst still green; the other leaves rapidly follow, the nuts, failing to receive proper nourishment, drop off unripe, and the tree which three or four weeks before was a fine healthy tree, loaded with nuts in different stages, is now left with nothing but a central spike with three or four bare leaves hanging on to it. [illegible] the centre spike [illegible] into a leaf, but the [illegible] eat it bare at once; the tree makes several struggles to put out fresh leaves, but these are all eaten [illegible] they appear, and very shortly the tree dies.

I [illegible] naturally viewed the ravages of this insect with considerable anxiety; I fully realise the great necessity [illegible], if possible, the progress of such a pest at the outset. I would, therefore mention the various remedies [illegible]. On a [illegible] I selected a small tree (trunk from 12 feet to 15 feet in height) which I noticed was covered with the insects; immediately beneath the tree I caused several large smoky fires to be made, and for an hour kept the tree enveloped in dense smoke, so dense that standing close to it I could not see it. I then allowed the smoke to clear away. On the ground I searched diligently for the insects; I could not find one. I looked up to the tree; there they were as numerous as ever, and apparently none the worse, the only difference being that they were crawling about instead of remaining in their usual dormant condition. Not satisfied with this attempt I determined to make another. This time I selected a very young tree, only eighteen months old, standing with its leaves about 12 feet high. Before doing anything I carefully counted the insects upon the tree—seven couples in all. I then for fully half an hour kept the tree enveloped in dense smoke; at the end of that time I counted fourteen insects upon the tree; the couples had separated and were crawling about, not one had been destroyed. I then tried the effect of burning sulphur. I put half a pound of sulphur into a tin, and, setting it on fire, held it immediately beneath a couple of insects, only 2 inches below them. After a while they crawled away together. I followed them with the burning sulphur, keeping it well under them, so that they should get the full benefit of the fumes. I kept this up for some time, but with no success, for it did not destroy the insects.

I then adopted the plan of one man climbing the trees and knocking the insects off; there is no use in merely shaking the leaf, the insects cling too tenaciously; but by striking the leaf suddenly half-a-dozen sharp blows with a short heavy stick the insects are taken by surprise and drop off. I commenced with first striking the heart leaves, then the leaves below them, and so on until the insects had fallen on to the lowest leaves, when a few blows brought them to the ground literally in showers, where ten other men chopped them to pieces with their knives; they do not drop, but extending their pink wings float to the ground. Some, however, I noticed were able to swerve suddenly to one side, and alight upon the trunks of the nearest coconut trees, up which they crawled, or rather ran with great rapidity. I thought I had at last discovered an effectual remedy, and for a while the trees showed signs of improvement, but it was only for a short while, for the insects soon returned, worse than ever, and although I have repeated the operation of knocking them off the trees, I cannot conquer the pest.

I have thought of cutting down all the trees that have been severely attacked, but feel convinced this would do no good, for the insects, when they have eaten a tree perfectly bare, leave it until it puts out fresh leaves, when they return to it.

I have tried the experiment of passing a lighted torch along under the midribs of the infested leaves, with the result that both insects and leaves are destroyed. The coconut leaf is very sensitive—a strong heat will wither it; but nearly the same damage is done by my method of striking the leaves, for it bruises the midrib, which soon breaks, one portion dropping to the ground, the other withering on the tree. A tree that has been operated upon in this manner presents a most forlorn appearance, and its growth, of course, is materially checked.

Towards the end of January two of my [illegible] showed signs that they were attacked; before the end of the same month four adjacent trees were in the same state; within four weeks no [illegible] of a green leaf was to be seen upon these six trees, and the trees immediately adjoining showed that they also were attacked. [illegible] would [illegible] the pest; [illegible] hurricane [illegible] passed I [illegible] that [illegible] would have the desired effect, and so on. I regret [illegible] I have now 11[illegible] trees attacked, many of which I am afraid will not recover. I do not think any of them

are more than fifteen or sixteen years old; they are all exceptionally fine trees, and until attacked were in full bearing, loaded with fruit—one tree dropped more than 100 nuts in six months.

The insects exhibit no preference for any particular variety of coconut tree, they attack them indiscriminately—the ones nearest those eaten bare becoming victims without distinction, for the trees attacked by them here are of many very different varieties.—D. R. SMITH.

BRAZIL: INDUSTRIAL CONFERENCE.

(*Rio Cruzeiro*, 17th July 1881.)

Invited by the minister of agriculture to state his ideas and to give information to the members of the *Centro da Lavoura e Commercio*, merchants and important coffee planters with reference to our principal product in its principal consuming market, Sr. Salvador de Mendonça expressed himself as follows at the conference held on the 15th, inst:—

He believes that so serious a competition is being developed to Brazilian coffee in the North American market that, if we do not at one provide against it, we will in the near future see ourselves vanquished by similar products, if not entirely excluded by them from that market.

Beginning with a recapitulation of the history of the movement of American capital for the enterprises in Mexico, he said that this movement dates from five years back. Even before the international exposition at Philadelphia, the North Americans said that the continuous and large balances which they paid to Brazil, of whom they bought so much and to whom they sold so little, induced them to seek other countries which would export products similar to our own in exchange for products of the United States.

He added that the existing triangular commerce, by the regimen of which the English steamers carry the Brazilian coffee to the United States ports and there receive bills of Brazil, aggravated the situation still more, for Brazil went to supply herself in Europe with the manufactured goods which she could buy in the United States.

It was calculated that for the service alone of transport and liquidation of the commerce between the two American nations England was receiving annually 12½% on about 100,000,000$, the total amount of that commerce.

Looking around, the country which the capitalists of the Union first fancied as capable to substitute us, was Mexico. On her they fixed their views; they spoke of incorporating companies for the culture of coffee, under the superintendence of General Escobedo, in a zone of Mexico which the North American capitalists, interested in the enterprise, insisted should be annexed to the Union. The difficulty in realizing this latter condition, the substitution of the Grant administration by that of Hayes, more rational and less adventurous caused the promoters of the movement to stop.

Studying the conditions of our economical relations with the United States, and endeavoring to remove the causes of discontent which had been manifested and which endangered the possession of the best market for our coffee, the Brazilian consul general in the United States saw that the remedy was in the development of those relations and in the facilities which should be granted in order to put the commerce of the two countries on a footing of exchange of their products as far as practicable. But as it is not given to human intelligence and human power to direct or change at will the laws of economy, Sr. Salvador de Mendonça repeated to the men in the United States who were capable of influencing the opinion of those interested, that, as soon as the North Americans would bring to Brazil better and cheaper manufactures than the similar European ones, they would exclude the latter from our markets. They objected that without direct steamer communication such competition was impossible; that there were goods which required to be delivered to the consumer in a fixed time, and others which required rapid transport; that neither the transport by sailing vessels nor that by English triangular steamship line could satisfy these necessities; that the result of the existing conditions was that the English continued as forced intermediaries in the sale of many North American products. As an example they pointed out what occurred in the commerce in butter and cheese; Brazil was importing those articles on a large scale, England was supplying them on a large scale to Brazil; but as England was not producing them in sufficient quantity for her own home consumption, she bought them in the United States. A pound of superior butter was costing in New York 20 cents or about 400 reis, and as it was worth 1$200 in Rio de Janeiro, the difference of 800 reis remained in the hands of the intermediaries for freight, packing, salt and duty (the whole of which cost about 200 reis), England gaining 100 per cent which the consumer paid and the producer did not receive.

As soon, however, as the project of a direct line of American steamers appeared, the Brazilian consul general called to this enterprise the attention of the imperial government who very rightly subventioned it. When this act of the imperial government was known, the Americans, to whom those interested in the estrangement of the two countries were continually talking of the ill will on the part of the empire towards the republic, seeing how promptly we here complied with the wishes for direct communication expressed in the presentation speech of their minister, Mr. Hilliard, not only stopped the import duty of 2 cents per lb. on coffee, proposed in the message of the President to Congress in the autumn of 1877, but promoted a special message of the same President, accompanied by an able report of Mr. Evarts, recommending a subvention to the established line. Only the special circumstances in which the administration was placed, in the face of a democratic opposition majority in both houses of Congress, caused until now the non-success of that recommendation.

Two years passed without modification of this state of things, though already better for us, when the return of General Grant from his voyage round the world, coinciding with the superabundace of United States manufactures seeking markets, and with the abundance of capital in Wall street seeking employment, caused the plan of enterprises in Mexico to be taken up again. Then, almost by intuition, there sprang up companies for railroads, coffee culture and immigration to the neighbouring republic with North American capital.

Continuing on this point Sr. Salvador de Mendonça showed the systematic organization of this undertaking and manifested his opinion that its results will be fatal to us if we do not prepare ourselves for this serious competition. With abundance of capital and labor, which we lack; with the perfected machinery which the inventive North American genius will supply them, and which we do not generally possess; with the proximity of the consuming market from which we are comparatively distant, we have already sufficient against us in order to see in Mexico a very serious competitor.

If we add to this that, in the near future, when the requirements of consumption are supplied and the frontier between the two countries is abolished, a duty on all coffee entering the United States by water may well be imposed; then it is clear that our product will become virtually excluded from that market.

The two advantages on which, under these circumstances, we can still rely in this struggle, are the following: 1st, our soil has the privilege, which nobody can take from us, of producing coffee with double the fertility of the Mexican soil and of producing coffee of strong qualities which it will be difficult to substitute by others in the present principal consuming centre;

2nd, whereas Mexico is only just initiating the culture of coffee, we are already the producers of almost half the total production of the world, and we have, therefore, precedence and time in our favor, the only thing which neither *Yankee* energy nor activity can suppress.

Given, therefore, the necessity of maintaining the possession of the principal market for our coffee, the means of satisfying it consist in a settled plan of complex and connected measures. Sr. Salvador de Mendonça does not think that each of those measures is infallible, but believes that the conjuncture of the same will bring a powerful remedy against the evil.

He divides those measures into external and internal ones.

Treating of the first, he says that the remedy to oppose to the greater distance from the consuming centre with which we have to struggle in regard to Mexico is rapid, direct and cheap transport and direct telegraphic communication. And having said four years ago, when recommending the establishment of the line of North American steamers, that their first voyage would be the cheapening of the coffee transport, he begs permission to show how practice has justified his saying. Up to the present the North American steamers have made 37 round voyages: the freight on coffee which before the establishment of this line was on the average 70 cents per bag, went down to an average of 40 cents by these steamers, which means a diminution of $360,000, or about 800,000$, in the freight on the 1,200,000 bags until now carried by them. And if we add to this that the North American line did not carry 50 % of the Brazilian coffee imported in the United States during the last three years, and that the other 50 %, thanks to the competition of the North Americans, must have enjoyed a similar reduction, for it is not credible that the patriotism of the English would go so far as to pay to their steamers the former freight when it could be had for little more than half, then it is evident that the benefit obtained, in the diminution of the freight alone on our coffee to the United States, amounted during the last three years to at least 1,600,000$; and as the contributors, who pay the yearly subvention of 200,000$ to the North American line, have disbursed 600,000$ during that period, there still remains a balance of 1,000,000$ to the coffee producers, who after all are the same contributors.

Putting aside, therefore, the benefit which other ports of the empire derive from the line, Pará for instance whose increment alone would justify this service, the cheapening of the freight and the demonstrated balance above place this expenditure in the list of reproductive expenditures, and counsel the immediate improvement of this service.

The monthly voyages are not enough and the ports of call are few.

The reason why the English steamers of the triangular line continue to take more coffee to the United States than the North American steamers is principally the following: They go two or three times a month and, without swamping the distributing market with a large stock, they carry the product in proportion as it is wanted. The arrival of 10,000, to 50,000 bags of coffee in a single steamer, when the market is already supplied, causes a fall in prices....

(Sr. Ramalho Ortigão: There should be set against this the rise of prices occasioned here by the fact that a large steamer is in port loading, and that it is known she will not leave empty.)

Steamers, therefore, which are smaller and more rapid than those at present employed on this line, and with other ports of call, will augment the benefit which the actual ones already render. An intermediary line, or a branch of the actual one from St. Thomas to New Orleans and other ports in the South of the Union, would give to our export to those destinations the benefit of reduction in freight which the export to New York already enjoys. By the excellent commercial retrospect of the first semester of this year, published in the *Jornal do Commercio* of the 14th inst., it is seen that the freight on coffee to New Orleans by the English steamers of the traingular line continues, from want of competition, at 70 cents per bag.

As to the direct telegraphic communications, they are the forced complement of the anterior measure. The trans-oceanic cables at present constructed a few years ago, permit of reductions in the tarift which are astonishing. The merchant who sends today one word from Rio de Janeiro to New York, *via* Europe, for 785$ and 10 % additional, will quadruple his telegraphic correspondence when a direct line will charge him only the fourth part of what he is being charged today. In view of the importance which this agent of commerce has assumed in all international transactions, we cannot remain subjected to that monopoly: on this ground also competition will be salutary.

The producers and consumers being thus brought nearer through those powerful ties, the steamer and the cable, Sr. Salvador de Mendonça suggested another measure which, being preventive, would be wrongly interpreted if it were published.

Passing to a consideration of the establishment of banks and direct exchange between the Brazilian and North American cities, he considered these measures premature because only the laws of economy and the necessities of commerce determine them. Nevertheless, it were to be wished that the North American capital, and the European capital which seeks in North America more remunerative employment than it can find in the markets of the old world, would here find facility and good acceptance, for only thus could we lead in our direction a part of the current which is overflowing Mexico.

Passing from the exposition of the external measures to the internal ones, Sr. Salvador de Mendonça presented three tables with statistical data, obtained from the bureau of statistics in Washington, and partially verified in the Brazilian consulate general at New York.

The first table, comparing the commerce of Brazil with the United States, England and France in 21 years, from 1859 to 1879, shows that in that period Brazil had constant annual balances in her transactions with the United States, which balances amounted in the 21 years to $443,267,846, the total of the reciprocal imports and exports amounting to $707,775,714; that during the same period, in her commerce with England, Brazil had a balance in her favour in 11 years and England in 10, the balance in favour of England during the 21 years being $15,104,579, and the total transactions between the two countries amounting to $1,218,502,853; and that finally in her commerce with France, Brazil had a balance in her favour during 8 years and France during 13, the balance in favour of France during the 21 years being $38,099,500, and the total transactions between the two countries amounting to $668,428,500.

After some observations with reference to these figures, Sr. Salvador de Mendonça proceeded to the reading and analyzing of the other two tables, one showing the production and the other the consumption of coffee in the whole world, indicating the position of each country both in reference to the quantity imported and the consumption *per capita*. In the observations which he made on the subject of the figures of those tables, he drew attention to the considerable increase in the coffee production of Central America (Nicaragua and Guatemala) and Mexico, noting that even before the effects of the North American capital the natural conditions already favoured that increase.

Finally he explained his view as to the measures which he called internal and which may be resumed in the measures to improve and cheapen the production of our coffee.

For the elevation of the reputation of the product in the markets of the world, he insisted upon the

necessity of discrimination in the qualities of the coffee, which should be exported with the brands of the producers. Nothing will give au easier victory to our competitors than their findiug our product badly quoted, discredited and charged not only with its real faults but also with underserved ones.

To conclude, Sr. Salvador de Meudonça dwelt upou the diminution of the consumption of our coffee in the United States during the last few years.

He attributed this diminution to three causes, fortunately trausitory ones.

Firstly, to the augmentatiou of our production and the unexpected abundauce of our crops, always difficult to foresee aud creating embarrassment to the distributor of the product; secondly, to the failure of important firms which imported the article, a fact which produced a certain cautiou and restriction amongst the other importers; and, finally, to the removal of population from the principal consuming centre.

To this latter reason Sr. Salvador de Meudonça attaches more importance than is generally done when he sees that, whereas the consumption iu the United States of coffee in general has increased, only that of our coffee has diminished. It is because our coffee, of stroug qualities, is chiefly consumed in the Mississippi valley; and as the agricultural population of that valley, from New Orleans to St. Paul in Minnesota, is gradually moving to the Far West, to open up new plantations, and those who take their place and prefer, though at a higher cost, the lands already cultivated, are the new Europeau emigrants, principally Irish, who drink little coffee as is demoustrated by the table of cousumptiou *per capita*, there does not at present exist au equal demand for the article in that valley. The former consumers, who have moved away, have not yet at their disposal the same facilities of transport which they had before, and, besides, they are occupied in opening new industries and without complete relations with the markets whence they formerly supplied themselves. The new ones require yet to be acclimatized before using the same aliment. But as the climate of the Mississippi valley does not change and the population of the United States is increasing in prodigious progression, it is to be believed that the consumption of coffee of the strong qualities will, within a very few years, increase instead of diminishing.

DRIED BANANAS FROM JAMAICA.—An attempt is being made to find a market for this product, and there is no doubt, from a sample submitted to us through the courtesy of Sir J. D. Hooker, that they will form an acceptable addition to the dessert-table, as they have the sweetness of the dried fig without the inconvenience of the numerous seed-like fruits. We have no doubt also that they have a considerable nutritive value.—*Gardeners' Chronicle.* [Since the days of Mr. Thurstau, no one in Ceylon seems to have taken up the work of preparing dried plantains, which, packed in tins, were very acceptable to friends at "Home," and especially to Ceylon children sent to England for education.—ED. *T. A.*]

EXTERMINATING COCKROACHES.—I put 2 quarts of beer into a large vessel, aud in one night I caught 500 full grown cockroaches, and how many young ones I cannot tell. If I could have gone on for a few weeks in that fashion, I should soon have lessened their number, but after a few nights I could only catch about half a dozen, although the stokehole and plant-stove is swarming with them. I have often killed numbers of these pests when the floor has been nearly black with them in the eveuing, but in the morning there has been very little sign of those I killed left, so I conclude they eat each other. I shall be glad if some one can tell how to get rid of them wholesale.—O. ORPET, Cirencester.—*Gardeners' Chronicle.*

THE RED PINANG PALM.—We extract the following from the *Straits Times* of August 25th:—"We learn that upou Mr. Murtou's recently paying a visit to the habitat, in the Siraugoon district, of the Red Pinang Palm, described by him in the *Gardeners' Chronicle* for December 18 last, he found that nearly all the finest specimens had been cut down by, as he was informed, the Parsee Theatrical Compauy. Mr. Murtou has very properly called the attention of Government to this piece of Vandalism, and we are informed that steps will be at once taken for the preservatiou of this rare and beautiful palm. During his recent exploration of the Sirangoon district, Mr. Murton, we further learn, discovered another undescribed species of Willughbeia, which affords a firstrate quality of indiarubber, and specimens are being prepared for transmissiou to Kew and the museum of the Pharmaceutical Society of Great Britain."—*Gardeners' Chronicle.*

EFFECTS OF LIGHT ON VEGETATION.—Herr Stebler has beeu making experiments lately on this subject, and finds that the germination of certain agricultural grasses, such as meadow grass *(poa)* is much more favoured by light than by heat. An experiment made with two groups, of 400 seeds each, of *Poa nemoralis*, showed that there germinated 62 per cent in light, and 3 per cent in darkness. Similar results were made with *Poa pratensis*, showing 59 per cent germinating in light, and 7 per cent in darkness. Sun light being a very variable force, experiments were further made with gas light, and with the same result—viz., that light favours the germination of certain seeds, especially grass, aud that these germinate either not at all, or very scantily, in darkness. The fact was verified by Herr Stebler in a whole series of seeds, such as *Festuca*, *Cynosurus*, *Alopecurus*, &c. In the case of seeds that germinate quickly and early, such as clover, beans, or peas, Herr Stebler thinks that light is probably not advautageous.—*Journal of the Society of Arts.*

SAWDUST AS MANURE.—In your answer to correspondents, you say, "Decomposed sawdust is a good manure, but useless when in a green state." I have a small farm in my own hands, and this does not agree with my experience. The sawdust of fine fir or any resinous wood is not only useless, it is positively injurious. Some years ago a fresh gardener came to a place near here. He found an old sawpit in the wood, where there were tons and tons of sawdust lying, and had been for more than fifty years; everything looked thoroughly rotten. He thought it was a grand find for the garden, and said nothing to anyoue (probably afraid of being forestalled), or he would have been told it was worse than useless; but had a lot driven down, and dressed some plots in the garden. He utterly ruined these plots for a time. It was years and years before he could get rid of the sawdust and bring back the ground to its former fertility. This was the sawdust of fir; the actual fibres of the wood had decomposed and gone into something like mould, leaving only the resin and the turpentine. (Would you like a sack of it?) I won't condemn the sawdust of hard wood, because I know nothing about it, but I should doubt of its being of auy value. Referring to the gardener and his find, do you think the canny Scotch farmers would have left the decayed sawdust lying in the wood if it had been worth the cartage? There is a good deal of sawdust now used instead of straw for bedding horses and pigs; it is mostly fir sawdust. I would not put such stuff on my land, though I could get it for nothing. No doubt the sawdust is saturated with sewage aud ammonia, but, when that is evaporated, it only leaves a resinous fibre behind. It is just like a dram of whisky to the land—gives it a start for a moment, but leaves it in a worse conditiou. Under the proposed new bill for unexhausted manures, no doubt some one would be found to put a value on it, but I don't think it would be the gardener.—J. DUNBAR BRANDER (Pitgaveny, Elgin, N.B.).—*Field.*

CINCHONA CULTIVATION.

COLONEL BEDDOME AND MR. R. CROSS ON THE NILGIRI PLANTATIONS OF THE MADRAS GOVERNMENT.

From Colonel R. H. Beddome, Conservator of Forests, Madras, to the Secretary to Government, Revenue Department, Madras, dated Ootacamund, 4th June 1881:—

Adverting to the G. O., No. 1,670, dated 8th December 1880, I have the honor to inform you that I have lately thoroughly inspected all the Government Chinchona Plantations at Naduvatam, Pykara, and Ootacamund, and I herewith submit my report on the same. I have given my field notes on each plot in the different plantations as taken when going over them with the officers in charge; to these I have added general remarks on the condition of the three different plantations; notes on the coppicing, scraping and stripping systems of harvesting the bark: remarks on the different species grown, condition of buildings, nurseries, &c., together with other remarks and suggestions.

NADUVATAM CINCHONA PLANTATION.

2. *No. I Plot*, 1862, *A.*—14·12 acres, east exposure, shola soil, steeper, stonier and not so rich as in the next plot of the same year's planting; growth good though not equal to plot B: planted originally with three-fifths succirubra and two-fifths officinalis, all of which have now been barked seven times; one block of about 5 acres of Officinalis is of poor growth, chiefly owing to wide planting.

In one spot 57 trees, succirubra, were coppiced rather roughly in October 1873; no suckers were left when the trees were cut, and 22 out of the 57 stools have since died.

The following are measurements of ten of the living coppice:—

	1.	2.	3.	4.	5.	6.	7.	8.	9.	10.
Height	..24′	22′	23½′	23′	24½′	17½′	18½′	19½′	16′	18½′
Girth	..17″	15″	15″	12″	13″	12″	13″	19″	11″	12″
Number of Shoots	.. 2	2	3	3	2	2	2	1	2	2

in the same place and standing in eight rows with the above, 58 trees were also coppiced in May 1873, the suckers being left when the trees were cut; only one stool is dead.

The following are measurements of ten:—

	1.	2.	3.	4.	5.	6.	7.	8.	9	10.
Height	..30½′	24½′	26½′	24½′	23′	26′	23′	24½′	24½′	23½′
Girth	..20″	20″	16″	15″	15″	17″	16″	16″	20″	19″
Number of Shoots..	2	2	3	2	2	1	1	2	2	1

In another spot 200 succirubra were coppiced in May 1871, when nine years old; suckers were left and only one stool died, the yield of the bark being 1,350 lb. green, drying to 453 lb.

These 199 were again coppiced in March 1881, when ten years old (all cut flush with the ground; no suckers left), the yield of the bark being 3,365 lb. green, drying to 1,312 lb.; none of these had commenced again to grow when I saw them on 1st of May, but there had not of course been time for this.

3. *No. II Plot*, 1862, *B.*—17·06 acres, shola soil, west exposure, but sheltered by a hill; nearly all succirubra, but some Officinalis and Pubescens.

The following are measurements of six selected succirubra:

Height ..	..35′	38½′	32′	33′	36½′	37′
Girth ..	.. 31′	34″	29″	26	33″	32′

All the Succirubra and Officinalis have been barked eight times.

Only about eight trees are left out of a quantity of Micrantha trees planted in one place. This species is reported always to die off, the blanks have been filled up with about 600 Pubescens trees (entered in Major Walker's report as supposed to be Anglica), which are growing well and luxuriantly. In this plot 115 trees of poor growth, unbarked, were coppiced in May 1875, yielding only 248 lb. of green bark. Thirty-three stools died; the surviving 82 average 9 feet in height and 5½ inches in girth, and the stools have from three to six shoots now growing (not barked).

4. *No. III Plot*, 1863.—5·41 acres, shola soil, the portion above the road sub-soil indifferent, growth fair; the portion below the road poor from wide planting and exposure to wind, nearly all succirubra barked seven times.

5. *No. IV Plot*, 1864, *A.*—8·86 acres, above the road chiefly succirubra with a few officinalis, fair growth where the soil was shola, poor in places where it was originally grass; below the road succirubra and officinalis mixed, very poor growth from wide planting and exposure to the wind, the soil is also rather poor, all sized trees, barked seven times.

6. *No. V Plot*, 1864, *B.*—4·46 acres, shola soil, chiefly succirubra with a few officinalis, all barked seven times, poor growth owing to wide planting, a few trees dying out owing to a combination of poor soil and exposure to wind.

7. *No. VI Plot*, 1864, *C.*—7·87 acres, shola soil, planted with succirubra and officinalis in nearly equal proportions quite intermixed, growth good but thin in portions owing to the original wide planting, all barked five times. In this plot ¼ acre (adjoining coppice in next block) coppiced in May and June 1879, 56 four times barked trees cut, 43 stools have grown well and 13 died.

8. *No. VII*, 1864, *D.*—17·04 acres, shola soil, succirubra and officinalis in equal proportions, growth very good, trees barked five times. In this plot a block of 4½ acres of trees four times previously barked was coppiced in 1879 (from 31st of May to end of June), 2,263 trees were cut and 2,091 are now growing. The trees were sawn through about 3 inches above the ground and adzed over with a convex surface to nearly flush with the ground; they bled excessively owing to the lateness of the season; hence I think the failures. The present growth of the remainder is most healthy and all that could be desired; each stool has from 1 to 3 stems, 4 to 6 feet high; there is also a late growth of smaller stems, which, I think, should be pruned off, but Mr. Rowson states that the Duke of Buckingham requested that these should be left.

9. *No. VIII Plot*, 1864, *E.*—11·58 acres, shola soil, succirubra and officinalis, the former in a greater proportion; growth of both very good and healthy; succirubra barked twice, officinalis barked five times.

10. *No. IX Plot*, 1864, *F.*—8·58 acres, shola soil, planted with succirubra and officinalis in nearly equal proportions; growth of both very good, trees barked three times.

11. *No. X Plot*, 1865, *A.*—18·32 acres, in two plots, waste land intervening; first about two acres grass land planted with officinalis and a very few succirubra, very much exposed to the South-west monsoon; growth poor, trees barked five times. Second portion shola soil (except a small corner of grass land with about 150 trees very poor growth) planted with succirubra, wind-blown and growth poor except in a low protected portion where the growth is fair.

12. *No. XI Plot*, 1865, *B.* 12·95 acres, shola soil, about nine-tenth succirubra, fair growth in portions, poor where wind-blown, one corner very exposed, trees very poor and dying out; about one-tenth officinalis, very good growth; all the trees of both species barked four times. There are some Pubescens trees.

13. *No. XII Plot*, 1865, *C.* 12·43 acres, shola soil, succirubra chiefly, officinalis about 3 acres, all splendid growth, all barked six times. The plantable is too crowded in parts, the trees not being three feet apart, the thin girthed trees not reaching the light should be uprooted.

14. *No. XIII Plot*, 1866, *A.*—4·10 acres, shola soil, nearly all officinalis, growth good but plauted originally too far apart, barked three times.

15. *No. XIV Plot*, 1866, *B.*—14·34 acres, shola soil, all succirubra of very fine growth, barked six times; there was a good deal of calisaya in this plot, but it all died out some years ago.

16. *No. XV Plot*, 1866, *C.*—12·45 acres, shola soil, succirubra except a small quantity of very fine old officinalis and some young Calisaya and Pubescens, growth of succirubra very fine, barked six times. About one acre formerly planted with calisaya, all dying or dead, was uprooted, yield of bark 730 lb., sale proceeds unknown. This block has been replanted with 2,000 young Calisaya and 600 young Pubescens.

17. *No. XVI Plot*, 1868, *A.*—3·71 acres, all shola, planted chiefly with succirubra, has been burnt over more than once, now poor and very thin, only about 300 trees remaining, soil poor and scarcely worth replanting.

18. *No. XVII Plot*, 1868, *B.*—8·13 acres, all shola, about one-third facing west very much blown, planted with succirubra, condition bad; about two-thirds facing east, succirubra and officinalis, about alternate trees very fair growth, all barked twice.

19. *No. XVIII Plot*, 1869, *A.*—9·96 acres, grass land, nearly all succirubra, growth fair, particularly in lower portion, trees not barked; 400 officinalis barked twice.

20. *No. XIX Plot*, 1869, *B.*—11·83 acres, grass land, all succirubra, upper portion exposed and growth very poor and thin, and should be uprooted and replaced by officinalis, lower portion fair growth of Red barks for grass land, trees not barked.

21. *No. XX Plot*, 1869, *C.*—13·69 acres, grass land, 2 acres officinalis, good growth, all barked, balance succirubra not barked, fair growth for the soil, but should all be uprooted and replaced by officinalis which may be said of all grass land planted with succirubra in these plantations.

22. *No. XXI Plot*, 1869, *D.*—13·26 acres, grass land, except a small patch of shola land, all succirubra except a few supplies of officinalis, not barked, except the small bit of shola soil, all poor growth and very thin in the upper portions, should be uprooted and planted with Officinalis.

23. *No. XXII Plot*, 1869, E.—12·18 acres, all shola land except a small corner of grass land (about 50 trees), all succirubra except supplies of officinalis, growth very good, not barked.

24. *No. XXIII Plot*, 1869, *E.*—11·54 acres, two-thirds shola, one-third grass land, all succirubra except supplies of officinalis, growth very good on the shola soil, fair on the grass land, trees not barked, 5 acres copiced in 1879, balance scraped in 1880, 5 acres succirubra coppiced in July 1879 (in the same manner as in Plot No. VII), 2,628 unbarked trees cut, all stools bled terribly, 973 dead and uprooted, 1,655 growth healthy, shoots 1 to 3 to each stool, 3 to 4 feet high, blanks from the uprootals to be planted with Pubescens. Six acres, 4,723 succirubra trees scraped in September 1880 on the new Java principle. None were mossed or covered in any way as it was not supposed to be necessary. 1,978 trees have failed to renew their bark, and the bark and cambium being apparently all dead, it is supposed the trees must die, and some have already died; the remainder are renewing their bark satisfactorily, and might probably be scraped again in 1882, but not before.

25. *No. XXIV Plot*, 1869, *G.*—20·19 acres, all shola land, all Succirubra and Pubescens except supplies of officinalis, not barked, splendid growth, Pubescens about 20 per cent.

26. *No. XXV Plot*, 1869, *H.*—9·20 acres, all shola except a small bit of grass land; shola soil planted with succirubra, not barked, growth very good; grass land planted with officinalis, all barked.

27. *No. XXVI Plot*, 1869, *I.*—2·25 acres, shola land, all succirubra of very good growth, barked four times.

28. *No. XXVII Plot*, 1870, *A.*—11·52 acres, grass land, now two-thirds officinalis and one-third succirubra, originally planted entirely with succirubra which mostly died out and was replanted in 1872-73. The remainder of the succirubra should be uprooted and replaced by Officinalis or Pubescens. The officinalis growth is not good owing to exposure and poverty of soil, but it will pay, not barked.

29. *No. XXVII Plot*, 1870, *B.*—16·37 acres, grass land, an entire failure, uprooted and abandoned, and now pitted for planting Australian acacias for fuel.

30. *No. XXIX Plot*, 1870, *C.*—4·30 acres in three separate blocks:—

First block.—Grass land, officinalis, growth good, but too widely planted, barked twice.

Second block.—All shola land, mixture of Succirubra, Officinalis, Calisaya, Javanica and Anglica, not barked, growth good, except the calisaya. The Anglica and shrubby Javanica of no value.

Third block.—All shola, chiefly succirubra with a few officinalis, growth good, not barked.

32. STATE OF NADUVATAM PLANTATIONS.

The Naduvatam plantations certainly show very fine growth, and though I inspected them at the beginning of May, after an unusually dry April, and at the end of a long season of drought when all the grass hills were as brown as the roads, they were in splendid condition and healthy foliage. Taking into consideration the mistake of too wide planting, I think they are all that could possibly be expected and in every way satisfactory. In planting up a large area like this site, it is of course impossible always to avoid too great exposure to wind, bad soil, bad drainage, &c., and there are here and there failures from these causes; but this could not be otherwise, and even in many places where the growth is poor it pays well at the prices bark is now realizing.

33. *Fencing.*—A considerable expenditure is necessary in fencing in several of the plots, if they are to be properly kept up, as the sambur are most troublesome; it will well pay.

34. *Wide planting.*—The great mistake here as elsewhere has been the wide planting. It was probably supposed that the trees would grow to a far larger size than they now promise; but even supposing that this had occurred, there was the established fact that such large trees as Teak and Eucalyptus had to be planted $6' \times 6'$ and afterwards gradually thinned out, otherwise good growth could not be secured: wide planting causes crooked growth and often no fair boll and gives the wind an unfair advantage. The planting was originally $12' \times 12'$, but reduced gradually afterwards down to $8' \times 8$ and $7' \times 7'$. I am of opinion that the planting of "Succirubra" should always be $5' \times 5'$ or certainly not more than $6' \times 6'$, and that the first thinning (alternate lines leaving the trees $10' \times 5'$ or $12' \times 6'$) need not take place till there would be some yield from the bark, and that at the final thinning the trees may stand $10' \times 10'$ or $12' \times 12'$. "Officinalis" should be planted $4' \times 4'$ or perhaps even closer; intermediate planting is always very precarious owing to the shade and drip of existing trees, and 25 or even 50 per cent very often appear to fail. Throughout the plantations one sees evidence of the great mistake wide planting has been.

35. *Is barking injurious or not to the trees?*—There is certainly no proof that barking in any way affects the health of the trees. I was formerly of opinion that it did, and fancied I detected it in the appearance of the trees, so I was prejudiced in a way, but I made most careful inspection of both barked and unbarked trees both from a distance and close, and could detect no difference in foliage or any way else, and it is a fact that the trees barked seven to eight times are some of the healthiest and finest in growth, foliage and every way, in the plantation, and that they are now flowering and seeding less prolifically, and that the barked trees have grown quite as well, if not better,

from coppice, which shows that their root system must be quite as healthy; this is also Mr. Rowson's opinion. Mr Rowson thinks that the trees appear to suffer somewhat for a month or six weeks after being stripped, getting somewhat yellowish in leaf, but that they rapidly recover, so that if inspected just after the barking a prejudice might easily be entertained against the system. Trees that have been barked several times often bear fewer branches, but this is owing to the pruning and to branches having been broken off; the foliage is just as thick as in unbarked trees. Some trees do fail to renew their bark after being stripped, but it is very uncommon, and it is very rare to find a really healthy tree die ont from its effects. The bark renews just as rapidly in the subsequent strippings as it does in the first, and there is no perceptible difference in its thickness, the renewal is always more rapid on rich soil than on poor. Carelessness in barking prevents immediate renewal and may cause the death of a tree.

36. *Elevation for "Succirubra."*—The "Succirubra" does not attain the same size at Naduvatam as it does in Wynaad and elsewhere at lower elevations; it grows to about 50 feet in Ecuador, and on the Tinnevelly ghâts, at 3,000 feet, it has been measured 52 feet in height; at Naduvatam no trees are quite 40 feet: 5,000 to 6,000 feet is probably too high an elevation for large growth, but it is said (I do not know how far correctly) that the bark at these higher elevations is more valuable; in any case "Succirubra" pays well on shola soil at Naduvatam.

37. *Longevity of "Succirubra."*—"Succirubra" is probably not a long-lived tree, but we cannot state the age it will attain when left unbarked, or when barked until we have actual data, and a good quantity of unbarked trees must be left for this purpose.

38. *Method of harvesting.*—With the established facts that the eight times barked trees are still perfectly healthy and that the renewed bark is far more valuable than the natural bark, it would not be advisable to adopt any other system than the present one, the credit of which entirely belongs to Mr. McIvor; and it should, I certainly think, be pursued as long as the trees appear healthy, but trees showing signs of decay should be either coppiced or uprooted.

39. *Coppicing.*—Certains paragraphs show the results of the coppicing at Naduvatam in 1879. The coppicing process was very well carried out, the stools being sawn through about 3 inches above the ground and adzed over with a convex surface to nearly flush with the ground; the growth is very healthy and promising wherever the coppice has succeeded.

In the 1864 planting, 2,319 "Succirubra" trees, all previously barked four times, were carefully coppiced early in June 1879; 185 stools have died, 2,134 are growing luxuriantly. In the 1869 planting, 2,628 unbarked "Succirubra" trees coppiced in the same manner in July 1879; 973 stools died, 1,655 growing luxuriantly.

Here we have a great anomaly: trees fifteen years old have succeeded from coppice with a far better percentage than trees only ten years old; this is quite opposed to my experience in the coppice of any other trees, the growth being generally far more successful in the younger trees; old or even mature trees often failing altogether to make coppice growth beyond a few twigs which die off, when saplings or young trees of the same species grow most readily; this is always the case with "Teak" and "Babul." Again, it is noteworthy that the four-times barked trees have succeeded from coppice with a better percentage than the unbarked trees.

Both these data, however, are more or less valueless, as the 1869 planting was coppiced nearly a month later than that of 1864 the sap was therefore more up and the trees bled much more which may account for the extra failures. The coppicing of both years was carried out too late, and I am inclined to attribute the failures to this cause as the stools bled terribly: if the coppice had been in April or early in May, it is probable there would have been no failures at least of healthy trees.

Of the old coppicing experiments carried out more roughly, where fifty-seven unbarked "Succirubra" trees of 1862 planting were clean coppiced in October 1873, all suckers removed, twenty-two have died, thirty-five have grown well and are about twenty feet high, and of fifty-eight trees of the same year coppiced in May 1873, but the suckers left standing, only one stool is dead; and of 200 "Succirubra" of the same year in another block coppiced in May 1871 (when nine years old) suckers left standing, only one stool died; the 199 again coppiced in March 1881 (when 10 years old) no regrowth yet, but sufficient time has not elapsed. The yield of green bark in 1871 was 1,350 lb., but in 1881 it was 3,365 lb., which is noteworthy; and of 115 "Succirubra" of the same year but of poor growth and unbarked, coppiced in May 1875, thirty-three stools died, the surviving eighty-two about 9 feet high and 5½ inches in girth.

I do not think we should carry out any further coppicing in blocks, but only coppice trees showing signs of decay. I observed here and there dead trees in the different plantations. A tree should never be allowed to die, as its bark then yields no alkaloids; the should be coppiced or uprooted when signs of decay are evident. It is an established fact that if a sucker or shoot is left when the tree is coppiced it never dies, and when trees have no shoots one can easily be produced by slightly injuring the bark close to the ground. It is also an established fact that if trees are coppiced in June or July, when the sap is well up, there must be many failures owing probably to the excessive bleeding that takes place. We have not sufficient data to say whether trees coppiced in April or early in May will all grow again without any failures.

40. *Uprooting.*—I do not think that this is to be thought of as a harvesting system, but I would uproot all "Succirubra" on grass land at Naduvatam and elsewhere, where it is advisable to replace it with "Officinalis" or "Pubescens." It is doubtful how far seedlings will succeed on land immediately after it is uprooted; it will probably be found necessary that it should remain fallow for a certain period.

41. *Scraping.*—As to the new Java method of scraping, we want, I think, more experience. This first attempt (*vide* paragraph 24) has, it will be seen, proved a failure with "Succirubra," and caused the loss of a great number of trees; it would probably not fail if the trees were mossed or grassed over after the scraping, but one of its advantages was the supposition that the expense of this would be unnecessary. I am inclined to think that the trees are much more likely to suffer from the complete scraping than from the partial barking in alternate strips; we have yet to learn if the scraped bark is more valuable in the market than the stripped bark.

42. *Grass, a substitute for Moss.*—For the last two years Mr. Rowson has employed the coarse Lemon grass of the hills (*Andropogon Martini* and *Schoenanthus*) as a substitute for moss for covering the trees after stripping off the bark; it appears to answer in every way as well as moss, the bark never failing to renew: the grass of course lacks the hydrometric properties of moss, and it is possible that bark renewed under it may not be so replete with alkaloids, but I see no reason to fear this; the grass costs only about one-third what moss does, and moss might in time be exterminated; the moss must act like a sponge round the tree in wet weather when the bark is growing most rapidly, and considering how replete the bark itself is with moisture, this is, I think, more likely to be injurious than beneficial; all that is probably required being protection from solar influences and from wind. The first report on bark renewed under grass, however, will be of great interest.

43. *Red Barks (Succirubra).*—Although this tree is not adapted to grass land on the Nilgiris, it grows very well in shola soil at Nadhvatam, and at lower elevations; Ootacamund is of course too high for it. The bark is not nearly so rich in quinine as the "Officinalis," "Calisaya," and some others; but it is perhaps the richest of all the species in the total yield of alkaloids, and on account of its easy culture, robust growth, and great yield of bark will probably always be the one most cultivated in the Wynaad, Coorg, &c., at elevations of 2,500 feet and upwards. It will grow almost everywhere on our western mountains between 2,000 or 2,500 up to about 6,000 feet, if forest soil be selected and a sloping situation; it is however apt to die out on flats as it did in Travancore, unless the subsoil drainage is carefully attended to; and it has been proved that it is useless to attempt its cultivation in the drier climates in the eastern or central parts of this Presidency. "Succirubra" should never again be planted on grass land at Naduvatam, and what there now is on this soil should be gradually uprooted and replaced by "Officinalis" or by "Pubescens."

[See page 593 for part here omitted, referring to Pubescens.—ED. *T. A.*]

Narrainsawmy of Dodabetta informs me that he sent it home to market for the first time in December 1880, and that two bales were forwarded, viz., 111 lb. of mossed "Pubescens" (not renewed) and 138 lb. of natural "Pubescens"; the report on this is not yet to hand, and will be of the greatest interest. There is not a tree of "Succirubra" in Dodabetta fit to be barked, so it is doubtlessly all from the true "Pubescens" or "Pâtâ de Gallinazo" of Mr. Cross; it is besides nearly all from the glabrous variety as very few trees of the pubescent form exist in this plantation. No bark of these sorts has as yet gone to market from Nadhvatam, so I think that some, both of the pubescent and glabrous varieties (from grass land and from forest soil separately), should be forwarded without further delay. If this species is really far more valuable in its yield than "Succirubra," Government have been losing enormously by the extensive propagation of the latter to the exclusion of the former. Mr. Cross states that it grows at a much higher elevation in its native country, and this is borne out by the fact that it is growing vigorously on Dodabetta above 7,000 feet elevation (where "Succirubra" is a complete failure), and by its more vigorous growth at Nadhvatam in exposed situations.

The questions, however; first, whether it is to oust "Succirubra" from the forest soil at Nadhvatam, and second, to what extent it is to be planted on grass land to the exclusion of "Officinalis" must entirely depend on the report on the analysis of a sufficient quantity of its bark.

Mr. Rowson informs me that he has 5,000 "Magnifolia" on the Hooker plantation and 2,000 at Nadhvatam, 5,000 "Pubescens" on the Hooker and 4,000 at Nadhvatam, and there are about 1,000 at Dodabetta, chiefly "Magnifolia."

In the 1869 planting at Nadhvatam 20 per cent of the trees are of this species.

45. *Unknown Species.**—I found five trees of a curious species in the 1865 plantation on Dodabetta. It has most curious rough bark like that of the Cork tree (Millingtonia) quite unlike any other Chinchona, and its leaves are exceedingly hairy on both sides, and it has hairy capsules; nothing is known of its origin except that it was received with the original seeds or plants. Mr. Cross thinks from the character of its bark that it may be of great value. Dried specimens of this species and fragments of the bark (to show its character) accompany this report with other specimens. "Asperifolia" Weddell is the only species I can find described at all like it in botanical works, but I have only De Candolle and Walpers for reference, not all the later works, such as Weddell's. There are very few species known with the leaves hairy on the upper surface. The bark of this has never been analyzed.

46. *Crown Barks.—Officinalis (Linn.)* (of which Condaminea (Lamb) is only a synonym) flourishes exceedingly well on grass land at Nadhvatam, Pykara and Ootacamund, as well as on shola land. It is a small tree of no great girth, but this is, I believe, also its characteristic in the Crown bark region in Loxa.

Uritusinga.—The tree known by this name in the Dodabetta and Nadhvatam plantations, and also called "strong-growing Condaminea" and "broad-leaved Condaminea" is evidently only a variety of "Officinalis." It is of much stronger growth with broader leaves, and promises to be a much larger tree; but twigs can often be gathered from ordinary "Officinalis," particularly from suckers or young growth, in which the leaves are quite indistinguishable from this "Uritusinga." Mr. Cross believes our tree to be the same as the "Uritusinga" of Pavon, which takes its name from a hill near Loxa, where he himself collected it, and which is now quoted in botanical works as a synonym of "Officinalis"; but it should certainly be considered as a variety, and its bark should be kept distinct from that of "Officinalis." Our plant is exceedingly strong growing and healthy, and I think it should be largely grown and receive more attention; at present there are about 1,000 of it in Dodabetta, but only about a dozen at Nadhvatam. "Uritusinga" is a lofty tree in its native habitat.

Angustifolia.—Evidently only a variety of "Officinalis"; it sometimes looks very distinct, the leaves being narrower and deeper coloured, but if is not always true to its characteristics, and broader leaves in no way distinguishable from "Officinalis" can often be gathered on it. There is none of this on the Nadhvatam side; some 700 rooted plants sent out from Ooty to Pykara as this variety have turned out to be ordinary "Officinalis." There are a few planted out in the Dodabetta plantations, but they do not show good growth, or promise to be a success; it is supposed to yield a very large percentage of quinine, and there are now 10,000 rooted cuttings in the Dodabetta nurseries propagated in the glass houses from the few stock plants. Considering its poor growth I cannot recommend its extended planting until its treatment is better understood or a more favourable habitat is found for it. Mr. Jamieson informs

* Since this report has been copied I got Mr. Cross to examine these trees. He writes: "great discovery! incredible fact!! the celebrated 'Chinchona Crispa' of the Loxa mountains, a packet of the seed of which we collected when collecting the Officinalis." He also tells me that it is a very valuable bark, that the plant is probably almost unknown and was only collected by himself, and that the seeds which were sent to the Nilgiris were said never to have germinated.

I can find no description of C. "Crispa," and the nomenclature and synonym of the genus seems in a most confused state at present; it can, however, scarcely be the "Crispa" of Tafella mentioned in Triana's work without description, as that is said scarcely to differ from "Officinalis," and is made a variety of it by most authors which this very distinct species could never be. If Mr. Cross is correct, the plants lately supposed to be "Crispa" are spurious, but I do not know where "Crispa" is originally described or by whom. Whatever this may be its bark should be analyzed at once; it has been in these plantations since 15 or 16 years without ever having been noticed; it is in flower and seed now, and has probably been seeding for many years, and might be propagated largely if advisable; in its bark, leaves and fruit it is utterly unlike anything else in any of the plantations.

Mr. Cross says he found it at 10,000 feet elevation, and that it grows at a higher elevation than any other known species of the genus.

me that Mr. McIvor considers it hopeless to grow this variety; its growth being so slow and poor, it would be far less profitable than the ordinary variety of "Officinalis," notwithstanding the superiority in its yield in alkaloids. I can always distinguish this plant at the first glance, but Mr. Cross considers it not even a variety but only a condition of growth of "Officinalis," conduced by poverty of soil or some other condition. I cannot say that I quite agree with this, but there is the fact that some 700 plants, supposed to be this species, in the nurseries at the Ootacamund Gardens, and planted out in rich soil at Naduvatam, turned out to be ordinary "Officinalis." There is not sufficient evidence, however, as to what the original plants really were.

Var. Crispa? Mr. Cross informs me that he recognizes many plants of the "Crispa" var. of "Officinalis" (at least the one known in Ceylon as such) supposed to be very rich in quinine, scattered about with "Officinalis in our Dodabetta plantations. I forward dried specimens of this form which Mr. Cross distinguishes by its rather smaller leaves, but I must say that I cannot distinguish it satisfactorily from ordinary "Officinalis," and it appears at any rate to run into it.

Var. with very narrow leaf.—There are a few plants of a very narrow-leaved form of "Officinalis" in the Dodabetta plantations, of which I also forward specimens. This variety is easily distinguished, and I believe it is the one Mr. McIvor considered as "Crispa;" it is only of shrubby growth, and cannot, I think, be of much value. I am very disinclined to attach too much valuo to the fact of a very favourable analysis (as we find in reports) of single individuals of varieties like "Angustifolia" or "Crispa" grown perhaps under very favourable conditions, or to attempt their extended cultivation on such grounds. It is of course evident that they are valuable yielders under certain conditions, but it would require stronger evidence, I think, to establish the fact that they are far superior to the ordinary type of "Officinalis," as a very high percentage of alkaloids has sometimes been obtained from single specimens of that also. If a cultivator takes a fancy to any particular variety he can probably get a very flourishing report on its yield by the high cultivation of a few individuals, but this does not hold good in a large plantation, and I should be sorry to place faith in it with varieties like "Angustifolia" and "Crispa." Uritusinga is, I think, valuable on account of its very strong growth and much greater yield in bark; the analysis of this from Dodabetta is given in G. O., No. 1,336, of the 23rd June 1879, under the head of "Condaminea" as distinct from Crown barks.

47. *Cultivation of Crown Barks by Government should be kept up.*—Crown barks will only grow at a high elevation, and there are few or no sites for them except on the Nilgiris, where only grass land and not shola is now available to the public. "Succirubra" and "Calisaya" on the other hand are spreading all over the Wynaad, Coorg, &c.; it is desirable therefore that Government should keep this in view, and, if possible, extend the cultivation of Crown barks, or at any rate work up their present estates without any stint as to expenditure.

48. *Yellow Barks.*—It is to be regretted that these are such a failure at Naduvatam; they all die out and the climate is evidently too cold and probably too dry for them; they grow at low elevations and in a very moist climate in their native habitat in Bolivia and Southern Peru, and it is useless to make further attempts at the cultivation of "Calisaya" or its variety "Ledgeriana" at Naduvatam; but I would strongly recommend that a small garden should be opened out for experimenting on their growth at 1,000 or 2,000 feet below our present plantations; they are, I believe, growing well in parts of Wynaad and in the Onchterlony Valley at about 3,000 feet elevation.

It is not easy to distinguish the variety "Ledgeriana" from ordinary "Calisaya" when in leaf only, but Mr. Rowson tells me he can always do so when they are in flower, as the "Ledger" has white flowers, whilst those of the ordinary "Calisaya" are pinkish,

Anglica, supposed to be a sport or variety of "Calisaya," is represented by a few trees at Naduvatam; its bark is said to be of little or no value.

Javanica, said also to be a variety of "Calisaya," is also represented by a few plants at Naduvatam; it appears to be of no value and not to be worth growing, at least in the form it assumes at Naduvatam, which is a small very bushy shrub. I do not know whether this is the variety usually called "Josephiana."

49. *Grey Barks.*—"Micrantha," "Peruviana," and "Nitida" from the Grey bark region around Huanico in North Peru are all represented at Naduvatam and Pykara, but they do not succeed and are in fact all fast dying out; they yield no quinine but are valuable for their yield of Cinchonine and Cinchonidine; it is useless to grow them at Naduvatam, but it would be a pity that they should be lost to India, and I propose that another site at a lower elevation should be opened out for them. "Micrantha" and "Peruviana" grow at about 4,000 feet elevation and in a much moister climate than that of Naduvatam, and could hardly be expected to answer in their present situation; but "Nitida" grows at high elevations and might have been expected to thrive at Naduvatam.

50. *Columbian Barks*—Pitayensis (Pitayo bark).—There are some few very healthy trees of this in the Dodabetta plantation, but the tree has not been propagated here as yet. Mr. Cross anticipates valuable results from its introduction, and informs me it grew to 70 and 80 feet high and 3 to 4 feet in diameter where he met with it at 9 to 10,000 feet in Grenada. Samples of the bark of our Dodabetta trees have been sent by Mr. Cross to Mr. Howard for analysis, and on this report the question of its extended cultivation must depend; it is supposed to yield much quinine.

Santa Fé—Soft Columbian (C. Lancifolia).—The plants brought by Mr. Cross from New Grenada (7 to 10,000 feet elevation) are healthy and are being propagated, so it is hoped this valuable species may ere long be established on the Nilgiris. It is known to yield a very high percentage of quinine, and Mr. Cross anticipates great results from its introduction. It grows, he tells me, 70 feet high with a diameter of 3 feet in its native habitat; it may be expected to answer well at Naduvatam and perhaps also in sheltered places in Dodabetta.

Carthagena Bark—(Cinchona Cordifolia).—The two plants brought lately by Mr. Cross from the Central Codillera near Bogota (elevation 4 to 6,000 feet) are healthy and strong growing and are being propagated, and the prospects of establishing it on the Nilgiris are promising. It is supposed to be a strong growing large tree, which its present appearance does not belie; its yield in quinine is much the same as that of Succirubra, and it will probably succeed in the same localities as that species. Mr. Cross tells me that he believes the "China Cuprea," the seed of which is promised to this Government (*vide* G. O., No. 630, of the 8th April 1881) from Bogota is the same species.

51. *Pubudiana.*—There are a few of this very distinct species in the Dodabetta plantations; it is said to be quite valueless, and its extensive propagation in Java, owing to its robust and rapid growth, caused much loss and annoyance.

See page 600 for extract on "Hybrids" from the report omitted here.—ED. T. A.

51. *Analysis of the various Barks.*—I fear that too much reliance may hitherto have been placed in the analysis of the barks of single individuals of one species or variety, grown under specially favorable conditions; soil, solar influences, shade, moisture, loss through exposure to wind, frost, &c., must probably exercise great influences on the bark and yield of alkaloids, and analysis should not be too much relied on, unless taken from a considerable number of trees subject to the varied conditions which they must experience in a plantation.

55. *Sites for Species requiring a Lower Elevation.*—A fine-sheltered shola in the "Silent Valley," elevation about 3,000 feet, has been reserved by the Collector of Malabar at the request of the Conservator, in case it should be required by this department for the growth of "Rubber trees," or any other products. I now recommend that this should be taken up by the Forest Department at Nilambúr, and that a small clearing should be at once made for experiments on the growth of "grey barks" and "yellow barks" at that elevation; if they grow well, there is ample room for opening ont a considerable area; it may also be necessary to try "Carthagena" and "Santa Fé" at this lower elevation. A small pucka building should be erected, and the Chinchona budget should furnish the necessary funds; it is also desirable to try some of the rubber trees and the "Ipecacuanha" (Cephaelis) in the same locality.

56. *Renovating Pits.*—Mr. Rowson has much improved the health of the trees in the plantations under his charge (at Naduvatam and Pykara) by the renovating pits (2 feet cube). In many parts of the plantations the trees have a far more vigorous look than they had two years ago; it has been surmised that the lateral roots might be injured by this system, but this is not the case; where the lateral fibrils have been touched, they shoot out again with great vigor through the humus in these pits; in some cases cattle-manure has been put in the pits, but much of this not being available, they have generally been filled up with dead leaves, and decaying vegetation, such as the weeds, cleared off the plantations; they have, I consider, improved the condition of the plantations in a most marked manner.

57. *Perfect Drainage most necessary.*—All the varieties of Chinchona appear to grow much better on slopes than on flats, the tree being most impatient of anything like insufficient subsoil drainage.

58. *Lichen.*—In wind blown situations the trunks and branches are often much covered with white lichen. Mr. Rowson assures me this in no way affects the health of the trees or bark; it is easily rubbed off.

59. *Diseases and Enemies.*—There is very little sign of canker at Nadnvatam, and the Chinchona seems to have few or no insect enemies; sambur and wild animals are, of course, destructive, and fencing is most necessary in some parts if the plantations are to be worked up to their highest possible yield.

60. *Number of Trees in Naduvatam.*—Appendix A is a statement of the number of casualties amongst the trees in Nadnvatam Plantation during the last three years (or since Major Walker's report), and the number of trees now existing based on Major Walker's enumeration.

61. Statement showing number of plants in the nurseries at Nadnvatam, 28th May 1881:—

Botanical Names.	Plants in Nurseries and Hot House on 31st March 1880.	Plants raised during 1880-81.	Total.	Plants issued during 1880-81.	Plants planted out permanently during 1880-81.	Balance in Nurseries and Hot House on 31st March 1881.
C. Succirubra	216,000	585,950	801,950	489,950	12,000	300,000
C. Officinalis	155,000	378,000	533,000	228,000	105,000	200,000
C. Calisaya var. Ledgeriana ...	4,400	*1,560	5,960	50	...	12,027
C. other varieties ...	4,000	1,305	5,305	...	2,305	3 000
C. Pubescens	...	20,010	20,010	1,000	8,010	11,000
Total ...	379,400	986,825	1,366,225	719,000	127,315	516,027

*Received from Dodabetta.

†3,983 seedlings have died.

(*To be continued.*)

LAHORE.—We have received a copy of the report of the Punjab Agri-Horticultural Society for the year 1880-81, from which we learn that much damage was done by hail in March last. The climate appears to be too cold for the rain tree (Pithecolobium Saman), but some of the Eucalypti succeed well, those specially recommended for planting in the plains of Punjab being Encalyptus bicolor, E. hæmatostoma, E. resinifera, E. rostrata, and E. tereticornis, besides others not yet named; Grevillea robnsta has also been distribnted, and is doing well. The Carob (Ceratonia Siliqua) succeeds well, and experiments are to be tried with grafted plants. The cultivated olive does not thrive on its own roots, but when grafted on the wild olive stock the result is very satisfactory. Apples and pears do not succeed in the plains. In Kulu, in the Kangra Valley, the success in fruit culture has been such that it is anticipated that Kulu Valley and the adjacent district will become a great fruit producing country. As regards vegetables, it is considered preferable to import seed each year from Europe rather than trust to Indian grown seed, but this remark apparently does not apply to peas, the "acclimated" seeds of which give a greater yield than the imported seed. Over 28,000 plants were sent out to various districts in the province, especially to places along the Indus Valley Railway. Mr. Edgar Spooner is the Superintendent of the Society's Garden.—*Gardeners' Chronicle.*

THE PHYLLOXERA CONGRESS AT BORDEAUX.—"A very slight study," says the writer in the *Saturday Review*, "of the conditions of vine culture in the more valuable vineyards is sufficient to reveal the fact that the growth of what may be termed high-bred vines is a singularly artificial matter, the conditions of which are most delicately balanced. One of the greatest difficulties of vine growing is to determine the particular kind out of the immense number known which is suited to the soil and physical conditions of a particular locality, and it is not unusual to find in the same vineyard a vine which bears abundantly on one side of a road, unproductive and all but sterile on the other. Quite apart from the phylloxera, much money has been lost by planting vines without previously ascertaining the kinds which are likely to succeed." It is not to be wondered that in making choice of the remedies to be applied, the cultivator should wish to do anything rather than interfere with the vines themselves when their produce is a valuable wine. The The culture of the vine is possible even in presence of the phylloxera where the soil is of a sandy character, and this may lead to the extension of the cultivation in the Landes. The American vines are but little affected by the phylloxera, that is to say, they have greater powers of resistance than the European vines, and hence their value as stocks whereon to engraft the finer kinds. The produce of American vines excites dismay in the minds of those who have tasted it, else it might seem feasible to raise hybrids between the American and the European grapes, which should possess the resisting powers of the former. The probable or certain deterioration of the flavour would be of the less consequence, inasmuch as the great loss at present is not in the higher class wines—the luxuries of the wealthy—but in the *vin du pays* of the peasantry, in which the question of flavour is not so important. Besides, in course of time, by repeated experiments, the evil flavour might be eliminated. All this, however, requires lengthened time, while immediate action is requisite to save the vines, for, as the writer we have already cited remarks:—"The vines of Europe have been the insensible growth of centuries of development; they are as much products of art as a violin. American vines in the nature of things are nearer to their uncivilized state, and one might as well place a tom-tom in the hands of a Joachim as offer American vines to the wine-growers of the Medoc to replace those they now cultivate."—*Gardeners' Chronicle.*

PREPARATION OF COFFEE.

In reference to the following article from the *South of India Observer*, we may mention that on most estates in Ceylon the weather is adverse to the final drying of the coffee, and casks could be obtained and transported only at great expense. In Java, curiously enough, the objection to sending coffee to a seaport to dried and prepared, is the paucity of available labour at the ports :—

The form in which coffee is put on the market has a good deal to do with the price of the article, and the omission of comparatively simple and trifling operations causes a serious loss to the grower. One of these operations which plays an important part in the drying of the coffee and so on its color and form, is the washing. The mucilaginous substance which covers the bean must be completely washed off, and most growers are content that this operation shall be performed by coolies who trample the pulped masses in the vats till this substance comes completely off. On one estate we have seen the washing done in a great wooden tub, fitted with a set of rotatary brushes which work horizontally. We believe this does fairly well, but an American invention, known as the "Coffee Washer," though on the same principle, is more complete, and washes with greater rapidity, and at a minimum of cost. It consists of a large cylinder from 7 to 12 feet in length, similar to a perforated sizer, but not more than 20 inches in diameter. This is fitted with a series of washers working on an axle. The cylinder is on an incline, and the delivery end is furnished with a gutter, out of which the coffee, which enters the machine through a hopper with water at the other end, comes out perfectly clean in a few seconds, and is emptied into a vat to receive it. The eight foot machine can clean 10,000 pounds of coffee, per day and weighs altogether 1 000 pounds. A one-horse power engine is sufficient to work the machine, or a water wheel with equal convenience. The Americans have brought out another serviceable machine for the coffee planter, namely, a Huller and Polisher. The most striking feature of the invention is the construction of the pestle and mortar in which the husk of the coffee is broken and pulverized after the drying process. Both pestles and mortars are provided with a succession of oblique ribs, set at a proper distance from each other, on the surface, so as to form channels, wherein the coffee is pushed up and down, and receives a considerable friction, which speeds the work without injuring the coffee in the least; on the contrary, owing to this increased friction, it acquires a beautiful polish, and loses all that silvery pellicle which gives such an ugly appearance to coffee cleaned by other processes. Not a single grain of coffee is broken by this machine. The pestle is so arranged that it can only penetrate or reach within an inch from the bottom of the mortar. The mortars are filled with coffee with the greatest facility, and by opening a valve at the bottom, on the outside, they are emptied in a few seconds, and then refilled. Of course, stop the pestle of the mortar that is to be emptied; this is easy to learn. In the meantime, the other pestles continue their work. This is a very plain, strong machine, easily worked. It can be arranged in round or straight batteries. The round arrangement is composed of thirteen mortars, each of which will clean from 150 to 200 pounds of coffee per hour. The amount of work to be done will depend on the number of mortars and pestles. About six horse-power will be required to run the battery of thirteen mortars, and about four horse-power to run the seven mortar battery. A straight battery of seven mortars and seven stamps will hull and polish 7,000 pounds of coffee per day. Beyond an improvement in the machinery, the principle of the coffee huller is not novel. It has for years been adopted as a rice-cleaner, chiefly to remove the husk. The cost of transport of produce to a coffee cleaning establishment, the cleaning and the packing of the coffee in bags or barrels, is a considerable item of estate expenditure, and whatever the selling price of the staple is this charge is always maintained at a uniform figure. With mechanical appliances of the kind to which we invite attention, every large estate will be able to clean and ship its coffee direct at probably a quarter of the cost incidental to the preparation of the bean for the London market at the present time. C. Adolphe Low and Co., of New York, are the manufacturers of both the Washing and Hulling Machine.

THE LONDON MARKET FOR INDIAN TEA.

After a period of severe and prolonged depression there has certainly been a great and encouraging reaction in the market for Indian tea. Low prices, although disastrous to individual planters, have had the usual effect of increasing consumption, and now there is evidently a large and increasing class of persons in Britain who, having acquired a taste for the superior Indian tea, will insist on being supplied with it in preference to the weaker China stuff. Leaving prices out of the question for the present, the comparative figures for deliveries and imports of Indian tea, in ten months of each of the past three years, are worthy of attentive consideration. In ten months ending 31st October 1879, the deliveries were 29 463,000 lb. against imports equal to only 28,177,000 lb., an excess of deliveries over imports of nearly 1,300,000 lb. In the corresponding period of 1880 the figures were 33,627,000 lb. for deliveries against 32,822,000 lb. for imports, the excess of deliveries being 805,000 lb. In the two years up to 31st October, therefore, deliveries exceeded imports by 2,105,000 lb. But this was as nothing to the enormous increase which has taken place in deliveries in the ten months of the present year. The figures are :—

Imports... ... ...32.609,000 lb.
Deliveries ... ...40 933,000 ,,

Excess deliveries... 8,324,000 lb.

So that in the three periods deliveries exceeded imports by not far short of 10½ millions of pounds. No doubt a great deal of this large and rapidly increased consumption (for "deliveries" in the case of Indian tea mean consumption in Britain) is due to prices in the period under review which were the reverse of remunerative. Prices in October 1881, however, presented a marked and most encouraging contrast to those which prevailed in the corresponding period of 1880. Prices in October 1881, notwithstanding a market which had fallen from the range of previous rates, ran from 1 3 per lb. to 2 3½, as as against only 10¾d to 2 1½ per lb in October 1880. These are *average* prices, peakes, in the case of Dooteriah Estate, Darjeeling, having actually realized 3 8½, as the following figures, quoted from Marsden & Walker's Report, will shew :—

BROKEN TEAS.—Eastern Assam Co. 1s 7d, barsimah 1s 7½d, Bishnauth Co. 1s 7½d, Scottish Assam Co, 1s 9¾d, Dinjan 1s 10d, Darjeeling Co. 1s 10d, Margaret's Hope 1s 11½d, Koomber 2s 1d, Gajiddoobah 2s 1d, Dooteriah 2s 8½d.

PEKOE SOUCHONG.—Dhunsiri 1s 6¾d, Upper Assam Co. 1s 6¾d, Moondakootee 1s 7d, Gielle 1s 7½d, Darjeeling Co. 1s 8d, Dinjan 1s 9d, Teesta Valley 1s 10d, Nagri 1s 10½d, Punchanai 1s 10¾d, Margaret Hope 2s.

PEKOES.—Amgoorie 2s 6¼d, Doom Dooma 2s 6¾d, Mahnaira 2s 7d, Koomber 2s 7¼d, Madoora 2s 7¾d, United Planters 2s 7¾d, Rungmook 2s 7¾d, Hoolungoorie 2s 7¾d, Ringtong 2s 8d, Margaret's Hope 2s 8¼d, Leesh Kal 2s 9¾d, Punkabaree 2s 10d, Burramsal 2s 10¾d, Dhunsiris 3s 1d, Hokongoorie 3s 1½d, Dooteriah 3s 8¼d.

BROKEN PEKOES.—Rungjo 2s 6¾d, Marionbaree 2s 6¾d, Grob 2s 6¾d, Doom Dooma 2s 7½d, Gielle 2s 8d, Ruttingdong 2s 8¼d, Singla 2s 8¼d, Selim 2s 9d, Mookumchierra 2s 9d, Hoolungoorie 2s 10d, Chargola 2s 10½d, Long-view 2s 10½d, Bishnauth Co. 2s 10½d, Turkvar 2s 11d, Teesta Valley 2s 11½d, Nagri 3s, Moondakoote 3s 0½d, Jhanzie 3s 0¾d, Margaret's Hope 3s 1¾d, Rungmook 3s 6d.

Although opposed to leading authorities, we have always contended that high-grown teas, if properly prepared, ought to be superior in quality. Every price current which comes before us supports this view. Darjeeling teas always top the market, and the majority of the Darjeeling estates range from 2,000 to 4,000 feet elevation. A good many are indeed more elevated, and it must be remembered that 2,000 feet in Darjeeling are the equivalent of 3,260 in Ceylon, while 4,000 feet there are represented by at least 5,260 here. In the average prices given by Messrs. Marsden & Walker, all from 2/ to 3/3½ refer to teas grown on Darjeeling estates, such as Rungjo, Ringtong, Moondakootee, Margaret's Hope, Rungmook, Teesta Valley and Dooteriah. Broken teas, too, from Gielle sold at 2/8, from Selim at 2/9, and from Tukvar at 2/11. On the latter estate, we saw tea growing at from 1,700 feet to 5,300 feet above sea level. The medium elevation was said to give the best results, and that medium, being 3,400 feet, would in 27° north in British Sikkim be equivaleut to 4,860 in 7° north in Ceylon. The yield per acre at high elevations may be less that at lower positions, but the persistent higher prices for Darjeeling teas prove that high-grown teas must have compensation in better quality. A gentleman who sent us a copy of Messrs. Marsden & Walker's report wrote opposite the list of average prices :—"Good figures for Ceylon men to look forward to." So say we, for we have known the figures for Darjeeling to be lower than those at which Ceylon teas are now generally sold. No doubt, we have something to learn in the preparation of our teas, and we must send larger "breaks." The prejudice against a new competitor will gardually disappear, and we confidently look for the period when Ceylon teas will rank in the London market with Darjeeling at least. As to large breaks we quote again from the report :—

The firm market reported in our last gave way early in October under pressure of very heavy sales, the quantity at each auction averaging nearly 4,000 packages : a quantity beyond the power of buyers to attend to. The growth of the trade, and the short time available in which to value each day's sale necessitates a more general bulking than is now carried out both in Garden and "Calcutta Bought" invoices, and strong representations have recently been made in the Auction Room against the practice of Invoices containing two or more breaks of similar tea. The fall in common teas during the last three weeks is from ½d to 1d, medium kinds 1d to 2d, and finer grades fully 2d to 3d, but at these reductions the month closes firm for all kinds. Deliveries for the season are still in excess of the Imports.

October Public Sales comprised 66,900 packages against 65,500 packages in 1880.

A written note opposite the above paragraph runs :—

The Trade have not *time* to devote to a many sub-divided parcel, and bulking *must* be resorted to.

"John Lloyd's Indian Tea Report" is dated 10th Nov., or a week later than the one we have quoted from, and the introductory remarks are :—

At the date of my last, a quiet feeling existed in the market owing to large supplies. The tone is now firmer, as deliveries continue to increase and offerings at auction are moderate.

Finest teas are becoming rather scarce. Pekoes are unchanged and offer very good value at current rates. Broken Pekoes are readily taken at previous quotations. Pekoe Souchongs show no change, but Souchongs are rather firmer particularly the lower grades. Broken teas sell freely at full prices.

If, with the largely increased demand for Indian teas, resulting in a British consumption in 1880 of not far short of 50 millions of lb, the crop is really 2 millions below that figure, there is evidently an era for Indian tea of great prosperity in which the product from Ceylon should share.

THE SEASON IN INDIA.

(For the week ending the 22nd Nov.)

More rain has fallen in the Madras Presidency and has much benefited the standing crops, but some localities are in need of a further supply. In the Bombay Presidency prospects continue much the same as in the previous week, rain being still urgently required in Ahmednagar and Nasik. The reports from Mysore, Coorg, the Berars, Hyderabad, Central India and Rajaputana continue favourable. In Bengal the prospects of the rice crop are generally satisfactory, but in parts of Orissa the outturn in unirrigated lands has been damaged through want of rain ; rain is also required for *rabi* sowings in some districts. Reaping of *sali* paddy has commenced in Assam, and both in that province and in Burma the standing crops continue to thrive. There has been no rain in the North-Western Provinces and Oudh, though it is urgently needed in parts and would everywhere be beneficial to the young crops. Fever is abating, but cholera has made its appearance in two districts of Oudh. The want of rain for the *rabi* is also making itself felt in the Punjab ; at present, however, the prospects in that province are generally favourable.

Madras.—General prospects good.—*M. Mail.*

LANKA PLANTATION COMPANY MEETING IN LONDON.

There were very few shareholders present, but they all seemed well contented with the satisfactory nature of the report. The proceedings lasted about half-an-hour.

In the unavoidable absence of the Chairman, R. P. Harding, Esq., the chair was taken by Sir H. B. Sandford.

The CHAIRMAN called attention to the report, which stated that three interim dividends had been declared at the rate of 8 per cent per annum. He thought the shareholders would agree with him that, for a young Company, and the present time not being very favourable in Ceylon, they had done very well in earning such a good dividend, and having such a respectable balance to carry forward to next year's account. The Company already stood very high in public esteem ; and he, himself, while travelling lately in Australia, had heard their Company mentioned several times as

"a Company that was making its way well, and was being carried on in a very business-like manner." The properties (estates) had been selected in different districts. The reason for this was that there are two seasons, or monsoons. Sometimes it is a good season in one part of Ceylon, and sometimes in another part. Therefore, by having the estates scattered there was a prospect of having a good season on one part of their property, even if it should be a bad monsoon on another part. They possessed now a total acreage of 3,265½, of which 2,541 was coffee and cinchona, and the rest forest and grass land. There was only one more property, now under consideration as to purchase. The Directors have thought it advisable to hold their hands for a short time to see if the property they already held was going on well, before they made any further ventures.

It was then proposed and seconded that the Report be adopted, which proposition was carried unanimously.

Mr. PRATT (a shareholder) then rose and said that he thought all present must be gratified at the business like way in which everything connected with the Company's affairs had been carried out by the Board. He was glad to hear that the Directors did not intend purchasing any more property at present; for to do so would only be burdening the Company with borrowed capital, which it was advisable to avoid. On behalf of his fellow-shareholders, he would express their very great satisfaction with the Report, and the manner in which the accounts had been put before them. If all Companies were able to give such a balance-sheet as that before them, he thought it would be a very good thing for the City of London. (Hear, hear)

Mr J. T. WHITE (Director) referring to the dividends said that two dividends at the rate of 8 per cent per annum had been paid prior to June 30th, and the third dividend since that at the same rate. These 3 dividends covered the period of 15 months working of the Company since its formation, the profit on this period being at the rate of 8 per cent per annum. As it was necessary that these dividends should be confirmed by the meeting, he begged to propose it. H. G. HAYES seconded it, and the proposition was unanimously carried.

The retiring auditor, Mr. John Smith, was unanimously re-elected.

The CHAIRMAN then rose to make a few further remarks. He said that as Mr. Pratt had made a remark as to its not being advisable to burden the Company with borrowed capital, he would say that that was quite the feeling of the Board. They did not wish to have any mortgage on their estates. The shareholders would see by the report that some of the estates were subject to unpaid mortgages; but these would be paid off as soon as possible. It was their firm determination not to borrow; and, if it was found necessary to have more money, they would prefer to increase the capital rather than mortgage their estates. He hoped in time they should be able to keep up a good reserve fund, and the balance of £1,485 39, which they now had, might be considered the nucleus of such a fund. In reply to a shareholder, he said that Mr Harding was still their manager (agriculturist) in Ceylon. He was a very large shareholder in the Company, and resided on the principal estate. As to their prospects for the season of 1881-2, he would like to make a few remarks. In the Haputale district, the season there has been very unfavourable, for us. The long-continued drought has prevented the wood from coming forward and the plants from ripening, so as to bring forward the usual abundant blossom, which is generally characteristic of this district. In all probability the crops for the coming season will be rather worse than past year. But they must recollect that last year there were only three estates to deal with, whereas for the current year, there would be six estates. The Thotalagalla was their finest and largest estate; and in the current year it would be necessary for them to incur exceptional expenses, which would be rather high, be feared, in order to road and drain it, to put the trees in good condition for bearing well. Their estates would give a good average crop, he expected, but it might be a little below the average. They were, however, in fine condition, and they might look for a bumper crop before long. In reply to a shareholder, he did not think the dividend would be less than 8 per cent for the next year. But he thought it would be wrong to hold out any certainty, as they were so very much dependent on the seasons. A very large amount of cinchona would always be growing. This was not so dependent on the season as coffee. They possessed 1½ million of cinchona trees; and they could easily strip the bark of these, if the coffee crops fell much below the average. They were a kind of reserve to fall back upon. The estate they were now treating for was altogether a cinchona estate.

A vote of thanks to the Chairman was then moved and seconded, and unanimously accorded. The Chairman, in returning thanks, expressed his regret that Mr R. P. Harding had been unable to be present.

NEW INDUSTRIES: GOLD-PROSPECTING; THE MADRAS RULES.

The task of initiating new industries in any tropical or oriental land must inevitably be attended with much difficulty. There are necessarily no exact means of ascertaining what the returns will be for the money invested; and the new venture, whatever it may be, is regarded as a speculation more or less rash and uncertain according to the temperament and attitude of the critic. In a Colony like Ceylon with so many undeveloped resources, with a good supply of comparatively cheap labour, a favourable climate and easy means of transport, every possible encouragement ought to be given to the pioneers in new industries. More particularly is this true in reference to the Government and gold-prospectors. The impetus that would be given to trade and to the development of local revenue, affords ample justification for the Crown, as the holder of immense reserves of land, setting its mining rights in abeyance altogether until the experimental stage had passed into one of settled and prosperous work. More than that it is the part of a Government situated like that of Ceylon to encourage prospecting and pioneering, by a system of well-considered "bounties." In several of the Australian Colonies this has been tried with success, and a bill is now before the Natal Legislature, with every prospect of being carried, proposing that the Natal Government should offer a premium "to anyone who, within three years from the 1st January 1882, shall introduce into the colony any new agricultural industry suitable and capable of general adoption in the colony by persons of moderate capital. The Council may make such regulations as they may deem fit for awarding the premium, provided that:—

a. No article at present exported shall be considered a new industry.

b. The claimant of the premium shall have grown, exported, and sold such product of a profit of not less than £100 value during the three years.

c. The Council may, with the consent of the Governor, waive the necessity for the full value of the export within the three years, provided that the new produce is of such a character as to attain to general cultivation, and fulfils the purpose intended.

d. Should two or more persons compete, and the product or products be such as to meet the general requirements of the reward, the Council may, with the consent of the Governor, apportion the whole or any part of the premium mentioned in Section 10 of this law in such manner as to them may seem fair and just.

The amount of premium proposed to be offered in this case is £1,000. The example is one that might be copied with great advantage in Ceylon; but we fear there is little chance at this time of the Government permitting the planting representative to widen the scope of his motion on Wednesday next. That motion has reference to "Mining Rights." It is extraordinary that the Ceylon authorities should have so long delayed to make their regulations known, seeing that the Madras rules, which they were supposed to be waiting for, were published some time ago. Our Madras contemporaries have criticized unfavourably the local Government rules, pointing out that they are far less liberal than those drawn up by the Mysore Government. The *Mail* advocates "free trade" in land for mining purposes, and supports its argument as follows:—

The Madras rules first limit the extent of land which may be granted, to one and the same applicant for mining, to 30 acres, in one block or more, though they allow land adjoining to be taken up for buildings, works, or what not, provided it is not used for mining. They next fix the assessment at the extremely high figure of R5 per acre on all land taken up, whether for mining or other purposes. They then provide that within three months of the grant, not less than five coolies per acre of the land granted for mining shall be regularly employed. And they forbid any assessment or sub-lease, without the consent of the Government being previously obtained. It is probable that the Government wish to discourage land being taken up for speculative purposes, and to prevent large areas getting into the hands of the same individuals. If, as in the early days of gold in Australia, men took up small pieces of land, and worked them themselves, washing the soil for gold, and using only the simple appliances each individual miner could command, and if there were any chance of all the available land being so taken up, we could understand the policy of limiting the area of mining grants—only we should then say, the limitation did not go far enough, and that instead of 30 acres being granted, the grant to each should not exceed a few square yards. But there is no chance of anything of this sort in India; the climate is against it; everything is different We are beginning where they only arrived in Australia after years of work—with quartz-crushing on a large scale, which demands the best machinery, and a capital so considerable that it is almost a necessity that the mines should all be worked by Companies which, now that everything comes out in £1 shares, will probably have their thousands of members. Now Companies, as a rule, want a good deal more than 30 acres; and if each shareholder had 30 acres it would have to reckon the extent of its property by square miles. Though only 30 acres may be given to the same applicant, there is nothing, so far as we can see, to prevent ten men going in for ten adjoining 30 acres lots, and making them over to a Company in one lot of 300 acres, except the rule prohibiting transfers without the consent of the Government, which we think, could never be enforced, and would be practically a dead letter. So again a man might apply for ten 3 acres lots, with say 27 acres of land for other purposes adjoining, and when he had sold one of these lots, the purchaser could, at once apply for a mining grant for other 27 acres, taking up the land for other purposes alongside. In fact whether the rule is wise or not, it is certain to be evaded. But we deny its wisdom altogether. We consider such speculation as it is (presumably) intended to prevent perfectly legitimate; and we look on it as only right and just that a man, who by superior skill, energy, or even luck, finds himself in the position of the discoverer of a valuable formation, in what was supposed to be valueless land, should be able substantially to profit by the position. Suppose that one of the pioneers after the expenditure of much time and trouble, and no inconsiderable outlay of money, finds a few square miles of auriferous lands; it is extremely hard that he shall only be able to get 30 acres of it, and that all the rest shall be given to Tom, Dick, or Harry, who never spent a rupee in the search, or gave a single thought to the subject.

Then again, take the assessment. The land wanted for mining will be waste; and not waste only, but in nine cases out of ten, unculturable, or practically of no value whatever for any purpose except mining. Land as good, or better, can be had for cultivation at rates varying from As. 4 to R1 an acre; why then this heavy assessment which is about the same as that imposed on the best class of irrigated land? It may be said that with a paying mine, the assessment will be a trivial item, and will hardly be felt. This we grant. We go further and say, that with such a mine, an assessment of R5 an acre will, by no means, represent the share of profit which the State may fairly expect to derive from the venture. But gold mining is at present in its infancy in India, and it is pretty certain, that some of the mines will come to grief, though others may pay handsomely. Take the case of a non-paying mine, with 30 acres of mining land, and adjoining land taken up alongside to the extent of 1,000 acres—of course with the object of eventually applying for for further mining grants if the concern is a success. This land will be burdened from the start with a yearly payment of R5,150, and may never make a rupee of profits! Surely it is unwise to handicap enterprize so heavily! It is not as if Government were giving up land, from which revenue could be drawn in any other way; for as we have already pointed out, if not taken up for mining it will never pay a rupee to the State in the great majority of cases. Again, suppose this Company is making a profit of £100 000 a year; would the payment of R5,150 be absurdly inadequate, Why then should not land be given on a very light assessment, say As 4 or As 8 per acre, and a royalty of, say 5 per cent. charged on the nett profits? Then while the prosperous Company would be a source of considerable revenue to the State, the struggling and unsuccessful one would not be unduly burdened. A royalty on nett profits would always be cheerfully paid, for the larger the payment to Government, the larger would be the profits to shareholders, and under such a rule as this, there would be a fair chance that all land giving promise of good results, would be taken up, and tried.

But bad as all this is is the labour clause is undoubtedly worse. Not less than five coolies per acre are to be regularly employed, that is one hundred and fifty coolies on 30 acres—representing probably an expenditure of R600 a month. It may be taken as tolerably certain, that if it pays to employ five coolies per acre, or double, treble, or ten times that number, they will be employed, and if it does not pay, we fail to see why their employment should be insisted on. And the beauty of it is, that Government gain nothing by it. Had there been a royalty instead of a fixed assessment, we could have understood the condition, though

we should still have considered it unwise; but as things are, Government get precisely the same amount, whether the mine is being worked at a loss, or is giving a magnificent return. Again, the cooly test is a somewhat rough and unscientific one. If it is desired to insure a certain expenditure,—which, however, we deprecate altogether—it would be better to say that so much a month shall be spent on mining operations. Most of the work is done by machinery; mining engineers and skilled English miners are found necessary; none of this is taken into account; the hard and fast coolie labor test holds good, and is brought into force three months after the grant is made—long before a Company could be got into working order, and put the necessary machinery and staff on the ground. This one clause alone is enough to condemn any rules of which it forms a part.

We trust the blunders pointed out so clearly in the Madras rules, and which it seems are not to be found in those operating in Mysore, will be avoided by the Ceylon Government. To help them to a right conclusion we append a list of rules for granting out mining land, drawn up by the *Mail* as embodying all that is required in the case of Southern India, and therefore well applicable to the case of Ceylon:—

Persons desirous of obtaining permission to mine, on Government waste lands, may apply to the Commissioner, or Collector for leases specifying the situation of the land required with its estimated area.

Each application shall be accompanied by a rough sketch, or by the survey map with the position of the block roughly indicated.

Applications will be dealt with in order of receipt.

No lot or lots in one application shall exceed one square mile in extent.

But the same applicant may apply for more than one square mile in other applications, and such applications will be granted should there be no reason against it.

On an application being accepted the lot shall be durably demarcated, and conveyed at the expense of the applicant, to whom a lease shall be granted.

An assessment of As. 8 per acre shall be payable by two half yearly instalments on 1st January and 1st July, the first instalment being due for the then current half year, and payable on the date of the execution of the lease.

The land may be thrown up at any time, but so long as the assessment is paid, and the conditions are not broken Government will not resume or interfere with it.

The land shall be liable to road assessment.

A Royalty of 5 per cent on the nett profit of any mining operations shall be payable to Government.

The works shall at all times be open for inspection by the Commissioner, or Collector, or by officers deputed for the purpose by him.

Accounts shall be furnished to the Commissioner or Collector yearly, and books shall be duly kept, which shall at all reasonable times be open to the inspection of the Commissioner or Collector, or officers deputed by him.

CINCHONA AND PRIVATE ENTERPRISE.—The *Times of India* writes:—Planters in Ceylon and India, and other private individuals who have put their money into cinchona will not hear with profound satisfaction that a few days ago upwards of three hundred bundles of bark were shipped from Madras, to the order of the Secretary of State for India. The supply was from the Government Cinchona Estate, and each bundle, it is said, was valued at R300. Private growers are naturally asking when Lord Ripon's policy of encouraging private enterprise is going to be applied to cinchona.

THE CRYPTOGAMIST'S LATEST UTTERANCE ON "LEAF DISEASE."

The long letter from Mr. Marshall Ward, in reply to criticisms on his reports, which appears on another page, will be carefully perused by the large class interested in the present condition and prospects for the future of coffee in Ceylon and in the Eastern world generally. When Mr. Ward wrote that "complaints" had reached him that portions of his reports had been "misunderstood by lay readers," he meant, of course, that certain statements in his reports were worded in such technical terms that lay readers—persons not learned in cryptogamic lore—failed to apprehend their meaning, or put a wrong construction on what was written. Now, as Mr. Marshall Ward is not only a scientist but a "'Varsity" man, and as he manifestly took great pains to clothe his conclusions in fitting language, we have little doubt he feels inclined to quote the writer who insisted that it was no part of his business to provide his readers with brains to understand matter which he had made "understandable." But sometimes words convey different ideas to different minds, and it must be due to this fact or to some natural obtuseness on our part, that we must be ranked amongst the lay readers who misunderstood him in regard to coffee leaves matured into a condition of "hardness." Until now corrected by Mr. Ward, we were inclined to believe that, as a leaf *hardened*, its *stomata* contracted to such an extent as to offer an obstruction to the access of the spores of *Hemileia vastatrix*, when, following the astonishing instinct implanted in them, they sought their food in the interior cells of the coffee leaf, *carefully discriminating the leaves of that plant from those of any other*. As we now understand Mr. Ward, it is a fact in vegetable physiology that a matured or hardened leaf has breathing mouths of the normal size just as much as in the case of the softest and most succulent, and bearing the same relation in the one as in the other to the spore tubes of the parasite that an ordinary house drain does to an ordinary snake! We confess also that the proportions of introduced door of entry, now so explicitly stated by Mr. Ward, constitute to us a new and most formidable feature in the life history of fungus and leaf, of feeder and fed; of guest and host. There is always an open door for the fungus, which is only too ready to enter within twenty-four hours of being started from dormant to active life by the influence of moisture. Our previous impression was that the moisture which enabled the fungus spore to germinate produced also an enlargement of the breathing pores of the leaf, so as to render facile the access of the enemy to the cuticle and its food stores. We thought and hoped, as we supposed many other lay readers did, that if we could get matured and hardened foliage on a tree that foliage would be impervious to the insidious spore—this cuckoo of the vegetable world. But we misunderstood the cryptogamist, whose invention it was merely to indicate that, if the planter can so order his weeding, pruning and cultivation generally, as to cover his bushes with a crop of matured leaves, before the spores of the fungus are driven by the winds of the monsoon on to the leaves while those spores are spontaneously awakened to active and destructive life—a life of systematic theft—by the monsoon moisture—they the

planters) will have enabled their coffee to derive the full benefit of the nourishment elaborated in such leaves, instead of getting only such portion as it can share with the parasites when once they form a lodgment. If only the spore tubes are present in sufficient quantity, all that is wanted is moisture to germinate them, in order not only to infect each leaf with one or a few but to fill each *stoma* of every leaf. That is the "owre true tale," the moral of which we have to study, and in its light, surely, the dullest of lay readers can understand that manure, so far from being a cure for "leaf disease," is an active agent in propagating the fungus which is the *cause* of leaf disease—disturbance of those functions on whose regular action the plant depends for healthy life. But manure can only act in this way when spores of the fungus are allowed to exist and obtain access to the leaves of the plant. Were the spores destroyed or prevented from obtaining access to the sap-cells of the leaves, then, as in the pre-fungus era, the whole benefit of the manure applied to the root of the tree would go first to the formation of nutriment in the leaves and then to the perfecting of a profitable crop of fruit. The planter's great duty then is, by all means within his reach, to destroy spore-infected leaves and twigs by burning or burying them. If buried, of course they should be thoroughly covered with quick-lime; and a portable incinerator, which we have heard of as manufactured for a planter by Messrs. John Walker & Co., which can be easily carried from place to place by a couple of coolies, may help to solve the problem of how, at a reasonable cost, to destroy refuse leaves, twigs, &c. Then shelter should be conserved or supplied to prevent the wind blowing the spores on the leaves of the coffee trees. If all this is done, then certainly even Mr. Ward would admit that manure might prove a cure for "leaf-disease"—not of the CAUSE, *Hemileia vastatrix*, but the EFFECT, debility superinduced by repeated visits of the voracious parasite to the life-supplying laboratory of the plant, contained in its foliage. But, if nothing is done: if neither burying nor burning is resorted to, if shelter is not provided, and if spores on the leaves are not killed by sulphurous gases before they germinate and enter the *stomata*, then manuring must be resorted to, even at the risk of propagating the fungus, because it is better to manure so as to foster fungus, plus leaves and fruit, rather than abstain from manuring at the risk of seeing tree, foliage and fruit becoming "small by degrees and [not] beautifully less," from the persistent presence and destructive effects of the fungus. To give up manuring would be to throw up the sponge and confess ourselves hopelessly beaten in the contest; but clearly our duty is if possible to follow Mr. Ward's advice and apply manure as a complement to operations calculated to annihilate or reduce to the smallest minimum those fungus spores, which, if present, would, in proportion to their number, deprive the coffee of the life sap elaborated in the leaf cells as the result of an application of manure. *Hemileia vastatrix*, so far from being the external development of an "internal ulcer," as an authority highly honoured by a certain sapient judge explicity taught, is so essentially an external agent, that its spores might, for an indefinite period, be scattered over the leaves of a coffee tree, without producing the slightest ill effects, provided the spores did not receive moisture to germinate them and enable them to enter the leaves by the mouths on their lower surface. The spores and the favourable conditions present, no condition of a tree can enable it to resist an attack, while no predisposition will intensify that attack. Once for all, planters, and critics of planting operations, may dismiss from their minds all ideas of "leaf-disease" having been caused by errors in details of cultivation or the constituents of manure. But for the mysterious development in 1869 of a parasite which had been previously latent, leaf-disease (the effect of the parasite's operations) would be non-existent, and the majority of our coffee estates would be still yielding average crops of 6 cwt. per acre or even more. Our one error, as we now can see, was the very natural one of growing in large and unbroken areas, to the almost total exclusion of other products, that which paid the cultivator best: that which gave the largest and the most profitable returns. That was the principle on which potatoes were so largely grown in Ireland and other places, and that is the principle on which wheat is grown in America and Australia; tobacco in Sumatra; sugar in the West Indies, Java, &c. When visitations of providence, in the shape of disastrous natural agencies, convey sharp lessons, then some of us can loudly condemn what their neighbours and even they themselves did, as unscientific and even immoral. As far as Ceylon coffee planting is concerned, all we can say is that unless we are suffering for the one error we have mentioned, or unless special chastisement has come upon us for special sins, we do not feel that planters are to blame. On most of the estates, all that capital and labour, care and skill, and scientific appliance, could effect was done to keep the soil in heart while it yielded remunerative crops. When Skobeloff had a great disaster inflicted on him, he said: "I blame no one: it was the will of God." So, without irreverence, we think we may assume that it was the will of providence that the great and once prosperous coffee enterprise of Ceylon and the Eastern world should be checked (we cannot and will not say destroyed) by the development of a new and terrible parasite. The plague having existed and operated injuriously for a considerable period of years, may we not cherish the hope that the time for its gradual lessening in virulence, if not its entire disappearance, is close at hand. Perhaps the theory of "cycles" may not be deemed scientific or worthy of regard by the school to which Mr. Marshall Ward belongs, but surely he must have at least adverted to the idea of the pest passing away with effluxion of time. Is there anything in the nature of *Hemileia vastatrix*, or in the analogy of like pests, to render the hope of its virtual disappearance within a few years unreasonable?

HEMILEIA VASTATRIX AND COFFEE LEAF-DISEASE: MR. MARSHALL WARD'S REPLY TO CRITICISMS ON HIS REPORTS.

(*To the Editor, "Ceylon Observer."*)

DEAR SIR,—In replying to Mr. Talbot's criticism on my third report on coffee leaf-disease, I propose to consider at the same time some of the various other remarks which have been made, both in private letters and in the newspapers, and which must be looked upon as adverse to proper views of the nature of this "disease": this I do the more readily, since a few

complaints have reached me to the effect that some points in my reports have been misunderstood by lay readers, and it may be possible, therefore, to render service by re-stating the important conclusions in slightly different language.

The chief points touched upon more or less in the criticisms referred to are the following, and I will take them in order after mentioning them as below :—

(1) The general conclusions to which the whole research has impelled me, viz :—that "leaf-disease" is caused by the ravages of a vegetable parasite derived from without;

(2) The statement in my 3rd report to the effect that "no special predisposition on the part of the coffee is required for its infection" ;

(3) The statement that "manure cannot be properly looked upon as a cure for the disease," and

(4) The conclusions arrived at respecting the use of remedial measures.

With regard to the first point, I need not occupy time and space with a lengthy argument to repeat what each step in my reports goes to prove ; but will shortly summarize the position for the sake of the few who still indulge in such expressions as "the fungus arises from a diseased state of the tree," "the disease arose from bad manuring," it is "in the sap," and other equally vague statements.

Hemileia vastatrix is a parasitic fungus with a definite, and, as we now know, very simple life-history, and is propagated by means of spores as are other similar plants. The chief peculiarity about this particular fungus, however, is that its *mycelium*, or vegetative system (acting somewhat like roots and stems of other plants), requires the organized materials found in the cells of living coffee-leaves for its food, and obtains these by spreading in the loose passages between the spongy tissues of the leaves, and imbibing the contents of the cells which compose these tissues.

These imbibed food substances, instead of going thus to satisfy the voracious appetite of the fungus, should normally have gone to benefit the coffee-tree as a whole, by supplying the materials necessary for building up tissues where required—it might be leaves, it might be flowers or fruit &c.

Hence we see that a direct *robbery* is perpetrated by the fungus, in appropriating food-materials which the cells of the coffee-leaf had, with great expenditure of energy, manufactured for the use of the coffee-tree as a whole.

Now such materials are manufactured or elaborated in the green parts of the coffee-plant, and especially in the cells of the leaf exposed to light and air, thence to pass into the branches, stems &c. to be distributed as required. To replace quickly the food-materials of which it has been robbed, therefore, the coffee leaf would require at least not less manufacturing capability than it had before ; but it *has less*, because the spreading mycelium, occupying space on and in the leaf, destroys eventually the little hardworking cells which would have made mere food-stuffs. Hence the fungus further does injury by destroying the tissues, and occupying space which should have benefited the coffee tree.

In doing these injuries to the leaf, the fungus shortens its period of usefulness, and the coffee-tree must provide more leaves in a given time, if it is to obtain the same amount of manufactured material that it normally derived from the activity of the leaves. Unless it can do this, or unless the total amount of active leaves &c. is more than the tree requires, the ability to produce crop must be diminished. In attempting to meet this difficulty (so to speak) the functions of the coffee-tree as a whole become still more disturbed, and it must be plain to all that, if such a condition of things lasts for a long time, or recurs often, the ability to manufacture and distribute the large quantities of food-material necessary for the production of the amount of crop looked for must diminish—the periodic losses of matter and local disturbance of function affect the whole tree, and it is said to be "diseased."

There can be no difficulty, therefore, in understanding the phenomena of "leaf-disease" which have so long and so generally puzzled the planting community : a tree cannot be expected to produce leaves, flowers and fruit &c., in the same proportions when thus afflicted, as it did when the numerous drains and disturbances were absent. In the local actions at numerous centres of the parasite we see a *vera causa* for "leaf-disease," and it becomes unnecessary to seek refuge in vague expressions.

I would now call attention to still further proof that the fungus *causes* the disease. In proportion as coffee plants are sheltered from the spores of the fungus do they remain free from the disease ; while exposed plants become diseased as the fungus obtains a hold on their tissues. On sowing spores of *Hemileia* on certain leaves I found that these leaves became diseased : not only so, but the "disease-spots" appeared on the area where the sowing was made, and nowhere else on the plant, unless spores were again sown. If a leaf has only one "disease-spot" on it, the damage done is little; but if many spots occur, the leaf is soon destroyed ; so, too, with the whole tree. If only a few "disease-spots" occur here and there, the harm is small : it is when many leaves (in proportion to the whole) are afflicted with many "spots," that the rapidly denuded tree suffers so much.

I need not here detail the experiments which led to these results, nor the numerous actual "infections" performed; but will simply refer to the reports published during the past two years. When, however, it is demonstrated that, of two plants grown from West Indian seed, in baked earth or in earth from England, the one which is sheltered from spores does not become diseased, while that which is "infected" (by sowing spores) *does become* diseased in due course, we have no longer any excuse for doubting that the fungus is the great cause of the disease. There is, however, much less doubt expressed regarding this point, than with respect to the next, viz :—

(2) "No special predisposition on the part of the coffee is required for its infection" Having discovered that a coffee-leaf could be "infected with leaf-disease" by means of the spores ; and having proved that natural infection occurs by the germination of wind-blown spores &c., it became necessary to ascertain exactly under what condition this takes place.

The first circumstance of importance is clearly that water or moist air be present, for in a dry atmosphere no spore can germinate : the spore remains on the leaf apparently unchanged for an indefinite period, unless sufficient aqueous vapour be provided, and in such cases no "di-ease" follows.

The other two conditions are always present (with rare exceptions when the temperature falls very low): they are, the presence of atmospheric air or oxygen, and that the temperature be suitable for the development of the fungus. Provided these three conditions of the environment be not absent, I find no difficulty in bringing about the germination of the fungus spore ; and if this takes place on the stoma bearing skin or epidermis which covers the leaf of coffee, the little germ-tube enters the *stoma* or spore, grows and branches inside the leaf, forming a *mycelium* or "fungus plant" in the cavities which drains the leaf cells of their food-substances as already described.

Now, putting aside for the moment the question whether a coffee-leaf which is rich in food materials or the reverse best suits such a "fungus plant," I proceeded to make experiments by sowing the spores of

Hemileia on all kinds of coffee-leaves, old and young, weak and strong, &c., to see *if any special predisposition to disease existed;* or, in more exact words, to see if any one kind was more "predisposed" than another.

The answer to these questioning experiments is a definite one. In all cases I found that the leaf could be infected; that the germ-tubes entered the stomata, and the tissues became "diseased." I here, in fact, asked nature herself "Are any kinds of coffee more predisposed to infection than the other?" And nature said: "No!" Such is the true interpretation of the successful experiments on coffee from Ceylon, Java, India, and Jamaica, of several varieties and at various ages.

Hence it will be seen that my statement is in no way of the nature of an opinion. I was biassed by no predetermined idea when commencing these enquiries; or, if any assumption was tacitly admitted, it was to the effect that some kinds might be more prone to "disease" than others.

It may be replied, although the above has been proved, it is surely true that when once inside the leaf the fungus does not do the same amount of damage in all cases. I will not here multiply examples, but will shortly examine the results of many observations bearing on this difficult matter.

We have seen that *Hemileia* differs from many other plants in being unable to construct its own food-substances from the air and earth &c., as does the coffee and similar plants: since, however, *Hemileia* requires these substances ready made, it steals them from the coffee. In a certain sense, therefore, we may look upon the coffee leaf as the soil in which the fungus-plant lives; and we shall not be surprized to find that according to the nutritive quality of this living soil, so to speak, the little fungus-plants flourish well or ill, much as coffee plants thrive or the reverse in good or bad vegetable mould, &c. It is important to bear in mind, however, that the roots of a plant like coffee send crude sap up into the leaves, and it is not until the materials have become elaborated in the leaves that they serve for food: the fungus, therefore, is more accurately compared with the crop than with the whole tree in this respect.

It becomes probable from the foregoing that a fungus-plant or *mycelium* might be found to grow more rapidly in some leaves than in others. I find that the finest specimens, botanically speaking, of *Hemileia vastatrix* are grown on those leaves from which the fungus can obtain its food most readily *i.*, *e.* on the succulent, vigorous, well-developed leaves of a fine tree, where the cells are readily broken into, and the contents rich in food-stuffs. Such leaves abound in the height of the growing season (April to June, and September to November near Kandy), and I need not remark further how terribly they suffer from the abundant mycelium about July and December as a rule.

It thus becomes evident that the fungus-plant can be placed in any kind of leaf with equal facility, just as coffee seedlings can be planted in any kind of soil; and that the former flourishes best in a well-nourished, succulent leaf, from which it can most readily obtain rich food, much as the latter thrives in deep, luxuriant mould. In both cases, of course, other things are supposed equal, since differences in temperature, the amount of moisture, intensity of light, etc. etc. have their due effects.

And now I come to the most difficult point. It will probably be replied that good coffee suffers least even though the fungus be plentiful, and that it is the poor, weak, "shuck" tree which exhibits the ravages of the pest so lamentably. But we must here take care lest we argue in a circle. In many cases known to me it is simply because the coffee has not yet become the prey of the fungus that it looks so well. Good, deep soil suffers little, although it supports many luxuriant plants: so, too, good strong coffee can afford to feed many little fungus plants, and yet its large leaf-surface supply material to produce crop as well. Much "good coffee," in fact, does support large quantities of *mycelium* as well as of crop.

But I have thus far allowed the assumption that *other things are equal*, while as a matter of fact, other things are commonly very unequal where coffee and its "disease" in one place, are compared with those at a distance. My reports abundantly show what are the chief factors in this connection; but I may call attention to one or two points which appear to be either unknown or ignored by many of the critics who so readily compare unequal things together, with the somewhat *naïve* surprize that the results are not equal. To expect two coffee trees on an estate (and the illustration may be extended to masses) to be equally "diseased" simply because they stand near one another is, to say the least, daring, since it involves one or other of the following comprehensive assumptions. It must be assumed either—(*a*) that the two trees were at the outset equal in all respects—that their root-masses, leaf-surfaces, &c. were alike in extent and exposure, and that the relations of these to the soil and air, light, &c. were similar in all respects—that equal quantities of food-materials were in the two trees, and that the supplies and demands connected with this were steadily equal, &c, &c. It must further be assumed that each tree received at the outset the same quotum of disease-producing fungus-spores, which developed with equal energy and effect, and were equally related, actively and passively in the two cases.

Or, if the above formidable details be not assumed, it must be allowed (*b*) that the various complex relations between coffee and its surroundings on the one hand, and *Hemileia* and its environment on the other, though differing in details in all possible degrees among themselves, amounted to the same final result in the cases selected:—that, although the trees were dissimilarly related to earth, air, light and the fungus, &c. as far as quantity goes, yet they became in the end diseased to the same extent.

Either of these assumptions would be rash in the extreme; and it is a bold argument to infer that because one of two trees, apparently similar in many respects, is "worse diseased" than another, that the reason is outside what has been stated.

In cases where trees or groups of trees are pointed out as "disease-proof or practically so," on what grounds are the assertions made? Have those who make the statements satisfied themselves that there are no other reasons than those they give for the comparative immunity from "disease spots," at the time of the particular trees referred to? Have they even proved that the trees remain "free from disease" for a year; or that the relations between the number of diseased and healthy leaves are not different in the cases cited. And yet, surely the onus of proof lies with those who controvert record of observed facts with unsupported statements: and it is, to say the least, rash to affirm that a tree is less "diseased" than its neighbours, without being able to say that the tree was carefully and closely observed for a sufficiently long time. But even admitting that "a tree here and there shows fewer "disease-spots" during a given period than surrounding specimens, who will undertake to prove that it has had as much chance of becoming infected as another? There is nothing remarkable, for instance, in more spores being distributed successfully on the leaves of one tree than on those of another: nor could we be surprized if many spores fall from the leaves altogether. The following simple illustration may make my meaning clearer, though it does not cover the whole question. Suppose several boys bathing in a stream near the banks, and suppose leeches to be borne down by the stream, and falling from

the bushes at various heights, would it be wise to argue that the boy who got most leeches attached to his body was "more susceptible" or "specially predisposed" to them?

(3) I now pass on to consider the third statement, to which so much objection has been raised, viz. :—"Manure cannot properly be looked upon as a cure for the disease." If the organized materials or foodstuffs in the cells of the coffee leaf are the proper food of the parasite *Hemileia*, as is found to be the case; and if manure, after being worked up into organized materials, is a proper food for coffee, as no one will doubt it is, then it follows that in manuring coffee to provide nourishment for the production of fruit, &c., we indirectly manure *Hemileia*. It should be remembered that the crop obtains its principal nutriment from the leaves, just as does the fungus; and, unfortunately, they both take similar materials.

It must be clear that we at least run a risk of increasing the amount of fungus and of its spores (the orange-red rust), and therefore of the leaf-tissues being destroyed, &c., as we increase the amount of food-stuffs by manuring; and if the fungus, *i.e.*, the *disease-producer* is increased, it is obviously absurd to consider the disease cured. I do not wish the above to be construed as meaning that manure should not be used in the cultivation of the coffee; it *must* be used, or the drains on the tree will be more than it can stand. It would be as rash to conclude that manure does no good to coffee suffering from loss of sap and functional disturbances induced by *Hemileia*, as to imagine that food could do no good to a man suffering from loss of blood, and certain consequences following it: in both cases, however, it should be borne in mind that the evil may be past remedy if the patient has been too long neglected. And it should also occur to all, that the prime cause of the loss of sap, &c., should be destroyed, by burning or burying all spore-laden leaves possible, by shelter, and other precautions.

A coffee tree badly afflicted with *Hemileia* and bearing a large crop suffers more than one bearing an equally large crop but less fungus, or than one bearing more fungus and less crop—other things being nearly the same. It is known that both the fungus and the crop drain the leaves of substances formed in their green cells exposed to light, air, &c., and since by manuring we supply crude sap (mineral and other substances in solution) in larger quantities to be worked up in the leaves, it is possible in a given case for a tree to support *both crop and fungus* until the former is all ripe, provided the functional activity of the leaves &c was not already too far disturbed.

It is now easy to conceive the following possible cases:—(1) A tree is deficient of manure and leaves, and suffers severely, because its tissues are not replaced nearly as fast as the fungus destroys them. (2) Sufficient manure is present to supply crude sap as required, and the amount of leaf surface is large enough to provide food for all purposes; new leaves form as the fungus destroys older ones, and the tree appears pretty even throughout. (3) The tree is so richly furnished with leaves, and so abundantly provided with crude sap, that the comparatively small amount of fungus mycelium is easily supported, and yet abundance of food materials remain for the tree, as the leaf-cells elaborate what comes from the roots &c. And every degree of complication of these circumstances occurs, and he who undertakes to explain the condition of a tree must carefully bear this in mind. Not only do trees differ in the number, size, density &c., of their leaves, but they differ in the quantity of spores which they receive. Not only do they differ as to the sources of income at the roots (clay, grub, water, "slab-rock" &c. have their different influences) and from the leaves (their stoutness, number, exposure to sunlight, moisture, wind &c, have to be considered); but they differ with respect to the number and kind of drains on their resources (crop, leaf-buds, and mycelium, &c.). It should not, therefore, be rashly concluded that the differences which can be readily explained by known agents are brought about by unknown causes: the wonder is not that two coffee trees should suffer unequally from "leaf-disease"; it is rather that any one should expect otherwise. I hope that I have now shown why, in manuring diseased coffee, without taking steps to remove the sources of reinfection as the leaf surface is increased, a serious risk of increasing the amount of fungus is incurred; nay, that unless the conditions for spore germination happen to be witheld (rain, dew, &c.) the risk becomes a certain danger. I may now pass on to consider the last point with which we are here concerned:

(4) It is agreed that, while the coffee must be manured, to enable it to support crop etc., the sources of reinfection should be diminished, in order that all the food-products formed in the plant may go for the benefit of the tree: how can the sources of re-infection be diminished? On a small scale (as with coffee plants grown in wardian cases, lighted rooms etc.) two ways are perfectly practicable.

The spores of the fungus may be prevented from alighting on the leaves, or, if they do alight there, water can be withheld from them, and no disease appears: this is the first and surest method of preventing infection. The second way is to kill the germinating fungus before its tubes enter the leaf and form the "disease spots": this method is less certain, because so many causes may co-operate to prevent the destructive agent from seizing all the germinal tubes. Nevertheless, with care, this method is also successful.

In the open air, however, and on large masses of coffee, under various kinds of control, the problem of destroying the spores becomes a much more difficult one, since it is impossible to guard the tree entirely from wind and moisture. Here also, however, both the above methods are available to a certain extent. We may, first, devote our energies to the destruction of all spore-laden leaves and prunings, provide as much shelter as possible, and in every way seek to prevent spores from reaching the coffee, since, when once there, we cannot withhold moisture and prevent germination. Secondly we may devise some method of applying a destructive reagent to kill these spores which do reach the coffee.

It is with respect to the second method that so much has been written and attempted, and I will examine once more what the application of an external remedy implies:

1st. It must effectually kill all the germinal tubes *before* they enter the leaf (which they commence to do in about 24 hours from the beginning of germination), and yet must not injure the coffee.

These two important conditions further demand other properties on the part of the reagent or "cure" employed, viz. :—(*a*) It must be capable of rapid and wide *diffusion*, so that it may extend into every corner of the trees, and so reach the most remote spore. (*b*) It must be very *soluble*, so that it may be taken up by the water in which the germ tubes are forming. (*c*) It must act for a long time, and *continuously*, in order that the later germ-tubes may be attacked as they form.

2nd. But this is not all. Several gaseous compounds can be named which would satisfy the above conditions of efficacy and safety, combined with properties of diffusibility, solubility, &c., but most of them would be too expensive. The reagents to be used on estates must be very *cheap* in the first instance, since large quantities will be necessary.

3rd. And the application of the remedial agents must be simple: the planter should be quite familiar

with all that takes place, no machinery or time-consuming processes being admissible on estates.

4th. Having decided that a powder which evolves a soluble gas meeting all the requirements is simplest, it becomes necessary to see exactly when the application should occur In my 3rd report are data on which this can be based, and we see that the re-agent should be on the leaves when the spores begin to germinate. What does this mean? Simply that the *soluble* chemical is to be active during the very *wet weather*, and consequently that it becomes washed to the roots of the coffee tree. Doubly cautious, therefore, must we be of such bodies as carbolic acid and mineral poisons, since the continued application at sufficiently rapid intervals would be a great source of danger at the roots. I may point out that, from this point of view. it matters little whether carbolic acid is applied as ordinary carbolic powder mixed with caustic lime, or in the chemically feeble compounds such as "carbolate of lime" &c.

5th. But the planter requires more than the above: it is not enough that he possesses the requisite chemical, and knows when to apply it. He also demands that a minimum of labour force shall be employed. I take it that, apart from other reasons, estates will not supply the labour necessary to go over all the acres once a week or so (as would be necessary in the wet season), and it does not seem wise to ignore this practical difficulty.

6th. But suppose the planting community to have overcome all the above difficulties: suppose that every estate has arranged for efficient and continuous application, at the proper times, of a suitable remedy, the danger of reinfection must still be guarded against; for a very few spores from native villages, abandoned coffee estates, the leaves on the ground, and from the jungle, may rapidly make things bad again, if no precautions are taken. It is quite certain, therefore, that a successful fight can only be made if the sources of reinfection are removed: in any case, the trees must be sheltered, and the diseased leaves swept and destroyed.

7th. And the coffee must also be cultivated: manuring and pruning must be carried on just as well. I need not comment further on the reasons for the advice given: it is useless to ignore any of the facts before us.

8th. I would now ask: is it not a wiser plan to turn our attention to the slower but surer method of protecting coffee as much as possible against infection? By carefully destroying all leaves and prunings a great deal may be done towards ridding the estate of what spores are then on it: by jealously preserving what shelter there is, and by providing more where possible, much can be done towards keeping spores from without.

Manuring *must* be properly carried on under any circumstances: the chief ends to be attained in the present difficulty are that the manure shall not be most active just when the rains come on. It is impossible to give any general directions for the whole island: planters on the estates can alone judge of these matters, since they are ruled by many and varying circumstances.

Pruning must also be conducted as carefully as ever; or even more so. And now let me make a few remarks on the system often employed. It is not uncommon for estates on the Kandy side of Nuwara Eliya to manure in January (say) and prune about the same time: on other estates the pruning has been left until June, while others perform the operation in the interval.

Those leaves which are formed very early, and have the dry sunny weather of January, February, and March to work in—*i. e.* to elaborate the sap, as they are exposed to light and air—possess this great advantage: the air is too dry for the vigorous growth of *Hemileia*, and little or no "disease" appears. In May and June the fungus is beginning to attack the succulent leaves formed in the preceding few weeks, and about July they will become badly diseased to disseminate more spores. If the pruning has been delayed until June, however, large numbers of the incipient disease spots, with the mycelium, become removed *before the latter has fruited*: there can be little doubt that this occurred in the case of the field mentioned by Mr. Talbot, and I would call the earnest attention of planters to the success of his experiment. In this connection planters require simply their own methods, suited in each case to the estate and climate; but, understanding the phases of the "disease," a great deal may be done by having either fewer leaves in May and June (so that a smaller surface for infection is offered) or many *hardened* and old ones—not because they resist infection, but because they will have been on the branches long enough to have done good work for the tree during a period of immunity from disease. I strongly urge planters to use all their thoughts and efforts on this part of the subject; for the gradual reduction of *Hemileia*, by depriving it of its best food at critical moments appears to me by no means a hopeless task.

I hope I have succeeded in rendering clearer the important points, and, in conclusion, I would indicate what appear to be some of the chief sources of error on the part of those who misunderstand the true nature of "leaf-disease," and its relations to coffee, and *Hemileia*. On the one hand, a confusion of ideas seems to exist with respect to the meanings of the terms employed, and, on the other, a difficulty in conceiving such large effects to be produced by such apparently small causes.

"*Leaf-disease*" is too frequently confounded with the parasite (*Hemileia*) which causes it: a disease is an abnormal state or condition of the organism, and we are here concerned with a disease of the leaves, *caused by* the ravages of a fungus.

"*Predisposition to infection*" implies that the tree must have undergone some profound internal change, before it could be attacked by the fungus: not only does no evidence exist to support this view, but healthy coffee is as easily infected as any other.

The coffee-plant or tree is a complex organism, and has a life of its own—a life which consists of the sum-total of the lives of its cells, harmoniously working together Kill a few cells or leaves, and little harm is done to the leaf or tree, because so many more cells and leaves remain to carry on the work; but, if many cells and leaves be destroyed at frequent intervals, the whole tree suffers.

Hemileia thus injures the tree as a whole, by destroying the tissues which prepare its organized food, robbing it of substance, and overthrowing the balance of its functions. Did this occur but once, the tree would put out fresh leaves, rapidly form new food-materials out of the crude sap passing up from the roots &c., and repair the damage done: the continued repetition of this damage, however, gives the tree too little time. New leaves must be formed ere much crop can be produced and supported, and if these also rapidly become destroyed, continual efforts to supply new foliage make up the major part of the tree's duty, and the tax of bearing much crop is too severe.

The sap of the tree does not simply flow up and down in definite channels, as does the circulating blood in animals: nor may the sap of a tree be too closely compared with the blood of an animal. Much error arises from misconception on these points It is not by pouring poisonous matter into a circulating medium, nor is it by merely tapping and drawing off fluids from the tree, that *Hemileia* does so much injury: it is in breaking down the little cells which manufacture the essential food of the tree, and thus

producing lesions, and disturbances in the relation between the cells &c., that so much direct harm is done. The whole is therefore injured by innumerable injuries to its harmoniously connected parts.

Those who imagine that manure acts as "a cure for leaf-disease" by rendering the contents of the tree palatable (so to speak) to the fungus, evidently misunderstand the nature of the "disease" altogether; while any who think that by thickening the skin or epidermis of the coffee-leaf the latter would be rendered impervious to the germinal-tubes overlook the fact that these tubes enter the stomata or "breathing-pores," each of which is to such a body as a moderate sized house door to a man, or an ordinary drain pipe to a snake With every hope that I have succeeded in clearing up difficulties, and with apologies for occupying so much of your valuable space,—believe me, yours truly.

H. MARSHALL WARD, *Cryptogamist.*

HEMILEIA VASTATRIX AND THE "COFFEE LEAF-DISEASE" IT SUPERINDUCES: IS THERE BALM [VAPORIZED] IN FIJI?

Mr. Marshall Ward, it will be observed, adheres to the position that a gas-producing substance, to be effectual, must be applied so as to kill the spores before they enter the ever-open *stomata* or breathing months of the leaves. The fungus, once inside and spreading its mycelium through the sap-cells, is, according to the Cryptogamist, safe from attack. If the *stomata* do not contract after the entry of the fungus, we scarcely see why the parasite should enjoy such complete immunity. Where a comparatively solid body entered, surely a subtle gas can follow. Mr. Schrottky certainly asserts that, by his process, the fungus is prevented from ripening its spores: killed inside the leaf, in fact. And why not, or why should a carbolate of lime, very weak in carbolic acid, applied to the foliage of a tree, do harm to its roots? Human nature is human nature, even in a cryptogamist, and the manifest determination to hold that nothing good can come out of Mr. Schrottky's Nazareth reminds us (we hope Mr. Ward will not be shocked) of "the Turk who can bear no brother near the throne." What the planters of Ceylon desiderate is a cure for leaf disease in the shape of a destroyer of the germs which cause that disease, and, provided the desideratum is discovered, their gratitude and due reward will be bestowed on the discoverer, whether he is known to the world as Marshall Ward of England, Schrottky of Germany, or Storck of far Fiji. The interesting and important letter from the latter gentleman, which reached us as we were writing our previous article on Mr. Ward's communication, dwells on certain subsidiary questions, before proceeding to state the merits of his alleged CURE BY VAPORIZATION. We suppose there will be a universal consensus of opinion in favour of Mr. Storck's argument that coffee planters in Ceylon would have done wisely had they more frequently and largely introduced seed from abroad: especially from Arabia or Abyssinia. But, while Mr. Storck's premises are, on general grounds of scientific and sound culture, admitted to be correct, Mr. Marshall Ward has, beforehand, effectually disposed of the conclusion that to the general use of local seed, and trees weakened in consequence, is due the development of *Hemileia vastatrix*. Plants grown from imported seed may have great merits of their own, but amongst those merits power to resist attacks of the insidious fungus spores cannot certainly be ranked. As regards grub eating coffee roots, we knew what that was long before *Hemileia* emerged from the obscurity of its jungle home. No doubt, the evil has not only been more observed, but has been far more prevalent and destructive since the advent of the leaf fungus. Few Ceylon planters, however, we believe, will be prepared to admit that increased prevalence of grub stands in the relation of consequence to the external fungus as cause. Whether, on the other hand, *root* fungi predispose to attack from grub or not is a moot question. A local scientist, Mr. A. Dixon, holds that the grubs never attack healthy rootlets: the attraction to the poochies, he insists, is to be found in the fungi which infest diseased roots. There is one planter of standing, too, who once asked at a meeting: "Has any one ever seen a grub with roots in its mouth?" and Mr. Dixon holds that the mandibles of the grub are unequal to the task of eating coffee rootlets. The vast majority of the planters, however, have no doubt that the white grub feeds on the perfectly healthy rootlets of their coffee bushes. Personally, we long cherished the conviction that insects ate only dead or dying vegetable matter. But there was no resisting the accumulated facts in the experience gained of white ants by the tea planters of India and the cocoa planters of Ceylon, and, to come nearer home, what the coffee planters of Ceylon have suffered from the ravages of the grubs of cockchafers. *Hemileia vastatrix* by enfeebling the coffee trees may render them less able to go through a recuperative process after being attacked at the roots by grubs; but the fungus is far less answerable for the grubs than Tenterden Steeple was for the accumulation of Goodwin Sands. What joyful holidays should we have in Ceylon, if we but felt assured that really "perfect cures" had simultaneously been discovered for the two destructive agencies which have so long been burning the candle of life of the coffee bush at both ends. Repeated and painful disappointments in the past render us liable to the suspicion that such news is "too good to be true." Still we are inclined to "hope for the best," in regard to the operations directed against the lives, vegetable and animal, of leaf fungus and root grub. The analogy of sugarcanes, which can be so easily changed, if disease, whether fungoid or insect, appears on them, scarcely holds good in regard to coffee, which could only be changed at a ruinous expense;—with the doubt if the same soil could bear coffee a second time, and with the *certainty* that introduced coffees are as liable to attacks of the destructive fungus as that which has existed in Ceylon probably since the time of the Muhammadan voyagers from Suez and Aden. The result of our observation and enquiries during a recent visit to the rapidly rising sugar district of Mackay in Northern Queensland was the conviction that whatever effect continued propagation from the same kind of cane might have in aggravating the effects of rust or insect blight, the varieties of cane, which are numerous to bewilderment, differ essentially in their liability to, or immunity from, attack. The young industry, which was nearly snuffed out by "a red rust fungus" in 1865, has now quite revived under the process of importing cane from all parts of the world, from places so far apart as the islands of

the South Pacific and the Antilles of the far West,—and growing those which experience has proved to be the best as disease-resisters and saccharine-juice-yielders. Amongst the worst, from its liability to disease, is the pale, soft, succulent "Bourbon"; amongst the best is the more slender and less succulent "Rose bamboo." Arguments, therefore, which apply with more or less force to sugar culture must be received with large qualification when the hard-wooded perennial coffee is in question. Of one thing there can be no doubt: both plants benefit largely by copious applications of *lime*, and were this substance available in large quantities at a cheap rate, and could it also be cheaply applied in its caustic state to the fungus-infested coffee of Ceylon, we could soon afford to laugh at leaf-disease, *Hemileia* being relegated with a specially hearty ha! ha! to the limbo of rare herbarium specimens. We have seen some warnings about the too free use of lime with reference to its effects on certain soils. But we should really like to see the coffee estate in Ceylon, the soil of which, as well as the plants, would not be benefited by a ton per acre per annum, dusted over the trees at frequent intervals and ultimately affecting fallen leaves, prunings, buried weeds and the soil. The latter is, over the vast proportion of the coffee-growing region, not essentially infertile, but in a state to yield up far less of its fertility than is desirable because of the over-prevalence of clay, that clay being in a bad mechanical condition because of the paucity of lime. We only wish some of our planters were able to try the experiment of how much lime dusted on the trees to destroy the fungus would be necessary before the soil was affected injuriously instead of beneficially. We are quite at one with Mr. Storck as to the value he places on caustic lime, the real limit to the use of which cure for leaf disease and soil imperfection is its cost in purchase, carriage and application. The cost of sufficiently copious and sufficiently frequent applications of lime being in the majority of cases prohibitory, most fervently do we hope that Mr. Storck's vapour cure may turn out as great a success as he "predicts" it will. The vast proportion of the substances required to produce vapour which will kill *Hemileia*, even when the parasite is inside the leaf, without injuring the tenderest leaf or the softest flower, exists, Mr. Storck tells us, on estates, and Mr. Fillingham Parr states that the estimate of £2 an acre for the first year, vapour being constant, is too high instead of too low. But what planter would grudge £2 per acre for the first year and £1 per acre for a few succeeding years, if he felt certain that the result would be so to banish spores of the fatal fungus, as to enable him to follow Mr. Storck's advice by applying organic manures, weeds, prunings, &c., to his coffee, without the disheartening conviction that he was fertilizing the fungus as much as the bushes it preyed on. We only wish that Mr. Storck, instead of "predicting" what his automatic (self-acting) vapour machines, operating constantly from centres over circumferences, will do for Ceylon, had been able to tell us that as a matter of fact and history he had succeeded in freeing Fiji from a pest introduced not by seed-coffee from Ceylon (Mr. Morris insisted that seed would not carry living spores) but by plants imprudently imported. Mr. W. F. Parr, a former Ceylon planter, no doubt speaks of Mr. Storck's process as an undoubted success. But in asking for the protection of a patent, or an adequate money reward in Ceylon, Mr. Storck's case would have been enormously strengthened had he been enabled to adduce the united testimony of the planters of Fiji, that the vapour had banished the fungus from the limited coffee culture of the archipelago, as effectually as St. Patrick banished the "varmint" (if he *did* banish them, which recent events make us doubt) from Ireland. The old adage that a prophet has no honour in his own country does not seem to apply to Mr. Storck, but probably in Fiji, as here he would like to be sure of his reward before he lets the public into the secret of all his processes. We suspect there is nothing for it, however, but trials sufficient to demonstrate perfect success, and then trusting to Government and the planters for remuneration. It will not be forgotten that Mr. George Wall gave a full trial to vaporization as a cure for the fungus, and that it failed. The use of multitudinous tins was expensive and the vapour did not fully and equally affect the foliage of the plants. From the use of the term "automatic," are we justified in inferring that besides being driven hither and thither by winds, the vapour from Mr. Storck's centres is mechanically driven outwards and upwards from those centres, so as to reach and effect every portion of every tree and every leaf of the foliage? As one average man can attend to 50 acres (only four for an average estate of 200 acres!) the automatic machines (Mr. W. F. Parr uses the term "tins") can be neither very numerous nor very complicated. The substances most abundant on estates, apart from varieties of soils and manures, are leaves, prunings and weeds, and we should have suspected that Mr. Storck combined incineration with vaporization, but for his denunciation of any movement of leaves and twigs. They are to be treated with lime *in situ* and then forked into the soil. We do not quite understand why Mr. Storck thought it necessary to state, what is so obvious, that the larger the area treated by his vapour the better, while the statement that an adjoining estate however badly affected by the fungus cannot infect one which has been vaporized is more satisfactory than clear. Amongst the subsidiary subjects treated by Mr. Storck is that of possible improvement in the bearing powers of coffee by resorting to cross-fertilization. We should be glad to know if any experiments in this direction have been tried in Ceylon, and with what result?

We observe that the Planters' Association of Ceylon has declined to offer any reward in the present phase of the alleged cure. But if Mr. Storck comes here, and under all possible conditions just to himself and yet permitting certain evidence of the success of his system, converts his prediction into absolute fact, we feel we can safely assure him that neither cordial gratitude nor liberal reward will be wanting.

(*To the Editor of the "Ceylon Observer."*)

HEMILEIA VASTATRIX: A COUNTERBLAST FROM FIJI.

Levuka, 3rd November 1881.

SIR,—I suggested to Mr. Storck that he should write you a few remarks about his newly-discovered cure for leaf-disease, and he forwards the enclosed, which I send on to you at once, instead of returning

them to him for correction and amendment. I wrote by last mail to my agent in Colombo respecting Mr. Storck obtaining protection from Government for his remedy; or, for a certain sum, he would transfer the cure to them. My own opinion is that Mr. Storck over-estimates expenses at £2 per acre, as it chiefly depends on the price the tin vessels can be made for in England. I feel very pleased to think that the honour of discovering this remedy should have been reserved for a Fijian settler.—Your obedient servant,

WM. FILLINGHAM PARR.

Upper Rewa, Fiji, October 20th, 1881.

SIR,—In several of the later issues of the *Observer* and the *Tropical Agriculturist*, I notice a controversy upon the advisability of gathering up and destroying the dead and dying coffee leaves falling in showers after an attack of leaf-disease. It strikes me, and indeed Mr. Ward's own showing bears me out, that the ground is the best place for such leaves. Just imagine a gang of coolies raking and brushing up a mass of such foliage covered with spores, dead and alive, and how it must make them fly. Any one wishing to diligently and mischievously propagate the fungus could do no better, not even taking into account the difficulty and expense of the task. Those leaves should be disturbed as little as possible, not even by the foot of a passing laborer. But if you *do* want to do anything to them, give them a liberal dusting, of which the trees will get their share, of good, active lime in dry breezy weather, about once in 14 days during the period of the leaf shower. Let all lie until they are quite black and dead; then fork them in, and you will find an abatement of leaf-disease for a twelvemonth on a field so treated. The empty shell of a spore is quite as dead and harmless under the ground as that of any other seed. Nor is there any fear of the formation of nidus of that fungus below the ground, as some of your correspondents seem to apprehend, because the fungus cannot live there in any of its conditions. I think the value of lime, as a disinfectant against *Hemileia vastatrix*, is not nearly enough appreciated. Its effects as a mitigant of that pest are far more important than it is generally credited with, and although a compulsory expense, its application serves a double purpose. I have by systematical application entirely and lastingly cured a considerable number of coffee trees with nothing but pure lime.

I was much pleased to see several of your correspondents take a rational view of the manner in which the Ceylon plantation coffee plant has deteriorated in physical condition, to which last the origin of leaf-disease may yet be traced. Only to mention the barbarous proceeding of using seed from maiden crops, and [illegible] for [illegible] of years in succession. Tropical plants will far sooner show a deterioration of species by indiscreet propagation than those of the temperate zone, where over-production and reckless propagation have already shown such dire effects among the fruits and vines of Europe. It is well known to gardeners that successive propagation by cuttings from cuttings and grafts from grafts [illegible] the [illegible] of any [illegible], which [illegible] noticed in their produce, whether flower or fruit. Although the art of grafting is very old, it has not been very extensively practised for purposes of systematical propagation (multiplication) of any given and previously improved variety of fruit until some 200 years ago. But some quarter of a century back many of the most intelligent fruit-growers of Europe, [illegible] and amateurs, became alive to the fact that many of the once standard [illegible] varieties of apples and pears showed unmistakable signs of deterioration, both in their physical appearance, and in the size and flavor of their fruit. So far, no epidemic has shown itself among that class of fruit, but let us look at the vines of the south of Europe. There are varieties grown there, which have been steadily propagated by cuttings since the days of Charlemagne, or, perhaps, the Romans, and what is the consequence? Both fungi and insect pests are combining to accomplish the extermination of the very species. Similar phenomena are already noticeable among the *native* sugar-canes of this young colony, after a course of carelessly conducted propagation by the whites of some six years only, from *tops*, persisted in after repeated warnings from the writer of this.

What I have said above on the pernicious effects of reckless propagation from cuttings and grafts, applies equally to that by seeds, and the indiscriminate propagation by seeds of the coffee-plant in Ceylon is the less excusable, as her planters have every opportunity of renewing their seed from the coffee-growing countries around them, as well as from the very cradle of the coffee tree itself—Arabia and Abyssinia. I have repeatedly, in Ceylon papers, met with the statement that plants raised from Ceylon seed are more subject to, and less able to stand the attacks of the fungus, than those raised from foreign seed, which is very probable, for Ceylon leaf-disease is of longest standing, and debilitation of the plant it preys on, is therefore more pronounced in its effects, than in countries where the habilitation of the fungus is of more recent date. The deterioration of the seed is only a natural consequence of that of the mother-plant; seeds are imperfectly nourished and often recklessly sown. A coffee-seed, as most other seeds, should always undergo a short period of slow and natural desiccation. It should be shrunk before it is sown, when this partial desiccation will not only be harmless, but will prove a stimulant to germination, very much in the same way and for the same reasons as with bulbs, tubers and even the live plants of some [illegible] for instance. Plants grown from such seed will be less succulent and hardier than those grown from green seed fresh from the tree.

I would be glad to know a little more of the rotting of the rootlets and the grubs etc., of which I read so many complaints. Did you have grub or damage [illegible] before leaf-disease became [illegible]? It would appear to me that there is some [illegible] in all this:—that the rotting rootlets [illegible] the natural consequence of a disturbance (stagnation and partial fermentation) of the sap of the trees during and immediately after an attack of [illegible], and [illegible] fall of leaves, causing a reaction upon the [illegible], which rotting would in that condition [illegible] for any kind of grub.

On the question of self-fertilization, I [illegible] know quite what to think. A [illegible] in [illegible] good weather, should [illegible], offer the most favorable conditions [illegible] tion [illegible] to judge from the [illegible], and the short period within which [illegible] take [illegible]. I should say that [illegible]—i.e., self-fertilization. To make [illegible] tion, by way of experiment, [illegible] brought about by artificial [illegible] by cutting off a well-set branch [illegible] it from tree to tree, tapping, [illegible] and [illegible]. The effects of [illegible] very likely show themselves in a [illegible] borne by other trees left to themselves. [illegible] towards the production of [illegible] seeds and [illegible] certainly not the contrary.

As to whether [illegible] the [illegible] any seed, I [illegible] for the purposes of the planter [illegible] in [illegible] indirectly through the [illegible] of a fungus

164

on the mother plant, but, however far the juices of a suffering plant may be vitiated, I do not see how such a condition could take place. The theory reads to the plain observer of nature something like a sensational novel to the lover of standard literature: it is overstrained and artificial. Plenty of Ceylon coffee seed has been sown in this country a few years past, but none of the offspring ever suffered from *Hemileia vastratrix* until it was bodily imported on live coffee plants.

For more than two years now I have been a close observer of *Hemileia vastatrix*, and have proved that whatever superstitions of its wonderful powers of dissemination and vitality may be abroad it does neither infest the soil nor the air in any other manner than other seeds, with superior means of traversing the air, and thereby widening the zone of their geographical distribution. As regards its vitality upon the surface of the soil or other uncongenial bodies, that is determined by the time it takes for germination, and finding food for the germ in a coffee-leaf. In the absence of that it must as surely DIE as any other seed germinating under conditions adverse to vegetation. The circumstance of spores of *Hemileia vastatrix* having lived and germinated after being kept for two years in a letter has surrounded it with a spectral halo of immortality which has made many despair of a successful treatment. I have known the spores of ferns under parallel conditions, *i. e.* kept in dry paper between the sheets of herbarium, germinate readily after more than 20 years from the time of collection. I have seen stumps of old coffee-trees, that were left after the destruction of a field thoroughly infected with *Hemileia vastatrix*, sprout again and grow apace free from it, because, being old and sluggish of growth, the fungus had actually died a natural death, before it could find a home in the new growth made by those stumps.

My first attack upon it was made by direct application, on the principle of *exhausting* the spores contained in the tissue of the leaf by killing them as they come out. I succeeded in this with all (some 30) the trees, applying moderately caustic lime only, after about eight weeks of daily applications. They are the same batch of trees that were spoken of in the *Observer*, and continued clean for (most of them to this day) a twelvemonth, when some of them were accidentally reinfected by a gang of Fijian labourers from the Upper River. The result proved to my satisfaction that a thorough and lasting cure was possible. At the same time, I became aware that this or any method of manual (direct) application was too laborious, even though weekly applications only would perhaps have answered the same purpose. It is open to failure through interruptions by stress of weather and the negligence of labourers, and every interruption would of necessity mean the whole work over again. Whilst working at and watching the effects of this experiment, I had been thinking of a method of vaporization, which could be made automatic and permanent. The principle suggested itself to me partly though Mr. Morris' more recent sulphur and lime treatment, and through what I had seen practised when a younger man at home, but under the shelter and confinemet of glass-roofs. But the problem to be solved was: how to adapt the system to the open field. The outcome of my cogitations and experiments is my

Method of Permanent Vaporization, which I hereby recommend to the planters of Ceylon and all othr coffee-growing countries suffering from *Hemileia vastatrix*. The chief features of the system are:—

(1) The greatest simplicity.
(2) The greatest economy of material and labour
(3) The most perfect control.
(4) Complete isolation of material from soil & plants.
(5) Unparalleled cheapness.
(6) Absolute and unconditional exemption from leaf-disease.
(7) The larger the area treated the better.

An average man can attend to fifty acres a week or more, and the bulk of the material is to be found on every estate, meaning a saving of 90 per cent in carriage, as compared with that of the materials hitherto used against the fungus.

The cost of the first year's treatment will not exceed £2 per acre, and that of any subsequent year be less than £1. The centres of vaporization in the field have to be supplied once a week, and the treatment may be started at any time, whether leaf-disease be visibly present in a field or not, with equal advantage. In the latter event, 4 weeks of the application will bring out every pinspot in the field, kill them, and save the greater part of the foliage. If, on the other hand, the fungus in a field be in full vigour, you will notice the action of the specific in the following manner:—Three or four days after starting the treatment, the spores will show a change in color from bright orange to dull ochre, until they turn from dirty yellow to greyish white. They all, instead of dispersing, stick to the leaves until they vanish from sight. In the second month, all rust coming out begins to look dull in color and sickly; many rust patches begin to show pale rings round them, indicating the limits of the mycelium, where its farther formation has been arrested. After the second month, a large proportion of the spots have white rings round a yellowish centre, as if drying up in the middle; sometimes they push out a few sickly spores, but oftener none at all. The spots then turn into dry tissue, and, unless the leaves had been too thickly charged with fungus, they remain on the trees. Thenceforth a little dirty rust may still appear, but the presence of the fungus will be chiefly indicated by dead and dying mycelia until it vanishes altogether. By this time a field of fairly vigorous trees will have recovered its full coat, or nearly so, of foliage, which under the *permanent* treatment remains clean.

In speaking of my lime treatment on the principle of *exhaustion*, I mentioned eight weeks as the time required for all the spores to come out from first to last, but, in giving the duration of my new process as of three months or more, I speak advisedly, since the two treatments are essentially different in their action. By outward and direct application, the spores are only killed as they make their appearance; that means the spores are all fully developed before acted upon, and therefore the leaves have to empty their tissue of all particles of the fungus, which takes from 7 to 10 weeks, according to the weather. The effects of vaporization are quite different, inasmuch as the vapor is inhaled through the breathing organs of the leaves, and so brought into immediate and deadly contact with the mycelia lodged in the cuticle; sickens and weakens them; and thereby retards and finally arrests their development, according to the different age and strength of the pinspots. All the leaves which bud and form after the establishment of my system will mature free of fungus, and, under its permanent influence, must remain so, no matter how thick the fungus may be in the next adjoining field for want of treatment, thereby securing to any one employing it the full benefit of his outlay. My method establishes a deadly enemy to *Hemileia vastatrix*, all pervading, ever-present,—nothing can escape it, nor is failure possible, except through the grossest mismanagement or wilful neglect of one operator, who may have as much control over the process as it is possible to have of anything. Not any part of the plant is injuriously affected through it: not even the tenderest flower bud or young leaf.

I have two Liberian trees to show: one among a cluster of five, the other in a batch of forty some distance off, which were infected at the same time as the nursery was. Through my treatment I completely isolated them from their neighbours, and confined the disease to those two individuals. Not a single spore reached the other trees alive, and none of them were infected. The nursery containing some 300,000 nine month old plants, had a very bad secondary attack, and although the treatment was carried out under the most unfavourable conditions, because on so small an area the vapors must of necessity be very diffuse, it was entirely successful: whilst on a small area the vapors depart in all directions, a large field would have the benefit of every breeze and air carrying the vapors through it in waves, and by turns in every direction.

Wherever my method of permanent vaporization will have become general in a district, I venture to predict that, after a twelvemonth, the chances of reinfection will be so far rarefied, that the treatment may be safely discontinued and only taken up again for a few months, in the event of local reinfection, from the selfsown coffee in the forest, a native garden patch, or through the intercourse of travel by accident from a distance. Your planters should endeavor to eradicate all sources of reinfection outside of the areas under regular cultivation. In the event of such reinfection, treatment must again be started at once, so as to prevent infection becoming secondary and general. One day will suffice to re-establish treatment over the largest estate.

Immunity from leaf disease will permit planters to think of improved cultivation, and I would suggest the employment of organic manures chiefly, and the utilization of every scrap of prunings and other refuse from the coffee tree, as well as all vegetable rubbish in particular.—I remain, sir, yours obediently,

JACOB P. STORCK.

"GERMS" AND DISEASE IN PLANTS.

(*Gardeners' Chronicle*, 5th November 1881.)

In our last issue, we alluded at some length to the action of "Germs" in producing certain forms of disease in animals and plants. We showed how modern investigation had sufficed not only to detect the germs, but even to isolate them and grow them under artificial conditions. The existence of these organisms has, of course, been known from the time people began to use the microscope; but it is only lately that it has been proved that they are not the mere accompaniments of disease and decay, but, in some cases at least, the actual cause. This has been proved by isolating the germs, cultivating them, and inoculating healthy animals with them, as detailed in our last number. Introduce these organisms, and disease and decay set in; prevent their ingress or destroy them by carbolic acid or other germ destroyer, and no disease is produced. Already, in the case of animals, the practical results of these discoveries may be called enormous, and the prospects for the future are even more hopeful. We refer to the subject again, because, since writing our remarks, some papers of Professor Burrill have come under our notice, in which the author shows that the "blight" in pear and apple trees and the "yellows" of the peach owe their origin to the presence of bacteria. We have ourselves noticed the occasional presence of "micrococci" in cankered apples, but we had looked upon their presence more in the light of a coincidence than a cause. With Professor Burrill's papers before us, however, we would urge those who have the requisite leisure to investigate this matter for themselves. According to Professor Burrill's statements he finds bacteria in the drops of whitish viscid fluid found oozing from the bark of diseased apple and pear trees. At the same time the cells of the bark, which should be full of starch, are nearly void of that reserve of nutriment. The bacteria are found, as we understand it, actually in the cells, but how they gain access to the interior is not made out. Inoculation of previously healthy trees was practised in a great number of instances, the disease being thus reproduced in a large percentage of cases, but not invariably. Actual inoculation by means of a needle charged with the virus, as in the case of vaccine lymph, is necessary, or the transfer of a portion of infected bark, as in the operation of budding are requisite, as it seems that the mere deposit of the virus by means of a brush upon the leaves is inefficacious. The progress of the disease is very uncertain and irregular, but always slow, no change being visible for nine or ten days. The chemical changes produced are the giving off of carbonic acid gas and the formation of butyric acid. In the Lombardy Poplar these ferment-producing agents follow the attacks of the wood-boring beetles, and complete the destruction set up by them.

Such in brief outline are the results obtained by Prof. Burrill. We do not know by actual observation what the "fire blight" of the pear and the "twig blight" of the American apple are, and what relation they bear to the canker and other diseases of our fruit trees, but we have said enough we hope to induce those with the requisite leisure and competence to investigate these matters for themselves. It may be requisite to point out that some only—not all such diseases—are likely to be caused by these organisms, that the presence of bacteria, micrococci, and the like need not necessarily cause diseased action, for assuredly they often occur where no ill effect is perceptible. Their presence is readily detected by the microscopist, but to prove that they are the actual cause of the disease requires prolonged careful experiments directly to prove and indirectly to show that no other cause is sufficient. Should it turn out—as we strongly suspect it will—that some forms of canker are due to these organisms, we may have a chance of combating the malady by cutting away and destroying the affected branches, and by the free use of carbolic acid as a poison to the germs.

A trial might be made of this substance at once, for in any case it would be as efficacious as any other remedy, and there is the probability that it may prove much more so. Practical points to be borne in mind are to take care not to take grafts from an affected tree, and not to use the same knife for pruning healthy trees as has been used for those that are in any way diseased. Who knows but that the explanation of the facts attributed by some to wearing out and degeneration of particular varieties may really be due to the dissemination of disease by means of the knife and pruning-saw.

The whole subject demands the most careful examination—practical men are too busy; few of us, indeed, have the requisite leisure, and unfortunately at present we have no schools of gardening or forestry, no experimental botanic gardens where such experiments could be undertaken by competent persons. Some day, perhaps, we shall be wiser. At present not only the Americans but the Germans and the Belgians, and to some extent the French, give us the go-by in these matters, to our certain loss in the future.

FIJI: THE COFFEE-LEAF DISEASE.—With reference to the cure described by Mr. Jacob P. Storck, Upper Rewa, in the Fiji *Times* of 6th August, the *Gardeners' Chronicle* says:—"We should be glad to have the testimony of some disinterested person on this matter, and some further explanation of the method adopted.—ED.

COCKROACHES.—We would recommend O. Orpet, Cirencester, to prepare a mixture of oatmeal and plaster of Paris in equal quantities with sufficient water to make it adhere, dropping it in small quantities in different parts of the floor or stokehole, where the cockroaches frequent. We believe with this method he will soon relieve himself of this disagreeable pest.—HARRISON & SONS, Leicester.—*Ibid.*

VEGETABLES FOR THE TROPICS.

(From *Sutton's Tropical Garden Guide.*)

(Continued from page 540.)

TOMATO *(Lycopersicum esculentum).*

Sow in October in seed pans, and transplant on any spare piece of ground. Fruit becomes ripe in February. No great care or attention is required for this plant, as it grows almost like a weed.

TURNIP *(Brassica Rapa).*

It is not desirable to sow Turnips until the middle of October. The seed may either be sown broadcast or in drills, but in either case the land should previously have been well trenched, and care should be taken that if the seedlings come up too thickly they are thinned out as soon as possible. Eventually, when well established, hoe out to 1 foot distance between the plants.

VEGETABLE MARROW *(Cucurbita esculenta).*

Cultivation same as for Pumpkin.

ENGLISH ANNUAL FLOWERS.

There is nothing more calculated to recall pleasant home memories and early associations than the sight of these flowers in the tropical garden. Though shortlived, their variety is so great and their beauty so engaging, that now the great difficulty of transit is overcome, Annuals may brighten every foreign garden. Some amount of care and trouble is doubtless necessary to ensure success, but attention to a few guiding principles will avoid much disappointment. A few remarks as to the times when seeds should be sown in India are necessary. In Bengal do not sow before the rains are well over. In the Upper Provinces, on the contrary, it is often well to sow much earlier to ensure good growth before the cold weather. In Bengal Asters, Cinerarias, and Salpiglossis should be sown very early, or they will not flower before the following hot season. Some of the quicker growing varieties, as Nemophila, Larkspur, and Virginian Stock, should not be sown before November.

MODE OF SOWING.

Sow the seeds in pots or pans, or in a seed gumlah supported on an empty flower pot standing in a pan of water, in a compost of leaf mould and sand. Be careful not to bury the seed too deeply under the soil. Keep shaded but give plenty of light and air, and at night when the weather is favourable stand the pans out in the open. Of course where pots and pans are not to be had, the seeds should be sown in the open ground in a shady but airy place. When sown in the open ground great care must be taken to protect the tender seedlings from the scorching rays of the sun and from rough weather at night. To effect this make a covering of Loogla on a bamboo frame about 3 feet from the ground. The red ants commit such ravages that it is useless to sow sparingly in the open ground. On the other hand, those seedlings which survive are far healthier and stronger than those raised in pots.

TRANSPLANTING.

We would recommend the transplanting of all varieties such as Mimulus, Aster, Cineraria, Balsam, &c., but those which delight in a dry sandy soil, as for instance Lupins, Portulaca, Poppy, Eschscholtzia, Mignonette, &c., are often irrevocably injured by the process. For some of those which will not bear transplanting and yet require some sort of protection at first, the following plan is recommended:—At the spot where the seed is to be sown scoop out the earth of the border and throw in some old leaf mould to mix with it, draw a circular drill of 6 or 8 inches in diameter, and from ½ to 1 inch deep. Cover lightly with moist soil, place a flower-pot inverted over them, and let it remain until the seeds begin to germinate. The pot should then be propped up on one side 2 or 3 inches high until the plants are able to bear exposure.

Annuals sown on the border require daily watering, and the morning should be chosen in preference to any other period of the day.

One of the greatest pests of a tropical garden is the ant. Every care should be taken to prevent the ravages of these insects, or they will destroy the young seedlings as they appear above ground, and often eat the seeds before they germinate. The result of this is not only disappointment to the purchaser, but is frequently the cause of complaint to the seedsman, who is charged with supplying bad seed. A saucer of sweet oil is an irresistible bait to them, into which they will rush and kill themselves. Captain Weston says:—

'The usual way of getting rid of the red ant is, I believe, by powdered turmeric or haldee. I however found a plan my málee had last year more successful. When the seeds were sown, a cocoanut with the kernel in it was cut in halves and laid near the seeds; the ants flocked to it, and when it was full of them it was immersed in hot water. The nuts were watched during the day, and in three days no more made their appearance. A few days after they made their appearance again, when they were treated in the same way and again similarly disposed of. My plan when I find a nest of red ants is to band the spot round with clay and pour in boiling water, and I have found it efficient in the destruction of the red ants.'

FLOWER SEEDS.

ABRONIA.

A very pretty trailing annual, with heads of flowers resembling the Verbena. Sow in October to bloom in February.

ACROCLINIUM.

Highly ornamental, producing large everlasting flowers. Sow in October, and transplant to the open border.

AGERATUM.

A very attractive annual, either for bedding purposes or for planting singly in the border. Sow in August, prick out singly, into pots, and transplant to the open ground in October.

ALONSOA.

A small showy annual, with bright scarlet flowers. Sow in October.

ALYSSUM.

A pretty dwarf annual, more valuable for its delicious fragrance than for any special showiness in colour. Sow patches in the borders during October, to bloom the middle of December.

AMARANTHUS.

Very handsome and ornamental. A few groups placed at intervals along a border produce a good effect. Sow in July.

ANTIRRHINUM (SNAPDRAGON.)

A beautiful and well-known flower. Sow in October. The plants will generally bloom the same season as sown, but it is better to keep them over till the next cold season and replant in good soil.

ASTER.

The Aster is one of the finest garden flowers, and is of easy cultivation. Sow on a bed of fine rich mould, or in a pot, any time from May till November. When a few inches high transplant carefully to where they are intended to flower, about 8 inches apart, the tallest kinds in the centre of the bed.

BALSAM.

This is one of the finest annuals, and is a native of India. Imported seed produces flowers much like large Camellias, but native seedlings should be destroyed, as not at all equal to plants from a carefully selected stock. Sow in the early part of September, as plants from seed sown in July or October do not thrive half so well—the rain injuring the plants in the former case, and the cold in the latter.

(To be Continued.)

NEW PRODUCTS: INTRODUCTIONS INTO CEYLON: "TOON" TREE TIMBER FOR TEA BOXES IN CEYLON.

If Mr. Wm. Ferguson is satisfied that the species (for there seem to be many) of indigo which grows wild around Colombo is the true *I. tinctoria* of Linnæus, which he seems to be, the question might still remain as to whether the best seed can be obtained from an "escape," which has probably been subjected to a process of deterioration. Seeing that Linnæus looked on the specimens from Ceylon as exotic, and that Sir J. D. Hooker doubts whether *I. tinctoria* "be truly wild," our correspondent's supposition that it is likely to be a native of Ceylon as of India may merely justify the conclusion that it is native to neither. *I. anil* is, confessedly, American, and the other may have had the same origin. For there are few of the more valuable vegetable productions cultivated in India, from cocoanuts to Chilé peppers, and from tobacco to pineapples, which the Orient does not owe to the Occident. This question about indigo culture in Ceylon, however, we confess we regard as more curious than practical. Where soil, climate and other conditions are suitable, no man can err in adding to the world's production of sugar and coffee, for the possible consumption of both is almost unlimited. But with indigo, in abundance and of the best quality, a few districts in India can supply the world. The subsidiary product from the manufacture, however, an excellent manure, is worthy of consideration. During the writer's voyagings through Torres Straits and his visits to the sugar districts of Northern Queensland, he had the company of the agent of a great sugar machinery company at Lille. Mr. Van de Velde was, however, a Belgian, and when, in lengthened discussions regarding all aspects of the sugar production question, he was directly asked how it was that the growers of beet in a cold country could possibly compete with the producers of cane in the tropics, his reply was: "If sugar alone were concerned, they could *not* compete. What renders the cultivation of sugar beet profitable, in Belgium at least, is the value of the refuse. It makes a food for cattle, so valuable as to be indispensable." We forgot if our Belgian friend dwelt on the resulting manure, but that would be very valuable in view of the large quantity of potash in beet fibre. From what we saw of green and flourishing fields of indigo cultivated by the Chinese on the island of Singapore, we could not help feeling that, if not too valuable otherwise, it would be a grand "green crop" to plough or hoe into the soil, and we have since read of the use of the plant for this purpose. As a green crop application for coffee, Liebig recommended lupins, and were our Ceylon plantations only moderately undulating, instead of being in the majority of cases, excessively steep, experiments in this direction might be tried. The Chinese, who utilize everything and something more, are sure to make the most not only of the dye but of the refuse of the indigo they cultivate. In the Straits there is doubtless a local demand for dyeing cloth the dark colour so commonly affected by the celestials. We fear there is no such local demand here. The last experiment in indigo culture in Ceylon was tried by the late Mr. Le Marchand (father of the well-known bank manager), who had been an indigo planter in Bengal. That experiment failed because the young succulent plants were destroyed by an army of insects. Neither past experience, nor the present state of the market for the dye, seems to us to offer encouragement for the cultivation of indigo in Ceylon. We, nevertheless, wish success to any experiment which may be made.

The pendent fruit of the *Kigelia* was brought from the Botanic Gardens at Buitenzorg merely as a curiosity. We certainly never had seen anything in Ceylon more closely resembling it than the fruits of the West India calabash tree. When the valuable *Cedrela toona* comes into question, the case is very different, and we are gratified that the public of Ceylon, and especially the tea planters, should hear that Dr. Primen is harvesting seeds of the *toon* tree. Years before going to Java (in the beginning of 1876), we had seen the *toon* trees, lining the roads of Dehra Dun below the northern Himalayas, and subsequently we made its acquaintance below Darjiling on the eastern Himalayas. On both occasions it was pointed ont to us as *the* tree for tea boxes. We saw specimens at Bandong and young trees everywhere along the roads of the Preanger Regency. In Java, indeed, it is one of the favourite trees for lining roads. But it was on Mr. Kerkhoven's magnificent tea estates at Sinagar that our admiration was specially excited by closely planted avenues of mature trees. We recognized the foliage as that of a tree familiar to us but which we had never seen so abundant and flourishing, and (being no botanist, as Brutus is) we could not recall the name. The only other trees in Java which, in our estimation, excelled it were the graceful pyramidal *Dammara* and the magnificent umbrageous *Ficus Benjamini*. Mr. Kerkhoven spoke highly of the tree as fast-growing and yet yielding good timber. The native name he said, was *Toon-ian*, no doubt a modification of *toon*. We most gladly availed ourselves of Mr. Kerkhoven's kindness in bringing a supply of seed to Ceylon, and a very large local supply indeed must have very suddenly developed to give any propriety to the comparison of "carrying coals to Newcastle," in this case. As the time is fast approaching when a large supply of timber specially suitable for tea boxes will be wanted, the wide cultivation of the *toon* tree is desirable for this and other purposes; while there are few handsomer trees for sides of public or estate roads or avenues anywhere. They flourish planted very close together. As shade trees they are excelled in Java by an acacia (*Albizzia Montana*) which becomes a grand forest tree in seven years. But the timber is brittle, and is fuel only for firewood.

From Balfour's "Timber Trees" we have obtained account of *Cedrela toona*, which we hope will be established and become largely prevalent in Ceylon. For combined quickness to grow and value of timber, it ranks with the best of the Australian *Eucalypti*.

CEDRELA TOONA, *Roxb.*

C. hexandra, *Wall.*

Tunna. BENG.	Toona. HIND. SANS.
Thit-ka-do. BURM.	Toon. MAHR. BENG.
Thundu CAN.	Kooruk „
Tunda „	Loodh? SANS.
Suola mara „	Cuveraca „
Toon tree ENG.	Toon maram. TAM.
Bastard cedar „	Wunjooli maram „
„ mahogany. ENG.	Maha timbo URIA.

This large and valuable tree grows in varying abundance at the foot of the Himalayas, also in the north-eastern provinces and to the south, in Bengal and in both Peninsulas of India. It is rare in the Central Provinces. In the Panjab it grows up to 2,500 to 4,800 feet with 7 to 12 feet in girth. Its growth is there rapid, its darkish wood is not subject to worm or warp, looks well when properly polished, and is there a favourite for cabinet work. Mr. R. Thompson says it grows to a large size in the outer moist valleys of Kumaon and Ghurwal, and hill-men will not sell their trees. In the hill provinces, it is used as posts, panels, and carved fronts of hill-houses, also, turned into milk and water pitchers. In Kumaon, trees with girths of 12 to 16 feet, yield planks up to 3 feet broad, but 2 feet is the average. Flowers white, but yield a rich yellow dye. It is said to be abundant in Travancore. A specimen of wood sent by General Cullen, as of this tree, showed the grain and polish remarkably well; it was however, of a brighter colour, and apparently of a denser quality than any met with in the market, inducing a doubt as to its being of the same species. It was stated to be abundant, 25 miles north-east of Trevandrum. It is found in the Mysore and Salem jungles in large quantities also along the crest of the ghats from Travancore to Goa. In Coimbatore, it is a valuable timber tree of large size, and its reddish-coloured wood it is used for cabinet-making purposes. It or an allied species is known also in Coimbatore under the name of Wunjooli maram; but, as this is a very heavy and strong hard wood, said to be admirably fitted for pestles and mortars and other purposes demanding great strength, but not for cabinet purposes, Dr. Wight suspected Roxburgh's toona and the Wunjooli to be different trees. Dr. Gibson reports that he had found this choice tree in one situation, viz., inland of Koorsulee; but adds, it probably exists all along close below the ghats. At another place, he says that it is not a common tree in the Bombay forests, but is found in some of the greenwood jungles about the ghats, and also in the hill range abutting on the Rajpooree Creek to the south. The wood is a choice one for cabinet purposes, but is not used for any others, except for house beams, when it is procurable in sufficient quantity. In the races of the south Konkan and lower Canara the tree is more common. It is, in as far as he was aware, never found inland. And, again, he says it grows abundantly in some of the deep ravines in western Kandeish and it grows in the ravines of the Concan. In Ganjam and Gumsur, where it is known as Mahalimbo, its extreme height is 70 feet, circumference 5 feet, and height from the ground to the intersection of the first branch, 22 feet. Under this tree's name, Captain Sankey describes a Nagpore timber as averaging 10 to 12 feet long and 3½ to 4½ feet in girth, and selling at 16 annas the cubic foot. At the Tambur river, in East Nepaul, the vegetation in some spots is exceedingly fine, and several large trees occurred. Dr. Hooker measured a Toon tree (*Cedrela*) thirty feet in girth at five feet above the ground. Southwards, Lieut. Nuthall, quoted by Captain Munro, mentions toon as one of the woods of Arracan under the name of "thit-ka-do." A tree is found, also, Dr. Brandis tells us, on the hills and on the plains of British Burmah, plentiful in some districts, and if not identical with the Toon of Bengal, certainly nearly related to it. A cubic foot of the Burmah wood weighs lb. 28. In a full-grown tree on good soil the average length of the trunk to the first branch is 40 feet, and average girth measured at 6 feet from the ground, is 8 feet. It sells in Burmah at 8 annas per cubic foot. It will be seen from the above, that it has a wide range throughout India, common in the northern provinces, where it is made into furniture of all kinds, and is much admired for its close-grain and beautiful colour, resembling, though lighter than and not so close-grained as, mahogany, to which it is deemed equivalent. It is used all over India by cabinet makers for furniture. It is called Bastard Cedar from the aromatic resin, exuding from it, resembling that of the American cedar. It is often sold in Madras under the general name of "Chittagong wood," and is the most valuable of the woods known by that commercial name. It has an erect trunk of great height and size with smooth gray bark. The flowers are very numerous, small, white, and fragrant like honey. The seeds are numerous, imbricated, winged. It seems probable that the trees known "commercially," as Toon are, at least different species; but all the woods sold under this name, are red-coloured, of varying hues. The Gumsur "*Mahalimbo*" wood, said to be this tree, and to be tolerably common, is described as not liable to be attacked by insects, and is, on that account, used for making boxes, &c. The fruit and bark are used medicinally for fever and rheumatism. The bark is powerfully astringent, but not bitter. The native physicians use it in conjunction with the powdered nut of the Cæsalpinia bonducella, an intense bitter. M. Nees Von Esenbeck has published an account of some experiments on the bark, which indicated the existence of a resinous astringent matter, a brown astringent gum, and a gummy brown extractive matter, resembling *ulmine*. The bark was used in Java by Blume in epidemic fevers, diarrhœa, and other complaints. Horsfield gave it in dysentery, but only in the last stage, when inflammatory symptoms had disappeared. Its flowers, in conjunction with safflower (Koosumba) are used by the inhabitants of Mysore, for dyeing the beautiful red colour called there Gul-i-sari. —*Roxb.* i 635 *Drs. Wight, Hooker, Mason Gibson, Cleghorn, Stewart, Ainslie, O'Shaughnessy, McCleland, Lieut. Co. Lake, M. E. J. R., Captains Macdonald, Sankey, Mr. R. Thompson, Voigt*, 137.

CEDRELA TOONA *var.* SERRATA.

Royle.

Dimri	Hazara.	Dori	Lahore.
Drab		Bisra	Panj.
Drawi		Guldar	„
Drawa		Daral	Sutlej, Beas.
Tuni	Hind.	Darali	
Deri	Panjab	Khishing,	Kanawar.
Chiti sirin	„	Khanam.	
Der. Chenab, Lahore			

The leaves of this are always saw-edged (serrated) in which alone it differs from C. toona *Roxb.* Its wood is often red but is of more open texture and lighter in colour than C. toona, and stands water well. In Kanawar it is used for bridges, and in some places the hoops of sieves are made from it. The wood has a fœtid smell when fresh: an ordinary leaf is 30 inches long.—Dr. J, L. Stewart, p.34.

THE CULTIVATION OF TEA IN THE UNITED STATES. An ingenious correspondent of the *South Florida Journal* writes to that journal as follows on the subject of tea cultivation:—"More than ten years since, I first saw the tea plant growing successfully on the ground of Dr. A. D. Bruce, of Sylvan Lake. Soon after that I requested some plants to be sent to me from the Agricultural Department at Washington, which was promptly done by the excellent commissioner, Mr. Le Due. I planted them in a soil which was a medium between white sand pine and muck, near Silvor Lake, Orange County, Florida. With but little fertilising or cultivation, they are now about four feet high, being each a cluster of dark green leaves and branches, not having lost a leaf either from drought, heat, or frost, without any protection, and having ripened seed resembling pulmetto, except that it is in pods of three or four seeds each. I have tried it repeatedly in the teapot, and while the drink was palatable it seems to *want the flavour and colouring* which the Chinese know so well how to give it. I am fully satisfied that by importing Chinese labourers tea plants of several varieties may be grown with the fullest success." The idea of American grown tea requiring the colouring as well as the flavour of China tea is an original one, which the correspondent of the *South Florida Journal* ought to have full credit for.—*Indian paper.*

A NEW PLANTING REGION:—THE SMALL ISLANDS BETWEEN MADAGASCAR AND ZANZIBAR.

BY A TRAVELLER LATELY RETURNED.

The only drawback to the cultivation of the island of Nossi-be has been the uncertainty of being able to send produce out of the country, and the length of time which has necessarily elapsed before its value could be realized. As to climate, I believe it is fairly healthy. Fever, of course, is met with, but the French officials living in Hell-ville told me that, when troops were quartered there, the health of the men was excellent. Of animal life there is but little in the island, a small black lemur being the only known mammal. Snakes are very plentiful, but I believe not poisonous. The lizard family abound, from the gigantic iguanas to little green members of the genus no bigger than a man's finger; and the quaint chameleon may often be seen assuming all the colours of the rainbow. Birds are tolerably numerous; and guinea-fowl, quail, and wild duck give sportsmen a good excuse for a walk. All round the coast fish abound, and the natives, being expert fishermen, a constant daily supply can be counted on. The bonito is the most common; but eels, shrimps, and crabs are also abundant, and in one part of the island a small but very delicate oyster is found. There is a small Arab town on the opposite side of the harbour to Hell-ville, and several good-sized native villages scattered over the island, the chief of which are Ambanonrou and Andavakontonkon. The total native population is estimated at about 12,000, and consists chiefly of Sahalavas and the mixed races of the Comoro isles. Without saying that Nossi-be is an island which will prove an El Dorado to white settlers, I believe it is a place where an energetic man with a very small capital would in eight or ten years be sure of acquiring a considerable fortune. It must be borne in mind too, that it is only one island out of many, all equally suited to the cultivation of tropical and sub-tropical produce.

Of the history of the island but little is known previous to the year 1810. In that year M. de Hell, the Governor of Bourbon, being anxious to obtain a naval station on or close to the coast of Madagascar, sent a French naval officer to Nossi-be to report on the adaptability of that island for the purpose. At this time the island was ruled by a Sahalava Queen, by name Ratsiomika, who had been driven from Madagascar by the Hawas. Not content with having driven her from her country, the Hawas were constantly making raids on her followers at Nossi-be, and on the arrival of M. de Hell's envoy she at once implored the protection of France. This was granted and the following year a treaty was made by which she ceded Nossi-be and the adjacent island of Nossi-comba to her protectors. Nossi-comba, which lies a little to the north-east of Nossi-be, contains no white settlers, though the French Commandant has a pleasant summer residence on one of its hills. There is a good-sized native village on the west side of the island, called Ampajowina. All that has been said of Nossi-be would apply equally to Nossi-comba; so I think we'll again take ship and I imagine that we have left Hell-ville far behind, and are entering the harbour of Mayotte.

This island, or rather group of islands, for the name is used to signify some seven or eight, which are now French territory, is one of the latest acquisition of the French Republic. They are situated in 12° 44' and 13° 5' south latitude and 42° 46' and 42° 48' east longitude. Here three small islands, Zaondri, Pamanzi, Bouzi, form, with the large island of Mayotte, a magnificent land locked harbour, completely sheltered from southern or easterly winds. The seat of Government is the little island of Zaondri, where all the official buildings are placed. On the large island there are a few planters who are doing well with sugar, and I noticed some paddy-fields which gave promise of a good crop. There is only one "vanillerie" at present, but that has shewn itself a very mine of wealth, and no doubt this industry will grow very rapidly. Coffee is grown on these plantations, and has been sold at Bourbon at the highest market rates. Unlike Nossi-be, Mayotte possesses no very extensive forest lands, though it is fairly well timbered. The ground, too, as a rule, lies much lower, being nowhere more than 2,000 feet above the sea level. Beautiful little streams, however, run in every direction through the valley, and any lover of a quiet picturesque scene would be enchanted with the views obtained, from different points of the island, of the deep blue sea literally studded with islets and the charming tropical vegetation in the foregrounnd. The large island contains about 32,000 hectares according to the French survey, and there are six or seven small islands lying close by, which have not yet been surveyed. Of this 32,000 hectares not more than 6 000 are under cultivation. Here, then, there is plenty of room for more settlement and every chance of making money. Sago, spices, cloves, tapioca, and cocoa could all be grown here, and with the new communications now to be opened up, these islands will be within easier reach of the European market than the Straits Settlements and Java, which at present mainly supply these products. The flora and fauna of this group are almost identical with those of Nossi-bé and Nossi-comba; the only different trees I noticed being the paupau, the custard apple, and the Bauhirea purpurea. The history of Mayotte, like that of most of these islands, is buried in obscurity. It apparently belonged to an independent Sultan as lately as 1835, and afterwards to have fallen into the hands of Abdullah Sultan of Johanna. This Abdullah seems to have conceived the idea of conquering all the islands belonging to, or lying near, the Comoro group; for after having captured Mayotte, he set sail the following year with a large fleet of *dhows* to attack the neighbouring Sultan of Mohilla. His fleet, however, was driven ashore at the latter place, and he was captured, thrown into prison, and starved to death. A quarrel between his son and his brother, as to the succession, brought about a state of civil war, and a Malagash refugee of the name of Souli assumed the sovereignty of Mayotte, and in the year 1842 handed it over to France. Since the French took possession, there has been no native trouble, and the present Sultan of Johanna is quite content to remain lord of his own small isle. Mayotte will be the terminus of the branch line of steamers at present; but as we have got so far, we will take a look at Johanna, Comoro, and Mohilla, before retracing our steps.

Johanna is situated about ninety miles to the west of Mayotte, and is of very remarkable formation, being little more than a long backbone of mountains rising in places abruptly from the sea. The harbour, on which the town of Johanna is situated, is not a good one, being very open to the north. The town itself is picturesque, walled all round, and with a fort perched on a projecting rock almost overhanging it. The population here is almost exclusively Arab, and Swahili is the language commonly spoken. There are, however, a good many slaves who have been brought over from the African coast and also from the neighbouring islands. There are only two white men living on the island, an Englishman and an American, and they live on opposite sides of the island. Both are engaged in sugar growing, and both are doing well. The crop was almost ready to cut when I saw it, and those who have only seen the cane in Mauritius would

hardly believe their eyes if they could see it in Johanna. It was certainly magnificent, in many places between five and six feet high and proportionately thick. Dr. Wilson, the American planter, has only been in the island seven years, but he has already erected a fine sugar mill, and this year expected to make between 400 and 500 tons of sugar. He has built himself a charming house on a lovely ridge about 1,500 feet above the sea, and he told me that since he had been there he had not had a day's illness. The climate, in fact, must be as near perfection as possible. In his garden he has almost every kind of tropical and sub-tropical fruit, strawberries, pines, peaches, and apples are growing side by side. He has also acclimatised nearly all our European vegetables. In his flower garden the roses were beautiful, and bougainvilleas of five or six six different shades made splendid show. One variety of a brilliant buff colour was quite new to me. About five hundred yards below the house is the native village, where all the station hands live—a curious mixed lot consisting of Comoro islanders, African negroes, and natives of Madagascar. The majority of them are slaves, but they all seem very well contented with their lot. The Sultan of Johanna is a very intelligent Arab, and is anxious to encourage as much as he can European settlement. A few of the Arab chiefs have started growing coffee and cloves, but though they have procured capital crops of both, they do not understand the proper manipulation of the berry, and consequently their products are not thought much of in Zanzibar whither they send them. I did not get over to Pomony on the other side of the island, where an English gentleman is doing well with sugar-cane; it would have been a very rough walk of about thirty miles, so I spent my time wandering about the forest in the neighbourhood of Johanna. I saw some beautiful banian trees and also plenty of ebony and sandal-wood. The hills are wooded up to the summit, and are very picturesque. There was but little life, however, in the forest, and during a long walk, I only saw a few birds of the thrush tribe, and some bright little honey-suckers Of course, as thing are at present, any one living in Johanna is cut off very much from the world. You have to depend for your post on *dhows* coming from Zauzibar, or a chance vessel from Mauritius, which may call in seeking cargo. Still it is a lovely spot, and I could quite understand Dr. Wilson when he told me that he did not think he could return and live in America now.

The other two islands of importance in these seas are Comoro and Mohilla. The former is the largest of the group, but a white man could not with safety settle there yet, as the natives are always fighting among themselves and making raids through the country. All that has been said, however, about Johanna, will be equally applicable to Comoro as far as climate goes, the chief difference being that there is much less timber on the latter island, and consequently a slighter rainfall. Mohilla is an independent kingdom under a King of Hawa descent, and there a European would receive every encouragement to settle.

The net result, therefore, of our inquiries about these islands of the Indian Ocean is this: situated in a most salubrious climate, between the southern tropic and the line, they are admirably adapted for the cultivation of sugar, coffee, vanilla, cocoa, spices, cloves, *et hoc genus omne*; many of which are pure articles of luxury, and will always command a high price in the European market. At present that market is more or less dependent for its supply on the Straits Settlements, and the distant islands of Java and Batavia. But by the facilities offered by the new line of steamships, the islands of the Comoro group and others scattered about in the South Indian Ocean will now be able to compete with the Far East on equal terms as far as distance from the home market is concerned. With regard to climate, there can be no doubt that the islands I have been describing bear off the palm. With regard to Madagascar, I have purposely said very little. Though its climatic advantages are similar to those of its neighbours, the laws of the island do not allow a European to acquire the freehold of land; so it is not so advantageous a place to go to as the island belonging to an independent chief. I certainly believe that no part of the world offers a more hopeful chance of acquiring a moderate fortune to men of small means than the islands I have mentioned. To go and live there is, of course, a species of exile, but with good luck it should not last very long, and "beggars cannot be choosers." At all events, by the next spring, it will be possible for any one who wishes to do so, to make a trip to Mayotte and see for himself. By the opening of the new line, a charming three months' trip will be provided for people in this country, who think a pleasant way of spending their furlough is seeing new countries and cruising in summer seas.—*Pioneer.*

THE INDIAN TEA CROP OF 1881.

As usual at this period of the year, forecasts of the probable crop of Indian tea are being made on all sides, apparently with the usual imperceptible effect on the Mincing-lane market. In last Saturday's *Times* we read, on the authority of the leading tea brokers, that the crop of 1881 received in London will, in all likelihood, range from 44 to 47 millions of lb., while consumption is at the rate of 50 millions. On Monday last the *Times'* telegram from India contained the announcement that in Calcutta the crop likely to be available for export is estimated at about 48 millions. The estimated outturn of 1881 has been a matter of conjecture since the close of last season, and has been in some quarters put as high as 53 millions, and in some quarters as low as 45. Whether it approaches the latter figure more nearly than the former, in the result, will be seen later on. Meantime, the market here is more likely to be affected by the way in which the tea on arrival is placed before the trade. It is a well-known fact that when more than 12 to 14,000 packages are put upon the market in one week, importers are playing in effect into the hands of the trade. The buying brokers cannot well taste more than 150 samples on the morning of the sale, and when selling brokers issue second catalogues of from 500 to 600 chests, in addition to the teas in the first catalogue, in a full market, clients and importers generally suffer in consequence. When teas are not tasted, of course, they have to be bought by the look of the leaf, and thus teas are often sold pence below their real value. It is to be hoped that, in the interest of the industry, the leading merchants will see their way to some arrangement whereby the quantity of tea to be put before the trade may, in some measure, be regulated with regard to the requirements and capabilities of the market.—*Home and Colonial Mail.*

COFFEE IN SAMOA.—A planter, formerly in Ceylon, wrote from Samoa, on the 1st Oct:—"While in Levuka, Fiji, I had an offer, which I accepted, and that was to come here (600 miles distant from Fiji) and open up some land for coffee. The offer was made by Mr. ———, partner in a wealthy firm of that name in Hamburg. It appears that coffee planting has never yet been started here, as Mr. ——— (who owns nearly two-thirds of this island) has hitherto been unsuccessful in procuring the services of any one who thoroughly understands coffee-growing; and, if you care to know how this enterprize succeeds here, I shall be only too happy to furnish you from time to time all information you may require." [Very good.—ED.]

MANITOBA FOR HARDUP PLANTERS.

A planter writes :—"I am desirous of obtaining some information about Manitoba, and shall be much obliged if you can give it. In the first place, I wish to know what is the cheapest and quickest way of getting there, and, if there is any way of getting there without going home first. If so, I should be glad to get an idea of the cost of passage. I enclose a letter from my brother who has been there a little over a year. It is in answer to one I wrote some months ago. You will see by it that, for a young man who started with almost nothing, his prospects are good. You will see by it that even a day labourer can make more than many a coffee planter. Not that I mean to run down coffee planting. Far from it. For those who have some capital, there is no life like it, but I think you will agree with me that, for a man who has no capital, but who has health, strength, and energy, Manitoba is a better field than Ceylon." We are sorry we cannot tell the exact sum which a passage to Canada costs. There are vessels occasionally leaving Colombo and Galle for New York, and by one of these no doubt our correspondent might obtain a passage at a moderate cost. We make the following extracts from the letter referred to by our correspondent :—

"You would find Manitoba a great change from Ceylon in many ways. To begin with, the climate is very cold in winter from November till March. There is no such thing as thaw, but a steady frost with a little snow occasionally. Some days are extremely cold, but the general run of the winter is similar to a hard frosty time in Scotland. The summer is a little warmer and drier than at home. I did not find the winter in any way disagreeable, but you might find it colder after living so long in the tropics. It is extremely healthy. For my part, I like the country in all respects very well indeed. You can readily understand that any new country such as this cannot have the social advantages of older countries. In my opinion, it is the best country in the world for any healthy energetic man or for men with capital. Free-grant lands are to be had in all new settlements, and land along the route of railways can be had at 10s per acre payable in instalments I have written to the Minister of the Interior to forward you pamphlets with the latest land regulations. I will tell you what I have been doing since coming here, and you will then have some idea of what your life would be here at first. I had fifty acres of grain, mostly wheat. I sowed it with a seeding machine and harrowed and rolled it all myself. I hired a self-binding reaper to cut it, which cost me 6s per acre, and stooked it myself, and with the help of one man at 8s per day for five days I drew it all in and stocked it. Threshing will cost me about 4s per acre, and the seed-wheat 2 bushels at 4s—8s, oats 2 bushels at 2s—4s, per acre respectively. The total cost of crop per acre on an average would be 17s, besides my own labor, and the yield I expect will be : wheat 25 bushels at 4s, oats 50 bushels at 2s 5d. You will see from these figures that farming pays pretty well. Potatoes and all other roots do well, but, of course, grain is our staple crop. One man can work about 100 acres of land himself, with the help of one hand in harvest. Owing to labor being so high (in some cases 2s daily) one has to do all the work himself at first, but I do not consider that any hardship. All our houses are wood, mostly built by ourselves and neighbours. Beef is, of stock we all buy well, but I have no cows of my own yet : only my horses. Butter has never been lower than 1s per lb, since I came, and the feeding costs nothing only the labor of cutting hay for winter. Cattle at three years old are selling at $30 per pair for labor and cows abut $19 each. Of course, I don't expect these prices will be so high for many years either for stock or grain, but they will always be at paying prices. Even though one sold nothing, after they are started, and all debts paid, he could live well, as we produce everything we require, excepting tea and sugar. My land is one mile from railway station, and there is wood and water in the place. The land is as good as any can be. I began with very little money and have sold nothing up to this but my income this year will be about £300, or about £260 clear cash. This will clear up anything I owe and set me on my feet. So you see it is far ahead of farming at home. At ——, where there is nearly £2,000 invested, there has not been one pound cleared for years. If I had £2,000 here, I am safe to say I could clear £1,000 yearly. Money is very dear : 12 per cent bank interest and on short convenience 15 per cent. You could start comfortably on £2 0. Many have started on less than half that amount and done well. A lazy man is no use here. Every one must be alike and work hard, when the work is to be done, but one has about six months of the year to himself only to haul and cut enough wood to burn, and feed your team, &c. The mosquitoes are pretty troublesome for a couple of months, and then the winter is colder than one could wish, but for any strong, hard-working young man, I unhesitatingly say : 'Come here.' Every one can't make a fortune, but all may make an honest livelihood. Your knowledge of business might stand you in good stead here, as storekeeping pays better than farming, if one only has the *stamps* 'to go in.' Retail prices are 38 per cent over wholesale."

SLAVERY AND PLANTING IN BRAZIL.

The first decade of the emancipation act of 1871 was completed on the 28th ult. Now that the eulogiums have all been pronounced, and the pæns have all been sung, a brief inquiry into the workings of the law may not be amiss. It is well, perhaps, that this tenth anniversary should have been celebrated with generous homage for the man, the Viscondo do Rio Branco, who achieved so much against so great an opposition. It is well, also, to give credit to the act itself, imperfect as it is, because it is a step toward emancipation, and has already broken the chains of many slaves. And too, it is well to refer to the work accomplished with words of praise and pride, and then to picture the coming of that time when the crack of whip and clank of shackles shall no longer be heard throughout this whole land. All this may be done with perfect propriety, providing, however, that the eloquium does not stop short just there. Beyond all this sentiment there is a practical record, an inner result, which should not be concealed and smoothed over with glowing figures of speech. The world will want to know the practical results of Brazilian emancipation, and the sincerity with which it has been carried out. It will want to know how many slaves have been liberated, how much has been expended, what steps have been taken to improve their condition, and how much longer it will take to accomplish the great work. This tenth anniversary should have answered these questions, but it did not. The day was honored and celebrated, but it brought forth no record of the work accomplished, no definite promise for the immediate future.

The law of free birth was passed on the 28th of September, 1871, and it provided not only for the freedom of all children born of slave mothers thereafter, but also for the gradual liberation of slaves. The total slave population of the empire, according to

the census of August 1st 1872—nearly one year after the passage of the emancipation law—was 1,510,806, but as some parishes were never heard from and as the census is notoriously defective, it is estimated that a total of 1 600,000* is much nearer the exact figure. The emancipation act itself provided for a general registry of slaves up to the 30th September 1872, and a special registry up to the 30th September 1873. All slaves not registered at this last date were declared free. Under this registry, however, which was made obligatory under fines and the granting of freedom to all unregistered slaves, the figures are fully as untrustworthy as those in the census. Even to this day the slave population of the empire at the closing of the books on the 30th September 1873, is not known. The returns as given by Veiga in his compilation of the laws and regulations relating to emancipation, and which he marks as defective, place the total registered slave population at 1,431,300, a total much below the census of the year preceding. In this last enumeration, however, the returns are given as complete from all the provinces except four—Pará, Pernambuco Minas Geraes and Goyaz. It is evident, not only from the testimony of the census, but from the occasional cases of the liberation of unregistered slaves, that this registry did not contain the total slave population at that time. As it is the official enumeration, however, and as all slaves not registered are legally free, we have no alternative but the acceptance of this total.

In 1878 another attempt was made to obtain definite information as to the vital statistics of the slave population up to the close of that year, but this effort also failed. Eight provinces and the capital, according to the last official report, compiled, while the reports from the other twelve were either incomplete, or were from statistics gathered in 1875 and 1876. From these reports the total slave population at the end of 1878 was placed at 1,419,168. On the 28th ult. the *Jornal do Commercio* published the latest statistics relating to twelve provinces and the capital—all of which are brought down to the end of 1878 except two, which are complete to the end of 1880—in which the changes of the slave population since 1873 are given as follows:—

Registered	683,497
Emancipated	24,651
Died	60,996
Registered arrivals..... ...	86,274
Registered departures ...	73,067
Present population..... ...	611,057
Relative decrease	72,440
Absolute decrease	85,647

For the period in which these changes took place, these statistics show a relative annual decrease of only about *two per cent.* The absolute annual decrease, however, is about *two and one third per cent.*, instead of the estimated five per cent. of the *Jornal*. This certainly is very far from a flattering exhibit of the operations of the emancipation law, especially when it is known that three-fourths of the manumissions are voluntary acts of slaveholders themselves. Another feature of this exhibit, which is worthy of further consideration, is the very low death rate among these slaves—it being about half that of this city. Under normal conditions one would expect to find a higher death rate in a class so badly housed, fed, and overworked.

Although the emancipation act provided for the annual application of the fund for the liberation of slaves, only two distributions took place during the first decade. The amount set apart for these two distributions—1875 and 1880—was 8,128 612 $ 309, of which 6,238,411$600 had been expended up to the latest reports. The absence of complete statistics renders it impossible to determine the whole number of manumissions under both of these distributions, the application of the fund being very slow and complicated. The *Jornal* gives the *per capita* expenditure at 700$.

All things considered we cannot see that the law of 1871 has accomplished the work anticipated. It has resulted in an approximate decrease of only 2½ per cent. per annum, including deaths, in the slave population, and it has guaranteed nominal freedom to some 250,000 children, who will remain practically in slavery until they reach the age of twenty-one years. Laying all sentiment aside, the law has partially failed, for it promised more than it has performed.—*Rio News*, Oct 15th.

* Vide *Jornal do Commercio*, Sept. 28th, 1878.

GEM AND GOLD MINING RIGHTS IN CEYLON.

General Rules promulgated December 1881.

1.—The Government will claim no royalty on or share of the gems or gold found upon land in respect of which a license has been taken out, and is in force under these rules, but such land will be liable to any taxation which may hereafter be found necessary to provide, at the expense of the grantees, the cost of such special police communication, water supply, sanitation or other similar administrative arrangements as may, in the opinion of Government, be dictated in the interests of the local community immediately or directly affected by the results of the grantee's operations.

2.—No license granted under these rules will convey any right to fell or destroy timber.

3.—No license granted under these rules will convey any right to divert any water course.

4.—Licencees who desire to divert any water course must first obtain special permission in writing from the Government Agent of the province for that purpose. Such special permission must limit the diversion of the water course to the area covered by the permission to dig, and must stipulate that all water running waste shall be returned within the limits of such area to its natural channel.

5.—The Government reserves to itself the power to alter, cancel, or add to any of the preceeding or subsequent rules.

Particular Rules: Prospecting Licenses.

6.—Prospecting licenses will be issued only for *Crown Waste Lands*

7.—No prospecting licenses whatsoever will be issued to dig for *gems*.

8.—Prospecting licenses will be issued to dig for *gold* on payment of R10 and on the following conditions:—

The area on which the license is to extend shall not exceed half a square mile.

The license shall be in force for six months.

The grantee to have the exclusive right of prospecting within that area for that period and to have the option, at the expiration thereof, of applying for a regular lease of not more than 50 acres within the said area on the terms hereinafter described.

Gemming Lands alienated by the Crown.

9.—The proprietors of lands on which the rights of the crown to gems have been reserved may obtain a license to dig for and appropriate such gems on the payment of R10 which license will be in force for one year, and may be renewed annually on the like payment.

Mining.

10.—The proprietors of private lands may obtain a license to dig for *gold* on their lands on the payment of R10, which license shall be in force till the then next ensuing 31st December, and may be renewed annually on a like payment.

Crown Waste Lands.

11.—Unlicensed diggers for *gems* on such lands will be prosecuted.

12.—Personal licenses will be issued to dig for gems on such lands on the following conditions:—area not to exceed two acres: period till the then next ensuing 31st December. Price to be R5.

13.—Mining leases will be issued to dig for gold on such lands on the following conditions:—

Area to be determined by Government as occasion arises but no lot is to exceed 50 acres, nor will more than 50 acres in all in one or more blocks be leased to one applicant. The minimum breadth of any lot to be 70 yards.

Period—a term not exceeding 20 years, at expiration of which the lease shall be renewable at the lessee's option on such terms as the then Governor and Executive Council may fix.

Price.—Prepayment by the applicant of survey fees and an annual rent of R5 for each acre or portion of an acre payable in advance by two half-yearly instalments on 1st January and 1st July in each year, the first payment to be made on the date of the execution of the lease for the then current half-year and payment thereafter to be made on or before the first day of the next calendar half-year.

General.—Government will reserve the right to resume and enter upon possession of any part of such land as may be deemed necessary for the construction of railroads, roads, bridges, or canals for public purposes, or for the benefit of the proprietors of other lands purchased from the Crown, and also the right for persons, acting under Government, to search, dig for, and take away indigenous timber, stones, cabook and other materials, the produce of such lands necessary or requisite for the making and keeping of the said roads and bridges and canals in repair or for any other public works whatsoever. The lease to become forfeited by non-payment of rent with power thereupon to Government to re-enter upon the land summarily without process of law and to remove all plant, buildings, &c., which may be thereon and lease or sell the land to others.

Departmental Rules.

14.—Applications for permission under the preceding rules should in the first instance be addressed to the Revenue Officer of the district in which the land is situated and should specify distinctly the situation of the land within which it is proposed to dig; its boundaries as accurately as can be stated and its estimated area. Every application should be accompanied by a rough sketch of the tract applied for.

15.—Applications will be dealt with in the order in which they are received.

16.—Immediately on receiving the application the Revenue Officer will ascertain whether the land is at the disposal of Government and whether there is any objection to the the grant, by reason of the land being required for public purposes, for sale, or agriculture, for timber or other reserves, for preservation of irrigating water courses, or on any other ground.

17.—The Revenue Officer shall report these matters to the Government Agent who shall thereupon determine in each case whether permission should be granted, and if so upon what conditions.

18.—The Government Agent must refer for final decision of Government all applications for mining leases and must in such cases procure the necessary survey of the property and forward it to Government, with a draft lease which will be executed in triplicate, one copy for the grantee, one to be on record in the Government Agent's Office, and one in Colombo.

19.—Application for licenses will be dealt with by the Government Agent without reference to Government, except in case where he requires instructions.

20.—Registers of applications for mining leases and for licenses will be kept in the Government Agent's Office in forms prescribed by Government.

SCIENCE IN CEYLON.

(*From the address of the President C. Branch R. A. Society.*)

GEOLOGY AND MINERALOGY.

Mr. A. C. Dixon, who is the most active member of our Society in the department of Geology and Mineralogy, has continued his visits to different districts for the study of their geological formations. The recent activity of gold-mining operations in Southern India naturally drew attention to the known existence of gold in several parts of this island, and Mr. Dixon read a short paper on the subject at our April meeting. He has since "prospected" several districts, and has been good enough to furnish me with a summary of the results of his researches. A small nugget taken near *Wakwella* (Galle) and weighing over 6 grains was tested and found to be genuine alluvial gold, which had been rolled some distance and deposited by an old stream. Careful search at the place revealed no further traces of gold. In the *Sabaragamuwa* district, Mr. Dixon visited Rakwana, North and Central Kukulu Korales and Kolonna Korale. In this district, there are several valuable deposits of gems still unworked, but no evidence of gold was found. In the stream which flows past the Assistant Government Agent's bungalow at Ratnapura further evidence has been found of the existence of gold in considerable quantities. Mr. Dixon has, however, not yet been able to explore this stream. At our meeting in April, Mr. Dixon alluded to his first visit to *Ramboda* and exhibited a specimen of gold from the district. On a subsequent visit several well-defined reefs were found, samples of which were sent to London and assayed, yielding 16 grs. to the ton. In *Dolosbage* two or three good reefs were found, but the yield here was only 4 grs. to the ton though one sample of surface quartz from the same reef gave 14 grains. In the lower end of Maskeliya valley (Thetherton) two good reefs were found. From these gold has been obtained, but not in paying quantities as yet, though the prospect of this district as regards paying gold is considered good. From *Rangala* surface quartz has been tested with a yield of 1 dwt 1½ grs. per ton. From *Hewaheta* quartz has been examined yielding 10 grs. to the ton. Traces of alluvial gold and platinum were found in the Deduru-oya. Mr. Dixon has found the reported *Mahara* gold to be *pyrites*. Specimens from a quartz reef in *Kandanuwara* contained 3 per cent of copper and the element telurium which is always found in company with gold.

CLIMATE AND METEOROLOGY.

The long connection of Col. Fyers, R. E., with our Society, of which he has been for many years President, has borne lasting fruit in the establishment of the meteorological observations which may now be considered, I suppose, as a permanent part of the work of his department. Systematic observations have been carried on under Col. Fyers' direction at the principal stations of the island since 1870. A daily weather report is now published in the Post Office Bulletin and the morning observations at Colombo, Galle, Trincomalee, are telegraphed daily to Calcutta for the storm signal service. Copies of the monthly return of daily observations and annual reports as well as diagrams giving the mean monthly rainfall for the number of years in which observations have been taken, are sent to London, Paris, Brussels, New York, Canada, Calcutta, Batavia and Algiers, and are noticed in the Administration Report of the Meteorological Department of the Government of India for 1879-80 as follows (p. 37):—

"The Island of Ceylon in which a system of Meteorological Observations has been carried on for some years under the direction of Col. Fyers R. E. communicates a monthly abstract of observations from which a selection is made for the tabular abstract given in the annual report, and I have lately included an abstract of the rainfall registers communicated to us from Singapore. Thus the extreme geographical range of the region for which Meteorological data are collected for discussion during the past years, comprises 53 degrees of longitude and 33 degrees of latitude."

The period over which systematic observations extend has been as yet too short for reliable deductions to be made from the statistics collected.

Mr Stoddart is at present investigating the subject of the very partial range of the rainfall in Ceylon, the prevalence of high winds over partial areas, and the influence of the monsoon-gales in the Bay of Bengal, and storms on the Bombay coast, and on the coast of Ceylon. In connection with Captain Donnan, he also taking observations to show the direction, force and altitude of the waves in the Colombo harbor, when the wind is in the North and North East.

BOTANY.

The parmount influence of agriculture on the prosperity of this Colony has, to a great extent, removed the department of Botany from the concerns of this Society to more open and more accessible channels of communication and discussion. The year has been especially marked by the publication of *The Tropical Agriculturist*, a monthly periodical established by the Editors of the *Ceylon Observer* constituting in the strictest sense of the word a repertory *(repertorium ubi omnia reperiri po sint)* of information on all subjects connected with tropical Botany and Agriculture. To its pages, to the Report of the Director of the Botanical Gardens, and the Reports of Mr. Marshall Ward on leaf-disease, all who are interested in this subject will naturally refer for the operations of the year. In connection with the Melbourne Exhibition, Mr. William Ferguson was good enough to furnish, at my request, a set of notes descriptive of 96 specimens of Ceylon timber sent to the Exhibition. I have sent several copies of these notes to the Government Agents, and their Assistants and to other persons to whom I believe them likely to prove useful. I will only add that an elementary Manual of Botany in Sinhalese has been prepared, and will shortly be published by the Department of Public Instruction. It will, I hope, be the means of carrying profitable instruction and amusement into many humble homes.

ZOOLOGY.

The first two parts of the beautiful engraving of Ceylon Lepidoptera with descriptive letterpress now being published by Government were received about the middle of the year, and the remaining portion of the work is expected very shortly.

A paper was read at our April meeting by Mudaliyar Samuel Jayatilaka on the honey-bees of Ceylon and the native method of bee culture. This paper derived unexpected interest from the visit of Mr. Frank Benton, an American Bee amateur, who had the intention of writing a paper for our Society on the subject of our bees, but was prevented by a severe attack of malarial fever caught whilst bee-hunting in the jungles of the Kurunegala district. Mr. Jayatilaka has stated that he got more practical information about bees from Mr. Benton in a week, than he had from all other sources in many years. Mr. Benton learned in Java that wax is imported into Netherlands India, chiefly from Holland to the annual value of two millions of rupees. The wax is, chiefly used in dyeing the sarongs and other cloths of the people. Mr. Benton's visit to Ceylon can hardly fail to be productive of useful results, as the Cyprian bees introduced by him are doing well with Mr. W. H. Wright and Mr. Jayatilaka who thinks that they are more industrious and faster workers and more tractable than our common Ceylon bees. It is stated that Ceylon bees do not seem to approach vanilla flowers when in bloom, whereas the Cyprians are found continually among them, and it is hoped that they may turn out good fertilizers, and thus save much of the labour now involved in the process of artificial fertilization. There seems to be no reason why bee culture in Ceylon should not become an industry of considerable importauce,

Dr. Vanderstraaten read at our October meeting a synopsis of a paper which he has prepared on Sericulture, illustrating in detail the process of raising silkworms. As this paper has not yet been forwarded to our Secretary for publication, I am unable to refer to it. The subject is one of undoubted interest, and I may mention that the Rev. Father Palla is endeavoring at Mount Calvary, Galle, to introduce the rearing of silkworms as an industry well adapted to the habits andinclinations of the people of Ceylon.

"THE TROPICAL AGRICULTURIST."

Mr. Bruce, in his address as President of the local Asiatic Society, is good enough to acknowledge that the paramount influence of Agriculture on the prosperity of this Colony, "had, to a great extent, removed the department of Botany" (and practical Agriculture) "from the concerns of the Society to more open and more accessible channels of communication and discussion," and he goes on to refer to the commencement of our "TROPICAL AGRICULTURIST" as a special feature of the year just closing, and to point to it as "constituting in the strictest sense of the word a repertory of information on all subjects connected with tropical Botany and Agriculture." We think the new President shews his wisdom and practical good sense in thus pointing out fields which are already fully occupied, so far as our little community is concerned. He might have added that with Ferguson's "Handbook of Information and Directory," the Government Blue Book and Administration Reports, the work of Statistical enquiry—indeed of a Statistical Society and Social Congress—in Ceylon is already being fairly well performed. There is little room for rivalry in such local work, and if the object of essays and reports bearing on the industrial condition of the people be their social and material advance, that object will certainly be best served by taking advantage of the medium of publication which secures the widest circulation and which is most generally recognized as a fitting representative. We make this remark to indicate to officers of Government —more particularly to revenue officers—throughout the island the readiness with which we shall welcome contributions to the "TROPICAL AGRICULTURIST" bearing upon the industries and material progress of the people in their districts. They will remember that our monthly periodical knows "no politics," is not a newspaper in the ordinary sense of the term (not even registered as such), and that the strictest interpretation of the "Government Minute" cannot affect such contributions We need scarcely say that the "TROPICAL AGRICULTURIST" affords far wider scope for the discussion of the subjects we refer to, than any other periodical in the East, probably in the tropics. Locally, even, it has a manifold wider circulation than any other occasional journal or periodical. It is officially filed in every kachcheri throughout the island, and we trust shortly that the Government will see their way to provide a copy for each headman in the country capable of reading English. The publication has attracted the attention of Collectors and Sub-Collectors in Southern India, and, if our application to the Madras Government is favourably received, the periodical will probably be filed in every kachcheri in Southern India. In Java, the Straits, and other colonies, East and West, the publication is gaining attention and is duly recognized in its representative character. We say all this, merely to shew that public officers as well as agriculturists in discussing the industries of the people, and 'new' and 'old products' worthy of attention, in sub-tropical regions, will have an 'audience fit' though *not* few, and one from which in return they may expect to receive valuable information and criticism. An interchange of views between revenue officers and agriculturists in Southern India, Ceylon and Java, for instance, could not fail to be beneficial. By-and-bye we may be able to arrange for Special Correspondents in different quarters of the tropical world, but meantime, so far as our little Ceylon world is concerned, we think it will be acknowledged that Mr. Bruce is right in feeling that his Society is relieved of the duty of attending to Botanical, Agricultural, or Industrial, topics, and that papers on such subjects—for example, on Silk-growing, Bee-keeping, Rice or Fruit Culture, or even Mining—will find the most fitting place in the pages of "THE TROPICAL AGRICULTURIST," which has already brought Ceylon and its enterprise so prominently before the world at large.

COOLY LABOUR FOR NORTHERN AUSTRALIA.—The Government have appointed Major Fergusson, D. A. A. G., to go to India and make the necessary preliminary arrangements for the introduction of a supply of coolie labour into the Northern Territory. Major Fergusson will very probably receive the advice and help of his brother, Sir James Fergusson, formerly the Governor of this province and now Governor of Bombay.—*S. Australia Register.*

Correspondence.

To the Editor of the Ceylon Observer.

MR. A. SCOTT BLACKLAW ON RUBBERS.

Clifton Cottage, Dollar, via Stirling, 21st Oct. 1881.

DEAR SIR,—Your people generally make pretty good work of my letters, considering they are written rather hurriedly, and the writer has no means of seeing the proofs. I must, therefore, be to blame for a mistake in the last paragraph but one of my letter, which you kindly inserted in your paper of the 17th September. It is *Pará* rubber seed I brought home two tins of, and which I sent to Ceylon on trial.

I have no doubt of *Ceará* rubber seed growing in Ceylon if it is closed in tins while in transit from Brazil to Ceylon.

They told me in Pará that *Pará* rubber seed would not grow if kept for more than a month in a dry place, and my friends in Ceará told me they had tried to grow Pará rubber from seed in Ceará, and failed. I did not get much information in Ceará regarding the collecting of the rubber. I had people working with me for the three years who were Indiarubber collectors in Ceará before the famine in the years 1877-78-79. Their account agreed exactly with that given by Mr. Cross as follows:—"The collector goes out in the morning with a basketful of cups made of clay and sun-dried and some soft clay. He makes incisions in the bark of the tree, and by means of the soft clay fastens a cup to the trunk of the tree, under the cut, taking care to form the soft clay at the same time into a channel for the juice to run with the cup. He taps a great number of trees in one day. The juice is put into a larger vessel and a piece of wood in the shape of an oar is dipped in it and held over a smoky fire. Dipping and drying goes on until a thick skin is formed on the end of the piece of wood; this skin is easily cut off. Some only lay bare a piece of the trunk and let the juice run down outside and dry as it runs." I did not see any Ceará rubber prepared for shipment, but at Pará I saw a large quantity, of what was collected up the Amazon of the Pará rubber. The best kind was in large sheets about three feet by two and about an inch thick. This was white and exactly like the white rubber in use when I was at school for erazing pencil marks. The rubber is all packed in large boxes of North American deal. The inferior quality of rubber is made in round balls the size of a man's head. Outside it looks good, but inside are pieces of bark, earth &c. sticking to the rubber—apparently the refuse gathered from the ground and cuttings from the corners and edges while shaping the square sheets of the good rubber. This inferior kind gets the name of "negro-head." It is also packed for shipment in large boxes, same as the square sheets.

In the collecting and preparation of rubber European intelligence will find out improved methods. Hitherto there has been no attempts at cultivation. The virgin forests have supplied it freely, and the natives cut down the trees in some parts to get at the rubber.—Yours, A. SCOTT BLACKLAW.

BORER IN COCONUT PALMS AND HOW TO PREVENT IT.

Johore, 5th Dec. 1881.

DEAR SIR,—I note in the report of Mr. Cockburn-Stewart, Civil Commissioner of the Seychelles, in the *T. A.*, for November that the coconut trees in those islands are threatened with destruction by the borer. We have the same here, to a considerable extent, and the only known preventative is by placing about 1 lb. ordinary salt in the top of the tree. This done twice a year has proved to be a good preventative and at the same time an inexpensive one.—Yours faithfully,

E. E. A.

CINCHONA: PROFIT OR LOSS?

Haldummulla, 5th December 1881.

DEAR SIR,—Those interested in cinchona estates would do well to consider whether the harvesting of bark is *always* profitable. Economy may be carried too far and *is*, in the practice in favor among planters; *i. e.* the collecting and barking of lopped branches or of young dead and dying cinchona trees—the bark on which is difficult and expensive to remove. The cost of this operation is of course variously estimated, but the moral is to be found in the prices obtained at the public sales held on the 20th October (vide the *Tropical Agriculturist* for December), when 2½ tons of bark realized from R0·07 to R0·29 per lb.

This quantity has gone into the market at a loss or no profit to the planter, and has tended to lower the price he can obtain for the better class of bark he may have for sale.

I have just heard of a case in point, where some 300 lb of chips and small peelings realized R2 less than the cost incurred in collecting &c. and transport to Colombo. In this case, the expenses incurred were carefully noted, with the object of testing the actual value of such young and broken bark: with the above result.

Let me commend this to those planters who study

PROFIT AND LOSS.

["'T is true, 't is pity; pity 't is, 't is true."—ED.

MR. KARSLAKE'S METHOD OF REMOVING CINCHONA BARK.

Dikoya, 6th Dec. 1881.

DEAR SIR,—I was not at all surprized when Mr. A. T. Karslake informed your readers that he had been refused a patent for his method of removing and renewing cinchona bark, and I wish he had given at the same time "the very good reasons" for such refusal. Will Mr. Karslake be so good as to tell us if the bark removed fetched the price it would have done had it been immediately dried, instead of being replaced: in fact, tell your readers what it sold for? I myself cannot help thinking that the bark so removed must be totally inert and *worthless*. This is the case with coppiced trees: all the bark on the original stem *above* the shoot allowed to grow being "dead bark," and without any market value.

Mr. Karslake must feel grateful to the present Government (the present "contemptible Government," whose mouth-piece is the Colonial Secretary,) for having saved his rupees, and the Madulsima Coffee and Cinchona Company congratulate itself on the introduction of "new blood."—Yours faithfully,

CINCHONA.

[We do not quite understand the tone adopted with regard to Mr. Karslake and his method. Had the bark, treated as he suggests, turned out inert and worthless, and had a trial of the market settled the question so, Mr. Karslake would certainly not have recommended his method for the adoption of his brother planters. Nor do we see the force of the slap at Government on the ground of the Queen's Advocate's refusal of a patent on what the party chiefly interested admits were good reasons. There are certain principles of originality, undoubted utility, etc., on which patents are granted or denied. The denial of a patent, however, does not prove that Mr. Karslake's method has been condemned. It seems to us worthy of full trial.—ED.]

NEW PRODUCTS: PIMENTO.

DEAR SIR.—I am glad to see the seed of a "new product," pimento, or allspice, being advertized in Colombo. It yields a very valuable spice, and the branches are largely used for walkingsticks and umbrella handles, and it ought to be very valuable. I believe there are one or two trees in Ceylon, and that they have thriven well. Can you kindly give me any further information on the subject?—Yours truly, PLANTER.

HOW TO PACK COCOA SEED FOR EXPORT.

Dec. 6th, 1881.

DEAR SIR,—I have, for a long time, been experimenting how to keep cocoa seed alive, with the view of importing or exporting it. I need not mention my failures. Packed seed in dry saw dust, 2nd July 1881, opened on 2nd September: seed all perfectly fresh-looking, with roots inch to inch and-half long. Plant out; keep well shaded; and water lightly.—Yours truly, COCOA.

ARABIAN COFFEE AT LOW ELEVATIONS.

6th Dec. 1881.

DEAR SIR,—"Never Too Old To Learn" could not have a better authority on clearing lantana land than Mr. Holloway. But Mr. Holloway's letter appears *to me* a little obscure. He writes: "Fifteen rupees for felling and clearing, and ten rupees for taking out roots, and burning same, per acre." Now a person might be inclined to think that Mr. Holloway means that you should pay a total of R25 per acre, but I feel certain that he only means R15 per acre for felling, clearing, and taking out roots. That is the price I have hitherto paid.

In my opinion, Mr. Holloway is the best authority on coffee cultivation at low elevations, and I can assure you from my own knowledge, that he has not in the least exaggerated the crops he has had on Maria and Eriagastenna during the last two years, as I have been over the places and have been astonished to see the same coffee bearing so heavily both years.—Yours faithfully, R.

KIGELIA, CEDRELA TOONA, AND INDIGO SEED FOR CEYLON: A THIRD CASE OF BRINGING COALS TO NEWCASTLE.

Colombo, 6th December 1881.

DEAR SIR,—Amongst the seeds brought from Java by Mr. A. M. Ferguson, was a large parcel of a thin-winged seed, the produce of a tree which he said formed beautiful avenues in Java, and which I guessed to belong to a tree allied to our satinwood. On sending a supply to Dr. Trimen, I received the following interesting note, which I take the liberty to quote:—

"I had just been harvesting our seed from *Cedrela Toona* when your parcel from Java came—another case of 'Coals to Newcastle.' Apropos of your note about *Kigelia;* the tree you remember outside the Garden gates was removed in 1862 with a vast lot of other things. We have a fine one near the pond and several smaller ones. In Kandy are several also; one in the Government Agent's garden near the Temple gate strikes every eye from the pendant 'sausages' which hang over the road. Two other genera of the Crescentieæ, *Collea* and Parmentiera (the Candle tree), are also common in the garden."

A small tree of this latter plant growing at the Whist Bungalow, now occupied by Mr. Stipperger, has been known to me for about 12 or 15 years, and I saw another some years ago at Pallakelle estate, but as I had no book in which this curious plant was described, I could not name it. Its pendant long cylindrical fruits are a good deal like dull wax candles. On sending a specimen to Dr. Trimen, I received the following note respecting it:—"The plant you send is the candle tree—Parmentiera cereifera, of my friend Seeman, who wrote an amusing account of it in one of his South American books of travel. We have many trees of it here, but I did not know it was so old an introduction. The ripe fruits are exactly like the old (now extinct) 'dip.'"

This singular plant is described in Kew Garden Journal vi., p. 273, Botany of Herald p. 132 (? 182), t. 32, and referred to in Walper's Ann. 5, p. 523, and by J. Miers in Lin. Journal, vol. 17, pp. 338-9. Found in the central parts of the Province of Panama.

But the object I had in writing was to refer to the attempts made to introduce seeds of the *Indigo Plant* to Ceylon, about one of which a correspondent in your issue of yesterday refers. I believe the facts of the case will justify the heading to this letter that this is a third attempt to introduce "Coals to Newcastle."

The indigo plant, Indigofera tinctoria, Linn., has been known to me as a common wild-like plant in various parts of Ceylon during the last forty years, and is quite common about Colombo, where it is well known to the dhobies and others as the nil (blue and green) awari, Sin. It and also the I. Anil were included in Moon's Catalogue in 1824, and the former was collected in Ceylon by Paul Hermann in 1670-1677, and is described briefly in the Flora Zeylanica of Linnæus 1747, at p. 125, No. 273. In 1857 I examined Hermann's collection in the British Museum, and found two plates and one set of specimens, viz., Ic. tt. 47 and 356, and specimens in p. 20 of vol. 2 referred to for this species. The specimens are good for the indigo plant. Linnæus expresses a belief that it was an exotic in Ceylon, but common at Paliacatta (?) and Coromandel.

When Paul Hermann collected his specimens of the indigo plant in Ceylon, the Portuguese had been here 151 years, and the Dutch, for whose Government he came on a botanical mission to the island, were here about 20 years, and if an exotic in Ceylon as hinted at by Linnæus, it was very likely introduced one hundred years before Hermann's time, but I think it is as likely to be a native of Ceylon as any part of India. I had no trouble this morning in finding specimens of the Indigofera tinctoria in good flower and fruit in the compound in front of the new Ice Company in Kollupitiya, some of which I send for your inspection.

When the Colombo lake during one period of each year gets very low, and the water in it loses its transparency, and in fact becomes very muddy, the dhobies are at their wit's ends to wash our calico or linen clothes white, and they resort to the indigo plant to somewhat conceal the color of mud imbibed by the clothes during the process of washing. The extraction of the color from the nil-awari is an easy process and well known to the washermen, who return white clothes with clouded patches of a color between mud and indigo! Talk of introducing the seed of the indigo plant to Ceylon.

I noticed several tall plants of the variety of the indigo plant known as the I. Anil, Linn., growing in the compound of the late Dr. Elliott several years ago, but it seems to have disappeared for a time.* I could write a great deal about the different plants producing indigo, some of which are also in Ceylon, but I think the following description of the Indigofera tinctoria, L., from the Flora of British India by Sir J. D. Hooker

* This is the plant figured opposite page 339 of Porter's "Tropical Agriculturist" though *Indigofera tinctoria* is written under the plate.

and others, vol. 2, p. 99, species 28, will afford all the information required by most people. You are aware, of course, that several attempts to make indigo in Ceylon have been made.

28. I. TINCTORIA, *Linn.*; *DC. Prodr.* ii. 224 (*excl. var. β*); shrubby, faintly argenteo-canescent, leaflets 9-13 large obovate-oblong, pod nearly straight 8-12-seoded not tornlose. *Roxb. Fl. Ind.* iii. 379; *Wall. Cat.* 5474; *W. & A. Prodr.* 202; *Wt. Ic.* t. 365; *Dalz. & Gibs. Bomb. Fl.* 59; *Brand. For. Fl.* 135. I. indica, *Lamk. Dict.* iii. 245. I. sumatrana, *Gaertn. Fruct.* ii. 317, t. 148—*Rheede Hort. Mal.* i. t. 54. *Fl. Zeyl.* No. 273, p. 125.

The universally cultivated indigo. Whether it be truly wild is doubtful.

A shrub 4-6 ft. high, with twiggy woody thinly silvery branches. *Leaves* 1-2 in. long; leaflets opposite, membranous, turning blackish when dried; petiole ½-1 in. *Racemes* lax, nearly sessile, 2-4 in. long. *Calyx* 1/12 in., silvery; teeth as long as the tube. *Corolla* ⅛-¼ in., reddish yellow. *Pod* ¾-1 in. long, 1/10 in. thick, glabrescent, scarcely at all recurved. *I. Anil*, Linn.; DC. Prodr. ii. 225, also commonly cultivated, a native of Americea, differs by its short congested racemes and pod turned back like a sickle. *I. flaccida* var. *constricta*, Thwaites Enum. 111, from Ceylon, is probably a distinct species, but the flowers are unknown. It has the habit and leaves of *I. tinctoria*, with a slender tetraquetrous subtornlose 4-6-seeded pod.

--Yours truly,

W. FERGUSON.

THE DIKOYA AND MASKELIYA CALISAYAS.

Maskeliya, 7th December 1881.

DEAR SIR,—The following snarl from this district appears in your issue of 5th instant:—"I should like to know why the cinchona calisaya seed was advertized as *Ledgeriana* last year and sold for R25, whilst this year it is called by its proper name *Calisaya* and is advertized at R50 per lb." Allow me to inform your correspondent that the calisayas referred to were classed as "Ledgerianas" by the highest authority in the island, at the time, and it was only after Mr. Moens' hurried and superficial inspection last year that they were said to be not Ledgerianas but inferior calisayas. This general condemnation has since been proved to have been wrong, as both on Emelina and Annfield true Ledgerianas are to be found. The news that the price has been doubled in the case of Emelina, I believe, is on account of the demand for the seed. These calisayas have been found to grow where other cinchonas will not, and from an elevation of nearly sea level, Udagama and Awisawella, to the Horton Plains. The following is an unsolicited testimonial from an experienced and intelligent Madulsima planter:—

"Lunugala, 29 h Nov 1881.

"I have by far the finest show of Annfields of any estate in Madulsima. I put a lot ont last December and they are now upwards of *four feet* high and looking well. They were planted in good *patana* about an elevation of 3,400 feet to 3,500 feet, and I have a great opinion of them and am planting 5 acres this year with nothing else."

Planters will do well to bear in mind and plant the variety of cinchona that grows best in their particular district. The true Ledgeriana *will not* flourish in a poor soil and wet district.—Yours truly,

A PROPRIETOR.

SHALL WE ABANDON PRUNING, MANURING AND WEEDING IN THE CULTIVATION OF COFFEE?

Kotmale, 7th Dec. 1881.

DEAR SIR,—It is surprizing that more planting criticism on Mr. Marshall Ward's third report has not forthcome. However, now that Mr. Talbot has turned the first sod, we may look for the assistance of a large force in clearing the way to some terminus of ideas, whence we can all start fairly. Mr. Talbot has not given us his reasons for disputing the cryptogamist's conclusion that "manure can in no sense be looked upon as a cure for the disease."

Nevertheless, he sums up his id as very pithily in the words:—"There is a good deal to be found out yet as to the best time to prune and manure, with a view to dodging the disease in July and August, and having healthy wood ready to blossom in January." Why not have said "December" in lieu of the last eight words? There *is* a good deal to be found out yet; a very great deal. In fact, everything hinges on this important discovery. But we have some hints from the report, which, though of a negative nature, are none the less of valuable assistance to us. These are to be found on page 15. The gist thereof is, that the formation of young leaves in the monsoon months should be discouraged. How are we to avoid such development? It has been the custom to commence pruning directly after crop, say in January, and this work would, in the ordinary course of events, be carried on for three months, which would land us with the whole estate pruned (allowing a good force to be employed) at the end of March or the beginning of April. Now, what appears to be wanted in all works undertaken with the view of "dodging the disease" is an impossible instantaneity. If you intend to try disinfectants, "sharp" is the word; sweep up the whole estate one day and apply your acids the next. So with pruning and manuring: the present pruning season is not the correct one; either hark back or go forward. The former seems impracticable, any period between January and August, reckoning backwards, being contemporaneous with crop operations, and forward leads us into the very jaws of the monsoon. Now is the chance for a philanthropic Phineus to pilot us between these crushing symplegades! Verily, the occasion is fleeting and judgment difficult.

But that the present crop is turning out far better than statistics warranted our calculating on, and compares (I trust my experience is the general one) favourably with its immediate predecessors, with an immediate past pregnant with ruin, and for the future the impracticable cryptogamistical remedies, our sorry song would be:—

"Ah! welladay! for we are souls bereaved;
Of all the creatures under Heaven's wide cope
We are most hopeless, who had once most hope,
And most believe-less, who had once believed."

You, sir, have told us that estates have not received that attention of late which was their annual treatment up to 1879. Can it be that the coffee, unpruned, has not put forth those enticing meals, those happy hunting-grounds of *Hemeleia*'s mycelium, and that this is the cause of our heavier crop and lighter hearts? Is it not worth while to try this simplest of experiments: whether it be or be not possible to drive *Hemileia* away entirely by minimizing our knife-thrusts into the healthy, vigorous wood, thereby starting a supply of shoots in the season most congenial to our enemy, shoots that, the chances are 99 to 1, will fall victims to the disease and drag their elder sisters with them? Similarly with injudicious, unscientific manuring, which is a delicate operation, when it is remembered what hacking of the trees' roots are entailed in it. Your ground is, from customary close planting, one network of lateral and bifurcating roots: while the tree is afflicted with bug-disease, don't go and cut off a toe here and a finger there. No wonder coffee cuts up rough after such treatment!—Faithfully yours,

POST TENEBRAS LUX.

MR. KARSLAKE IN EXPLANATION OF HIS METHOD OF REMOVING AND RENEWING CINCHONA BARK.

Mahadova, Lunugala, 8th Dec 1881.

DEAR SIR,—The ambiguities in my letter, I think, disappear, if it is borne inmiud that, in the first part of my letter, I recommended "loosening" the bark, and in the latter, where I quoted the words used in applying for the patent, I recommended "removing and replacing."

As regards suitable instruments, much depends upon the variety and age of the tree, but if the tree is healthy and the sap full up, you can loosen the bark with almost anything; but if, the contrary, nothing will enable you to make a good job of it.

I would, however, suggest tortoiseshell, ivory, horn, or metal shaped like the handle of a teaspoon for the purpose, and I daresay a piece of gut or wire fastened to a two-pronged fork, the prongs the same distance apart as the strip to be operated upon, and worked up and down would answer. There is no harm in making the bottom cut, if necessary, to facilitate operations.

The second point is important if the bark has to be left on for a long time; but this, as far as my experience goes, is not necessary. I have just looked at a tree operated on in October, and the bark removed at the end of the month, ten days after the operation. The renewed bark has had to withstand the alternations of sun and rain, and a few days' high wind and has not suffered at all.—I remain, yours faithfully,

A. T. KARSLAKE.

COST OF CLEARING LANTANA LAND.

Kadugannawa, December 8th, 1881.

DEAR SIR,—I think that Mr. Holloway pays R10 too much, at least, for clearing lantana land. The contractor who wanted at first to fell my land wanted R25 per acre, but others hearing that I wanted land to be felled began bidding lower and lower, till I managed to get it done for R12. I have at the beginning of next year to fell about 40 or 50 acres of land, which I gave out for R10; but another man will at this moment take the same for R9. My experience in planting lantana land is rather limited, but I have not yet found out that, if lantana roots are heaped and burnt, no plant grows on the spot. I am sure that the lantana here grows as thick as it does anywhere else. I enclose my address, and, if Mr. Holloway wishes to see what sort of land I have, I will gladly show it to him. KADUGANNAWA.

A CROP OF MUSTARD AS A CURE FOR "GRUB": WORTH TRYING.

SIR,—In a letter recently received from an old Ceylon planter, who has still large interests in Ceylon, the following reference to grub occurs, which may prove of interest and value to those afflicted with this pest.—Yours faithfully, V. A.

"*Grub.*—Since last hearing from you, with regard to this pest, a curious fact has been brought to my notice, which may have a value as an antidote against 'grub' in coffee. It is quite a common practice, in many parts of England, to clear the ground of wire-worm and other pests by growing a crop of mustard; which is allowed to attain a height of 8 or 9 inches, and is then dug into the soil. My gardener brought this to my notice by asking me to have it done in my garden, assuring me that it is thoroughly effectual for several years. The experiment is certainly well worth a trial, especially on estates where 'grub' works on patches. It will cost little, and can certainly do no harm. It is, I suppose, the intense bitterness of the plant which kills or drives away the grub."

THE "SACK" CURE FOR "GRUB."

Dimbula, 10th Dec.

DEAR SIR,—I believe "H. G. P." to be on the wrong track when he calls his cure for grub "suffocation." With a close covering over the ground, such as he recommends, the tender rootlets rise to the surface, and so the grub follow up for their food, and suddenly removing the cover and exposing the fresh rootlets to a dry, hot sun must in a way injure the tree. What I have tried and believe to be much better than the sack covering is to thatch the ground closely over with mana or other grass, first dibbling the ground thickly over with small holes about five or six inches deep, turning the dibble (which must have a sharp point) round and round to harden the sides of the hole. The grub come to the surface under the grass covering; soon fall into the trap; are unable to extricate themselves; and soon decay into an oily sort of substance in the bottom of the hole. I have seen as many as twenty grub caught in a hole in this manner. The practice is common enough amongst gardeners at home to perforate seed beds with small holes to catch any grub that may be about. Where mana or other grass is handy, the expense of covering is little, and being allowed to remain and rot on the ground makes a valuable addition to the soil, as well as keeping down weeds for a time. It would take about 4,000 sacks, I think, to cover an acre, which would have to be renewed twice a year. So say a stock of 8,000 bags to cover two acres and to remain 20 days on the same spot, the surface treated would only be some 36 acres at the year's end. Let my dodge be tried alongside the sack cure, and see which shows best. I have the greatest confidence in the former, and give it over free to the public.—Yours truly, X.

LEDGERIANA SEED NOT GERMINATING.

Colombo, 11th December 1881.

DEAR SIR,—I am glad to see the letter in Friday's paper signed "X. Y. Z." I bought two pill-boxes of the seed sold by Mr. Symons on or about 12th October last and paid over R100 for them. I put in the seed immediately and tended it personally—with the greatest care—for three weeks. Subsequently my manager took charge of it, and not a seed has germinated. The seed looked bad and I have no doubt it was bad. I should be very sorry to buy any more from the same quarter. You may give my name if it is asked for.—Yours truly,

ONE WHO BOUGHT AND WAS SOLD.

QUININE IN CHINA.

DEAR SIR,—On page 542 of the *T. A.*, in an extract from the Jamaica *Gleaner*, occurs the following passage:—"At the same time, a vast market is being found in China, where, until now opium has been the cheapest drug as a cure and a preventive of fever and where from 30 to 40 per cent of the population use it to their own ruin and England's disgrace."

Can you, or any of your numerous readers give me any statistics about the consumption of quinine in China and whether (which I fear is not the case) quinine is supplanting opium? I remember about a year or 18 months ago reading an article in the *Pall Mall* on the subject, but as far as my recollection goes the article dealt more with suppositions than facts.—Yours truly, W. O.

[We suspect that both the article in the *Pall Mall* and the remarks in the Jamaica *Gleaner* arose out of our own remarks in the Introduction to the Ceylon Handbook written in 1878, that a great field for the use of quinine, in place of opium, ought to be found in China. We shall watch the Consular Reports from time to time, to see if the bark or the extracts are being used in the "Flowery Land." Eventually we have no doubt China will be a good customer.—ED.]

COTTON IN THE SOUTHERN PROVINCE.

Dec. 12th, 1881

DEAR SIR,—I send a sample of cotton: it grows freely in the Southern Province. Can you or any of your correspondents give me any idea of its value per lb.—yours faithfully, A. R. WIGGIN.

[This is reported by an expert to be silky, long-stapled cotton, very similar to Brazil and Egypt and worth perhaps 7d. a lb. Sea Island cotton stands No. 1; Egyptian and Brazil No. 2 (one peculiarity of No. 2 being the ease with which the cotton separates from the seed); Tinnevelly is a poor cotton save for its whiteness which enables it to be mixed with American. But our correspondent will find it to be rather more difficult to get a good return in staple and quantity from an appreciable acreage of cotton than from a few plants, we fear.—ED.]

CINCHONA BARK.

Dec. 14th, 1881.

DEAR SIR,—Is "Cinchona," who dated his letter to you on the 6th Dec., in a position to assert that the bark on the original stem of a coppiced tree has no market value? If "Cinchona" has proved by analysis the truth of the statement he makes, his information is of considerable value, but it strikes me he is romancing.—Yours faithfully, SULPHATE.

INSECT TROUBLES AMONG TEA AND COFFEE PLANTS IN BURMAH.—Another enemy to the tea and coffee plant, and one that is to be found in all parts of India, has made its appearance amongst the experimental cultivation carried on last in the Karen hills, north-east of Tounghoo. This is the mole-cricket, and Mr. J. Petley, who was in charge of the cultivation, says in his report on this year's experiments:—"Towards the end of the rains of 1880, large numbers of the mole-cricket made their appearance and much destruction was done amongst young tea and coffee plants, killing them by nipping off the tops, principally amongst the coffee. Boys were employed to catch and kill these destructive insects." The tea plants do not seem to be attacked to such an extent as the coffee plants, for, out of 25,636 young coffee plants sown last season, over 20,000 were destroyed, as well as a large number of this year's seedlings.—Calcutta *Englishman*.

NOTES FROM WYNAAD.—At time of writing, we are all busy with crop, and, judging from reports, results are likely to be better this season than last. The Association has been so far successful as to get the Coffee-stealing Act continued to the main roads in the low country and so on to the coast, and we hope the day is not far distant when it will be extended to the entire district. Even this extension will not entirely suppress coffee-stealing, although no doubt it will reduce it in a great degree. Labour this year is plentiful: in fact some estates have too many coolies for their requirements. Tamil coolies from Palghaut and Coimbatore seem to be coming in larger numbers every year, but whether they can be really depended on remains to be seen. The Association have done and are still doing their best to get a Labour Act passed, but with no result so far. However, we hope, with the advent of a new Governor, we may at last get what is of such vital importance to us all. Most of us this season have put out cinchona, as a "fall back," the chief variety being succirubra, as most suited to our altitude. The numerous new products of Ceylon have not yet found their way here, but will do so, I fancy, in time. With regard to the gold industry, I believe that in Devala some of the companies will soon be crushing regularly. In the south, matters are not so forward.

CARBOLIC ACID.—Those to whom the smell of carbolic acid is disagreeable will be glad to learn that a perfumed carbolic acid is made which possesses the odor of lemon without undergoing any deterioration of its antiseptic properties.—New York *Hour*.

PERUVIAN BARK.—India (says a home journal) is rapidly coming into the market as a competitor with South America in the supply of Peruvian bark. The amount sent to the London market in 1879-80 is divided as follows:—

	lbs.
Colombia	6,002,330
India and Ceylon	1,172,060*
South America (except Colombia) ...	959,030
Jamaica, about	21,140
Besides Java, for the Amsterdam market	70,088

COFFEE ADULTERATION.—Mr. W. F Courthope has kindly forwarded us at Mr. G. Wall's request, a cutting from the *Evening Standard* of 17th Nov. in which it is stated that a grocer had been fined for selling coffee that was 90 per cent chicory, and butter that contained no butter at all. In the letter in which Mr. Wall enclosed the cutting, he writes:—"At the food exhibition at the Agricultural Hall last week, I saw *date* coffee, coffee *extracts* (any number), *French* coffee, *dandelion* coffee, all sorts of so-called *coffee*, except real coffee, of which I saw only *one* poor neglected miserable dishwith about half a pound of roasted beans, a sort of scarecrow amongst the flashy piles of attractive canisters full of abominable shams. So it is."

COFFEE IN FIJI.—A Taviuni planter writes:—"As regards coffee we are in a transition period just now, some estates are doing or showing well, others poorly. I am erecting a pulping-house and store on the estate and curing-mill at Wairibi on the coast. There must be something definite as regards coffee in Fiji said soon. On open well-ventilated estates, comparatively sheltered from the prevailing south-east and north winds, the *Hemeleia vastatrix* is a myth. The black bug is the prey of a small ant. Such good fortune may be the precursor of some dire misfortune, *e. g.* a fall in price of the commodity. I enclose a few beans from last year's maiden crop." [Good, clean parchment of a fine colour, but small.—ED.]

MINNESOTA EARLY AMBER CANE.—In a Madras Government paper is published a letter from Mr. W. R. Robertson, Superintendent of the Government Farms, to the Secretary of the Board of Revenue, acknowledging the receipt of few ounces of "Minnesota Early Amber Cane" seed, and stating that this variety of Sorghum had already been in cultivation on the farm for about two years. Half a bushel of the seed was presented to the farm by Messrs. Allen and Co., of New York, and was received in May 1879. The results obtained with a portion of this seed in the Experimental Grounds were satisfactory, seeing that it was "imported" seed. The crop was grown entirely as a fodder crop, and no estimation of the amount of saccharine juice in the canes was made; but they did not seem sweeter to the taste than the canes of ordinary Sorghum. From the produce of this plot another plot was sown in the Experimental Grounds in August 1880; and on the farm one or two plots of land were sown with this crop and treated as ordinary crops, but the average outturn was small, about 250 lb. of grain and 2 tons of straw per acre. Mr. Robertson adds:—"At the present time, we have two small plots under this variety of Sorghum. I intend to crush the whole of the canes and to convert the juice into jaggery and sugar. The results of these experiments I will communicate in due course as well as those obtained with the packet of seed received with the proceedings under reference."

* Ceylon alone sent 1,204,197lb in 1879-80 to London! —ED.

IRRIGATION IN MAURITIUS.—Government is introducing an ordinance to facilitate irrigation enterprizes, the draft of which has already been submitted to Council; and we may remark that the law, if carried into effect, will have the result of enabling individual sugar planters to do a great deal in the way of irrigating their own estates.—*Mercantile and Commercial Gazette.*

SPONGES are now grown by cutting small portions from the parent sponge and fixing them under water by skewers on a sandy bottom. They at once begin to grow, and are said to be ready for the market in three years. In the experiment made abroad, 4,000 sponges were grown at a cost of $50, and successful experiments of the same kind are now being made on the coast of Florida.—New York *Hour.*

TEA.—The attempt made by a Calcutta Syndicate to introduce Indian tea into Australia has proved highly successful, so far as Melbourne is concerned The *Indian Tea Gazette* states that no less than 671,000 lb. have been sold there up to the 30th June 1881, and the Syndicate alone proposes this season to send about 400,000 lb. to Australia. The efforts to introduce Indian tea have so far been only strikingly successful in Victoria, but the other colonies will no doubt follow. The Syndicate is now directing its attention to the United States, where, owing to the demand being for green and semi-green teas, such as Oolongs, it is to be feared that more difficulty will be found than in the case of Australia. It would appear that Russia, a hitherto untried field, was a much more hopeful one, especially for Darjeeling and other fine hill teas, which if introduced would no doubt sell exceedingly well there. The Russians are not only great tea-drinkers, but are real connoisseurs and prepared and accustomed to pay very high prices, so that the finest Indian teas would probably be better appreciated there than anywhere else. These attempts to open up new markets on the part of a Syndicate of planters and merchants, aided by a Government subvention, are highly interesting, and, indeed, admirable adaptations, of comparatively small means to a highly important end An individual could not afford to venture on an unknown market. but an association, especially backed by Government, can readily do so, and can afford to risk an immediate loss in the hope of opening up a new demand. They can also bulk the tea and feed the new demand with regular small supplies, till the usual trade inquiry is created. The Indian planters can hardly be urged too strongly to seek fresh outlets for their produce. The cultivation of tea seems to be spreading rapidly through the tropics, while the demand does not increase in proportion. In this country the low prices of the past few years have made 2s per lb. the chief retail price, and an increasing quantity of tea is sold at that exceedingly low quotation. With a duty of 6d per lb. and the cost of carriage, delivery, packing, paper, string, &c., together with the profit of the wholesale and retail dealers, this looks as if in a few years the average selling market price of Indian tea here would have to fall to 1s per lb—fine tea, of course, fetching more, and common tea less. This is a serious outlook for the Indian planters, but steadily faced it can doubtless be overcome, as other difficulties in India have been. It has constantly to be borne in mind that good sound ordinary China tea can be laid down here at a profit at a selling price of 8d. per lb. while all idea of such tea being adulterated should be dismissed as baseless. The *Produce Markets' Review*, from which we take the above, being issued by a firm of tea dealers, we can scarcely be surprised at the concluding paragraph. We may, however, offer our own opinion for what it is worth, that good, unadulterated tea is sold at 8d per lb. either the grower, the middleman, or the merchant will be ruined. Profit at such a price is impossible even to Chinese.

SALE OF CALISAYA LEDGERIANA SEED by Mr. C. E. H. Symons at public auction, 13th Dec. 1881 :—

[or about R310 per ounce.—ED.]

COPPER ORE IN CEYLON.—Mr. A. C. Dixon writes :—"I do not know whether you remember a specimen sent to you some time ago. I said I thought it was iron pyrites: it was much tarnished; and afterwards you said some authority called, and said it looked like a manganese ore which he had seen in Spain. I tested it yesterday and find it to be peacock copper ore containing over 20 per cent of copper with iron and sulphur. Can you tell me what locality it came from?" The sample referred to must have come to us some four to six months ago, and unfortunately we cannot now trace it. The specimen was finely variegated like a peacock's tail. Who has got the copper deposit or reef with 20 per cent of metal—more valuable than most gold mines?

RAPID GROWTH OF THE BLUE GUM IN CEYLON.—Unless it be on the rich-soiled, moist mountains of Fernshaw, Gippsland, and similar localities, the *Eucalypti* grow much more rapidly in the hill region of Ceylon than in their own native habitat in Australia, or even Tasmania. We have *seen* trees of this species growing so frequently at an incredibly rapid rate, that we are not surprized at what a planting correspondent writes, thus :—What do you say to the following growth of a blue gum tree on this estate? The seed was sown in the nursery in October 1879, and the plant was put out in August 1880. I measured the tree this morning, and found it about 27 feet in height and 18 inches in girth, about a foot and half above the ground. If only our "Ledgerianas" would grow like that!

TEA CULTURE IN AUSTRALIA.—With reference to this subject a Sydney journal, *Town and Country*, has the following paragraph :—The tea plant was introduced and cultivated in Sydney more than fifty years ago. It was from this first introduction that the plant was first distributed throughout this and the neighbouring colonies, although, more recently, fresh importations, claiming to be the first, have been made. There have been large quantities of tea seeds produced in many Sydney and country gardens for more than forty years past. In the year 1846 or '47 a fine sample of tea of Sydney growth was exhibited by Mr. T. W. Shepherd at one of the Horticultural Society's exhibitions. It was prepared from the very young leaves, and had the appearance and flavour of what is known as gunpowder tea. A sample of the latter which cost 16s per lb. in China, was shown with the colonial-made sample, and there was very little difference either in appearance or taste. This, we presume, was the first sample of tea made in Australia, and publicly exhibited. The honour has been claimed for persons in at least two of the sister colonies, both as to the introduction of the plant and the preparation of the leaves. The plant might be grown in every garden in the colony where the climate is not colder than will suit the orange tree. The best teas in China are gathered in mountain districts, in the valleys and slopes formed by mountains whose summits are sometimes capped with snow. The plant is hardy at Melbourne and Hobart, as well as Sydney. We need scarcely repeat our belief that without Indian labour, and even with that labour, Australia is never likely to grow its own tea.

TEA.—A project is on foot, and runs a fair chance of success, pushing for the sale of Indian tea in the bazaars. At present natives of India—those, that is, who are in humble circumstances—buy such tea as they drink by the ounce. They cannot get Indian tea in this way; and it is Chiua tea, of the poorest quality, which they consume. Mr. O'Conor, in his trade report, reckous that of the three million pounds and more of Chiua tea imported last year into this country, the greater part was taken by natives. By making up the cheaper kinds of Indian tea in small quantities, the China article, might in time, be driven out of the market. This additional outlet for the produce of Indian tea gardens is one which has b en too long neglected.—*Pioneer.*

"REAL TEA," describ d iu the following paragraph, is a favourite hot weather drink in Aurstralia, very silightly alcoholic and very refreshing:—Tea d inkers are not likely to grow enthusiastic over the beverage made in the manner described by Colonel Irly, one of the first Englishmen who ever visited the Karakorum Pass. Now took place a very curious and important operation—the brewing the real tea—not the "make-believe" as the Marchioness styled the choice liquors she concocted for Dick Swiveller. The tea being immersed, a ladle of ghee is put in. and four or five table-spoons of salt added: then much stirring and mixing takes place, a curious implement beiug used to froth the beverage, like what in the navy in my younger days—perhaps, the very name now forgotten—was called a "swizzle-stick," which by rapid revolution between the hands, aerated the grog in the tumbler, giving it a pleasant sparkliug appearance and freshness of flavour. Many a time I applied it in my first voyage from England to Hobart Town, via Canada, instructed by the veterau purser Tucker; and a by no menns contemptible beverage it made in tropical latitude at eight bells. Well, the t a well mixed, and frothed, and repeatedly tasted, was laded out to the anxious party, and much relished.—*South of India Observer.*

INDIAN TEA: OUTTURN AND DISTRIBUTION OF CROP.—SEASON 1881-1882:—

Regading the crop of the preseut season the following figures, supplied by the Hon. Secretary of the Tea Associatio, show that the amount available for export to Great Britain will probably not exceed 45,000,000 lb.

Crop 1880	46,569,631 lb.	
Increase in 1881.	500 000 ,,	
Total crop 1881	47,069,681 ,,	

This quantity will be distributed as under:—

Australia and Colonies ...	1,250 000 ,,	
Local consumption ...	750 000 ,,	
Great Britain	45,000,000 ,,	
	47,000 000 ,,	

The above figures, which we take from the *Indian Tea Gazette*, excite our surprise in as far as they refer to the consumption of Indian tea in India. Only three-quarters of a million of lb. for 250 millions of people*! Surely, there must be some mistake, for, years ago, estimates for local consumption were as high as two millions, not including China tea. The masses in India are, no doubt, poor, but there must be many millions who can afford to use tea and who ought to be encouraged to use it The figures are to us most disappointing if they are really reliable. Surely the 200,000 or more Europeans in India consume half the quantity estimated.

* 3 million lb. China tea are consumed.—ED.

A BEETLE EATING THE LEAVES OF LIBERIAN COFFEE BUT REFUSING TO FEED ON THE LEAVES OF C. ARABICA.—From a Liberian coffee estate about seven miles south of Henaratgoda station we have received a beetle mottled with white, with this record of his poings:—"The beetle feeds on the coffee leaves: the plant from which I took it was reduced to tatters. They are not very common in this part." The poochie having been submitted to our entomological referee, that gentleman sends the following reassuring report:—"I know the beetle well. It is one of the *elaters*, resembling *Al us mœrens*, described by the Rev. J. G. Wood in his 'Insects Abroad,' page 157. The specimen sent from Henaratgoda declines to eat the leaves of Arabian coffee that I supply it with, but perhaps the coffee at Henaratgoda is Liberian." Our correspondent judges correctly, and (unless confinement in a matchbox took away the beetle's appetite) we may conclude that the large leaves of Liberian coffee are more succulent and agreeable to insect taste than are the smaller leaves of the Arabian species.

THE NEW METHOD OF DECORTICATING THE RHEA (China grass) plaut ought not properly to be spoken of as a process involving the use of machinery. At any rate the machine required is nothing much more complex than a kettle of hot water. In fact, inventors have beeu looking up to the stars for a solution that lay at their feet. Whilst Government was gazetting resolutions and stimulating the activity of experts by the offer of handsome rewards, which brought forth a variety of more or less ingenious failures, no one seems to have tried the simple process of mere super-heating by steam—a process which is now found to be absolutely successful. Unfortunately for the man who hit upon this expedieut, his discovery is of such a nature that it cannot be successfully protected by patent. A Mr. Anderson, of Belfast, has however, perfected a process of greatly improving the fibre, which has been patented already, aud the joint result of these processes will probably be to give a great impetus to the demaud for Rhea, which China very imperfectly meets. and for the growth of which many parts of India are admirably fitted.—*Pioneer.*

MADAGASCAR RICE.—A Madras Government paper publishes a dispatch from Lord Hartington regarding samples of paddy and rice produced from Madagascar seed cultivated at the Government Farm, Madras, and inclosing valuations by two London firms of brokers. One firm reports:—"A. Madagascar paddy: bright and clean, but wanting in plumpness. Value about 6/ per cwt. (the freight would be a heavy item in importing rice in this form as paddy is usually charged at 15 cwt. to the ton for weight). B.—Very imperfectly cleaned rice: value for starch-making 8s 6d per cwt; it would have to be recleaned for eating purposes. C.—Fairly cleaned rice from paddy unhusked in boiling water: value 8/6 per cwt.; (there is an unusual demand for this sort of rice just now). All the samples much wee illed." The other firm says:—"A. Madagascar paddy:—This is difficult to value as the amount of paddy is unknown, but we should think it would be about 25 per cent; in that case the value would be about 6s to 6s 6d until a portion had been cleaned. It would be impossible to give a nearer quotation. B.—Madagascar rice, raw:—Badly weevilled; value 7s to 7s 3d per cwt. C.—Madagascar rice, boiled:—Considerably weevilled; value 7s 9d to 8s per cwt. The samples B C being weevilled would, in the process of cleaning, break very considerably, and for that reason we are afraid to quote a higher valuation. The present prices of all rice on the spot are low, and distant shipments of soft grain rice (Rangoon, Basseio, &c.,) are about 9d per cwt. dearer than spot values, chiefly owing to the unfavourable harvest prospects. We think, therefore, that during the next two or three months we mayreasonably expect better prices."

POSITION AND PROSPECTS OF INDIAN TEA

Of the great improvement in the market for Indian tea there can be no doubt, and the figured statements in the article which we today quote from the Indian *Statesman* vividly indicate the rapid change of taste in England for Indian in preference to China tea. In recently writing on the subject, we attributed much of the increased demand for Indian tea to the low prices at which the article had been selling for several years back. But we suppose the writer in the *Statesman* has authority for his assertion that a great deal of the revolution in public taste is due to sustained efforts made to place Indian teas within direct reach of the consumer, instead of the latter being, as previously, dependent on interested middlemen. Both causes and others also have, no doubt, contributed to a change which in itself and in the present, but much more in its promise for the future, is calculated to be most cheering to those interested in the strong pure teas of India,—and let us add Ceylon, for OUR turn *will* come. The change in 11 years in the relative consumption in Britain of China and Indian tea is very remarkable. In 1871 the quantity of Indian consumed on an average per month was represented by 1,141,000 lb. [In the *Statesman* the sign £ is used, but evidently lb. were intended.] This average monthly consumption increased steadily during the whole period until, in 1881, the figures rose to 4,052,000 lb. In the same period the history of China tea has been that in 1871 the monthly consumption was 9,135,000 ; in 1879 it had risen to 10,546,000 ; next year it fell by very nearly 1 million pounds per mensem, while in 1881 the figures were down to 9,301,000 lb., or only a quantity slightly in advance of 1871. Of 10,294,000 lb. of tea consumed in each month of 1871, no less than 9,153,003 was from China, and only 1,141,000 from India. In 1881 the average monthly consumption had increased by more than 3 millions of lb., the figures being 13,353,000 ; of which 4,052,000 lb. were Indian teas, against 9,301,000 lb. China. That is to say, while only 11·5 per cent of the tea consumed in 1871 was derived from India, in 1881 the percentage of this kind had risen to 30·2, or not far short of one-third, instead of only a decimal over 11 per cent. The total consumption of tea of all kinds in Britain had gone up, it appears, from 2 600 lb. per head in 1860, to 4·571 in 1881 : a nearly doubled quantity. But, while in 1860 Indian tea was represented by only the decimal ·033 lb., against 2·622 China, in 1881 the proportion of Indian had risen to 1·379 lb. as against 3·192 China. Of every pound of tea consumed in 1860, the merest fraction (scarcely appreciable) was Indian ; in 1881, out of every pound consumed, very nearly one-third was Indian, and the prospect is (looking at consumption in 1882) that this proportion will now go on increasing until the relative positions of the two descriptions of tea are entirely reversed, and the old China "thea" which figured so largely in the commerce of the famous East India Company takes rank below the produce (mainly) of the indigenous plants discovered only half a century ago in the jungles of Assam and cultivated there and in other parts of India. Indian tea planters are benefiting and will benefit by the change, and no effort should be wanting on the part of Ceylon tea planters and manufacturers to derive their full share of the favourable crisis. It is not mere faults in preparation we have to contend against, but the d termined prejudice of a portion of "the trade." But we shall conquer all obstacles, including this prejudice. The Indian planters have had a hard battle to fight against tradition, interest and calumny. But they have persevered to see victory crown their efforts.

NORTH CEYLON (JAFFNA) PRODUCE.

(*C. Patriot.*)

CHILLIES.—We are glad to find that there is a good demand for our Jaffna chilly at the market of Galle and Colombo, to which places we are daily exporting it.

COPPERAH.—This being wet weather we cannot cure coconut into copperah, but we are sending coconuts in husks to Akyab ; our vessels that go to buy grain, take out coconuts thither.—*Com.*

COLLU OR HORSE GRAM.—This was once very extensively cultivated in the Pachchellapally district ; but now the owners of land have found it more advantageous to utilize the soil for tobocco, and we are now importing collu from India.

GINGELLY SEED.—There was a time that we grow sufficient gingelly seed to meet our local demand and we exported it to India from Mannar and Trincomalee to meet the demand of some of the adjacent ports of India, but this year we are importing a large quantity from Negapatam for our home consumption.

JAFFNA GRAIN MARKET.—As already noticed, on the Prince of Wales' birthday four vessels arrived with grain from distant ports such as Akyab in Burmah, Coconada and Musulipatam. There has been an import in that month of nearly sixty-thousand bushels of paddy, besides about 6,000 bushels of rice, which is just one-tenth of the quantity of paddy imported. While almost all the ports in the Northern Province are shut up during the monsoon the Jaffna ports has earned nearly ten-thousand rupees in November. Paddy is selling at R1·25 ; the best samba rice keeps up its price at R9 per bag. There is not the slight fear that we shall run short of grain during the wet weather, as we did in former years. There is plenty in the market. Chetty traders are hesitating to import largely, lest the market price should fail and make them losers.

OUR TOBACCO TRADE.—Notwithstanding the exorbitant rate of import duty levied upon our tobacco sent to the Indian markets, such as Cochin, Quilon, and Travancore, yet we should consider it as a great boon that our staple article of export sold in those markets. There will be no knowing what to do with the tobacco we grow if those markets are shut to us. There are two sorts cultivated and grown here, that sort from which cigars are made is only grown in the Mannar and Pachchelapally districts ; and what we grow is not sufficient to meet the demand for home consumption and for export coastwise to the Colombo and Galle markets, although the extent of land under cultivation of the latter sort of tobacco is increasing yearly. This is certainly good news. But the other sort is grown all over the Peninsula of Jaffna and the several Islands, and is sent out in an unmanufactured state to Colombo, Galle and Kandy, but since the failure of the coffee crop the consumption in those places has been much reduced. During this month we have sent out a very large quantity of tobacco to the Indian markets and coastwise to Colombo and Galle. There was a time our own countrymen traded very extensively in tobacco and made their fortune but now they are trading on the capital borrowed of chetty traders. After deducting interest, discount, and compound interest there is hardly any margin of profit left. Even many of the chetties who carry on this trade sustained heavy loss last year.

CINCHONA CULTURE IN MADULSIMA.

Our attention has been attracted to Mr. Symons' analyses of cinchona bark taken from trees only two to three years old on Coeogalla estate, Madulsima, as follows :—

"Copy of analyses of Coeogalla cinchona barks, November 28th, 1881 :—

Ledgeriana	...	...	4·416
Officinalis	...	...	1·433
Condaminea	...	...	2·233

all 2 to 3 years old barks. C. E. S."

There can be no doubt of the very promising character of these analyses, but we do not quite understand the distinction drawn between "officinalis" and "Condaminea." Does the latter term in this case refer to the fast-growing, robust "hybrid," as Dr. Trimen inclines to consider it? If so, its superiority to ordinary crown bark is here very marked.

NEW PRODUCTS IN CEYLON.

LOWCOUNTRY, 12th Dec. 1881.

A quarter has elapsed since my last report. My planting operations in the interval have been almost *nil*. Now that I find we have had such a wet season, I am heartily sorry I did not plant for the N.E. rains. The failure of the south-west monsoon deceived me. Every interval of bright weather I looked upon as the end of the rains, and so on from day to day, till we have now reached I fear the tail-end of the wet season. In spite of the season being so wet, and it being spoken of as a most favourable one for planting operations in the lowcountry, I have been most unsuccessful with my south-west monsoon planting. In the intervals of fine weather we have had, the sun shone with a fierceness that entirely scorched the heads of my plants that had been for months in the ground, and which I fondly hoped had established themselves sufficiently, to be proof against hot weather for a long while. My experience of planting in the lowcountry, though short, has been in what is generally called a favourable season, and, if, in spite of the season being favourable, I was so unsuccessful in my planting, I think I can safely attribute my want of success to planting new products without shade—natural, overhead shade. As far as shading with twigs, ferns, &c., was concerned, my plants were amply shaded ; but I am convinced this does not make up for tree shade. If I had the planting of new products in the lowcountry, I would, when felling, clear only the undergrowth, and such big trees as were too close to each other—the shade trees, if in a cacao field, to be permanent, with occasional lopping ; if in a field of Liberian coffee, to be gradually removed from the 2nd to the 3rd year of the planting. The patch I last reported as being planted with cacao, and quincunxed with Liberian coffee, and which was coming on tolerably well, is now all but bare. In spite of repeated shading, the week of hot scorching sun we had towards the middle of October played sad havoc with these plants. Castor seed for shade I planted three or four times over in this field, but the young plants only served to afford amusement to crickets in their destructive propensities. When next I plant this field, I intend to shade it with manioc cuttings stuck at intervals, or with a brinjal plant put down about 12 or 15 inches from each cacao plant, so as to completely overshadow it in a short while. The brinjal plants can be thinned from time to time as occasion requires. In the meantime, I am providing for permanent shade with fruit plants, which, as they grow up, will serve as supports for vanilla creepers; so that this field will be a cacao walk, orchard and vanillerie combined if my planting proves successful. My tea plants are already in the Liberian coffee patch where I intended planting them, and are doing exceedingly well. I have not as yet discovered one failure, and I attribute my success mainly to using two clips of bamboo, or what is commonly known as Phipson's transplanter, in pulling up my plants. I can recommend this as a cheap and efficient transplanter. Bamboo has only one drawback, its thickness, which occupies too much space. I purpose getting a transplanter made, something like a garden trowel, only not so broad, for then too much earth will be removed with each plant. A pair of these and paper cones to receive the plants will be as efficient, and a far cheaper transplanter than any yet invented. As far as I can judge, the cinchona plants I mentioned as having been planted in a narrow belt of jungle have made no progress at all, even in this weather. The plants in the nursery too are mostly all dying out ; so that I fear that does not make up for want of elevation. I have taken in my crop of tobacco. Its sale will settle the question whether cultivating this product on a small scale will pay. I very much fear it will not. Curing is a slow, tedious, and consequently costly operation. I think this cultivation ought to be undertaken on what is known as the *gowiya* system. By that the owner of the ground must prepare the ground for planting and contribute half the labour towards planting. After that he has nothing to do but to wait till the crop is cured to get his half-share. Each *gowiya* is supposed to be able to tend only 500 plants : that is water and manure them. Watering I must say is a very costly operation. I was to a great extent saved the cost of this by timely rain. What I want greatly to learn is a proper mode of curing. The native style is at the best defective. Though I appealed directly to Messrs. Macartney and Bisset in my last for a few hints, none have been given. Am I to infer that they wish to keep the special knowledge they have acquired to themselves? I am likely to prove no rival to them, as I have barely an acre of ground to grow tobacco in. Let me again ask these gentlemen for a few bints on the style of cultivation and curing.

SOUTH COORG, 28th Nov. 1881.—I have to thank your Maskeliya correspondent for the information regarding his cinchonas. I do not expect ours will equal his, at the same age, as we have a long and trying dry season to contend with, when, for a time, all vegetable growth seems to beat a stand still. It is very satisfactory, however, to know we have no cause for complaint. The weather, at all times much abused, has during the past two months been censured in the strongest, and, at times, not the choicest language, the proverbial oldest inhabitant never having experienced its like. Not being the "proverbial old man," I simply take the past five years of which I have authentic written record, and find the past October has been the dryest of any, excepting 1876. The total rainfall was only 1·51 inch, against an average of 5·446 for past five years. Whilst October was the dryest, November has been the exact reverse. During the past 18 days the sun never once showed his face, and on 16 days we had rain, the total being 8·19 inches. This is far above our average, which is only 1·342 for the whole month. With this we are still nearly ten inches below the average, and that amount tells greatly where the average is only 54·536 for the year. We can expect but little in December, the average for which is 2·86. The result of short rainfall is already telling at our pulping-houses : many estates being short and several with none, so that the crop has to be carted to some more favoured estate and cured there. Crops are ripening fast, and as a rule are to be well up to estimates, some few being over. This variance is alike pleasing to proprietors and itinerant agents. The average rate for picking has been about two annas for a heaped box 14" cube, but there is a tendency

to raise this to 2½ annas. Curing during the early part of the month was rather difficult, as we have no drying sheds; and, as most of our drying grounds are in ravines and surrounded by shade trees, we are dependent in great part on the sun. A scanty supply of water is the great drawback in South Coorg. In some notable instances there is barely sufficient for the coolies and the little there is, is of the very worst description, nccessitating filters at every bungalow and a supply of clearing nuts (*Strychnos potatorum*) with the more careful of the coolies. Leaf disease is gradually disappearing, leaving our chicks in most cases leafless, and the more hardy Coorgs little the worse. On some clearings I have noticed a good deal of ringer, but nothing to alarm us as we are quite prepared for all these contingencies now, "borer" having taught us the necessity of always having large nurseries; and no matter how large they are, somehow the plants are always used. In some cases, however, they are exchanged for rupees, much to the profit of the seller and at times dead loss to the purchaser. In your last *Observer* I notice some land sales. The prices have gone down greatly from what they were five years ago. In Coorg the price has been steadily rising, the highest figure for a block of any size being about R120 per acre. Coorgs ran the price up I believe, and in every case where an application is made to Government for waste land some one or other of the ryots manages to have what he considers a claim: often imaginary, nevertheless vexatious. We have a so-called Coffee-stealing Act, but it is a mere sham compared to the Ceylon one, loads of coffee being purchased in smalls from our coolies on bazaar days, who when once in the receiver's hands are mere tools, knowing the consequences if blown on, yet afraid to "peach." We hope for a change and big crops next year, the estates being in splendid form.—BAMBOO.

THE PROSPECTS OF INDIAN TEA.

(Friend of India.)

With the beginning of the present year the prospects of Indian tea began to revive, and while considerable doubt existed in the minds of many well qualified to form an opinion as to the cause of this revival, and as to the likelihood of its permanency, all were agreed that at the moment the change first showed itself, the prospects of the industry could not well be worse than they were, and had been, and that any change must therefore be for the better. We might have been sure that the improvement was a permanent one, because it was based on sound principles. For years past an effort altogether unworthy of tea planters was made to introduce Indian tea to the English public by a side wind, by mixing it with China tea, and thus gradually educating the English taste. This we have all along felt was a great mistake, and we persistently advocated the plan of establishing a system of retail sales in such a manner as would dispense with the services of the middleman. By this mode the tea would have reached the consumer pure and unmixed, and we never had a doubt that Indian tea would very speedily assert its superiority. Latterly this plan has been followed. In most of the larger towns agencies were opened, selling tea in original packages from India, these packages being of a size suitable to private requirements. The result which we felt sure would follow has been achieved, and the taste for Indian tea is now rapidly spreading. Tea cultivation and manufacture are of such a nature that it is impossible—except to a very limited extent—to manufacture in such quantities as the market requires, and unfortunately the extensions made from 5 to 10 years ago led to very materially increased production, which told in the market in the shape of heavy stocks. These in turn kept down prices, and disheartened planters. Extensions for the past three years have been on a much smaller scale, and we may therefore expect that the exports to Great Britain will not increase in the same rapid ratio; stocks will fall—in fact, are falling—and prices will resume their wonted rates. The increase in recent months is remarkable, and will best be illustrated by the following table—

MONTHLY CONSUMPTION.

	Indian. lb	China. lb	Total. lb
1871 ...	1,141,000	9,153,000	10,294,000
1872 ...	1,388,000	9,362,000	10,750,000
1873 ...	1,506,000	9,494,000	11,000,000
1874 ...	1,503,000	9,949,000	11,452,000
1875 ...	1,868,000	10,253,000	12,121,000
1876 ...	2,145,000	10,282,000	12,427,000
1877 ...	2,321,000	10,385,000	12,606,000
1878 ...	3,062,000	10,079,000	13,141,000
1879 ...	2,841,000	10 546,000	13,387,000
1880 ...	3,653,000	9,561,000	13,214,000
1881 ...	4,052,000	9,301,000	13 353,000

It will be observed that the consumption of Indian tea has steadily increased during these 11 years, while that of China seems to have reached its maximum in 1875, when it remained practically steady till 1879, after which date a change for the worse set in, thus showing that the absolute increase in consumption of tea was composed entirely of Indian. The following table will show this in an even more marked degree. It shows the consumption in lbs. per head of the population for the past 21 years :—

	China.	India.	Total.	o/o India.
1860	2.622	·038	2·660	1·4
1861	2.625	·045	2.670	1·7
1862	2.622	·058	2.680	2·2
1863	2.802	·078	2.880	2·7
1864	2.886	·094	2.980	3·1
1865	3.163	·097	3.260	3·0
1866	3.266	·146	3.412	4·3
1867	3·484	·206	3·690	5·6
1868	3·198	·242	3·540	6·8
1869	3·334	·346	3·680	9·4
1870	3·396	·443	3·839	11·5
1871	3·478	·442	3·920	11·5
1872	3·488	·522	4·010	13·0
1873	3·537	·579	4·116	14·1
1874	3·681	·549	4·230	12·8
1875	3·728	·712	4·440	16·0
1876	3·697	·803	4·500	17·8
1877	3·664.	·836	4·500	18·6
1878	3·464	1·087	4·551	23·9
1879	3·524	1·037	4·561	22·7
1880	3·314	1·269	4·583	27·7
1881	3·192	1·379	4·571	30·2

From the above statements it will be seen that the proportion of China teas consumed has steadily decreased since 1875, while that of Indian teas has as steadily increased. The rage for rasping, pungent teas has now somewhat cooled down, and the full rich flavour of the Indian leaf is having fair play. The large shipments now being regularly sent to Australia must tell in keeping down stock, and from the amount of business done in that market during the past year and-a-half, we are in hopes that Australia will almost absorb the increased production resulting from extended area, thus leaving not more than fifty million pounds to go to Great Britain. This will have a beneficial effect on the home market, and tend to keep up prices.

As a natural consequence the value of tea property is improving, and shares are quoted considerably higher than they were twelve months ago, as will be seen from the following statement:—

	Paid up.	*Quotations.* 16 Nov. 1880	19 Nov. 1881.	*Increase.* /°
Bisnauth Co.	200	210	240	14
Holta Co.	100	65	95	46
Punkabaree Co.	100	62	95	53
Tukvor Co.	200	152	190	25

CEYLON PRODUCE AT THE MELBOURNE INTERNATIONAL EXHIBITION, 1881.

To His Excellency Sir J. R. LONGDEN, K. C. M. G., Governor, &c., &c.,

We, the Committee appointed under Your Excellency's instructions dated 19th January, 1880, to secure the representation of Ceylon at the Melbourne International Exhibition, have the honour to report that our duties are now completed.

2. Although the time at our disposal for the collection, arrangement, and transmission of exhibits was limited to a very few months, we believe that the natural and artificial products, which form the chief sources of the wealth and industry of the colony, were fairly represented.

3. We annex for record a copy of the Catalogue of Exhibits. The value of this catalogue was much increased by the Notes, Statistics of Commerce, and Epitome of Information regarding the Colony, for which the Committee were indebted to Messrs. A. M. and J. Ferguson.

4. Your Excellency was pleased to approve of the appointment of Mr. A. M. Ferguson as Commissioner to represent the colony at Melbourne, and we are of opinion that the energy and ability displayed by him in that capacity attracted towards the exhibits of the Ceylon Court an attention which they would not otherwise have obtained. The endeavours of our Commissioner, in co-operation, wherever mutual interests were concerned, with the Indian and other Commissioners, to secure the introduction of Ceylon products, and especially tea, into the Australian market will, we confidently hope, result in substantial and permanent advantages to the colony. We shall be glad if Your Excellency will consent to express to Mr. Ferguson the thanks of the colony for his services.

5. About 800 exhibits were sent by 78 contributors, not including the interesting collections, containing over 500 specimens, forwarded by the Government Agent of the Northern Province (illustrating the products and uses of the palmyrah palm); Dr. Trimen (exhibits from the Royal Botanical Gardens, Peradeniya); and Mr. Dixon (Geographical and Mineralogical specimens). Messrs. Lecchman also sent a very complete collection of exhibits, illustrating the uses of the coconut palm.

6. We annex a copy of the list of awards assigned to Ceylon exhibitors. There were awarded to the Colony:—

Gold Medals 3; Silver Medals 21; Bronze Medals 4; Diplomas 3; Certificate equal to Silver Medal 1; Honorable Mention 11; First Certificate of Merit 2; Second Certificate of Merit 26; Third Certificate of Merit 53; Fourth Certificate of Merit 17; Fifth Certificate of Merit 7.

Of these awards there were assigned:—

For Teas.—Silver Medals 11; Certificates 24; for Coffee:—Silver Medals 7; Certificates 5; for Cinnamon:—Bronze Medals 2; Certificates 2; for Cinchona Bark:—Certificates 4; for Fibres:—Silver Medal 1; Certificates 2; For Oils:—Silver Medal 1; Certificates 4; for Plumbago:—Certificates 4; for Gold and Silver Work and Jewellery:—Certificates 12; Honorable Mention 1; for Fancy Work:—Bronze Medal 1; Certificates 10; For Lace:—Certificates 4.

7. The payments made by us on account of the Exhibition amounted to R28,057·55, the details of which are shown in the statements annexed. Deducting the sum of R7,286·64 paid to exhibitors for goods sold, the cost of the representation of Ceylon at Melbourne amounted to R20,770·91. Of this sum R14,170·38 were spent in Melbourne and R6,600·53 in Ceylon.

8. We shall forward to the Hon. the Colonial Secretary for record our files of correspondence, minutes of our meetings, and detailed accounts of expenditure.

F. R. SAUNDERS, F. M. MACKWOOD, CHAS. BRUCE.
Colombo, 30th November, 1881.

CEYLON PRODUCE IN LONDON.

The quarterly cinnamon sales on Monday will present a total of 6,300 bags against only about 3,000 at the same time last year, and you must not be surprised, if there is a very serious fall in price. In conversation with the leading brokers in this article yesterday I was aked to explain how it came about, that after the repeated assurances received from the colony in July and August, of an unusually short crop in prospect, something like 5,000 bales had come to hand since. Were the statements made untrue, or was it merely that in consequence of the large rise in August, shippers had pressed forward supplies with unwonted rapidity? I was obliged to confess my inability to answer these pertinent questions, but with a view to the future it would be desirable that those interested in the trade on your side should give a categorial explanation, which I will take care reaches the right quarters. It is urged with great force here that if there was any truth at all in the short crop theory, it would have been far wiser for growers and exporters to limit the quantity arriving in time for this sale at any rate to the normal figures, reserving the balance for the February sale, instead of stripping the plantations bare now, as must presumably have been the case, and leaving very little for shipment during the next three months. Had this course been adopted, the prices of last sale might have been maintained, not only in this sale, but in the next. I suppose, however that every one was anxious to take advantage of a rise believed to be permanent, and hence exceptionally high freights have been paid to get every available pound of the spice into the market as quickly as possible, but I fear the result will be to prove once more the truth of the old adage about the "more haste." It is believed that there are orders in hand here for about 3,000 bales, and it is obvious that if importers press more than double that quantity for sale, a very heavy drop is inevitable. The present circumstances furnish a fresh argument for a change from quarterly to monthly sales, for it is clear that the fluctuations in price would be far less violent if the sales were more frequent. The present stock of Ceylon cinnamon in London is about 3,000 bales in excess of this time last year.

On Friday last there was a considerable sale of Ceylon tea amounting to 190 chests and half chests which were disposed of as follows:—Common 10d. pekoe dust 6¾d, broken tea 10¾d, broken pekoe 1s 1¼d to 1s 2⅜d, pekoe souchong 1s 2¼d, Yesterday Messrs. W. T. and H. Thompson sold 10 packages of Kobanella tea at 1s 2½d per lb.—"C. Times" London Cor.

THE TOON TREE ATTACKED BY BORERS IN CEYLON.

A planter sends us the following information about a trial of *Cedrela toona* in Ceylon, which is by no means encouraging. It would be interesting to know if the trees at Peradeniya were attacked by borers. In Java the tree required good soil to flourish in, being in this respect different from *Albizzia Moluccana*, which grew on poor and worn-out patches. But we heard nothing of inseet enemies attacking the toon in Java. In view of what is now stated, perhaps Dr. Trimen will advise as to further trials with what is certainly a a very fine timber tree. Our correspondent writes:—

"I notiee your editorial in *Observer* received today about Red Cedar or Cedrela Toona trees, and I think I may as well write a note to tell you my experienee of them here. I got seed from Mr. Gammie which came up splendidly in the nursery, and I planted out about thirteen thousand plants along the roads on the estates I superintend. They grew very rapidly where not windy, but in very windy places they were doing no good. They grew better in the lower or middle parts of this estate than higher up, and evidently liked good soil. They grew for I think about two-and-a-half years, when in the dry weather

about March a borer attacked every tree of them, by dozens and hundreds, from the bottom to top of the estates, all of a sudden. The borers or grubs bored into the stems and branches through the soft eyes; and the terminal buds of stems and branches, most particularly were all bored through and rotted. The borer seemed to remain in the pith inside, and could often be seen crawling on the stems outside. The softer parts of the wood at top of stems and ends of branches all rotted and died off. The tree shot forth new buds, but in harder wood lower down. It was clear, they would never become proper trees whilst affected by this borer. I was afraid of the borer attacking cinchona or some other soft-wooded large-pithed plant, and I dug all of the trees out. I sent specimens of the borer to Dr. Thwaites of Peradeniya. He managed to bring out the fly or moth or whatever he called it, and said it was a new one to him though he showed me several others allied to it and pretty similar in a general way. About that time, too, I had been seeing accounts in the papers of the destruction of orange trees, &c., by some insect introduced with some plant or seed from Australia to the Cape, and I made a clean sweep of the whole, except three trees. Some of them were about eighteen feet high. These three trees remain, and a sucker here and there has come up since from roots which the coolies had not cut low enough down upon. The next year at same season these three trees were affected again, but with comparatively few borers; and since then I have not noticed any on them, nor on the stray suckers growing elsewhere. But I have not watched or searched for them narrowly. Anyhow these few scattered plants are apparently allowed to grow when the large number of trees were bored to destruction. But that first boring has so spoiled the three trees I left that they will never be properly formed trees. I gave some plants to Dr. Thwaites at Peradeniya, as he said he had not got the plants in the gardens, and I gave some to Mr. Maitland, who planted them at Arthur's Seat, Kandy. These were first attacked by the borer some years after mine."

PEACOCK COPPER ORE IN CEYLON.

We call special attention to the discovery of this valuable ore in the Hewaheta district. In reply to our enquiry the other day Mr. Walters writes:—

Gonavy, December 19th, 1881.

SIR,—I notice the remarks in your Friday's issue (*Ceylon Observer*) respecting a specimen of ore sent you some time since, which Mr. Dixon then pronounced to be iron pyrites. Probably had I mentioned, when sending it, that it had been tested with a strong acid, the peculiar colouring it had assumed would have attracted more particular attention. I now send you a piece of the ore freshly broken off. Will you kindly allow him to compare it with the specimen previously sent. This ore was found in Hewaheta.—Yours faithfully,

W. H. WALTERS.

This letter recalls to our distinct recollection the fact that Mr. Walters sent us some months ago the specimen which at first was pronounced to be iron pyrites and again a manganese ore, but which, on being tested, Mr. Dixon found to contain 20 per cent of copper. But, if there had been any doubt, this second sample sent by Mr. Walters would remove it, for it is a beautiful little specimen of peacock copper ore. Hewaheta is evidently going to take the lead as a mining district. It is from Great Valley estate here that the quartz has come which Mr. Harvey declared should yield 4 or 5 dwts. of gold to the ton, being identical with the quartz from one of the best of the South Indian mines. This quartz is very "dirty," almost dark brown in appearance, and might almost be taken for a copper-yielding ore. Mr. Hart of Great Valley has been most energetic in his prospecting, going down seventy feet into his reefs, and he well deserves success. He sends us some separate samples of quartz and of the clay and schistose deposits surrounding the reef which seem very promising. Meantime, to return to the copper ore, we feel sure that Messrs. Sabonadière & Co., agents for Gonavy, will not lose time in looking after what may prove more valuable than the best auriferous quartz in the country. One who has evidently had practical experience of copper ores and mines writes to us as follows:—

DEAR SIR,—Your paragraph about Peacock copper ore I think certainly deserves larger letters than you have given it. If the ore mentioned by Mr. Dixon was found here, it is I should say the most valuable find that has yet been made, and no pains should be spared to discover its whereabouts. Peacock ore is usually found in pockets in large deposits of less rich but still very valuable copper pyrites: its presence would therefore lead one to expect the existence of a larger deposit in the same locality. I have often looked for copper ore in Ceylon (but without success). The formation appearing in many parts similar to that of the immense deposits of Santo Domingo in Portugal and the Miua del Tarsis in Huelva, Spain. A simple way of distinguishing copper from iron pyrites is that copper pyrites can be scratched or cut with a penknife, while iron pyrites cannot, and the softer the pyrites the richer it is in copper. 7 to 10 per cent is a paying ore in S. Europe, and I dare say would pay here also. Iron pyrites is usually valueless. R. I. P.

We had heard that under favourable circumstances, such as cheap labour and transport, three per cent of copper in the ore would prove profitable; but, even if seven to ten per cent be required, Mr. Dixon's twenty allows a handsome margin. The "peacock" ore, as our correspondent points out, is generally found in pockets in the reef:—here a rich pocket, then a faint streak of the copper ore running through the reef to the next pocket, and so on. Mr. Dixon does not think it at all improbable that the Gonavy reef may run through Maturata and crop up even in Udapussellawa, where, it is said, a quartz with indications of copper and sulphur has already been obtained. A careful examination is called for, and, as Mr. Dixon leaves for the Pussellawa and Ramboda districts on Monday next, we trust he may find time, before his return, to visit the other side of the Pedro range and give his opinion on the course of the reef. Individual proprietors will, of course, be anxious to get an opinion on their prospects, and they cannot do better than communicate with the "Geologist."

MOUND HEDGES IN COFFEE PLANTATIONS.

With reference to a letter on another page, the idea of thickly planted fences of the Assam hybird tea, allowed to grow to its full height, has often suggested itself to us, and to some slight extent we experimented in this direction. The additional height gained by the mound would be of value, if we could build mounds so as to resist our tropical rain-storms. Turfing would be very difficult, and even then we

fear the effect of a monsoon burst would be disastrous. There can be no possible doubt that the coffee fungus lived in the jungle, "remote from public view," before attacking the cultivated coffee, and we only wish it had been contented to remain in that native obscurity, to which planters wish to relegate it.

CINCHONA BARK HARVESTING.

With reference to the letter on another page, we are bound to say that the specimens of bark sent to us, quite bear out our correspondent's statement. The hint he gives about suckers is valuable. Yes: *officinalis* is more liable to die off than *succirubra*, after coppicing or beforehand. Colonel Beddome gives judgment on coppicing, after going over the Nilgiris plantations:—

The results of the coppicing at Naduvatam: in 1879; the coppicing process was very well carried out, the stools being sawn through about 3 inches above the ground and adzed over with a convex surface to nearly flush with the ground; the growth is very healthy and promising wherever the coppice has succeeded.

In the 1864 planting, 2,319 "Succirubra" trees, all previously barked four times, were carefully coppiced early in June 1879; 185 stools have died, 2,134 are growing luxuriantly. In the 1869 planting, 2,628 unbarked "Succirubra" trees coppiced in the same manner in July 1879; 973 stools died, 1,655 growing luxuriantly.

Here we have a great anomaly: trees fifteen years old have succeeded from coppice with a far better percentage than trees only ten years old; this is quite opposed to my experience in the coppice of any other trees, the growth being generally far more successful in the younger trees; old or even mature trees often failing altogether to make coppice growth beyond a few twigs which die off, when saplings or young trees of the same species grow most readily; this is alway the case with "Teak" and "Babul." Again, it is noteworthy that the four-times barked trees have succeeded from coppice with a better percentage than the unbarked trees.

Both these data however are more or less valueless, as the 1869 planting was coppiced nearly a month later than that of 1864 the sap was therefore more up and the trees bled much more which may account for the extra failures. The coppicing of both years was carried out too late, and I am inclined to attribute the failures to this cause as the stools bled terribly; if the coppice had been in April or early in May, it is probable there would have been no failures at least of healthy trees.

Of the old coppicing experiments carried out more roughly, where fifty-seven unbarked "Succirubra" trees of 1862 planting were clean coppiced in October 1873, all suckers removed, twenty-two have died, thirty-five have grown well and are about twenty feet high, and of fifty-eight trees of the same year coppiced in May 1873, but the suckers left standing, only one stool is dead; and of 200 "Succirubra" of the same year in another block coppiced in May 1871 (when nine years old) suckers left standing, only one stool died; the 199 again coppiced in March 1881 (when 10 years old) no regrowth yet, but sufficient time has not elapsed. The yield of green bark in 1871 was 1,350 lb., but in 1881 it was 3,365 lb., which is noteworthy; and of 115 "Succirubra" of the same year, but of poor growth and unbarked, coppiced in May 1875, thirty-three stools died, the surviving eighty-two about 9 feet high and 5¼ inches in girth.

I do not think we should carry out any further coppicing in blocks, but only coppice trees showing signs of decay. I observed here and there dead trees in the different plantations. A tree should never be allowed to die, as its bark then yields no alkaloids; they should be coppiced or uprooted when the signs of decay are evident. It is an established fact that if a sucker or shoot is left when the tree is coppiced it never dies, and when trees have no shoots one can easily be produced by slightly injuring the bark close to the ground. It is also an established fact that if trees are coppiced in June or July, when the sap is well up, there must be many failures owing probably to the excessive bleeding that takes place. We have not sufficient data to say whether trees coppiced in April or early in May will all grow again without any failures.

But in some soils all cinchona trees die, or refuse to live. As regards Mr. Karslake's process, he states that he found it safe after ten days to take the loosened bark away, the renewing bark being able to take care of itself. Of course, others can try the process on a small scale before adopting it.

THE MARKET FOR CINCHONA BARK.

We do not regard the intelligence of a rise of 2s in quinine, privately reported by telegram, as a matter for special rejoicing on the part of Ceylon planters. Taking into account the interests of the community whose heavy crops of bark will become available three to five years hence, there can be no doubt that cheap quinine in the meantime would lead to one of the greatest benefits which could be conferred on them. Cheap quinine, resulting of course from low prices for bark, would mean a rapid extension of consumption. It would mean that science and practical ingenuity would set to work to find new uses for the precious and potent alkaloids, and, as a consequence, the position of the cinchona bark cultivator—even with the standard price of quinine never exceeding 10s and continuing nearer to 6s per ounce—would speedily be on a more stable basis than ever before.

We think very little of all this cry over Cuprea bark: whether the supply continue for some considerable time longer, or as is more likely gradually die off, does not matter much to the cultivator of East Indian and Ceylon barks. The competition from original South American bark of the really marketable, valuable kinds is fast dying out; and what we have now to dread far more than importations of 'Cuprea,' is the *cultivation* of calisayas and even Ledgerianas in their native habitat, by the men who find they cannot profitably penetrate the more remote forests and transport for long distances the resulting bark. Interesting and pertinent remarks on the London market will be found in the extracts from the reports we append:—

(Brookes and Faith's Report:— November 25th.)

The owners of Cuprea continue desirous sellers, and a further small reduction in value has resulted.

West India. In auction yesterday about 4,500 packages were brought forward, and in the auctions 271 bales carthagena were sold without material alteration in values. At mid since the sales about 1,200 packages Cuprea changed hands, owners accepting a further decline to make progress. These repeated reductions have caused the value of this bark to show an aggregate fall of about 60 per cwt. during the present year.

We give below the valuations of several marks of Cuprea, at different dates, which point most conclusively to the course of the market:

Mark JJ in April last, 18s. 3d. to 19s. in August, 9s. in Nov., sold in sale yesterday at 5s. 8d. per lb.

KS JJ JJ do do 3s. do 2s. to 2s. 1d. do value about 1s. 6d. to 1s. 8d.

Last week. The only description represented at yesterday's sales was Cuprea, the quantity being 250 packages. Quality on

the whole was rather unattractive; over 90 packages were ordinary twigs and branch, part of the former being sold at 3d per lb. We must repeat a suggestion often made in our reports, that it would be better to leave these thin twigs growing than send them forward, as these low prices can scarcely be remunerative.

The remainder of the piles were generally so small that we do not give details.

The price of English quinine is 8s per oz.: it is now approaching a price that ought to considerably increase consumption.

It will be seen from figures given below that the quantity of bark landed during the last month was 3,000 packages in excess of quantity delivered, thus further increasing the previous heavy stock.

One good feature of the article is the largely increased delivery for the first 10 months of present year over any previous year, but then the imports have increased to a still larger extent; the question naturally arises will the latter be maintained. The large supply is mainly owing to the arrivals of Cuprea, and there are reports now and again that the shipments of this description are likely to fall off, but, in the absence of any definite information fully confirming this, we give the statement for what it may be worth.

The stock, imports, &c., of East India bark are not returned separately; the following figures include all kinds of medicinal bark:—

Landed during month of Oct. 1881 .....10,747 packages.
Delivered do do do ..... 7,423 do

	1881.	1880.	1879.	1878.	1877.
Total stk. 1st Oct. pkgs.	45,720	25,763	19,341	11,270	11,531
Total imports from Jan. 1st to Oct. 31st.	99,746	63,760	54,126	38,264	26,879
Do deliveries do	80,015	56,955	43,722	30,959	24,174

(Jas. Cook & Co.)

London, 40, Mincing Lane, 24th Nov. 1881.

CINCHONA BARK.—There is nothing cheering to report this week; the market is depressed by the heavy arrivals and prospective supplies of Cuprea Bark, the "*Humber*," just arrived, having brought 7,000 serons. The public sales were a little smaller this week, and there being an evident disposition to sell, a much larger proportion than usual of the South American Bark was disposed of. Cuprea, which formed the bulk of the quantity offered, went at lower prices, 1s 2d to 1s 6d, but the Carthagena sold with competition at full rates—VO WO 1s 10d at 1s 11d, VO 2s, WO S 2s 2d, and WO Z 2s 8d to 3s 1d per lb.

CEYLON.—Although the quantity offered this week was larger the 228 packages brought forward comprised a number of small lots of poor and undesirable qualities, which sold irregularly and in buyers' favour. A large proportion consisted of twigs—which in many cases sold on about the same terms, whether Crown or Red. For 20 cases good Red Druggist quill, RSCS B (*in diamond*), which sold two months since at 2s 10d to 2s 11d, an offer of 3s was made in the room. A price, doubtless, obtainable only in consequence of the great scarcity of Bark suitable for Druggists' purposes.

There are no arrivals from Ceylon, but the "Para" and "Humber" bring 7,500 packages Central American.

Writing on November 30th, Messrs. Lewis & Peat report little or no change in the market: the arrivals and sales during the fortnight had been very large.

COFFEE LEAF DISEASE.

We regret to learn that *Hemileia vastatrix* has appeared rather badly on the estate in the Dumbara valley, which was lately visited by Mr. Schrottky and Dr. Shipton, and which was accepted as a test of the system adopted by the former. It was hoped that the immunity from disease then observed would continue till after the blossoming season.

Our Aberdeen correspondent, writing about the end of last month, said:—

Yesterday I sent to Mr. A. Stephen Wilson your copy of Mr. Ward's report. I expect the letter I told you of in a few days. He was to wait till he saw Mr. Ward's report. I had a talk with Mr. Wilson 10 days ago, and he thought it was not impossible that something might be done to check leaf-disease, reasoning by analogy, from potato disease in Champion. There is a something in the Champion—a difference of some kind or other,—that presents a *check* to the progress of the disease. The disease or fungus, attacks the Champion *in the same way exactly as other varieties*, but "the something" prevents its *progress* and the destruction of the tubers. What that something is has not been discovered. It *may* be some slight structural difference. From this fact it is not unreasonable to infer the possibility of discovering a disease-resisting coffee, or a something that will render old coffee disease-resisting. Some 18 years ago I suggested in a "News from the North," hybridizing Coffea Arabica with Liberian, in view of obtaining an extra development of some feature in the cross that might, as in Champion potatoes, resist disease, but I have not heard of any one making the hybrid and testing it.

I told Mr. Wilson, any suggestion he could make for experiment would be gladly received by planters.

The position as a Cryptogamist of acknowledged ability and considerable experience attained by Mr. Stephen Wilson (an independent lauded proprietor in Aberdeenshire) has been recognized by the first authorities of the day, and we take credit to ourselves for having interested this gentleman in our Ceylon pest. All the literature at our command has been sent to him from time to time. Mr. Wilson has been for some years engaged in investigating the club-root fungus infesting turnips, the rust of wheat and the potato fungus, with some others of less note, and he has made important discoveries in connection therewith which had escaped the attention of specialists, and which have been duly acknowledged. Mr. Berkeley has recently been naming a parasite discovered by this gentleman, which destroys the leaves of the lilac. We may therefore look for an interesting and instructive letter from Mr. Stephen Wilson, and we trust shortly to lay it before our readers.

CEYLON PRODUCE IN THE LONDON MARKET: TEA AND CINNAMON.

The latest sale of Ceylon tea is more encouraging than several of those preceding it. On Wednesday there were sold 70 half chests and boxes per S.S. "Bancoora" in lots ranging from 5 boxes to 19 half chests. As I have already explained, the dealers will not take the trouble to draw samples of small "breaks" and hence they do not obtain their full intrinsic value. This tea is described to me as having a pleasant, rather spicy flavour, and better to be used by itself than for mixing purposes, because it lacks that strength and roughness which makes Assam so popular with retailers for helping off poor cheap China cargoes, etc. In make, pour Ceylon teas are generally speaking as good as Assam, and I am surprized at this, for I should have thought the skilled labour would have been too scarce for that at present. The following are the details of Wednesday's sale:—

Sembewatte, 19 half chests pekoe souchong 1s 3½d; 10 half chests broken pekoe 1s 4½d.

Ruanwella 5 half chests pekoe souchong 1s 2½d, 5 boxes broken pekoe 1s 0½d.

Dunedin, 8 boxes pekoe souchong 1s 4½d, 17 half chests souchong 1s 4½d, 6 half chests 1s 2¾d.

The Cinnamon sale on Monday, the biggest ever held, was well attended, but it was quite evident, from the first, that a substantial fall was expected and would have to be conceded in order to effect sales. You are aware of course, that very little, if any cinnamon, is ever bought on speculation. The buyers have either orders actually in hand, or are well assured that they can place their purchases at once. Mr. Kilby was the first occupant of the pulpit, but he received small encouragement in the shape of bids, and so bought in the whole. Messrs. Lewis & Peat came next with a comparatively light catalogue which was partly disposed of at a reduction of 2d to 4d on the previous sale prices, and then came Messrs. W. J. and H. Thompson, who, as usual, held the lion's share of the sale, not only as regards quantity but quality. At first they got on better than might have been expected, the finer going at a reduction of 2d to 3d, but rates on prices became irregular, and some of the commoner sorts showed a reduction of as much as 6d. When their catalogue was about half through, it became evident that the buyers had been pretty well supplied, and so the rest was wisely

withdrawn. A similar fate awaited the other cinnamon growers and not quite 3000 bales in all passed the hammer out of a total of 6,200 bales. The wisdom of not forcing sales has since been demonstrated, for there has been a good deal of private enquiry since, and fully 1,500 bales more have been disposed of at 1d advance, whereas otherwise there would certainly have been a further decline.

The new crop of Ceylon Coffee that has come to market thus far is unusually mixed in quality, and on the average decidedly small, not a little of the plantation being no better than ordinary low grown. I suppose this is one of the first arrivals of the late crop, and that it will disappear by and bye. I heard a Ceylon proprietor comforting himself yesterday with the reflection that present prices would not pay Brazil growers, and hence the supply would necessarily fall off; but I think there is a fallacy underlying this argument. The low rates now current would certainly not be remunerative if crops were also very short, but every Ceylon planter knows that it pays better to get 7 cwt per acre at 75s per cwt. than 3 cwt. at 100s.—"Ceylon Times" London Cor.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, December 3rd.

The question of pasture and meadow lands is assuming important proportions in France, and the recent work of M. Joulie has only added to the interest felt in the subject. It is a fact officially stated that, in the regions where pasture lands abound, farming is more flourishing than elsewhere. In presence of such data, examination becomes a necessity. Connected with the matter is the rearing of stock, which also has largely increased of late, owing to the cost involved in the cultivation of wheat, the supplies of grain exported from other countries, and the assured demand for meat in the home market. Many agriculturists have not hesitated to solve the question practically, by converting their land into meadows or pasturages. M. de Gasparin has made a profound remark: many farmers are ruined in consequence of having too much land, but not one has ever come to misfortune by having too much meadow. In all good grass land, whether artificial or permanent, there must be a relative proportion between the gramineous and leguminous plants. Taking as a base ten tons of hay, produced from such a mixture of plants, that eminent chemist, M. Joulie, finds therein 376 lb. of nitrogen, 156 lb. of phosphoric acid, 211 of lime, 59 magnesia, and 303 of potash. Thus compared with other cultivated crops, it is not the most exhausting: with sugar beet for example, which extracts the largest quantities of chemical substances from the soil; 20 tons of sugar beet per acre carry off from the soil 163 lb. of nitrogen and 136 of phosphoric acid; then follow many varieties of wheat which are also exhausting. Now manurings are reserved for root and grain crops, grass land receiving none. How then does it arise that meadows retain their fertility? They become poorer, but do not disappear: the valuable grasses die out, and are succeeded by inferior kinds: it is then not so much the quantity of the return that is affected, as the quality. Further, meadows are generally established on the best soil, often in valleys, where the filtering waters bring down nutrition from the more elevated lands.

In 2 cwt. of dry ordinary arable soil, there are: nitrogen 34 oz., phosphoric acid 54, lime 17, magnesia 10½, potash 8½ oz. Taking the average depth of a cultivated soil at 8 inches, an acre would contain about 32 cwt. of nitrogen and the same quantity of phosphoric acid: the other chemical elements in proportion. There is here an enormous difference between what the soil has in store of chemical food and what vegetation exacts. An acre of beet requires, as we have seen, 163 lb. of nitrogen, while the soil contains 32 cwt. of this element, or a sufficiency for 22 crops of beet. A like observation will apply to the other inorganic nutriments. M. Joulie explains this disproportion by the fact that each chemical element exists in the soil in two forms, assimilable and unassimilable. Did the soil contain all the food in the former state, it would be washed away and the land rapidly exhausted. Existing in an insoluble or fixed form, the azote, phosphoric acid, &c., yield only each year their treasures to vegetation in fractional quantities. M. Joulie draws a comparison between grazing and cutting meadows. He inclines to the former, because the animals find in the succulent, and above all, the young grasses, more nitrogenous matters, and of greater digestibility than when in the form of hay, where so much is woody matter passing through the system, without undergoing any transformation. Hence, why weight for weight of stock, pasture land will support a greater number of cattle, than if the crop was converted into hay. The chemist also avers that, in an economical point of view, the droppings of the animals restore immediately to the soil all the nutritive elements that the animal has not utilized, thus saving the labour of being converted into farmyard manure. Chemically, all soils are not suited for grass culture, but they cannot the less be made so, by judiciously selecting the kinds of grass and clover most propitious, resorting to fossil phosphates, lime, marl, and fertilizers to supply richness. M. Joulie belongs to the school which believes in the atmosphere supplying azote to the nutrition of plants. In the department of the Nièvre, the rearing of stock is the chief feature of agriculture, and the farmers have become immensely rich since half a century. Meadows there are not permanent, and the land receives no other manuring than the droppings of the cattle: lime is added largely to stimulate clover, and when, after eight years, a meadow is broken up, oats are sown on the lea, then three grain crops, the fourth, oats along with clover and selected grass seeds: the meadows are never mown, and one head of cattle per acre is the ratio allowed. The stock are duly sent to the best sugar growers of the north to be fattened. The general rotation in the Nievre is, eight or ten years grass, then oats two wheats, and oats as above, but no manure is ever added to the soil; the soil is a sandy clay and lets readily for fr. 32 to 40 per acre.

Professor Kühn of Halle is occupied with the crossing of the cow with the yak. There is nothing new to be demonstrated that animals of different species, will breed: the evidence exists in the affirmative in the case of the goat and the sheep, of the hare and the rabbit. A cow, the product of a mother crossed by a yak, was covered by a short-horn, and in turn produced a calf, with all the traits of the yak at the tail and head. The products of these crossings, however, are not fruitful between themselves, simply because they are hybrids and not crosses; the male of a hybrid is next to rarely so. Mules have been successfully crossed by asses and horses, but the same has not been the case with a male mule, although the researches of Babini invite caution in this respect.

There was a Gascon once who boasted that he gradually reduced the rations of his mare to a point where the animal lived upon nothing; only at this stage the mare died which constituted a drawback. Discussions are taking place as to the practicability of diminishing the rations of horses in the cavalry or under the omnibuses, by employing maize cake, beans, &c., in place of costly oats; or, feeding the horses more highly, and by exacting more work from them, requiring fewer to feed. Professor Munk lays down there is a point in the feeding of horses that cannot be overstepped, that high rations to one horse will not produce a result of work equal to that produced by two moderately fed. In the case of the omnibus horses, the animals exceptionally overworked, though well fed, are ever those first on the sick list.

In the conservation of green food, maize, clover, &c., in trenches, a fermentation ensues, of which the seat is the vegetable cell: carbonic acid; alcohol, and acetic acid are produced at the expense of the immediate principles contained in the forage; over 2 per cent of carbonic acid in the case of maize, and nearly 1½ per cent for clover, is given off during fermentation: if a part of the nutritive principles be lost, the remainder are made more utilizable: also; the fatty matters are increased during the fermentation.

M. Deherain has repeated de Saussure's and Corenminder's experiments, that of testing the influence of carbonic acid on vegetation. But little of this acid is contained in the atmosphere: 10,000 quarts of air containing not more than 3 or 4: the professor placed haricots, colza, and tobacco plants, under bell glasses, so as to exclude all communication with external air: then pure carbonic acid, in measured daily quantities, was introduced. The beans and colza showed any excess of acid to be unnecessary; but the tobacco leaves became very plethoric, owing to immense deposit of starch-matter in the leaves. The experiment was controlled by kindred plants also placed under bell glasses, but supplied with common air. The tobacco leaves assimilated more carbon than was supplied by the introduced acid. From whence did it come? From the disengaged oxygen, acting on the carbon, in the soil contained in the pots, and thus producing additional carbonic acid.

Since 1847, Belgium has adopted the plan, and with best results, of decorating artizans and laborers with a medal, to be suspended from the coat buttonhole. The idea is about being introduced in France. Indeed humble distinctions would be appreciated, more particularly, if accompanied by a slender pension, or a donation to be paid at fixed intervals.

THE "TROPICAL AGRICULTURIST": NEW PRODUCTS FROM SOUTH AMERICA, &c.

Mr. A. Scott Blacklaw writes:—"I received your *Directory* from Mr. Westland, Aberdeen. The book has risen to a respectable size, and the contents of the volume have increased in value to the planter in an equal proportion.

"The *Tropical Agriculturist* I have only seen the first number of, and I am waiting for the remaining numbers. I hope you have them. The value of it cannot be calculated. The tropical farmer can now have the information necessary for enabling him to experiment on any plant that the climate he lives in is capable of producing. It will be so convenient to file and carry about after it is filed. I notice Ceylon is well supplied with nearly everything that can be grown at a profit: Liberian coffee, cocoa, tea, and cinchona. Some of the finer qualities of the last-named plant would no doubt be acceptable. I had several conversations with native merchants in Pará about seeds of the valuable kinds grown in some of the Bolivian forests. I came to the conclusion that the only way of procuring these was to go among the Indians one's-self, and even then, they were difficult to get, owing to the Indians setting such a high value on those trees.

"The people of Pará and those along the banks of the Amazon are not free from jealousies, and are unwilling that other countries may be put in the way of supplying the world with products of which up till now they have had a monopoly. The wax-producing palm and the vegetable ivory palm could both the cultivated in Ceylon. I expect some seeds of the former, and, when I get a chance, I 'll send you some candles made from the wax as it comes from the tree. The ivory plant will be difficult to get, as it grows in the forests far up the valley—the river Purus,—in Peru and Ecuador. None of these can ever take the place of coffee, but they will be convenient to cultivate as an auxiliary, and as something that can keep coolies in profitable employment during the idle season.

"I was very much interested in reading the letters of your chief on his voyage home from Australia, particularly that part on Queensland. I am glad to see he has got back again in sound health."

Mr. A. S. Burnett (a well-known Uva planter) writes:—

"I shall return to Ceylon again probably early in 1882, and write to ask you to keep for me copies of *The Tropical Agriculturist*. There is no publication extant, which really occupies the special field you have entered on, and whether in the East Indies, or the West, its pages will be carefully perused by all who feel an interest in tropical cultivation. By none, perhaps, will it be more gladly welcomed than by old colonials."

PRACTICAL PLANTING NOTES ON TOPICS OF THE DAY IN CEYLON:

MR. PARSONS' "PERFECT CURE" FOR GRUB:—SUCCESSFUL EXPERIMENTS;—GREEN GLASS FOR NURSERY FRAME (NOTHING LIKE 'GREEN SPECTACLES');—THE CINCHONA MARKET: CUPREA BARK AND THE PRICE OF QUININE.

Agrapatana, 27th Dec. 1881.

You will be interested to learn that Mr. Parsons' method or invention for destroying grub has now been pronounced a complete success. It is a *fait accompli* of which the importance can hardly be overestimated.

Those who have had flourishing fields of coffee reduced to so deplorable a condition that it is hard to believe they will not die out altogether will welcome these tidings.

I, in common with many others, was sceptical at first, but conviction has, for some time past, been forced upon me, till the other day I witnessed, in company with Messrs. Fairlie and Campbell, an absolute proof of the efficacy of this plan.

Mr. Parsons in our presence removed some sacks, which had been laid down in the prescribed manner a little more than a week, and under them we saw a great number of grub of all sizes comfortably curled up in small round holes on the surface of the ground, On the arca, which had been covered by one sack (cut open of course), we counted 56 grub. These were removed and then we dug carefully over the whole space the bag had covered, to eighteen inches deep, with the result after careful search of finding six more grub, who seemed on their way up. It is not taking too much for granted to suppose that in four days more they would have joined "their cousins and aunts."

It seems certain now that Mr. Parsons has found a means of attracting all the grub to the surface of the soil, where they can be at once captured and destroyed.

The main question: How much does it cost per acre? he is prepared to answer in a satisfactory manner. Old bags are cheap, and, when used on one field, can be removed to the next, and as ten days does the business, it follows that 20 acres of bag surface will cure a 200 acre estate of grub in under four months. A visitor, who watched us testing the method with great interest, made the excellent suggestion that old sail cloth would be the very thing. Manure bags rot very soon, and would never last four months in the rain and sun; also each bag would have to be taken up separately. Now a bolt of sail cloth would lie between the lines of coffee for ten days, and then might be rolled up, turned round, and unrolled along the next 53 yards, which, I am told, is its length. The only expense would

be, after its purchase, the careful clearing and sweeping of the ground. If another length were laid cross-ways, the whole surface of the ground would be covered, once, and part of it doubly protected, which, I suppose, would have the effect of bringing the grub up quicker still. Those estates where young cinchonas are growing all over the coffee would have to be content with bags cut in all sorts of sizes to fit in; but in all estates where grub is beginning the soil should be well swept and covered somehow.

"What is it brings them up?" is a question which will at once suggest itself to many. I fancy myself the want of air, for the better the surface is swept, *i. e.* the closer the bag lies and the more it is weighed down with soil or stones, the quicker the grub come up. However, others may find a better solution and may laugh at this idea; and this reminds me that, before closing my letter, I have to say a word in defence of green glass for nursery frames.

The human eye is most susceptible to the rays of the sun: what is the best protection for it? Have your readers forgotten what colour the spectacles were, of which silly Moses brought a gross in triumph back to Wakefield with him from the fair?

But, seriously speaking, I have the best authority from Kew for repeating that coloured green glass or glass lightly coated with green paint on the under side, is the best protection for the seedlings.

We cannot agree with you, Mr. Editor, in not considering the rise in the price of cinchona as an unmixed blessing. Just reflect what it means. More than a year ago Mr. Dobree made a calculation of the number of cinchonas being planted in Ceylon and of the amount of bark which would flood the markets of the world in five years' time. Many others shook their heads, foretold a glut, and a great lowering of price. What has happened? Quite unexpectedly a new kind of cinchona has been found and suddenly an enormous quantity of Cuprean bark, as much in bulk as would make a whole average year's supply of the before existing kinds, is thrown as an extra on the market. No test could have been more complete of the stability of the market. The price naturally fell considerably,—for no time had been allowed for consumption to increase,—but only for a few months and already cinchona is growing up again.

Therefore, what the rise means is this: That the produce of Ceylon, India, Java, and Jamaica, coming gradually on the market, will be productive of no glut and that in all probability quinine will touch no lower price for the next six years than it touched during the last fall. Cuprean need not be feared. Before long collectors will have to go as far for it as for the other kinds. The late great influx of it has been caused by the discovery that this kind of bark was cinchona at all, and fairly valuable trees hitherto neglected were found growing round the very doors of the collectors, and now they are cutting away at it with a will, and the welcome rise in the price of cinchona, besides proving the elasticity of the market, probably indicates the partial exhaustion of the Cuprean variety.

Luckily this new bark is difficult for manufacturers to work, and is not very rich; for it possesses this great advantage that like a pure ledger, though in a much lesser degree, it contains quinine alone and no other alkaloid.—Yours, &c. E. H. C.

SALE OF INDIAN TEA IN MELBOURNE.

(*From Our Correspondent.*)

Choice Indian Teas, 3,303 half-chests, from the celebrated districts of Assam, Cachar, Darjeeling, Dehra Doon and Kangra Valley: all sold.

FROM CALCUTTA.

8 packages Cachar orange pekoe 50lb. (Each 2 tins.) Very handsome small even wiry greyish leaf full of pekoe tips. Brisk full ripe rich flavor. Fine Cachar pekoe. 2s 0d.

30 quarter-chests Assam pekoe 20lb. Boldish even blackish well made leaf Pekoe tips. Pungent very brisk strong full true Assam Pekoe flavor. Strong and pleasant tea. 1s 4d.

39 quarter-chests Indian buds 20lb. Black small even roundish Pekoe buds few tips. Good strong rich flavory. Indian buds. 1s 2d.

12 packages Terai pekoe 80lb. (Each 4 tins.) Very handsome small well made wiry tippy leaf. Choice rich full strong rather pungent liquor. Finest Terai pekoe. 1s 9½d.

37 half-chests Assam pekoe souchong 40lb. Greyish black well curled and even made leaf. Malty fruity rich liquor fine flavor and strength. Useful tea. 1s 2½d.

29 half-chests Darjeeling pekoe souchong 40lb. Well made crisp hard even blackish leaf. Rich fruity brisk choice liquor very flavory. Fine tea to drink alone 1s 2½d.

46 half-chests Cachar pekoe souchong 40lb. Blackish grey hard twisted leaf. Richly fired choice heavy infusion. Mixer. 1s 1½d.

25 half-chests Indian tea 38lb
25 do do 38lb
24 do do 38lb. Pretty small curled even blackish leaf. Heavy malty pekoe flavor. Fine mixer. 0s 11d.

27 half-chests Assam broken souchong 50lb. Brownish black small open evenish leaf. Briskly fired strong deep heavy liquor Thick liquor. 0s 11d.

25 half-chests Darjeeling pekoe 40lb. Handsome even blackish grey leaf full orange tips. Delicate fragrant strong rich infusion choice in the cup. Most delicious tea. 1s 11d.

22 packages Assam pekoe souchong 44lb. (Each 2 tins.) Greyish black fairly made even rather small leaf. Heavy liquor pungent strong and very full flavored. Strong tea. 1s 3½d.

25 half-chests Darjeeling pekoe souchong 40lb. Boldish black fairly made even leaf. Rich delicate ripe telling liquor wonderfuld flavor. Splendid tea in the cup. 1s 3½d.

50 half-chests Cachar broken pekoe souchong 45lb. Greyish black even hard made leaf. Very pungent and strong rich full bodied tea. Powerful mixer. 1s 2d.

25 half-chests Terai pekoe souchong 38lb. Fairly even greyish black rather loosely twisted leaf. Fairly strong brisk ripe pekoe flavor. Pleasant tea. 1s 1½d.

60 half-chests Assam pekoe souchong 40lb. Handsome bold blackish even leaf full pekoe tips. Rasping telling infusion very strong with fine flavor. A fine mixer. 1s 4½d.

15 half-chests Darjeeling flowery pekoe 38lb. Handsome even wiry orange tipped pekoe leaf. Very strong full rich and fruity Darjeeling. A most delicious tea. 2s 5d.

42 half-chests Assam pekoe souchong 45lb. Greyish blackish even curled and rolled leaf. Strong brisk full ripe flavory. Mixer. 1s 0½d.

18 half-chests Darjeeling broken tea 39lb. Neat small blackish very even leaf. Full bodied rich ripe deep infusion. Delicious tea. 1s 4d.

25 half-chests Cachar pekoe souchong 30lb. Boldish blackish brown crisp leaf full pekoe ends. Malty strong thick heavy liquor very flavory. Mixer. 1s 2½d.

19 packages Assam broken pekoe 50lb. (Each 2 tins.) Handsome small neat pretty leaf full golden tips. Brisk burnt full ripe rich very flavory. Very strong thick liquor. 2s 1d.

50 half-chests Cachar brok. pek. souch. 50lb. Brownish fairly made rather broken leaf strong full little pungent brisk flavory useful mixer. 0s 11½d

50 half-chests Indian tea 38lb.
45 do do 38lb.
Rather bold blackish with twisted pekoe souchong leaf few tips strong brisk burnt and flavory. Pleasant tea. 1s 0½d.

40 half-chests Darjeeling pekoe souch. 40lb. Even curled blackish well curled even leaf delicate full flavored rich Pekoe kind. A pleasant tea. 1s 3d.

16 half-chests Assam broken pekoe 50lb. Small brownish red open even leaf pekoe tips strong full rich brisk pekoe flavor. Thick heavy mixer. 1s 2d.

50 half-chests Cachar broken pekoe 50lb. Blackish grey rather small and little broken leaf strong full ripe pekoe flavor. Fine mixer. 1s 1½d.

27 quarter-chests Assam pekoe Souchong 20lb. Crisp well curled rather large but even leaf rich malty choice infusion strong and flavory. Strong tea. 1s 4½d.

50 half-chests Darjeeling Pekoe 38lb. Handsome well made wiry leaf full of tips strong rich ripe very full Darjeeling flavor. One of the best Darjeelings. 1s 9½d.

25 half-chests Indian tea 38lb.

COFFEE LEAF DISEASE INVESTIGATION.

ABERDEEN, 1st Dec. 1881.

I told you, Mr. Editor, in a private letter that I expected to have the honour of sending you an important contribution to the life-history of *Hemileia*. I have now to inform you that I send it by this mail in a sealed letter and trust it will arrive safe.

After your Government scientists have announced "the subject thoroughly exhausted," a contribution that upsets their conclusions and turns on a good deal of new light; that explains unsolved problems, (among them the non-setting of blossoms *before* the "attack" of leaf-disease); that directs war at a new point; and that distinctly says your old modes of cure can be of no avail; cannot but excite some curiosity about the writer of the contribution. Well, he is a hard worker in the field of cryptogamic science, and one who has scored several successes, and acquired much distinction by his investigations of the fungi affecting our agriculture. He is a most painstaking and accurate experimentor in the relations between seeds and crops and has, from time to time, a good many years, given the public the results of his labours. It happened that an article of his on club root found its way to your office, and was re-published in the *Observer*, prefixed by an editorial recommendatory note. The leaf of the *Observer* containing the article came into my hands from a friend in Aberdeen, doing duty as wrapping paper. Being desirous of enlisting Mr. Wilson to an interest in the struggle planters were having with leaf disease—as he was the only man I knew who was likely to contribute any suggestions that might be of use—I sent him the leaf and offered to procure specimens of the fungus from Ceylon. They came, and you, having learned of my communications with Mr. Wilson, sent him the book and papers he acknowledges in his letter. Since then I have met him frequently, and am indebted to him for sundry calls, when I always found him interested in any information I had to make regarding the progress of investigation, spread of the disease and curative experiments. I felt under a burden of debt to him for interesting himself in your struggles, but he assumed the indebtedness, and, besides thanks, acknowledged it in a gift of a beautiful autographed copy of his work "The Botany of the Three Historical Records." In a "News from the North," I told you of his getting spores of *Hemileia* to germinate on glass, and later, of his finding the embryo in Ceylon coffee seed infested with fungus mycelium. (Here I may acknowledge receiving from him 36 cross sections of coffee seed mounted for microscope.) As he states in his letter, it was "for side light," he turned to the leaves lying beside him, and, although they corroborated the discovery he had made in the pursuit of his investigation of potato disease, he wanted yet another proof before he would write to you, and so applied to me to get him some healthy leaves from Ceylon. They came, and now you have his letter. I was glad to notice your intimation of being in a position to execute illustrations, and at once informed Mr. W. of it: so, if it is any extra trouble to reproduce the sketches that accompany his letter, you have me to blame for it.*

THE MELBOURNE TEA MARKET: GREAT AND SUCCESSFUL SALE OF INDIAN TEAS.

(From Our Own Correspondent.)

MELBOURNE, 6th December 1881.

Indian teas are selling freely with us, and the sale by public auction on the 24th November was a most successful affair. Some 3,368 half chests were offered, being the largest quantity ever catalogued for one day, and the whole sold well:—

Assams showing an advance of 1d. to 2d. per lb.
Cachars " " ½d. to 1d. "
Darjeeling ruled up to 2s. 5d. per lb in bond.

The catalogue, which I enclose, with its 18 pages of printed matter, is a creditable production, and the auctioneers deserve some credit for the get up of the same.

You will see that Messrs. Jas. Henty & Co. still keep up the analysis of their teas, in spite of the verdict of the China tea merchants of "Tooley Street," who in council assembled (vide *Age*, 25th October) passed solemn resolutions that chemical analysis was of no value, and especially the investigations of Messrs. Cosmo Newbery and Dunn:

At that meeting, held to denounce Indian teas, you will recollect Mr. Lemmer, the chairman, put in the evidence of Mr. Forbes of Foochow to show that no but sound teas came from that port. Mr. Lemmer, the

* Our correspondent is too sanguine. Mr. Wilson's letter (which will appear later on,) though interesting will not effect a revolution.—ED.

staunch advocate of China teas, has now changed front, and made the following statement in the Legislative Council, during the discussion on the Tea Bill. He said (vide *Argus*, 25th November) :—"No shipment of tea came into this colony that did not contain exhausted leaves. * * * They were exhausted by wet weather before being picked from the bush." After denouncing Messrs. Cosmo Newbery and Dunn for making such a statement, Mr. Lorimer turns round and admits the truth of it, but says exhaustion is done by the rain whilst the leaf is on the shrub! I wonder if Mr. L. ever studied the use of the essential oil and chlorophyl in the economy of nature. Probably not, or such an absurd statement would not have been made by him. However Mr. Lorimer admits that all teas from China contain exhausted leaves: Messrs. Cosmo Newbery and Dunn say the same thing, but that the exhaustion is caused by the leaves being once used before sending to Melbourne, a most essential difference.

Mr. Lorimer, continuing his arguments in Parliament, says "that, as exhausted leaves are not injurious to health, they should not be interfered with and might be consumed," *Proh pudor!* where is our commercial morality? It is bad enough to be taken in by imitations, instead of genuine tea from China, without finding defenders for the roguery of the Chinese amongst our own merchants.

It is gratifying, however, to see the steady progress that pure teas from India are making with the public, and there is every prospect of consumption increasing this season 50 to 100 per cent over last; and this in the face of high prices ruling on your side, and the heaviest stock of China teas ever held in Melbourne.

No Ceylon teas have been offered to the public since the sale on the 18th October, or the larger saleon 16th August. It is advisable to keep your teas steadily before the Melbourne buyers, and I feel sure you will find a better market here for well-made leaf than London can offer.

ELECTRIC LIGHT AND VEGETATION.—Dr. C. W. Siemens read a paper before the British Association detailing a series of experiments he had made with the view of showing the influence of the electric light on vegetation and the application of electric energy to farming operations. The most recent of these experiments were made between October of last and May of the present year, the electric light being in operation from 5 and 6 p.m., until the dawn of every day except Sunday. The general results of these experiments went to show that the electric light was capable of producing on plants effects comparable to those of solar radiation and favourable to healthy growth. As to the theory of diurnal rest being necessary to plant life, Dr. Siemens gave it as his opinion, as the result of his experiments, that, although periodic darkness evidently favoured growth, the continual stimulus of light appeared to promote healthy development and to accelerate the plant through its different stages of flower and fruit. The questions, however, of temperature and the proximity of the electric light still remained to be dealt with experimentally with the view of determining the best conditions. Dr. Siemens also gave the results of experiments which he had made in applying electric energy to farming operations, including the pumping of water, sawing of timber, &c. He had been so strongly impressed with the results obtained that he thought the electric transmission of power might eventually be applied to thrashing, reaping, and ploughing; in fact, that all the work of a farm might be directed from a central station of electric power, instead of being carried out, as at present, through the agency of steam. So far as he had gone, the electric apparatus had been under the sole charge of his head gardener, with the assistance of under gardeners and field labourers, who had probably never before heard of electricity.

THE SIKKIM QUINETUM is the subject of an important letter from Mr. Grammie in another column, in which he shews that so far from the cost to Government being still over R16 per lb. (as Mr. Howard supposed), it is not more than R8 per lb.

ALOES IN MAURITIUS.—The last mail brought news of an advance in the value of Aloe fibre in England, which has given an impulse to the establishment of mills for the extraction of this article and it seems likely to be produced on a more extensive scale.—*Mauritius Mercantile and Commercial Gazette.*

NEW PRODUCTS IN THE EASTERN PROVINCE OF CEYLON.—On Mr. Fielder's plantation of Mahaoya situated near the side of the Badulla-Batticaloa road, there are some 49 acres planted with Rubbers, Cocoa, Liberian Coffee and Sapanwood. The district is rather too dry—although at present wet enough—for coffee; cocoa is doing pretty well; Sapanwood growing apace, and Rubbers a great success. A tree of the latter, only eight months old, measures 22 feet by 5 inches.

LEDGERIANA SEED.—It will be seen from an advertisement in our local paper that there will be little need to trouble Java planters further, for a supply of seed of the valuable 'Ledgerianas.' The analyses of Yarrow trees, from which seed can very soon be had, are as good (with from 4 to 7½ per cent of quinine) as the average of the trees from which seed has been imported from Java, and we have no doubt the Ceylon seed will germinated well being freshly gathered.

NILGIRIS.—The weather is still undecided, and we alternate between frosty cold and mist. It is time the frost had set in, as after the heavy and protracted North-East monsoon, a spell of dry weather is looked for to ripen the coffee. The coffee crop in parts will be very late this season. Cinchona planters are actively employed bringing in fern to shelter the last season's young planting against the severity of the frost, and tea manufacture will continue for some months to come in favored localities.—*South of India Observer.*

KEEPING BUTTER:—The plan described below is a very old one, and it enjoys the reputation of being good:—To three gallons of brine strong enough to bear an egg, add a quarter of a pound of fine white sugar, and one tablespoonful of saltpetre. Boil the brine, and when it is cold strain carefully. Make your butter into rolls, and wrap each separately in a clean white muslin cloth, tying up with a string. Pack a large jar full, weight the butter down, and pour over it the brine until all is submerged. This will keep really good butter perfectly sweet and fresh for a whole year. Be careful not to put ice upon the butter that you wish to keep for any length of time. In summer, when heat will not admit of small jars, take large ones, and, using the same brine, allow it to cover the butter to the depth of at least four inches. This excludes the air, and answers as well as the first method suggested.—*Australasian.*

LIEUTENANT DE HOGHTON gives the Australian press a strange account of a tree he saw on one of the islands in Torres Straits, which reminds one of the romance of the man-eating tree of Madagascar, or some of Jules Verne's stories. He declares that this tree picks up bones from the ground and carries them into its upper branches. He describes one tree which came under his observation as being 30 feet in height, with the extremities of all its branches and twigs covered with bones, apparently adhering to them. The tree stood outside some huts, and the bones thrown under it were taken up, he supposed, by the leaves, until it was quite loaded. It is allowable to imagine that Mr. de Hoghton did not examine into the matter with much critical acumen, and that he believed too readily what he was told. Were the pendant objects really bones? Perhaps some aftercomer will confirm or disprove the story.—*Straits Times.*

Correspondence.

To the Editor of the Ceylon Observer.

A QUININE FACTORY FOR COLOMBO.

Edinburgh, 1st December 1881.

DEAR SIR,—Upon having a talk with a mercantile gentleman, who is utterly unconnected with Eastern produce, on our present system of shipping cinchona bark, he expressed his astonishment at the waste of money entailed upon the producers, in freight, consequent upon the increased, and annually increasing, production of bark, all over the East, and in the present tendency of the age to employ capital in the establishment of Companies, in order to secure suitable returns for money. Why not take measures to initiate a quinine factory, either in Ceylon, or on the Indian coast, where producers of bark could, as in the case of coffee, either sell their bark at the mills, for cash, or, have it prepared into quinine, and shipped, on their own account?

If the country is not ready for this plan, *yet*, depend upon it, if the cinchona industry succeeds, as it at present promises to do, *it must come to this*, sooner, or later; and the first in the field will make the most. I have no idea whatever of what would be the capital required for such an undertaking. No double it would be large, but so also would be its profits. Neither have I the least knowledge of what sort of material or plant would be requisite for such. All this remains to be calculated by those who know, and by such the subject may be worth consideration.

Our present system of shipping barks is even a much more wasteful one than if coffee planters were to ship their coffee, dried in the husk.

As your pages are ever open to all notions of advance, I just write you on the subject, in order to draw out further opinions, either from yourself, or through correspondents. In the present scarcity of tonnage all over the world, what a waste of room!—not to speak of cash!—And in the present difficulty of finding lucrative but safe investment for capital, it would appear to me that an undertaking in this would meet the difficulty.—Yours truly,

P. D. MILLIE.

LEDGERIANA SEED.

13th December, 1881.

DEAR SIR,—With reference to the letters of "X. Y. Z." and "One Who Bought And Was Sold," I am glad to be able to say that the seed bought by me at Mr. Symons' sale, on the 21st September last, has germinated and come on very well. I mention this, as the last paragraph of the letter of "One Who Bought and Was Sold" might lead people to think that all the seed purchased "from the same quarter" turned out bad.—Yours faithfully, R.

QUINETUM MANUFACTURE IN SIKKIM: MR. GAMMIE IN REPLY TO MR. HOWARD.

DEAR SIR,—In your weekly edition of the 31st October appears a letter from Mr. Howard to the Secretary of State for India, in which he offers remarks on what he considers to be the very unsatisfactory condition and prospects of the manufacture in Sikkim of cinchona febrifuge, or, as I shall call it in this communication, for the sake of brevity, quinetum. It is well-known that Mr. Howard, as becomes his name, takes a lively interest in the production of a febrifuge that shall be an effectual remedy for malarious fevers, and at the same time be so cheap as to be within the means of the very poorest of India; and I feel sure that he will be thankful for my poor attempt to set him right in a few errors he has fallen into—no doubt through an over-hasty perusal of the cinchona papers sent to him for criticism—and will rejoice to know that the Sikkim quinetum is already produced at a little over half the cost he quotes, and that year by year the opinion of the Indian medical profession steadily grows in favor of the drug, so much so indeed as to have reduced the imports of quinine to Calcutta last year by no less than 44 per cent.

It is unfortunate that Mr Howard begins by omitting dates, for from the fact of his letter bearing so late a date as the 21st June of the current year, the public will naturally infer that the results up to nearly that date are given, and his arguments and calculations founded thereon. But in the very first paragraph details are given of the financial year ending 31st March 1877, when quinetum manufacture in Sikkim was in its infancy, without any remark to show that they are not for a later year; and to make confusion more intensified a quotation is given—in the very same paragraph—from Mr. Moens' report for the year 1879, the year in this case being specified. For that year—ending 31st March 1877—the figures are correctly given; the out-turn of quinetum was less than 2 per cent of the bark worked, and its cost over R16·3 the pound. But the figures for last year show that the cost had been reduced to under R9·4 the pound, and the out-turn increased to considerably over 2½ per cent. For the year before, the figures for which Mr. Howard must have overlooked, as his letter bears internal evidence that he had the cinchona papers published up to the latter part of 1880 before him, the cost was R10·2 the pound, and the out-turn also over 2½ per cent. So the price is being steadily reduced, and the day is not far distant when the producing cost will be as low as R8 the pound, and probably lower; for, as the plantations have hitherto been under-cropped, there is a wide margin for contingencies and every prospect of still more favorable results. Mr. Howard will be glad to know that long accomplished facts have placed beyond dispute that he was in error in assuming that the cost could not be "much lessened" from R16·3 the pound. He then goes on to show that the supposed *cheapness*—italics are Mr. Howard's—is all a fallacy, and to compare the quinetum unfavorably, both as regards cost and efficacy with cinchonæ sulphas which, it is stated, could be bought at R5 the pound. But it appears to me that it would have been fairer to have compared it, at least as regards cost, with the quinetum manufactured by Whiffen, which is avowedly a similar drug, in appearance and composition to that made in Sikkim. The price of it Whiffen puts, as manufactured by him for the Madras Government, at 53 shillings the pound, which is about double the cost charged to the Bengal Government for the Sikkim quinetum, viz. R16·8. Mr. Whiffen at the same time puts the price of the cinchonine alkaloid, which is, I presume, commercially, an inferior drug to cinchonæ sulphas, at 15s. a pound. I venture to say that had sulphate of quinine itself been tried, in the experiments Mr. Howard refers to, against cinchonæ sulphas the cost would have been still more in favor of the latter than when compared with quinetum. And as regards efficacy these same experiments showed that, whilst about 22 per cent of the patients treated with cinchonine sulphate were returned as uncured,* 7 per cent only of those treated with quinetum were returned uncured. It is to be regretted that whilst what at first might appear to be damaging quotations against the quinetum are given by Mr. Howard from the paper referred to, those in its favor are entirely omitted, the more especially so as he continues at paragraph 7:—

* Mr. Moens told us that cinchonine has been excluded from the German Pharmacopœia.—ED.

"The present papers confirm the opinion I expressed in my last letter of its decidedly emetic properties." The paper is by Dr. Cornish, Surgeon-General of Madras, and the omitted quotations I refer to, and which give a very different aspect to the efficacy of quinetum, are as follows:—"The average shortest time under treatment was when the Sikkim drug was exhibited," and:—"The results of these experiments show that quinetum does not cause any more unpleasant symptoms than sulphate of cinchonine or chinchonidine. My impression is that, as a rule, all these drugs are given in too large doses by our medical subordinates, and that with proper precautions as to the mode and times of administration, they may all be used without inconvenience." This opinion, of so eminent a medical authority, supported as it is by similar published opinions of the highest in the profession in Bengal and other parts of India, should convince most people that the supposed emetic property of the quinetum does not exist when properly administered.

At paragraph 8, Mr. Howard quotes, with admiration, that "the miseries caused by Indian residence and illness are depressing enough in themselves, without being intensified by nauseating agencies quite foreign to the therapeutic effect required." This, on the face of it, is clearly an attempt at fine writing only, and the writer should have known that it was calculated to convey a false impression. The phrase "Indian residence" appears to imply that Government intended the drug to take the place of quinine among European residents, who are, as a rule, well able to buy sulphate of quinine. This, I need scarcely say, is very far from being the wish of the Government of Bengal, and I have already shown that the "nauseating agency" is a bugbear only. But even were it nauseating, which it is not, the fact of it curing fever in a shorter time than the sulphates other than quinine would be considered by everybody who has had the misfortune to experience fever more than a counterbalance to the passing inconvenience of a little nausea.

At paragraph 9 Mr. Howard states that "apart from these (nauseating) effects the efficacy of the remedy is universally admitted." Taking into consideration this universal admission, the fact that the supposed nauseating property scarcely, if at all, exists, and the low cost of the drug, it is not too much to assert that the benevolent intentions of the Bengal Government, as regards supplying an efficient febrifuge for the fever-stricken poor of India, at a cost within their means, have been amply fulfilled; and this is not the less gratifying to those entrusted to carry out those intentions that they have been able to do so without loss to the rate-paying public. JAS. A GAMMIE.

PIMENTO OR ALLSPICE.

Nella Oolla, Madawalatenna, 15th Dec. 1881.

DEAR SIR,—Perhaps the following, with regard to "pimento," may interest your correspondent who signs himself "Planter," in your issue of the 13th inst.

The allspice is a native of the West Indies, and is cultivated particularly in the hilly parts of the country. It begins to bear fruit when three years of age, and arrives at maturity in seven years. The berries are collected before they are ripe, at which time the essential oil, to which they owe their pungency, is most abundant. They are spread out, exposed to the sun, and often turned. In about a week they lose their green colour, and acquire that reddish brown tint, which renders them marketable: they are then packed in bags and casks for exportation. When dried the berries are rather larger than a pepper-corn. Some plantations kiln-dry them, which expedites the process very considerably. The plant itself is a handsome evergreen with a straight trunk about 30 feet high, covered with a smooth grey bark. In Jamaica, "pimento walks" are talked of, and as the tree is a large one they cannot be planted very close together.

If you think the above information will be of any use to "Planter," kindly insert it and oblige,—yours faithfully, ALLSPICE.

MOUND HEDGES FOR *HEMILEIA VASTATRIX*.

Kotmale, 15th Dec. 1881.

DEAR SIR,—Mr. Marshall Ward's long letter in Tuesday's paper is lucid enough for any "lay readers," couched as it is, as far as possible, in language that "may be understanded of the people." Still the "non possumus" mist, which I ventured to put forth as my judgment on his remedial measures, has not been dispelled even by the bright light now thrown on the disease.

Setting aside the question of disinfecting the coffee in a space of time too brief for possibility of adoption, the one matter which seems most worthy of consideration to me—I speak as a layman—is the prevention of a general distribution of spores by wind. Of course, a great deal has been attempted by the planting of belts here and there, but these cinchona screen plantations are never thick enough to be impervious to the passage of spores, and I would suggest the construction of *Devonshire coppice mound hedges* along ridges throughout the coffee.

Now, the manner of construction in that country is to carry up a stratum of earth between two sod facings "battering," *i.e.*, leaning somewhat inwards, to the required height, say 5 or 6 feet. Given the mound of this height and about this width at the top, it is usual to plant sturdy beech stumps on the summit, and to keep the hedge thus formed close and thick by annual trimming.

The kindly shelter such hedges afford to man and beast in wild weather is well-known. In Ceylon a modified form might be made use of, say 5 feet high, 6 feet broad at low and 3 feet at top, and surmounted by a thick tea hedge, kept thick by such trimming as the privets get in London square gardens. For such a hedge two or three rows of coffee, which, by the way, is generally thin on ridges, would have to be sacrificed.

Spore-laden leaves would collect in large numbers against these hedges and could be easily destroyed on the spot. One could calculate on a few rows of coffee to leeward of the walls being free from the disease.

Can Mr. Marshall Ward explain why *Hemileia* did not forsake the jungle earlier?

Has *Hemileia vastatrix* ever been discovered in the jungle? Supposing that it really did emerge from the jungle, is it right to say that the chief peculiarity about this particular fungus is that its mycelium requires the organized materials found in the cells of living *coffee-leaves* for its food? It is surely worth while to search for the jungle growths which were the home of this fungus till 1869, and, when found, introduce them among our coffee.—Faithfully yours,

POST TENEBRAS LUX.

BARK OF COPPICED TREES BECOMING INERT.

Dikoya, 16th Dec. 1881.

DEAR SIR,—In reply to "Sulphate," writing on the 16th inst., I beg to assure him that what I stated is correct. Several lots of root bark were lately sold by me, aggregating 7,000 lb., and each lot was analysed by Mr. Lixon, who rejected a large percentage of each lot as "dead bark." I found this was not from dead trees, but from the stock of coppiced officinalis, whose stem bark sold for 6s per lb. two years previously. I think this goes to prove that you run some risk in adopting Mr. Karslake's system, especially if you

do not make the horizontal cut at the bottom and so prevent the sap, and with it the alkaloids descending. To prevent the bark thus dying the *highest* sucker or better, three or four should be left on the stool, instead of the lower ones, although they are generally the strongest. Succiubra are not so liable to die off as officinalis.—Yours truly, CINCHONA.

P. S.—I enclose pieces of the bark of a healthy tree coppiced two years ago, showing you how it is affected.

RUBBER GROWTH IN THE UVA DISTRICT

Badulla, 18th Dec. 1881.

DEAR SIR,—I send you the measurement of a Ceará rubber tree growing in the Pa-sara-Bullutwatta valley. Would you kindly publish it, as information of this description is interesting to those engaged in the cultivation of *New Products*?—Yours faithfully, E. C. SWEETING.

Dimensions &c.

Spread of branches	... ...	18 feet
Height	... ...	22 ,,
Circumference of the stem 4 feet from ground	... ...	10¼ inches
Age	... ...	20 months.

100 ripe seeds have been gathered from this tree, and there are now some 300 more partially matured and a small quantity of flower showing.

CALISAYAS IN MASKELIYA AND DIKOYA.

Maskeliya, Dec. 18th, 1881.

DEAR SIR,—I was very glad to see Mr. Kay-Shuttleworth's letter in your issue of the 16th. As he remarks, there was a *sale* of the above bark, before Mr. Moens visited the island, and why should not the analysis of the above bark be published? I do not by any means wish to say that the analysis should be necessarily published, but, at the same time, it would be beneficial to the proprietors of the estate and to the public, and especially to former purchasers, as they would know whether the plants raised from the seed they had bought at such a fabulous prices are valuable enough to remain in the ground or whether it would not be better to have them grubbed up, to make room for a more valuable species.—Believe me, yours truly. H. I. B. P.

[We cannot understand all this revival of an old controversy. Immediately after the return of the proprietor of Annfield, he published a series of analyses by Mr. Howard of the barks of his trees. As for Mr. Moens' inspection, that gentleman we beg to say once more, was not infallible. He pronounced Mr. Roberts' Pussellawa calisayas to be inferior and practically not worth cultivating; while Mr. Howard's analyses and the crop and market returns, shew them to be especially valuable.—ED.]

COCOA.

Dec. 23rd, 1881.

DEAR SIR,—Will your correspondent "Cocoa" kindly add to the information he gives us in your issue of the 13th, about packing cocoa seed for export, by stating whether he extracts the seeds from the pods and then packs them in sawdust, or packs the pods entire in sawdust? I ask, because I have seen it stated that the seeds should be put into the ground direct from the pod.—Yours truly,

ANOTHER COCOA.

METEOROLOGICAL OBSERVATORIES AT HIGH ELEVATIONS.

Colombo, 23rd Dec. 1881.

DEAR SIR,—With reference to a new Meteorological Observatory established at the residence of Mr. Morris of the Jamaica Botanical Department, an extract from the *Jamaica Gleaner* published in your edition of the 21st contains the following remarkable statement:—

"It is beyond question the highest observatory in the British Empire, the elevation being 4 900 feet."

The following is a list of Meteorological Observatories in India and Ceylon at a greater elevation, included in the annual Report published by the Indian Government:—

	Lat. N.	Long. E.	Elevation in feet, above sea level,
	° '	° "	
Leh ..	28 59	76 42	11,538.
Simla ...	31 6	77 12	6,952.
Ranikhet. ...	29 38	79 29	6 069.
Darjeeling ...	27 3	88 18	6,912.
Wellington ...	10 22	76 50	6,200.
Nuwara Eliya ...	7 0	80 42	6,150.

The above all forward daily weather reports to the head office at Calcutta. C. H. A.

COFFEE IN SOUTHER INDIAN.

Scottish Indian Coffee Co. Limited,
Colachel, Travancore, 27th December 1881.

DEAR SIR,—In the weekly *Observer*, No. 47, of date 12th December, under the above heading you published a statement by Messrs. Alstons & Co. of Tellicherry, of exports of coffee from the Malabar coast, for the year ending 30th June 1881, which is not by any means complete as regards Travancore; the port of Quilon, from which about half the produce of the coffee estates in South Travancore is annually shipped, being entirely omitted. The coffee shipped at Quilon during the two years for which statistics are given aggregated over 20,000 cwt.

As the statement published is apt to mislead, especially as it has been backed up by your editorial reflections on the poor outturn for Travancore, I trust you will give prominence to the above facts in an early issue.—Yours faithfully,

THOS. HENDERSON.

[Would Mr. Henderson kindly furnish us with the exact figures for Quilon and Colachel for the several years we require to fill up our table, so as to make the information in our "Handbook" complete, and much oblige.—ED.]

"NEW PRODUCTS": ALLSPICE OR PIMENTO.

Colombo, 28th Dec. 1881.

DEAR SIR,—The allspice or pimento trees can scarcely be considered new products in Ceylon. In 1747, Linnæus devoted nearly the whole of page 83 of his *Flora Zeylanica*, No. 186, to a description of, and notes on, the plant identical with the long narrow-leaved Allspice, now the Eugenia Pimenta, D.C.; but strange to say, there is no reference to Hermann's collection of plants made in Ceylon, as regards this one, though it is most likely the pimento was introduced to Ceylon by the Portuguese or Dutch long before Hermann's visit to Ceylon (1670-7). The Eugenia (Myrtus-) Pimentæ, is included in Moon's Catalogue of Ceylon plants, p. 59, and was therefore here before 1824. In 1856, the Rev. William Ellis, the eminent Polynesian and Madagascar Missionary, paid a visit to Ceylon, and, in the course of a botanical trip I had the pleasure of making with him in the direction of Mutuwal, we called at Elie House and found a fine tree of the broad leaved allspice there in full fruit. This is the Eugenia acris, W. & A., and must also have been introduced into India and Ceylon many years ago.

The pepper called allspice or pimento is the dried fruit of Eugenia acris, and E. Pimenta. Many years ago, on visiting at Lake House, Colombo, when

occupied by the Hon'ble Judge Stewart, I was asked to name some old foreign trees growing in the grounds, and amongst them were trees of the Eugenia acris and Pimenta. About a fortnight ago, I went to see these trees, in reference to the correspondence in your columns on the subject of introducing Pimento to Ceylon, and found several trees of E. acris, and one of E. Pimenta, but no fruits or flowers on them; and Mr. Auwardt, who now occupies the house, says he has not seen them in flower lately. There is no lack of information in books on the subject of pimento, but to everyone who wants full information on this or any other useful plant, I beg strongly to refer them to Bentley and Trimen's magnificent work, consisting of 4 quarto volumes of coloured plates from the living plants or authentic specimens, with every information, scientific, as well as familiar, and references to every author of any consequence who preceded them, and who had written on the plants figured and described in this work, the title of which briefly is Bentley and Trimen's Medicinal Plants. I notice that the Planters' Association intend getting up a library of useful books of reference, and this work should be one of the first selected.

—Yours truly, W. FERGUSON.

[Our readers must, of course, understand that we do not confine the term "New Products" to new introductions into Ceylon: in that case, strictly speaking, very few of what are popularly known as new products could be so designated: tea having been produced and manufactured here by the Brothers Worms forty years ago, and old trees of cocoa growing in Ceylon for a generation back. We called Pimento a new product in the sense of European planters in Ceylon, beginning for the first time now to pay attention to it for its commercial value.—ED.]

REPORT OF THE EXPERIMENTAL GARDENS AT BURMAH.—Mr. J. Petley has submitted to the Chief Commissioner of British Burmah a report on the cultivation of tea, coffee, cinchona and potatoes in the Karen hills, North-east of Toungoo. Towards the end of 1880, large numbers of mole crickets made their appearance, and caused much destruction amongst the young tea and coffee plants by nipping off the tops. Of the growth of tea, we are told that there are now 1,000 trees, three years old, uninjured; 2,000 of two years' old; 8,000 one year old; 7,500 used in filling up vacancies, and 5,000 new trees planted out this year; so that the plantation should shew 32,500 healthy and flourishing plants. Of 25,636 young plants of coffee sown out last season, 20,000 were destroyed by the ravages of the mole cricket, and the unusual heat of March and April 1880. The ground has, however, been all filled up again, and the garden return shows 1,447 trees from four to five years old; 3,620 two years old, of which number 2,000 are bearing; 5,636 one year old, and 24,000 sown out last July. The plantations have thus 34,703 healthy and flourishing coffee plants. There are also 4,878 cinchona trees, amongst which the loss has been very slight, and of which the report speaks hopefully. Before extending the cinchona gardens, the superintendent is awaiting an analysis of some trial shipments of bark sent to London. The attempt to grow potatoes on the Karen hills, as a dry-season crop, has proved a failure. The plants suffer from the ravages of deer, grubs, and insects to an extent which makes the crop a dead loss. Of the main crop, the importation of seed was 21,290 lb., of which 9,700 lb. rotted off before sowing; one-fourth of the balance rotted away in the ground after sowing: so that only 8,690 lb. of seed thrminated and yielded a crop. This quantity of seed produced a crop of 48,776 lb. It is hoped that this quantity will keep well, and that, although she dry season crop fails, the main crop of potatoes may be established in the Karen hills.—*Indian Daily News.*

"DATE COFFEE," which under the promotership of a celebrated, but not too popular, financier, was a nine days' wonder, especially to those who were bold enough to drink it, is making a fine harvest for the lawyers. Not only is its patent being disputed in the courts, but the right of journalists to say that they do not like its taste, and that it does not suit their palates, is about to be questioned. Anybody who has hinted that date coffee will not drive every other beverage out of the field, and become the universal breakfast table drink of the whole world on the day after tomorrow, making the fortunes of everybody who has bought a single share, has received notice of an action for libel. Two society papers are already in for it. More are expected to follow. Meanwhile, an action in Chancery has yet to decide whether date coffee has any *locus standi* at all anywhere.—*Home paper.*

MICA.—A German manufacturer of mica wares, Herr Raphael, of Breslau, now makes mica masks for the face, which are quite transparent, very light, and affected neither by heat nor by acids. They afford good protection to all workmen who are liable to be injured by heat, dust, or noxious vapours, all workers with fire, metal and glass melters, stone masons, &c. In all kinds of grinding and polishing work, the flying fragments rebound from the arched mica plates of the mask without injuring them. These plates are fixed in a metallic frame, which is well isolated by means of asbestos, so as not to be attacked by heat or acid. These masks allow the turning of the eyes in any direction, and, as against mica spectacles, they afford the advantage of protection to the whole face. In certain cases, the neck and shoulders may al so be guarded by a sheet of cloth impregnated with fire-proof material, or by asbestos sheet, attached to the mask. The interval between the mica and the eyes allows of workmen who have poor eyesight wearing spectacles, and of workers with fire or in melting operations wearing coloured glass spectacles under the mask, with fear of breakage of the glass, mica being such a bad conductor of heat.—*Ibid.*

THE COST OF TEA TO THE CONSUMER.—A planting correspondent sends us this extract from a home paper, which is well-worth reproducing. Such exposures will not tend to increase the popularity of China tea in England:—

"Souud common congou is quoted by late telegrams as selling in Shanghai for ten taels per picul; steamer freights 45s., and exchange 5s 2½d. This lays it down in London at a fraction over 6d per lb., its present value in the market. This ten taels is divided in China as follows:—

Taels 5·88, paid to the teaman;
" 4·12, paid to the Chinese Custom-houses (*e.g.* taels 2·75 at the shipping ports, and 1·37 "Lekin," or upcountry squeezes.)

Out of this 6d per lb., laid-down price, there has to be paid London dock charges, say ¼d per lb.; freight, on the average, 1d per lb.; chests, leads and packing in China, ¾d. The calculation will, therefore, stand thus:—

Paid to the teaman in China, out of which he has to pay inland carriage	1¾d.	per lb.
Duty in China	1½d.	"
Chests, leads, and packages	0¾d.	"
Freight	1d.	"
London dock charges and extras	0¼d.	"
Total... ...	6d.	"

Upon leaving the bonded warehouses there is another 6d to be paid for duty, and it is sold in the poorer districts in this country at 2s and upwards per lb. Here we have a commodity sold first hand in China at 1¾d—and even this carries part of the cost of transit—selling in this country at about 9s per lb. This may possibly account for the poverty of the quality, and explain the dissatisfaction expressed in this important branch of commerce."

INDIAN TEA SALES IN AUSTRALIA.—The *Indian Daily News* says:—"The Calcutta Tea Syndicate now command a steady trade of 2,000 half-chests of tea per month, in addition to a not inconsiderable trade in private hands. Tea planters should try and maintain the good name of Indian teas in Australia, by shipments of good quality. There is no reason why the exports should not reach a limit of 20,000 half-chests a month, if the same superiority over China tea, that now prevails, is allowed to continue."

BARBADOES TAR (says the *Queenslander*) rubbed on the nose, has been found in England to be a complete cure for mange in dogs. A landowner near Manchester, by the same means, preserved his herd of cattle from foot-and-mouth disease, whilst every herd around him and in his neighbourhood was suffering. The tar was simply rubbed on the muzzles of the cattle twice a week. If Barbadoes tar possesses the quality it is here credited with, it might be convenient for owners of valuable dogs and cattle to have a plentiful supply of it when mange and pleuro-pneumonia are about.—*Australasian.*

MAGNETIC SEPARATION OF IRON SAND.—Under this heading the *Scientific American* for July 1881 states that Edison has invented a magnetic separator which enables the valuable ore in black sand (such as is common in Ceylon) to be separated from the valueless titanite iron. The sand falls from a height and a magnet deflects the pure iron particles. A machine which cost $100 is worked by a boy, and iron is obtained at a cost of $1 per ton, which sells for $6. The machine treats 100 tons of sand per diem. The machine is worked by a company at Long Island. Who will introduce and work a similar machine in Ceylon?

A PROBABLE DIMINUTION IN NEXT CROP OF SANTOS COFFEE is thus indicated in the *Rio News*:—"The *Provincia de São Paulo* of the 26th ultimo publishes the opinion that the drouth and great heat have caused so much injury to the coffee orchards in blossom that the next crop will be greatly diminished. And the following paragraph represents Rio as suffering equally from heat:—"The *Opinião Liberal*, of Campinas, S. Paulo, is informed by one of the most important planters in that vicinity that the next coffee crop has been greatly damaged by the long-continued heat and drouth. The next crop in that municipality, and in those adjoining, will be very light. Nearly all the first blossoms were killed, and if the drouth continues, the last blossoming will suffer the same disaster. Reports from the province of Rio de Janeiro complain of the same results."

"THREE YEARS' COFFEE PLANTING" is the title of a series of papers in the London *Globe*, the third of which appears in the issue for December 2nd. The writing, so far as we have seen is practical and pro die enough and no reference is made to any particular coffee country. An exception is found in the paragraph introducing the third letter which we may quote as follows:—"The deep stillness of the tropical jungles in the morning is very noticeable. They are full of a beauty of their own which the exile never grows too familiar with or ceases to admire as he does many other scenes in this far away country. For a time after dawn the mist hangs about in dense silvery veils, from which the higher clumps of trees stand out like islands in some quiet sailless ocean, and under this canopy the dewdrops hang thick and glitter like on all sides, gemming the spiders' webs with diamonds, among which the great red bodied spiders show up like rubies whilst the white vapour circles about and coils in between the tree stems in fantastic shapes with every light breath of air. Under such circumstances, and while the morning is still cold, the planter each day starts for the scene of his labour."

LEAF DISEASE AND MR. MARSHALL WARD'S REPORT: THE GOOD EFFECT OF HEAVY CONTINUOUS RAIN.—It is a great pity planters do not more generally read Mr. Marshall Ward's report *in extenso*. If they did, I think many statements which appear in your paper would be modified. For instance, in your issue of 28th instant "the patriarch of Dimbula" is made to say that "Ward tells us that it is the rain which enables the enemy of coffee to spread." Quite true, but he also tells us that with rain spores should be produced within 3 weeks and may continue for 5 or 6 weeks more. If so, then, speaking only for my neighbourhood, I hold the worst to be over. We have had rainy weather for over two months, and such leaves as have dropped during that time have ripened very few spores. So, if all the old spores have grown, as they ought to have done by now, and have not produced any great number (I speak comparatively) to replace them, it may be presumed that not very many are now available for fresh growth.—E. H.

AGRICULTURAL EDUCATION IN SWEDEN:—A hint to Britain and to British Dependencies is found in the following from a review of Du Chaillu's new book in the in the *Pioneer*:— In one respect at least Englishmen would do well in these times agricultural depression, to copy the example of Sweden. There are twenty-seven agricultural schools in that country, and they are considered to rank among her most useful institutions. They are said to have greatly encouraged the development and improvement of agriculture, and they are very popular with the farming classes. 'The students," says Du Chaillu, are required to remain under instruction for two years; the course of study comprizes the principles of agriculture and horticulture, the care of domestic animals, the improvement of breeds, drawing, surveying, drainage, carpenter and smith's work carriage-making, forestry, mathematics, agricultural chemistry, meteorology, veterinary surgery, botany, a little of zoology and geology, butter and cheese-making, the art of building and of making fences and walls. Connected with some of the principal schools are dairy schools for women, where they go through a year of butter and cheese-making. What would our farmers (and their landlords) give now to have enjoyed the benefits of similar instruction in the day of their youth? Ignorance has not proved to be their bliss, in the struggle against bad seasons and American competition.

CARBON AND PLUMBAGO.—The *London Magazine* states:—"If we wish for some substance which will catch fire from the smallest spark, we find that among the thousands of bodies, simple and compound, that exist in nature or are produced by art, the most suitable for our purpose is pure carbon in the form of tinder. On the other hand, when we want a crucible that will bear without taking fire the flame of the hottest furnace, we make it of pure carbon in the form of plumbago. The wax mould of the electroplater is a non-conductor of electricity, and it is, therefore, necessary to cover its surface with some good conducting material; it is found that the best material is finely pulverized plumbago; but this same element when crystallized, as in the diamond, is the most perfect of all non-conductors! Carbon, in one state, is as soft as lamp-black; in another it is the very hardest substance known; in one it is brilliantly transparent, in another it is perfectly opaque; in one it is the most costly ornament in the crowns of kings, in another it is shovelled out of the way as worthless." In all these changes in the condition and properties of carbon law no can be discovered, with the single exception that the temperature at which the various kinds of charcoal will take fire are in fixed relation to the temperature at which the several kinds are prepared. This is of the utmost importance to the manufacturers of gunpowder; they have caused it to be investigated with great care."

COFFEE ENEMIES.—Kotmale, Dec. 15th.—I enclose in a matchbox some caterpillars; also a branch of coffee shewing the damage they do. The coffee looks a sad sight when they have finished with it. This is surely a new pest? I put a cooly to exterminate the rest. [The caterpillars evidently belong to the family of moths named Bombycidæ. During the day they reside in large numbers under a web constructed by them, and common to all, out of which they issue at night in search of food. They are, from their great numbers, very destructive.—ED.]

THE PUBLIC SALE OF COFFEE IN LONDON.—An attempt has recently been made to alter the method of offering coffee, similar to that which was tried with Indian tea sometime since. The custom has always been to have each parcel bulked on landing, but in two or three cases lately brokers have offered parcels as "not bulked." The trade wisely, on Wednesday last, refused to have anything to do with such parcels, for although the samples shown were supposed to have been drawn from several of the bags, there was of course no proof that many of them did not vary very materially, and if so on such terms no claim would be entertained. The only advantage that could be derived would be a slight saving in the importers' landing charges, but it is highly improbable that had the parcels been sold dealers would have paid so much for them as if offered in the ordinary way. It is true that this system has so far only been attempted with Brazil descriptions, such as are used solely by the export trade, but if once allowed to be adopted, Ceylon and other importers would probably try a similar plan.—*Produce Markets' Review.*

GOOD OUTLOOK FOR INDIAN TEAS IN AMERICA, AND WHY NOT CEYLON TEAS ALSO?—The circular lately addressed to the local tea planting interest by the Committee of the Calcutta Syndicate reporting the results of Mr. Sibthorp's efforts to create a market for Indian teas in America, opens up a vista of unprecedented prosperity in the future. That the population of America, the bulk of which consists of the same races among whom Indian tea has grown in favour so rapidly in the United Kingdom, should persist in rejecting it after a fair trial was *à priori* highly improbable. It was, therefore, reasonably to be presumed that whatever difficulty might beset the opening up of this new market, would consist chiefly in the obstacles to securing such a trial. Mr. Sibthorp's report not only bears out this view of the case, but justifies a confident expectation that the obstacles in question, so far as they have any real existence, will speedily disappear. In Chicago, so far from having had to encounter any of these strong trade prejudices which were met with at first in Australia, Mr. Sibthorp found the leading importers, Messrs. J. Doane & Co., ready to render every assistance and confident of being able to dispose of five thousand half-chests the first season, without forcing the market. Similar success seems to have attended his efforts in New York, and a telegram has been received from him ordering a thousand half-chests for shipment to that port. The importance of this new market is immensely enhanced by the circumstance that the American consumption of tea is destined to increase, owing to mere growth of population, at a rate not to be looked for in any other country; at such a rate, in fact, that, if India could only secure the annual addition to the demand from this cause, she would probably have to double her production in less than a generation, to enable her to meet it. So far from seeing any reason why she should not secure this amount of custom in the new world, we see none why the proportion of Indian to other teas consumed in America should not ultimately be as large as in England, where there was once a strong prejudice against Indian tea.—Calcutta *Englishman.*

FUNGI.—Matale, Dec. 16th.—The enclosed leaves were plucked from a jungle tree growing in the midst of some coffee, suffering very badly from *Hemileia vastatrix.* Can you tell me what the blight spots are, which you will observe pretty thickly spread over the surface of the leaves? Do they not look remarkably like having caught the infection from the coffee trees? [The injury to the leaves has apparently been caused by the attack of some insect, probably a scale bug, which has left its shield on the leaf.—ED.]

BREWING IN INDIA AND CEYLON.—From an article in the *South of India Observer* it would seem that brewing on the Nilgiris is not the success it was hoped it would be. The Government are not giving the industry any encouragement, but whether this is the cause or the consequence of the liquor being poor is not apparent. We learn that wheat, barley and Indian corn are used indiscriminately by the brewers for malting purposes, but the wheat and barley grown on the hills are not of a quality fit for brewing, and the cultivation by the natives has been stationary for some years. Although the best seed has been sown it has rapidly deteriorated. The attempts to introduce hops also have been a total failure. Altogether the prospects of the Nilgiri breweries are anything but bright. We hope the Nuwara Eliya one will fare differently. We suppose barley could be procured from Australia for our local brewery?

CUPREA BARK.—Apparently there is a species of this cinchona allied to the Carthagena bark, plants of which Mr. Cross has successfully established on the Nilgiris. We extract as follows from Colonel Beddome's report:—

Carthagena Bark—(Cinchona Cordifolia).—The two plants brought lately by Mr. Cross from the Central Cordillera near Bogota (elevation 4 to 6,000 feet) are healthy and strong growing and are being propagated, and the prospects of establishing it on the Nilgiris are promising. It is supposed to be a strong growing large tree, which its present appearance does not belie; its yield in quinine is much the same as that of Succirubra, and it will probably succeed in the same localities as that species. Mr. Cross tells me that he believes the "China Cuprea," the seed of which is promised to this Government (*vide* G. O., No. 630, of the 8th April 1881) from Bogota is the same species."

BREWING IN THE EAST.—It is a well-established fact that the colder the climate the better the grain; hence the superiority of English and Scotch barley over the Indian grown article, and we are not surprized to learn that experiments in malting Indian wheat and Indian corn have been unsuccessful (in the Neilgherries). The breweries in Upper and Northern India have not been failures; for we have only recently heard of the renewal of their contract with the Indian Government for a further period of five years. The quality of their beer has always been considered good, a fact which may no doubt be explained by the climate; and this is what will be in favour of our Brewery Company in Nuwara Eliya, the managers of which intend using none but British grown barley and hops. We shall probably hear more about our own local industry before very long. In spite of an unusually wet season, which has much interfered with building operations in Nuwara Eliya, the works at the brewery are now almost complete; and huge packages of malt and fermenting vats are now on their way up from Colombo. An unforeseen difficulty in the size of these packages has presented itself; the ordinary carts being found too small to carry them, whilst impediments presented themselves on the road in the form of overhanging rocks. But all these difficulties will be overcome, and the visitors at the next Jymkhana will be able to quench their thirst in draughts of home-made foaming ale.—"C. Times."

CINCHONA CULTIVATION.

COLONEL BEDDOME AND MR. R. CROSS ON THE NILGIRI PLANTATIONS OF THE MADRAS GOVERNMENT.

(Continued from page 635.)

PYKARA.

The Hooker Cinchona Plantation, Acreage 134·19.

62. *No. I Plot*, 1866, *A.*—Acreage 10·91, about half grass land and half shola land. The grass land chiefly Officinalis, only a few Succirubra; the crown barks have been planted too far apart, but the gaps are to be filled in this season. The shola land all Succirubra, growth good (about 20 feet high) except a small bit on the upper portion, which is much wind blown and thin from failures, and in which supplies are to be put down this season. All the plantation has been barked five times.

63. *No. II Plot*, 1866, *B.*—15·09 acres; about one-third grass land planted with Officinalis; about two-thirds shola land planted with Succirubra; growth good or fairly good; in portions there is a yellowish appearance in the foliage which is not noticeable at Neddivattam; it is probably due to the long drought and east wind, and will disappear with the monsoon. All the plantation has been barked five times.

64. *No. XIII Plot*, 1873.—10·59 acres, all shola land, planted with Officinalis; a few Succirubra put in as supplies; there are about 20 Pitayensis; but 726 plants sent out from Ootacamund as Angustifolia have turned out ordinary Officinalis; growth of trees good, but the plantation is very patchy and the trees far apart caused by the inroads of sambur. In addition to the 10½ planted acres, there are some 15 or 20 more of abandoned shola cleared in 1873, but now over-grown; it would be a good plan to fence in the plantation and to re-clear and re-plant this portion, and to plant up the vacancies in the 10½-acre plot, but it would be useless without fencing on account of wild animals. This plantation has not been barked.

65. *No. X Plot*, 1869, *A.*—3·58 acres, grass land, Succirubra and Officinalis in nearly equal proportion; growth not good; soil poor, rocky, and gravelly. Has been barked four times.

66. *No. VII Plot*, 1868, *A.*—18·36 acres, chiefly shola land, good soil, planted with Succirubra; the growth of the trees is good, but the plantation is very patchy from many trees having died out; cause not known; the gaps are to be filled in with Officinalis, but I fear this will not answer unless the plantation is fenced in, as sambur are exceedingly troublesome in this plot, and destroy most of the young plants put out. The above trees have all been barked four times. Some grass land planted with Officinalis very far apart; growth short; pits have been dug for filling in more trees; the soil is good, and it would have shown far better results if it had been planted 4′×4′ instead of 8′×8′. All the trees have been barked four times.

67. *No. III Plot*, 1867, *A.*—14·24 acres. Two-thirds grass land formerly very stunted Succirubra, only a few feet high, which has last season all been up-rooted, and the ground is now pitted for Officinalis, which is to be planted out this season. One-third shola land Succirubra; fine growth and barked three times.

68. *No. XI Plot*, 1869, *B.*—9·35 acres, all shola land, planted originally with Succirubra, growth good, has all been barked four times; there are supplies of Officinalis; some grey barks were dying out, and have been all up-rooted. Five acres coppiced in June 1879, the stools bled excessively; there are 1,379 failures out of 2,226 stools, but the 847 which succeeded have grown well, and are three to six feet high with one to three stems to each stool.

69. *No. VIII Plot*, 1868, *B.*—23·71 acres, chiefly shola land, planted with Succirubra; the plot is very patchy as very many trees were injured by the hail in 1879 and died out subsequently; growth of in remainder good, now pitted for supplies of Officinalis. All barked four times. About two acres of grass land covered with very fair Officinalis; all barked four times.

70. *No. XII Plot*, 1869, *C.*—6·52 acres, about three-fourths shola land and one-fourth grass land, planted almost entirely with Succirubra which nearly all died out after the hailstorm in 1879, and has been up-rooted and the plot re-planted in 1880 with Officinalis, doing well; there is a sprinkling of good old Officinalis (scattered about the plot) which were put down at the same time with the red barks.

71. *No. V Plot*, 1867, *C.*—2·71 acres, chiefly shola upland, originally planted with Succirubra which all died out after the hail-storm in 1879; it was afterwards rooted and re-planted with Officinalis in 1880 which is doing well.

72. *No. VI Plot*, 1867, *D.*—16·07 acres, all grass land, about two-thirds, formerly very stunted Succirubra which died out after the hailstorm in 1879, was up-rooted and the plot re-planted with Officinalis in 1880 which is doing well; about one-third covered with very good Officinalis which has been barked four times.

73. *No. IX Plot*, 1868, *C.*—16·04 acres, all grass land, about two-thirds covered with fine Officinalis; all barked four times; about one-third, originally covered with stunted Succirubra which mostly died out after the hailstorm in 1879, re-planted in 1880 with Officinalis, doing well; 1,020 old Succirubra still survive, and there are 1,100 old Officinalis.

74. *No. IV Plot*, 1867, *B.*—7·02 acres, about three-fourths grass land, planted with Officinalis, fair growth (12 feet high), but very patchy from wido planting, has been pitted for supplies which are to be put down this year; all barked four times. About one quarter shola land planted with Succirubra and Officinalis, growth good but patchy, the plot being much wind blown, pitted for supplies to be put down this year. All barked four times.

75. *State of the Hooker Plantation.*—The growth here is far inferior to that at Naduvatam, considerable tracts of grass land being planted originally with "Succirubra," which was a perfect failure, only attaining a stunted growth of a few feet; this has lately been nearly all up-rooted, and has been, or is being, replaced with "Officinalis" which grows very fairly on the grass land soil; there are still some tracts where the Succirubra must give place to Officinalis or to Pubescens.

76. *Fencing.*—Plot No. XIII, 1873, must be fenced, and a portion of the shola, which has been abandoned and allowed to revert to rank coarse growth, should be re-cleared and planted. Fencing is also required in Plot VII, 1868, A.

77. *Coppicing.*—2,226 Succirubra trees in No. XI Plot of 1869, four times previously barked and of good growth, were coppiced in June 1879; 1,379 stools have died, 847 are growing fairly, height three to six feet.

78. *Number of Trees in Hooker Plantation.*—Appendix B is a statement of the number of casualties amongst the trees in the Hooker Plantation during the last three years, and the number of trees now existing based on Major Walker's enumeration.

PYKARA.

The Wood Cinchona Plantation, 72·18 *acres.*

79. *No. V Plot*, 1865, *C.*—8·80 acres, all shola land, planted with "Succirubra" and a very few "Officinalis;" trees a good height, often over 20 feet, but not healthy in appearance, and numbers of failures; sub-soil very inferior; sized trees barked six times.

80. *No. II Plot*, 1864.—10·87 acres, all shola land, "Succirubra" and "Officinalis;" growth all poor and spindly; many failures and many blank spaces, and trees still dying out; suffers much from the north-east wind; and the sub-soil bad. All barked five times.

81. *No. VIII Plot*, 1867, *C.*—10·87 acres, all shola land, all "Succirubra;" growth good, over 20 feet high. All barked five times. Five acres, 2,500 trees coppiced in June 1879; 885 stools failed to grow, 1,655 have succeeded; growth good, height 4 to 7 feet and very healthy.

82. *No. IX Plot*, 1868.—6·12 acres, all shola land, all planted with "Succirubra," nearly all gone out, except about 100 trees; re-planting has been attempted more than once without success. Soil rocky and bad.

83. *No. VII Plot*, 1867, *B.*—9·62 acres all "Succirubra," except a few "Officinalis," shola land, chiefly a flat; drainage insufficient and sub-soil sour; nearly all the trees gone out. All barked five times.

84. *No. VI Plot*, 1867, *A.*—8·39 acres, all shola land, nearly all "Succirubra;" a portion sheltered on a slope, good; the greater portion very poor growth and thin from many failures, and the remaining trees apparently dying out. Sized trees barked five times.

85. *No. I Plot*, 1863.—2·55 acres, all shola land, "Succirubra" and "Officinalis," mixed in equal proportions; very poor growth and thin, more than half died out, and many still dying; soil rocky and poor. Sized trees barked six times.

86. *No. IV Plot*, 1865, *B.*—4·88 acres, lower avenue, all shola land, chiefly "Succirubra" with a few "Officinalis;" growth good in some places but patchy, as there are many blanks; casualties chiefly caused by insufficient drainage on flat portions, where there is percolation from the channel. Sized trees barked six times.

87. *No. III Plot*, 1865, *A.*—10·08 acres, upper avenue, "Succirubra" and "Officinalis;" about half and half, growth in some places fair, but not always healthy, in other parts very poor, and has been much injured by hail; many trees dead and many showing signs of dying out; upper portions very much exposed to the south-west monsoon. Sized trees barked six times.

88. *State of the Wood Plantation.*—The lower portion of this plantation exhibits very poor growth (all except Plot No. VIII, 1867, C, about 10 acres, may be pronounced a failure); it should, I think, be uprooted and abandoned, as the money required for its upkeep might be far better spent in keeping up the other plantations.

89. *Coppicing.*—2,500 Succirubra trees, previously four times barked in Plot No. VIII, 1867, C (the only good growth in this lower portion of the Wood Estate) were coppiced in June 1879; 885 stools have died; 1,655 are growing and very healthy; height 4 to 7 feet.

90. *Number of Trees in the Wood Plantation.*—Appendix C is a statement of the casualties amongst the trees in the Wood Plantation during the last three years; and the number of trees now existing based on Major Walker's enumeration.

DODABETTA PLANTATION.

Acres 320·47, *elevation over* 7,000 *feet.*

91. Ascending to the plantations from the Government Gardens the first thirteen plots, as follows, are on the slope looking down on to Ootacamund or with a south-west exposure.

92. *No. XXI*, 1868, *A.*—1·61 acres, chiefly grass land with a little shola at the bottom of ravine, all planted with Officinalis 7′×7′; ground very steep and soil being gradually washed away; growth in fair condition and not many failures since the renewals were put down four years ago which are doing well; no late renewals, too steep for terracing, average height of the trees 15 feet; 714 trees barked once, 11 trees barked twice.

93. *No. XXVI*, 1869, *B.*—3·22 acres, nearly all grass land very steep, soil gravelly, and being rapidly washed away, but too steep for terracing; all planted with Officinalis; trees healthy, but very far apart owing to the original wide planting, and many failures; many renewals were put down three years ago, which are doing well, but none since; average height 15 feet; 1,138 trees once barked, remaining trees small.

94. *No. XXV*, 1869, *A.*—1·68 acres, grass land, very steep; remarks the same as for No. XXVI. A portion was terraced in 1880; remainder too steep for terracing; 2,295 trees barked once, 70 trees barked twice.

95. *No. I*, 1863, *A.*—2·32 acres, all shola land, steep, and the soil has been subject to much wash, but the whole plot was terraced in 1880: all planted with Officinalis 8′×8′; average height 20 feet, not in very good condition; very far apart owing to wide planting and subsequent failures; renewals about 10 per cent put down three years ago, no later renewals; 967 trees barked four times, 161 trees barked once, remainder small and not barked.

96. *No. II*, 1863, *B.*—1·67 acres, all shola land, planted with Officinalis 7′×7′; trees healthy; average height 22 feet, but there have been many failures; renewals one to four years of age; 1,221 trees barked five times, 47 trees once.

97. *No. III*, 1863, *C.*—3·57 acres, all shola land, planted with Officinalis; condition fair, but trees very far apart from very wide planting; average height of original trees 22 feet, many renewals one to four years of age; 1,959 trees barked five times, 65 trees once. There are a few "Pahudiana" not growing well; also one "Angustifolia" growing well.

98. *No. VI*, 1864, *B.*—7·28 acres, originally patches of shola dovetailing with grass land, very steep, and soil much washed away, but the whole was terraced in 1880, planted with "Officinalis," except some 50 Succirubra, condition bad; 6,000 seedlings planted out in alternate lines in 1880; 4,969 trees barked four times, 2,146 barked twice, 311 once.

99. *No. V*, 1864, *A.*—4·06 acres, all shola land, steep, terraced in 1880, all planted with Officinalis 8′×8′ and 7′×7′, condition fair; lately thicker planting has been attempted, 2,500 seedlings being put out in alternate lines doing fairly well; pits have also been dug for further planting; 1,900 trees barked three times, 167 barked once; 400 trees have lately been scraped on the Java principle, some are mossed and some left bare, all are renewing their bark, but those mossed more rapidly.

100. *No. IV*, 1863, *D.*—0·98 acre, all shola land, planted with Officinalis; trees fair growth, but very far apart; 900 late renewals, and now pitted for further planting. 556 trees barked five times, 58 trees once.

101. *No. XVII*, 1867, *A.*—5·62 acres, grass land, planted with Officinalis; condition good, but trees much branched from wide planting, intermediate planting between the old trees last year to the extent of 1,800 seedlings doing well; a small area where the ground is level nearly all gone out from frost; 2,853 trees barked twice, 830 trees once.

102. *No. XX*, 1867, *D.*—4·02 acres, grass land, Officinalis; condition fair, average height 14 feet; very few failures; original planting 6′×6′; 2,572 barked twice, 644 trees once; 5 trees coppiced in June 1880 as dying, no re-growth.

103. *No. XVIII*, 1867, *B.*—6·24 acres, grass land; condition fair, but growth rather stunted; 8′ to 10′ in height only; originally planted 7′×7′; no late renewals; 2,241 trees barked twice, 1,539 trees once.

104. *No. XIX*, 1867, *C.*—5·90 acres, grass land, growth stunted; 6′ to 8′ in height; trees gone out on a flat portion of about 1 acre said to be caused by frost; 1,692 trees barked twice, 1,314 trees once, 28 trees cut down, dead from frost.

105. The next plot, No. X, is chiefly on the ridge or saddle; all the remainder, 25 in number, are over the saddle, and have a north-east exposure, except small portions of Nos. IX and XXVII which over-top a grass hill and face south-west.

106. *No. X*, 1866, *A.*—7·44 acres, grass land, but a little shola in hollows, chiefly hill-t p, much blown; growth stunted and many failures; growth better in hollows; 1,007 trees barked twice, 351 trees once.

107.—*No. XI*, 1866, *B.*—12·18 acres, about two-thirds shola, one-third grass land, Officinalis; growth good; 4,627 trees barked three times, 2,615 trees twice, 1,859 trees once. 5 acres, twice barked trees, upper portion (shola land) coppiced in 1879; 3,350 trees cut, 157 have failed to sprout; growth good of remainder.

108. *No. XVIII*, 1869, *D.*—15·33 acres grass land, Officinalis, planted 7′ × 7′; condition fair but growth stunted; height 8 to 10 feet, not barked; no late renewals but now pitted for intermediate planting to an extent of about 35 per cent; 5 acres coppiced in 1879; 2,493 unbarked trees cut, failures 400; coppice growth of the rest good; 400 seedlings planted to re-place the casualties, 100 unbarked trees scraped in October 1880, some mossed and some left bare, all are renewing their bark, but those mossed renew more rapidly.

109. *No. XXIX*, 1869, *E.*—8·05 acres, grass land, Officinalis; growth good in the lower portion only a small area, rest very patchy from many failures; trees healthy but stunted; no renewals the last three years; 2,467 trees barked once, eight large dead trees felled.

110. *No. XXIV*, 1868, *D.*—13·37 acres, grass land and fern land, Officinalis; a rather flat portion of about 3 acres suffers from frost, and has gone ont almost entirely; in the remainder growth stunted, but fairly healthy; many failures; no late renewals; 3,579 trees barked once. Five old dead trees cut down. Twenty-one Angustifolia trees not growing very well.

111. *No. XIV*, 1866, *E.*—4·33 acres, shola land, Officinalis; growth average, but a good many failures from frost; several spots quite bare; no renewals since four years; 715 trees barked three times, 672 trees barked once.

112. *No. XXII*, 1868, *B.*—6·04 acres, grass land, Officinalis, originally planted 7′ × 7′; many failures, and trees far apart; growth generally stunted, but fairly healthy; no renewals since four years; 706 trees barked twice, 1,709 trees once.

113. *No. XVIII*, 1868, *C.*—11·76 acres, fern land, Officinalis; very poor growth with numerous gaps, the rank growth of the common Bracken *(Pteris aquilina)* is robbing the soil of much of its virtue; it should be thoroughly eradicated as far as possible, and this plot should be pitted and planted up; 1,895 trees barked twice, and 1,302 once, two old dead trees cut down.

111. *No. XV*, 1866, *F.*—3·24 acres, about 1 acre shola, the rest grass land, Officinalis; growth poor and stunted, and many failures; 1,412 trees barked three times, and 697 trees once.

115. *No. XII*, 1866, *C.*—11·16 acres, shola land Officinalis; growth good but patchy in places from many failures; 3,573 trees barked three times, 1,771 trees once; no renewals since four years.

116. *No. XXXIX*, 1873.—1·81 acres, shola land, 44 large Pitayensis trees; growth good, 15 feet high, not barked, except four for analysis; 557 large Officinalis doing very well, not barked; 1,000 Officinalis put down in 1880.

117. *No. XIII*, 1868, *D.*—12·68 acres, shola land, and good soil, very steep in parts and subject to much wash, but was terraced in 1880; trees have been pruned and the growth is good and promising, but does not cover the ground which is steep and rocky in places, originally planted 8′ × 8′ which has prevented straight growth of boll; height of trees 8 to 15 feet; there was a good deal of intermediate planting four years ago: 2,971 trees barked four times, 1,521 trees once.

118. *No. VII*, 1865, *L.* 10·20 acres, shola land, soil very good, ground terraced in 1880, chiefly Officinalis, growth very good, originally planted 7′ × 7′, but not very regularly, fairly covers the ground, trees 16 to 18 feet high; 6,601 trees barked four times, 816 trees once; there is a gap in one portion of about half an acre which has been re-planted twice, but has failed owing to frost. About 100 Calisaya trees, growth thin and lanky. A few Pubescens trees growing very luxuriantly; 26 Micrantha and Succirubra; growth very poor. One of the best plots on the north-east side of the hill.

119. *No. XVI*, 1866, *G.*—9·57 acres, shola land, Officinalis, planted 7′ × 7′; growth good, but suffers somewhat from frost, does not cover the ground and requires intermediate planting; renewals 15 per cent four years ago, of which many have failed; 1,000 seedlings put out in 1880; 3,622 trees barked three times, 1,484 trees once.

120. *No. XXXV*, 1869, *K.*—6·10 acres, shola soil, a very steep ravine and very irregularly planted with Officinalis, all lately terraced; growth good on slopes, but trees generally very far apart; about lower portions of the ravines large gaps owing to failures from frost; 531 trees barked twice, 1,663 trees once; there is one Micrantha tree not showing good growth, and a few Pubescens with very fine growth.

121. *No. XXXVIII*, 1872.—8·36 acres, chiefly grass land, steep hill side, soil poor and gravelly, Officinalis; growth poor and many failures, suffers from frost and much blown; many renewals, amongst which there are failures, re-pitted in portions for intermediate planting; the extreme upper portion suffers much from frost and wind, and has almost entirely gone ont; and it would be useless to re-plant this; the upper portion of the slope has been lately terraced, and should be planted up; the Bracken should be eradicated as it is ro bing the soil; about one acre shola land in the lower portion of the plot exhibits good growth; trees not barked.

122. *No. XXXIV*, 1869, *J.*—7·28 acres, grass land, planted with Officinalis, steep, rocky, and gravelly, very poor growth, many failures; 567 trees barked twice, 1,746 trees once; six old trees cut down.

123. *No. XXVIII*, 1869, *I.*—12·33 acres, grass and fern land, Officinalis, except a few Pubescens; very steep, several small land-slips; trees far apart and very irregular, at least 25 per cent failures; a very poor plot; 271 trees barked twice, 3,487 trees once.

124. *No. XXXII*, 1869, *H.*—12·82 acres, grass and fern land, steep with rocky, gravelly, poor soil, planted with Officinalis; growth very poor and numerous failures; 627 trees barked twice, 2,150 trees once; 300 seedlings planted out in 1880.

125. *No. XXXI*, 1869, *G.*—14·08 acres, grass and fern land, steep and gravelly, Officinalis; growth very poor and numerous failures; 707 trees barked twice, 2,242 trees once; four old dead trees cut down.

126. *No. XXX*, 1869, *F.*—17·62 acres, grass land and fern, steep and gravelly, Officinalis; very poor growth and thin from many failures; 2,643 trees barked twice, 2,113 trees once; 11 old dead trees cut down.

127. These last five plots of 1869 planting, viz., F, G, H, I, and J form the lower portion of the north-east side of the Dodabetta Plantation, and are by far the least successful, and the trees will never cover the ground, as there are considerable portions on which growth will always fail; there is, however, here and there much fern land, on which there is now a rank growth of Bracken robbing the soil, and if money was expended in uprooting this, the growth of the Cinchona might be much improved in these portions.

128. *No. XXXVII*, 1870.—8·92 acres, grass land, planted with Officinalis, much of the plot is hill top with poor rocky soil; the trees were originally put down at 7′ × 7′, but they are now very far apart from many failures, and the growth is poor and stunted, generally from 5 to 10 in height; intermediate planting up should be undertaken, but there are several perfectly bare spots on which perhaps planting would not succeed: 168 trees barked twice, 1,295 trees once.

129. *No. XXXVI*, 1869, *L.*—2·19 acres, grass land, planted with Officinalis; poor rocky soil; trees far apart and of stunted growth; height 5 to 10 feet; 176 trees barked twice, 100 trees once.

130. *No. VIII*, 1855, *B.*—17·54 acres, grass land, good loam, planted with Officinalis 7′ × 7′; growth good; trees average 15 feet high; not many failures; renewals 10 per cent some four years ago, none since; 7,567 trees barked four times, 2,347 trees once.

131. *No. IX*, 1865, *C.*—13·65 acres, grass land, good sub-soil, planted with Officinalis; growth good, but somewhat stunted; trees 10 to 13 feet high; rather too much exposed to the north-east monsoon; renewals 15 per cent some four years ago, none since; not many failures; the trees covering the ground well; 7,602 trees barked four times, 3,605 trees once.

132. *No. XXVII*, 1869, *C.*—14·50 acres, grass land; little shola land in ravine; soil generally good, but situation high and exposed; planted with Officinalis; growth fair but stunted; some of the highest part gone out; growth good towards bottom of plot; 207 trees barked twice, 1,618 trees once.

133. *Nurseries.*—The nurseries are in good order; in the Dodabetta nursery there are 2 lakhs of Officinalis seedlings. In the nursery near the old jail about 10,000 rooted cuttings of Angustifolia transferred from the propagating houses. In the lower nursery (near the tea) there are 20,000 Officinalis seedlings.

134. *Glass Houses.*—In the glass propagating houses 12,000 *Calisaya Ledgeriana* seedlings (from Java), 100 Pitayensis seedlings from plantation trees, 400 Pubescens seedlings from plantation trees, 40 Calisaya seedlings from plantation trees, 100 stock plants of Angustifolia; also the "Santa Fé" and "Carthagena" plants brought lately by Mr. Cross.

135. *State of Dodabetta Plantation.*—This I consider on the whole promising, and there can be no doubt as to their paying well; the great mistake has been wide planting at the commencement, and every endeavour must now be made to plant up closer, and this is receiving every attention; the plantations have been much improved of late in places by terracing, but in some parts the land is too steep for this, and should never have been opened; there are besides large blocks where the soil is very poor, and where planting must be always more or less a failure, though it will pay at the present high prices of bark; the effects of frost and wind are also very evident in many places. The eradication of the bracken fern in some of the plots requires immediate attention, and would greatly improve the growth of the Chinchona.

136. *Coppicing.*—In Plot No. XI, 1866, 3,350 "Officinalis" trees (5 acres) which had been twice barked previously were coppiced during the first ten days in June 1879; the stools bled very much and 157 died; the coppice growth of the rest is good—

Yield in green bark = 13,762 lb.
Yield in dry bark = 5,400 lb.

In Plot XXVIII, 1869, 2,493 unbarked Officinalis trees (5 acres) were coppiced from 13th to 19th June 1879; they bled very much and 400 stools died; the coppice growth of the rest being good—

Yield in green bark = 4,853 lb.
Yield in dry bark = 1,700 lb.

I attribute the failures, to the coppice having been carried out too late in the season; it is noteworthy that here, as at Naduvatam, there are many more deaths amongst the stools of the unbarked trees than from those which had been barked, which is proof that the root system of the tree does not suffer in any way from the barking process.

137. *Scraping.*—In Plot XXVIII, 1869, 100 Officinalis trees were scraped on the new Java method on 3rd October 1880, yield of bark 246 lb. green and 100 lb. dry; and in Plot V, 1864, 400 trees were scraped during October 1880, yield of bark 856 lb. green and 400 lb. dry. Some of the trees have been mossed over and others left unprotected, but all are renewing their bark satisfactorily, though more rapidly where mossed; and there are no failures whatever as far as I can see.

138. *Number of Trees in Dodabetta Plantation.*—Appendix D is a statement of the number of casualties amongst the trees in the Dodabetta plantation during the last three years, and the number of trees now existing based on Major Walker's enumeration.

140. *Dried Specimens.*—The following dried and mounted specimens accompany this report:—

Red Barks.

Chinchona Succirubra (red bark)	From Naduvatam.
Chinchona sp. called Magnifolia at Naduvatam and Pâtâ de Gallinazo by Mr. Cross; supposed to be a new species; was collected by Mr. Cross at high altitudes in the red bark region; called also Mr. McIvor's hybrid	Several specimens from Naduvatam and Dodabetta from forest soil and from grass land.
Chinchona. Called Pubescens at Naduvatam and also on Dodabetta, where it is not distinguished from the last, of which it is supposed to be only a slight variety	Do.

Crown Barks.

Chinchona Officinalis, typical (crown bark)	Specimens from Naduvatam and Dodabetta.
Chinchona Officinalis, var: Uritusinga (called broad-leaved or strong-growing Condaminea)	Specimens from Dodabetta.
Chinchona Officinalis, var: Angustifolia	Do.
Chinchona Officinalis, var: Crispa of Ceylon	Do.
Chinchona Officinalis, var: with very narrow leaf, probably Crispa of Mr. McIvor	Do.
Chinchona Pitayensis	Do.

Yellow Barks.

Chinchona Calisaya	Specimens from Dodabetta and from Naduvatam
Chinchona Calisaya, var: Anglica	Specimens from Naduvatam.
Chinchona Calisaya, var: Javanica; so called at Naduvatam, probably "Josephiana," only a bushy shrub	Do.
Chinchona Calisaya Ledgeriana	Do.

Grey Barks.

Chinchona Micrantha	Specimens from Naduvatam and Dodabetta.
Chinchona Nitida	Specimens from Naduvatam.
Chinchona Peruviana	
Chinchona Pahudiana	Specimens from Dodabetta.
Chinchona. Unknown species with cork like bark; leaves hairy on both surfaces and hairy capsules; supposed by Mr. Cross to be the genuine "Crispa" of Loxa	Do.

141. It appears to me important that I should proceed to Darjeeling to see the large Chinchona plantations there, and the different species in cultivation, and take notes on the system of cultivation pursued and other matters which might be of use to the officers in charge of these plantations; so if Government wish it, I shall be prepared to proceed there shortly.

APPENDIX A.—NADUVATAM.

Statement showing the Number of Chinchona Trees enumerated in 1878, and those that were cut since being dead, and the Balance existing on the Government Plantations, Naduvatam.

	Number as per Major Walker's Report.			Casualties in 1878-79.			Casualties in 1879-80.			Casualties in 1880-81.			Total Number of Dead Trees Cut.			Balance.			Number of Plants Planted in 1880-81.			Total number of Trees Existing.

Dodabetta,
23rd May 1881.

(Signed) T. NARRAINSAWMY NAIDU,
Head Overseer in charge.

FURTHER CORRESPONDENCE.

From Colonel R. H. Beddome, Conservator of Forests, to the Secretary to Government, Revenue Department, Ootacamund, dated Ootacamund, 6th June, 1881, No. 207.

Referring to G.O., No. 781, of the 17th ultimo, I have the honor to inform you that I have just sent in a very long report on the Chinchona plantations after a careful inspection and study of them for about two months. I did not receive this Government order until after my report had been despatched, nor had I seen Mr. Cross's report before, but it will be seen that I had arrived at much the same conclusions as he had on the question of hybrids and various other matters.

I have treated in my report fully on the subjects of the cultivation of Pitayo, Calisaya and other species; necessity of coppicing or uprooting (as the case may be) trees the decay of which is evident; the ill effects of the original wide planting, and the advisability now of intermediate planting as far as possible; and hybrids; so I need not add more here.

2. *Coppicing.*—Mr. Cross objects to such a large area having been coppiced, and states that the trees have been coppiced too low down and that four to five inches of the trunk or collar should have been left. There has always been a difference in opinion as to the height the collar should be, and I find in my letters to Mr. Barlow, the Commissioner at the time (*vide* also G.O., 1,161, of 27th May 1879), that I was anxious to restrict the area to about 3 acres, and that I wished three systems tried as experiments for data: first, to adze the collar flush with the ground: second, to leave about six inches of collar; third, not to coppice without first establishing a shoot. The Commissioner was in charge of the plantations at the time and I had only been ordered to select the area to be coppiced, and those suggestions of mine do not seem to have carried weight, as they were not acted up to and all the stools were adzed nearly flush to the ground. I have no reason to find fault with the result as will be seen from my report, and I think if coppices were a main object and in the absence of actual data, which I was anxious to

obtain, I would rather give the preference to the flush collar than to a collar several inches high.

I do not think we shall have more coppicing as a system over given areas. I am much opposed to it for many reasons, and I think my report will go to prove that it is not desirable; but if we did again coppice, I should prefer the plan of first establishing a shoot. It will be seen by my report that when this plan is followed there is not a single failure, and that this is fully proved from several blocks of older experiments which I was quite ignorant of at the time that I made the proposition. Mr. Cross appears to think that the young coppice growth was thinned out prematurely, but I do not understand how he could give an opinion on this point without having seen the growth at the time it was thinned. It is very easy to tell the proper time; it is of course allowed to grow up till there are several prominent leaders; the growth of these would then be seriously retarded and interfered with unless the rest were cut away, and it is then apparent whether it is advisable to leave two, three, or four shoots. Adzing off with a rounded top is in my opinion preferable to a sloping cut or wedge form of coppice.

3. I do not agree with Mr. Cross's remarks as to the climate of the Nilgiris being unsuited for the "Pubescens" form of Red bark, and I think that he would now be inclined to modify these statements from his subsequent observation, as many of his letters to me quite contradict them. Mr. Cross calls this tree "Pàtà de Gallinazo," and he informs me that he found it at a much higher elevation than "tile" or Red bark. He now considers it a new and undescribed species, and I agree with him; but whether a new species or only a variety of the "Succirubra," it has evidently found its home on the plateau of the Nilgiris, and would probably not grow so well at lower elevations. It succeeds admirably on Dodabetta, over 7,000 feet, where "Succirubra" will make no growth, and on the higher exposed situations at Naduvatam and Pykara where "Succirubra" never grew more than three or four feet high, and is now being uprooted, and Mr. Cross has himself lately written to me on the subject of its hardy character and robust and splendid growth. I agree with Mr. Cross that the Nilgiri is to high and cold for "Succirubra," but still it is grown to a good profit in the forest soil of Naduvatam, and exhibits exceedingly healthy growth.

4. Mr. Cross is inclined to taboo "Succirubra," altogether on account of its inferior yield of quinine. Its growth is so rapid compared to Crown bark, and its yield in "bark" so far greater than that and several of the finer kinds, and its cultivation is so much easier, that I expect it will hold its own; its yield besides in other alkaloids is very great; it may have to be ousted in favor of its congener "Pubescens" or the "Urituzinga" var. of "Officinalis," but this is a question for further experience and research.

5. I cannot agree with Mr. Cross in his suggestions about forming a dense sort of underwood of Chinchona in the plantations; it would be opposed to every system of arboriculture and would be simply ruin to the plantations; the trees that did not get their heads to the light would come to nothing and interfere with the root room of others, and the result would be little or no bark of any value. We are not growing osiers or scrub firewood.

6. Regarding the remarks on "collection of seed" by Mr. Cross and the Collector, I cannot believe that this has not received attention. "This selection of the fittest" is the first aim of all florists and arboriculturists as well as breeders of animals, and was so long before Mr. Darwin's voluminous writings on the subject; a practical man, with the training Mr. McIvor had before he came to this country, must have been fully alive to the importance of this. During my inspection I observed muslin bags tied round the panicles of seed on some of the finest trees, which is proof that attention is paid to this subject. Regarding the cutting off of the panicles of flowers which the young trees produce so prolifically, I would observe that I strongly recommended, many years ago, when the trees first commenced to flower so profusely, that this should be done as an experiment over about an acre, as I thought it would favor the growth of the trees and perhaps the virtue of the bark, and at any rate be a very interesting experiment; but I was met by the statements that it would be too expensive to attempt it in large plantations, and that expensive tools would be necessary, otherwise the branches would be much broken and injured.

7. The Calisaya will never answer at Naduvatam, but I have written fully on this question in my report. There are four varieties only, "the ordinary Calisaya," "the Ledger," the "Anglica," and the "Javanica;" the two former are known to be most superior; they are scarcely distinguishable, and I shall be surprised if farther research proves the "Ledger" so very superior. The very favorable reports on this variety are probably due to the high cultivation of a few individuals; however, I may be wrong. Mr. Rowson told me that "Anglica and Javanica" had been analysed and gave a very poor yield; and this has been found the case in Java, where their cultivation is given up; the last named is only a brushy shrub.

8. I quite agree with Mr. Cross that grafting could be of no value when the object is "bark;" and Mr. Cross agrees with me that the art of hybridizing would not be at all likely to increase the value of the bark.

9. Mr. Cross appears to be of opinion that the natural bark may be richer in alkaloid than renewed bark; this is opposed to all the experience hitherto gained. I believe I am right in saying that every analysis has hitherto proved the great superiority of the latter, and that it always fetches a much higher price. Mr. Cross is also wrong in saying that a tree once barked will always require to be wrought after the same manner as long as it lives, as it is a fact that trees which have been many times barked are now growing splendidly from coppice.

10. We must be careful not to be guided too much by any report on the analysis of Mr. Cross's thirty small selected specimens. I much fear more harm than good has been done by the analysis of only favoured individuals, and that it is likely to be the result of much annoyance; I do not myself believe in the vaunted superiority of such varieties as "Angustifolia" or "Crispa" over ordinary "Officinalis" nor of "Ledgeriana" over ordinary "Calisaya." It is due probably only to high cultivation or to other favourable conditions appertaining to the selected individual; time only, however, can fully prove this.

11. The plantations have only lately been handed over to this Department, and it is my intention to draw up a full memorandum of instructions for the officers in charge, but this would be premature till Government have reviewed my report and expressed their wishes as to various points.

From Colonel R. H. Beddome, Conservator of Forests, to the Secretary to Government, Revenue Department, Ootacamund, dated Ootacamund, 6th June 1881, No. 208.

Referring to paragraph 4 of the G. O., No. 398, dated 4th March last, I have the honor to forward a letter* from Mr. Cross.

2. I quite agree with Mr. Cross as to the elevation required for "Calisaya" or its variety "Ledgeriana," and that there is no site on the plateau of the Nilgiris adapted for it. I have fully treated on this question in my report on the plantations just submitted to Government, and I have recommended that ground should be taken up on the slopes below Naduvatam or in the Silent Valley.

---

* Dated 23rd May 1881.

ENCLOSURE.

Letter from Robert Cross, Esq., to Colonel R. H. Beddome, Conservator of Forests, dated 23rd May 1881.

I beg to acknowledge receipt of communication of 21st of this month respecting the Chinchona Ledgeriana. I have not the slightest doubt that both Naduvatam and Dodabetta are unsuited for this sort, the elevation of both places being far too high.

2. If the Forest Department possessed conveniently any good moist wooded ravine somewhere along the course of the Western Ghâts with an elevation of from 3,000 to 4,000 feet, the tree might be expected to thrive well in such a site. Planting in the ordinary manner, 4 feet apart each way, would suffice.

3. With a proper elevation and suitable climatic conditions, the success of the experiment is further insured if the plants are *strong and healthy when put out and fairly cared for afterwards.*

4. The Ledgeriana is manifestly a rank-free, strong-growing species of much the same character as the Succirubra or Red Bark.

From Colonel R. H. Beddome, Conservator of Forests, to the Acting Secretary to Government, Revenue Department, Ootacamund, dated Ootacamund, 22nd June, 1881, No. 293.

I have the honor to inform you that I am this day in receipt of "particulars of bark sales," 5th and 10th May 1881. This document is of great interest as containing the prices realized by the two bales of "Pubescens" bark sent to England from Dodabetta, as noticed in paragraph 44 of my report on the Chinchona—the bale of *natural* "Pubescens" (138 lb.) sold for 7*s.* 1*d.* per lb., and the bale of mossed Pubescens (111 lb.) for 5*s.* per lb. In these two bales the trees we call "Pubescens" and "Magnifolia" were mixed* indiscriminately, and I think it very important that Government should ask for more information regarding them, if forthcoming, viz., what was the analysis? Did the quality justify the high price given? Was all the bark in each bale fairly equal in quality, or was any great difference detected?

2. In the same sale list it will be seen that the 128 bales of *natural* "Officinalis" (Crown bark) only realized 4*s.* 6*d.* to 5*s.* 7*d.* per lb., or very considerably less than "Pubescens." If "Pubescens" is to keep up this high price, and if the purchasers of these two bales can report that it has answered their expectations, we are losing much by propagating "Officinalis," a spindly, weak-growing tree, so largely, to the exclusion of "Pubescens," a tree of strong and vigorous growth. Looking also at the very small prices realized by "Succirubra" in this and other lists, there is not a doubt about the fact that we are enormous losers by propagating "Succirubra" so largely at Naduvatam to the exclusion of "Pubescens," and that "Succirubra" must in the future be relegated to the Wynaad and similar elevations, where probably "Pubescens" will not succeed so well, and that the sooner this is done the better.

3. The 35 bales of *renewed* "Officinalis" sold for 7*s.* to 9*s.* 5*d.* per lb. We have yet to learn what *renewed* "Pubescens" will realize; but judging by the analysis from a small quantity as given in G. O., No. 1,336, of the 23rd of June 1879, it will probably fetch a very high price.

4. These sale lists give us data of bark in the bulk, which is, I think, far more valuable than the analysis of picked specimens from one or two favoured trees. In "Pubescens" and "Magnifolia" we evidently have most valuable trees, and it is most important to learn all we can about them, and I trust that the copious specimens in flower and fruit, which I have forwarded, may lead to their identification at Kew. Mr. Cross assures me that he found "Magnifolia" on the Chimborazo at high elevations under the name of "Pâtâ de Gallinazo," and that he believes it to be an undescribed species; but although "Pubescens" is to me only a slight variety of it, Mr. Cross's opinions regarding it, at different times, have been most contradictory, and I am very anxious to ascertain whether there is or is not any difference in the quality of the bark. It would also be interesting to have experiments on the growth of these two trees at lower elevations.

5. In all the lists *renewed* bark fetches a much higher price than *natural*; but it is to be noted that *mossed* "Pubescens" sells at 2*s.* per lb. less than *natural* "Pubescens," whereas in the different reports on Nilgiri Chinchonas mossed "Crown" ("Officinalis") and mossed "Red Bark" ("Succirubra") always fetch more than natural, though much less than renewed; this may be a coincidence of no value and likely to be upset at other sales, but I should be glad of an explanation, should it be available.

6. The prices realized in these lists under notice, and the lists for March and April by the South American "Soft Columbian" and "Carthagena," the species we are going to so much expense in introducing, are not very encouraging.

From Colonel R. H. Beddome, Conservator of Forests, to the Secretary to Government, Revenue Department, Ootacamund, dated Ootacamund, 10th August 1881, No. 498-A.

In accordance with G. O., No. 1,105, of the 25th July last, I have the honor to forward Mr. Cross's remarks on the analysis of bark submitted by Mr. J. E. Howard and recorded in the same Government order.

2. I must myself observe that Mr. Cross's samples go a very short way towards testing the relative excellence of all our different species—22 out of his 30 specimens (*i.e.*, 1 to 14, 16 and 17, 21 and 26 to 30) being all from ordinary "Officinalis" or "Crown Bark." Of the other eight samples, No. 15 is the Pitayo, No. 18 the so-called "Magnifolia," Nos. 19, 20, 22, 23 and 24 "Succirubra" (or Red bark), and No. 25 "Calisaya;" so that only five out of our eighteen species or varieties were sent, and these were, I regret, not accompanied by botanical specimens.

3. Mr. Cross informs me that he could not now identify all the trees from which the different samples of Crown bark were sent; he identified No. 4, which gave the highest yield of natural bark (6·52 per cent), and this is quite the ordinary "Officinalis;" he could not, however, identify No. 11, which gave the highest yield in renewed bark (7·69 per cent).

4. From what Mr. Cross tells me the whole of these 22 specimens were from the ordinary "Officinalis," which forms the bulk of our Dodabetta plantation. It will be seen from the analysis how the yield in quinine differs in some of the individuals, the smallest yield of natural bark being 2·01 per cent in quinine and the highest 6·32 per cent, and the renewed bark (of which only a few samples were sent) varying from 4·01 per cent to 7·59 per cent, which, however, is easily accounted for by difference in soil, aspect, age, &c.; it does, however, to prove what I have already said in my report on the plantations, that it is a great mistake to attach too much value to the analysis of single individuals. If, however, the average of the 22 samples were taken, it would, I consider, give fair data as to the yield of this species in our plantation.

5. "Urituninga" was, as Mr. Cross states, not sent at all. I am not sure that what we know by this name is really this variety (it is called here "strong-growing

* There are 1,012 "Magnifolia" and 170 "Pubescens" in the Dodabetta plantations, and I learn for this consignment 236 trees of the former and 33 trees of the latter were barked, all from the different plots of 1869, most of which (*vide* my report) are the worst soil and exhibit the poorest growth of all the Dodabetta plantations.

Condaminea" and "broad-leaved Condaminea," as well as "Uritusinga"); the specimens, however, that I have forwarded with my report should settle this question. It is very like "Officinalis," only with much larger leaves and of stronger and quicker growth, promising to be a large tree. There are only about 1,000 of it scattered in the Dodabetta plantation and about one dozen only at Naduvatam, so that there is some mistake in the supposition that Mr. McIvor planted 70 acres with it in 1875. There are many applications for the seed of this from various parts of the world, probably owing to reports of Mr. McIvor or Mr. Money; and, considering its healthy, strong growth and close affinity with "Officinalis," I should not be surprised if it turns out our most valuable species. I learn from Narrainsawmy that small samples of the bark were sent to England for analysis, and that these are the Nos. 18, 19 and 20 under "Condaminea" from Dodabetta given in the table of analysis in G. O., No. 1,336, dated 23rd June 1879; it is a species or variety, however, that we must learn more about.

6. The analysis of No. 15 "Pitayo" is a valuable addition to the chemical knowledge of our species—we have 44 good-sized trees of this species near the Dodabetta Jail, but it has not been further propagated. This analysis differs considerably from that given in G. O., No. 1,336, of 23rd June 1879, when it was much younger —this giving 3·98 per cent of quinine, Mr. Paul's specimen only 1·50. Mr. Howard urges its propagation, partly because of its yield in quinidine which in his specimen is 2·01 per cent (though in Mr. Paul's only 0·82). I observe the yield in quinidine is as high as 2·20 in some of Mr. Cross's samples of "Crown bark" now analysed by Mr. Howard, and in root bark of the same species it is as high as 3·45. The extended propagation, however, of "Pitayo" seems desirable, if only the yield of quinine is considered.

7. No. 18 is one of the two species or varieties confounded under the name of "McIvor's hybrid" or "Pubescens;" it is the so-called "Magnifolia" of my report (not "Pubescens") and the "Pàtà de Gallinazo" of Mr. Cross. Mr. Howard now says it is the "Chinchona coccinea" of Pavon; but he has only seen bark, no specimens of leaves or flowers having been forwarded. I regret such a small sample only of this was forwarded, as it is not a fair criterion; it is very similar, as far as the natural bark and the yield in quinine, to the analysis given by Mr. Paul in G. O., No. 1,336, of 23rd June 1879, under the head "Hybrid Pubescens," Naduvatam and Dodabetta, which samples were from the same variety (the glabrous "Magnifolia" not from "Pubescens," as Mr. Cross examined the trees from which Mr. Rowson stripped it at Naduvatam, and I examined them on Dodabetta. The yield in Chinchonine, however, in the specimens analysed by Mr. Paul differs enormously from the specimens sent by Mr. Cross, but a similar difference is observable between many of the Crown bark samples now analysed by Mr. Howard. As already reported two bales of the natural bark of this species went to England from Dodabetta last December, and sold at 7*s.* 1*d.* per lb. under the name of "hybrid Pubescens." Mr. Howard and Mr. Cross both advocate the propagation of "Succirubra" being given up in favor of this species. I quite agree with this, considering the healthy and splendid growth of this species which I have written about very fully in my late report.

8. I much regret that samples of the "Pubescens" bark were not forwarded.

9. Mr. Cross states that in the samples forwarded to Mr. Howard, Nos. 21 and 24 have evidently been changed.

10. If the samples 19 and 20 be compared with 22 and 23, it will be seen what a very poor yield in quinine the original bark of "Succirubra" gives compared with the renewed bark; this alone quite taboos the coppicing system of harvesting for this species at least. Nearly all the Red bark trees at Naduvatam are now yielding renewed bark, and the yield of these samples (viz., 3·08 and 2·04 per cent of quinine) is very high for Red bark; but here, again, we have to be cautious as they are only small samples taken perhaps from exceptionally fine trees grown under favourable conditions; in any case the yield is inferior to that of the "Magnifolia."

11. Of the "Crown barks" only five samples of renewed bark were sent against sixteen of original bark; but the result is sufficient, I think, to show the great superiority of the former, and that coppicing is a mistake to be avoided, when I have shown in my report that after some careful inspection the trees have not as yet suffered in the slightest degree from the stripping process.

12. Of No. 25 "Calisaya", I must write further later on. We have at Naduvatam of yellow barks "Calisaya," "Calisaya Ledgeriana," "Calisaya var. Auglica" and "Calisaya var. Javaniea." Mr. Cross informs me that he looked upon all as the same, and that he does not know which No. 25 was taken from; but he thinks Mr. Rowson knows the exact tree, so I may be able to identify it, if from one of the few trees now alive of "Ledgeriana." I have no remarks to make, but the only shrubby variety at Naduvatam is the "Javaniea."

13. At the present stage of our plantations when most of the species and varieties are of a good age and well developed and easily recognized, I consider that the employment of a competent chemical analyzer up at Ootacamund, if only for a few months, would result in the greatest possible benefits in the future both as regards the Government plantations and the wide field of private planting. In Mr. Broughton's days many of the species were young and not developed sufficiently in their characteristics, and there is most evident proof that the question of species and varieties was in a great jumble.

14. I attach the greatest importance to the careful collection of seeds from the healthiest and largest trees of "Officinalis" as well as from our other finer species or varieties, and I have already given very full directions on this point to the officers in charge.

15. I do not understand Mr. Howard's remark that the quantity of bark sent to England from Dodabetta seems disproportionate and exhaustive, or on what data he surmises this to be the case. We are not up-rooting or even coppicing; the "superior quality" of this Crown bark, which he alludes to himself, is proof I think that it is not harvested prematurely, and as long as this is guarded against the sooner the first stripping of the natural bark takes place the better, as the renewed bark is far more valuable in the market; the subsequent strippings can always be taken off every two years, and to delay removing it after maturity is of course a dead loss. On account of sufficient room for drying and storing our estimates this year at Naduvatam have calculated for a shorter crop than we ought to gather. I have, however, quite lately received Mr. Morris's interesting report for last year on the Jamaica gardens and plantations, which contains much valuable information on Chinchona, and he has proved that sun-dried Chinchona bark is more valuable than that dried by artificial heat. I hope, therefore, if we have any continuation of sunny weather this September or October, to try this system of drying, although it has hitherto been supposed here (I do not know from what experience) that bark dried in the sun loses in virtue.

ENCLOSURE.

From Robert Cross, Esq., to Colonel R. H. Beddome, Conservator of Forests, dated 10th August 1881.

I beg to acknowledge receipt of your communication with date of 9th of this month, enclosing a report from the Secretary of State for India of the analysis of 30 samples of bark by Mr. David Howard collected by me at the Government Plantations of Dodabetta and Naduvatam.

1*st.*—Mr. Howard's remark than an undue proportion

of these samples were of Condaminea, when the aim was to ascertain the comparative value of each species, is no doubt correct, but the fact is that very few trees of the remaining good sorts such as Calisaya and Pitayo would have yielded sufficient bark for more numerous samples of these kinds.

2nd.—The samples of Condaminea, both of original and renewed bark, were collected in different parts throughout the plantation. Respecting the "Uritusinga" trees at the head of the ravine to some of which gauze seed-bags have been attached, an attempt was made to collect bark from these trees which was abandoned owing to the thinness of the bark and the difficulty experienced in getting it to rise. These "Uritusinga" trees, if distinct, form no feature in any part of the plantation, and the statement that 60,000 had been planted seems to me a mistake. Nor can I see any trace of the "22 varieties" of Crown bark reported to have been recognized by the late Mr. McIvor. The plantation is indeed chiefly composed of the Condaminea or true Loxa bark, and the steady yield of the samples seem to me a good proof in this respect.

3rd.—The proposal to change the specific name of the Loxa bark from Condaminea to Officinalis, as recommended by Mr. Howard, is truly unnecessary. The term Condaminea bestowed on the tree by Humboldt, who visited the Loxa forests, has been adopted for the last 50 years by nearly all Professors of Botany in European Universities as well as by the majority of botanical writers.

4th.—The Red bark has proved even of less value than I expected, and the Pàtà de Gallinazo and Carthagena or Columbian may well take the place of this sort. The Pàtà de Gallinazo was obtained in the following manner:—On packing up the Succirubra plants on Chimborazo for the journey I found one of the packages was not quite filled, so in company with two sons of a bark collector a hasty trip was made up to a ravine to a distance of three miles up the wooded slope of the mountain. In the bottom of the ravine at the base of a cliff a number of plants were found which were at once identified by the lads as the sort of bark alluded to. The package was afterwards filled up with these plants, and this is the way the Pàtà de Gallinazo came to India.

5th.—The samples of "Original bark" were, as suggested by Mr. David Howard, collected from the lower part of the stem of each tree immediately above the roots, owing to the renewing process having been performed on the upper portions of the trunks.

6th.—No. 21 was no doubt exchanged by mistake with No. 21.

7th.—It seems to me that cordial thanks are due to Mr. J. E. Howard and Mr. David Howard for the very interesting and practically useful analysis of these bark samples.

8th.—A further analysis at a future time might, I think, be made by some quinine manufacturer of renewed barks of different ages and also of "scraped" bark from the best species, likewise of barks obtained from varieties on individual trees considered to possess special excellence in order to meet the views for the dissemination of superior sorts as expressed by the Secretary of State for India.

For the Government General Order, on Colonel Beddome's Report and the above correspondence, dated 29th August 1881, No. 1,[illegible]0, see page [illegible]2.—Ed. *T. A.*

THE EFFECT OF THE GROWTH OF PLANTS ON THE AMOUNT OF MATTER REMOVED FROM THE SOIL BY RAIN.

By E. W. [illegible], Ph. D.

Herewith I send you *Chemical Journal* for October. I think article p. 475 useful for your *T. A.*, at any rate the first three pages of article, showing that the soil is much more famished by loss of solid matter when *no* vegetation is growing.—*Cor.*

(Journal of the Chemical Society for October 1881.)

In a paper which I read last year before the Society, I gave an account of experiments which showed the influence exerted by the growth of plants in a soil of the drainage-water from that soil. In those experiments the composition of the water which flowed from soil 4 inches deep, and in which clover was growing, was found to be greatly different from that which flowed from the same soil, but in which there was no vegetation. The amount of solids removed was 12·5 grams (48 grains per gallon) from "clover soil," and 50 grams (220 grains per gallon) from the "blank."

During the past season I have repeated the experiments, but using in the place of shallow pans large glazed stoneware pans, 18 inches broad, with perpendicular sides 10 inches high, and provided with a hole at the bottom, from which the drainage-water flowing was collected in jars placed below.

In these pans were placed 100 lb. of soil, which, when beaten down, filled the pans up to 1 inch of the top, leaving a clear 9 inches for the growth of the plants. The following is an analysis of the soil:—

Moisture	5·06	per cent.
Calculated on the dry soil—		
Soluble salts (containing sulphates and traces of chlorides)	0·680	"
Organic matter	11·80	"
(Containing nitrogen equal to ammonia	0·436)	"
SiO_2	24·54	"
P_2O_5	1·185	"
$CaCO_3$	53·98	"
Al_2O_3	3·065	"
Fe_2O_3	3·84	"
MgO	0·58	"
K_2O	0·451	"
	99·441	

Owing to the delay experienced in obtaining the kind of pan which I desired, I decided to repeat the same experiments as last year in shallow pans, holding only 28 lb. of soil (depth of soil 4 inches), which had been coarsely sifted: therefore on May 4th I sowed in No. I clover seeds, and No. II was left "blank."

It was not until late in the season that I was able to sow seeds in the large pans, but on June 18th there was sown in No. 3 cabbage seed; in No. 4, wheat; in No. 5, beans; in No. 6, "cow-grass" (common perennial clover); in No. 7, garden turnips; and No. 8 was left blank. All the pans were placed in a moderately sheltered spot, and surrounded by a spacious wire cage, so as to exclude birds, leaves, &c.

As the season was favourable, the plants flourished up to the date when it was considered necessary to discontinue the experiment, and, with the exception of the wheat and turnips, all reached maturity, [illegible] the growth of the clover had been strong enough to allow of a crop being taken off.

When it appeared that the plants were suffering from drought, equal quantities of distilled water were poured upon them evenly, and this [illegible] amounted altogether to 2 gallons (9 litres). The drainage-water which had collected in the jars below the pans, and had been from time to time [illegible] [illegible] amounted [illegible] [illegible] to 2[illegible] litres, No. II, to [illegible]; No. [illegible], No. [illegible] to [illegible]; No. [illegible], to 11·[illegible]; No. 6, [illegible]; No. [illegible], [illegible]; No. [illegible], to [illegible]. The [illegible] Sept. [illegible] 21, [illegible] [illegible], [illegible] [illegible] the quantity [illegible] gal-

lons of distilled water must be added, making therefore a total "rainfall" of 18·38 inches (16·87 gallons = 76·45 litres), and 16·88 inches (15·529 gallons = 70·56 litres) respectively.

The drainage-water when evaporated yielded, in each case, of solid matter:—I, 7·092 grams; II, 25·576; (3), 5·039; (4), 6·463; (5), 6·942; (6), 5·422; (7), 7·024; (8), 12·862.

The plants, after careful cleansing so as to remove as far as possible all adhering soil, which was found to be most difficult, as the fine fibres persistently retained a certain portion of soil, yielded on ignition the following amount of ash:—

I = 21·32 grams; 3 = 3·53; 4 = 8·05; 5 = 10·42; 6 = 18·503; 7 = 3·69.

During the evaporation of the water, a small amount of organic matter separated ont, and this being different in each case, as regards quantity and colour, affected the appearance of the dry residues, which were of varying shades of pale reddish brown and very deliquescent.

The following Table I shows the amount of solid matter removed from each sample of soil by the drainage-water, the total ash of the crops, &c. In the fourth column will also be found the amount of solid matter removed per gallon of drainage-water, the mean quantity obtained from 3, 4, 5, 6 and 7 being 34 grains per gallon, a quantity not widely differing from that obtained by Völcker in 1866-69, viz., 33·3 grains per gallon, from unmanured fields in which wheat was growing. Table II shows the amount of all the constituents present in the drainage-waters in grains per gallon, and the percentage composition of the total solids removed by the water from the soil; and in III will be found the absolute quantities of each of the several constituents.

TABLE I.

Plants.	Drainage-water, in litres.	Solid matter in drainage-water, in grams.	Solid matter in drainage-water, in grains per gallon.	Total dry matter of crop, in grams.	Total ash in crop, in grams.	Total solids removed from soil by drainage water and crop, in grams.
I. Clover *a*	20·26	7·092	24·500	121·90	21·32	28·412
II. Blank..	24·54	25·576	73·11	—	—	25·576
3. Cabbage*b*	10·91	5·039	32·39	30·64	3·53	8·569
4. Wheat *c*	14·90	6·463	30·43	41·86	8·05	14·513
5. Beans *d*	11·97	6·942	40·68	138·24	10·42	17·364
6. Clover *e*	9·12	5·422	41·703	134·37	18·503	23·925
7. Turnips*f*	18·95	7·024	26·00	22·01	3·69	10·714
8. Blank ..	14·95	12·862	60·451	—	—	12·862

Development of crop.—*a* Very strong. *b* Poor. *c* Strong and healthy, blossom barely reached. *d* Very healthy strong pods, well formed. *e* Very strong and healthy. *f* Poor, leaves healthy and developed, bulbs not so.

HORÆ HORTULANÆ:—ON SOILS.

(Gardeners' Chronicle, 22nd October 1881.)

(Continued from page 616.)

The actual amount by weight of nitrogenous and saline matters taken by even a luxuriant plant is very small compared with the quantity which, through lack of knowing exactly what to do, we find it best to put into the soil; if any one doubts this let him burn a cabbage to ashes and carefully weigh the amount he obtains. Even the so-called "gross feeders" really take up very little; their grossness consists in their appearing to delight in wallowing in manure. In all probability, had we the proper knowledge, we might so conduct a small quantity of food to the plant that it would at once take up all we give it—we might, so to speak, feed the plant with a spoon, directing the aliment straight into its mouth, instead as we do now, bathing it in nourishment, in the hope that somehow or other a little may trickle in through its lips; or, to change the metaphor, we might fire single shots, making sure that each shot told, instead of blindly letting off volleys in the hope that some of the bullets will hit the mark. In the meantime, while the plant is taking up its mite of the dearly-bought manure so profusely surrounding it, heavy rains are washing the soluble elements rapidly away, and carrying them away from our garden to places where they are of no use but rather harm. Let me end by drawing upon my fancy by picturing what the gardener of the future, happy master of the science which we now lack, will do when he takes in hand a plot of rough ground, intending to make it blossom with flowers.

His first step, I am sure, will be to convert the raw earth into good live soil, and secure the all-important physical features of which I spoke at the beginning of this essay. He may still find it cheapest and best to bring this about by freely incorporating ordinary farmyard manure, and simply adding special substances according to the constitution of the native earth and the habits of the plant which he proposes to grow. He may do this, but I think it more probable that, just as we now-a-days, when we grow Mushrooms, do not trust to the chance spores present in stable droppings, but sow definite spawn, of special character, in fixed amount, so he will rapidly work up his soil by the systematic addition of prepared substances and specially cultivated ferments. Of this at least I am confident, that he will carefully watch his soil, testing it from time to time to see how the processes are working, just as a brewer tests his wort or the manufacting chemist tests the mixtures which are transforming in his vat. And I imagine that from time to time he will assist the due ripening of his soil by growing in it certain temporary preparatory crops, for the plant re-acts on the soil in as marked a manner as the soil acts on the plant, and the well known precept of agriculture, called "the rotation of crops," is, so to speak, but a mere jutting corner of a great principle of the effect of plants on land, whose full dimensions we have not as yet realised.

When he had thus prepared the ground and secured to an adequate depth a general basis of live soil, retentive of moisture but yet not wet, porous and friable but yet giving a firm holding for tender rootlets, eagerly absorptive of all the sun's rays, its particles agitated through all its depths by incessant change, the harder part of his labour will be over. Probably during this preliminary handling he will, in different plots, give somewhat different turns to the several changes as they are being evolved, securing here more, or there less permanent moisture, making this patch of firmer and that of looser texture, and varying here or there the general composition of the soil. Henceforward his task will be lighter. He will have, it is true, to keep a watch upon his soil, taking care that its activities never slacken, nor its general character deteriorate; but, that done, his chief toil will be the physically light but mentally heavy task of adding to the area of soil belonging to each plant, or group of plants, a few pinches of the particular things needed for their growth. And we may, without any great stretch, imagine that the prescription for the pinch will vary according as he wishes to call forth luxuriant foliage or solid bloom. This, and the struggle to grow together, or in succession, such plants as, while satisfying æsthetic desires, should mutually benefit each other, and do good in common to the soil, will be his chief care.

After some such fashion will I imagine the gardener of the future work—his manual labour lightened, but his mental work increased by the power of knowledge. To him the laboratory will have to be as familiar as the tool-house and the potting-shed, and he will have to

strengthen practical wisdom and insight—for these will always make themselves felt—with a backbone of science.

Some such man, I hear the reader say is the gardener to the "mansion in Spain." That is very true; but it is equally true that again and again castles once in the air have been found after awhile firmly resting on solid ground. The scientific gardening of the future may be a long time coming, but come it will, and each of us can hasten its advent by careful observations, intelligent trials, and conscientious reflection.

DIETES.

HYBRIDISM AMONG CINCHONÆ.

[A correspondent writes:—"In case Broughton's article on the Hybridization of Cinchonas and Howard's note on same have not been quoted in Owen's handbook or by you, I send you a vol. of *Linnean Journal*, in which you will find it, pp. 474-5. I have no doubt that Broughton refers to the very hybrid called *C. pubescens* referred to by Beddome, our Ceylon supposed one between Officinalis and Succirubra."]

Introductory Remarks to Mr. *Broughton's* paper on Hybridism among Cinchonæ. By *J. E. Howard, F. L. S.*

[Read March 3, 1870.]

At the particular request of Mr. Broughton I engaged to read the accompanying paper. The author also wished that I should adduce any arguments that might occur to me against any point that he has mentioned. This his desire, I conclude, arose from my having frequently urged the study of the different kinds cultivated in India, in order to the selection of the sort most adapted for the production of Quinine, as a necessary point to be attended to by those who would cultivate with profit. I have also expressed my belief in the general permanence of the forms, even of the sub-species or varieties of the plant.

I have nothing to urge, however, against the views expressed by Mr. Broughton as to the occurrence of hybrids, but on the contrary, living specimens which have occurred in my own limited sphere of observation which seem to me to confirm their truth. I am more doubtful about the occurrence of hybridism in the native places of growth of the Cinchonæ, as I do not think there can be in general the same favourable conditions for the interference of the pollen of different species that occur in their cultivated state. I have not, therefore, so much expectation of light being thrown on the botanical arrangement of the genus as is expressed by my correspondent.

Note on Hybridism among Cinchonæ. By *J. Broughton, B. Sc., F. C. S.*, Chemist to the Cinchona Plantations of the Madras Government.

The Cinchonæ have long been known as plants whose flowers shew in each individual that singular difference in the respective prominence of the stamens and pistil which has since received the name of *dimorphism*. The special forms have been named by the Spaniards respectively *macho* and *hembra*, according as the male or female organs are prominent in the blossoms of any single tree. The researches of Mr. Darwin have shown the consequences of this peculiarity as it affects the fertilization of the seed in the parallel cases of *Primula, Oxalis, &c.*

On the Cinchona plantations of the Madras Government are now growing, blossoming, and fruiting nearly all the valuable febrifuge-yielding species. Individuals of the various species are, in very numerous instances, planted in close proximity. The seeds are produced in great abundance, and have been used for the purpose of obtaining seedling plants for the extension of the plantations: under these circumstances, it might have been predicted beforehand that hybrids would appear.

These considerations did not, however, occur to me as a chemist. But as it is my duty to make a chemical examination of the bark of all varieties occurring on the plantations, some circumstances occurred which brought the above prominently under my notice. Among some young trees raised from Neilgherry seed was a plant of great beauty, quite distinct in appearance from any of the older or originally introduced kinds. It had the general aspect, pyramidal habit, and luxuriance of *C. succirubra*, but at the same time the lovely purple tints and velvety appearance which characterize the leaves of the "Grey Barks" when young. Its bark resembled that of *C. succirubra*, but was lighter in colour. But on analysis it yielded 1·45 per cent of nearly pure *cinchonine*, instead of about 3·00 per cent of alkaloid, mainly consisting of quinine and cinchonidine, as was the general yield of its neighbours of *C. succirubra* of the same age. So unusual a result led me to repeat the analysis and to make full inquiries into the origin of the plant. I then learned from the Assistant Superintendent in charge of the plantation that the plant had been picked up under a tree of *C. micrantha* as a natural seedling, its parent growing in proximity to trees of *C. succirubra* which blossom at the same period.

This circumstance set me examining young seedling plantations in order to find, if possible, other instances. I found among them forms which are not to be met with among the parent trees, and which are new to the plantations. One of these is a variety which combines resemblances to the very dissimilar species of *officinalis* and *succirubra*, having the large leaves and habit of the latter with the ovate-lanceolate leaves also of the texture characteristic of the former. Some of the leaves also possessed scrobicules. The bark of one individual yielded 2·8 per cent of alkaloid consisting of Cinchonidine and Cinchonine, while that of another gave me 2·8 per cent of alkaloid consisting of 1·3 of quinine and the remainder of cinchonidine and cinchonine. In the latter case the quinine crystallized as sulphate with the ease which marks this alkaloid when obtained from *C. Officinalis*. I cannot but consider the chemical character of the bark an independent corroboration of the hybrid character of the plant.

Other varieties are appearing among seedling trees, which, though their origin can be less clearly made out than in the former instances, can scarcely be explained without assuming that they are natural hybrids.

Among the hundreds of thousands of trees of *C. Officinalis* growing on the Neilgherries, very various and numerous differences are to be found. If each of the characteristic forms were to be distinguished by name, more than twenty new varieties might be constituted possessing, in certain specimens, as distinct an identity as that attributed to the vars. *Banplandiana*, *Uritusinga*, &c., which are now recognized by botanists. These numerous varieties merge into one another by insensible gradations; and as it would be impossible to keep seedling plants of each separated, they are all mixed in the plantations. I submit that this natural confusion of varieties and sub-varieties is a consequence of the interbreeding of the various kinds. As many of the kinds were introduced by seed into India, it appears to me to be highly probable that certain of these are not the pure descendants of plants possessing in all respects the recognized botanical characters of the respective kinds. As a matter of practical experience, I find that the yield of alkaloids is tolerably constant in very various varieties of the same species, even when the difference in habit, foliage, &c., is marked.

The variations are also clearly apparent in the species *succirubra* and *calisaya*.

The object of this note is to call the attention of competent botanists to these facts as being well worthy of consideration in carrying out any future classification

* After numerous trials I have not succeeded in detecting any clear difference between the amounts of alkaloid contained in the bark of the *macho* and *hembra* forms.

I cannot forbear expressing a hope that they may lead to a simplificatiou in the botanical arrangement of the genus, which at present is so confused as to be in some cases almost a hindrance to the correct appreciation of the actual living realities.

LIME FOR SOILS.

(*To the Editor, "Tropical Agriculturist."*)

6th January 1882.

DEAR SIR,—The enclosed extracts from Donaldson's "British Agriculture" may be of interest to you and your readers, as bearing on the question of "Lime as a Manure" in the October issue of the *Tropical Agriculturist*.—Yours truly, S. G.

MANURING WITH LIME.

(Extracts from Donaldson's "British Agriculture.")

"Having been engaged in the cultivation of land in the neighbourhood of Breedon magnesian rock in Leicestershire, an opportunity occurred to use the lime on arable lands, and to observe the results. The farmers entertain very strong prejudices against it, and will travel many miles to fetch a purer carbonate and of a mildcr nature. The land under management was a deep earthy soil, black and inclined to hazel, on a bottom of very compact dry clay, of good quality, but had been most miserably scourged and impoverished by the former tenants. During the first summer, two fields were fallowed for green crops, and being in a very harsh state, and naturally stiffer than the proper turnip soils, some considerable labour was required in reducing the texture to a proper tilth. In May, the Breedon lime was brought to the fields in hot cinders from the kiln, and laid on the headland in a long narrow heap, turned over and powdered by water, spread on the land at the rate of 200 bushels an acre, and harrowed into the ground as applied. The lime ran from the carts like quicksilver, and the handling of it in that condition requires a sufficient force to keep the process in quick action. The land was drilled for turnips, potatoes, and beetroot, which were regularly planted in the respective seasons. On one field a double allowance of lime, or 400 bushels an acre, was applied on a space of four ridges in width and extending half the length of the field, which, being both a large quantity and in a caustic state, would test the supposed noxious quality of the lime. In every case the green crops were good, and the space which had the double allowance showed no difference in the turnip crop, nor was damage or benefit visible from the extra application: the season was rather dry, and it is scarcely possible to apply lime in a hotter state. One field was sown with barley, which yielded a most beautiful crop of 7½ quarters per acre, and the other produced 5½ quarters of wheat; both very good crops when the exhausted state of the land was considered. When the wheat brairded in November, the space which had got 400 bushels to an acre immediately showed a great superiority, which continued to the time of reaping, being much thicker on the ground, of darker colour throughout the season, and afforded more produce, as the shocks of grain were thicker on the ground, and discernible on the first run of the field. The succeeding crop of hay on that space showed an equal superiority, and for some years in succession.

"The same lime was used in the same quantity of 200 bushels to an acre, and with the same beneficial results, without a single exception. On the headland, where the heap of lime lay, and on which any damage might have been expected, there grew a very close and heavy crop of beet, with roots not often equalled in size and weight. An usual quantity of well-prepared farm-yard dung was applied in the drills for the green crops, and the principle was adopted of bringing the lime and dung into contact, and of reducing the soil as fine, if possible, as the lime itself, in order that the different bodies might be mixed and incorporated. The decomposable animal and vegetable matter had been dissipated by previous cropping, and a fresh supply was required to secure the action of the lime—the finer the soil, the more particles it affords for mixing with the lime, and a clod is so much land lost—for the roots of plants cannot penetrate there in search of food, and the particles are too distant from each other, and too few are in contact. No apprehensions of danger can be entertained from the corroding quality of the caustic lime on the dung in the drill; the lime is mixed with the soil, and the quantity exposed to contact will soon be modified by the moisture in the land and in putrescent manure."

"Lime is hurtful in mixture with farm-yard dung, or when brought into contact in a caustic state with unreduced vegetable matters, it corrodes the substances and tends to render the extractive matters insoluble, and it always, in a certain extent, diminishes the effect of animal manures, by producing new combinations and arrangements. It converts unreduced organic matter into a mucus or mucilage, which quickly decomposes unassisted; and though the lime does not afford direct nutriment to plants, it converts other substances into a state suitable for the purpose. The improvements effected on the coarse and sour herbage of moors and pastures have been attributed to this property in lime, of decomposing by the assistance of water; but the quantity applied on the surface must be very great. On clays, it reduces the adhesive properties by combining with the other ingredients, and hence it acts as an alterative; but the application must be liberal, and the land well prepared for mixing. On sands, it is thought to have a mechanical operation, and to give a consisteucy to the soil by combining with the finer particles, and attracts moisture from the atmosphere. A cooling effect has consequently been ascribed to lime on hot burning sands: but with some sands it will combine and form a mortar, and it may be proper in such cases to mix the lime with earths and clays. The general conclusion assumes that lime acts both as an alterative and a stimulant in rousing the dormant qualities of soils, moulds, and manures, and in changing substances into forms more speedily favourable to vegetable life. The mechanical agency ascribed to it consists in renderiug the texture of lands more open, porous, and friable, by mixing with the constituents of the soil. Some think that a part of the phlogiston of the fuel adheres to the lime, and also that it contains a quantity of the matter of pure fire; but such points have not been ascertained, though to this suppositiou of some latent quality in fire being a chief agent, there seems to be a more than probability attached.

"The quantity of lime applied to an acre of land varies much, and on no point in modern agriculture does more vague uncertainty prevail. From 50 to 1,000 bushels have been applied with various success, and 150 to 200 may be stated as an average quantity in all middling circumstances of application. That quantity has been applied on lands with great effect, and in many cases with visible benefit, where circumstances fully justified the expectation. The general character of lime is, that after being powdered by calcination, it is a violent caustic, imbibes one-third of its bulk of moisture, and becomes a hydrate of lime—and after lying a determinate time exposed to the atmosphere, it imbibes carbonic acid gas expelled by the calcination, and becomes a carbonate of mild lime. Some have extended the period of causticity to one year, if the lime be not spread out and exposed for the purpose of absorption. In the caustic state, it is said to be pernicious to vegetable life, to corrode animal substances, kill insects, and to form insoluble compounds, very unfavourable for the purpose to which it is applied. But the expression 'determinate' being indefinite as to time, leaves it uncertain at what period after exposure from calcination lime loses the causticity and becomes mild—and consequently it may be doubted if at any time and in any case lime has ever been applied

to land in a purely caustic state. The hurtfulness of it to animal and vegetable life is even doubtful, for various insects are known to live and thrive in hot lime alone—and if it does possess the power of corroding fresh animal and vegetable substances when laid in quantity and in close and immediate contact with it—that is not the way in which animals and vegetables are fed, and is very far from proving the fact that hot lime will produce any similar effect on vegetables, when it is mixed with the soil, absorbed or suspended in water, and after undergoing the changes and combination that take place in the preparation of the food of plants."

INDIA-RUBBER IN THE UNITED STATES OF COLOMBIA.

(*Journal of the Society of Arts*, 2nd Dec. 1881.)

A very considerable trade is carried on in Colombia in gathering india-rubber, and the trade accounts of that country show a large increase in the export of this article for 1880 over the previous year, the greater part of it being consigned to the United States. Consul Smith, of Carthagena, in his recent report, gives an interesting account of the system pursued by the rubber hunters in collecting this article, and, at the same time, calls attention to the wasteful custom they have of cutting down every tree from which they extract the rubber instead of tapping them; in this way all the trees near the rivers have been long since destroyed, and the hunters have now to go several days' journey into the forests, crossing swamps and mountains before they can find the rubber and bring it out on their backs over these rough trails. Each succeeding year the quantity gathered is less, and it is a matter of surprise that the Colombian Government has not enforced its regulations against the systematic destruction of one of the most valuable forest trees. The trees which yield the largest supply flourish along the banks of the Sinu and Aslalo Rivers. The hunters before entering the woods, provide themselves with guns, ammunition, flour, salt, and tobacco. The flour is made from plantains, which are cut into slices, dried and ground, and is generally mixed with corn meal; this will keep sweet for months. For meat the hunters depend upon the game they can kill. Each man starts out with his gun and macheté alone, hunting for rubber and game. As soon as a rubber tree is found he cleans a space round the trunk, cutting away all vines, underbush, etc., and again marches off in search of more rubber trees, not returning to camp till nightfall. Accordin to immemorial custom, a tree belongs to him who has cut round it. The hunt is continued until all the trees in the vicinity of the camp are thus secured, and then begins the work of gathering the rubber. A hole is dug in the ground near the rubber trees, unless another party is encamped near, in that case the holes are dug near the camp. The bark of the tree is first hacked with a "machet" as high as a man can reach, the cuts being in the form of a V, and the milk, or sap, collected as it exudes, and put into the hole which has been dug for it. After the sap ceases to flow from the cuts, a pile of wood or brush is made at the foot of the tree, and the tree itself is chopped down, the branches keeping one end of the tree off the ground, and the piles of wood at the foot of the tree doing the same at the other end, thus the tree is suspended. The hunter, after carefully placing large leaves on the ground under the tree, proceeds to cut gashes in the bark throughout its whole length. The sap is collected from the tree and from the leaves placed under it, and added to the milk first collected. The sap when it first exudes from the tree is as white as milk and as thick as cream, but it soon turns black on exposure to air and light, if not properly watched and cared for. The quantity of milk which is put into one hole, depends not only in the size of the trees, and their distance apart, but also in the strength of the man who is to carry the rubber from camp to the rivers, and the track and trail he must carry it over. As soon as the milk is placed in the hole, the rubber is coagulated by the addition of some substance, such as the root of "mechvacau," hard soap, or other substances, and these cause the milk to coagulate so fast as to prevent escape of the water, which is always present in the fresh sap, and as the rubber and water will not mix, a piece of rubber coagulated in this manner is full of small cells containing water. It costs no more to make the rubber perfectly clear and transparent as amber, in which case it is infinitely more valuable, than to make it full of holes, water and dirt. As soon as all the rubber trees are cut down, and the rubber coagulated, the pieces are strapped on the backs of the hunters, by thongs of bark, and carried by them out to the bank of the river, and brought to market by canoe or raft. Consul Smith says, in concluding his report, that the importance of the india-rubber tree, in connection with the many and useful purposes to which it is now applied, can hardly be estimated, and that the attention of the planters of Colombia has never been turned to its cultivation, and he expresses an opinion that a good field for investment lies in this direction, as a plantation of india-rubber trees would prove a most valuable source of profit. There are places on the Sinu river where the trees will grow from eight to ten inches in diameter in three or four years from the planting of the seed; the trees require but little attention, and begin to give returns as soon, if not sooner, than other trees.

NEW PROCESS FOR EXTRACTING TANNIN BY DIALYSIS.

BY O. KOHLRAUSCH.

Dingl. polyt. J., 240, 72-75. From the *Journal of the Chemical Society*, Sept. 1881.

Some time ago it was proposed to prepare tannin extracts in Hungary, from a variety of barks and woods, especially chestnut wood and oak. The author has thoroughly investigated this question, and succeeded in devising a process of extracting tannin in almost theoretical quantities from different kinds of bark. The mode of procedure, necessary apparatus, and plant are described in detail. With regard to the experimental part of the paper, the author concludes that as in tanning the tannin enters the skin by osmosis, it similarly leaves the cells of plants through their permeable membrane, chemical and microscopical examination having shown that the interior of the uninjured cells is the same as the exterior of thick bark which had already been utilized. It is therefore not the solution of the tannin set free by finely dividing the bark, and taken up by the skins, but dialysis of the tannin through the permeable membrane of the plant cells, and also through the animal membrane of the skin. Hence it is not requisite to divide the bark into very small particles, but pieces may be used with advantage which are small enough to allow the dialysing operation to take place in a battery of closed vessels, thus avoiding any danger of choking up the valves or pipes of the apparatus. The result is that purer extracts are obtained in a more economical manner, so that lighter coloured leather is produced; and if the freshly prepared extracts are used at once, the author believes that considerably less of the tannin in a fresh active state will be required for tanning. Experiments have shown that tannin passes through the animal membrane very rapidly in the dialyser; that in a short interval the extract is run from a battery, and that the residual bark (of the size of peas) is almost entirely free from tannic acid.

OIL OF PEPPERMINT.

Boston Bulletin. From *New Remedies*, Sept. 1881.

The peppermint crop of the United States has, for the last few years, reached the amount of 70,000 pounds per year, of which about 30,000 pounds were annually ex

ported. Two-thirds of the peppermint oil of this country is produced in New York State, and about one-third in Michigan. The best oil comes from Wayne County, New York. The plant is a perennial one, and is planted in the spring. The next year it is ready for cutting, and generally may be cut for three years.

The best yield is given in the first and second year of cutting; in the third year the plant becomes bitter. After the plant becomes four years old it is not cut, and the field is ploughed over and a new crop planted. The usual method of planting is in rows, and in August the plant is ready for cutting, which is done by mowing down with a scythe. The leaves are then placed in a still and the oil extracted. There was a report that a considerable number of the roots were damaged by the cold weather of last winter, but it is claimed that this will not affect the price, as there is an increased acreage, and the damage is not as great as has been claimed. The plant is a very hardy one, and will yield from ten to thirty pounds to the acre. The cultivation of the peppermint is now being introduced into the Southern States, where it will furnish a profitable crop in the middle of the year, but as yet none of the Southern oil has reached this market.

INFLUENCE OF RAINFALL ON WELLS AND RIVERS.

(*Field*, 12th November 1881.)

Some new sources of occupation and interest for those with time to dispose of are suggested by Mr. Joseph Lucas, F.G.S., in a pamphlet which appears monthly on the "Wells, Springs, and Rivers of Great Britain," published by Vacher and Sons, 29, Parliament-street. "There are thousands of persons in this country," says Mr. Lucas, "who have the opportunity of adding to our stock of knowledge valuable contributions by simply measuring the depth of water in their wells each day. There are thousands of others, residents near streams, who might perform an equal service to themselves and their fellow-men by measuring the distance of the river below a fixed mark every day."

The depth of the water in a well, as everyone knows, is not a constant quantity. It varies with the season of the year—that is to say, with the rainfall, and also with the demands made upon it. There is utility in ascertaining how the level of water changes by drought, or by the heavy pumping of wells in the same basin. It furnishes data from which the quantity of available water can be calculated. Again, it is interesting to note how some wells rush up rapidly after a rainfall, and how they subside during dry weather. Such are usually very shallow wells. The deeper wells take a sensibly longer time to feel the effect of rainfalls, so the rapid fluctuations in the readings of the water level in a deep well may lead to the discovery, otherwise difficult to ascertain, of faults or subterranean cracks, permitting surface water to descend with rapidity into deeply-buried strata. As the editor of the pamphlet remarks, "It may be safely averred that, if anyone who is not already in the habit of doing so should begin to observe the daily variations of the water in his well, he will not readily give up the habit. By the constant change of level of the water in his well, a curiosity as to the state of the water-line is excited, which is not satisfied until the position of the water is determined by a new measurement." Such investigations will be of interest, even from isolated observers, but the maximum information would only be derived when several persons experiment and compare observations in the same locality.

Persons of a high degree of enthusiasm may proceed still further, and endeavour to ascertain what proportion of the rainfall sinks into the earth to replenish the subterranean water system. This may be ascertained by comparing the rain-gauge results with the amount of water which percolates through a cylinder of a depth of some few feet, containing soil in its natural condition. Besides that which sinks into the earth, the quantity which flows off it is worth ascertaining, and the information is not difficult to get. "Few bridges are without a 'broad arrow,' or 'bench mark' as it is called, cut by the Ordnance surveyors in some conspicuous place, and of which the height above mean sea level (Ordnance datum) is known and recorded on the Ordnance maps; and from these marks it is easy to measure to the surface of the stream. Even when there is no such mark, it is easy to make a mark on the parapet, and to determine its level in the ordinary manner from the nearest Ordnance bench mark. Now, what is the service the observer thus performs? Simply this. The section of the river at that point and its velocities being determined, he gives us the gauging of the water at each height. By the labour of one minute daily, he gathers information of potential value to himself and his fellow-men. Then, again, there are in this island thousands of other persons in a position to make daily observations on the volumes of springs as they issue from the earth. In many cases, by erecting a small gauging board, this observation may be made even easier than any of the foregoing. Moreover, in certain positions, when neither wells, rivers, or springs are accessible to observation, information of a most interesting kind may be gained by similar observations on the height of the water in ponds. And what is wanted to do all this? Nothing but a foot rule, with which the village carpenter is already provided—not a real foot rule, forsooth in most cases but a measure graduated in feet and inches, of sufficient length for the particular purpose for which it may be required."

Mr. Lucas, in addition to experiments as to quantity, suggests that the *quality* of the water may be judged by such observations; but he does not, we think, develope the subject as he might have done. It is well known that the chief objection to shallow wells is the facility with which the drainage of cesspools and noxious surface water gain access to them. Careful measurements might frequently reveal such dangers when they would otherwise remain concealed. A shallow well, for example, which contains water when its neighbours of equal depth are dry, might, on inquiry, prove to be deriving its surplus from unpleasant sources; whilst, as we have suggested above, if a deep well, instead of acknowledging a rainfall by a gently rising curve, give an almost instantaneous bound, it would indicate subterranean channels more easy to traverse than proper soil percolation.

Mr. Lucas says: "A water which dribbles in exceedingly small quantities through the interstices of a rock will gen rally, if not always, be found to be supercharged with mineral ingredients or salts—in other words, an excessively hard water. It would, therefore, be desirable, wherever possible, to ascertain the hardness of water under observation." There is a good deal of truth in the above observations, but the author has apparently forgotten one thing—that is, that the water of surface wells are frequently as hard, and oftentimes much harder than that of deep wells, due, not, of course, to percolation, but to sewage, which, in addition to its own mineral ingredients, obtains more by its energetic chemical action on the soil. Hence the estimation of hardness is useful, but it would not necessarily give the data Mr. Lucas wants. Of course, another characteristic of deep wells would be its uniform temperature as compared with those near the surface.

At the end of Mr. Lucas's pamphlet are details of the observations of such gentlemen as have already joined the movement, and we feel convinced that information of this character, if properly carried out and compiled, will be of the highest value, both to the individual observer and to the nation at large. We trust, therefore, that the matter will be warmly taken up.

PIONEER FARMING AND TEA IN NORTHERN NEW ZEALAND.

TO THE EDITOR OF THE "FIELD."

SIR,—The paper on this subject by Mr. W. Delisle Hay, in your issue of the 9th of July, has just reached this part of the world, and, as I have been in Northern New Zealand for over three years, I naturally read through Mr. Hay's article with much pleasure, and can testify to its general truthfulness, and plain unvarnished description of the early life of a settler, which contains the "whole of the truth and nothing but the truth;" but as he is not, I fancy, a resident here now, there are one or two important omissions from his article, and one statement, at least, which is calculated to mislead anyone who might be thinking of trying one of the most delightful countries in the world, so far as climate is concerned, as well as in many other respects. I trust, therefore, you will allow me to add a few things which Mr. Hay has omitted to mention.

He says in the beginning of his article, "No land, of whatever kind or quality, is now to be had for nothing, though at one time Government used to grant small allotments on the condition of settlement thereon."

Mr. Hay is mistaken on this point; the "Homestead Act," to which he alludes, is still in force, and under it any person of the age of eighteen and upwards may select from the blocks of land open for that purpose, which I shall presently mention, 50 acres of first-class land, or 75 of second-class, and for persons under eighteen years of age of first-class lands 20 acres, or 30 of second class; no household, however, is allowed to take up more than 200 acres of first-class or 300 of second-class land under this system. The only payment the settler is called upon to make is for the cost of surveying and marking off his selection; and a Crown grant or conveyance of the land is obtainable under very easy conditions, viz., a continuous residence on the land for five years; the erection of a permanent dwelling-house, valued £50, within twelve months from the commencement of such residence; annual cultivation of one-fifteenth of area selected if open land, or one-twenty-fifth if bush land. There are some minor regulations regarding frontage to roads, rivers &c., but the above are the fundamental conditions, which anyone will readily see are framed with a view to encourage *bona fide* settlers and farmers, as opposed to land speculators.

Between the parallels of 34° and 37°, with a climate wonderfully like Italy or Greece, there are no less than twenty-two blocks, ranging from 400 acres up to 8,000 each, and aggregating a total area of something like 63,000 acres, open for selection under the homestead system; and other blocks could easily be obtainable from the Government almost for the asking. There are signs of this plan of settlement becoming more popular than it has formerly been, as several selectors have recently come up from the southern island. There are at present in the north about 260 to 300 families settled on "homesteads," with an average area of 180 acres to each family.

Many settlers are now taking up land in the same localities, under the "deferred payment system," the principal features of which are as follows:—Anyone over eighteen years of age may select an allotment of suburban land not exceeding 20 acres, or not more than 320 acres of rural land, at the upset price named by Government, which now ranges for rural lands from £1 per acre upwards—several blocks have been recently taken up at £1 5s., £1 10s., and £2. The minimum price for suburban lands is £4 10s. per acre. The principal conditions for purchase under this system are these: The applicant must deposit on application for the land, one-tenth the value of suburban land, or one-twentieth for rural lands; for the former his licence is for five years, for the latter it extends over ten years; and he must reside on the land within six months of the issue of his licence, and has to pay in five yearly instalments for suburban land, or ten for rural lands. There are certain very easy terms as to cultivation and improvements to be made; but a selector who has complied with the conditions is entitled to a Crown grant at the end of three years on paying up in full, and may, of course, assign his rights and interest to whom he pleases.

There is yet one more system now in force, very suitable for people of the humbler classes, called the "village settlement." Blocks of land are set apart with village allotments of one acre each, and small farm lots of 50 acres each, the cash price for the former being £5, and for the latter not less than £50. These may also be taken up under the deferred payment plan, or on lease, with a purchasing clause, which will enable the lessee, at any time during the continuance of his lease, to take up the land at a price agreed upon at first.

The Crown lands in the provincial district of Auckland open for selection, at various prices, according to quality of soil, &c., are over 2½ millions of acres. Arrangements have just been concluded by which over two millions of acres of land, now in the hands of natives, will be available for settlement, and this block is of the very best quality. The cultivation of the grape is extending up this way, a party of French wine growers having been settled on the Wairoa river. I am now drinking a really good Burgundy, made on the same river, which costs from 5s. to 6s. per gallon only.

Several experiments in growing beetroot in the Waikato district shows clearly that the sugar industry will ere long be opened up, as 14 per cent of sugar is obtainable, and the plant grows well with very little trouble and without manure. The two natural enemies to the grape—viz., the pheasant and the cricket—are likely soon to be reduced in number, if they do not imitate the example of the Kilkenny cats. All the pheasants I killed in the early part of the season had their crops full of crickets; and in several places in the district the pheasants, having cleared the land of the crickets, have taken their departure to new fields. Sport up this way is very fair; ducks and teal in abundance, quail ditto, and a good sprinkling of pheasants: it is not easy to make a bag of the latter. Your battue sportsman would be out of his element here; but the man who is prepared to do his ten to fifteen miles a day may rely on his three to five brace of birds almost anywhere.

Trout are doing well in some of our rivers; but I am afraid that neither they nor salmon will ever succeed well up this way, unless something can be done to lessen the number of eels, which literally swarm in every stream, and grow to an immense size. I have no hesitation in saying they might be taken out of the Wairoa river in tons with the greatest ease.

One other matter which Mr. Hay has omitted to mention, with reference to the settlement in Northern New Zealand, and I have done—that is, the "Kauri gum" fields. The settlers of limited means, and to many of those who fall into the very common mistake of taking up or purchasing more land than they have capital to work, the gum fields afford a capital stand by. A crowd of 'gum-diggers is usually a very motley crowd; yet many a now well-to-do settler has been indebted to the gum field for helping over many a difficulty. Any man who chooses to work can earn his 7s. to 10s. per day; and £1 per day in summer time is not at all an unusual thing. All the capital required is a spade and an iron spear; an old Enfield ramrod makes a splendid one. With

this the digger probes the soil until he hits upon a piece of gum, which he then proceeds to dig out; it only requires washing and scraping a little and it is ready for the market.

In conclusion, I may mention that I have just received some Assam tea seed direct from India, and am very sanguine about its growth here; and should another new industry be added to those already rooted, I shall most gladly send you some particulars at some future time.

J. LINDLEY.

Northern Wairoa, Auckland, N.Z.

ROYAL GARDENS, KEW.

The report on the progress and condition of the Royal Gardens at Kew, during the year 1880, has just been issued.

INDIAN AND COLONIAL BOTANIC GARDENS.

The remarks made in the Kew Report for 1878 on the relations of this establishment with the botanic gardens of our various dependencies have to a considerable extent anticipated the actual course of events. A great increase of activity, arising from a variety of causes, has characterised almost all these institutions with which we are in regular correspondence, entailing a very great extension of the official work transacted at Kew, independent of the purely administrative work of the establishment itself. I may refer to a paper read by the Assistant Director at the Colonial Institute on May 11, of last year, on the Botanical Enterprise of the Empire [see *Gardener's Chronicle*, 1880, vol. xiii., pp. 615, 624], as giving some idea of the extent to which the ramifications of the foreign relations of Kew have extended, and of the growth of the demands of all kinds which are now made upon its resources. Two of our most important botanical departments, those of Ceylon and Jamaica, have been to a large extent reorganised under new Directors within the last two years. I trust that in the future these will become more and more the head-quarters of botanical enterprise for our eastern and western tropical colonies respectively, and will not be content with the limited scope of departments strictly confined in their operations to their own local spheres.—*Gardeners' Chronicle.*

PRACTICAL HINTS FOR PLANTERS ON ARBORICULTURE.

(*Gardeners' Chronicle*, 19th November 1881.)

Nothing saves time in the growth of trees and other plants like the careful cleaning, culture, and nourishment, if need be, of the soil in which they must perforce spend their whole lives. The longevity of the trees, their value in a state of maturity, and the worth of the prunings and thinnings at various stages, all appeal to planters to give them a fair and liberal start in good, sweet, clean soil. To plant choice trees or shrubs in sour soil, already full to repletion with the roots of Brambles, Briars, and coarse weeds, is to court failure. In the struggle for life which the plants are thus forced to engage in, the survival of the fittest seldom proves that the trees were the fittest for the position selected or preparation provided for them. Next to the wholesale culture of the soil here advised was the old plan of digging out the holes for the plants several months or a year before the planting takes place. If the holes and the earth on their sides be kept free from weeds, and frequently broken up during the season, sufficient mellow, sweet, warm soil will be available to allure the roots to a fresh start and vigorous growth in their new quarters. Where no such preparations have been nor can now be made a third mode of fostering rapid rooting in new quarters is still available. This consists in giving each tree a few spadefuls of good soil or compost immediately under or over the roots. This will give them a good start, which will not only save time, but ensure an augmentation of growing force at starting. The latter is of the greatest importance, for a vigorous start often ensures a healthy growth throughout the whole, or the major part, of the life of the tree or plant. Not only is a good preparation the surest means of insuring a vigorous, healthy, and rapid growth of timber or other trees, but it is also the best antidote to accidents from such storms and gales as we have had this autumn. A practical survey of hundreds of trees prostrated by the gales reveals the fact that it is those on shallow or unprepared soils that have been destroyed by wholesale, whereas trees on deeper land have either withstood its force, or broken off sharp rather than give up their root holdfasts. Nothing fosters deep root growth so much as a vigorous start immediately after planting in good well prepared soil. As far as resistance to storms and the formation of fine timber is concerned, there can be no doubt that the best mode of all is to sow the seeds where the trees are to grow. Each tree would then be perfect with its tap-root intact, and hence virtually storm-proof in this country. In many cases there would also be a gain of time by thus sowing on the permanent site of the timber, provided the sets were properly prepared, and the seedlings kept clean from the first, and thinned in time. When this is impracticable, small and healthy trees should be chosen in preference to larger, and the shorter the interval between nursery beds and permanent quarters the better for the well-being of the trees.

VANILLA.—According to Mr. Horne, vanilla of excellent quality is grown in the Seychelles Islands, an acre yielding about 250 lb. of vanilla, which realizes a net profit of 2,500 rupees. Seychelles vanilla obtained the first prize at the Paris Exhibition.—*Pharmaceutical Journal.*

IMPORTING PLANTS.—In answer to "Tree Fern," ferns and palms, if small enough, might best be brought from Calcutta in Wardian cases. Many orchids, if they are collected when at rest, may be sent home as cargo in ordinary packing cases, through the sides of which a few large auger holes have been bored, so as to ensure perfect ventilation. In shipping cases of plants, directions to stow them away quite clear of the heated engine rooms, &c., should be given. Large trunks of tree ferns may be packed in long packing cases or crates in dry moss, after the fronds have been removed, and thus shipped as cargo. Very rare orchids should be tied firmly on teak-wood blocks (or have their roots packed in coconut fibre), and should then be grown for some months in Calcutta in order to establish them, and enable their fleshy roots to cling firmly by growing naturally on the blocks, after which they may be screwed firmly to the sides of close Wardian cases, and thus brought home on the poop of a steamer, safely lashed below the awning. Unless "Tree Fern's" friend in Calcutta is *au fait* at preparing the plants named for exportation, he will find the expenses more apparent than the success in getting home living plants. Models of Wardian cases may be seen in the Calcutta Botanical Gardens, or at Messrs. Veitch's, Chelsea Nurseries, London, and any Chinese or native carpenter in Calcutta will make such cases at a moderate price. I should not advise the attempt to import the plants named, unless "Tree Fern's" correspondent is practically acquainted with the particular species or varieties of plants he requires, add the best way of preparing them for export in the way he desires. Most amateurs pay very dearly for their experience in such matters.—F. W. B.—*Field.*

ALMONDS.—86,763 cwt. of Almonds, of the value of £334,713, were imported in 1880.—*Gardeners' Chronicle.*

POTATOS.—The imports of Potatos in 1880 amounted to 9,755,514 cwt., of the value of £2,847,027.—*Ibid.*

ORANGES AND LEMONS.—The total number of bushels of Oranges and Lemons imported in 1880 was 3,658,799, the value being £1,463,019.—*Ibid.*

THE CAPSICUM which yields the cayenne pepper alluded to, is *C. tetragonum*, called by the Spaniards "Pimento," under which name it has often been imported from Spain. This large and handsome capsicum, often as large as a good-sized tomato, is of two colours, scarlet and golden-yellow. Its appearance is familiar to all who have visited the vegetable markets of Southern Europe at the season when it is ripe. It is largely used in salads, and the large heaps exposed for sale are very conspicious by the beauty of their colours. When ground the pods are both used for a peculiar fresh flavour which they possess, and also for colouring some dishes.—*Pharmaceutical Journal.*

SNAKE POISON.—In reference to the use of permanganate of potash as an antidote to cobra poison, Mr. A. Wynter Blyth points out, in the *Lancet* (November 5, p. 812), that his experiments were made in 1877, some time before Dr. Lacerda published his results, and that he only found permanganate of potash of use if applied immediately after the insertion of the poison.—*Ibid.*

THE AGRICULTURE OF THE WORLD.—A carefully compiled and comprehensive agricultural chart, by the well-known agricultural writer, Mr. H. Kains-Jackson, showing the comparative food production of the chief countries of the world, is published with the *Graphic* for this date. By means of coloured diagrams the yields of the various cereals, such as Wheat, Rye, Maize, &c.; the Wheat and Flour imports into the United Kingdom for the past five years; the Hop and Grape average harvest; the amount of live stock, including horses, cattle, pigs, and sheep, for the current year, are strikingly compared. This chart affords an admirable survey of the subject with which it deals, and at the present time, when the question of foreign and home agriculture is so universally under discussion, it will prove of great value for reference purposes, and of the highest interest to all concerned in agricultural operations.—*Gardeners' Chronicle.*

WATER AND TYPHOID FEVER.—Dr. Lowe, of King's Lynn, throws out a valuable suggestion in the *Lancet* (November 12, 1881, p. 853), which deserves the attention of pharmacists. He points out the great danger of contracting typhoid fever by total abstainers or travellers, from drinking impure water. His experience has led him, when travelling, always to carry a small case containing a kettle and spirit lamp, and invariably to boil water before drinking it; also to apply Nessler's test to it. He suggests that if 10 or 15 drops of that reagent were enclosed in a thin glass capsule and hermetically sealed, the fluid would keep for a length of time, and a dozen or so packed in a box would form a valuable addition to a traveller's outfit. One of the capsules, broken in a wineglass, and a spoonful or so of the suspected water added, would show at once if it were of a dangerous nature, and might thus be the means of saving life. The danger of drinking unfiltered water was also strikingly shown by Dr. Cobbold, at a recent meeting of the Linnean Society. A gentleman, who had been on a shooting expedition in Egypt, incautiously drank some canal water without using a pocket filter, and consequently became infested with an internal parasite, *Bilharzia hæmatobia*. Some hundreds of the ova taken from a drop of urine were exhibited at the meeting, during the course of which they were hatched under the microscope, and the larvæ appeared under the form of cone-shaped ciliated infusorial animalcules. These, of course, would easily be overlooked in drinking water, and would give rise to hæmaturia.—*Pharmaceutical Journal.*

MANURES.—In 1880 the quantities and values of imported manures were:—Bones of animals and fish for manure only, 78 138 tons, value £436,186; guano, 80,497 tons, value £810,177; unenumerated, 192,040 tons, value £537,279—the total values being £1,783,642. —*Gardeners' Chronicle.*

VEGETATION IN CHINA.—The British Consul reporting on the trade of the port of Wenchow in China, describes a short journey made by him in April, 100 miles westward up the river Ou, on which Wenchow is situated, to the prefectural city of Ch'u Chow. He describes the natives as being extremely amiable all along the route, whereas those to the south are most uncouth and unfriendly. At a distance of 40 miles from Wenchow lies the small and dilapidated city of Ch'ing T'ien, famous for its iron and soapstone; the iron is of excellent quality, but the natives do not understand the art of manufacturing it well, and consequently import a considerable amount of foreign nail-rod iron in preference to it. From Ch'ing T'ien to Ch'u Chow a succession of rapids have to be crossed, which makes it a tedious journey for the traveller, and a most laborious one for the boatmen, who have to get out and haul their flat-bottomed boats by sheer force over the rapids. In times of drought there is not sufficient water for any but the smallest boats to come down, which is a considerable hindrance to the trade of the port. Though it was early in April there were splendid crops of Wheats, fields upon fields of the opium Poppy in full bloom, as well as Peas and Beans, almost ready for gathering. The hills were covered with the valuable Tea-oil shrub (Camellia Sasanqua); the small fruits are abundantly produced, and when ripe they burst, and two or three brown seeds drop out: from these the oil is expressed. There were also quantities of a beautiful flowering tree, which produces another valuable oil, much used for varnish and to oil the native umbrellas. Vegetable tallow trees were also abundant, but not yet in foliage, whereas in the autumn they quite light up the country with their scarlet leaves and innumerable bunches of snow-white seeds. It is from the neighbourhood of Ch'u Chow that the Bamboos and timber-poles are brought down in endless quantities to Wenchow, for export. Ch'u Chow, too, is the principal seat of the Coir Palm, from the fibre of which excellent rain-coats and mats are made. For about 2s. a fisherman can get a coat that will last him for years.—*Ibid.*

SPONGES.—Some time since mention was made in these columns of the mode of growing sponges from cuttings, proposed by Professor Oscar Schmidt of Gratz. According to *New Remedies* (p. 321), several dealers in New York are exhibiting sponges that have been grown in this way, so that the industry has become an established fact. In one experiment four thousand sponges were thus grown, at a total cost of 50 dollars, and the cultivation is now being repeated successfully at Pine Key, in Florida. Whilst speaking of sponges attention may be directed to an interesting paper by M. J. Hamilton, M.B., in the *Edinburgh Medical Journal* (November), in which he shows that sponge, rendered antiseptic and inserted in a wound, acts in the same way as blood clot or fibrous lymph in becoming vascularized and replaced by cicatrical tissue. In ten days it seemed to be slightly vascular, and bled when pricked. In one case after the sponge had become filled with tissue and had completely disappeared, the clipping out of a small portion was not attended with pain, showing that probably nerves had not found their way into the new mass. Mr. Hamilton considers that the blood vessels are the primary, and the connective tissue elements the secondary factors in the organizing process, which he looks upon as a healing up rather than as a contracting down one, the capillaries being thrown up as granulation loopsby the propelling action of the heart.—*Pharmaceutical Journal.*

COD LIVER OIL JELLY can easily be prepared in the following manner :—

R Cod liver oil	5	fluid ounces
Best isinglass	2	drachms
Sugar (white) powdered ...	1½	ounce
Oil of bitter almonds ...	4	drops
,, allspice	4	,,
,, cinnamon (Ceylon)	2	,,
Water	1	fluid ounce

Having placed the cod liver oil, isinglass and water in a suitable vessel over a water-bath, apply sufficient heat to melt the isinglass, then add the sugar, the essential oils having been mixed with it by trituration, and remove from the fire, stirring the mixture as it cools until it thickens. When it is cold a firm jelly will result, which will keep without spoiling for any length of time if put up in corked bottles. The consistence of this jelly is such that it may be taken in water, milk or wine without tasting the oil. —*Pharmaceutical Journal.*

CHANGE OF CROP.—We frequently hear it urged that a complete change of crop in cultivated ground is necessary to success—such, for instance, as the four-course system often provided for in agricultural agreements between landlord and tenant. Yet, although this kind of change has its advantages in the case of some crops, more or less according to the nature of the land, the idea is often pushed much further than there is use in, or need for. In Messrs. Osborn's nursery at Fulham there is this year, as usual, a considerable breadth devoted to maiden Peaches remarkable for their unusual, strong, even condition; and we understand that on this identical piece of ground maiden Peaches, alternating with Seakale, and nothing else, have been grown for forty-years, and Mr. Pitman, so long in charge of the fruit tree department here considers them the best maidens he ever had. Although, doubtless, some plants more than others exhaust the soil of the particular elements they require to build up their substance, yet, at all events, this piece of ground has not had its ability exhausted to grow the plants that without change it so long has borne.—*Gardeners' Chronicle.*

BROOM CORN IN AMERICA.—In connection with the subject of the more extended utilization of Broom Corn (Sorghum saccharatum) in America for sugar-making, a correspondent in *Land and Water* gives the following history of its introduction and cultivation in America :—This plant is said to have been introduced into America by Dr. Franklin, who, having accidentally seen a small wisp of it in the possession of a lady at Philadelphia, found, when examining it as an imported curiosity, one little seed left in it, which he planted, and from this has sprung all the present Broom Corn in the United States. The Shakers are the people who chiefly used to cultivate Broom Corn in America, and they did it in the first place for the purpose of manufacturing it into brooms. A little of the seed was sown, like other corn, in some gardens belonging to the Society of Shakers at Watervliet, New York, in 1791, and in the course of four years it began to excite attention. Some brooms were made of it, the handles being of soft maple timber, and they sold well at 50 cents each; so some machinery was erected of a very simple description, which has of course been gradually very vastly improved. But now a great part of the brush of Broom Corn raised in the valley of the Ohio, together with broom-handles, is shipped to England, it having been found that the brooms can be sold cheaper over here if made by us than if made there and exported to this country. The seed fattens sheep and poultry as well as Indian Corn does, and when ground and mixed with Wheat-bran it is given to milch cows,—*Ibid.*

SOY BEANS IN CHINA.—The Soy Bean (Soja hispida), as is well known, is very largely used in China as an article of food. A kind of curd is prepared from them, but they are mainly used to manufacture an edible soil, and the refuse pulp after the expression of the oil is manufactured into cakes, the size and shape of large cheeses, weighing about 60 lb., which are used either as fodder for animals, or more frequently as manure, especially for Sugarcane plantations in the southern parts. The beans are known under three distinct varieties, black, yellow, and green: the yellow are said to be the best, as producing most oil. It is stated in a recent report from Newchwang that the natives of that place boast that the oil made on the spot is much better than that made from the same beans after their arrival in the South. The harvest takes place in August and September, and the beans from the neighbouring localities are shipped from Newchwang before the river closes, and during the winter, when the roads are hard and the rivers can be crossed on the ice, thousands of carts arrive from the more distant districts with produce that is shipped away the following spring or summer. In fact, the shipment of produce goes on all the year round as long as the port is open. Bean-oil and bean-cake can be kept any length of time without spoiling; the beans themselves are more perishable, but will keep for a year or more if preserved from damp.—*Gardeners' Chronicle.*

ORCHARD PLANTING AND CULTURE.—Now that many an acre of wood, hop-garden, pasture, &c., is being converted into orchard, in the belief that fruit growing is one of the best objects to which capital and labour can be employed in these days of agricultural depression, it is well to note that it is most essential that a good deep loamy soil should be selected, and which should rest on a dry subsoil—at least one through which there is natural drainage. Many an orchard has failed for want of attention to these essential conditions. Trees will flourish for fifteen or twenty years, and then decay, and it is a painful disappointment when such a disaster occurs. The farther north the site of the orchard, and the moister and colder the climate, the more necessary is it to have a proper subsoil. An old cultivator of fruit in orchards has remarked, that if the ground be sheltered it is best to plant each tree upon a small raised mound of earth; by this means the roots are always near the surface, and the trees are uniformly more fruitful in consequence. There are many orchards scattered about the country in which the trees are gradually becoming barren, and decaying for want of proper drainage, and those who plant now should endeavour to avoid the errors committed by their forefathers. In Kent and other fruit-growing districts where orchards are systematically cultivated, the matter of pruning receives greater attention than in some other parts. To have fruitful trees it is necessary to keep them open in their heads, not to allow a great quantity of small and cross branches in the insides, which prevent the wood from properly ripening in autumn, and the sun and air from circulating in summer. With proper pruning the fertility of the tree is promoted and finer fruit rewards the cultivator. Whether the soil should be sown with grass seeds or be kept cultivated is an open question, but modern practice follows the lead of the latter course, as bush fruits are in a large number of cases planted alternately with standard trees. In the case of a Cherry orchard the trees appear to flourish best when the soil is carpeted with grass, and thus it is that Cherry trees are generally planted by themselves and not mixed with others. An open cultivated soil, care being taken not to injure the fibrous roots on the surface, is the best for standard Apple, Pear, and Plum trees.—*Ibid.*

1881 IN CEYLON.

Commercially, the year closes with marked depression in the markets for several of our staples: coffee has touched a point so low that consolation is found in the fact that it cannot go much lower, that consumption is bound to increase, and that a check will be given to the production in Brazil even if the Slave Question, gradually but surely ripening for an outburst, does not come to a head. Coconut Oil and Cinnamon are so very cheap, that nothing but abundant crops can encourage the native planters to keep up the exports. On the other hand our New Products promise well. Tea is steadily advancing in importance, and its home prospects are good, and in this connection the benefit gained from the representation of the Colony at the Melbourne Exhibition is one redeeming feature worthy of notice in the history of 1881. The Cinchona bark market too has satisfactorily passed through the strain put upon it by large importations of Cuprea bark from South America, and the prospects of the cultivators of the fine descriptions (Crown, Hybrid, and Calisaya) continue favourable.

The position of our planting enterprise *per se* is certainly more satisfactory and encouraging than it was twelve months ago. It is acknowledged on all hands that a great improvement has taken place during the past four months in the appearance of our coffee fields, notwithstanding that estimates of crop have as a rule been exceeded and in almost all cases fully realized, while strict economy has been maintained. For the first time for six years, a season of the good old normal type, with rain falling more or less steadily all through crop from October to December, has been experienced, and the trees are now in splendid condition for blossom. Fine weather may be anticipated from the present appearances in Colombo, and certainly the New Year breaks with much to raise the hopes of the coffee estate proprietor in the Central Province. There is no reason either to abate one jot of the fair expectations based on "New Products." The growth of tea in Ceylon satisfies the keenest critic; the manufacture as a whole will improve every season, and this colony is destined to be a great tea-producing country. So with Cinchona, Cocoa (which is flourishing space) and Liberian Coffee (trees of which at four years old are yielding at the rate of 2 tons per acre), Cardamoms and Rubber.

Native industry in grain and fruit has been rewarded during 1881 with more than average returns, and the country has been free from any epidemic disease or local scarcity of food.

THE CEYLON COFFEE CROP.

A merchant writes:—

"Can you tell me what the estimate of last season's (1880-81) coffee crop was *at this time last year*? Also what do you estimate the present crop (1881-82) will turn out? We require above information for the mail, and I know no one more able to give reliable figures than yourself."

In January 1881, our estimate of the then current coffee crop, or rather export, fell as low as "three-fifths of the total shipped in season 1879-80," which was 669,614 cwt. In other words, we estimated for 1880-81 a possible minimum export of 400,000 cwt., although we hoped 450,000 would be made, and even exceeded. The actual result on the 30th September 1881 was a total export for the season of 453,758 cwt.

For the current season it is very difficult to make an approximate estimate, so great has been the discrepancy between the reports of different authorities. In most districts on the Kandy side, estate estimates are being fully realized, but the Uva spring crop is to be a poor one. About a month ago we took a note of four different estimates of the season's outturn—chiefly by Visiting Agents—which ran as follows: 450,000 cwt.; 550,000 to 580,000 cwt.; 600,000 cwt.; and 650,000 cwt. Up to the 5th instant, we have only shipped 118,689 against 146,671 cwt., 165,926, and 209,216 cwt. up to the same date of previous seasons. But the present crop is admittedly a very late one, and in 1879 we shipped 600,000 cwt. for the nine months from January to September. Our inclination is to adhere to 600,000 cwt. as the safest present estimate for the total export of coffee from Ceylon during Season 1881-82.

CEYLON COMPANY, LIMITED.

REPORT.

To be presented at the half-yearly meeting, to be held at the Cannon Street Hotel, in the City of London, at 2 p.m., on the 20th December, 1881:

1.—The Directors have reason to expect that their Ceylon coffee crop for the current year will amount to about 18,500 cwt., or about 5,000 cwt. more than that of last year; but it is yet too early to speak with certainty on this point. The prices already obtained have been good.

2.—The Directors regret that they cannot yet report any very considerable diminution of the coffee leaf-disease, which has so very injuriously affected all estates in Ceylon, and lessened their crops; but it is satisfactory to know that the disease has entirely disappeared from certain coffee districts in India, and that it is the opinion of many practical planters that it has never yet killed a coffee tree in Ceylon.

3.—The crop of tea from the Company's estates will probably be about 120,000lb. That of last year was 82,275lb. and better prices have so far been obtained than last year. There is a marked improvement in the quality of recent arrivals.

4th.—The directors are extending the cultivation of cinchona on the Company's Estates, and from this source they look for considerable future profits.

Ceylon cocoa has lately realized very high prices in this market, and the Directors' attention has been for some time turned to the cultivation of this article. Other products receive much attention, and already some profit has been obtained from them.

5th.—The directors have been anxious as to a lawsuit in Ceylon, that has been mentioned before to the proprietors. About August this year the plaintiff obtained a decree from a district court in Ceylon for the appointment of a receiver, and the management of several estates passed from the Company, but on appeal to the Supreme Court, in October last, the judgment of the district court was reversed, with costs on both sides, and in both courts in the Company's favour. The Company has regained possession of all the properties, and is pressing for the objections alleged against the accounts, and thus every reasonable effort is being made to close this matter altogether.

6.—Mauritius.—Most of the sugar is now made and being

sold at Mauritius, and by the latest estimates the crop is likely to be about 6,000,000lb. against 4,362,804lb. last year, 1880-1. Prices are, on the average, slightly higher, and, as the disbursements are rather less, it is now confidently hoped a credit balance of some amount may this year come to profit and loss, instead of the adverse balance of last year. The small lawsuit in Mauritius, which the directors considered at an end, has been revived on appeal, but it is likely to come to a trial soon, and the amount involved is not of great importance.

7.—It is not customary or possible at the half-yearly meetings to report much upon the accounts. The following statement may, however, be interesting to the proprietors:—

The amount of mortgages and other securities at Mauritius which in the last report was	£64,026 3 3	
Is now	43,025 19 5	
Being a reduction in amount of investments in Mauritius of		£21,000 3 10
The Directors have also sold property in Ceylon for about		£900 0 0
The amount of debentures on 31st March, 1881, was ...	£78,238 10 0	
On the 1st January, 1882, it will be	60,500 0 0	
Reduction ...	£17,738 10 0	
The calls that have been made in 1881 amounted to ...	£88,781	
Of which there has been received	75,349	
Leaving arrears	£13,432	
The arrears for calls in 1880 now amount to	6,612	
Making the total arrears of calls on shares not otherwise dealt with		£20,044
Since the 31st March last, the directors have forfeited 450 shares, upon which capital had been paid		£3,380
And in connection with these forfeited shares there has been a surrender of 232 fully paid shares upon which capital had been paid		4,640
Making thus		£8,020 to be applied

in the yearly account 31st March, 1882, to the credit of the account estimated deficiency in value of assets.

All the remaining over-due Calls are receiving constant attention.

7.—The directors have again warmly to thank the proprietors for the general promptitude with which the calls have been met and it is with regret that they find it will be necessary to make a call of £1 per share in April next.

GEORGE STUART SIMPSON, Chairman.

THE CEYLON INVESTMENT ASSOCIATION, (LIMITED.)

Report by the Directors to the fourth ordinary general meeting of the Company, to be held on Wednesday, the 14th day of December, 1881, at twelve o'clock, within the Accountant's Hall, West Nile Street, Glasgow.

The Directors submit herewith the accounts of the Company for the year ending 30th September 1881.

In view of the continued difficulty in finding suitable investments for the Company's funds, the Directors have not deemed it expedient to press for debentures during the past year, consequently a sum of only £11,830 has been added to this account, while a sum of £500 has been retired.

The investments made by the Company during the past year amount to £16,333 6s 8d, whilst there had been repaid £3,946 11s 1d. A very large number of applications for loans have been received since the date of last report, but the security offered in many cases did not admit of their being entertained.

The directors are glad to be able to report that the security for the invested funds of the Company continues satisfactory, and that the interest on all Bonds has been punctually met, with the exception of £800, which the directors have every reason to except will be settled shortly.

The Board obtained much benefit from the information received from their Secretary, Mr. Kirwan, as the result of his visit to Ceylon. While in the island, this gentleman made a careful inspection of all the estates in which the Association is interested, and his report may be held as extremely satisfactory.

Prospects in Ceylon are reported to be slowly, though steadily improving. The cultivation of new products is being rapidly extended, and the success which has already attended the growth of these promise well for the eventual rise in the price of land in the colony.

The Directors have to report with much regret the resignation of their late managers, Messrs. Grahames, Crum & Spens, owing to a change in the rules of the Glasgow Stock Exchange, whereby members thereof are prohibited from holding the appointments of managers of Public Companies.

The election of a new manager has been left to the first statutory meeting of the new Board, meanwhile Mr. Kirwan continues to act in that capacity.

By the Profit and Loss Account, it will be seen that the balance at the disposal of the Company amounts to £2,837 15 11

The Directors advise that the sum should be applied, viz.:

(1.) In payment of a dividend at the rate 6 per cent. to the shareholders	£1,800 0 0	
(2.) In writing off the whole balance of expenses in connection with the debentures issued during the year,	51 9 5	
		1,851 9 5
Leaving a balance of		£986 6 6

of which it is proposed to place £800 to a Reserve Fund, and to carry forward the balance of £186 6s 6d to next account.

The Directors falling to retire at this time are Messrs. King and Aitken.

The Directors regret that Mr. Aitken, owing to the distance of his business from town, is unable to continue his seat on the Board.

The Board recommend that Mr. King be re-elected, and that Mr. Nathaniel Spens of Messrs. Grahames, Crum & Spens, late Managers of the Company, be elected to fill the vacant seat.

It also falls to the Shareholders to elect Auditors for the current year, Messrs. Alexander Moore, C. A., Glasgow, and David Cowan, C. A., Edinburgh, are eligible and offer themselves for election.

J. BROOKS WRIGHT, Interim Chairman;
J. MAITLAND KIRWAN, Secretary.

Balance Sheet as at 30th September 1881.

Dr. Liabilities.		Cr.
Capital Account— 15,000 Shares of £10 each—£150,000— of which paid up £2 per share ...	£30,000 0 0	
Debenture Account, ...	67,540 0 0

CEYLON CINCHONA CULTURE AND ITS CRITICS.

The Nilgiri paper (the *South of India Observer*) draws some rather sweeping conclusions from Col. Beddome's report on Cinchona Culture in Ceylon, thus:—

We do not gather, from a careful perusal of the proceedings before us, that Ceylon possesses any special advantages for the growth of cinchona. On the contrary, both in soil and climate, the conditions are such as will never make it a formidable rival of Southern India in cinchona cultivation. The extreme moisture of the climate, combined with a characteristic subsoil, clayey and impervious, render it unsuitable as a home for permanent cinchona estates. Canker is induced as soon as the tree, from the exigencies of development above ground, begins to strike root into the cold sour subsoil. This condition of the soil may help to explain what has puzzled our Ceylon friends, namely, the dying out in patches of parts of cinchona plantations, and to the same cause may be ascribed the extreme difficulty of establishing plants in the field, necessitating replanting for three or four years in succession of the same field. Proprietors of Ceylon cinchona property have not been slow to perceive the unsuitability of the climate and soil in this respect, and hence we find them adopting uprooting as a mode of harvesting which, with present prices, has proved very remunerative. The lengthened droughts of the Nilgiris are favorable to officinalis, and a natural inference to draw from this fact, is that close planting of the species is imperative to give the surface soil that shelter from the sun's rays which will enable it to retain its moisture. This is what Mr. Cross recommends, when he advocates close planting and the encouragement of undergrowth, on the drier parts of the Nilgiris. Colonel Beddome remarks that the heavy monsoon and rain all the year round induces "early maturity and the too early flowering of the trees." Mr. Cross attributes early flowering to open planting and general dryness, excessive dampness does not, seem to be absolutely necessary here, and the Cinchona is so varied in habit and character that a variety can be found to suit a locality as well as a locality to suit a variety.

We are greatly surprised to see an authority like Col. Beddome attributing early maturity and flowering of cinchonas in Ceylon to the dampness of the climate. Excess of moisture surely has the very opposite effect. Apart from the fact that certain species and varieties, often in proportion to their inferiority, flower at an early stage of their existence, there can be little doubt that the pre-maturity of cinchonas in Ceylon occurs not because of the moistness of the climate, but in spite of it. The true cause, apart from the tendencies we have mentioned, is the unfortunate prevalence of stiff clay subsoil, into which the cinchona roots cannot penetrate. The instinct which leads cinchona trees so circumstanced to make an effort to propagate their kind is common to all plants. But the Indian journalist is quite mistaken in drawing from Col. Beddome's report the inferences that both soil and climate in Ceylon are unfavorable to the growth of cinchona. There is abundance of free and fairly rich soil in Ceylon, in which cinchonas flourish and will flourish, and, as far as climate goes, ours is superior to that of India or even Java. It is not because of prolonged droughts, but in spite of them, that cinchonas flourish on the Nilgiris and in Java. It is the rich soil which, in the case of Southern India and the Dutch colony, enables the cinchonas to survive the trying droughts to which they are occasionally subject.

On the question of Ledgeriana cuttings the same contemporary states: —

We think, however, that Colonel Beddome's observations as to the facility with which the cuttings are propagated is not borne out in practice. Mr. Grant's nursery of Ledgerianas, to which reference is made, may have been what Colonel Beddome describes it at the time, but we know that the cuttings of this species look green and fresh for a long time without putting out a single rootlet.

We should like to have full details of the success obtained in Ceylon with cuttings of the best kinds of C. Ledgeriana. Our personal experience and observation favour the position that a large proportion of cuttings from Ledgerianas grow well in nursery beds and especially under glass. But what is the history of the resulting plants when put out into the field? This question of being able to propagate the best Ledgerianas from cuttings, such cuttings resulting in strong healthy trees when planted out, is one of the most important connected with cinchona culture. Mr. Mocns's process of grafting on succirubras has been a success so far; but it is slow, troublesome and expensive, and it will be much in favour of planters in Ceylon if they can save the time and the expenditure involved.

What are the results of experience in Ceylon, so far?

COFFEE—TEA—CINCHONA: THE PROSPECT OF A FAVOURABLE BLOSSOMING SEASON.

LINDULA, Ceylon, 9th Jan. 1882.

We are now rejoicing in the true Christmas and New Year holiday weather, which would have been so acceptable had it, in due season, taken the place of the heavy rains and dense mists which prevailed. I am estimating the weather from the sensations of a lay mortal now, for experts in coffee planting declared that nothing could be better for their plant than the copious rains which have now ended. In the midst of them a spike of blossom was to be seen here and there, and I suspect the blazing sunshine which bathes the mountains and brightens the valleys as I write will bring out a very appreciable blossom. I was glad to hear from an intelligent and experienced planter, here that he believes in much of this exceptionally early blossom —early for this elevation—maturing into fruit. The genial weather is, of course, favourable for the growth of cinchonas, and as for tea, the rate at which it is putting on one golden flush after another is a cheering sight to see. The qualifications in this latter case are the operations of that minute moth which can so rapidly convert succulent leaf into cindery débris and the occasional dying out of from two to half-a-dozen bushes, from the poisonous effects of the roots of a species of *symplochos*. This tree seems more prevalent in the higher forests of Ceylon than in the lower. The tree and its effects must be well-known in Assam, for my attention was first attracted to this enemy of the tea tree somewhat more than two years ago by Mr. Anderson, an Assam tea planter, who came to Ceylon on a visit to his brother, Mr. Anderson of Acnfield estate, Dikoya. While going round the plantation from which I write and giving the most unqualified opinion in favour of the soil, as a perfect tea soil, he asked if plants surrounding the stump of a particular tree did not die off. I said I had not noticed anything of the kind, but I had scarcely so replied when Mr. Anderson found what he was looking for; and since then more cases of the kind have been observed than is deemed desirable. Has the particular tree (the trunk always twisted and the wood soft) been identified, and has the poisonous principle been discovered? In my own reading I have seen no account of this

tree.* Neither have I seen a description of the moth which becomes specially prevalent and harmful to tea at this season of the year. It is not so formidable as red rust in India or *helopeltis Aantonii* in Java, but it is bad enough occasionally. There is nothing, apparently, which can be cultivated that has not its enemies. The foliage of the blue gums suffers from a kind of fungus spot (Dr. Thwaites asked as to look out for a bug, but we never detected an insect) which is capable of infecting cinchonas and tea, and occasionally a gum tree breaks off about the middle from a species of canker. While it is only right to mention such drawbacks, the vast majority of the plants referred to shew luxuriant growth, and our old staple coffee, although its chief enemy is present and its effect manifest in particular spots, looks better than it has done for years back. May the improvement be permanent and the recovery complete!

To revert to the weather, which I last noticed on earthquake-day, the last day of 1881. On the morning of that day, the thermometer shewed that, in the previous twenty-four hours, the mercury had been up to 70° and down to 58°, the rainfall being ·20 of an inch. On the morning of New Year's Day the record gave a maximum temperature of 73° and a minimum of 58°, mild enough; but there was a heavy plump of rain after the earthquake, measured as ·58 of an inch. Since then we have had no rain to speak of: ·21 recorded on the 2nd and ·13 on the 3rd, while for the six days following there has been only a trace on one day. During the heavy rain on Christmas Eve (1·80 inch recorded on the morning of the 25th of Dec.) there was a marked "blowing" from the south-west. There was, then, no wind to speak of until the night of Friday, the 6th, when the north-east commenced in full force, blowing and "soughing" all night long and so continuing well on into next day. On Saturday night we had "another of the same" in the shape of a strong north-easter, but, as previously, unaccompanied by rain.

Had there been rain in proportion to the wind, we should have had many more than a couple of trees (acacias) blown down. To see the swaying of the trees and the tossing of their arms, on "the gum ridge," was a sight of animation, in strong contrast to the stillness which has prevailed since yesterday (Sunday) morning. Yesterday was lovely, and today is lovelier still. The atmosphere has so cleared that the moonlight has been exquisite, enabling us to read small type easily. While the sun has shone hotly in the daytime, heat has radiated into space at night, the result being that the maximum temperature has risen from 66° in the twenty-four hours ending on the morning of the 5th to 74° recorded this morning. But in the five days the maximum has gone down from 58° to 52°. Last night and this morning, therefore, were *cold*; and the view between 6 and 7 a. m. of the circlet of mountains which ramparts the grand valley, or rather series of valleys, of Dimbula was wonderfully distinct and beautiful. The only feature wanting in the landscape was a lake. And this reminds me that the expanses of patanas which so largely atoned for the want of glassy-surfaced, calm water are being circumscribed in consequence of the extension of cinchona culture. If the encroachment adds to the ability of planters to resist the effects of lessened returns from coffee, we must not complain of some small diminution of scenic effect in a view which is so profusely rich in the elements of grandeur and loveliness. From the brightness and power with which the sun is shining today, I have no doubt that the next twenty-four hours will shew a still greater disproportion between maximum and minimum temperature, and the prospect seems to be that fine weather will prevail in these mountain regions from now until the end of March or the beginning of April, occasional rainfall for short periods only rendering this weather still more pleasant. Now is the time to see the mountains, valleys, rivers and waterfalls of the upland regions of Ceylon at their best.

P. S.—I have given last night's figure for minimum temperature at this bungalow, which is situated on an elevated knoll 5,800 feet above sea level. In the assistant's bungalow, lying in a valley, 1,100 feet lower, enclosed on all sides and through which several streams run, the cold was actually represented last night by so low a figure as 48°. The lowest ever recorded by Mr. Heelis was over 44°. That was in the month of March. In damp, grassy, low-lying spots, no doubt the temperature has been occasionally considerably lower.

* When in the Ouchterlony Valley a few years ago, we were told by Mr. Grant that the cause of the similar dying out of coffee bushes was the existence of the stock and roots of the wild cinnamon tree.

COFFEE PROSPECTS.

There is always information worthy of attention in the monthly report of Messrs. Robert Von Glehn & Sons, London. We quote as follows from the latest to hand:—

The price of middling plantation Ceylon Coffee remains at 77s to 82s, or about the same as at the beginning of last month, and the few lots of colory bold and fine which have been brought to market have realized what are called fancy prices. The common and medium kinds of foreign coffee are, however, decidedly lower for the month and would be lower still if it were not for the firmness of holders. East India Plantation, though scarce and mostly well held, is also decidedly lower for the month, and for good colory B size old crop Tuttapolum estate, —the highest bid in Public sale this week was 71s. In Havre the price of Santos, good average, has fallen during the past month from 64 fr. @ 64.50 fr. to 60 fr. @ 60.50. The confidence of the Havre speculators remains unabated and the large holders are reported as still among the chief buyers. A new feature in this market is that a great deal of coffee has been bought by speculators for monthly deliveries up till as late as June 1882. As far as we can learn there is not the slightest fear of a break-down in the Havre market, while should the position of coffee improve, it is probable that nearly the whole of the stock would be taken off the market and held for much higher prices, giving thus a great impulse to the coffee markets of the world.

In New York the price of fair Rio has fallen from 11 cents on the 1st November to 10¼ cents, and this is a very heavy fall considering that the stock of Brazil coffee in the six chief ports of the United States is about 75,000 bags less than last year, and that the consumption of Brazil coffee in the United States from 1st Jan. 1881 to the 1st November last averaged 190,434 bags per month as compared with a monthly average during the same period last year of 167,625 bags. But we believe that the New York market has lost much of its importance, and should no longer be looked upon as the regulating market for the United States, for we are informed that nearly one-half of the coffee now arriving in New York and the other chief ports of the United States goes direct through to the interior, (the ports being used merely for transit from the countries of production to the interior) and leaving but a few cents dock charge per bag as a remembrance. An agitation is now on foot in New York to try and regain some of the old ascendancy over the market by means of public auctions, but this is not likely to succeed, as the tendency of all trade is to go more and more direct, and to suppress middlemen.

It is a great question whether the large increase in the consumption, as shewn by the monthly averages given above, is not apparent rather than real, and is not in some way attributable to the altered course of trade, for we do not believe in a large increase in the actual consumption of coffee, cheap though it be; when the cost of living

has increased as enormously as it has done in the United States. Some idea of this increase may be formed by the following comparison of the wholesale prices of—

	16th November, 1881.	1880.
Butter ...	34 cents ...	28 cents
Sugar ...	9¾ a 9¾ do ...	9½ do
Potatoes ...	$1 a 1.25 do ...	60 a 70 do
Flour ...	$8.25 ...	$7.15
Bacon ...	11 cents ...	8½ cents
Pork ...	18 do ...	15 do
Lard ...	12¾ do ...	9½ do

From Rio we can get no reliable information respecting the probable outturn of the present crop, We believe there is no doubt whatever that, as we stated in our circular of the 11th October, the quantity of the 1880-81 crop remaining in the interior on the 1st July last was greatly overestimated in being put at 1,500,000 bags. On the other hand, it seems equally clear that the 1881-82 crop must have been considerably underestimated in being put at 3,200,000 bags.

But leaving estimates aside, let us look at the facts as far as they go.

The total shipments from 1881.	1880.
Rio from 1st January to 30th	
November have been ...2,032,000 bgs. against	1,872,000 bgs.
Stock in Rio 1st Dec.... 325,000 „ „	220,000 „
Together ... ... 2,357,000 „ „	2,092,000 „

The excess in the supply of Rio coffee this year as compared with last year is therefore 265,000 bags.

At Santos the receipts keep very high, and the crop promises to be as large as it was expected to be.

	1881.	1880.
The shipments from Santos,		
1st July to 30th Nov. have been...	543,153 against	450,771
Stock, 30th November...	142,000 „	86,000
Together bags -	685,153 „	536,771

The excess in the total supply of Santos coffee over last year amounts, therefore, so far to 149,000 bags.

From Ceylon the total shipments this season are reported to be:—

Plantation -	3057 tons against	3200 tons	last season
Native -	91 „	430 „	„

For the identical five high-grown plantation crops, which we bought last year, at about this time, for the Mediterranean ports, planters now ask 1s to 2s more than we paid them last year. On what misconception of the position of coffee these pretensions are based we cannot imagine. It has prevented a fair amount of business which might have been done to the Mediterranean this year at relatively high prices, and, seeing that nearly all coffees are 20 to 30 per cent. cheaper than last year and that the Ceylon crop is about 15,000 tons larger than last year, it does not seem reasonable to ask 1s to 2s more.

It is to be regretted, for their own sakes, that a class of men who have shown such intelligence and determination to overcome all difficulties in the cultivation of their estates should, when it comes to selling their crops, use such little wisdom or thought. They go on in the same old groove, consigning their coffee to London, where it is put up in public sale, incurring the heavy London Dock charges, two brokerages of ½ per cent., heavy tax for sampling, and the exporter's commission before it reaches the consumer—as if there existed no lines of steamers to the Mediterranean at lower freights than to London, and as if it was not far more economical to sell the coffee direct to the consumer, paying one brokerage. As an instance of how little judgment is sometimes shown in the sale of Ceylon crops in London we may cite the sale, which took place two weeks ago, at about 75s of a parcel of Ceylon coffee, imported in August, 1878, for which 113s had been once refused!

Rather hard this criticism on Ceylon merchants and planters: is it for Ceylon? The estimate of an excess of 15,000 tons is too much: we should be glad if season 1881-2 gives 10,000 tons more coffee than the previous one.

MR. GRANT DUFF ON AGRICULTURE.

Mr. Grant Duff, in opening the new buildings of the Agricultural College at Saidapett, delivered an address, which is thus summarized in a telegram to the Calcutta *Englishman*:—

His Excellency stated emphatically:—"It is my opinion that none of the many good influences which are now being brought to bear upon this Presidency is more likely to lead to the great increase of its prosperity than the diffusion of sound views on the subject of agriculture, a subject which mainly occupies the thoughts of 75 per cent of the population. We English have passed through many phases during our brief rule in India, *viz.*, the pacificatory phase, when we beat down armed wrong and gave the land rest from internal wars; the railway-building phase, which first made it possible for India to be something more than an aggregate of provinces; the codifying phase, when we established in the land a new idea of justice, and to some extent a new morality; and the educational phase, when we opened to the studious and aspiring youth the long hived-up knowledge of the West. We are now entering into the agricultural phase. We have given the land peace, have destroyed scourges which have kept down the population, but one-fifth of our people are already under-fed in consequence and increasing rapidly every year. What is to be done? Something may be effected by fostering the manufacturing industry, and the mining industry may help to draw off a part of the agricultural population; still we have only begun a solution of the problem. Shall we then look to emigration? It can do little, not much. Shall we try transposition of population? It can do somewhat more too. There is much room in some parts of India, and a good deal of room in this Presidency, for an increasing breadth of tillage, but the chief increase must be lateral and not perpendicular, not extensive but intensive. It must be the result, in short, of more intelligent cultivation of the lands already tilled. To learn by actual experiment how the general maxims, common to agriculture everywhere, are to be made applicable to the circumstances of Southern India, and then to spread in all directions the knowledge obtained by actual experiment, are the two main objects in this institution." After referring to the opinions of the officers of the institution. His Excellency expressed great satisfaction that there were now a fair number of Brahmin pupils and most of those who seek admission were matriculated students of the Bombay and Madras Universities. "The warning given by that terrible calamity which bad farming had made so much worse than it might otherwise have been," he added, "has been taken somewhat to heart in many of the European countries. Agriculture ranks higher than almost any other profession in England. There are few of our nobles who are not more or less devoted to it. In urging the natives of India to avail themselves more of the institution, we take a thoroughly consistent course."

CINCHONA BUILDINGS IN THE NEILGHERRY DISTRICT.

During the latter months of last year our Government had under consideration a Report made by the Superintending Engineer of the Circle, with estimates accompanying, on the subject of constructing certain buildings required for preparation of bark, the produce of the State Plantations on the Neilgherries. And as the plan had been approved of by higher authorities, through whose hands it passed, sanction was given to the execution of the works proposed the sum of R32,700 being appropriated for them in the current year's Provincial Budget. But of that amount, R10,700 were surrendered by the super-

intending engineer, leaving R22,000 to credit, as it appeared that the completion of the buildings would not take place for 18 months. The undrawn balance of R22,000, has not, however lapsed, but will be available as required; and in addition thereto, Government have now promised to provide the balance requisite for the completion of the buildings, viz., R8,889, in the P. W. Provincial Budget for 1882-3, at the same time directing "that every effort should be made to push on the work," so as to bring it to an early close. When all the details of the plan shall have been carried out, the structure in progress will amply provide, we should think, for all the needs of the establishment that is to operate in it. Since "the drying shed for the purpose of heating the barks with hot air, will consist of 10 rooms, each 14 × 14 feet, and 14 high, except the end rooms near the furnace and chimney flue, which will be somewhat larger and surrounded by a 10-feet verandah, required for packing bark." "Each of these rooms will contain 2,744 cubic feet of partly dry bark; hence the 10 rooms have a total storage capacity of 274,400 cubic feet,—or sufficient for 23,600,000 lb. of bark of all kinds, [there being ten varieties at Naduvatam], and space will be provided for 2,000,000 lb. of dried bark." So that there is no risk of supply falling short of demand, when once stocks shall have accumulated to anything like the extent of the accommodation that has been provided for them.—*Madras Athenæum.*

THE BRAZIL COFFEE ENTERPRISE:—EXPORT DUTIES AND SLAVERY.

We call the attention of our readers to the following extracts from the *Rio News* on the condition and prospects of the planting industry in the great South American Empire. When to the imperial duty of 13 per cent, nominally, but in reality nearer 15 per cent, are added the provincial, municipal, church and other dues, the total impost on Brazilian coffee must be equal to 20 per cent on its value. As Brazil is deeply in debt (chiefly for railway), and few sources of taxation other than coffee are available, it is not likely that the duties on the staple export will be abolished or even reduced. But that in the face of such enormous burdens the production and export of coffee should have increased so largely, shews that the Brazilian planters must possess greater advantages than we had been in the habit of allowing in the shape of abundance of cheap land and cheap, that is to say slave, labour. The former advantage will long remain in favour of Brazil, but, if the emancipation policy is more honestly carried out in the future than it has been in the past, the labour difficulty will put Brazil more on a level of fair competition with other countries than is the case at present. As regards the heavy export tax on coffee, too, the planters are not likely to demand its abolition or reduction, so long as they receive more than equivalent advantages in the shape of large and rapidly supplied railway facilities, such as have been so promptly and admirably conceded during the past ten years. We quite feel that export duties are objectionable if they can be avoided. But we equally feel that they are justifiable when a great object has to be gained. Had the policy we recommended been adopted, and the 2½ per cent export duty in Ceylon continued to be levied, but applied exclusively to railway construction, not only the line to Haputale but many others would now be in operation. Even better would it have been had the Ceylon planting community fourteen years ago stipulated for all the surplus profit on the main line being funded for Railway and Road Extension. In 1867, the Government of Sir Hercules Robinson would have been quite content if they had been guaranteed the interest and sinking fund contribution for the debt on the Kandy line; for no one then anticipated that our railway was to be such a splendid financial success. Had the surplus since realized, of £150,000 per annum on an average, been separately funded, we should long ago have had a complete system of railway communication which would pay the Government well in saving outlay on roads and in fostering agricultural and planting progress. Brazil on the other hand has got her railways with marvellous rapidity, and now other means of cheapening production engage attention. We read:—

We are glad to note that the gentlemen in charge of the coming exhibition of Brazilian coffee in this city have so far adopted our suggestions as to secure samples of the foreign product for a comparative exhibit. Incomplete as this competitive exhibit must necessarily be, owing to the brief time in which to secure samples and to their purchase in the market rather than their acquirement from *bona fide* exhibitors or producers, as will be the case with the Brazilian product, it will still be an incalculable improvement upon the original project of limiting the exhibit to Brazilian coffee alone. As we have before stated, there can be no real value in a domestic exhibit unless it can be used to improve and cheapen production; and one of the valuable means to this end is a comparison with the foreign product.

In connection with this comparison of products, which should be made on equal terms and between similar grades, there should also be a thorough and honest comparison of methods of production and preparation. The chief value of this comparison will lie in the material aid which it will give to the planters themselves. For them it is not enough to see the two products side by side and to note the comparative sizes and appearance of the berries. They will need know also the conditions under which the foreign products are produced:—the climate, altitude, soil, cultivation, quality and kind of labor, preparation for market, and average cost of production. If the planter can learn all these facts, while holding the product itself in his hand, he will then be able to determine the relative standing of his own product, and to decide just where his chief efforts must be directed in order to overcome competition. From the haste with which the exhibition of the 10th instant has been organized, and from the crude conception of the subject at the outset, it is probable that all this valuable information will not be forthcoming this year, but still there will be much value in what has been accomplished, and more in the better appreciation of the real value of the enterprize. And then, when next year's exhibition takes place, we shall hope to see such a mass of information about the methods and costs of foreign production as will fully meet the needs of the Brazilian planter.

Another question which should claim the attention of coffee planters and merchants is that of the purely artificial costs of production, the first of which is that of export taxes. Beginning with the municipality this product is taxed at every step until it is shipped and cleared for a foreign port. The church taxes it, the municipality taxes it, the province taxes it and then the general Government taxes it. Add to that the excessive transportation charges, and the many charges and commissions which it encounters in the port of shipment, and it will be seen that an enormous percentage of the proceeds are swallowed in the purely artificial costs of placing the production the market.

We have again and again urged the reduction of some of these charges and the total abolition of the others, and in this we have been cordially supported by many of the most influential journals of the empire. Thus far, however, no steps have been taken to lighten the burdens which are imposed upon this industry: on the contrary, new taxes are being levied constantly, and the revenues of the country are becoming more and more dependent

upon it. The inevitable result must be—as it has been in the case of other products—that these various burdensome taxes will not only be a fatal hindrance to Brazilian competition in consuming markets, but they will eventually render the industry so unprofitable that planters will be compelled to abandon it altogether.

We have before urged the abolition of export duties, on the basis of their being contrary to the well-established laws of economic science. In so far as they are a tax upon the producer, just so far do they lessen his profits and decrease his ability to compete in the open market. And in another sense, which we have not before discussed, they are highly unjust and discriminating, as well as economically wrong. Nominally the tax imposed upon coffee exported from Rio de Janeiro is 13 per cent but in reality no such percentage is paid. This tax is imposed upon an arbitrary official valuation for the week, and is uniform for all grades. Applying the specific rate, as derived from this percentage upon a fictitious average valuation, it will be found that the actual duties paid are widely different from the imaginary one imposed. To illustrate this fact, let us take the *pauta*, or official average valuation, for the week beginning October 24th, and the actual market quotations of that day for the several grades. The *pauta* for the week was 373 reis per kilo, or 38730 per 10 kilos Thirteen per cent on this valuation gives 485 reis, which is the specific duty upon 10 kilos. Applying this rate to the current quotations, and tabulating the results, we have the following:—

Quotations and percentages of export duty on coffee shipped from Rio de Janeiro during the week beginning October 24.

Pauta, 373 reis per kilo.

Duty on 10 kilos at 13 per cent., 485 reis.

grade	*current quotations*	*duty*	*equivalent to*
Washed	...4$200 *a* 5$900	485 rs.	11·55 *a* 8·22 per cent.
Superior	...5 000 *a* 5 200	„	9·70 *a* 9·33 „
Good 1st	...4 350 *a* 4 450	„	11·15 *a* 10·90 „
Regular 1st	...3 850 *a* 3 950	„	12·60 *a* 12·28 „
Ordinary 1st	...3 400 *a* 3 550	„	14·26 *a* 13·66 „
Good 2nd	...2 850 *a* 3 050	„	17·02 *a* 15·90 „
Ordinary 2nd	2 450 *a* 2 650	„	19·80 *a* 18·30 „

It will be seen from this table that the actual duties paid on coffee range from about 8 per cent. to 20 per cent.—the high rates falling upon the lower grades. If an equal quantity of each grade were sold, the high rates would be balanced by the low ones, and the exporter, or producer, would be subjected to no injustice—the average rate being about 13 per cent. But as the low grades make up the greater part of the export, it is manifest that an average rate of over 13 per cent. is paid. And then, insomuch as the low grades of coffee are produced and marketed at the same cost, it is clear that they are compelled to bear more than their share of the burden. From this cause, these districts which naturally produce the lower grades, and those which have been visited by drouth, disease, or any hurtful influence, are further punished by this discriminating tax.

It must be admitted that, if the export duty is to be continued, there is no apparent remedy for this discrimination. The only remedy—and it is demanded alike by the economic requirements of the country and by the just and equal imposition of the burdens of taxation—is the total abolition of the whole system. A tax which works so great discriminations must be inherently wrong, and should have no place in the laws of any country. The injustice, which it occasions, and the losses which it causes, can not be balanced by the revenues which are derived from it, and it becomes therefore a matter of economic policy as well as of justice to suppress it in every form and feature.

If we turn to the other great question in Brazil, Slavery, we find the *Rio News*, with a courage and force of argument highly creditable to a paper published in a slaveholding country, thus denouncing the policy of a Government which, after having decreed freedom, sells human beings by public auction as slaves:—

On the 10th instant an official sale of slaves is to take place at the Valença slave mart in which the *services* of eleven *ingenuos*, varying in age from two months to seven years, are to be sold at public auction. Under the law of September 28th, 1871, these children are nominally free, though their master has the right to their services until they reach the age of twenty-one years. This right, however, has been quietly stretched to include the right of property in such children, limited only by the period fixed by law; and under this interpretation the master assumes the same powers of control and sale as with his older slaves. In such a state of affairs, it is difficult to determine just what benefits this law is conferring upon the free-born children of slave mothers. Nominally they are free; but practically they are sold in the open market. And besides, they are sold by government officials, after due advertisements, in cases where they are placed under judicial control through death, bankruptcy, or other similar cause. The exercise of this right by the judicial authorities implies a corresponding procedure on the part of private individuals by whom *ingenuos* can be bought and sold without let or hindrance. This certainly could not have been the intent of the author of this law, nor can it be the interpretation of any intelligent man today, who honestly desires the just enforcement of the law and the final extinction of slavery. The custom, as now practised by slave-holders, and legalized by judicial authorities, is clearly an infraction of the spirit, if not the letter, of the law, and is unequivocally a damning disgrace to the country. There can be no condemnation too severe, no denunciation too scathing in convicting it of perjury and oppression before the world? What excuse can be urged in its behalf? A child only *two months* of age, still babbling in its mother's arms, is advertized for sale in the leading newspaper of the country, with an official valuation of 15$000 placed upon its *services*! What services upon which a valuation may be placed? or, are the planters and courts of Brazil speculating upon its future life and limbs as the slave-dealers once did? Is this the vaunted desire for emancipation of which we hear so much? Is it the law of free birth? And is it an honest execution of the law which has been praised before the world, and which has been so recently used to check the adoption of any other measure more radical than itself? We have before called attention to this shameful practice, but the government has simply turned a deaf ear to every appeal. "*O governo não cogita dessa questão*," says the cabinet—and the accursed traffic goes on unhindered! There will be a day of reckoning for all these crimes, and it will be a reckoning for which this country will pay with tears, and blood, and bitter humiliation. It will be easier to do justice today than to meet the penalties of an outraged justice tomorrow.

COFFEE IN SOUTHERN INDIA.

Messrs. Alstons & Co. favour us with the following supplementary information:—

(*To the Editor of the "Ceylon Observer."*)

DEAR SIR,—As suggested in a recent issue of your paper, we send a statement of coffee and pepper exported from this coast for the year 1879-80. It includes exports from Madras and Tuticorin as well. We regret we have no statements for previous years but trust the enclosed will be useful.

The coffee crop in the Coorg and Wynaad districts

is turning out larger than estimated, and we trust will be quite double that of last year.—We are, dear sir, yours faithfully, ALSTONS & Co.

N. B.—Returns from Colachel, Tuticorin and Madras do not particularize Plantation and Native Coffee separately.

The addition of the ports of Tuticorin and Madras only makes a difference of 44,000 cwt. in the coffee exports for 1879-80. We now want the export return for these ports for last year, and for Quilion, whence we are told as much as 20,000 cwt. were sent in two years. Travancore as a whole, in the year ending August 1880, exported 44,168 cwt. of coffee, including a good deal from native gardens. Less than 30,000 cwt. of this are accounted for in the above return.

THE CEYLON TEA ENTERPRISE.

The great *desideratum* being improvement in the preparation and manufacture of our Ceylon tea, in order to ensure its ready acceptance with the dealers at remunerative prices, the question of "machinery" will now become the one of most practical moment to the planter. Unlike coffee,—the final and more tedious part of the preparation of which is attended to in Colombo, outside the planter's responsibility altogether,—it is pretty evident in the case of tea, that to do full justice to the produce, the "factory" should be a local one, so far as each district, if not each large plantation, is concerned. "District Tea Factories," in fact, must become the order of the day. It is however, impossible, in these hard times, to expect each tea-planter with from 40 to 100 acres under cultivation to be able to provide rolling, drying and sifting machinery for himself in an adequate tea-house. Under these circumstances, we are glad to learn that in more than one district, arrangements are being made to establish a Central Factory at which the tea leaf can be delivered and either cured at a fixed change for the planter or bought from him outright, as delivered, and prepared on account of the Factory owner.

In connection with tea preparing machinery we have just been looking over the magnificent album of Messrs. Marshall of Gainsborough, who give a number of very clear representations of Jackson's patent machines, of which they are the makers. These photographs include the following:—

Standard cross-action Tea Rolling Machine.
An improved single action ditto.
The improved Excelsior ditto.
Improved Excelsior cross-action ditto.
Improved small size universal ditto with suitable vertical engine and boiler for driving same.
Ditto in connection with suitable Bullock gear for

There is here enough of variety both in size, character and cost to suit all local requirements, and we have no doubt that Messrs. John Walker & Co., who are the Ceylon Agents, will be able to give full information and to shew models of most of these machines. Already they have fitted up more than one factory in our planting districts; and we are inclined to believe that, as time rolls on, as great a business will be done by them and other Firms in Ceylon in tea machinery, as has been done in the past in coffee pulpers, peelers and sizers. Not only so, but we may anticipate, by and bye, special improvements by Ceylon planters and engineers in the most approved tea-preparing machinery of the present day; for, in reference to the preparation of tea as of other new products, there is considerable scope for invention and modification before Ceylon colonists.

COFFEE LEAF DISEASE: THEORETICAL INVESTIGATION, AND PRACTICAL EXPERIMENTS IN CHECKING ITS RAVAGES.

We can do little more today than call attention to the two important communications on the subject of *Hemileia vastatrix* which will be found elsewhere. Mr. Stephen Wilson has brought to his investigation of our coffee-leaf fungus considerable experience and acknowledged ability displayed in pursuing a very similar enquiry into three of the great enemies of British agriculturists, namely, club-root in turnips, rust in wheat, and the potato disease. He has interested himself in our local pest purely as a scientist accustomed to investigate fungoid life, and the very modest relation of the result of his study of the "leaf-disease literature" and of the examination of the leaves and spores sent to him from Ceylon cannot fail to be interesting. It will be observed that Mr. Wilson has felt himself justified in applying to "this most important fungus" what he believes to be "the true life theory of a great many fungi which become parasitic in the tissues of higher plants." At the same time, he guards himself against being supposed to have made a complete substantive investigation of the coffee fungus, seeing that he has had no access to the living plants, and he refers to the labours of Messrs. Abbay, Morris and Ward as rendering such an investigation unnecessary on his part. "Side-lights" have been all Mr. Wilson hoped to cast on the coffee pest, and yet it seems to us, as non-scientists, that this gentleman's theory of "Apogestation" affects very materially the life history as finally laid down by Mr. Ward. It would seem, for instance, as if Mr. Wilson afforded the explanation of the experience of Captain Bayley at Monrovia, Galle, where the existence of the disease was apparent on his young coffee (from imported seed) almost before a pair of fully-formed leaves were developed. The practical lesson, however, that Mr. Wilson would wish to convey is the uselessness of protecting the full-grown leaves from the disease-spores "atmospherically conveyed" when the germs of the fungus are already within such leaves from their very earliest stages. Nevertheless the practical value of endeavouring to starve or to prevent the germination of the pest is fully acknowledged. We regret that we cannot reproduce the tracing of the various stages of the fungus sent us by Mr. Wilson: to attempt to lithograph the figures with the means at our command locally, would, we fear, only afford a misleading representation; but we shall be glad to shew the tracing to any one interested. Mr. Wilson endeavours to represent in it the life-cycle of *Hemileia* divided into its parasitic and non-parasitic systems. Mr. Ward's final Report only reached Mr. Wilson after he had written his letter; but our "Aberdeen Correspondent" enables us to infer that his opinion is not specially affected thereby. Our correspondent writes: —

"Mr. Wilson's letter anticipates the publication of this paper on Potato Disease. It is not ready yet but will *have* to be in print before the *Observer* with the letter comes to this country. It is to be sent to the London *Times* 'if they will accept of it;' so will likely be bagged by your London correspondent for you.

"I sent Mr. Wilson Mr. Ward's Report, and two days later I had a mile and a half's walk with him. I told him you wanted his opinion on it. He said 'It would hardly do to criticize another man's work. I might bring a nest of hornets about my ears.' I asked 'Is there anything in it that affects your theory?' and 'Was there anything in your letter you would not have said, had you read Mr. Ward's Report before writing?" Ans., 'Nothing but what can be explained, and I would not have said 'where does the first spore of the season come from?' as I see he accounts for that as coming from diseased leaves on the ground.

"In course of our talk he said: 'It is an *assumption* to say the mycelium *enters* the stoma, as no microscope can show it doing this. The leaf being opaque, a high power prevents this being seen, and with a low power you cannot see the mycelium at all.

"Damp and steamy atmosphere promotes fructification of *Hemeleia*. Mr. Ward treated a leaf or leaves to steamy atmosphere in a wardian case *plus* a sowing of spores, and, on seeing disease fruit, concluded his spores dit it. To have made his proof absolute he would have to treat a leaf of the same plant to the steaming atmosphere of the wardian case *minus* he spoors and noted results.

"If the Planters' Association would *minute thanks* to Mr. Wilson, and send him a copy of the minute, I am certain he would be gratified. It might stimulate him to undertake experiments of a cultivate kind. Unfortunately he is nothing of a chemist, but accurate microscope examination may be more essential for such experiments than knowledge of chemicals. Of course, he has not coffee to experiment on, but he might try something on potatoes."

A vote of thanks formally conveyed would, indeed, be an easy way of acknowledging Mr. Wilson's services and of stimulating him to further investigation: we commend the suggestion to the Committee of the Planters' Association.

But we may now turn from Mr. Wilson's scientific investigation and interesting theory of apogestation, to the paper in which Mr. Schrottky is understood to sum up finally the results of his experiments in checking and eradicating the disease on a plantation in the Dumbara Valley. Since April last year, a fair trial has been given to the treatment with carbolized powder on Gangapitiya, the estate in question, and with the reports before us dating up to the 2nd instant it is difficult to see how the value of the application can be denied. We learn that, with the exception of Gangapitiya, not an estate in Dumbara is at present escaping one of the worst outbursts of the fungus that has been witnessed for some time back. Why should this estate be comparatively exempt? There is nothing in its conditions of soil, age of coffee, or surroundings, to explain the difference, and assuredly there is no evidence after nearly nine months' experience of the carbolized powder doing harm to the roots of the coffee trees. On the contrary, the coffee is described as luxuriant and in splendid condition, as compared with neighbouring estates, for the blossom which is now appearing. Nothing succeeds like success, and of course the planters will be glad to welcome satisfactory practical results more than the most interesting scientific theory. If Gangapitiya fulfils its present promise and passes through the blossoming season satisfactorily, we may be sure that on a good many more properties the application of carbolized powder will receive a systematic trial. March and April, Mr. Schrottky tells us, are the best months to begin, and a supply of the material must be provided in time. Gangapitiya therefore should be once more visited about the end of this month by representatives

of the Planters' Association with the Chairman at their head, for if it be, as described, an oasis in the midst of an epidemic of disease visibly spread over all the other coffee in the district, it should be at this moment the most interesting spot in the island to our coffee planters.

"FROM THE HILLS" OF CEYLON.

CINCHONA AND BLUE-GUMS TO REPLACE NATURAL FOREST; BREWING.

January 1882.

Nuwara Eliya has lost one of its haunts richest in beauty and botanical interest, a strong responsibility rests on the workers of the ruin (estimable in all the ordinary relations of life) to repair that ruin as rapidly as possible by the growth not only of the cinchonas and blue-gums which have already gone far to reclothe "One Tree Hill" but of other exotic and natural plants, combining beauty with utility. Cinchonas and blue-gums in combination have certainly done much to redeem the steep-hill side beyond the "Lover's Leap" waterfall. To us, who, so many years before this plantation was formed, urged the liberal use of encalypti, grevilleas and other Australian trees as breakwinds, and with reference to the ultimate value of the timber, it was very gratifying to see and hear of the success of the experiment of running rows of such trees between fields of cinchonas. In the case of the "Lover's Leap" plantation, it is very striking to see the effect of the long rows of bluish-green eucalypti running straight down hill, contrasting with the rich green of the fever trees. These latter, we have been assured, have benefited greatly, not merely by the shelter of the gums but by the mechanical action of the roots of the Australian trees, in loosening and rendering free the soil, for the more tender roots of the American plants. If, ultimately, stiff soils, where at present cinchonas refuse to grow, can be rendered suitable for their cultivation, then the benefits conferred on us by the introduction and growth of the so-called "gum-trees" of Australia will be greater than most of us anticipated. The difficulty is that on such soil, in exposed situations, the blue-gums themselves are sometimes slow of growth and apt to die off. Probably deeper and wider holes may largely remedy this difficulty. Certainly the rapid and effectual manner in which blue-gums have restored the shelter of forest to the eyrie on Oliphant, at an elevation of about 6,600 feet above sea-level, shews that these singularly cosmopolitan trees are capable of flourishing where altitude is great and exposure to wind extreme. They are, however, impatient of the transplanting process, and if proper weather could be calculated on, no doubt the most successful mode of growing them would be *in situ*, spaces at proper distances being prepared and a few seeds dropped into each. Then the most robust and promising of the resulting seedlings could be retained.

But to revert to cinchonas. The shaving process, so simple and, when only applied to one side of a tree at a time, productive of so much less of shock to vitality, than stripping, is, naturally, largely resorted to. Some do not apply any covering, in which case the bark, as it renews, is liable to become cracked and perhaps corky. Others, and amongst them a neighbour of mine who has given considerable attention to the subject, insist on a covering of grass or straw; mana grass can generally be procured. But I have been concerned to hear that Mr. Whiffen, the quinologist, who has recently been travelling amidst the cinchona plantations of Ceylon, and has been, on the whole, favourably impressed, has been advising planters not to shave their bark, on the ground that the succeeding crop is far inferior to the first. If Mr. Whiffen has been correctly represented, the question arises whether the secondary bark he has tested had been allowed sufficient time to mature. It is only consonant with reason that very young renewed bark should not be compared with mature natural bark. But surely the shaving process has now been long enough tried in Ceylon, to allow of renewed bark of one and two years growth, subsequent to the shaving process, to be gathered and its value in alkaloids ascertained? If not, it is certainly time the question were settled either by analysis on the spot or by sale of the bark in London. A planter whom I met in Nuwara Eliya has promised to supply a well-grown sample of bark renewed after the shaving process, as also details of the ingenious but simple and effectual mode of removing bark from cinchona twigs, by the application of a bottle filled with sand or earth. The introduction of this simple process of rubbing the polished surface of the weighted bottle down the twig has largely economized labour while securing the maximum of bark.

From Cinchona Bark to Beer Brewing is not so violent a transition as might be imagined, for some of the German brewers are said to use the bitter bark as a substitute for hops. My friends in Australia told me that trials there resulted in a decision favourable to the orthodox use of hops, of which splendid specimens were shewn at the Melbourne International Exhibition, some grown by the aborigines of Victoria under European superintendence at Corranderk, en route from Melbourne to Fernshaw. The plant flourishes in the alluvials by the sides of the beautiful Mitchell river, near Bairnsdale in Gippsland. It was winter time (July) when I saw the Gippsland hop fields, and the most striking objects were the pyramidal stacks of poles, made from the ti (popularly tea) scrub, which flourishes in swamps so as to be, in the temperate regions of Australia, the equivalent of the various species of mangrove in the tropical latitudes. Finer and straighter poles than are yielded by the swamp-growing ti trees (there are several species, one of which lines the banks of Hobson's Bay, and is beautiful when covered with white blossom) it would be difficult anywhere to find, and from Victoria and Tasmania there is a large export of poles for fencing purposes to those parts of New Zealand where timber is scarce. The various colonies are competing with each other in the growth of hops, and the largest growers in Australia (having been the first to go into the enterprise), the Messrs Shoobridge of Norfolk Valley, Tasmania, are heavily handicapped by the protective duty which, according to her narrow policy, Victoria has imposed on their produce. A similar duty on fruit ruined the once flourishing orchards, which may still be seen studding the sides of the Tamar as Launceston is approached. It says much for the superior quality of the hops produced at Bushey Park, on the side of the noble Derwent and close to the dark waters of the appropriately named Styx, that they are able to hold their own in Victoria notwithstanding a duty, the intention of which was to shut them out; while in England Shoobridge's Tasmanian (Bushey Park) hops take rank with the very best Kentish. Visitors to Messrs. James Henty & Co.'s office and stores in Little Collins Street, Melbourne, will be struck with a sweetish odour, more apparent even than the aroma of their specimens of fine teas. After a time we learned to recognize this odour as due to the magnificent specimens of Shoobridge's hops which were always on show and the transactions in which were large, for the supply of local brewers. Prominent amongst these is the Hon. Nicholas Fitzgerald, son-in-law of Sir John O'Shanassy (and formerly connected with the firm of Parlett, O'Halloran & Co., Colombo) whose "Castlemaine Brewery" ales are famous all over the colonies. It was New Zealand ales, however, which won the first prizes at the Melbourne Exhibition, the colder climate probably giving them superior advantages. If we have judged rightly, then

the fact may be quoted as a favourable augury by the projectors of the Brewery in Nuwara Eliya. With reference to the probable success of this enterprise, a planter close by in Udapussellawa is trying an experiment in the growth of hops, having, we believe, obtained plants from Australia, probably from the Bushey Park hop grounds in Tasmania. My visit to the extensive orchards and grounds there was unfortunately in the winter. Still I saw the mode of cultivation and carried away one curious and important fact, established by long experience. From the stools a considerable number of "bines" sprouted, just as suckers rise from a copiced cinchona tree. But instead of preserving the most robust stems, as the cinchona planter does, the intelligent hop grower, taught by experience, sacrifices the thicker shoots in favour of the more slender, knowing that the latter will yield hops of a far finer flavour,—hops being chosen by the sense of smell, as much as tea is. Appearance, too, goes a long way, however, specimens of well prepared hops constituting ornaments worthy of a lady's drawing room. There is a Ceylon shrub, plentiful in the lowcountry and lower hill ranges, with masses of curious bracts or seed vessels, which resemble tufts of hops, and in crossing a piece of forest between Nuwara Eliya Plain, proper, and "the Barrack Plain," in order to get to the Brewery buildings, I could not but be struck with the resemblance to hops of the developing blossoms of a species of nilu, large white blossomed. I do not suppose that either plant has any of the qualities of the hop blossoms. If any substitute is ever tried, Messrs. Bremer and de Bavay will doubtless resort to the bark of some of our cinchonas. One thing is certain, they will avoid the error committed on the Nilgiris of using malt made from Indian barley. They will import the best English or Australian malt and hops (unless the latter are locally grown) in air-tight vessels. The climate is favourable and the water everything that could be desired: ever cool in temperature and so pure in quality that the nitrate of silver test shews no precipitate. The proprietors of the Brewery have secured ten acres of land in elongated strips on each side of the stream which forms the locally famous waterfall of "the Lover's Leap." The water has its source in the top of a forest-covered mountain, so that pollution above is impossible, and fears of pollution below the Brewery may be dismissed, because it will be the interest of the Company to utilize all the "bye products," and these are such as to be eagerly competed for in the local market. Indeed, a couple of planters, whose cattle establishment costs them R15,000 per annum, have already made an offer for all the "grains" which can be supplied; while the market for yeast may be estimated by the fact that one baker in Nuwara Eliya uses coconut palm toddy, got up from Colombo, to the value of R1,500 per annum. There will, we suppose, be some demand for hospital purposes. The great desideratum is that the Company produce good beer, and on this head Messrs. Bremer and de Bavay are confident,—the latter being an experienced brewer and a good chemist. In the face of considerable difficulties, the necessary buildings are advancing to completion, and a striking contrast they are to the specially dilapidated and wretched Government pioneer lines close by. The brewing plant, we understood, had reached Colombo, and, although too large a proportion of the shareholders had failed to respond to calls, operations will soon be commenced. There is a duty on malt, imposed when the Brothers Baker attempted a previous experiment, and of which they grievously complained. We understood that the directors of the present enterprise do not so much complain of the duty on malt as of the refusal of the local Government to promise that, for such a period as will be necessary to settle the question of the success of the experiment, an excise shall not be imposed upon the beer brewed and sold. We certainly think that a period of three years, at least, should be allowed for the encouragement of the local enterprise. We were much interested in all we saw and heard, and not least, of course, in the intimation that a few sample bottles of Nuwara Eliya ale, brewed some eight months ago, are lying at a bungalow three miles away waiting for our presence to be opened and tasted! We were not able to try and judge on the present occasion, but all in good time, and as people will drink beer, and the Ceylon Brewery Company Limited promise to supply good stuff, our readers generally will join us in wishing them success.

COFFEE LEAF DISEASE: MR. SCHROTTKY'S EXPERIMENTS

The following report by the Chairman of the Planters' Association, and extracts from reports by the visiting agent and manager of Gangapitiya estate, have been placed at our disposal for publication:—

I.

Kandy, 5th December 1881.

At Mr. Schrottky's request, I accompanied him with Mr. Munton and Mr. C. Young, on the 2nd inst., to inspect Gangapitiya, for the purpose of observing the condition of the estate as regards leaf-disease, and noting what effect (if any) had been produced by the treatment of carbolic powder, since the beginning of April last.

On our way to the estate, we passed through part of Pallekelle, Ambacotta, and Lower Rajawella, making frequent observations of the coffee as we went along. There was more or less of the disease in the condition of mature, and healthy fungus, and also "pinspots," on all these estates, especially on Ambacotta, where it was abundant, on every tree we examined, and almost on every leaf. There was less on the young coffee on Lower Rajawella, but even there, whole branches on some trees were covered with the disease and, though the trees presented, at first sight, a luxuriant appearance, there was no difficulty in finding diseased leaves on raising the branches, and I should think that 50 per cent of the trees were more or less affected.

On reaching *Gangapitiya*, a most marked difference presented itself. The 30 acre flat looked luxuriant and healthy, and it was only after considerable search that one tree, here and there, could be found at all affected by the disease, which was confined to one leaf on a branch with generally only one spot on each leaf, and *no* "pinspots." On ten or fifteen acres, where the powder had not been applied since July, there was rather more disease to be found, but even there it had to be looked for, and the trees affected were quite the exception. The only portion of the estate, where the disease existed to any serious extent, was about 10 acres close to the river.* I should mention that this field is situated to leeward of a native garden.

Without venturing to express a decided opinion on the general merits of Mr. Schrottky's system, I must say that I was considerably impressed by what I saw, and am bound to believe is the result of his treatment on this estate.

The prevalence of the disease on all the estates in the immediate neighbourhood—(we passed through Rajawella, No 2 and No. 1, on our return,)—and the almost total absence of it on this estate, seem to indicate that its immunity is due solely to the remedy

* This part has been specially treated and the disease has been successfully got under, and this field was found by me on my last examination of the estate (12th January 1882), not to have suffered to any appreciable extent.—E. C. S.

applied, for I may mention that the estate has not been recently manured, and has certainly no advantage in climate, soil, or general cultivation, over the other estates in the district, with which it is compared, and previous to Mr. Schrottky's treatment it had not suffered less from *Hemileia*.

I should add that no injury whatever from the powder could be seen on the tenderest leaf.

Whatever the ultimate result of the experiment may be, the most sceptical observer must admit that, *on this estate*, it has been so far highly satisfactory, and such as to justify, at least, further continuance of same treatment.

J. SHIPTON.

II.

Extract from Mr. Young's, the Visiting Agent's, report on Gangapittiya estate, dated 3rd Dec. 1881:—

"I visited this estate on the 2nd Dec. with Messrs. Schrottky, Shipton and Munton. All the coffee was looking remarkably strong and vigorous. In fact, I do not think I have ever seen it looking better; leaf-disease was scarcely to be seen, and it was only after a good deal of searching we found diseased leaves here and there, while on neighbouring estates there was more or less disease on most of the trees."

III.

Extracts from estate reports sent by Mr. P. A. Raymond, the manager, to Messrs. Whittall & Co.:—

12th December 1881.

"The estate books very well indeed. There is more or less leaf-disease here and there about the place, but as yet it has not spread and there does not appear to be more now than there was when Mr. Young and Dr. Shipton were here."

21st December 1881.

"Leaf-disease is showing on various places in Gangapitiya, it has increased during the last ten days, but as yet it is *very little*, when compared with the other estates in the district."

2nd January 1882.

"I am glad to be able to report that, during the last ten days, there has been no visible increase of leaf-disease and no perceptible fall of leaves has taken place. The coffee looks remarkably well and the new wood is growing apace and as yet has resisted the disease so well that I have great hopes Gangapittiya will pass through the season with the minimum evil-effect from leaf-disease.

Mr. Schrottky's concluding notes:—

The north-east monsoon has passed away, and with in the time during which serious attacks of leaf-disease take place. We know from experience that during January (or in fact during any dry part of the year) we can keep the disease successfully within bounds by the carbolized powder treatment, and I feel therefore justified in finally closing the results of these experiments.

The above reports on the result of the treatment at Gangapitiya estate should be read together with those previously published.

The estate is one that for years past has been chronically suffering from leaf-disease, most severely during the month of September, October and again during December. Leaf-disease began to show in surrounding estates during July, and from that time forth a series of attacks took place, the most severe of which occurred in the middle of Dec. The comparative freedom from disease enjoyed by Gangapittiya estate leaves no room for doubt as to the merits of the carbolized powder treatment. The carbolized powder on the estate being finished and no more procurable in the island, we could not prevent, even if possible, the enormous mass of spores supplied by the surrounding estates affecting Gangapitiya to a small extent during almost the very last week of (for the development of the fungus) favourable weather: but nothing can now qualify or reduce the importance of the established fact, that the carbolized powder treatment has kept this estate, practically speaking, free from disease for six months, during all which time it was prevalent in adjoining estates.

The elements of success here have been:—

1st. Systematic treatment of the estate during the early part of the year.

2nd. Unremitting attention on the part of the manager, Mr. P. A. Raymond.

The months during which the fungus can be most successfully battled with are, in most districts this side of Nuwara Eliya, March and April; very little headway can be made against it at a later period. At Gangapitiya estate we succeeded in virtually stamping out the disease by the end of May, and the benefit derived from the treatment I am bound to consider mainly due to this.

We had of course to gain experience as regards time and mode of application, and the thanks of the planting community are due to those of their number who, at a considerable expense, have carried on experiments which concerned the whole community; for in not every instance has the benefit derived from the treatment been great enough to pay for the trouble and expense. And this applies more especially to estates where the treatment was commenced at what we now know to be a wrong time of the year.

The carbolized powder possesses one great defect. It cannot be used with commensurate benefit against the fungus when it is most wanted, *i. e.* during the rainy season. The rain washes it into the soil, before it can affect the fungus to any appreciable extent. I have, however, devised a method of developing the carbolic acid vapour, which will make it more active and permanent during this critical period; and I shall carefully test it before I leave the island. But, during the dry season, with sufficient dew to supply moisture for contact, no form of carbolic acid will, I am of opinion, be found to give better results at such a small cost, as the carbolized powder used by me.

In the *résumé* of my preliminary experiments, dated 7th June 1881, I stated as my conviction that "*if an estate is dosed in a proper manner, and a proper time, with this carbolic acid powder, it may be carried through the period of an attack with little appreciable damage:*" and I think it will now be admitted that this has been proved. It cannot reasonably be doubted any further that, with some modification so as to ensure greater permanency of the action of the carbolic acid vapour during rainy weather, the treatment recommended by me has some claim to be considered a useful and cheap remedy against coffee leaf disease.

EUGENE C. SCHROTTKY.

Colombo, 16th January 1882.

"ALL ABOUT THE COFFEE GRUB."

We given the following remarks as the critique of one of the few who refuse to believe that the grub attacks healthy rootlets and who hold that the grub is rather a useful scavenger to clear away deleterious matter. The writer's sentiments are deserving of respect, but he is no more infallible than we are in feeling ourselves compelled to arrive at a very different conclusion:—

I have perused with interest your useful little publication, "All About Grub," being the observations of Mr. Haldane. It consist of 24 pp. of letterpress and 4 plates hand-painted.

With respect to the cause of grub, surely we have not planted more suitable food for the grub than that which was its natural food. If so, why then does not the grub like the young tender rootlets of coffee under the age of four years?

In the primitive state before coffee was planted, food for these creatures must have been more abundant than it is now. At the same time we must remember that birds and other creatures, which kept them in check, were much more plentiful.

The sour and disordered condition of the soil referred to in the essay, has probably more to do with it than anything else, as being inducive for them to scavenge and so cleanse and purify the soil. Note D in the appendix

confirms this. It is suggested that very likely the soil is deficient in alkalies. It is indeed in many cases more of an acid nature, and is exceedingly deficient in lime.

Decaying timber, and the still more tender decaying rootlets of patana grasses, of coffee trees, and a host of other plants, are the great attraction. On several occasions I have seen grub dug from places which were of a swampy nature. That the primaries and secondaries do die back is too true—a sad sight—but poor grub is not always the cause of this. In several districts, the same thing occurs from other causes, and there is no doubt that, if the grub could only find these out, he would be quite satisfied with their condition. It seems strange that estates, after being severely punished by an attack of grub, recover. Is it not because the scavenger has done his work and put the soil in better order?

In the last para of p. 13, a most valuable remedy is proposed: remove the sourness and they will quit the place, but on p. 14 we are told that lime is no remedy. Why should draining, the great loosener and acrator of the soil, be recommended, for, on p. 10, we are told that the excessive rainfall has loosened the soil and made it easier for the grub to work in? Will not draining have a similar effect? On the same page we are told to prune heavily to cause the tree to send out fresh rootlets, for what,—to be devonred.

What is the instinct of the beetle, and what is the food of the grub? We want to have the conditions present which are necessary for their enticement and for the sustenance of the grub and at the same time be exempt from its attack. A very good use of the grub is referred to on p. 16: that is, as a manure. Then follow very good descriptions of the various cockchafers and notes regarding experiments.

On the whole, Mr. Haldane must be congratulated on giving his attention to the subject and noting down so carefully his observations and furnishing us with drawings of the various beetles and their larvæ which will serve as a basis for future observers.

[In an appendix the latest information on the subject is given.]

CINCHONA PLANTING IN JAMAICA.

(*By Mr. D. Morris.*)

With regard to Cinchona Planting in Jamaica, the question is often asked: What will it cost per acre to start a Plantation in the Blue Mountains and establish it, up to the time it comes into bearing? This question is one which cannot be definitely answered in all cases. But as an approximate statement, based on actual experience, we have been supplied with the following by the Director of Public Gardens and Plantations. It is understood that the land is taken up under the recently published system of Grants made by Government, and that no buildings are required beyond labourers' barracks, sheds, and a small house for the Headman or Overseer. The plants are supposed to be *Cinchona Officinalis* planted at 3½ feet by 3½ feet, giving 3,500 plants to the acre. If only about 5 acres are intended to be opened, the relative cost will be a little more than the following:— Whereas if a larger area is opened and nurseries established on the spot, the relative cost will be considerably less. Also, when the plantation is opened from a neighbouring plantation, the cost of superintendence will be much reduced.

Detailed Statement of expenditure on a Cinchona Plantation in Jamaica for planting 5 to 50 acres of *Cinchona Officinalis* 3½ feet by 3½ feet, with 3,500 plants to the acre.

	Per acre. £ s. d.
1. Prime cost of land (2s per acre) according to terms offered by Government and incidental expenses for Surveyors' fees, &c....	0 5 0
2. Cutting down forest, burning and cleaning ready for planting (contracts according to nature of forests and locality). Some as low as £2 per acre and some as high as £5, say	4 10 0
3. Lining, 8s per acre; Pegs, (3s per 1 000) 10s 6d; Holing (50 large holes for 1s), £3 15s	4 13 6
4. Plants, 3,500 to the acre; if raised in nurseries on the Plantation itself about 25s or 30s per 1,000; if bought probably 40s to 45s per 1,000. Cost say for an acre of 3,500 plants	7 0 0
5. Planting by day labour, shading, &c...	3 0 0
6. Staking, weeding and supplying to end of first year	2 5 0
7. Share of Superintendence... ...	1 7 0
8. Barracks, house for headman, roads and field paths, weeding and supplying up to the end of the 4th or 5th year when Plantation begins to yield, say	6 19 6
Total outlay on Plantation up to the 4th or 5th year £30	0 0

As to the returns from the Plantation—the earliest crop of bark may be yielded by thinnings or uprooting of weakly trees at the end of the 4th year.

Taking these at 25 per cent of trees planted, and yielding 6 ounces of dry bark per tree, we have say 330 lb. of bark at 3s per lb. (less 10d per lb. cost of barking, drying, shipping and broker's expenses) yielding a net return of say £35 per acre. This it will be noticed will more than cover expenses of the Plantation up to the end of the 4th or 5th year.

There will then be left some 2,400 trees to the acre, well established, and capable of yielding regular crops of bark at the rate of £30 to £60 per acre up to the time when the whole plantation is cropped.

The total yield of the Plantations (deducting cost of barking, curing and shipping expenses, up to the end of the 9th year) will probably be not less than £175 per acre, against a total outlay for planting operations for that period of about £40 to £45 per acre. The estimates in all these cases are based on that price of Creole labour as at present existing in Jamaica, viz., men 1s to 1s 3d per day; women 9d to 1s per day. The weeding is entirely *by hand*, done mostly by children and women at rates varying from 4½d to 9d per day.

SEEDS OF SUPERIOR CINCHONAS FROM THEIR NATIVE HABITAT.

We publish the following letter from Mr. Thomas Christy, and we trust he may succeed in the introduction of valuable species of cinchona. It is hard to suppose, however, that anything can excel trees, the bark of which yield up to 13 per cent of quinine. Mr. Moens got that in Java; and Mr. W. Smith from Matakelle, from trees much younger, got 9 per cent. If Mr. Christy can do better than this, he will be a public benefactor.

To the Editor "Ceylon Observer."

London, 7th Dec. 1881.

SIR,—Having carefully followed the history of the introduction of the "Ledgeriana" seed, which has appeared in your paper, and also in the transactions of different scientific Societies, I applied, through a house in the city, who was working direct with Eastern Bolivia, and, on placing sufficient data before them, I begged of them to endeavour to open the question of obtaining for me seeds from the district in which the Ledgeriana was originally obtained.

After some years, and an immense amount of correspondence, we obtained a package of seeds in the husk. The tin-lined case ran through many vicissi-

tudes, being seized by the Chilians, and by them liberated and forwarded to the address on the bag. It shewed marks of having been opened several times. As the export of seed is entirely prohibited, the greatest precaution was taken not to identify the sender in any way, and an extremely scanty description was sent with the seed, saying that it came from one of the best varieties of cinchona trees. This seed I tested, and found to germinate well; so I put it into circulation at once amongst your planters. From suggestions I received from many of them, letters were sent out, begging that leaves and flowers, as well as specimens of the bark, might be sent home with full descriptions. The leaves arrived with the names that the trees were known by locally. I then sent out a copy of a map of the district, shewing the hills and valleys, at the same time asking that some of the seed might be collected and sent home from the actual trees that the former supply was obtained by Ledger's men.

This request has been at last complied with, and seed is now on its way home to me, which I expect to arrive any day, if no mishap befalls it.

By a singular accident, a gentleman has lately arrived here, from this very district, and he has brought with him specimens of the bark taken from the different varieties of trees which he considers to yield the best results commercially. The local names of these trees we have compared with those yielding the sample of the leaves that was sent direct from a planter in the same neighbourhood, and he at once explained to us the distinctive marks by which the trees were known.

The leaves in only one instance corresponded with the names on the samples of bark that was produced, thus shewing there were several valuable varieties. This gentleman perfectly well knew where the Ledger seed was obtained from, but his opinion is that the bark and the leaves representing different varieties of cinchona yield a larger percentage of sulphate of quinine than the trees, which, for the sake of distinction, we will call the "Ledgeriana." Hearing this, we have begged that supplies of the different varieties of seed may be collected and sent home. Taking an entirely commercial view of this subject, I followed up the question to find out where this bark went to, and I asked my friend, Mr. E. M. Holmes, Curator of the Pharmaceutical Society, to be present at one of the interviews. Mr. Holmes examined the samples of the bark, and, without an analysis, he pronounced it to be a very high quality. We learned that this bark was principally sent to Germany. We also extracted another piece of valuable information, viz. that, although the bark of certain varieties of trees yielded a larger percentage of sulphate and fetched consequently a higher price per lb., yet, for a planter, some of the varieties yielded a much larger percentage of bark, by having a more robust habit and consequently for a planter was a more economical tree to grow.

I am trying to ascertain if the cinchona tree is governed by the soil, as the cocoa tree ("Theobroma cacao"). As far as I can learn at present this is not the case. They do not judge the trees by the flowers, but by the colour of the leaves and the veins in them.

Should I be able to gather any more information of an important nature, I shall send it to you.—I am, sir, your obedient servant, T. N. CHRISTY.

NUTMEG CULTIVATION.

This morning's post has brought us from Peradeniya Mr. Dobree's promised *MS.*—which bears decided marks of age and decay—and we take the liberty of quoting from Dr. Trimen's accompanying letter in order to see if any of our readers can help us to the *Pharmaceutical Journal* for 1852. There was no Civil Medical Department then in Ceylon, and so, we fear, the file for that year will not be found in the island. If not, we must just do the best we can with the *MS.* as it stands. Dr. Trimen writes regarding it:—

"Mr. Dobree sent me the enclosed MS. some time back, and asked me when I had read it to send it on to you that you might use it for your *Tropical Agriculturist* if you pleased.

"It refers to the cultivation of nutmegs and cloves in South Sumatra (Bencoolen) at a time when that district was part of the British Empire (1819-20); and contains much interesting and valuable information as to the first introduction and early culture of these spices.

"I am, however, under the impression that part or the whole has been already published: I think in the *Pharmaceutical Journal* for 1852. Is there a file of that journal in Colombo?

"Lumsdaine's remarks on the proportions of the sexes are important, and his expressions very amusing. The influence of the Linnean system of classification was then supreme, and writers did not hesitate to write about the sexes of plants in terms as warm as those he uses. I have not noticed any monœcious trees myself, nor do I recal any notice of them; but in other dicecious plants, notably the hop, such an admixture of the flowers of both sexes on the same plant is not very unusual.

"The first two pages are beyond my powers of restoration, and all the paper is very brittle. Should you print it, great care will be needed."

LIBERIAN COFFEE CULTIVATION IN CEYLON:

AT A LOW ELEVATION.

We received some days ago a sample of very fine large cherries picked from a Liberian coffee tree on Udapolla plantation, between Polgahawela and Kurunegala. From this one tree there were gathered at one picking, previous to the 1st instant, as many as 2,600 cherries from a blossom that came out on 21st January 1881. But this is not all, for the same tree still carries 2,900 cherries which are ripening up satisfactorily along with the crop generally on the place. The tree which has thus been singled out for this calculation is by no means an exceptional one. It was an ordinary tree in the field and received precisely the same treatment as the rest. The result of the reckoning is that with about 800 trees to the acre planted 8 by 7 feet the crop at the above rate would be equal to *two tons of coffee* per acre. The unusually wet season has been very favourable to the ripening up of crop in this district, but there can be no doubt of the margin for profitable cultivation, shewn by an experience like theabove.

FLOURISHING AT 4,200 FEET ABOVE SEA-LEVEL IN CEYLON.

Some 2½ years ago the senior editor of this paper handed two Liberian coffee plants to Mr. W. I. Cotton for trial in the district of New Galway, ex acting a promise that the result should be reported. Mr. Cotton has parted with his interest in the land in which the plants were placed, but the present proprietor states that the plants have blossomed and the berries set. The plants on which berries have thus set cannot be much over three years from the period of germination. Allowing for the fact that New Galway, like all the districts on the Uva side, possesses a specially genial climate, we think Mr. Cotton is largely justified in writing:—"There is no saying at what elevation Liberian coffee will not grow and fruit." It may be that the seed may be so acclimatized as to enable the tree to flourish at high elevations on the western side of the mountain zone, as well as in Uva.

TRIAL SALE OF NILGIRI CINCHONA BARK.

(Madras Mail.)

Under instructions from the Deputy Conservator of Forests in charge of the Government Cinchona Plantations, and in conformity with the direction of the Secretary of State to the Madras Government to test the Indian market, Messrs. Oakes & Co. yesterday sold 10,000 lb. of cinchona crown and red barks in lots of about 100 lb. each. This is the first sale of the kind in India. The following prices were obtained per bale:—

		Upset price.	Sold at
6 bales	natural crown bark...	R.242	R.243
2 do	trunk ...	do ... 212	221
6 do	mossed ...	do ... 318	340 to 345
2 do	trunk mossed	do ... 265	270
4 do	renewed crown	do ... 353	354 to 358
2 do	trunk renewed	do ... 303	316 to 321
3 do	branch crown	do ... 55	60
	Neddiwuttum.		
5 do	natural crown	do ... 232	236
5 do	branch crown	do ... 149	150
30 do	trunk red	do ... 138	139 to 151
2 do	mossed red	do ... 143	147 to 151
5 do	natural	do ... 106	111 to 120
8 do	branch	do ... 72	73 "
	Pykarra.		
20 do	branch	do ... 80	81 to 83

[The highest price, 358 rupees per bale is equal to R3·58 cents per lb. for renewed crown: the lowest realized is 60 cents for branch; red bark realized as high as R 1½ per lb.—ED. C. O.]

THE THREE GREAT COFFEE COUNTRIES. IN THE WORLD: BRAZIL, JAVA, AND CEYLON.

We reprint elsewhere an article which has appeared in the *Statist* and which has a painful interest for readers in Ceylon. Up to 1869, the year in which the fungus pest first invaded the cultivated coffee of our island, the progress of our planting enterprise was steady until in that very year (calendar) the export of coffee exceeded 53,000 tons, and the reasonable anticipation seemed to be that Ceylon would speedily overtake if she did not overpass Java as a coffee exporter. But the figures quoted shew that the course of both the Eastern countries has been downwards, leaf-disease telling on Ceylon after a fashion from which Java may possibly be saved to a larger extent by its magnificent soil. The effects of the fungus were obvious in Ceylon coffee exports in the first year of the decade ending 1880-81, and, although, in 1872-73 the highest previous figure was approached, and attempts made to reach it in 1874-75 and 1876-77, decline has been the rule even in the face of the greater breadth cultivated, until 1880-81 gave considerably less than half the figures of nine years previously, —23,000 tons against 49,750. The average for the first five years of the decade was 40,700 tons: for the second five years it went down 35,150 tons, a reduction of over 5,000 tons or more than 13½ per cent. That is the history of the coffee enterprise in Ceylon, during the period in which *hemileia vastatrix* has compelled attention to *its* "life history." Let us hope that we are now about to enter on a decade, the record of which shall be very different in regard to coffee and its most insidious and formidable foe.

Amongst the causes which have affected the export of coffee from Java in the same period, the undoubted existence of the leaf fungus has not, *as yet*, told materially, although in some places its influence has certainly been felt appreciably. From other causes, as much political, perhaps, as meteorological, the Java coffee crops have fluctuated, and the exports have, like our own, decreased, though not in the same degree. The decade began with an export of 68,000 tons and ended with 59,000, the figures in the interval rising so high as 96,000 tons and going down so low as 42,300 last year. As in our own case, the lowest figure was considerably less than half the highest. The averages have been 67,800 tons for the first five years of the decade, and 63,620 for the second quinquennium. The decrease has been 4,180 tons, or about 6 per cent, a trifling falling-off when compared with ours.

While thus the second and third coffee countries in the world have been losing ground, the progress of what is beyond compare the first coffee country in the world has, especially in the latter half of the decade, been not only steady but beyond precedent rapid. To a practically unlimited area of suitable land was added, in the case of Brazil, a large supply of slave labour, which she could and did concentrate on coffee, when the culture of that product became profitable far beyond sugar, tobacco, or any other of the old staples. The factor of rapidly added railway facilities, too, in Brazil, must be taken into account. Under their influence, largely, Santos the second great coffee port of the South American Empire, has raised her export of coffee (much of which competes with Ceylon plantation in quality), from 29,700 tons in the first year of the decade to 70,160 in the last. Santos began with figures far lower than those of Java and Ceylon; she ends considerably ahead of both. The averages in this case have improved from 35,670 tons in the first five years to 59,775 in the second. The increase has been 24,105 tons, or 70 per cent. The increase in the case of Rio has been simply enormous: from 123,200 tons to 254,400, or considerably more than a doubled export now compared with ten years ago! But 1880-81 was exceptional, so let us look at the averages, rising from 151,551 tons to 189,390. The increase has been 37,839, or 25 per cent. The joint averages for Rio and Santos, which practically represent Brazil, were 187,221 tons, rising to 249,165. The increase has therefore been 61,944 tons, or nearly 33 per cent.

The contrast is far more striking when we take the figures for the opening and concluding years of the decade. In 1871-72 Brazil exported:—

From Rio	... ...	123,300 tons.
,, Santos	... ...	29,700 ,,
Total	... ...	153,000 ,,

In 1880-81 the exports were:—

From Rio	... ...	254,400 tons.
,, Santos	... ...	70,160 ,,
Total	... ...	324,560 ,,

The increase has thus been 171,560 tons, or about 112 per cent. While in the past five years the production of Ceylon and Java fell off by 9,180 tons average as compared with the preceding five years, Brazil not only made good this deficiency but threw 52,764 tons in excess of it into the consuming markets. In truth, Brazil has in the past three years swamped the coffee markets of the world, and, if she could possibly go on at the same rate for three years more, other producing countries would have to retire from a competition which to them would mean inevitable ruin. But the main cause—the concentration of slave labour almost entirely on coffee, which has led to such enormously increased production in Brazil is obviously no more permanent than, we hope and believe, will be the depressing effects of the leaf fungus in Ceylon. That led to decreased production modified by high prices. The high prices brought Brazil with her ten thousands of fat acres and her hundreds of thousands of slaves into action, and now not only is production low in Ceylon but prices also: the

fungus mainly responsible for the one effect; Brazil entirely for the other. There will be a reaction in Brazil, the natural and inevitable effect of her extravagant action. We look for a reaction here, also, but in a very different direction. We have but to hold on tenaciously, persevere bravely for a few years longer, and the cloud will not only shew a silver lining but brighten all over with the light of restored success. We have seen dark days before now, and they have passed away. Have we not a right to look into the future by the light of the experience of the past? Thirty-five years ago, all the probabilities seemed to support the conclusion that the scale insect pest and low prices combined would snuff out the coffee enterprise in Ceylon. But coffee recovered from depths of depression then, lower than our lowest depth now, and it is surely only reasonable to look for a like process in the near future. As a Haputale proprietor (Mr. H. C. Bury) now on a visit to his fine properties, said to us yesterday:—There is far too much outcry over the falling-off in Ceylon coffee production. Taking the estimate for the current season of 600,000 cwts. and contrasting it with our highest outturn, the decrease is not much more than a third. Now what would British farmers say if they could during their cycle of depression point to crops of even one-half those they harvested some years before. Ceylon is not alone in her planting depression; agriculture all over the world (save perhaps in certain favoured portions of North and South America) has been suffering; but a turn in the tide must be approaching. It cannot, surely, be in the designs of Providence that the fungus should be permanent in Ceylon, any more than that the iniquity of slavery should continue to exist in Brazil. The latter is doomed, and so, we hope and believe, is the former.

As regards consumption, while Britain (largely owing to the iniquitous and semi-legalized system of adulteration) is worse than stationary, looking at the great increase of population, America is largely increasing her use of coffee. So is the Continent of Europe, even in the face of a policy which wastes national wealth in bloated armaments.

"FROM THE HILLS."

SHADE AND SHELTER TREES FOR NUWARA ELIYA.

It is natural and justifiable that the destruction of trees in and around Nuwara Eliya should be regretted by other than ethereal beings, seeing that the great want of the Sanatorium is the shelter which well-grown trees can give. The difficulty is to get trees to grow in the exposure and on the grass-peat soil of the plain. Dressings of caustic lime would probably help. On the sides of the hills, in what *was* forest land, the blue-gums are growing splendidly, and the contrast of the strange bluish-green hue of the long straight rows of eucalypti with the normal greens both of the native forest trees and cinchonas is very striking. When I speak of the normal green of cinchonas, I must not forget the red tints of withering or withered leaves of succirubra and officinales, or the brilliant scarlet of the calisayas. The scarlet colour as well as the bewildering variety of type in the yellow barks can be seen to perfection in the plantation up the Pass, on the road to Ramboda. The "sporting" propensity of the calisaya is so well known, and nature, as a general rule, is (Tennyson to the contrary notwithstanding) "so careful of the type," that I long resisted belief in the hybridizing theory. But "facts are chiels that winna ding," and, besides what my good friend Mr. Moens shewed and told me of the doings of butterflies and bees in Java, there is my own experience. I got seed from what I considered a fairly good description of calisaya growing in Ceylon. There were no trees of other species of cinchonas near them. The highest succirubras were on an opposite hill, about a quarter of a mile away, and officinalis trees were still further off. The resulting plants were, in foliage, so like succirubras, that I asked my superintendent if he had not put out the wrong plants alongside a path. There was no mistake; but, to quote Wordsworth, "Oh! the difference to me." The plants have developed into everything except pure calisayas. It is vain to resist the evidence of one's senses. Variation has its bounds, but hybridization *plus* sporting has apparently none For one plant which conveys the idea of calisaya there are a dozen shading off from officinalis to succirubra, with new and astounding varieties, some specially robust, but nearly all seeding prematurely, between. Very reluctantly do I become a believer in the crossing theory, but the evidence of my senses, added to the testimony of scientific experts, is conclusive. Take the one fact, that the progeny in Ceylon of seed sent by Mr. Moens himself from some of his best Ledgerianas were nearly all condemned as inferior on his visit here by the Dutch quinologist, who, to secure the purity of the superior trees, has got his government to consent to the extirpation of *Calisaya pahudiana, hasskarliana schuhkraft, josephiana, javanica*, &c., from the Java cinchona plantations. Meantime he has resorted to the grafting process, about which, and an important Ceylon improvement upon it, we hope to have something to say at an early date. The dwarf habit and ruddy tints of the calisayas above Nuwara Eliya seem to shew that elevation is too high, exposure to wind too much, or soil unsuitable for this species. A group of succirubras, on the other hand, at the foot of the range behind Barnes' Hall, look flourishing, although naturally, at an altitude of 6,300 feet, they are somewhat slower of growth than the officinalis species, which flourish abundantly all over the eastern face of the range which bounds the plain on the westward, up to 7,000 feet altitude. How little General Fraser, Major Skinner and Capt. Galwey imagined, when, in the course of their triangulations, they fixed the first "trig-point" on the summit of "One Tree Hill," that the name would be rendered a misnomer by the invasion and presence of trees from the far-off Andean regions of the great Western Continent! There has been so much of the unexpected in the past, in the introduction of the fever trees, the cocoa and the "rubber" trees from the Americas; a new species of coffee from Africa; cardamoms from India, and fast-growing forest trees from Australia, that we ought, on the soberest grounds, to be sanguine and hopeful for the future of agricultural, horticultural and aboricultural enterprise in Ceylon. We have a vivid recollection of the emphasis with which Sir Wm. Gregory, in the course of the discussion he originated on the permanency or otherwise of coffee, repudiated the idea that even if coffee disappeared from the list of its products Ceylon would be played out. He anticipated a process of which he saw the beginnings, which is going on, and the end of which no one can foresee, of the introduction and culture of *new products* suited to our soil and climate. Not the least valuable addition to our exotic sylva has been the introduction of the Australian eucalypti and acacias, with some of its auracarias. The blue-gum flourishes to the highest altitude in Ceylon, and it does not seem so liable to be infested by that insidious parasite the *loranthus* (close relation to the English misletoe) so prevalent on and so destructive to the acacia which is known as the black wattle. So highly is this fine timber tree valued in Australia, that, when all other trees on "runs" are ringed and burned, these are spared. Besides its value as a timber tree (blackwood of Australia) the frequent pyramidal habit of the black wattle renders it very ornamental, and as it preserves its lower branches and their thick foliage up to maturity it is most valuable for shelter purposes. Amongst the most striking sights in Ootacamund are enormous single specimens of this tree, and we recollect a closely planted avenue of black wattle tree which was very effective. In Ootacamund the loranthus attacked these trees with such destructive effect that Dr. Bidie was, some years ago, specially deputed to enquire and report on the subject. There, as

in Nuwara Eliya, trees have been, in too many cases, exhausted of their juices by the *loranthi* and destroyed. We have seen casuarinas and even jak trees killed from the same cause at Colombo. But the parasites were allowed to have their will, instead of a cooly being occasionally sent up the trees to rid them of their enemies. Instead of climbing the trees, the cooly could use a long pole with a sickle or crooked knife at the end, and could so clear the trees and keep them clear of the bird-carried parasites. Superior, perhaps, in the brighter species of beauty is the other form of Australian acacia, *grevillea robusta*, with its fern-like leaves and its tufts of fragrant orange-blossoms. We are glad that many specimens of this "silk oak" are yielding seed in Ceylon, for it is not easy to get seeds in Australia. The special habitat of the tree is Queensland, but neither in that colony nor in any of the others did we see grevilleas to compare with our own in Ceylon. This is *the* tree for staves for tallow casks, and the silk oaks have been so used up for this purpose, that a gentleman in Australia, when I told him how well the tree grew with us, seriously suggested the idea that silk oak timber might yet be exported from Ceylon to Australia for the manufacture of casks! Talk of "sending coals to Newcastle" after that. The river sides in Australia were blazing with the bright, sweet flowers of the golden wattle when we left in August, and it was in that very month we saw these trees in their glory at Queen's Cottago and other places in Nuwara Eliya. I was glad to see that specimens which had been planted by Mr Murray, about three or four years ago, opposite the new buildings between THE PLAIN proper and Barrack Plain, have grown well. No tree can be more beautiful when its masses of golden and fragrant flowers contrast with its separated green leaves, and the bark is useful for tanning purposes. So is that of the more common kind, *acacia dealbata*, against which a prejudice has arisen from its habit of sending up fresh trees from its roots, and so spreading into groves. So rapidly has it spread and so prevalent are groves of this tree in Ootacamund, that serious efforts are to be made to extirpate it on sanitary grounds! But surely lanes at right angles could be cut through the thickest groves; good firewood being thus obtained, and the spread of the tree could be checked by drains. We cannot conceive of anything better suited to bind banks, if kept closely cut down, judging from what we saw in the South India sanatorium. To bungalows in Nuwara Eliya this plant affords valuable shelter, which, in a place so liable to strong, cold and often rain-laden winds, is, after a time, desiderated even at the expense of extensive views; the still more indispensible requisite of a plenteous supply of water, by gravitation or in wells close at hand, has decided the position of most dwellings at the foot of knolls instead of on their tops. The majority of the villas we have visited are so snugly sheltered by spared natural forest, or exotic ornamental trees obtained from the Government gardens at Hakgala, that the fine views as well as the fresh air of the mountain sanatorium must be sought out-of-doors. The collection of eucalypti, acacias, cypresses, junipers, firs, casuarinas, auracariis, &c., around a bungalow I visited yesterday was rich and beautiful. But plants of *auracaria excelsa* (the Norfolk Island pine), one of the noblest trees in creation at its full height of 300 feet, must have been in plentiful supply when the grounds were laid out, for half-a-dozen of these trees are placed as close together as they can stand. It would be wise, if possible, to separate them. Two Norfolk Island pines, one of them 150 feet high, form the central objects in the exquisitely beautiful Botanical Gardens on the shores of Sydney Bay. The space their branches shade, over which many seats are placed, is probably equal to the whole of the grounds in which we saw six trees of *auracaria excelsa* wasted by being packed close together. If any proof were wanted of the close observing powers of the great Captain Cook, it will be found in the fact that he insisted on the specific difference of another *auracaria* which Banks and Solander classed as a mere variation of *auracaria excelsa*. Nearly a century after the death of the great navigator, Mr. Charles Moore, of the Sydney Botanic Gardens, procured the cones of the tree from which Captain Cook obtained masts and spars and confirmed the opinion of the shrewd mariner. *Auracaria Cookii* closely resembles that which justly bears the name of *excelsa* and the cruciform habit of the branches of which is so striking. *Auracaria Cunninghamii* is different from but still resembles the other two. But very different, quaint and curious is the growth habit of *auracaria Bidwillii*, popularly "the monkey puzzle," of which we saw a couple of fine specimens, a proper distance apart, in the grounds where the finer species were so crowded, and the tree is to be found near many plantation bungalows. It is, we believe, almost confined, in Australia, to particular portions of Queensland, and it is strictly preserved by Government on account of the value of the seeds of its huge cones as food for the aboriginals. Once in three years, generally, there is a grand harvest, and the blacks assemble from all quarters. They eat and are filled and go away as fat as pigs to resume their precarious diet of shell-fish, screw-pine fruits, varied by an occasional kangaroo, wallaby, native bear, or opposum. Many of them would gladly add not only "cold missionary" but roast white man generally, to their cuisine, but for the emphatic manner in which the whites have expressed their objections to such marks of affection. It is only metaphorically that the blacks are being "eaten up" by the whites. The aboriginals *might* quote Shakspere, if they could, and say:—"You take my life when you do take the means [the hunting-grounds] by which I live." But as our subject is not the race which roved the forests of Australia, but the trees of the forest, we may express our regret that one of the most beautiful and dense growing of the Australian casuarinas, is short-lived in our hill regions. But for this it would be invaluable for shelter purposes. I may here again say that I did not see a casuarina in Australia, (and I saw them lining the banks of streams), to be compared in height to the fine specimens in the grounds of the Galle Face Hotel at Colombo. Indeed the giant eucalypti, the tallest trees in the world, as the California trees are the trees of greatest diameter, are only to be found in damp, rich-soiled sites such as exist in Gippsland and especially at Fernshaw. In the mountain valleys at the latter place the closely set, white-barked, tall, branchless stems resemble the pipes of a grand organ built for the Anakim. I saw specimens 350 feet high, and it seems certain that some have reached 500 feet, for a fallen one, of which the top was gone, was measured to 474 feet. Old Dr. George Bennett of Sydney poohpoohed such an altitude, pointing to the 150 feet high tree in the Sydney gardens and exclaiming: "Just fancy a second tree of the same height placed on the top of that!" It did seem astounding, but absolute measurements afford evidence not to be resisted for what is incredible to those who have not seen what Revd. Mr. Abbay both saw and described! Baron von Mueller, the first authority on the subject in the world, accepts the height which to my good friend, Dr. Bennett, seemed incredible. But lower trees will suit us in Ceylon, and, although *auracaria excelsa* is valuable for shelter purposes, it is not in this respect to be compared to *pinus insignis*, which I found to be the favourite for sheltering dwellings and orchards in Melbourne. But I must draw this already too long communication to a close. Trees for shelter are wanted all over our hill plantations; but especially are they wanted on the cold and often windswept plain which will soon by means of the railway be the central station of Ceylon. Those who contemplate building bungalows need not be in a special hurry with their masonry and carpenter work, but they cannot at too early a date lay down their groves of sheltering trees, of which we have indicated the names and characteristics of a few most likely to succeed and be useful.

NEW PRODUCTS IN THE LOWCOUNTRY.

GENERAL REPORT: THE EXPERIENCE OF 1881; LIBERIAN COFFEE; LEAF-DISEASE; RUBBER; CARDAMOMS; PIMENTO; COCO.

12th January 1882.

In that section of the Western Province, lying between the Kelani and Mahaoya, the year 1881 has been specially favourable to the planter of new pro-

ducts, who was prepared to avail himself of it. 21 days was the longest period without rain, and the other spells of dry weather were fifteen and eight: the latter on two occasions. The fact is that, for nine months, planting might (with proper precautions) have been done any day, with perfect safety. I am only sorry that in my individuality I had not many plants to put out.

I planted some thousands of Liberian coffee plants on the two last days of 1880, and they are now from 2½ to 3½ feet high (*not meters*), and some of them have flowered more or less, though I had no plants with more than three pair over the seed leaves. Plants of the same size, planted in July and August last, are now one foot high, and many of them more. It is not, however, the inches of rain that fall between the two ends of the year that constitute a good planting season. We could do with much less than our average amount of rainfall, would it only fall at the right time, and not too much. Unfortunately, the most common season here is a mighty succession of heavy showers, for one, two, or three weeks, and then not a drop for one, two, or three months. I fear we may wait and wish long for another year like 1881.

If Mr. Ward's dicta are to be accepted, that the *hemileia* needs wet weather to obtain a settlement, there has been one evil attending the frequent rains of the past nine months. I was aware, nearly a year and a half ago, of the presence of the pest, but it only began to extend with the rains, and there are now hundreds of plants, of all ages, more or less affected. I thought at first to circumvent it, by stumping every young plant I found affected, but the small percentage of those so treated, that did after long delay send out a sucker, had spots on the very first leaves opened. I have nothing new to offer on a subject that has engaged the attention of so many hundreds of my brother planters, for a dozen years; but it is impossible to stand by and do nothing, or to follow the costly, all but impracticable, and, on the face of them, necessarily ineffectual, recommendations of Mr. Ward. If *hemileia* finds its way to the most remote coffee fields, and even to single plants, grown from imported seed, and no other of any variety within many miles, small service will be done by destroying a few local millions out of the hundreds of thousands of millions of spores carried by every wind that blows, to every square foot of the island's surface. It is easy to understand, how a given space may be cleared, by the application of a vapour that has been found capable of destroying the vitality of the spores it comes into contact with, but it is not easy to see how any vapour that is not heavier than atmospheric air can effect even so much. Suppose that such a remedy is found, its effect must only be temporary, because, though you have destroyed the vitality of every germ produced on your own estate, every wind that blows brings you germs from a distance, with which you have to continue the war. It is not the business of a practical planter, who probably never spent an hour of his life in a laboratory, to make haphazard experiments with chemicals, but the planter is supposed to know the treatment that conduces to the health of his cultivated plant, and this knowledge it is his duty to apply, so far as power and his means extend. It may be, probably is, true, that all coffee is liable to the intrusion of *hemileia*, but I think the bulk of planting opinion tends to the conclusion that *all coffee trees are not equally liable where all are equally exposed.*

I have here, at least, half a score of well-defined varieties of Liberian coffee. One of those varieties (of which I have several hundreds) scattered all over the estate gets the disease early, and keeps it. Not one specimen escapes, but the effects are different on different points. One special tree has had the disease for fifteen months, and every leaf, except the last developed pairs, has more or less of the pin-spots, yet this tree has not dropped a leaf from this cause. Other trees of the same variety do drop leaves, but none of them get utterly denuded. Another variety, not originally so hospitable to the uninvited guest, as the above, drops every leaf within two or three months of the first spot appearing. This is an unfortunate circumstance, for the variety in question is otherwise one of the most desirable, branching low, flowering early, and bearing heavily. I cannot assert that any of the varieties are absolutely proof against the disease, but there are two that have hitherto kept it at the stave's end: whether I may be able to say the same twelve months hence remains with the future!

Among the *newer* products, out of three-quarter lb. of Ceara seed I have had 85 plants, of which I lost 10 in the nursery, and 8 in the field. Those that remain are getting on tolerably, some of them being two feet high in two months from sowing.

The Cardamoms have given 75 per cent for seed, but they are very tender things at first, and are liable to be washed out by the usual watering with a common pan. Out of 1 lb. of Pimento seed, I have possibly one plant, but am by no means certain.

The Cocoa that was so troublesome and costly during the first two years, and promised so little, is now getting on, and I have better hopes of it, especially as the oldest plants are coming into bearing. I now feel inclined to give it another trial, instead of putting other products on the spots where it failed—at least, on the spots where the survivors are now flourishing.

I think we are now in for a spell of dry weather; it is what we have to expect, and is seasonable. The mornings are cold, the sky clear, and the sun fearfully hot; but the wind is not so constant and steady as the January winds usually are. This is the more satisfactory, as the dry breezy wind is as important a factor in injurious drought as the sun itself. So far, however, all cultivated plants seem to benefit by the suspension of daily rain. It is only after two weeks of hot, dry weather, that even the youngest plants in the field begin to show symptoms of distress.

18th January.

We are having the genuine January weather: hot sun and strong wind. This is only the 13th day, but it is beginning to tell on the weaker plants, those especially that were affected by *hemileia*. Since the dry weather set in the pest has ceased to extend its operations, and all the diseased leaves are dropping. I have at length the promise of a few pods of cocoa. I have finished my felling and hope to burn in a week. I am putting out my young plants from the sheds and fully testing what shade and water can do. Not one of them has turned a leaf. There is very little blossom out yet, and it is not progressing lately. How long it can remain in spike it is hard to say. The coffee to be gathered this season is very little, but little as it is it makes no advance towards ripening. That which coloured a month ago remains precisely the same: no softening of the pulp; no deepening of the colour.

I would be glad to have more lime, and must get it, *not by rail, but by cart*, which costs less and gives less trouble. The two tolls still remain between us and the station and have become even more stringent with the new year.

THE COFFEE PRODUCTION AND TRADE OF THE WORLD.

We extract the following review of the Coffee trade from the *Statist*. The writer does not hold out any hopes of a rise in price during the season of 1881-82, as there is no immediate prospect of a reduction in

stocks. There are, however, many disturbing causes to upset the most elaborate figures and the profoundest forecasts. We are hopeful of the future, and believe that, when the temporary causes of depression have ceased to operate, Coffee will rise again and proclaim its title to continue "King."—"For the last twelve months Mincing Lane brokers have been complaining of the continued depression in the coffee trade, and apparently with reason, as the average price of 1881 is much below that of any year since 1872. The course of the price of coffee, like that of many other commodities, is partly affected by the quantity of stock held, but to a greater extent by the volume thrown upon the market from time to time. Other considerations affectiug the market are the abundance or otherwise of the crops, excellence of quality, increaso or decrease of consumption, position of the money market, &c. From 1867 to 1871 inclusive, prices, it will be seen on reference to the chart we give, were low, owing to the three successive large crops in the Brazils, which caused stocks held in Europe and the United States to accumulate. Frum 1871 to 1873 there was a contiuuous strong riso mainly due to the very small Brazilian crop of 1871-2. Stocks were drawn upon so largely that at the close of the year 1872, they were at the lowest point—viz., 64,811 tons—of the fourteen years for which we give statistics. The rise iu prices and a bettter crop caused very large arrivals in the early months of 1874, and owing to reaction from the excessively high points to which speculation had driven them, prices in about two months dropped 35s. per ewt.—equal to a loss of a quarter of the January quotations. The maintenance of consumption and smaller imports during the year again brought the stock down to a very low point. In 1876 stocks again fell off, but were rapidly replenished in the first four months of the followiug year, the large arrivals causing a sharp fall in price. The average stock since 1877 has been greater each year, and at the end of May last was very nearly double the amount held at the same date in 1873. At the same time we must remember that consumption on the continent, and more especially in America, has grown, and the stocks now are comparatively less excessive than they were ten or twelve years ago.

For the four years ending Dec. 31st, 1878, the average price was about 104s. per cwt. for 'low middling' Ceylon plantation coffee. From Aug. 1878, to July 1879, there was a fall of 24s. from 105s. to 81s. A recovery took place in the last half of 1879, owing to sympathy with the general rise in prices in all markets, and was maiutained for just four months to the end of February last year. A slight fall and hesitation in movement left the price at 82s. in October, and in two months a further fall was shown, till 70s. was reached in December 1880—the lowest point in any year since 1871. During 1881 there has been a slight temporary recovery, with a rather sharp riso early in August, partly due to buying by French speculators. Since thon prices have gonerally been weak, and are now tending dowuwards, owing to the heavy arrivals in the Brazils.

The reason for the present low level of prices is that the increase of cultivation and the recent extra, ordinary good crops in the Brazils, from whence about two-thirds of the world's supply is derived, has caused production to be in excess of consumption, and authorities consider that there are no signs of a falling-off in supply for the immediate future.

There is a general impression that, owing to the spread of the temperance movement in this country, we are using much larger quantities of coffee. An examination of the Board of Trade returns does not confirm this, for, in spite of the reduction in price and lower duties, the consumption is only about the same as ten or fifteen years ago. The amount of coffee (and chicory !) consumed in this country during the last six years, in tons, has been as follows :—

	1880.	1879.	1878.	1877.	1876.	1875.
Coffee...	14,540	15,489	14,970	14,656	14,884	14,520
Chicory	5,709	5,295	4,772	4,971	4,741	4,708

For the nine months ending Sept. 30th, the comparison in tons with the corresponding periods of 1880 and 1879 is as follows :—

	1881.	1880.	1879.
Coffee	10,841	10,843	11,696
Chicory	4,302	4,213	3,933

One of the most extraordinary facts connected with coffee statistics is that coffee as a beverage does not gain ground in popular estimation. One cause is that so few persons in this country really know how to make a good cup of coffee. Forty years ago the consumption in Great Britain was 1·08 lb. per head of population. In 1847 it increased to 1·34, by 1850 it had dropped to 1·13, again rose to 1·35 in 1854, and has since gradually declined, until, last year, the consumption was only equal to 0·92 lb. per head. The other two beverages, tea and cocoa, show a very different movement. Tea, in 1840, was 1·22 lb. per head of population; last year it was 4·59, and in 1879 had been at its maximum, 4·70 lb. Cocoa has increased from 0·08 lb. in 1840, to 0·31 lb. last year.

The comparison of the duties is as follows :—

	1840.	1881.
Tea	2s. 2¼d. per lb.	6d. per lb.
Coffee foreign ...	9d. ,,	1½d. ,,
,, British possessions	6d. ,,	

In Germany the consumption is estimated at about 100,000 tons per annum. The next country of importance is France, which shows a steady increase. The quantity used in 1878 is estimated at 53,300 tons, increasing in 1879 to 56,000 tons, and last year to very nearly 57,000 tons. Austria consumes about 35,000 tons; Holland, owing to its imports being free of duty, uses 34,000 tons. Its consumption per head of population is the largest of any country, and is about sixteen times that of Great Britaiu. The total European consumption has been placed by authorities as about 350,000 tons to 360,000 tons per annum.

The chief sources of supply of coffee are Brazil, Java, Ceylon, India, Jamaica, and Central America. The berry is grown in other parts of the world, but the production is unimportant. According to Messrs. Wilson and Smithett, who have compiled, as far as possible, their information from official sources, the crops of Brazil, Java, and Ceylon coffee since 1871-2 have been as follows :—

	Rio. Tons.	Santos. Tons.	Java. Tons.	Ceylon. Tons.
1880-81... ...	254,400	70,160	59,000	23,000
1879-80... ...	172,780	61,530	42,300	33,480
1878-79... ...	210,460	70 510	86,800	41,225
1877-78... ...	150,000	58,950	59,000	31,015
1876-77... ...	159,310	37,720	71,000	47,050
1875-76... ...	165,030	44,590	96,000	36,020
1874-75... ...	180,775	48,500	45,000	48,450
1873-74... ...	119,050	38,900	75,000	30,750
1872-73... ...	170,600	31,660	55,000	49,750
1871-72... ...	123,300	29,700	68,000	37,900

The shipments of Brazil coffee to Europe in the crop year ending June 30th, 1881, is returned as 169,000 tons, or 66,000 tons more than the previous year. The above figures show how enormously the production of Brazil has increased during the last ten years. It will be seen that in 1871-2 the total production of the country was about 150,000 tons, which compares with just 325,000 tons for the year ending June 30th, 1881. Java remains about stationary, and Ceylon declines, owing to the leaf-disease.

For the particulars respecting the stocks held in Europe and the United States, we are indebted to

Messrs. James Cook & Co. The actual figures of August 31 in each year are as follows:—

	Tons.		Tons.
1881 ...	175,000	1883 ...	100,871
1880 ...	147,266	1872 ...	90,935
1879 ...	133,218	1871 ...	132,786
1878 ...	116,259	1870 ...	129,182
1877 ...	122,572	1869 ...	139,944
1876 ...	114,377	1868 ...	142,677
1875 ...	114,253	1867 ...	102,693
1874 ...	110,685	— ...	—

These stocks include the amount in warehouse in the whole of France, Holland and England, and the ports of Hamburg, Antwerp, Trieste, Genoa, and Bremen, and in the six principal ports of the United States. The stock held in France has increased very considerably of late. In 1879 it ranged from 30,000 to 45,000 tons; in 1880, from 36,000 to over 47,000 tons; but this year the stock, which at Dec. 31 last was 41,000 tons, has accumulated, and at present is about 73,000 tons. This is mainly due to the action of French speculators, who bought largely in the spring, notwithstanding the stock being equal to about nine months' consumption, irrespective of exports.

The effect of the lower values received for their produce sent home by the Coffee Companies is seen in the reductions of dividends paid by three joint-stock Companies below. The dividends paid are much below those of four or five years ago:—

Company.	1880	1879	1878	1877	1876	1875
Hunasgeria (Ltd.)	nil	nil	5	5½	5½	7
Moyar (Ltd)	2½	2½	nil	4	5	12
Ouvah (Ltd)	8	8	3	12	12	15

—*South of India Observer.*

CINCHONA AND TEA.

Lindula, 19th Jan. 1882.

The fall in the minimum temperature to 51°, as noted yesterday morning, betokened rain, and during the day masses of vapour gathered and slight drizzle fell, resulting in ·16 of an inch as gauged. During the night the conditions favourable to rain increased, and this morning we found that the figures for maximum temperature had gone down from 74° to 72°, while the minimum had risen from 51° to 54°. The morning rose close, misty and drizzly, and we had a few showers of most grateful and welcome rain. They have freshened up the face of nature wonderfully, and there is a decided promise of the continuance of this weather. "The January rains," occurring in the latter portion of the month, are indeed a regular institution and relied upon by many for planting out cinchonas, gums, &c. It will require a week yet to decide whether the experiment can be safely tried. Of the beneficial effect of the rain on tea bushes and their flushes and on tea seed put into beds, there can be no doubt. We are now, at length, after a lapse of five to six years from the sowing of best hybrid Assam plants, obtaining a plentiful harvest of seed. While the best quality is thus slow of seeding, the difficulty is to prevent the inferior kinds from blossoming and bearing seed in their infancy. I suppose others, besides myself, were unfortunate enough to be supplied, in the early days of the enterprise, with seed from Hakgala of a variety which throws all its energies into fruit, and which would be valuable were tea seed desiderated as food for cattle (the coolies eat them), or were tea seed oil an article of commerce. We saw the effect of low elevation (1,500 feet) and hot dry climate with a stimulating soil in Java, where Assam hybrids, grown with considerable difficulty, were bearing seed at 3½ years old. We have found by experience that the best sites for tea nurseries are flats or swamps, where moisture for the seeds and plants rises by capillary attraction through the soil of beds which are well raised, and over which is spread a coating of the ashes of burnt timber, weeds and earth. The careful shading originally resorted to has long been entirely abandoned, the discovery having been made that tea, instead of being a tender plant, is one of the most robust and tenacious of life we can grow,—provided it is not poisoned by the symplochos.

P.S.—3 p.m. Raining steadily.

CEYLON PRODUCTS.

(To the Editor of the *London and China Express.*)

SIR,—In your issue of the 21st Oct. last you were good enough to insert a short article under the above heading, with a view to induce Government to assist the planting enterprize in our island, by sending us scientists to discover the cause of certain so-called failures in the cultivation of various products. The article was written in a kindly spirit, for the benefit of our planting community, and, indeed, of all interested in Ceylon, and we must give you thanks for taking up the cudgels on our side; but it is unfortunately very misleading, and calculated to make would-be investors hesitate before embarking in any new enterprize in Ceylon, and I venture to hope you will give space to the following remarks, and allow me to contradict your statement, "that little success has attended the cultivation of our new products in Ceylon." It is no secret that the ravages of leaf-disease (*hemileia vastatrix*) and other causes have injured the enterprize in coffee arabica, and planters have been turning their attention to other products, but you will find that all those that have been started long enough for us to judge of their results have been successful in a very remarkable degree, and that there is nothing to lead us to fear that others will not not prove equally successful.

Whilst the old enterprize in coffee arabica is under a cloud it is of importance that capital should be attracted to the island, and I believe there are no better openings for capitalists in the world than they can now meet with here. Even planters of long experience who have pinned their faith to coffee arabica for the last twenty or thirty years will tell you that the prospects now offered by new products are far better than any that the most sanguine could at any time expect from coffee arabica. I need not tell you that cinchona (perhaps the oldest of the new products) is succeeding very well in the more elevated districts, but will pass on to

Liberian Coffee.—Several estates have come into bearing, and I am told that on one estate the estimated crop this season is 24 cwt. per acre, of which 11 cwt. have already been picked. This is a lowcountry product, and it is doubtful whether it will ripen its crop properly at an elevation over 1,500 feet. No doubt those who have tried it at a higher elevation may have discovered this, and have, therefore, condemned it as a failure, but if you could interview the owners of Putupaula Estate (Kalutara), and one or two others I could name, you would soon lose any fears you may entertain regarding the success of this cultivation, and the recent sales in London and New York point to a ready market at top prices.

Cardamoms are doing well wherever they have been tried, and on one estate, in a very unfavourable district for coffee, indeed on which the coffee (arabica) has been abandoned, they are now yielding very large profits.

Pepper and Nutmegs promise almost fabulous returns. The managing director of our Company has recently made a visit to the Straits, for the sole purpose of inquiring into the cultivation of these two products, and expresses it as his opinion that they will yield very large profits, as they are there doing.

Tea.—Although our labour is dear, cheap transport and large crops will enable planters to compete successfully with India and China. The competition, however, is so great that large returns cannot be looked for.

Cocoa.—Some difficulty has been experienced in getting this plant past its infantile stage, owing to the attacks of its inveterate enemy, the white ant, but this will soon be overcome, and when once past this danger success is assured. This is one of the cases in which the services of able scientific men will be invaluable, and the appointment of such persons will be of great assistance to us; but I emphatically deny that our new cultivations have any of them been proved to be failures. On the contrary, many have proved very successful, and I could enumerate many more which show prospects of great success. Certain soils and certain districts are suitable to the growth of certain plants, and until experience and science teach us how to avoid planting new products in unsuitable places an occasional failure must be anticipated; but I trust that all who have formed an opinion that our new products have met with little success will be soon disabused of such an error, and will believe that we have met with a *good deal of success*. Should any doubts still exist in their minds, I shall be very glad to give them any further information they may require.

At an early date I shall send you some further particulars regarding our new products, showing in detail what results have been obtained.—I am, &c.,

A SHAREHOLDER IN THE CEYLON LOW COUNTRY PRODUCTS COMPANY (LIMITED).

Galle, Nov. 28th.

THE SEASON IN INDIA.

(*For the week ending the 10th January.*)

Scarcely any rain fell during the week under report in any part of Bengal, the North-Western Provinces and Oudh, and the Punjab. In the two latter Provinces rain is much wanted, as the cold-weather crops on the unirrigated lands are suffering from want of moisture. In the Central India States there has been no rain, but the crops are reported good. In the States of Rajputana and in the Central Provinces showers fell in a few places and prospects are favourable. In the Bombay Presidency the outturn of the *rabi* crops is expected to be poor in two districts and in others generally good. In the Nizam's Territories the *rabi* has much benefited by slight showers. In the Madras Presidency the rainfall has been more general during the week under report, and prospects are on the whole good. In other parts of the country, *i.e.*, in Berar, Coorg, Assam, and British Burmah, prospects continue favourable.

Madras.—No rain in Kistna; general prospects good.

THE SUPERINTENDENT of the Government Gardens at Saharunpore has, during the past year, been engaged in the production of vegetable drugs, for the Medical Department. Besides henbane, he has been able to prepare taraxacum at a considerably lower cost than its purchase in England entails.—*Madras Mail.*

JAFFNA AND COLONIZATION.—In our opinion the only feasible method of ameliorating the condition of the people of Jaffna consists in emigration towards the Eastern and Central portions of the island, and in colonizing the fertile districts watered by the Mahavile Ganga or situated in proximity to the large tanks like Kanthalai and Giant's Tank. A colonization conducted on a large scale would not only relieve Jaffna of its surplus inhabitants, but convert, in a short time, fever-stricken jungles into smiling villages and fields teeming with a rich, contented and thriving population.—"Lanka Suabian."

CHEMICAL SOCIETY OF LONDON.—At the meeting on Dec. 15th, a paper was read "On a new Alkaloid from Cinchona Bark," by Messrs. D. Howard and J. Hodgkin. The authors have extracted from the bark of the China Cuprea an alkaloid closely resembling quinine in its general properties. It differs in the solubility of its salts and the readiness with which the alkaloid crystallizes from ether. They have named it homoquinine.—*Athenæum.*

GRASSES AND CINCHONA CULTIVATION.—We understand that the next annual report of Dr. George King, superintendent of the Botanical Gardens, Calcutta, will be of special importance for its bearing on the vexed questions of the growth of grasses for paper fibre, and also of cinchona cultivation for quinine. In a paper just received from Dr. King, in which he gives a special account of his examination of cinchona cultivation in Java, he suggests Burmah, the Andaman Islands, and the Khasia Hills as new sites for the cultivation. A cinchona plantation, we may remark, has already been tried at Nongklao, in the Khasia Hills, and abandoned.—*Academy.*

COFFEE BLOSSOM PROSPECTS.—The weather has set in fair all over the country according to today's [10th January] telegraphic report, and so far as the coffee districts are concerned the change could not come more opportunely. The rain of the past three months has been most beneficial; but high, as well as low districts now require dry weather to "harden" the wood preparatory to blossom. Indeed, in the lower districts there was risk if wet weather continued longer of blossom being lost: some in spike going into 'brush'; but we have no doubt now, early and good blossoms will be seen in the low as well as high districts if the dry weather continues. So far everything is most favourable for a really good season throughout the Ceylon coffee districts. So mote it be!

GANGAPITIYA ESTATE, in the Dumbara Valley, was the test plantation we referred to a few weeks back in reference to Mr. Schrottky's system. In the middle of December there was some room to apprehend a general attack of leaf disease; but subsequent reports shew that the apprehension was groundless, no attack having developed. On the 2nd instant, the report was to the effect that:—the coffee looks remarkably well, and, as yet, has resisted the disease, so that there is good reason for anticipating that the estate will pass through the blossoming season with the minimum of evil effect from the fungus. Isolated trees are still found with the disease; but, although the weather was more or less showery all through December, it has not spread. This is certainly a striking fact and worthy of careful attention.

THE CEYLON INVESTMENT ASSOCIATION LIMITED.—We have received this afternoon a copy of the report of the above Company for the year ended 30th Sept. 1881, which will appear in full tomorrow; but meantime we may mention that the result of the Company's operations is a dividend of 6 per cent to the shareholders with £800 carried to a reserve fund. Considering the hard times, this must be regarded as satisfactory. The Company's investments in Ceylon now amount to £87,114, of which £16,333 have been made during 1880-81, while £3,946 had been repaid in the same time. One paragraph from the Directors' report we give at once to shew their opinion of our planting industries:—

The Board obtained much benefit from the information received from their Secretary, Mr. Kirwan, as the result of his visit to Ceylon. While in the island, this gentleman made a careful inspection of all the estates in which the Association is interested, and his report may be held as extremely satisfactory. Prospects in Ceylon are reported to be slowly, though steadily improving. The cultivation of new products is being rapidly extended, and the success which has already attended the growth of these promises well for the eventual rise in the price of land in the colony.

Correspondence.

To the Editor of the Ceylon Observer.

A QUININE FACTORY FOR COLOMBO.

Dear Sir,—Mr. P. D. Millie's idea has been anticipated, and the setting up of a quinine factory in Colombo has been determined on. Orders are in course of execution for the machinery, and an experienced man is to be imported with it. B. B.

THE CRYPTOGAMIST AND LEAF-DISEASE.

Dear Sir,—Like the postscript of a lady's letter, the last remarks of the cryptogamist are the most interesting of his communications. At best, however, it is but painful, disappointing reading; so little hope, so little practical information, so much more that we would like to know.

1.—Mr. Ward still stoutly maintains that there is "no evidence of a necessary predisposition to disease on the part of the coffee plant," and that "no special predisposition on the part of the coffee is required for its infection." To prove this Mr. Ward "proceeded to make experiments by sowing the spores of *Hemileia* on all kinds of coffee leaves, * * to see if one kind was more predisposed than another." Now I submit that this *artificial* test was not a fair one Planters don't want to know whether if artificial means are employed all coffee trees are equally liable to take in the fungus, and to suffer from disease, but whether they are so or not, when subjected to the ordinary operations and conditions of nature. His experiments moreover, such as they were, seem to have been incomplete for he makes no reference whatever to Liberian coffee. When an epidemic breaks out, say cholera, it is pretty well known that some men naturally seem less liable to take it than others in ordinary and similar condition; but if all were artificially inoculated with the virus, it is but reasonable to conclude that all would become affected. Mr. Ward tries to support his conclusion by the analogy of bathing boys attacked by leeches. But unless the leeches were as plentiful as the myriads of spores are, there is no ground for analogy; if they were, and the boys by position were all equally liable to attack, then if some were more bitten than others, I would undoubtedly conclude that their bodies were more susceptible to attack, more liable to suffer from the leeches. From impurities of the skin leeches will often refuse to attack by themselves, much more to bite. If then there be any analogy in Mr. Ward's parallel, it is rather against than for his conclusion. In another part of his remarks Mr. Ward says: "in many cases known to me it is simply because the coffee has not yet become the prey of the fungus that it looks so well." This surely implies a want of predisposition, or if not, will Mr. Ward explain? I make no attempt to controvert his theory, but I cannot see that he has proved its truth, while observed facts seem to be against it. Every planter knows of fields dotted all over with fine vigorous coffee trees apparently free, or comparatively free, from the fungus, while the surrounding trees are covered with the pest. To all appearance the natural conditions are similar, same soil, elevation, climate, exposure, treatment. There may of course be dissimilar conditions, but if so what are they? Planters would be only too glad to know for they evidently are the cause of the exemption.

2.—Mr. Ward has not made it clear that there is no hope to be got from the suggestion that the trees might be made to take up something by their roots into or with their sap which would destroy the fungus without seriously injuring the trees. Although he discountenances this notion, we know that trees will take up by their root into their system substances other than food, and we also know that what may kill minute life will often not merely not harm but may do good to larger life. If the sap can bathe the leaf cells, and the mycelium find its way through the passages between the loosely arranged cells, then surely there is scope for the weak solution of some remedial substance.

3.—Mr. Ward considers that damp corners, ravines, and hollows, are particularly subject to the germination of the fungus. My experience, however, and I should think that of most planters, is just the opposite. It is the fine ravines and hollows that seem to escape, while the exposed ridges and faces are often chronic in their suffering.

4.—Again as a matter of experience I am not satisfied that shade is a good thing: it may for a time ward off an attack, but when the visitation does come I have often seen it worse, and remain longer, than on adjoining unshaded coffee. This experience seems to be theoretically supported by many of Mr. Ward's other remarks, as for instance, when trying to explain why the leaves on lower branches are more affected than those on the higher branches.

5.—The many reasons Mr. Ward gives for gathering up and destroying the fallen leaves would tell more strongly in favor of actually plucking the diseased leaves from the trees, but both suggestions must I fear be consigned to the limbo of the impracticable.

6.—Mr. Ward is not very clear, but he seems to recommend the postponement of pruning till about June on the Kandy side. Evidently Mr. Ward has overlooked the fact that even in Ceylon there is a special growing season, particularly for our coffee: and the general concensus of planting opinion is that early pruning say in January and February is, if one can afford the labor and expense, much better for the tree, even as regards leaf disease, than a late pruning such as he recommends.

6.—If spores are so very numerous, if a generation is often so very short, some three weeks, how is it that there used to be, and still is to a great extent, such a periodicity in the attacks of leaf disease?

7.—If belts are such a protection how is it, that a natural belt of forest some dozen miles in width over hills some two thousand feet at least above the coffee on either side, is no protection, though only from that side is there any source of infection.

We come now to the Harrow experiment. It was regarding this experiment, I some time ago warned the planters, that Mr. Ward had very unfairly told us all that was good, without giving us the slightest hint of anything that was unsatisfactory.

It would seem that the number and weight of foliage on the sulphured and limed coffee was rather greater than on the untreated coffee, The treated coffee was however at a rather higher elevation, and less exposed apparently to the S. W. monsoon. It would be difficult also to say to what extent the lime alone, acting as a manure, would darken and increase the foliage. It is to be regretted that in the conducting of such an exact scientific experiment no attempt was made to compare the number and weight of foliage in the respective fields, preparatory to the making of the experiment. Why also were leaves of two inches in length and upwards only taken. It must in the taking of such a vast number of leaves have been very difficult to avoid taking leaves a shade under, and having leaves a shade over, the arbitrarily fixed two inches.

However the proof of the pudding is the eating of it, and the question must be asked "Did it pay?" In answer we find that to put it in the strongest light, coffee with an *extra* expenditure of R20 47 per acre on sulphur and lime gave some 15 lb. more an acre of produce ready for shipment, worth at the rate of R50 per cwt. the sum of R6.70. The quantity

however was considered by all to be inferior in color, and by some also in size. On the other hand the untreated coffee with a *less* expenditure by R20·47 per acre gave 1·6th of a bushel more per acre of parchment worth at the rate of R10 per bushel R1·66. It is true that the parchment had a larger percentage of light, but as the whole was under 5 per cent. this need not be taken into account.

It is to be exceedingly regretted that Mr. Ward in no way refers to Liberian coffee in connection with leaf disease or *Hemileia vastatrix*. Those who have invested in this product are naturally anxious to know if it be, as is supposed, less predisposed than Arabian coffee, and if it be so, is it likely to continue so? Mr. Ward ought not to be allowed to leave the country till he can speak decidedly on this matter.

In short, though Mr. Ward is very inaccessible, and seems to have somewhat of contempt for the lay mind, yet it is to be hoped, he will again try to make things more plain for men who, though disappointed at getting so little, are still anxious to learn all they can.—Yours truly, A. G. K. BORRON.

WILL CULTIVATION AND MANURING GIVE A COFFEE BUSH IMMUNITY FROM ATTACKS OF *HEMILEIA*?

DEAR SIR,—I have perused Mr. Ward's reports with much interest, and his scientific view of leaf-disease I have no doubt is accurate and valuable; but from a practical point of view there will be many who will differ from him. I am prompted to give my reply to his challenge, in his letter in your issue of 13th instant, which runs as follows:—

In cases where trees or groups of trees are pointed out as "disease-proof or practically so," on what grounds are the assertions made? Have those who make the statements satisfied themselves that there are no other reasons than those they give for the comparative immunity from "disease spots," at the time of the particular trees referred to? Have they even proved that the trees remain "free from disease" for a year; or that the relations between the number of diseased and healthy leaves are not different in the cases cited. And yet, surely the onus of proof lies with those who controvert records of observed facts with unsupported statements; and it is, to say the least, rash to affirm that a tree is less "diseased" than its neighbours, without being able to say that the trees was carefully and closely observed for a sufficiently long time. But even admitting that "a tree here and there shows fewer 'disease-spots'" during a given period than surrounding specimens, who will undertake to prove that it has had as much chance of becoming infected as another?

This time last year I commenced the following system, upon the most worn-out piece of coffee that could be seen, where the trees were alive with a few straggling branches and had been every year severely attacked with the disease. The soil, however, is fairly good but exhausted from overcropping and neglect. The area treated is nearly five acres, part of a field of about 10 acres, and surrounded by fields much in the same condition still to be compared with the experimented part. I opened holes 18 inches from the stem and above the tree, 2 feet long × 16 in. × 12 in. deep, breaking into the subsoil, casting the soil round the trees, and covering well over the ground above the roots. Very soon afterwards rootlets began forming in the loose soil and the branches to show fresh vigour. In the month of March of this year, I sprinkled about 30 bushels per acre of caustic dolomite lime over the trees and ground and into the holes. A month afterwards I half filled the holes with soil and then applied a basket of well-rotted cattle manure with a pound of fish manure, mixing the whole well with the soil and covering it up by opening fresh holes between the trees. In about a month, the rootlets had entered freely into the manure, and they are now one mass of fine feeding rootlets and the trees are all clothed with a magnificent growth of young dark-coloured foliage, some of the branches being more than a yard long; and the coffee only wants fine weather to bring out a fine blossom, where it did not give a quarter of a cwt for years.

This acreage has entirely, "practically," escaped the attacks of leaf disease, while the coffee on every side of it was several times covered with severe disease.* The next two months, however, I dread the attack more than at any other time, as I find, when the rains cease, that a chill wind follows, which often develops the disease in less than 24 hours.

I have searched in the manure holes for grub but found none, while the year previously, to another field, I applied cattle manure in semicircular holes, without lime, and found that grub had entered in considerable numbers very shortly after application, and the coffee had not shown any very marked improvement. I have, therefore, arrived at the conclusion that, during the dry months, the grub follows the moisture downwards, and the application of the lime on the subsoil, before the rains commence, deters them from finding their way up again.

The five acres treated this year "had as much chance of becoming infected as another," and, in my opinion, the richness of the new foliage afforded a tempting receptacle for the disease, if floating through the atmosphere in search of a resting place.

There are several other points of Mr. Ward's theoretical views that can be contested, but I do not wish to make this article longer, but will add that he can see the results I state at any time, should he wish.—I am, yours truly, J. R. G.

COFFEE LEAF-DISEASE.

North Kinmundy, Summerhill,
by Aberdeen, 24th Nov. 1881.

DEAR SIR,—When I received from you, on the 9th February 1880, copy of "The Campaign of 1879 against Coffee Leaf-Disease," along with two diseased leaves, I intended, after giving the leaves a cursory examination, to thank you for your interesting communication. But, although my gratitude did not evaporate, attention to some fungi nearer home, and a wish that I could be able to say something about the *Hemileia*, have prevented my returning thanks till now. But now, accept of my best thanks for the means of enabling me to extend to this most important fungus what I believe to be the true life-theory of a great many fungi which become parasitic in the tissues of higher plants. I have also been very obligingly furnished with leaves, diseased and undiseased, by Mr. James Westland, Goleonda estate, Hayntale, through his brother, Mr. Wm. Westland, who is an agent for Ceylon products in Aberdeen. To these gentlemen my best thanks are also due.

Now, I wish you to understand that I do not pretend to have made any complete substantive investigation of the coffee leaf fungus. Without access to the living plants, this would have been impossible; and besides it would have been unnecessary; because the labours of Messrs. Abbay, Morris, M. Ward and others have brought most of the facts of the life and the structure of this fungus fully into the arena of common knowledge. My work upon it has been in search of side lights. I have been occupied for some years on the clubroot fungus, the rust of wheat, the potato

* "Several times covered with disease." The Cryptogamist will probably ask whether the disease was not continuous, merely shewing more at times; while there may not have been wind enough to carry spores to infect the fresh foliage of the trees renovated by digging and manuring?—ED.

fungus, and some others of less note. And it was while investigating the structure of the *scutellum* or *cotyledon* of the cereal grasses, for a purpose altogether apart from mycology, that I discovered that the mycelic sporidia of the red rust, in its non-parasitic system, entered the structure of the embryo through the absorptive apparatus of the scutellum, mixed up with its albuminous food, and that these sporidia lay in the tissues as little sclerotic granules, in a condition which I propose to call *apogestation*; that is, gestation in living tissue, away from the generating species of plant, preparing to come into fruit under the necessary circumstances at the proper time.

I had been vainly working at the potato fungus, the *peronospora infestans*, on some points not altogether cleared up by De Bary and Mr. Worthington Smith, on the current assumption that the infecting conidia were carried atmospherically, and that the mycelium of their zoospores, entering the stomata of the leaf, took a turn about there among the cells to see what was doing and came out again into the open air to produce fruit. In which assumption, I may say in passing, lurks the weak point that the fungus must have a stock of ripe fruit before it becomes a parasite at all—which is absolutely fatal to the theory. But now, here was a new point of interrogation; and in the application of it to the potato disease the results have been beyond anything that I anticipated. I cannot go into the whole subject, which has not yet been made public, but may state that the stomata of the leaves, young tubers &c. are inoculated by the sporidia produced along the mycelic threads of the nonparasitic system of the fungus during the germination of the potato buds under ground. The fungoid plasm spots can be detected in the leaf before it comes through the suface of the soil, and during the season they become perfectly definite *sclerotiets*, which may be dissected out of the tissue, sometimes in great numbers. They dissolve into streams of loose mycelium at the proper season and come out at the stomata to produce the fruit or conidia of the fungus. The disease for the current crop is gestating in the tissues of the plant from a very early stage; and, although the conidia or fruits may be carried upon the air, they do not produce or increase the crop to which they belong, but only the crop of the following year. Some of them may immediately yield germinating zoospores, but these do not mean any instant onslaught on the already destroyed leaf-tissue, having like other young people an education to go through.

It occurred to me, in the course of my observations (all of which are vouched for by the microscopic literature of mounted slides), to return to my coffee leaves, and try whether the principle of *apogestation* did not apply to the *Hemileia*. By stripping off little bits of the lower epidermis the mystery stood revealed; the induction took another step. I have sent you very rough tracings of the fungus, not as being correct (such you will get elsewhere) but for the purpose of explaining my meaning more clearly. Figure No 1 is the stoma of a leaf which has not been inoculated by any sporidia from the non-parasitic mycelium. In No. 2, there are sporidia, both hyaline and becoming brown, lying about gestating in the air-chamber of the stoma. Probably it is the action of the young bud-leaf itself which absorbs the minute plasm-granules. But that they are absorbed, and that they undergo a process of gestation within the leaf, is past any doubt (on my part). Stoma figure 3 shows the sporidia grown into a labyrinthic mass of fungoid matter called a *plasmodium*, the "dark bodies" seen by Mr Abbay, any point of which is capable of germination. The process of growth goes on at various rates in different cases, some never coming to birth, and in figure 4 (*a*) you see the plasmodium, by reversing the epidermis grown over the whole stoma; (b) shows the same mucous mass vertically down into the tissue. No. 5 (a) and (b) shows the germination of the plasmodium in the interior, as seen from the interior by reversing the epidermis, in plan and in vertical aspect. The growth is not towards the stoma, but away from it; away amongst the loose cells on the lower side of the leaf. No. 6 (a) and (6) shows the fruit on the outside of the leaf growing from all points of the plasmodium, now mostly converted into mycelium, out at the mouth of the stoma, just as in the potato fungus and in many other fungi. They all grow from what is practically a parasitic *schrotium*, that is a compact mass of fungoid plasm. Ergot is the best known of the non-parasitic schrotia.

We now come to an important point for the clear understanding of this subject. When once the conception takes definite shape, it becomes obvious that a fungus, which, at one stage of its life, is a parasite, must have a non-parasitic system, or must spend a part of its cycle as a non-parasite; more especially is this obvious where the parasite kills its host. Against the contention that the uredospore by direct germination infects the leaf, I place the question: where, then, does the first uredospore of the season come from?

Well, fig. 7 and 8 show the beginning of the non-parasitic stage of the *Hemileia*. There the fruits begin to germinate. Call them spores, uredospores, sporangia, or conidia, they are simply a sac of granular plasm, the parts of which may come out as zoospores and germinate into mycelic lines, or may form zoospores inside and there germinate, or may aggregate into a plasmodium and germinate, or partly one thing and partly another. But, as these conidia can germinate anywhere, they are independent of any host plant, and are thus purely non-parasitic. The non-parasitic mycelium is of an entirely different character from the parasitie; and the probability certainly is that the non-parasitic system can reproduce itself non-parasitically and non-fructively upon the ground, or the branches of trees, or in any other situation. But you will notice that this non-parasitic mycelium is of two varieties. What is produced directly from the conidia or their zoospores is thin and hyaline or translucent, and it produces small resting spores. These resting spores, or equivalent bits of plasmodium inside the crumpled conidia, produce a secondary or resting mycelium of a brown colour and torulose or jointed structure. And within these are produced a granular plasm and minute sporules which come partly to the outside and adhere loosely to the surface, or form little floats around the young growing lines. And it is only when, as in fig. 8, where this mycelium, effusing a mass of mucous granules, flushes the young bud of the coffee plants, inoculating its stomata with fungoid plasm, that the fungus again goes into the parasitic condition and after gestation attains its perfect state in the production of fruit.

There are many points to which I have not referred and on which my knowledge is defective. I am rather an intruder, and do not wish to poach on other men's preserves. But the principle of *apogestation*, by which the higher plant carries the germ of the lower to its birth and perfection, embraces a vast field with far-reaching philosophical implications, to which I cannot now refer, and in this field, of which the *Hemileia* forms a corner, I am, perhaps, not an intruder; and it is at this turn possibly that some hope of mitigation or cure may be found. I daresay everything has already been tried to destroy the fungus in some of its forms. If it is already within the leaf in the very earliest stages of that leaf, the idea of protecting the leaf at a later period from an outside enemy does not apply. The enemy is already entrenched, winking at you from his borrowed ovary; hatching the vilest treachery against the unsuspecting plant which is befriending him. You cannot eject him. But if you could starve him out; if you

could apply any solution to the leaf, which would prevent him from germinating, he would do little harm. Numberless fresh potato tubers now laid up with us for winter store are infested with quiescent schrotiets of their own fungus ; many solutions could easily be tried on the various leaves (marked with coloured threads) of a single plant, before the granules become developed! You see that isolation of your experiment is unnecessary. If grafting on some suitable stock has not been tried, possibly the alteration of sap arising from this process might have a tendency to arrest the germination of the germs lodged in the stomata. And trusting that some lucky dog may hit what others have missed, I am, dear sir, yours very truly,

A. STEPHEN WILSON.

P. S.—I should like to have an opportunity of investigating more fully the resting system of the *Hemileia*. I have recently discovered a parasite which destroys the leaves of the lilac which Mr. Berkeley has named *Ovulane syringae*, the conidia of which give rise to a great crop of opalescent resting spores which stare at you from a jungle of mycelium like the eyes of wild cats. And if you could find an opportunity of sending me a packet of coffee leaves and buds in all states of health and disease, you would lay me under further obligations.—A. S. W.

CEYLON TEA IN LONDON.

33, Basinghall Street, London, E. C., 16th Dec. 1881.

DEAR SIR,—There have been three different parcels of Ceylon tea up in public sale this week, the prices realized being 3d. per lb. above valuation and considerably in advance of earlier sales. We give you marks, description, and prices realized :—

W. E. S.	58	chests Pekoe Souchong	... @	1/1	per lb.
	49	half-chests Pekoe Souchong	,,	1/1½	do.
	17	chests Souchong	... ,,	1/1½	do.
	45	half-chests Broken Pekoe	... ,,	1/1½	do.
	8	chests Congou	... ,,	/11	do.
	10	,, broken tea	... ,,	/10½	do.
	22	half-chests ,, ,,	,,	/10¼	do.
	22	,, ,, ,, Pekoe	... ,,	1/1½	do.
	15	,, ,, Pekoe Dust	... ,,	/7	do.
	8	,, ,, Dust	... ,,	/4½	do.
	30	,, ,, Pekoe	... ,,	1/1¾	do.
Hope	25	half-chests Pek. Sou.	... ,,	1/3¼	
	17	,, ,, Bro, Pek.	.. ,,	1/3	
Windsor for GHDE	19	chests Bro. Pek.	... ,,	1/7½	
	6	,, Pek. Sou.	... ,,	1/2½	
	19	,, Bro. Pek. Sou. about	... ,,	1/1 aftersale	
	21	,, Souchong	... ,,	1/1½	do.
	4	,, Bro. Sou.	... ,,	/11½	
	18	,, Dust	... ,,	/9½	
	14	,, Fannings	... ,,	/9	
	3	,, Fngss. Dust	... ,,	/7	
M R	2	,, Lots	... ,,	1/	

The brokers say that, while the make is good, the infusion is still very inferior, particulary that marked M.R. although the leaf of this lot is pretty enough. The buyers were various, and an offer made after the sale of the C. C. L. tea at an advance of ¾d. per lb. did not secure the parcel, which was purchased for some firm in the North. The bidding was brisk and the inclination to deal with the article very apparent. The verdict of the public from all quarters is that Ceylon tea has a "smoky" flavour. This is the fault of the fermenting, and until further care is exercised in this branch the private sales, resting on the merits of the pure article solely will be limited.—Yours faithfully,

HUTCHISON & Co.

COPPER IN MATALE.

Matale, 26th Dec. 1881.

DEAR SIR,—I see that attention is being paid to the subject of copper ore, and I will be glad if you will tell me if the enclosed is a piece of copper pyrites. There is plenty of it here, in large and small pieces, at times, to be picked up. With regard to its being found in pockets, some time ago my attention was attracted by a burnt appearance on the face of a large rock, and, on picking at it with a knife the crust broke, and inside, in a neat hollowed out space, I found a quantity of green powder, which I soon discovered was mixed with a bright metal, and on applying fire to the powder it burnt up, giving out a strong smell of sulphur. Mr. Dixon analyzed it, and declared it to be a mixture of sulphur, tellurium, copper pyrites and some other substances. I have since discovered the same stuff cropping up in a reef, which readily burns in dry weather. I think, if trouble were taken, the pyrites could be found in considerable quantities.—Yours faithfully, YOU KNOW WHO.

P. S.—Since I enclosed this, I have procured some of the sulphurous earth. The reef in which it appears seems to be a sulphur rock. I will send it to you when it is dry.

[The enclosure, if any was made, has failed to reach us. We know that Mr. Dixon mentioned he had found copper in samples sent him from our correspondent's neighbourhood.—ED.]

HOW TO COMBAT COFFEE LEAF-DISEASE: VALUABLE HINTS IN PRUNING AND MANURING.

Yoxford, Dimbula, Dec. 26th.

DEAR SIR,—Mr. Marshall Ward's dictum that manure is in no sense a cure for leaf-disease is probably a correct one. At the same time, my own experience is that a proper manure enables the trees to pass through an attack of leaf-disease comparatively uninjured. The question, therefore, is what is a proper manure, and this, I believe, cannot be answered, in a thoroughly satisfactory manner, for every estate, without the proof of accurate experiment. In this connection, I hope shortly to send you the results, so far as they go, of a series of experiments laid down here on the Rothamstead system and as recommended by M. Ville. Mr. Talbot says that what we want to know is how to get our wood ready for blossoming in January, and, as this has been my chief aim for some time, and accompanied, I think, I may say, by a fair measure of success I will say what I consider chiefly necessary for the attainment of this object. In the first place, I consider that the pruning should be completed by the end of March or the middle of April. This is not only necessary to give the trees the required impetus for the setting of the blossoms, but also to clear the way for manuring operations which should be begun in May. I should like to say a good deal upon the subject of pruning, but space will not permit. However, I would ask the advocates of heavy pruning what they hope to gain by cutting off wood which is in a condition to bear crop and which has at the expenditure of considerable energy, stored up within itself the food drawn from the soil for many previous months, with the object of producing blossom and maintaining the crop when set. If handling has been systematically done previously, there will not be any matured wood going in a wrong direction. In my own practice I handle steadily from about the middle of June up to crop time and again just before pruning where the trees are thick.

However, pruning being over and all made ready for the application of manure by May, my experience here and elsewhere leads me to the opinion that all backing up of crop should be completed by the end of June, or it will fail of its full effect, and after that that the fields which are to be pushed forward for the next season be dealt with. In high-lying coffee the manure should be in before the middle of

July at latest; at lower elevations it may be applied up to the middle of August. At high elevations, *i.e.* 4,200ft. and upwards, less nitrogen should be used than lower down, as the trees do not require any extra forcing to make wood, having only too great an inclination to do so naturally. I have seen a good many estates being manured in the early months of the year, which appears to me an unscientific proceeding, for, during the dry blossoming months, the trees are not drawing actively upon the soil, but living upon the food previously stored up, and, if the trees were to find their stimulus at this time, the effect would be to throw them into full leaf just at the time when leaf-disease was becoming active. I may mention that the only pieces of coffee which seem to suffer after crop here are those which were manured before the commencement of the true growing season. As most of the Dimbula coffee is above 4,200 ft., I should say put in the manure before the end of June (unless you have at hand a very quick acting manure) and after that date resort to forking and application of lime for the occupation of the coolies.

Though leaf-disease passed over all my manured fields, to a greater or less extent, yet where the manure used was a complete one and applied before the end of June the trees appeared to suffer very slightly. One piece of coffee, in which I had experimented with a patent manure sent to me for trial, stood out prominently, the coffee all round it suffering considerably, while this remained a dark green, losing but little leaf; and it has since matured a crop of 6 cwt. an acre and promises to give a good deal more this season. In applying manure, I advocate strongly the forking-in system, which I have practised for over six years. I have increasing proof of its advantage over the old custom of holing. I fear I may be thought somewhat conceited in thus giving out my views, but, as the majority of the ideas were taught me by better men than myself, and I have put most of them to practical proof on this and various other estates which have come under my control, I hope that, writing, as I have done, for the general weal, I shall be exonerated. Wishing you all the compliments of the season,—I remain, yours faithfully,

W. D. B.

TRAVANCORE AND COFFEE EXPORTS. I.

Travancore, 27th December 1881.

DEAR SIR,—Messrs. Alstons of Tellicherry have been sending you a list of exports of coffee from the Malabar coast. If their list is as inaccurate for the rest of the coast, as it is for Travancore, it may be, as you say, interesting; but I question its being instructive.

My coffee does not go to Colachel: it goes to Quilon. A neighbour of mine sends his to Tuticorin: another sends to Coimbatore; northern estates, no doubt, ship via Alleppy. But Messrs. Alstons assert—and not only they, but you too, sir, who ought to know better—that Colachel is the only port for Travancore. This is very severe on Alleppy and Quilon. The inhabitants of the latter port, I know, are just making up their minds to their becoming inevitably the first port on the coast when they get their railway and harbour; and yet you ignore their existence altogether.

It is true we have not much to boast about in Travancore: generally speaking, we are despised and rejected of men. But we exist; we jog along: to ourselves, in our ignorance, we seem to do as well as our neighbours. On this side the Pamban Channel we certainly do not assert that, if a product is produced in Travancore, it must, on that account, be immeasurably superior to the same product produces anywhere else. Nevertheless we do acknowledge to a weakness for turning when we are trampled on; and if you won't let us alone, we must defend ourselved

No doubt you have, on your editorial table, a copy of the last Travancore Administration Report. Kindly take it up, and you will see on page 26 that Travancore paid during the year in question the sum of R22,084 in export duty, which represents at 8as. per cwt. an export of 44,168 cwt. You credit us with 11,000 cwt. The Government have mulcted us at the rate of 4 cwt. per acre; you say we only grew 1 cwt. per acre. Do you think it at all probable, sir, if I went into the presence of the Dewan with Messrs. Alstons' list in one hand and the *Ceylon Observer* of Dec. 5th in the other, that he would refund to me any of the extra export duty I paid last year? Please print this and much oblige your obedient servant, A TRAMPLED-ON POOCHY.

[Once again, why do our correspondents not send us the coffee export returns for Alleppy and Quilon as well as Colachel, for a series of years, in place of writing "long yarns"? It is impossible to do justice to Travancore until the statistics, which our correspondents can easily procure, are forwarded to us.—ED.]

II.

31st Dec. 1881.

SIR,—In a recent issue of your paper, I note a return of coffee shipped from the Malabar coast during last year, in which Colachel is given as the only port of export for Travancore, and the shipments from there, in an editorial remark, compared with the acreage under cultivation, in such a way as to show an average of only 1 cwt. an acre for Travancore. This return is misleading and incorrect. It takes no notice of Alleppey, Tuticorin and Quilon. From the latter alone, I know that over 10,000 cwt. were exported last year. Deducting abandoned coffee, the shipments from Quilon and Colachel alone would average over 2 cwt. an acre on the area now under cultivation in South Travancore. This is by no means all, however. On page 26 of the Travancore Administration Report for the year ending August 1880, the duty collected on coffe exported during the year is given at R22,084, which means an export of 44,168 cwt. or something over 3 cwt. an acre on the whole bearing area in Travancore.

A return, such as that of Messrs. Alstons & Co., appearing with the authority which a prominent place in your paper gives it, is apt to convey a false impression of the country, and, although, we have no crops which cause us in the least to feel proud, still we should like, when our statistics go forth to the world, that they bear some semblance to the truth.

TRAVANCORE.

NUTMEG CULTIVATION.

Udagama, Jan. 15th, 1882.

DEAR SIR,—I have sent a pamphlet to Dr. Trimen, on nutmeg cultivation, which was given to me by Mr. W. H. Reade of Singapore. It was written very many years ago, and describes the introduction of the spice from Amboyna into Sumatra and the Straits, and has a very practical description of the manner of cultivating that spice, and cloves. I have desired Dr. Trimen to forward it to you, as you may like to publish it in the *Tropical Agriculturist.* I have now planted and well established in this district over 4,000 young nutmeg plants. In 1882 this number will be doubled, which, judging from the trees in the surrounding villages, will, when they come into bearing, give very large returns.—I remain, yours faithfully,

T. S. DOBREE.

[The information respecting nutmeg cultivation will readily find a place in the *Tropical Agriculturist.*—ED.]

COFFEE PLANTING IN JOHORE: A CORRECTION.

SIR,—A paragraph which appears in the December number of the *Tropical Agriculturist* is somewhat misleading, and I should be glad, if you will kindly publish this correction. It is stated :—"We are sorry to hear bad news from Johore. The large clearing of the Company of that name, under Mr. Watson's auspices, at an elevation of about 700 feet above sea-level, has been condemned for coffee Arabica.....Mr. Dobree's report was so unfavorable that the directors decided to plant no more ordinary coffee at this elevation, if they do not abandon what has already been put out."

The only clearing on which Mr. Dobree reported formally, as far as I know, was that of the "Pulai Planting Company." It could hardly be the "Johore Company," which is in quite another district, and about the planting of which there has been no question. As to the Pulai Planting Company, the elevation of the clearing is from 700 to 1,400, and so far from Mr. Dobree's report having induced the directors to abandon the clearing, they are now pushing forward the planting up of 30 acres more with coffee Arabica to complete the 150 acres they originally decided to plant. On the portion already planted, I am happy to say the coffee is looking strong and well, and very forward for its age.—I am sir, yours faithfully,

ONE OF THE DIRECTORS.

LEDGERIANA SEED.—At Mr. Symons' sale at noon today (Jan 13th) of the Ledger seed advertized, only a portion of it was sold at R15&R12 per box of two grammes.

ARTESIAN WELLS IN AUSTRALIA.—We have before us a photograph of the outlet and standpipe of an artesian well at the town of Sale, Gippsland, Victoria, the depth of which is 232 feet, diameter of borne 2 inches and daily outflow 46,000 gallons. The water runs 43 feet above the surface and is fresh, pure and palatable. The well was sunk by the direction of the Brough Council in 1880 and cost £300 instead of £30,000 required for the construction of a tank and channels for an ordinary water supply!

QUININE IN DISEASES OF THE EYE.—In the *Scientific American* for June 1881 toere is a review of a work on the ophthalmic use of quinine and its therapeutic action, from which it appears that not only in ophthalmia but in cases of extraction of cataract and other surgical operations quinine is of great value. Dr. Sibley Campbell believes the curative action to be due to the direct action of quinine on the vascular system, through its power of contracting the smaller bloodvessels, especially on the smaller arteries. As our readers are aware, the great use of quinine in fever is its power of rabidly lowering the temperature of the body. On the vascular system it acts as a *constringent*. Hence its value as an application in diseases of the eye. Day by day new uses for this substance are being discovered.

A TEST FOR LIME IN SOILS.—Sir—Can you or any of your readers give a simple test to discover whether a particular soil is deficient in lime? If no such test exists, can you state the best analyser and probable cost of a qualitative analysis?—NEW CUMA. [Grind soil to a mortar, and place a small quantity of the substance in a glass vessel; add some dilute hydrochloric acid, and agitate for a few minutes. Allow the mixture to settle, and then decant a portion of the clear liquid into a test tube or other glass, and breathe into the liquid through a tube (a clean straw will answer the purpose). If lime be present in quantity the clear liquid will become cloudy, but if there be only a trace of lime in the soil no change will be noticeable. The explanation of this is—the carbonic acid of the breath unites with the lime, forming carbonate of lime.—ED. *Australasia*.]

TROPICAL READING BOOKS.

THREE SERIES.*

These Reading books contain carefully arranged and pleasantly selected short chapters on subjects as familiar to a child in a tropical country as snow, holly, apples or daisies are to one in the old country. They are in fact easy and interesting lessons on familiar objects with a large number of good illustrations. Thus, in Book I, we find, amongst the 79 titles of chapters such headings as: Cocoa-nut, Pepper, Job's Tears, Gandasi and her Puppy, Tou's Bad Habit, Spinning Tops, Calabashes, Mango Stalks, Date Palm Tree, The Cat and her Master's Bags, The Banyan Tree, Christopher Columbus, and Alick's Humming Bird.

Book II becomes still more instructive as well as entertaining. It consists of nearly 200 pages and contains 56 chapters, some few being poetry. Several chapters are devoted to animals and insects, such as ants, crocodiles, monkeys, mosquitoes, and bees; then we have interesting biographical sketches or anecdotes, very interesting stories with a moral; pieces on the uses and properties of various vegetable products, cacao, the cocoa-nut, cassava, india-rubber, the sugar-cane, plantain and soap berries. Another attractive element in the book is the large amount of conversation introduced. Beth Gelert and Little Jim, or the Collier's Home are the best poems in the Second book.

The Third book contains fewer object lessons, so to speak, but takes the reader to many lands, and introduces him to various domestic scenes or national amusements, gives a chapter to the Telephone and Mieroscope, to a Coal fire and to Gas in London, others to English houses, the Polytechnic, the Jamaica Robin Redbreast, the Poor Men's Weather Glass and an English Winter's Day in January. It contains valuable reading that would interest older people quite as much as the young student, and deserves to be generally used in the Tropics.

(Extract from Book II.)

XVI.—GUINEA-GRASS IN JAMAICA.

Tri-fling—unimportant, of small value.
Flour-ish—grow luxuriantly, thrive.
Il-lus-trate—explain, set in a clear light.

Very great results will sometimes arise from very trifling causes, and as it is interesting to trace the origin of things in the different countries in which they flourish, I will, to illustrate this, tell you how the tall, waving guinea-grass, on which horses and cattle so delight to graze, found its way into Jamaica.

A native of Africa, it was brought to the West Indies in a very strange manner.

A gentleman, named Mr. John Ellis, sent to the coast of Guinea, in Africa, for some birds, and at the same time for some seed on which to feed them.

The birds died, and the seeds were thrown away as useless, but instead of being useless beautiful grass sprang up from them, and to this grass Mr. Ellis led his horse and cow.

They not only eat the new herbage greedily, but grew fat upon it.

The Guinea-grass was transplanted into a garden, begun to be cultivated in the island, and thence, no doubt, was transplanted into other islands.

You all know what a useful plant it now is.

Questions:—

Of what country is Guinea-grass a native?
How was it brought to Jamaica?

* "Tropical Reading Books, in Three Books," published for use in the West Indies and elsewhere. Compiled by E. C. Phillips. Price in England Book I 9d., and Books II or III 1s.

FLOWERS FOR THE TROPICS.

(From *Sutton's Tropical Garden Guide.*)

(Continued from page 656.)

BARTONIA.

A free flowering and showy plant, requiring plenty of water, a rich soil, and a sunny position. Sow in October, and transplant to the border.

BRACHYCOME (SWAN RIVER DAISY.)

A very pretty dwarf annual: flowers in great profusion. Sow in October, and plant out 3 or 4 together in the border. Very useful also for edgings.

BROWALLIA.

An effective annual of upright growth, producing a profusion of blue and white flowers. Sow in October.

CACALIA.

A very pretty annual, common in Indian gardens. Always blooming.

CALANDRINIA.

This showy annual produces beautiful crimson umbels of flowers. Do not transplant. Sow in a sunny spot in October.

CALCEOLARIA.

The strains of this beautiful annual have been greatly improved by us.

CANDYTUFT.

This may be cultivated in India with considerable success. Sow at the end of the rains, where they are required to flower, and thin out to 3 inches apart. A friable rich soil, and watering freely, are necessary. The plants flower during the cold season.

CHRYSANTHEMUM.

A well-known flower, attractive in borders, and should be in every garden. Sow in October, and transplant 3 together.

CALLIRHOE.

A showy annual, producing a great number of bright crimson blossoms. Sow in October, and plant out 3 or 4 together. Thrives remarkably well about Calcutta.

COCKSCOMB.

A handsome and showy plant. Will grow well either in pots or in the open ground, in good rich soil. Sow in July to bloom in December.

CINERARIA.

Sow early in October, as this plant cannot stand the hot season. Is a most valuable plant, but requires frequent shiftings and a good rich soil in a shady spot.

CLINTONIA.

A dazzling and beautiful annual, suited only to pots and rock work. Light, sandy soil required. Plant 3 together in pots, using plenty of well-rooted manure. Thrive best if the pots are stood in pans of water.

COLLINSIA.

This annual, when in full bloom, is an effective border plant. Grows from 6 to 12 inches high. Sow in October to bloom at the end of January.

CLARKIA.

This well-known annual should be in every garden. Requires good soil and plenty of manure. Sow in October.

CONVOLVULUS MAJOR.

A splendid class of climbing plants, very useful for trelliscs, verandahs, &c. Great variety of colour. Requires good rich soil. Sow in October.

CONVOLVULUS MINOR.

Most useful and effective in clumps or beds. Sow in October on rich soil.

COREOPSIS.

This well-known annual should have a place in every garden; is very brilliant in colour, and remains in bloom for a long time. Sow in October, and plant out when 3 inches high. Comes into bloom in March.

CENTAUREA.

The seed should be sown in October, and transplanted into the border, in good, rich soil, as soon as large enough.

DATURA.

A magnificent annual, with large trumpet-shaped flowers; very sweet scented. The plants will grow for some time after flowering, but should be destroyed. Sow in July.

DIANTHUS. (INDIAN PINK).

Sow about the middle of the wet season on friable, rich soil. If the rainfall is heavy protect from wet; a moist atmosphere will cause them to damp off.

ESCHSCHOLTZIA.

A very showy plant; comes to great perfection in Upper India during the cold months. Sow in October, and do not transplant afterwards.

ERYSIMUM.

A showy annual, especially suitable for large beds or mixed borders. Sow in the border in October.

EUTOCA.

A profuse blooming annual, bearing clusters of bright blue flowers. Thrives best on light soil. Sow in October.

GERANIUM (OR PELARGONIUM).

Sow any time during the rains.

GILIA.

A straggling plant, very useful for clumps: produces tufts of flowers. Sow in October.

GLOXINIA.

A mixture of leaf mould and sand with good yellow loam is required for successful cultivation. Sow the beginning of the rains in pans or pots, and transplant as soon as large enough.

GODETIA.

A splendid free flowering annual, suitable for rock-work or bedding.

GYPSOPHILA.

Dwarf annuals, suitable for bouquets. Sow in October.

HAWKWEED.

A very showy annual, producing large flowers. Sow in October.

HELICHRYSUM.

These everlastings are easily cultivated, and are useful for indoor decoration. Height from 2 to 3 feet. Sow in October.

HIBISCUS.

A beautiful annual of trailing growth. Sow in October on a light, sandy soil.

HOLLYHOCK.

This should be cultivated in a good rich light soil, otherwise it does not grow well. Sow in October in the open ground, as the plants do not bear transplanting.

KAULFUSSIA.

A dwarf and pretty annual; useful for edgings. Sow in October, and plant out when 2 or 3 inches high.

IPOMŒA.

A beautiful class of climbers, admirably adapted for verandahs, trellis-work, &c. Should not be grown on the same spot two years in succession. Sow early in July.

LARKSPUR.

This is a beautiful annual, with many shades of colour, producing a good effect in a garden. The flowers grow on hyacinth-like stems, and form a compact and showy spike. Sow in the early part of December.

LEPTOSIPHON.

A profuse blooming dwarf annual. Sow in October.

LINARIA.

A pretty dwarf annual, bearing a profusion of small flowers. Sow in patches in October.

(To be continued.)

NUTMEG CULTIVATION:

REPORT ON THE CULTIVATION OF SPICES AT BENCOOLEN.

By J. Lumsdaine in 1819-1820.

[The first leaf with the introductory portion of this report has fallen to pieces, parts of which have been lost, so that we must perforce begin at paragraph 3, but nothing of any material consequence is lost.—Ed.]

3. The geographical position of this Island, its local adaptations, and the general influence of its sky and climate on the vegetable kingdom, but above all, the similarity of the latter to that of the Moluccas, induced a belief that the spice trees would thrive as prosperously in these districts as in their native clime. Accordingly, the Deputy Governor in Council of Port Marlborough despatched in 1796 a small vessel to Amboyna for the purpose of throwing in supplies into that garrison, and returning with spice plants, owing, however, to some untoward accident on the voyage, it was necessary to bear away for Prince of Wales's Island, where the vessel was declared not seaworthy, and thus the object of the mission was frustrated. It was nevertheless re-attempted and accomplished in 1798 by the ship "Phœnix," which landed 346 nutmeg and 66 clove plants at Fort Marlborough, the whole of the former and two-thirds of the latter being in a vigorous healthy condition. Those were distributed to such of the gentlemen of the Settlement and natives as engaged to take care of them, and a few were sent to the out Settlements, in order to ascertain the soil most favourable to their culture. A considerable share fell to the lot of Mr. Edward Coles, by whom they were planted out at Paunatang Ballam in virgin forest land, where the most forward of the nutmeg trees blossomed and perfected its fruit towards the close of the year 1803. The cloves pined and dropped off in rapid succession. Out of the whole number, four only arrived at maturity, one of which flowered in 1803, and the most vigorous of them did not survive the 18th year. Numbers of these trees perished from neglect and improper management, for, unfortunately, Mr. Jones, Commercial Resident at Amboyna, stated in his letter to this Government under date the 5th June 1798, that the spice trees required little or no care in their cultivation.

4. Notwithstanding the indifferent success attending this first essay from the loss of numbers of the plants, the general result was satisfactory, and inspired a belief that these valuable exotics might by perseverance and increased attention become naturalized to the soil. An opportunity of putting this to the test of further experiment accordingly presented itself in 1803, in which year the late Mr. William Roxburgh reached the Settlement with a supply of upwards of 22,000 vigorous nutmeg plants, and between 6 and 7,000 clove plants from Amboyna, which were put under charge of the late Mr. Charles Campbell for general distribution; but the applications for plants were so urgent, that they greatly overbalanced the stock imported.

5. The Settlement now assumed the resemblance of a busy agricultural community connected by one common link of reciprocal interest; the operations of commerce slackened for a while, and discussions on the properties of the soil were the daily topics of conversation. Unfortunately for agriculture, this, with the exception of the alluvial tracts, had suffered a sweeping verdict of condemnation, founded on a few unsuccessful attempts conducted by men perhaps who had neither sufficient leisure to attend to the subject, nor the inclination to go to the necessary expense to ensure a favourable result.

6. The soil throughout the plantations generally is a red mould with stony fragments or pebbles frequently intermixed with it, the surface of it in the forest alluvial and low lands being of a chocolate colour, varying in depth from 3 to 10 or 12 inches. In the former this is occasioned by the gradual spontaneous decomposition of vegetable matter, and in the latter by deposition of the finer parts of the mould of the mountainous and elevated slopes. After a long duration of dry weather, this brick-like mould, as it has been termed, is frequently found to be so stiff and unyielding as to require a good deal of labour to effect a mechanical division of its particles, so as to befit it for the purposes of agriculture; for it is doubtless true, that the texture or organization of the soil has a considerable influence on the growth of vegetables, be they herbaceous or ligneous. It is susceptible however of very great amelioration by means of tillage and appropriate composts, and indeed the soil of Ceylon, in which the cinnamon tree thrives so luxuriantly, is of the same description. The lowlands and swamps are highly productive, in proof of which it is sufficient to mention that the lowlands at Benturin were at one time under a course of culture for 20 years without a fallow. A marly-looking soapy soil is met with at the distance of 10 or 12 feet from the surface, which at a still greater depth is considerably indurated by the action of the waters that percolate through the ground in all directions, and in combination with sand forms the substance called nayal.

7. The mode of culture adopted in the different plantations is nearly the same. The beds of the trees are kept free from grass and noxious weeds by the hoe, and the plough is occasionally run along the interjacent spaces for the purpose of eradicating the lallang (Andropogon Caricosum) which proves greatly obstructive to the operations of agriculture. The trees are generally manured with cowdung and burnt earth once a year in the rainy season, but the preparation of suitable composts and their mode of application are but imperfectly understood. The pruning knife is too sparingly used; very few of the planters lop off the lower verticels of the nutmeg trees or thin them of the unproductive and straggling branches.

8. The site of a plantation is an object of primary importance, and doubtless the alluvial grounds are entitled to preference from the acknowledged fertility of their soil and its appropriate organization and capability of retaining moisture, independent of the advantage of water carriage. Several of the nutmeg trees of the importation of 1798 at Moco Moco are placed in soil of this description; although never manured they are in the highest state of luxuriance and bear abundantly; and I have been informed by a gentleman recently arrived from that station, that the stem of one of them measures 38 inches in circumference. Some of the trees in my own experimental garden corroborate the truth of this assertion: one of these blossomed at the early stage of two years ten months and a half, a degree of precocity ascribable solely to its proximity to the lake which forms the southern boundary. This was the first tree that blossomed of the importation of 1803, which consisted of upwards of 20,000 nutmegs plants. Next to the alluvial deposits, virgin forest land claim pre-eminence, their surface being clothed with a dark-coloured carbonized mould formed by the slow decay of falling

leaves and mouldering trunks of trees; and next to these are to be ranked the open plains. Declivities are objectionable from the risk of the precipitation of the mould and manure into the subsequent ravines by the heavy torrents of rain that occasionally deluge the country. Above all, the plantation must be protected from the southerly and northerly winds by a skirting of lofty trees, and if nature has not already made this provision, no time should be lost in belting the ground with a double row of the casuarina littorea and cerbera manghas, which are well adapted for this purpose. This precautionary measure will not only secure the planter against eventual loss from the falling-off of the blossom and young fruit in heavy gales, but will prevent the uprooting of the trees, a contingency to which they are liable from the slender hold their roots have of the soil. If the plantation is extensive, subsidiary rows of these trees may be planted at convenient distances. No large trees whatever should be suffered to grow among the spice trees, for these exclude the vivifying rays of the sun, and arrest the descent of the salutary night dews, both of which are essential to the quality and quantity of the produce. They further rob the soil of its fecundity, and intermingle their roots with those of the spice trees. It is true that by the protection they afford they prevent frequently the premature bursting of the husk occasioned by the sudden action of a hot sun upon it when saturated with rain; but the loss sustained in this way is not equal to the damage that spice trees suffer from these intruders. Extensive tracts of land are to be met with in the interior of the country well adapted for the cultivation of the nutmegs and cloves, and to these undoubted preference is due.

9. In originating a nutmeg plantation, the first care of the cultivator is to select ripe nuts and to set them at the distance of a foot apart in a rich soil, merely covering them very lightly with mould. They are to be protected from the heat of the sun, occasionally weeded, and watered in dry weather every other day. The seedlings may be expected to appear in from 30 to 60 days, and when four feet high, the healthiest and most luxuriant, consisting of 3 or 4 verticels are to be removed in the commencement of the rains to the plantation previously cleared of trees and underwood by burning and grubbing up their roots, and placed in holes dug for their reception at the distance of 30 feet from each other, screening them from the heat of the sun and violence of the winds. It is a matter of essential importance that the ground be well opened and its cohesion broken, in order to admit of the free expansion of the roots of the tender plants, and that it be intimately mixed with burnt earth and cow manure, in the proportion of two-thirds of the former to one-third of the latter. The plants are to be set in rows as well for the sake of regularity, as for the more convenient traversing of the plough, which is now to be employed in clearing the intermediate spaces of lallang and other noxious grasses, carefully avoiding to trespass on the beds of the trees. They must be watered every other day in sultry weather, manured annually during the rains with four garden baskets full of the above-mentioned composts to each tree, and protected from the sun until they attain the age of five years. They will now be sufficiently hardy to bear the sun, and from that age until their fifteenth year, the compost should consist of equal parts of cowdung and burnt earth, and from 8 to 12 baskets full will be required for each bearing tree, a lesser proportion being distributed to the males. From the power of habit the trees will after the 15th year require a more stimulating nutriment; the dung ought not therefore to be more than two or three months old, and the mixture should consist of two parts of it to one of burnt earth, of which the suitable proportion will be from 12 to 16 baskets to each tree biennially. In all cases the prepared compost must be spread out in the sun for 3 or 4 days previously to its application, in order to destroy grubs and worms that may have lodged in it, and which might injure the roots of the plants.

10. In all plantations, whether situated in forest land or in the plains, the necessity of manuring at stated intervals has not been found indispensable, and is indeed identified with their prosperity. The proper mode of applying it is in a circular furrow in immediate contract with the extremities of the fibrous roots which may be called the absorbents of the plant. Where there is a scarcity of dung recourse may be had to the dregs remaining after the preparation of the oil from the fruit of the Arachis Hypogora in mixture with burnt earth, which is a very stimulating manure; or composts may be formed from the decomposition of leaves or vegetable matter of any description. A very fertilizing and highly animalized liquid nutriment for plants is obtained by macerating human ordure in water in proper pits for 4 or 5 months, and applying the fluid to the radical absorbents of the plants. Seaweeds and many other articles may also be resorted to, which will readily occur to the intelligent agriculturist.

11. During the progressive growth of the plantation, the beds of the trees are to be regularly weeded and the roots kept properly covered with the mould, for these have a constant tendency to seek the surface; the growth of the lateral branches alone to be encouraged, and all suckers or dead and unproductive branches are to be removed by the pruning knife, so as to thin the trees considerably, and to admit of the descent of the night dews which are greatly contributive to their well being, especially during the dry and sultry weather; creepers are to be dislodged, and the lower verticels lopped off, with the view of establishing an unimpeded circulation of air. The conclusion of the great annual harvest is the fittest time for pruning the trees. After the eradication of the lallang, the growth of innoxious grasses is to be encouraged in the intervals between the trees, which will give the plantation the appearance of a park, and the plough is now to be abandoned.

12. The nutmeg tree is monoecious as well as dioecious, but no means of discovering the sexes before the period of inflorescence are as yet known. The relative proportion of male and female trees to each other is also undefined, and is indeed the result of chance. Setting aside however all pretensions to mathematical precision, the number of productive trees may be roundly estimated at two-thirds of the whole cultivation. However presumptuous it may appear to arraign the operations of nature, I cannot but think that, with reference to the genus Myristica, she has made a most unnecessary provision in the creation of so many male trees, since the monoecious plants are fully as susceptible of the rapturous impulse of connubial bliss, and equally competent for the purposes of ardent and successful love. The number of male trees therefore necessary to be retained will depend entirely on that of the monoecious kind; all above this number being considered as superfluous should be cut down, and other trees planted in their stead. Were I indeed to originate a nutmeg plantation now, I should either attempt to procure grafts on male stocks from such trees as produce the largest and best fruit, by the process of inarching, notwithstanding the speculative hypothesis of the graft partaking of the gradual and progressive decay of the parent tree, leaving a branch or two of the stock for the purpose of establishing a regular polygamy, by which means the plantation would consist of monoecious trees only, or I should place the young plants in the nursery at the distance of four feet from each other, and force them to an early discovery of their sex, by lifting them out of their beds once a year and replacing them in the same spot, so as to check the growth of wood and viviparous branches. The sex might thus be ascertained on an average within the fourth year, and the trees removed

to the plantation and systematically arranged, whereas in the usual mode of proceeding it is not ascertainable before the 7th year in general.

13. Upon an average the nutmeg tree fruits at the age of 7 years, and increases in produce till the 15th year, when it is at its greatest productiveness. It is said to continue prolific for 70 or 80 years in the Moluccas, but our experience carries us no further than 22 years and a half, all the trees of which age that have been properly managed, are still in the highest degree of vigour and fecundity; and for this reason no term for planting a succession of trees can as yet be fixed upon. Seven months in general elapse between the appearance of the blossom and ripening of the fruit, and the produce of one bearing tree with another under good cultivation may in the fifteenth year of the plantation be calculated at five pounds of nutmegs, and a pound and a quarter of mace. I have observed however that some trees produce every year a great quantity of fruit, whilst others constantly give very little. It bears all the year round, but more plentifully in some months than in others. The great harvest may generally be looked for in the months of September, October, November and December, and a small one in April, May and June. Like other fruit trees on this portion of Sumatra, I have remarked that it yields most abundantly every other year. The fruit having ripened, the outer integument bursts spontaneously, and is gathered by means of a hook attached to a long stick, and the mace being cautiously stripped off, and flattened by the hands in single layers, is placed on mats for 3 or 4 days in the sun to dry. Some planters cut off the heels and dry the mace in double blades, from an opinion that the insect is apt to breed in or about the heels, and that the double blade gives a better and more substantial appearance to the mace. The former idea is entirely groundless, for if the article be properly cured, kept in tight packages, in a dry situation and exposed to the sun for 5 or 6 hours once a fortnight, there need be no apprehension of the insect; and if it is not, it will assuredly be attacked by it whether the heels be cut off or not; again, the insect is much more likely to nestle within the fold of the double blade, and the fancied superiority of appearance has so little weight with the purchaser as not to counterbalance the risk of probable deterioration and eventual loss. In damp and rainy weather the mace should be dried by the heat of a charcoal fire carefully conducted, so as not to smoke it or blacken its surface.

14. The nuts liberated from their macy envelope are transported to the drying house, and deposited on an elevated stage of split neebongs placed at a sufficient distance from each other to admit of the heat from a smouldering fire beneath, without suffering even the smallest nuts to pass through. The heat should not exceed 140 of Fahrenheit, for a sudden inordinate degree of heat dries up the kernels of the nuts too rapidly, and its continued application produces fissures in them; or a fermentation is excited in them, which increases their volume so greatly as to fill up the whole cavity of the shell, and to prevent them from rattling when put to this criterion of due preparation. The fire is lighted in the evening and kept up for the whole of the night. The smoking house is a brick building of a suitable size with a terraced roof, and the stage is placed at an elevation of ten feet from the ground, having three divisions in it for the produce of different months. The nuts must be turned every second or third day, that they may all partake equally of the heat, and such as have undergone the smoking process for the period of two complete months and rattle freely in the shell, are to be cracked with wooden mallets, the worm-eaten and shrivelled ones thrown out, and the good ones rubbed over simply with recently prepared well-sifted dry lime. They are now to be regarbled, and finally packed for transportation in tight casks, the insides of which have been smoked, cleaned, and covered with a coating of fresh water and lime. If packed in chests, the seams must be dammered to prevent the admission of air or water. There is no necessity for sorting them, as previously to their sale, they are classed into sizes in the Company's Warehouses in London.

15. The mode generally practised in preparing nutmegs for the market, is to dip them in a mixture of salt water and lime, and to spread them out on mats for 4 or 5 days in the shade to dry. I am however convinced from much experience that this is a pernicious practice, not only from the quantity of moisture imbibed in this process encouraging the breeding of insects and rendering the nuts liable to early decay, but from the heating quality of the mixture producing fissures and occasioning a great loss in the outturn; whereas by liming them simply in the dry way as I have recommended, the loss ought not to exceed 8 per cent. In May 1816, I made some experiments on this subject. I cracked a quantity of nutmegs that had been smoke-dried for two months, and distributed them into four equal portions. I prepared the nuts of one parcel with a mixture of lime and salt water; those of the second were rubbed over merely with fine well-dried shell lime, such as the natives use with their betel, although I have no doubt but that recently prepared and well-sifted common lime would answer equally well; those of the third parcel were mixed, unlimed with one-third of their weight of whole black pepper; and those of the fourth also unlimed with the same proportion of cloves. They were then put into separate boxes with sliding tops, and numbered 1, 2, 3, and 4, in the order I have mentioned them. At the expiration of the first year they were all sound. After that of the second, I found three worm-eaten nuts in No. 1, and two in No. 3, but those in Nos. 2 and 4 remained untouched. The injured nuts were allowed to remain, and after the lapse of the third year, five worm eaten ones were discovered in No. 1, three in No. 3, and two in No. 4, those in No. 2 being in their original state. Four years and four months have now elapsed since the commencement of these experiments, and upon examining the several parcels the other day, the number of decayed nuts has not increased in Nos. 1, 3, and 4, those in No. 2 are as good as the day they were put into the box. These experiments not only prove the superiority of liming in the dry way, but also the fact that the progress to general decay in a heap of nutmegs, even after the insect has established itself, must be a work of years. In the shell they will keep for a great length of time. I have myself kept them in this state for six years, and when cracked they were found perfectly sound. From the report of the London brokers, however they will not answer in Europe on account of the heavy allowance for shells, which is one-third of the weight; but the Chinese merchants are in the daily habit of exporting them to Penang and China, where they are in request. It is stated on the best authority, that unlimed or brown nutmegs as the Dutch denominate them, mixed with cloves as in experiment N° 4 are highly esteemed in England, and even preferred by some to the limed produce; most probably from the greater facility of detecting the flaws in them in their naked state.

16. Although the clove tree attains great perfection in the red mould of these districts, it is more partial to a less tenacious soil. Its cultivation has

been established for many years in the West Indies and at Bourbon, and is of secondary importance only. The mother cloves are planted in rich mould at the distance of 12 inches from each other, screened from the sun and duly watered. They germinate within five weeks, and when four feet high are to be transplanted at intervals of 30 feet, with a small admixture of sand with the red mould, so as to reduce its tenacity, and are to be cultivated in the same way as the nutmegs, only that when full grown they require less manure in the proportion of one-third. They yield generally at the age of 6 years, and at that of 12 are in their highest state of bearing, when the average produce may be estimated at 6 or 7 pounds of marketable fruit each tree during the harvest, which takes place in the rainy months, but with us they have hitherto borne two crops in three years only. The fruit is terminal, and when of a reddish hue is plucked by the hand, so that the process of gathering it is tedious. It is then dried for several days on mats in the sun, until it breaks easily between the fingers, and assumes a dark brown colour. It loses about 60 per cent in drying. When past its prime, the clove tree has a ragged and uncombed appearance, and I am led to suppose that its existence is limited to 20 years, unless in very superior soil, in which it may drag out a protracted and unprofitable state of being to the period of perhaps 24 years. Hence it becomes necessary to plant a succession of seedlings when the old trees have attained eight years of age, and this octennial succession must be steadily kept in view.

17. With reference to the number of labourers, cattle and ploughs necessary for a plantation of 1,000 nutmeg for clove trees, after the ground has been thoroughly cleared of underwood and stumps of trees, I consider that 7 Chinese or Bengalee labourers, 50 head of cattle and 2 ploughs would be sufficient for all the purposes of the cultivation, with the exception of collecting the clove harvest, which being a very tedious process would require an extra number of hands, and indeed the best plan would be to gather it in by contract.

18. If the stamp of civilization is truly due to a nation only in proportion to its progress in agricultural improvements, this portion of Sumatra may justly be said to rank very low in the scale of civilized society. The causes of this backwardness are neither occult nor of difficult solution. They may be traced to the fostering of a spirit of commercial enterprize among the people, and to the facilities afforded them of purchasing supplies of grain at all times from the Company's Granary without subjecting themselves to the labours of the field in raising it. The general cultivation of rice, inasmuch as it leads to an increase of population, and to a reduction in the price of labour, is so intimately associated with the interests of the spice plantations, as to be inseparable from them; whilst it is the first step towards the amelioration of the country and the prosperity and happiness of its inhabitants. In order however to place the anticipated results of such laudable exertions beyond the risk of dubious issue, it becomes a measure of paramount policy to transfer the dispensation of the laws from the native chiefs to the British administration, to which the people ought to be tutored to look up as the fount of mercy, justice, and provident wisdom.

19. I have very great satisfaction in affording my individual testimony of the energy and zeal which actuate the great body of the planters, and of the correspondent improvement of their respective plantations; but in a report of this discription it would be as invidious to record the names of such as have been foremost in the race of emulation, as it would be unjust to particularize those, who acting under the restrictive orders of their constituents, have been compelled to yield the palm of their more successful competitors. Suffice it to say, that the plantations generally exhibit tokens of progressive amelioration, and that such of the trees of the importation of 1798 as have been duly cultured, are in the highest degree of health, vigour and productiveness.

20. It would be unreasonable to expect that such felicitous results could have been realized without proportionate sacrifices. In the first era of the speculation, the cultivators had to contend on the one hand with nature in exploring and eliciting the latent properties of a soil notable only for its supposed indomitable sterility; whilst on the other the problematical success of the undertaking and extent of capital requisite to conduct it to a prosperous issue, involved considerations of no trivial importance. It is to their industry, spirit and perseverance that we owe the naturalization of these valuable exotics, the established reputation of their produce both in Europe and India, which is equal, if not in some respects superior, to that of the Moluccas, the abolition of the odious monopoly and exclusive pretensions of the Dutch to this trade, and finally the assured possession to Great Britain of this promised scene of national and colonial wealth. I consider that I am within bounds in estimating the total amount of European and private capital in this speculation at 436,000 dollars and of native at 35,000 dollars from the first commencement of the plantations until the trees respectively came into bearing, but of this a considerable portion has been redeemed in produce.

21. The difficulty of hiring efficient labourers, the high price of labour, the want of capital, the length of time which must elapse before the cultivator reaps his produce, and the impracticability of obtaining a ready sale on the spot for it, in consequence of the depressed state of commerce, are the principal obstacles that have hitherto impeded, and still continue to impede the further extension of the plantations. If, however, the exigencies of the public service would admit of the transfer of Bengal convicts to the planters at such rate as would indemnify the company against any loss on this account; if Government would advance money to adventurers of good and steady character, secured on the lands, and payable in produce, if it would offer a fair equitable price for produce payable on the spot, or in Bengal, agreeably to the option of the cultivator; and if it would interpose its influence in obtaining a remission of the duties in England as has been effected in India through the exertions of the Honorable the Lieut.-Governor, there is every reason to believe, that the cultivation of the species might eventually be carried to double its present extent.

22. Having at length arrived at the conclusion of my labours and imparted all the information that at present occurs to me as worthy of record, I have to offer an apology for the prolixity into which I have been led from the interesting nature of the subject, and for the minuteness of detail into which I have judged it necessary to enter in some places, in order to prevent a misapprehension of my meaning. Both in cultivating and curing the spices, I have differed materially from the mode adopted by the Dutch, from a conviction of its inexpediency, but I have not recommended any plan in substitution, the superior utility of which is not sanctioned by my own personal observation and experience, or founded on solid and substantial data.

I have the honor to be, Sir,
Your most obedient servant,
(Signed) J. LUMSDAINE.

Fort Marlborough,
2nd September 1820.

(*For table, see next page.*)

ABSTRACT STATEMENT OF THE PUBLIC AND PRIVATE SPICE PLANTATIONS AT AND IN THE VICINITY OF PORT MARLBOROUGH FOR 1879-80.

	Above 20 years of age.		Between 10 and 20 years of age.		Between 5 and 10 years of age.		Total under 5 years of age, including plants in nurseries.	Total number of trees in cultivation.	Buffaloes.	Head of cattle.	Number of labourers employed.	Pounds in use.
	Total number.	Bearing trees.	Total number.	Bearing trees.	Total number.	Bearing trees.	Not bearing.

REMARKS.—The great decrease in the number of nutmeg trees this season has occurred in the planting districts and is owing partly to the extirpation of the unprofitable individuals. Numbers of plants have also been suffered to perish in the nurseries in consequence of a want of demand for them.

SIGNIFICANT.—The *Rio News* states :—"The general election in the 2nd São Paulo district resulted in the election of Sr. Moreira de Barros to the next General Assembly. Sr. Barros was one of the leading opponents of emancipation in the last parliament." São Paulo is the great coffee district of which Santos is the port.

TOBACCO FARMS (THE PUNJAB).—We see it stated that Messrs. Begg, Dunlop & Co. have renewed their lease, and for a long period, of the tobacco farms at Ghazipore, and Poosah. Tobacco manufactnre at these farms began only two or three years ago during which interval the monthly sales have risen from 2,184lb. to nearly 9,000lbs. Abont four hundred acres are under cnltivation. Most of the produee is sold in India. The tobacco industry is so very promising, and its progress has been so very difficult hitherto, that we are glad to take the present opportunity of directing public attention to this particnlar instanee of success.—*Civil and Military Gazette.*

THE NORTH BORNEO COMPANY.—There can be no doubt of the great importance and responsibility of the step taken by the Secretary of State in granting this charter, and it just shews how, in practiee, Liberal and Conservative, act pretty much alike when it comes to be a question of taking up new territory or allowing some other European nation to be before us. That was really the position in Borneo. If a British Protectorate were not extended over Mr. Dent's Company, there can be no doubt that the Dutch and Spanish would speedily extend their sway over North Borneo. Possibly they might be forestalled by a settlement of an even more warlike European nation; and it only requires a glance at the map, to see how little we could afford to have our trade in Chiuese and Japanese waters threatened from a vantage point like Borneo. It is bad enough to have Russia threatening British commerce from Vladivostock on the North, but it would never do to have to run the gauntlet of another great station in North Borneo. We think therefore that Lord Kimberley took the only wise course in granting the Charter and recognizing the need for a British Settlement in that region-

THE EXPERIMENT OF COOLIE IMMIGRATION has been tried in Fiji on a small scale, but the result appears to be rather disappointing. Sir A. H. Gordon believed that the Indian would be a cheaper labourer than the Polynesian, but, according to the *Fiji Times*, the coolie costs the planter £18 10s. per annum, while the Kanaka costs only £13. It would, however, be idle for the planter in the Northern Territory to look to Western Polynesia for a supply of labour. If the Indian coolies are not available, it may be necessary to resort to the Chinese after all. These industrious people, however, very soon acquire a just appreciation of their own value, and will not labour in the eane brakes for £3 or £4 a year, like a Fiji native, or for a Snider rifle and a supply of cartridges, like an unsophisticated Kanaka.—*Australasian.*

TERRACING IN TEA GARDENS.—The *Darjeeling News* writes :—Even in tea planting fashion exists, and the fashion, like all other fashions, varies from time to time. A few years ago there was almost a mania in these hills for terracing tea gardens, and it would be impossible even to hazard a guess at the amount of money wasted in constructing miles of nice looking terraces on land where such terraces were not only not required, but were positively injnrious. It was the fashion to constrnct terraces, and, rather than be out of the fashion, men used to bnild terraces on land nearly as flat as a billiard table. After a time a rnthless iconoclast appeared on the scene and preached a rnthless *jehad* against terraces. The fashion ehanged almost at once under the influence of the new prophet: all, or nearly all, the terraces in the hill portion of the district were levelled. Since then terracing has only been resorted to on ground really so steep as actually to require it; but the position seems about to ehange again, as on several new extensions in the distriet, terraces have been made on land which, if not absolutely level, slopes very gradually indeed, and on such land as nobody wonld have thought of wasting money on in making terraces where they were by no means required. The fashion is evidently beginning to change again, and probably before very long the old, costly, troublesome, useless system of indiserimmate terracing will again become the almost universal fashion in this district.

WATERING YOUNG TREES: A GOOD IDEA.—A method of watering young trees, until they have overcome the evils attendant on their infancy, appears to have been successfully adopted in the North-West Provinces. This is effected by burying an ordinary *ghara* of porons earthenware close to the roots of the young tree, with its neck on a level with the snrface of the ground. "The *ghara* is kept full of water, which reaches the roots of the tree by percolation through the pores of the earthenware, so that no surface irrigation is required at all. By this means no water is ever poured over the soil round the roots, and, in consequence, the hard crust which is so prejndicial to the health of young growing plants is not formed." Where water is procurable tolerably close in the neighbourhood, the system is far cheaper than that ordinarily pursued of watering the surface by bhistis; and it is calculated that 550 trees may be watered by one bhisti at a cost of 1*a.* 3*p.* per tree per annum, including the price of the *ghara*s. The plan has been tried in most districts of the N.-W. P., and has met with unanimous approval. To supply water for the *gharas* along lines of road, an ingenious water cart, consisting of a beer barrel placed on 4 *kka* wheels, has been invented, which enables two common coolies to do the work of six bhistis. The only drawback to the system is that the cowherd boys are fond of testing the bottoms of the *gharas* with their sticks, just to see if they are still sound, and how strong they are.—*Madras Times.*

THE AGRICULTURISTS OF MALTA are in a state of alarm, owing to the drought, which has continued five months, not more than half-an-inch depth of rain having fallen during that time.

THE TEA TRADE.—The custom house returns show that large supplies of tea continue to be shipped to London and Melbourne from Madras and the Coast ports. In November last the shipments of tea from Beypore aggregated 16,682 lb; from Calicut 1,705 lb and from Madras in December 6,005 lb. Of the latter quantity, 5,000 lb were sent to Great Britain, 975 lb to Bombay and 30 lb to Melbourne.—*Madras Standard.*

CUPREA BARK.—In *Comptes Rendus*, p. 593, Oct. 17, M. Arnaud describes a new alkaloid which he has obtained from a dark red-brown bark with a resinous fracture, imported from Sautander, and which may be presumed to form part of the recently imported China Cuprea. He finds the bark to contain 0·8 per cent of cinchoniue and 0·2 per cent of the new alkaloid. He obtains it by treating the bark with milk of lime, drying the mixture, exhausting with boiling alcohol, treating the resulting extract with hydrochloric acid in excess and crystallizing. The hydrochlorate of the new alkaloid is less soluble and crystallizes out first, the hydrochlorate of cinchonine remaining in solution. This alkaloid he has named cinchonanime. It appears to occupy an intermediate position between quinanime and cinchonine, in having two atoms less hydrogen than the former and two more than cinchonine.—*Pharmaceutical Journal.*

BRAZIL AS A FIELD FOR INDIAN EMIGRANTS.—The Calcutta *Englishman* in advocating this scheme says:—Brazil as a field for emigrants is quite unknown to this country; but there appears no reason why a system of emigration there should not be capable of organization. It is true that Brazil is a foreign country; but any objections on this score are no greater than those which also apply to the French colonies to which the emigration of labourers from this country is sanctioned. Brazil is suffering much from a scarcity of labour. The resources of slave labour, on which she has hitherto been mainly dependent, are rapidly failing, inasmuch as, though the law has not gone to the extremity of abolishing slavery throughout the kingdom, it has decreed for some time now that the children born thereafter of slave parents are to be free from their birth. The result of the measure has been that, while the old slave stock are dying out, there is no labour population to take its place. The children declared free by the law are as yet mostly too young for work, or, when of sufficient age, are described as not having the capacity for voluntary toil. The Brazilian experience in this latter point is not without example on other occasions of slave emancipation. The demand for labour is thus increasing. The attempts made to supply it are by way of European immigration, and a large proportion of the Italian, Spanish, and Portuguese emigration is diverted to Brazil. The demand, however, is chiefly for agricultural labour, particularly for the great coffee industry, of which, immense as it is, the further development is said to be hindered only by this want. In the tropical climate of Brazil field labour is well-nigh impossible for Europeans, even of the above class. Hence the demand is growing for labour capable of the work. This demand India appears very well suited to supply. No doubt proper guarantees, such as are usually required, would be granted for the treatment of emigrants, and the Brazilian Government might be approached with advantage on the whole question. It should be remembered by way of encouragement that the West Indies are not very far from Brazil, and to them a stream of emigration has been successfully arranged from the shores of India.

RANGALA, 17th Jan.—Fine weather for the last ten days, after a spell of nearly three months' constant rain. Leaf-disease bad again, and prospects for coming year not over brilliant. Fine hard dry weather during February, March and April will make things look brighter. Let us hope for another dry year like 1876—our last dry one. I think Government should ask Mr. Ward to investigate the coffee root-disease: leaf-disease is comparatively a trifle. How about the little insect seen on the fungus? I believe Mr. Ward makes no mention of it in his report. Why, I don't know, but, somehow, I have great faith in Mr. Storck and his remedy for *Hemileia vastatrix*. I hope the reward to be offered will be a liberal one. Government should offer not less than R100,000, and the planters might back it up with a 12 cent export duty for say five years. This, I think, would induce a good many to come forward, and experiment and perhaps discover a remedy. The late wet found out the weak places in our cinchona fields. Spots are looking reddish and unhappy, but, on the whole, our fields are doing very well. Coffee down to 75s. What next?!!

A BUMPER CROP.—We learn from our Mercara correspondent that, on an estate in South Coorg, about twenty-five miles from Mercara known as the Du Barri estate, the crop of coffee this season has exceeded all expectations. Du Barri estate is about 180 or 190 acres in extent, and for this comparatively moderate plot the yield of coffee this season has been one hundred and twenty tons, and it is supposed that there are still some thirty tons to be gathered, so that the lucky owner will have one hundred and fifty tons for the season's crop. Our correspondent says that nothing else is talked of in Mercara among the planters, as well as by the other classes of residents, but the "wonderful estate" which has given its owner fully seventy tons above the estimated quantity of coffee. We are glad to learn that, on many estates in Coorg, very good crops of coffee are being gathered and that the planters are in high spirits. But for the prevalence of leaf-disease, which is gradually extending, and which all the efforts made by the planters to exterminate have, up to this, proved unsuccessful, coffee in Coorg would just now be a most successful enterprize.—*Madras Standard.*

COFFEE IN LONDON.—In looking over the catalogues of the last day's sales, I see that a parcel of new crop coffee of a well-known and favorite mark was put up. It was of that peculiar blue-greenish tinge so much admired by export buyers, and accordingly it brought the top prices of the day the O size 109s, and the No. 1 85s 6d., the latter being classed as good middling. Now I refer particularly to this sale because I happen to know that, about two months ago, an offer was made for this particular crop, by a Continental House, of 89s, cost and freght or equivalent to fully 94s, delivered terms, and it was refused because the proprietor thought he could do better. Well, I sincerely hope he may do so with the remaining consignments of the season, but at any rate this first parcel will return him between 8s. to 9s. less than he might have had paid down on delivery in the Colombo stores. When will Ceylon estate owners become convinced of the fact that if they are free to sell on the spot, they can always do better there than by shipping to London? The reason is so obvious, and the teaching and experience so plain, that I cannot understand how any one can be so blind to his own interests as not to see it. Merchants in Trieste and Venice can always afford to pay 3s. or 4s. more for direct shipment, than in London, and it is admitted that the continental trade governs the prices in this market. Moreover there are often Australian or American orders in Colombo at limits above the London equivalent. I fear, however, that it is now too late for much to be done in crops until next season.—Lon. Cor. "C. Times."

COFFEE AND SILVERSKIN.—A Travancore correspondent writes:—"Can you tell me why the silverskin sometimes adheres so closely to the parchment?" [? To the bean our correspondent means:—to beans not fully matured the silverskin adheres closely or possibly to coffee not fully dried.—ED.]

AGRICULTURE.—Owing to the heavy increase of correspondence, connected with the cinchona and the carob seed cultivation, as well as with mule-breeding operations, the Bengal Government is believed to have in contemplation the creation of a distinct Agricultural Branch of the Financial Department of the local Secretariat.—*Madras Mail.*

CUPREA BARK.—During the past year a new kind of cinchona bark is said to have been discovered in the neighbourhood of Buecaramanga, Province of Santander (United States of Columbia), which contains about two per cent of quinine, and is free from all other alkaloids. This bark was brought into the market under the name "Cuprea" bark. Reports from Columbia state that two rival Companies, with about 1,700 labourers, are working these districts. It is estimated that a labourer is able to collect daily 20lb. of fresh bark; 7lb. of fresh yield 3lb. of dry bark; hence the 20lb. of fresh yield 8·57lb. of dry. The daily production of 1,700 labourers is, therefore, on the average, 14 569lb. which amount in thirty days to 437,070lb. or about 4,000 bales, each 110lb.—*Madras Mail.* [This bark represents about one kilo of quinine per bale or 2 per cent.—ED.]

CHARGES ON TEA IN THE MELBOURNE MARKET.—A Ceylon tea planter sends us the account sales of some tea in which he was interested which was sold in Melbourne, and he complains of the charges which importers are subjected to. He says:—"I wrote to a firm asking them to send me few *pro forma* account sales, to shew the Melbourne charges. These are by another Melbourne agent, and are rather worse if anything than mine, and you will see that the unfortunate produce has to pay Government duty, pay commission on ditto to agent, and another commission of $2\frac{1}{2}$ per cent + $2\frac{1}{2}$ = 5 per cent. The last commission is because tea is given into the hands of purchasers two weeks before the purchaser pays for it, though he still gets another discount of $2\frac{1}{2}$, supposed to be for cash payment. Surely these roundabout ways of doing business should be put an end to if possible. The points I consider to be attacked are the following, and should be altered as under:—Purchaser to pay duty. If a discount is allowed to the buyer, and at present a very high one is, viz., $2\frac{1}{2}$ per cent, he should pay before delivery. On what principle is a period of two weeks to be allowed? It is an arrangement merely to give the agent a commission for guaranteeing that the purchaser will pay up at that date. At present $\frac{1}{2}$ of the gross value of tea goes in charges. There is $2\frac{1}{2}$ discount to buyer, agent, gets 5 per cent *clear*, broker $1\frac{1}{2}$ or $2\frac{1}{2}$ per cent *clear*: for interest on these charges are made (vide my account), and even postages and every charge paid for (vide customs charges and petties, delivery, &c.). It is not too much to ask the Melbourne people to follow the custom of the London market, especially as the latter is the more simple and straightforward one. Who was the man who wrote that seller did not pay discount? Nos. 1, 2, and 3 are account sales of an unknown party, and as they all fetched fair, in some cases very high prices, quality was good. There is something rotten (*scent as musty*) in the Melbourne tea market. Can the Chinese afford to pay these sort of charges?" Certainly the accounts sent are anything but encouraging to tea producers, and we cannot make out the payment of duty on tea which sold at such high a price as 2s. These charges require revision, and a uniform scale in the matter of commission and drawbacks on freights and landing charges.

QUININE IN THE UNITED STATES.—It will be remembered that not long since, after a considerable struggle, the heavy duty previously levied upon quinine imported into the United States was abolished. But at the same time a ten per cent *ad valorem* duty on imported bark was retained, and this is now giving rise to some agitation as being unfair to the native manufacturer of quinine. At a recent meeting of the Western Wholesale Drug Association, at Cincinnati, the subject was discussed, and a resolution was passed expressing the opinion that Congress ought to restore the customs duty on quinine and its salts to the extent of ten per cent *ad valorem.*—*Pharmaceutical Journal.*

CINCHONA.—Mr. Cross, the Quinologist, is at present at Madras, and having submitted a report to Government upon the cinchona plantations at Neddiwuttam, Dr. Bidie, at the request of Government, has left for a joint inspection of the plantations with Mr. Cross. They will, during this inspection, make test collection of the leaves, flowers, fruit, and bark of the various species, in order that it may be determined what are the best species to be grown at Neddiwuttam. The Surgeon-General has been requested to make arrangements for the conduct of Dr. Bidie's duties for the fortnight he will be away, and Dr. Bidie's actual expenses will be paid and met from the Budget head cinchona, Mr. Cross is to be considered still on duty on similar terms as before.—*Madras Times.*

NEW INDUSTRIES: PALM SUGAR.—The idea of establishing a quinine manufactory in Colombo seems a very sensible one, but with the vast source of sugar supply we have in the millions of existing coconut trees we do not see why it should not be possible to establish a sugar refinery too. As it is, a considerable quantity of the toddy extracted from coconut trees is converted into jaggery and molasses for local use, as the owners of the trees find it more profitable to use them for that purpose than for the production of coconuts. The present low price of coconut oil has not indeed produced any such general depression in the maritime districts that coffee leaf-disease has caused in the Central Province. This is owing to the fact that the quantity of coconut oil exported represents relatively only a small portion of the entire produce of coconut plantations. The local consumption of coconuts must be about a million a day, if not more, and besides the coconuts used as food and for making oil for local use, the tree is often cultivated more for the sake of the toddy than for that of the fruit. This is the raw material of all the arrack that is made, and which brings to Government an annual revenue of about two million rupees, and besides what is made into arrack a considerable quantity is consumed in the raw state, and for making vinegar, jaggery, and molasses. Yet with all these varied uses of the produce of the tree, the present low price of coconut oil is not without its appreciable effect on the value of coconut plantations, and if the produce of the trees could be converted into marketable sugar it might counteract the depreciating effect of the low price of coconut oil. The price of coconut oil may improve somewhat and it is probable that it will do so before very long, but with the competition of petroleum and African palm oil, no very great improvement in the trade in coconut oil is to be expected. Indeed it is more likely that new substitutes for coconut oil will be discovered than that the substitutes already discovered will go out of use. What we propose would be too great a risk for one individual to undertake, but it might be managed by a limited Company in such a way that in the event of a failure the loss would be so diffused as not to be much felt. But we do not see why the result should be a failure, because if it pays to make sugar from beetroot, and if it pays to use jaggery and molasses from palm juice, we do not see why it should not pay to convert jaggery into refined sugar.—"C. Messenger."

OUR WATER POWER.—Said Sir W. Thomson, at a meeting of the British Association :—Taking Niagara as an example, and with the idea of bringing its energy usefully to Montreal, Boston, New York, and Philadelphia, I calculated the formula for a distance of 300 British statute miles (which is greater than the distance of any of those four cities from Niagara, and is the radius of a circle covering a large and very important part of the United States and British North America), I found almost to my surprize that even with so great a distance to be provided for, the conditions are thoroughly practicable with good economy, all aspects of the case carefully considered. The formula itself will be the subject of a technical communication to Section A in the course of the meeting on which we are now entering. I therefore at present restrict myself to a slight statement of results. 1. Apply dynamos driven by Niagara to produce a difference of potential of 80,000 volts between a good earth-connexion and the near end of a solid copper wire of half an inch (1·27 centimètres) diameter, and 300 statute miles (483 kilomètres) length. 2. Let resistance by driven dynamos doing work, or by electric lights, or, as I can now say, by a Faure battery taking in a charge, be applied to keep the remote end of a potential differing by 64,000 volts from a good earth-plate there. 3. The result will be a current of 240 webers through the wire taking energy from the Niagara end at the rate of 26,250-horse power, losing 5,250 (or 20 per cent.) of this by the generation and dissipation of heat through the conductor and 21 000-horse power (or 80 per cent. of the whole) on the recipients at the far end. 4. The elevation of temperature above the surrounding atmosphere, to allow the heat generated in it to escape by radiation and be carried away by convection is only about 20degs. centigrade : the wire being hung freely exposed to air like an ordinary telegraph wire supported on posts. 5. The striking distance between flat metallic surfaces with difference of potentials or 80,000 volts (or 5,000 Daniells) is (Thomson's "Electrostatics and Magnetism," § 340) only 18 millimetres, and therefore there is no difficulty about the insulation. 6. The cost of the copper wire, reckoned at 8d. per lb., is £39,000 ; the interest on which at 5 per cent. is £1,900 a year. If 5,250-horse power at the Niagara end costs more than £1,900 a year, it would be better economy to put more copper into the conductor; if less, less. I say no more on this point at present, as the economy of copper for electric conduction will be the subject of special communication to the section. I shall only say, in conclusion, that one great difficulty in the way of economizing the electrical transmitting power to great distances (or even to moderate distances of a few kilomètres) is now overcome by Faure's splendid invention. High potential, as Siemens, I believe, first pointed out, is the essential for good dynamical economy in the electric transmission of power. But what are we to do with 80,000 volts when we have them at the civilized end of the wire? Imagine a domestic servant going to dust an electric lamp with 80,000 volts on one of its metals! Nothing above 200 volts ought on any account ever to be admitted into a house or ship or place where safeguards against accident cannot be made absolutely and for ever trustworthy against all possibiltity of accident. In an electric workshop 80,000 is no more dangerous than a circular saw. Till I learned Faure's inventions I could but think of step-down dynamos, at a main receiving station, to take the energy direct from the electric main with its 80,000 volts, and supply it by secondary 200 volt dynamos or 100-volt dynamos, through proper distributing wires, to the houses and factories and shops where it is to be used for electric lighting, and sewing machines, and lathes, and lifts, or whatever other mechanism, wants driving power. Now the thing is to be done much more economically, I hope, and certainly with greater simplicity and regularity by keeping a Faure battery of 40,000 cells always being charged from the electric main, and applying a methodical system of removing sets of 50, and placing them on the town supply circuits, while other sets of 50 are being regularly introduced into the great battery that is being charged, so as to keep its number always within 50 of the proper number, which would be about 40,000, if the potential the emitting end of the main is 80,000 volts.

CEYLON TEA IN LONDON.—We call attention to the full report of the recent sale of Ceylon tea in London, furnished by Messrs. Hutchison & Co. The highest price realized, 1s 7d, was for Broken Pekoe with Mr. Elphinstone's mark. Improvement in manufacture is still the desideratum.

TEA.—THE *Indian Echo* is the name of the organ of the "Indian Tea Direct Supply Association" recently established in London. The paper in question is published in the interests, apparently, of one Tea Association only, but doubtless the experiment will be adopted not only by Ceylon tea grower's agents, but by those interested in the older staple, coffee.—*Madras Mail.*

WILLOW LEAVES AS A CURE FOR FEVER.—The December number of the *Indian Medical Gazette* contains a paper by Asst. Surgeon Chetan Shah on the use of willow leaves in intermittent fever. As the writer says, the remedy is not a new one, nor can its efficacy be compared to that of quinine or strychnia, but amongst natives, especially females, quinine often causes great irritation of the alimentary canal and induces dysentery : in such cases the juice of fresh willow leaves diluted with water proved very successful. Where willows did not exist narcotine was found to answer the purpose.

LOWER DIKOYA, 17th Jan.—Nothing could be finer than the weather. So far, the rains in December no doubt encouraged a light attack of leaf-disease, which we would not otherwise have had, but the good done to coffee was far more by the one than the harm by the other. January is as it should be—hot, dry days and cold nights. A good blossom is appearing in the bud, but it will take a month's or six weeks' drought to check growth sufficiently to bring out a large general blossom. And I think the trees are in a better state to bear than they have been for some years. All depends on the weather for the next three months. No in is required before the end of February. It is too early even to guess at what *next year* may be. However, it promises to be favourable.

OSTRICH FARMING IN MAURITIUS.—We received an interesting addition to our zoology by the "Day Dawn" from the Cape, viz., five full-grown ostriches. I believe that several more were shipped, which, however, unfortunately died on the voyage. These birds were put up at auction; but didnot realize more than the following prices, which, I am afraid, will not encourage further shipments of this stock to our island:—

1 male	...	...	R320
1 „	...	...	310
1 „	...	...	290
1 „	...	...	274
1 female	...	...	810

The principal buyer was Mr. A. Colin, who intends to follow the example of another of our large landed-proprietors and establish an ostrich farm on one of his estates. The French Imperial Government has presented to that of the neighbouring French Colony of Réunion the cost of two very important undertakings, with a view to give an impetus to trade in that colony, viz. first that of the railway encircling the island, the amount expended on which has amounted to about a million sterling; and secondly, that of a harbour, the cost of which is estimated (for it is not yet finished) at 40 millions of francs. These enterprizes, when completed, will undoubtedly give a great impulse to trade there. According to the circular of Messrs. L. Aubert & Co. of Reunion, sugar is selling there still at the comparatively low price of Fcs. 21·50 for quality indicating 88° or No. 12 Dutch Standard.—*Mauritius Correspondent.*

CINCHONA CULTIVATION IN CEYLON.

At a time when a good deal of despondency prevails in reference to the market for our chief staple, coffee, it is more than usually satisfactory to have cheerful accounts of the prospects before the cultivators of cinchona. There are few planters in Ceylon who cannot be counted among that body, and notwithstanding all the drawbacks of unexpected supplies of bark from South America, variable quotations, and still worse the large proportion of failures in local plantations, the financial success of the cultivation has been proved beyond all doubt. We may be told that the case of the fortunate proprietors of Frotoft estate, Ramboda, to which we are about to refer, is an exceptional one; but we do not see why it should be so regarded save in respect of their fortunately early commencement of work in the formation of a regular cinchona plantation. Frotoft and Tymawr consist of 250 acres fully planted with cinchona officinalis, and the result last year of cutting down 40 acres, when the trees were from 4½ to 5 years old, has been a gross return of £8,000, a sum sufficient to cover the whole outlay, so far, on the properties. These properties cannot now be valued at less than £15,000, and we feel sure the owners would not part with them for less, so that we have a profit of 200 per cent within half-a-dozen years. The average yield of bark in the case of the Frotoft clearing was 1 lb. per tree, including root bark, and planted 4 by 4 feet, there were fully 2,700 trees per acre harvested. The trees, it will be noted, were rooted out, and it is particularly satisfactory to learn that young plants put down on this once-cropped land are flourishing, shewing no such signs of failure as have been observed to be the case in clearings twice planted in some other districts. Mr. Traill, to whose care and intelligence the success of Frotoft is so largely due, was trained in a good school under Mr. Taylor of Loolecondera, and he had the advantage of watching the profitable result of the first experiments made by Messrs. Keir, Dundas & Co., when, from 15 acres on Stelleuberg alone, no less than £6,000 worth of bark was taken. The prices secured for the Frotoft bark were on the whole good, but not higher probably—the bulk being at 3s rising to 5s per lb.—than can always be got for good Ceylon crown bark. On other clearings in the Ramboda district, we hear that there are, perhaps, more failures than on the plantation we have particularized; but in the early days Frotoft had large patches of failures; 4 and 5 acres going out at a time. We are sorry to learn that the supposed exemption of Uva from canker and failure of cinchonas has been rudely shaken by experience on some of the Haputale estates, although one current report makes the case much worse than it really is. The fact is that no extensive continuous clearing of cinchona can be free from a considerable proportion of losses, varying with the character of the soil and climate. The Kandapola and Udapussellawa districts are perhaps as highly favoured as any in the country, and "Lover's Leap" with its intersecting belts of blue-gums—the careful design and work of Mr. James Taylor—may probably be regarded as the model cinchona plantation of the country for its size and age. A discouraging piece of experience from the younger districts is that cinchonas do not seem to prosper on "grubbed" land. Again, one of the most interesting experiments in the country is that carried on under the energetic direction of Mr. R. P. Hart on Great Valley estate, Hewaheta. Here the forest has been cleared in small fields of five or six acres surrounded by belts of the natural vegetation, so that the cinchona is growing up in detached groves very much after the fashion in which it is found, according to Markham, in its natural habitat on the Andes. So far this experiment gives promise of being a complete success, and we have here as well as on Lover's Leap the key probably to the remedy for canker, namely, small fields well protected and well drained of superfluous moisture.

The great activity now manifested in the propagation of the best (Ledgeriana) cinchona adds a further feature of interest in connection with the enterprise. The fortunate possessors of clearings, plants, or even nurseries of this rich species may well be congratulated, and now there come reports of the success of grafting far beyond even Mr. Moens' achievements. Of this experiment and of other important facts in connection with the Ceylon and Java enterprise, our readers will hear in good time.

TEA AND COFFEE FOR AUSTRALASIA.

(*North China Herald.*)

Some of the Indian papers have lately been discussing the trade with the colonies and various official and other suggestions which have been made for its extension. The assistant secretary to the Indian Department of Agriculture and Commerce has made a report on the subject, in which he says that he believes the Australians will, in a short time, take five million pounds of Indian teas. He recommends coffee-growers to look to the colonial markets, and seems to think that a trade in indigo, shell lac, cinchona, fibres for rope making, and even gram might be initiated and carried on successfully. But to foster this enterprise, he proposes, first that Indian exhibitors at Australian Exhibitions, and other dealers as well, should be represented on the spot by an agent whose duty it would be to explain to the colonists the quality of the products, the places of their growth, the modes of shipping and packing them, and so forth. Indian dealers and exhibitors might associate themselves for the maintenance of such agencies. Secondly, an agent of the Indian Government should also be on the spot to assist the agents, and make himself generally useful. Thirdly, the agents should inquire into, and report upon, the products and resources of the Australasian countries, with a view to fostering an import trade into India, from the colonies. And fourthly, a Company, availing itself of the information thus collected, should establish itself in Calcutta or Bombay, for the purpose of carrying on a general business with the colonies. These suggestions seem to have been favourably received in India, and whether they are carried into effect or not they are an evidence of the energy with which the official and commercial public in India are trying to extend their trade. As regards the articles with which Australia could supply India less information is forthcoming. At present the colonial export to India is represented, one paper says, principally by "Walers" and a few thousand tons of coal, and at present there does not seem a prospect of the list being greatly extended, though Australian commodities are to be sent to Calcutta for quarterly sale, and wools are for conversion into matting in the

jails. But if Indian merchants are successful in establishing a considerable export trade with the colonies, the returns for it can be made in gold of which India is taking an ever increasing-amount.

It seems rather peculiar that, while the Indian teas are strongly recommended on account of their freedom from adulteration, a correspondent of the *Indian Tea Gazette* should draw attention to the South American maté, as what, "it is just possible might make an admirable blend with our excellent, though to some people peculiarly-flavoured, Indian teas, and give them a value in the British Colonial markets which they do not now possess." *Yerva Maté* is used in the greater part of South America as tea is by Western people, and its flavour, though peculiar, resembles the coarser qualities of China tea; but it has virtues and defects which the cup that cheers but not inebriates does not possess. It is a wonderful sustainer of strength even in circumstances requiring great physical exertion, but it produces excitement of a very unpleasant kind to Europeans. It derives its stimulating and restorative properties from the same principle that is found in tea and coffee, namely theine. The correspondent of the *Tea Gazette*, when combatting the objection that the introduction of the cultivation in India of the Ilex from which maté is made because it might be used as an adulterant, says, that in time it would stand in the same relation to tea as chicory to coffee; that is, as an accepted adjuvant. He considers it possible that the tea with which it was mixed would modify, if it did not entirely counteract, its excitant properties, and further that, as it would cost little to cultivate and cure maté, it must needs be profitable to the producer. The advocacy of maté, as something which would improve Indian teas and render them more pleasant to consumers, seems an unfortunate proposal on the part of those who are so strenuously urging their merits on the world generally. In a report of the proceedings at the opening celebration of the business of the Calcutta Tea Association in Sydney, contained in the same *Gazette*, we do not find any allusion to the necessity for an adjuvant in any of the speeches which were then made. A great deal was said about Indian tea not being liked by the public because of the difficulty in obtaining a good blend of the various growths; something more of the indifferent quality of the China teas; but nothing about improving the Association's imports by maté or any other addition, which would be to them what chicory is to coffee.

MESSRS. TYTLER AND SCOTT BLACKLAW ON BRAZIL: IS A REVOLUTION IMPENDING?

It is now about a quarter of a century since Mr. R. B. Tytler, so well-known in the annals of the planting enterprise of Ceylon, contributed to the *Observer* a startling communication on the preponderating influence of Brazil in regulating the coffee market of the world. That was before the era of railways in the South American Empire and long before the process had been commenced of practically concentrating the whole available slave labour—far larger in amount, evidently, than the slaveholders were willing to let the outside world know—on the growth of one product, to the abandonment or neglect of the formerly important staples of sugar, cotton, &c.

Again, a few years ago, Mr. Tytler embodied his sentiments regarding the then position of Brazil and her possible future, in a pamphlet, taking as his text the facts embodied in Mr. Scott Blacklaw's interesting and important communications to this paper; especially his elaborate report of the discussion on future labour supply by planters and others interested in the leading enterprise of Brazil in conference assembled. At this conference, to the amusement as well as the astonishment of the world, strong objections were offered, on the ground of probable contamination of race, to the introduction of black or coloured free labourers to a country, the majority of whose inhabitants must consist of indigenous or half-bred Indians and negroes (slave and free), and the mixed race arising from intercourse between the latter and the whites.

A third time, in consequence of having had the advantage of obtaining the most recent information from Mr. Scott Blacklaw, personally, Mr. Tytler has elaborated his views on Brazil, and his letter which appears in this day's issue supplements in some most important particulars the communication with which Mr. Scott Blacklaw himself has simultaneously favoured us. It will be seen that almost the whole purpose of Mr. Scott Blacklaw's letter is to shew how mistaken he and we and many others were in the conclusions we drew, from apparently authentic information, as to the crisis which we believed had overtaken the supply of slave labour in Brazil, in consequence of the operation of emancipation laws, the decrease of slaves by death and the state of public feeling. Making every allowance for the vast advantages conferred by rapid and large railway extension, in freeing human beings and cattle from carriage of produce and goods to labour on estates, as well as in facilitating the transport of crops to Rio and Santos, we cannot but feel that the census figures for the slave population, have been deliberately, systematically, and for a purpose, falsified. That is the opinion of the able and well-informed editor of the *Rio News*, from which honest paper we have learned much of *the truth* about Brazil instead of the self-complacent romance in which Brazilians themselves are so fond of indulging. Our reasoning and conclusion would have been correct enough, had our premises been as sound as we naturally imagined them to be. The result is just the reverse of what we reasonably arrived at and honestly promulgated. Coffee production in Brazil since the cessation of the slave trade and the promulgation of the emancipation law, instead of going back or even remaining stationary for want of labour, has increased at a rate which is positively astounding. We knew that the great South American State commanded an almost unlimited area of rich coffee soil; we knew that she was adding to her railway facilities at a rate which was a reproach instead of being an example to our rulers in Ceylon; and we could easily infer the vast advantages these conferred on coffee planters by setting free mules, bullocks and their drivers for estate work. But we knew also how enormously coffee was taxed, bearing most of the burdens of Government, Imperial and Provincial, in fact, and by the trumpet flourishes of the statesmen and public writers of Brazil, we were led—*misled*, we should say—into the erroneous belief that in addition to the high death rate to which slaves are

subject, there was a general and a sincere desire, accompanied by efforts correspondingly general and sincere, amongst the community, to rid the empire of the blot, the reproach and the curse of human bondage. We were mistaken, and we shall no longer rate the ruling races of Brazil as so much higher in rightcousness of motive and justness of action than the anarchical peoples of mixed Latin and Indian race around them: peoples who have made the terms republic and liberty stink in the nostrils of the nations.

Mainly by the conservation of their slave force and its concentration on the growth of coffee, the average exports (in excess of a home consumption equal to 1,200,000 cwt.) have risen from 3,500,000 cwt. in the ten years ended 1866 to 5,000,000 cwt. in the five years ending 1881: an increase of 45 per cent in fifteen years, the figures being for Rio and Santos only. Nor does our well-informed correspondent, Mr. Blacklaw, anticipate any early decrease in this rate of production. The probability indeed, in view of the increased breadth brought into cultivation, is, that the export will go on increasing for some years to come, until arrested by disastrous proof that the slaveholders of Brazil have not only competed unfairly with those who have had to pay the fair price of free labour but have also competed with each other to the verge of mutual ruin. If we were asked why middling plantation Ceylon coffee is down to 72s, our answer would unhesitatingly be: "Brazil." But Mr. Tytler, professing to reflect information obtained from Mr. Blacklaw, anticipates for Brazil a catastrophe more terrible than could arise from merely material losses and a commercial crash, the result of inordinate diversion of labour and capital to one pursuit. Mr. Tytler predicts at no distant date a political revolution with social trouble and commercial disaster in proportion to the extent and violence of the change from imperial to republican government, amongst such races as constitute the population of Brazil. We cannot but admit the possibility of such a revolution, followed by such anarchy as are predicted; and, but for the high personal character, wisdom, prudence and forbearance of the present Emperor, it seems probable that revolution and retribution which is sure to follow the crime of enslaving human beings would have been precipitated. But our previous vaticinations and their results ought to teach us modesty in drawing conclusions from facts which may seem to us unimpeachable. We should be glad to have Mr. Scott Blacklaw's own utterances before us, ere we venture to pronounce on the possible future of a country, interesting to the whole world from the vast extent of its territory and its natural resources, and for the so-far successful experiment (unique on the American continent) of rule on the model of constitutional monarchy; as well as painfully interesting to Ceylon, in consequence of her position, mainly by means of slave labour, as by far our most formidable competitor in the production of coffee. To coffee planters in India, in Java, and in the free South and Central American States,—to all indeed who grow coffee or are connected with the important trade in this article,—the questions discussed by our correspondents are of great interest: and we think we shall not be accused of being actuated by merely selfish motives, if we express the hope that, even if the Brazilians condescend to waive the question of colour and express their willingness to relieve the British Possessions in Hindustan of a portion of the surplus population, the Government of India will not consent to permit emigration to the South American Empire, until slavery has been there abolished. Those who know what human nature is will hold most strongly that it is next to impossible to those accustomed to command the labour of slaves to mete out proper treatment to free labourers. The inevitable tendency of slavery, besides brutalizing master as well as slave, is to create a public opinion which considers labour disgraceful. The two systems, slavery and free labour, cannot be worked well and harmoniously together; and to a country where slave labour exists with the public opinion always engendered by that inhuman and degrading institution, the Government of India (acting *in loco parentis* to those who though free are very much children) should not sanction systematic emigration. Even to Ceylon, which geographically and socially is so closely allied to India, free emigration was not allowed until our Government passed a law forbidding the engagement of Indian coolies in this island for labour in places beyond its bounds. We are in favour of free trade, even in the case of slave-grown produce, simply because of the impossibility of carrying out discriminating laws. But moral principles ought to be applied where possible, and on every possible principle of morality and expediency, the benefit of Indian free labour should be refused to Brazil until she has, at whatever cost to herself, righted the great wrong of treating human beings as soulless brutes or inanimate chattles. Having ourselves suffered the retributiou and paid the price of this species of wrong, we can with a good grace refuse to aid the continuance of the same wrong by others; even if we do not protest so emphatically as we ought against its existence.

BRAZIL AND ITS COFFEE-GROWING ENTERPRISE.

(*From Mr. A. Scott Blacklaw.*)

Scotland, 15th Dec. 1881.

Since I wrote you last, one of the coffee fathers and a benefactor of Ceylon, has been paying me a visit—R. B. T. I was surprized to see him looking so hale and hearty. Your climate has not on the whole treated him badly. The conversation for the greater part of two days and a night was all on coffee:—Ceylon, as it is; Ceylon as it would have been, had not the leaf-disease found lodgement in it; and Brazil and its enormous crops formed the chief topics. This latter subject is one which engages the attention of all coffee growers at present. The extra quantity of coffee thrown into the market has, by keeping large stocks continually in dealer's handss, brought down the price not only of Brazilian, but of other coffees. How wrong all our calculations eight years ago! We thought that, as Brazil's large crops were produced by slaves, that, that shipments would gradually diminish. We reasoned thus: "The whole civilized world is against slavery and Brazil alone cannot continue to hold in bondage 1,500,000 human

beings. Has not a law been passed freeing all children born of slave mothers since 1872? Was not an emancipation fund formed to free so many slaves every year; and was there not a dying-out process going on by which the number of those already slaves would be gradually diminished? and we all concluded that in ten years slavery would be nowhere. This has proved to be mere matter of opinion. The institution flourishes as grandly as ever it did. Children are being valued as property separate from their parents. The larger part of the emancipation fund has not been spent in freeing slaves, and the official returns of the number of slaves in the whole empire are still quoted about 1,500,000 or the same as ten years ago.

I was to have given you an account of the reasons for the gradual increase of the coffee exports from Brazil, but, as usual, I have been two long in commencing.

Dollar, Scotland, 22nd Dec. 1881.

My dear Sirs,—As mentioned in my last, it was a natural error for us all to fall into—the imagining that the Slave Law of 28th September 1871 had given a fatal blow to the coffee enterprize in Brazil. Previous to that date, the planters had been feeling the effects of the stoppage of the slave trade, and labourers for coffee, cane, and cotton plantations had become scarce. While the proposed law was being discussed, previous to its passing, the planters themselves believed they were going head-long to ruin. They sanctioned the law, because the civilized world was against them. The Emperor had ordered it, and their most enlightened statesmen were in favour of it. Besides, the first proposition, which was to decree unconditional emancipation to all slaves in the year 1900, was not insisted on. Although the law of September 1871 left all to remain in a state of slavery, who were born slaves before 1871, until their death, the planters still believed the country had made a great sacrifice; and like us, they thought the cultivation of coffee could not be extended. Four years after, the great crop of 1875 was believed to be quite exceptional, and was owing to there having been small crops for the three previous years, 1872, 1873 and 1874, and the trees having been loaded with young wood, when the favourable blossoming season of 1874 came round. The bad state in which the 1875 crops reached the market only further convinced us of the impossibility of the Brazilians being able to pick and send to the seaports larger crops than the maximum 4,000,000 cwts.

Let us see what the figures show, as regards exports from Rio and Santos alone, leaving out Bahia and Ceará, for, as I mentioned in one of my letters to you, this last-mentioned place must be included in all calculations as regards the Coffee Supply of the World:—

For the ten years ending
June 1866 Rio and Santos
gave an average of .. 3,500,000 cwts. p annum.
For ten years ending 1876 ... 4,000,000 ,, ,,
For last five years ending
June 1881 in round numbers ... ... 5,000,000 ,, ,,

[N.B.—There are 17 Brazilian coffee bags to a ton.]

It is not expected that the production will be less than this last figure for some time, and it seems to be picked, cured, and sent to seaport, much more easily than the 3,500,000 cwt. a year were; and, moreover, the quality of the crops, owing to improvements in machinery, and better care being taken of them as regards curing and preparing, is much superior to what it was in former years.

Now what are the causes which have brought about this increased prodution?

First come railways.—The first railways were opened in 1866-67. About that time the Don Pedro II. railway was opened into the interior of the province of Rio de Janeiro. Certainly the terminus was a long way from many of the finest coffee-producing districts: still it wasa help, and a beginning in that way of ransporting produce, and showed the leading men of the country the advantage of continuing the system futher, until, by the end of last year, the railways—trunk and branches included—bringing produce to the city of Rio de Janeiro have a total length of 650 miles.

In 1867 a railway had been opened from the town of Santos to the town of São Paulo. This was only 45 miles from the coast, and still 80 miles from the nearest coffee districts of the province of São Paulo. By 1870 these districts had, however, been reached: and, year by year, after this steady progress in railway extension had been made, until the railways in the province of São Paulo, counted 750 miles at the end of last year; and over a hundred more are in construction and will be opened by end of this year, or early in next year. Although the transport by rail is very costly in Brazil—about a shilling per ton per mile—still it can be depended on as a quick and safe means; and the farther inland the railways go there is the less dependence on the muleteer and bullock cartman, for, in former times, coffee transport was at a standstill during the rainy months—December till April following. During the making of the railways, the planters' labor-market was not affected, as the railway labourers were Portuguese, Italians, and Spaniards—a class of men brought out from Europe for this purpose, and who have no taste for agricultural pursuits. On the other hand, the opening of railway threw those who had found occupation as muleteers and bullock-drivers on to work on the coffee estates.

The opening-up of the country in this way was the means of sending men into the interior as purchasers of land, who would not have thought of attempting a long journey on horseback. People with capital flocked from the large towns and from other provinces of the Empire. Agriculture has an attraction for the retired tradesman and the sugar-cane and cotton planter looks on coffee-planting as a superior occupation to his. Besides the sugar planters in Mauritius and British Guiana could produce a better article and could make sugar pay at a price that left nothing for the unskilled Brazilian planter. Cotton, which, during the American war, and for some years after, paid the Brazilian planter well fell to such a price, after the freed American negroe began to work, that the Brazilian planter, after paying 13 per cent of duty on it, found the cultivation of cotton gave little return for the capital lying on his slaves. These all turned their attention to coffee-planting. A great many people in the interior of the other provinces, who owned slaves, but produced very few articles for export, owing to their distance from the seaport, came and bought land near the railways. They found they could grow corn and bran sufficient to feed their negroes, and sell enough fat pork to buy clothes for them or for that, they could still grow a small patch of cotton, make the children prepare it for spinning, the old women spin it, and the men take their turn at the loom at night as usual, and thus be independent of buying anything; and then the price got for the *coffee* in Santos was found money to them. This last operation you will think overdrawn, but I have had Brazilians treating several thousands of coffee trees for me with slaves of their own do this. I gave them land, in a place not suited for coffee, to grow whatever they liked, and, from what grew on that piece of ground, they would keep their whole household and the yearly payment for treating the coffee trees was clear profit.

I shall return to this subject next mail day, m anwhile I find it is time to send this to post. With kind regards, yours very truly,

A. SCOTT BLACKLAW.

COFFEE PLANTING IN BRAZIL.

(From Mr. Tytler.)

Having interviewed *Scott Blacklaw* at his home at Dollar, in the Scottish Kingdom of Fife (or Clackmannan), I am to offer you the result for publication, if you should deem it worthy of your pages. The interview leaves no room for question as to Brazil being on the eve of an impending thorough revolution—political, social, and financial. It is only the life of the present popular Emperor which prevents an outbreak which is inevitable when he dies. *The Empire* is more than nine-tenths Republican. The slaveholding class, with their one and a half million slaves, are confined to only three of the twenty-three provinces, and are the subjects of the most intense jealousy on the part of all but a minority within the officials of Government, and h ving exclusive privileges hitherto dominant, bnt now fast losing hold. As for example, for many years past they, finding that the coffee enterprize was the better paying, transferred their human "stock" from the northern (hitherto producing sugar) provinces of Bahia, Pernambuco, &c, to the south—to Rio, to Santos, and Sã o Paulo—where vast tracts of virgin land having rich soil, wholly suitable for coffee, were brought under cultivation of the latter produc', resulting in the production of the present enormous export of from six to eight million cwt. But the jealousy, and interests of the other provinces have caused the enactment of a law prohibiting such transfer of the slave popnlation, and there can therefore be no more extension of coffee-growing by such labour. These three provinces have now to depend only upon the hands they at present possess, which are found to be inadequate to their requirements. The consequence is that the coffee interests, for a year or two back, have been trying by the introduction of free immigrants from Europe—German, Portuguese, &c.—to supply the want of labour by a system of *colonists*, under which families of such immigrants are settled on the estates, with abont ten acres of coffee allotted to each family to cultivate, for wages and allowances, being paid as by contract. Thus, one thonsand acres would require a hundred separate European dwellings with all etceteras, and cow pasturage, while the quality and working of such a class is most objectionable—in fact, impracticable: and this especially so as alongside a slave system. The free indigenous labour—African, half-breed, or Portuguese—are much of the following stamp. A smart gentleman of colour rides up (they all have their riding horses) and seating himself in the verandah sends for you, and after mutual civilities, with comments on the weather and such like, being asked his business, announces that he is open for engagement, stating terms, including keep of horse, c ws, &c., and when informed that he is not required, there is handshaking and *adios*. Not, however, that such men are not in the majority of cases excellent and efficient workers, but, as a class of labour, too expensive, independent, and precarious for the growth of coffee. There are also gangs of slaves to be hired by the job, or by time, and they are the most to be depended upon of the class of hired labour. Where employed they have barracks wherein they are locked up at night. They receive rations of food, and are attended to in sickness, and are worked under the whip. Their babies and young children (now no longer "property" but free born), are put into *crèches*, mostly *al fresco*, and the aged and used up, *die*. The slave population are fast diminishing. No fresh importation has been permitted for many years, while laws providing for emancipation have been for long in operation, such as that children shall be held to be born free. Hence there are a large increasing number of young people, children of slaves, whose parents are still under bondage with all the contingencies of such a condition, and it is contrary to nature that such a state of things could continue long. Another element of labour presents itself in the free Europeans who have been imported as *navvies* for forming the extensive railways, who are now getting out of that work, and seeking employment, and they are open to contracting for minor jobs, such as roadmaking, fencing, ditching &c., bnt are not the class for coffee cultivation, or for settlement to steady periodic employment. They gravitate to the towns, and finally disappear.

Of recent years, the Brazilians, and their Government have foreseen what was inevitable in the future, and have been in throes for some remedy. With the results of West Indian Slave Emancipation before them, knowing that the liberated African slave will not, when freed, work for hire, but will squat, they have been casting abont for a supply of labor, thinking of Hindustan and Chinese coolies. But apart from the expense and difficnlties attending their being supplied from these countries, they are met by an insuperable objection, on the part of the general Brazilian people, to the importation into the empire of more blacks, and more especially of the yellow Mongolian Chinese. On the score, therefore, of labor to depend upon for the maintenance of the coffee culture, Brazil appears to be in extremity to such an extent as to render it certain that, before many years, its labor supply must collapse by the operation of inevitable causes, and the crisis will probably be precipitated by forces already operating, and the climax be calamitous—decrease of exports of the grand staple. This would be a calamity indeed to such a conntry, the revennes of which is to so large an extent dependent on coffee, on the export of which alone there is a direct duty of thirteen per cent. Already overtaxed, and coffee handicapped, with the enormous railway and other debts to meet—there is not only no margin for imports, but the prospect of railway revenue diminishing—Brazil can in no way look forward with hope. Cuba, having last year reduced her slavery to a system of apprenticeship, after oceans of bloodshed and vast waste of treasure; and America free of the foul blot upon humanity at a terrific cost, after a war of giants—and England let off with a fine of twenty millions and the forfeitnre of her valnable West India possessions, now, alas, in ruin; is it possible or probable that Brazil can avert the catastrophe or prolong its advent? We may look any day for fearful intelligence from that Empire.

The system of cultivation of coffee in Brazil was something as follows. Over the ridge behind Rio Janeiro runs the valley of Parahiba, presenting an aspect of steep ridges clad in primitive forest, which fell by successive onraids after the collapse of West India coffee had raised the price. Cultivation was after the fashion we call "native" in Ceylon. Indeed, there has never been what we call "cultivation," pruning or manuring being deemed Quixotic. The trees are planted twelve feet apart, allowed to grow anyhow, with any number of stems, the intervening space being occnpied by maise, manioc, bananas, yams, arrowroot, &c. Crops were (and still are) shaken off the trees when ripe, and the husks swept up and dried anyhow. Croptime falls there in the dry season. This enterprize succeeded; abundance of the most suitable land: labour found by drafting slaves from the north, and everybody anyhow going at it. Extension overflowed to the south, to the districts, inland from the seaport of Santos, and away up into the province of São Paulo. It is here where the richest of young coffee life is in vigor, much of the Parahiba and Rio having worn out, and been washed out, and played out, (as alas is much of our old Ceylon!) though still largely swelling the exports of Rio. São Paulo is mainly a tableland, an undulating expanse of prairie and wooded ridges, two

thousand fect above the sea-level, about the latitude of the tropic of Capricorn; and frost is not uncommon in the hollows during some periods of the year. But coffee thrives on the slopes, bearing abundantly, some ten cwt. per acre, and all good plants *luxuriate*; mankind alone being absent, excepting a few small tribes of roaming savages, all the way across the dip of Rio Plata and other great rivers, to the roots of the Andes, some two thousand miles.

Labor from first to last ever being the chief factor affecting all operations in Brazil, and the enormous distances having to be dealt with, Government pledged its then hopeful credit in contracting great loans to construct railways, to bring the imports and exports to meet, and to foster its great enterprize, setting free for employment in extension large bodies of men hitherto employed in transport service. There was no lack of the needful capital. Brazil thus extended fabulously its investments in reproductive industry, producing enormous exports of coffee, and leading to further loans for railway extension, with the inevitable interest to be met. The United States, when Brazil was exporting a million cwt. took about half: now that the exports are about seven millions she takes the half. But for this where had we been as coffee-growers in Ceylon? However, Mr. Blacklaw is of opinion that, were coffee growing reduced in Brazil to the bare question of so much cash down for cost of production, as is the case with us in Ceylon, Brazil coffee could not be shipped for fifty shillings per cwt. Hence the plain English of it is that she is already entrenching on her capital for current expenditure. Her slaves, valuing the able-bodied at two hundred pounds, do not return interest on that valuation by proceeds of their labor, and how many years' purchase are they worth in the face of probabilities? America opens a wide gullet for coffee. How is it to be filled when Brazilian exports diminish, not to say collapse?

R. B. TYTLER,
December 1881. Aberdeen.

THE EXPERIMENTS IN CHECKING COFFEE LEAF-DISEASE IN THE DUMBARA VALLEY.

Gangapitiya estate was again visited on Saturday last by Mr. Schrottky, accompanied by the same gentlemen who took part in the last inspection. The following facts were established at this visit:—

Regarding the bulk of the estate, no falling-off in the general appearance, such as luxuriance of foliage and vigour of trees, is observable. There is cousiderably more disease about than there was at the previous visit, and, in parts of the estate, it is bad, especially in patches in the ten acres which were not treated during October and November. Ordinarily speaking, one would say that the estate was on the eve of an attack; but this loses greatly in significance, when it is borne in mind that more than a month ago the resident manager reported to that effect. There was at least a fortnight of showery weather since his report, and the attack is still found undeveloped in by far the greatest part of the estate. New wood is being rapidly made, and there is no fall of leaf perceptible, past or present. The ten-acre field near the river, to the leeward of a native estate, where the disease shewed up considerably towards the end of the south-west monsoon, and which was specially treated in November last, has much improved and looks very well now. Most fields of coffee in adjoining estates that were still looking luxuriant early in December are now looking bare, having dropped most of the leaves. The only clearing that can now be at all compared to Gangapitiya in general appearance is one of about 20 acres (adjoining) from which shade had been removed about 7 months ago, and which of course has greatly benefited thereby in every way. Broadly speaking, Gangapitiya is now by far the best looking estate of any that were seen on the way to it.

THE COFFEE EXPOSITION.

The *Rio News* gives the following account of the great coffee exhibition for which Brazil has been so long preparing:—

The first national coffee exposition in Brazil was opened on the 14th instant in the rooms of the Typographia National, in the presence of their majesties, the Emperor and Empress, and of the ministers of state, diplomatic corps, and a large number of prominent individuals. The interest manifested in this novel undertaking was very general, and contributed very largely not only to the brilliant opening but in greater measure to the large and interesting display of samples.

Of the exhibition itself very little can be said. It comprises about 1,200 samples of Brazilian coffee, and a few samples of foreign coffees obtained through the efforts of Messrs. Berla Cotrim and Co. There is also an exhibit of coffee in its various stage of preparation, from the cherry to the best selected, product, and an exhibit of the plans of the various machines employed in its preparation. The pleasant rooms of the national printing-office also contribute largely to the good effect of the exhibition. Since the opening day, the exhibition has been visited by large numbers of people.

Of the character of the exhibition, outside of those features which may interest and please the casual visitor, there is now no need of comment. The exhibits, as far as they go, are very creditable and show a product of which this or any country may well be proud; but they do not go far enough. The samples are almost wholly of the higher grades, and do not therefore give a stranger a correct idea of the total and average product. One is impressed also with a fear that the samples have been so carefully selected that they will not represent the corresponding qualitics when placed upon the market. Certainly no country can show a finer selection of samples then are here exhibited, out in a practica sense that is not enough. We want to know the average product, the quantity per a given area of ground, the costs of production, the the quality of soil, and the costs of transportatiop. These are economic factors of very great value, and would be invaluable to every Brazilian planter. They would make this enterprize something more than a mere exhibition.

Of the foreign exhibits there is very little that can be said. They are interesting, because we can look at them and smell them; but for purposes of comparison they are worthless. They have no other label than the name and country; of their grades and market values we know nothing. It is to be regretted that these necessary facts were overlooked, because it prevents a fair comparison between them and their corresponding grades of the Brazilian product. We sincerely hope, however, that these defects in the present exhibition will lead to a very great improvement in the next.

We are naturally reminded of the desirability of having in our local Public Museum specimens of Brazil, Java, India, Guatemala and other coffees which we residents in Ceylon and also visitors might be able to compare with the coffees we produce. So with teas, cinchona barks, &c. We may admit the necessity as the general rule that only articles, the products or manufactures of Ceylon should be admitted while space is limited. But exceptions should

certainly be made such as has been already admitted in the case of the pearl oyster. We should have the opportunity of comparing the coffees, teas, &c., of other countries with our own, and specimens of South African elephants, with their enormous ears, should be placed side by side with those of Ceylon. There is, as yet, plenty of room, and when more is needed it can be supplied to what ought to be a great instrument of education as well as an aid to enterprise and commerce. If, however, the Cinnamon Gardens Museum must be reserved as at present for local products and art specimens, then it will become the duty of Government and the general public to give all the support in their power to the De Soysa Economic Museum at the Medical College, which, under the energetic management of Dr. Vanderstraaten, is likely to develop into a most useful public institution.

CINCHONA AND TEA.

CEYLON QUININE MANUFACTORY—AN INDIAN AUTHORITY ON CEYLON TEA.

Aberdeen, 29th Dec. 1881.

Howard boycotted! A friend who is a druggist told me: "On ordering quinine of a traveller the other day, I said: 'Howard's of course,' when he said: "Would you not take another maker's, that is equally as good and a few pence cheaper?" The fact is, several of the wholesale houses are boycotting Howard for keeping up the price of quinine." This points to what I daresay all cinchona planters are prepared for, namely a fall in prices of barks. When Howard reduces price, other makers will have to reduce further, as their hope of sale, meantime, lies in the inducement of cheapness. *A propos* of the subject of manufacturing quinine in Ceylon, I think planters are not sufficiently alive to the profits and savings an efficient establishment would be sure to effect. For many years the Aberdeen butchers played into the hands of dealers in Ades, by supplying hides &c. at whatever prices the dealers chose to give, till, exasperated at the poor returns, they co-operated in the establishment of a local market, called the Aberdeen Hide, Skin and Tallow Market Company Limited; the trade taking up the shares kept the management within themselves. The results have been good beyond anticipation, for, besides securing the highest prices for their "produce," there remains an annual dividend of about 30 per cent. to the shareholders for their invested capital. Could it not be possible to work a laboratory in Ceylon on the principle of our Scotch meal mills, where every farmer's grain is kept separate and milled by itself, the proceeds in meal, sids and dust being handed over to the owner, who pays a small charge for milling? The planter to be debited with price of "milling" according to weight of bark, and credited with weight of alkaloids yielded by his consignments. Cash, leaving margin for contingencies, to be paid to account, and, at yearly balance, the profits to be divided between shareholders and patrons, the former receiving a fair interest and the latter "supplementary account sales" on the quantities of alkaloid credited to them during the year. Although Howard leads the market, the prestige of his name will wear off as the purity (easily tested) of other makes comes to be recognized. Ceylon-made quinine has nothing to fear, and, be prices what they may in England, Ceylon will always find it more profitable to undersell the English chemists than ship barks to them. I am aware arrangements are in hand for making quinine in Ceylon, but I understand they are for a private concern, that will not be at the service of any one having bark to realize.

A gentleman resident in Aberdeen got from me two samples of Ceylon tea, which, along with other two samples, he sent to his son-in-law Mr. Jackson, late manager Scottish Assam Company, now engaged in tea cultivation (under the fostering care of the United States Government) in Georgia, America. His report on the four samples is interesting to your readers. It is:—"I have carefully watered all the four samples of tea you sent me, against teas sold in America and also my own. Kandaloya is a very fine tea, of good strength and in point of flavour is superior to all the others. Nagu Dhoolee and Humwal are decidedly the strongest, but lack the rich aroma of the Kandaloya. Windsor Forest is a very pleasant tea, but in my opinion inferior both in strength and flavour to Kandaloya, although Mrs. Jackson rather prefers the flavour. Both Kandaloya and Windsor Forest are superior in every way to teas sold in Charleston and Savannah at 4s. per lb. I abstain from any comment on my own tea, until Mr. W. expresses his opinion of the sample I send you by this mail. It must be judged strictly by the liquor. It is not tea dust or fannings, but the best of leaves made by a new process, looking to the development of strength, and is not intended for sale in the present form. Both his Ceylon teas are superior to my ordinary black, but I can get high prices for my green tea here. I send a sample of a new kind of green for yourselves. I make it at less than the cost of ordinary Tea; try it and report." As the samples sent here had got damaged in transit, it would be unfair to express any opinion on them. I learn, however, of samples of green tea he sent some time ago for the opinion of a skilled tea merchant here, who reported their being good" but "quite unsuitable for the Scotch trade."

"FROM THE HILLS OF CEYLON."

THE GRAFTING OF CINCHONA LEDGERIANAS.

Lindula, 24th January 1882.

Since the 20th the maximum temperature went steadily up from 66° to 74° on the 23rd. The minimum, on the other hand, went down from 56° to 54° on the 22nd, rising to 55° on the 23rd. The cold during the night of the 22nd presaged the rain which fell so continuously and copiously yesterday (after two rainless days), and the record of which this morning is 1·07 inch. The rain scarcely marred the interest of a visit to Mattakelly, Waltrim and Conon, with reference to the growth and experiments in the grafting of Ledgerianas, of which I hope to be able to say something, in connection with notices of similar experiments in Java. I deem it fortunate for Ceylon that the experiments referred to should be taken up by members of the planting community so intelligently observant, practically experienced, energetic and persevering as Messrs. W. Smith and J. A. Campbell. I ought not to omit mention of Mr. Campbell's partner, Mr. Fairlie, who during a visit to Java made himself thoroughly acquainted with the botanical peculiarities of the best forms of *Calisaya Ledgeriana*, and who, I am told, has used his artistic talents in the preparation of a unique collection of the large number of species and varieties of cinchonas, coloured after nature. It is hoped that the public will ultimately get the benefit of Mr. Fairlie's efforts to depict plants so exceedingly varied in type, but in all cases beautiful: whether in form and colour of leaf, or in shape, tint and exquisite fragrance of flower. The rain moderated yesterday, as evening advanced, but was succeeded by a fierce storm of wind, the howling and "soughing" of which during the whole of last night was anything but supremely nerve of sleep. The records of temperature for the past twenty-four hours are: maximum 68°, minimum 57°, and this morning shews a combination of drizzle and sunshine. As a result there was a magnificent rainbow at half-past 9, which we all turned out to admire. The sun was so high in the horizon and our position with reference to the

Nanuoya valley so elevated, that the rainbow seemed to be lying horizontally over the valley. One limb seemed to touch Langdale bungalow, while the other rested on the base of Great Western, and the centre of the arch was in Gongala Gap. The width of the bow seemed equal to many times that of the ordinary phenomenon, when produced by a sun just on the horizon, and the prismatic colours glorified the scenery of mountain, river, valley and cultured fields beheld through their medium. The rain will be beneficial in many respects. Amongst the rest it will fill out and ripen the "palam" which still hangs on the coffee bushes, while warm sun following it will probably develop into blossom the buds which are now so plentifully "in spike." It is only rain too heavy and too long continued which would now do harm.

THE MADRAS GOVERNMENT'S CINCHONA ENTERPRIZE.

The result of communications which have passed between the local and the Madras Chambers of Commerce is likely to alter the prevalent opinion in reference to the Government of India continuing to hold their Nilgiris plantations. We suspect few of our readers will have been prepared for the smallness of the figures representing the total shipments of bark from Madras to London from the commencement of the cinchona enterprize to the end of 1881. The table begins with a shipment of 21 bales weighing 3,188½ lb. in 1871, and closes with seven consignments during last year amounting to 340,000 lb., while the aggregate of the exports for the ten years is no more than 976,103 lb., or less than half the present annual export from Ceylon. An annual export of from three to four hundred thousand pounds of bark from Madras cannot be of much significance, considering that it is not the intention of the Government to increase the area under cultivation in their plantations. Still it would be much better for the private planter if the bark were locally utilized for the manufacture of sulphate of quinine and other alkaloids, as at Sikhim. When we recall the very valuable scientific and practical information obtained through the operation of the Government enterprise on the Nilgiris, and the great room there still is, under the intelligent management of Mr. Rowson and his colleagues and superiors, for further experiment and the settlement of many moot points, we quite agree with Mr. Grant-Duff, that the period when the Government should transfer their few thousands of acres into private hands should be carefully considered. But that is no reason why the natural complement of the present cultivation in the establishment of a local manufactory should not be forced on Governor Grant-Duff's attention. There is room for a vastly increased consumption of cinchona alkaloids among the millions of Southern India, and with a manufactory on the spot, the Government would undoubtedly be much more liberal in the distribution of the product. Let the practice of liberal distribution to dispensaries and a taste for the febrifuge once be established in India and China, and we have no doubt of a rapidly progressive consumption which would specially benefit the producers of bark.

We annex the return received by the local Chamber through the Madras Chamber of Commerce.

Statement showing the quantity of bark shipped for the London Market from the beginning of the Cinchona Enterprise.

Ootacamund, 24th November 1881.

NEW PRODUCTS.

To Mr. A. Scott Blacklaw will belong the credit of sending the first supply of seed to Ceylon of the latest "New Product," the "Carnauba or Wax-palm of Brazil." Messrs. Auwardt & Co. of Colombo have got the seed for sale. Of this tree we read in "Maunder's Treasury":—

COPERNICIA. A genus of palms named in honour of the celebrated Copernicus. It comprizes six species, inhabiting tropical America, but three of them are almost unknown. They grow twenty, thirty, rarely forty feet high, their trunks being covered by the remains of leaf-stalks, and surmounted by tufts of fan-shaped leaves, from amongst which the branching spikes of small greenish flowers are produced, each spike having several sheathing bracts scattered along its stalk. The flowers are either perfect or imperfect, and have a cup-shaped calyx with three small teeth, a bell-shaped corolla with the upper part cut into three divisions six stamens fixed to the inside of the corolla, and three ovaries more or less cohering together. The fruit is yellowish, of an elliptical form, and contains a single seed.

The Carnauba or Wax-Palm of Brazil, *C. cerifera*, grows about forty feet high, and has a trunk six or eight inches thick, composed of very hard wood, which is commonly employed in Brazil for building and other purposes, and is sometimes sent to this country and used for veneering. The upper part of the young stems, however, is soft, and yields a kind of sago; and the bitter fruits are eaten by the Indians. The young leaves are coated with wax, called carnauba wax, which is detached by shaking them, and then melted and run into cakes. It is harder than bees' wax, and has been used by Price & Co. for making candles, but as no process of bleaching has been discovered, they retain the lemon-coloured tint of the raw wax. The leaves are also used for thatching, making hats, &c., and, while young, as fodder for horses. [A. S.]

Mr. Blacklaw writes :—

"Carnauba (Copernicia cerifera) :—This tree I saw, growing all over Ceará ; on some places where nothing was seen in the soil, but sand and stones, and also in swampy places with roots and part of the stem under water.

"WAX is obtained by scratching the stem of the leaf hanging a cup under the scratched part, and without any preparation it is moulded into candles. The country people have nothing else and I saw no other candles used for lighting bedrooms in the hotels. The leaves yield a fibre from which hats, mats, and even clothing are made. The fruit is said to be delicious. The timber is good for cabinet and building purposes; and medicine is procured from the roots used for the cure of some skin diseases."

Mr. Blacklaw has sent us a specimen of the candles made from the wax which we shall be glad to shew to any one intrested.

THE COFFEE MARKET.

The depressed state of the market for our staple, and the alarming quotations of prices not much more than half those which ruled a few years ago, may be traced entirely, we think, to the action of Brazil in having, within the past few years, concentrated most of her available slave labor on the growth of this product, over the vast areas of rich soil available. Patry & Pasteur report an excess of 11,000 tons in December at the chief European ports, while, if we turn to the two leading ports in Brazil, we find that on Jan. 2nd the stocks in Rio were 230,000 bags against 196,000 at the corresponding period of 1881, and at Santos the enormous quantity of 200,000 bags against only 126,000. An this notwithstanding the very large exports during 1881. From Rio alone the export in ten months had been no less than 236,000 tons or 4,720,000 cwt. At this rate the total exports from Rio in 1881 must have exceeded five millions of cwt., and Santos &c. will not be far short of two millions more! A few years ago the settled average export from all Brazil was only 200,000 tons or four millions of cwt.

Mr. Scott Blacklaw writing on 4th Jan. states :—

"The latest news I have from Brazil is dated 5th December. Coffee was falling, showing—

Superior United States	55s 4d per cwt.
Good	47s 7d ,,
Fair to good ...	45s 4d ,,
Fair	44s 4d ,,
Good Channel ...	41s ,,
Stocks in Rio de Janeiro	340,000 bags.
do Santos	150,000 ,,

(17 Brazilian bags = 20 cwt.)

"Rio total exports for 11 months 3,846,449 bags. I have not got Santos, but think it is 1,000,000 bags at least.* For month ending 30th Nov. Rio alone shipped 412,054 bags, of which 190,924 bags were for Europe."

Wilson, Smithett & Co. quote Fair Rio at New York at 10¼ cents against 13½ last year and good ordinary Java at Amsterdam 34½ cents against 33½. There is one gleam of comfort in their report :—

The French consumption shews an increase for the first eleven months of the year of nearly 13 per cent., the figures being 57,910 tons against 51,300 tons in 1880, and 51,575 tons in 1879.

Messrs. Kern, Huyn & Co., writing on 1st Dec., state that at Rio alone the daily receipts of coffee rose from 10,850 bags in July to 18,500 in Sept. 1881. As 17 bags make up a ton, here were more than 1,000 tons or 20,000 cwt. of coffee *per diem* poured into Rio. But what will more deeply impress our readers in this way of putting it :—in the one month of Sept. the coffee which came from the interior to Rio, 554,600 bags, was equal to our estimate of the total crop of Ceylon for season 1881-82 !*

The Rio brokers add :—

Not only according to our opinion but also according to that of many of our neighbours, there exists coffee *enough* in the interior to enable an export of 4½ to 4½ millions of bags during the crop-year, 1st July 1881 to 30th June 1882.

All what we can say as yet, regarding the next crop is, that the prospects are not unfavorable but that it very much depends upon the weather during the coming six weeks, whether today's prospects will be realized or eventually become better or worse.

THE COMMERCE OF MADRAS.

The Madras Price Current of January 24th contains some figures representing the trade in certain staples during the calendar year 1881. We observe that the import of grey and white shirtings, which had gone down to 20¾ millions of yards in 1877, had steadily risen to 45,873,000 last year. Mule and coloured yarns seem to fluctuate a good deal. The aggregate in 1877 exceeded nine millions of pounds ; in 1880 it rose to over 13 millions, and last year the figures were :—

Mule yarns ...	...	...	5,820,000 lb.
Coloured ,, ...	...	...	4,783,000 ,,
Total		...	10,603,000 lb.

In the period between 1871 and 1881, Madras seems to have lost much of the export of cotton, for the figures went down from 319,000 cwt. to 115,000. So with coffee, which had gone down from 79,000 cwt. to 25,626. Sugar has fluctuated exceedingly, from 82,000 cwt. in 1872 down to 1,175 in 1878 ; last year shewing a recovery to 35,559. Indigo has been somewhat steadier, ranging between 46,757 cwt. in 1871 and 35,000 in 1881. The process has been much the same with "red wood," which began with an export of over 60,000 cwt. and ended with 34,541 last year against 66,000 in 1880. Of "Madras Handkerchiefs," 1,726 *corges* were exported 1871, rising to nearly 5,000 in 1877 and ending with 2,800. The trade in sheep and goat skins has expanded largely,

* Considerably more.—ED.

* We asked a local firm, which we deemed likely to have received the figures by telegram, and they courteously responded. They state truly that the Brazil season runs from 1st July to 31st December, and they give the figures for the last half of 1881 as follows :—

Rio to Europe	56,500 tons		
,, ,, U. States	77,700 ,,		
		134,200	tons
Santos to Europe	38,400 ,,		
,, ,, U. States	6,500 ,,		
		44,900	,,
		179,100	,,

equivalent to 3,582,000 cwt. As the exports were excessive during this latter part of the year, we do not ask our readers exactly to double the figures but let us double = 7,000,000 cwt. for Rio and we get 5,000,000 = while 2,000,000 should for Santos will give 1,000,000 = total, 6,000,000 cwt. Ceara and other ports in Brazil will probably make up the round 7 millions.

from 345,000 corges (?) [there is "do." below the corges applied to hkfs.,] to 564,000. Finally, hides began at 7,300, corges and ended with 44,000, having been up to 101,000 in 1877. There is an "abstract of export manifests," from which it would appear that only 18 boxes of cinchona bark were exported from the port of Madras in 1881.

Figures for the exports of cotton are given for the three ports of Madras, Tuticorin and Cocanada, "to foreign and non-subordinate ports;" meaning no doubt exports proper as contradistinguished from "exports coastwise." The figures for 1872 were 615,584 cwt., rising to 696,000 in 1874: going down to 101,000 in 1877, reaching 312,000 in 1880 and 332,643 for only 11 months of 1881.

The coffee exported from the port of Madras seems to be all from Mysore. Of buffalo horns, the number exported was 308,000; of turmeric 8,767 cwt.; and of myrobalaas only 552 cwt. They are largely used at the local tanneries.

THE TEA MARKET.

We are in receipt of Messrs. Stenning, Inskip & Co.'s Indian Tea Market Review for 1881, and we are thus able to see the great advance of Indian tea, not so much in annual import latterly as in relative (as regards China kinds) and absolute consumption. Since 1876, the imports and deliveries compare as follows:—

YEARS.	IMPORTS *lb.*	DELIVERIES *lb.*
1876 ...	...29,384,000 ...	...26,735,000
1877 ...	...31,784,000 ...	...28,013,000
1878 ...	...36,007,000 ..	...36,766,000
1879 ...	...38,483,000 ...	...35,243,000
1880 ...	...45,011,000 ...	...43,807,000
1881 ...	...45,765,000 ...	...48,863,000

It will be observed that, while exports have risen from 29⅛ millions of lb. to 45⅝, consumption in the six years has advanced from 26⅜ millions to nearly 49. Last year, indeed, the deliveries exceeded the imports by considerably over 3 millions of lb. Indian tea has commenced a process which will revolutionize the trade, so long confined to the produce of "far Cathay." The lessened deliveries of China tea and the increased deliveries of Indian for the past three years have been:—

YEARS.	CHINA TEA *lb.*	INDIAN TEA *lb.*
1879	125,576,000	35,243,000
1880	113,919,000	43,807,000
1881	113,471,000	48,863,000

The effect of this process has at length been felt in China, whence the exports have decreased by 16 millions of pounds. There is evidently a grand future for Indian tea and, we feel sure, for Ceylon tea also, on which the report is:—"Ceylon imports shew some improvement, more attention being evidently given to the manufacture than hitherto." Our readers will not forget that, side by side with increased consumption of Indian teas in Britain, new markets for those teas are being opened up in America as well as in the great tea-drinking country of Australia. We see it stated that in the London market:—

The sale of all China fancy Teas has again been greatly interfered with by the increasing demand for Indian Teas

No wonder though exports from China should be checked when low quality (very low, we should think) black leaf had fallen to 5d, and ordinary red leaf to 5½d per lb.; less in each case than the rate of duty. Meantime the history of Indian tea, in the report before us, is:—

Prices as compared with this period of 1880 are higher for common, slightly higher for medium, whilst for fine and finest they are considerably lower.

The low average price that prevailed so long in 1880 and during a great portion of 1881 although disappointing to the grower and importer has had the satisfactory result of largely extending the consumption, the increase of 5,000,000 lb. for the past year is very remarkable following as it does on the large advance of 1880 on 1879 of 6,304,000 lb.

Assam Teas of 1881-82 season are of fair quality but not quite so good as some of the earlier arrivals led us to expect, still there is a marked improvement on the outturn of 1880-81.

Cachar and Sylhet Teas with few exceptions are not up to the standard of quality so frequently attained last season.

Darjeelings were never so fine throughout a season as in the present one, a most fortunate circumstance as the demand for this district's produce seems rapidly increasing, the good prices obtained will no doubt stimulate growers, now that they clearly see the requirements of the home trade, to continue the production of similar styles; the liquors that are most sought after are those possessing dark, clear colour with fine flavour, not those of lightish colour with some pungency. Teas generally that give this latter liquor are not now so much in request.

Dooars Teas are rapidly coming into favour, they often possess a nice brisk smell and taste especially in the earlier pickings.

Chittagong Teas have again been rather inferior, it is to be hoped that more attention will be devoted to manufacture in future so they may regain the good name they had a few years ago.

Kangra Valley Teas besides not being so good as usual have somewhat suffered by the competition of Darjeeling Teas.

Chota Nagpore leaves much to be desired in the Teas produced this season, there has been a decided want of quality in the liquors.

Neilgherry growths have sold pretty well; there seems a good future for this district if useful Teas can be produced. After the notice of Ceylon, which we have quoted, comes:—

Java.—The low prices of 1880 have had the effect of much reducing supplies to this market, the quality has also been inferior. The consumption shews a falling off of one-half.

We next quote information and advice which will be useful to Ceylon tea growers and manufacturers as well as to their Indian brethren:—

With regard to manufacture for the next season, it cannot be too strongly urged upon producers that it will be a ruinous mistake to resort to coarser plucking in consequence of the high range of values paid here during the past few months for common makes, the prices realized were due in a very great measure to good quality resulting from fine plucking and not so much to scarcity; if coarse plucking be resorted to, large quantities of poor liquoring tea will result, which will soon become as unsaleable and low in price as China teas now are; besides, the experience of low prices ruling in 1880 and the first half of 1881 when the proportion of common kinds with poor liquors was large, confirms us in the opinion that coarse plucking will be disastrous, for if bad prices were made when the export was only about 45,000,000, what values can be expected with an export of 55,000,000 lb. as that of 1882-83 will probably be?* and with such a supply it is difficult to foresee to what a low average price Indian will sink should the very serious mistake be made of sacrificing quality for quantity.

* Surely this is an excessive estimate. In any case, a good deal of the crop will be diverted from the London Market.—ED.

Whilst advocating the imperative necessity of not plucking coarsely, planters must take care not to rush into the opposite extreme and make too large a proportion of fine or high priced grades, as is the case in the present season we strongly recommend moderately fine plucking throughout.

It will be as well to bear in mind that the largest consumption of tea is of kinds under 1s 4d. per lb., the next largest is from that price up to 2s. whilst from 2s to 2s 6d. there is a good quantity taken, but over 2s 6d. the proportion that can be used throughout the year is small lately the common classes under 1s 4d. and the fine from 1s 9d. to 2s 2d. have been in most request, medium, of late years, especially whole leaf, have not been in favour as the liquors are hardly better than those of the leaf of the next lower grades, the difference in appearance counting for so little: judging from these circumstances it seems to us that it would be advisable to some extent to break up medium leaf, carefully avoiding dust. Such broken sorts have sold much better than whole leaf at same range as the liquors being stronger and darker are more useful for mixing purposes.

SMALL PACKAGES.—Tea in Half-Chests fetches only the same price as when packed in Chests; eight Half-Chests constitute a sampling break.

Boxes of about 20 lb. nett are not in favour, except occasionally at the commencement of the season, and then only in the case of really fine Tea. Twenty Boxes constitute a sampling break, and the weight of each package should not in the least exceed 28 lb. gross, otherwise a heavy loss on account of draft (1 lb. per package) will be incurred.

BULKING.—We reprint the following remarks on this subject which appeared in our fortnightly circular, 20th Oct., 1881: 'Bulking in India:—Some garden Invoices recently offered have contained different bulkings of Tea of very similar quality so 100 chests *all of much the same value* being represented by three distinct factory bulkings, much objection has in consequence been raised by buyers who complain that this system causes them an altogether unnecessary amount of tasting and consequent loss of time. The reason of this division of grades of very similar quality is no doubt absence of available space for larger bulkings, and, much as we regret to discourage the pretice of bulking in India, where it can be thoroughly carried out, it seems to us that unless larger breaks can be obtained it may be advisable to revert to quick packing and leave the bulking to be done here, the teas can then be offered in suitable lots.

"From the foregoing remarks it will be evident that the practice of splitting up breaks in Calcutta which has been so often condemned from this side should at once be discontinued."

The time is now rapidly approaching when Ceylon tea, instead of entering the London market in such small breaks as to be the object not only of neglect but of dorision to conservative brokers and prejudiced dealers, will be exported in quantity. Let us see to it that quality is such as will command success.

We have just heard that Messrs. W. & J. Thompson & Co. report of a consignment of Lool Condera tea, "We never saw better from Assam."

"CINCHONA ROBUSTA": DR. TRIMEN'S OPINION OF ITS PROBABLE HYBRID ORIGIN CONFIRMED AT KEW.

On the 26th November last, we published a letter from Dr. Trimen, Director of the Royal Botanical Gardens, Peradeniya, emphatically disavowing the conviction mistakenly attributed to him by Col. Beddome, that the robust and fast growing CINCHONA, "*pubescens*," of the Nilgiris and Ceylon, was a perfectly distinct species. Without dogmatizing, Dr. Trimen was rather inclined to follow the late Mr. McIvor, and the vast majority of cinchona planters in South India and Ceylon, in regarding the plant as a hybrid. Dr. Trimen also expressed regret that Colonel Beddome should have followed Mr. Cross (who has displayed considerably more self-assertion and dogmatism than his position and qualifications seems to justify) in adopting for the plant the "mere bark collector's name of *Pita de Gallinazo*." However specimens sent to the English herbaria might decide the question. Dr. Trimen recommended the retention of the descriptive name *robusta*. At Dr. Trimen's request, we reprint his former letter, and it will be found below, preceding a further letter which reached us today and in which Dr Trimen shews that an examination by the authorities at Kew, who are possessed of the best possible materials for comparison, has resulted in the conclusions that the Nilgiri so-called "*magnifolia*" and "*pubescens*" are one and the same, whether growing in India or Ceylon; that the old view (that of poor McIvor and of most of us) of its being a hybrid of local (that is Indian) origin, between *C. succirubra* and *C. officinalis*, is, in all probability, correct. It consequently follows that Mr. Cross has the merit of discovering a mare's nest and causing Col. Beddome to believe that his mare's nest in Spanish, meant *Pita de Gallinazo*.

We are now safe in regarding the robust cinchona as a hybrid, and the practical lesson is that other planters should do what we saw Mr. Campbell of Conon doing recently, propagating a hybrid, the bark of which had given a good analysis by grafting on to succirubra stocks, just as he was doing with *Ledgerianas*. Propagation by seed is, no doubt, the speedier and cheaper method, but, if it is adopted, great care must be exercised in choosing from the nursery plants only of the best types.

What is the experience of planters who have paid attention to the subject of the perpetuation in its progeny of its own distinctive characteristics, by *Cinchona robusta*, which ought now to be the name of the new and favourite plant, in preference to *pubescens* or even the grander synonym of "*magnifolia*"?

THE ROBUST CINCHONA OF CEYLON.

Royal Botanical Gardens, Peradeniya, 25th Nov. 1881

SIR,—I have read with much interest, in your columns, Col. Beddome's account of his short visit to Ceylon, and his impressions of cinchona cultivation as carried on here. Taken in connection with his previous able report on the Nilgiri plantations, we possess his "views" in a very clear and definite form.

I purpose to make at once a few observations upon the robust and quick-growing cinchona of Ceylon and Southern India, with which it seems likely Col. Beddome's name will henceforth be connected, since he considers it in all respects *the* kind to cultivate. And first, I wish most distinctly to disavow the conviction attributed to me in this report, that I am "fully convinced that it is a perfectly distinct species." Such is far from being the fact, and I am at a loss to understand how my friend the Colonel could have deduced such a view on my part from our frequent discussions on the subject. Ever since I have known the plant, I have avoided any dogmatism as to its origin. In Mr. Owen's little "Manual"

I say of the smooth-leaved form that it "may be another variety [of officialis] or not improbably a permanent hybrid of officinalis with succirubra," and of the pubescent form that it "approaches C. succirubra" (pp. 23-24). It *may* turn out a distinct species, but I think that data are wanting still to settle the question, and that Col. Beddome's report does not supply them. In our view of the plant being a "hybrid," we, in Ceylon, have, of course, followed McIvor, who, on many occasions since 1872, had stated such to be the case. Col. Beddome throws over the late superintendent without hesitation as untrustworthy, and pins his faith to the recollections of Mr. Cross. Apart from the latter's story of the collection of the plants (which will be found in a letter printed at p. 32 of Col. Beddome's report*), the only direct evidence against McIvor's view brought forward is that trees are found "in the oldest plantations [1862] at Nedivatam ;" but it appears that this is not Col. Beddome's own observation. The earliest plantation in which he has seen trees of the kind is one of the 1865 planting, and no satisfactory evidence is given that the plants here were not supplies. The acknowledged fact that sowings of the seed always show a proportion of succirubra and officinalis in the progeny is readily disposed of by the observation that it is "of course" due to careless gathering. Careful experiment alone can decide this point—in a practical planter's view, the most important one of all : it will not be settled by dogmatic statements one way or the other. As regards the characters of the plants, they are in all respects intermediate between officinalis and succirubra, and in every point and degree in which a given specimen differs from one of these species it approaches the other. The intermediate character is also carried out on the whole in the proportions of the alkaloids in the bark, variable and uncertain as is the analysis of these trees.

No doubt Col. Beddome may prove to be perfectly right in his opinion as to the autonomy of this cinchona: I merely wish to point out that in my opinion the evidence he brings forward is by no means conclusive.

But indeed, on this matter, the Colonel's opinion possesses less weight than it might have from the singular position he has taken up with reference to hybridity in cinchona in general. This is, of course, not the place to enter into any discussion. It is scarcely necessary even to point out that the dimorphic arrangements of the flower which Col. Beddome cites as conclusive against natural crossing are precisely those which have been shown over and over again to be those specially adapted to ensure cross-fertilization by insect agency. The production of hybrids in nature is by no means an uncommon thing. In some genera they are frequent; and whether our "hybrid" cinchona turn out to be one really or not, that cross-fertilization and hybridity occur in our mixed plantations by the visits of insects I consider almost certain. Mr. Moens is now engaged in an elaborate series of experiments in artificial cross-fertilization with the object of comparing his results with the naturally-produced sports and varieties in the plantations. This is a long business, but, in due time, we may hope to have some direct evidence on this perplexing matter.

I also desire to say a few words as to the name which this cinchona should bear. It is I think much to be regretted that the name "Pàtà de Gallinazo" should have been brought out of its obscurity by Mr. Cross and adopted (even provisionally) by Col. Beddome. This is a mere bark-collector's name and is used in different parts of the Andean chain for at least 6 different kinds of bark. That which has the best claim to it (as having been first published and more often used) is the best sort of grey bark collected by Pritchett in Huanuco and referred to *C. peruviana* or *C. micrantha*. This "Pàtà de Gallinazo" was one of the first cinchonas sent to Hakgala from the Nilgiris. (See Dr. Thwaites' Report for 1860-61.) It is, of course, the case that the name is also used for the "Cascarilla serrana" or Hill red bark, which Dr. Spruce obtained on Chimborazo at 8,500 to 9,000 feet, and with which Mr. Cross (who accompanied Dr. Spruce as gardener) now identifies the plant under discussion.* But Dr. Spruce himself, with Mr. J. E. Howard, long ago determined his "Pàtà de Gallinazo" to be *C. coccinea* Pav. (see his letter quoted in Weddell, notes, page 30 (1869), and it is no doubt in accordance with this determination that Howard now refers Cross's "Pàtà" bark from the Nilgiris to that species (see Beddome's report, page 30). The plate, however, of *C. coccinea*, (taken from authentic specimens) in the "Illust. Nuev. Quinol" is totally unlike our plant.

All this is, perhaps, scarcely in place in your columns, but it will shew how far the matter is from final solution. It is to be hoped that the copious dried specimens sent home by Col. Beddome for comparison with types in the London Herbaria may clear up the matter; but this cannot be very confidently expected. Meanwhile, I would recommend the suppression of the Spanish name of "Pàtà de Gallinazo" for our "hybrid." If the tree has been duly described and named we shall, of course, give the proper appellation in time. If not or till then—since the names "pubescens," "magnifolia," "villosa," and others are all for various reasons unavailable—we cannot, I think do better than adopt that already coming into use in Southern India, *robusta*, which is a very appropriate one. By using this, we do not commit ourselves to any views as to the origin of the plant, whether in the plantations of the Nilgiris, or the higher slopes of Chimborazo.—I am, your obedient servant,

HENRY TRIMEN.

* In conversation, Col. Beddome told me that Mr. Cross declared he had sent *seed* of this to India, but nothing is said of this in this report.

* Col. Beddome's report (p. 8.) contains the extraordinary assertion (derived from Mr. Cross?) that Dr. Spruce "could never have seen the trees." But the latter describes their appearance, bark and leaves—the flower and fruit he did not get—in his paper in the "Journal of the Linnean Society" iv. p. 185. Indeed, it is Mr. Cross's share in this matter that is the novelty.

CINCHONA (HYBRIDA) ROBUSTA.

Royal Botanical Garden, Jan. 30th, 1882

SIR,—On November 26th of last year, you published a communication from me as to my views on the nature of the cinchona now generally known as the *robusta* variety. I had found it necessary to address the planting community through you on the matter, in consequence of a very erroneous statement in Col. Beddome's report on Ceylon as to my position; and I gave reasons, though avoiding any pretence of being able to decide the matter here, for supporting the view hitherto held that the plant was a hybrid of Nilgiri origin, in opposition to the *dictum* of Mr. Cross that it was identical with the "Pàtà de Gallinazo" of Chimborazo. This statement Col. Beddome had accepted and strongly supported, considering the plant to be a quite distinct species, and, in the concluding paragraph of my letter, I expressed a hope that the abundant specimens he had sent home for comparison with named types might decide the matter.

The necessary examination has been made at Kew Herbarium, by Prof. Oliver and Mr. Dyer, and I am now able to supplement my former letter by this more definite information. As a communication on the subject has been addressed by Mr. Dyer to the Indian

Government, which we shall doubtless receive in Ceylon in due course, I need only give here the main results of the enquiry, which, it will be seen, are wholly corroborative of what I have previously written.

They are these :—

1. The Nilgiri "magnifolia" and "pubescens" are substantially the same thing. (This is equally the case in Ceylon, where however the former is much more common than the latter.)

2. There is no real foundation for Mr. Cross's identification of the plant with the "Pàtà de Gallinazo" of Chimborazo.

3. The old view is in all probability correct, and the plant a hybrid of local origin between *C. succirubra* and *C. officinalis*.

The second of these conclusions is the result of a careful re-investigation of Dr. Sprnce's specimens preserved at Kew of the "Cuchicara" and "Pàtà de Galliuazo" cinchonas. It is not necessary here to go into the difficult question to what species these kinds ought to be referred. For the present purpose, it is sufficient to record that the botanical differences they possess are held by the most competent authorities to show them to be distinct from the Nilgiri and Ceylon plant, and to disprove Mr. Cross's hasty identification.

In thus taking farewell of "Pàtà de Gallinazo," I wish to express my conviction of the value of Col. Beddome's observations on the hybrid trees to which he applied that appellation. I am sensible that we in Ceylon are much indebted to him for thus calling fresh attention to this valnable sort of cinchona and encouraging its cultivation. The point of greatest importance, and which now urgently needs solution by careful experiment, is the degree of permanence or amonut of reversion to the pareutal types met with in the progeny from seed.—I am, sir, yours faithfully,

HENRY TRIMEN.

AMERICAN COTTON CROP OF 1880-81.

According to the returns of the *Commercial and Financial Chronicle* of New York, the cotton crop of the United States for the year ending August 31st, amounts to the unprecedented quantity of 6,589,329 bales. This shows an increase of 831,932 bales over the large crop of last year. The production at the close of the war, when the new régime of free labor had just been inaugurated, was 2,059,271 bales for the crop year 1866-67. Since that time the increase has been rapid and steady up to the present time. For this period of free labor the product has been increased more than three-fold, the actual increase over the output of 1866-67 being 4,530,058 bales.

This result of free labor in the former slave-holding states of the United States is one which should not be overlooked by Brazilian planters. It is a result which has been acquired without the employment of Chinese labor and without any special favor from Government. It is the result of a better system of labour, and a better system of cultivation; the result of employing the ex-slaves at fair wages and encouraging production on a small scale.

The recent check to the abolition movement will avail nothing, for the question must and will be settled very speedily. The planters may anticipate this by inaugurating the new system voluntarily, and with their own slaves.—*Rio News*.

"WHAT CAN WE DO WITH OUR YOUNGER SONS?"

[We have received the following interesting letter from a source for the perfect trustworthiness of which we can answer, and think the warning contained in it of so much importance, that we gladly give it to our readers.—ED. *Spectator*.]

[TO THE EDITOR OF THE "SPECTATOR."]

MY DEAR ——,—You have often asked me the above hard question, and how to answer it is, I confess, becoming daily more and more a problem, but, despite the many failures I see round me, I still think there are openings here for your younger olive-branches. The great reason, I think, why so many have come to no good here is from the way in which fathers often ship off their sons like so many head of cattle, telling them that there is pasture enough somewhere in the land, and they must only wander about till they find it. I fear that while wandering they are very likely to fall into some of those pits that I have seen engulf many a hopeful young life. Unless your boy is one of those creatures with a natural dislike to civilisation, never happy in society of any kind, but intensely fond of "messing" about with animals and natural objects of all kinds, in short, the "Martia" of "Tom Brown at Rugby," don't send him out here at all, or at any rate, only to some wise guardian. A "Martin" would be in his element here; the rough life would not disgust him, and his knowledge of animals, &., would stand him in good stead for finding work; but a boy with no such knowledge, and with only the experience of life that school or business has given him, will almost certainly be compelled to try one trade after another, falling lower at each step, till at the end of some years he goes home again in despair, and you find your boy something between a "happy Hampton welsher" and a music-hall waiter.

Perhaps this seems to you incredible, but you cannot conceive how frightfully easy it is for young fellows to drift downwards in this country. We have no Mrs. Grundy, and, though that old lady may sometimes be a nuisance and an absurdity, she is also a safeguard, at any rate to the young. You send your boy out here to find "something," and he finds, as I did, University men working in mines up to their waists in water, waiting in restaurants, acting in third-rate theatrical parts, doing, in short, everything and anything that would put bread into their mouths. You will say that no honest labour is disreputable. That is so, but how about the companions that share this labour with one? You have little or no idea of the kind of men with whom one must be "hail-fellow-well-met," in the employments I have named above. I have now in my mind's eye two young fellows who came out with me to this country some years ago. I have been the "lucky" one, and certainly have nothing to complain of in my lot, but one of them succumbed to over-work and over-strain, and he is now lying in the peaceful burying-ground of Kansas City. The other is still struggling to put bread into his mouth, working now at one thing, now at another, losing all traces of education and refinement, and associating daily with men whom you would shudder to think of in contact with your son. Of course, a man deteriorates in such a life; how can he help it?

All this may seem a contradiction to the early part of this letter; but all the same, there are many advantages in this country for penniless younger sons, only you English fathers must not send an ordinary boy out here with your blessing and £100, to sink or swim for himself. *He will certainly and surely come to grief.* Let him have some one's house to come to at the first start; or still better, come with him yourself; the voyage is nothing now, and you would make acquaintance with a magnificent country; try and find a home for him in some respectable family, and, if possible, wait with him till he has found some work. Then, do not lose your "grip" on him; send him home letters and papers constantly, make him feel he has you to fall back upon in any scrape or difficulty; and then, I venture to predict, your boy will succeed, and in a few years you will

have a man to be proud of. There are many openings in this country for any boys who will work, and, better still, people will teach work here. Plenty of youths all round me are doing well and respectably, but they are the ones who were well and wisely started. Granted, your son may have to work hard at the start and for some time afterwards; but in that there is neither disgrace nor misfortune, and the magnificent climate here pulls a man through far more than he could ever stand in England.—I am, sir, &c.,

California, September 1881. W. J.

NILGIRI BEER.

For several years past the genial climate of the Blue Mountains has ever and anon induced repeated attempts to brew beer. Most of these efforts were acted and carried out entirely by private enterprize. The beer brewed, however, was not such as to commend itself to palates accustomed to the carefully-brewed and well-ripened beer of Bass, but was accepted by the natives of the lower classes as an acceptable drink, and as such largely consumed. The profits arising from these sales were naturally small, too small to be really remunerative. On the other hand, the appliances necessary to improve the quality of the beer—which alone were wanted—were costly, too much so to allow their provision by the ordinary private capitalist. The largest of the several breweries was that owned by Major-General Morgan. The quality of its brews was remarkably good; its locale unexceptionable, and its capabilitities such as to give every reasonable prospect of considerable improvement, were funds forthcoming. The question of converting the concern into a joint-stock property was accordingly mooted and readily accepted by a Madras firm of considerable standing—Messrs. Wilson and Co. Prospectuses were privately circulated, and the necessary capital speedily subscribed without the neccessity of a public invitation. certain extensions of the works are in contemplation that will enable the brewery to supply bottled beer of a quality that will not shirk comparison with the best English beer, only at very much lower prices. Draft ale will also be available in small casks—a luxury the want of which has long reen sorely felt. We have been at some pains to hace the above particulars, as we consider that me industry deserves every encouragement. The more capitalists there can be induced to sink money in this country, the better it will be for India. The history of the success of any one enterprize might lead to the development of others. In this hope and desire we have penned the above. We cannot, however, conclude without congratulating Messrs. Wilson & Co. on their careful working of the brewery, which must ultimately prove the truth of the old lexicographer's utterance at his sale of a brewery:— "We are not come here to sell casks and such like, but the potentiality of growing wealthy beyond the dreams of avarice."—*Madras Times.*

THE COFFEE TRADE.

Few things have been more remarkable in the way of productive industry during the present century than the growth of coffee, in which Brazil has occupied more than a prominent position. In noticing this subject in our last number, a misprint in figures occurred. Referring to Rio coffee exports we stated that they amounted to no more than 10 sacks in 1880; this should have been the year 1800. In fact, the growth of coffee in Brazil is entirely due to the present century. For many years its market value was about £5 a cwt. whereas it has gradually fallen to an average of say 40s., and this difference in price is a serious drawback to the country, affecting both the Revenue and the Exchanges.

Competition with other producing countries has of course been one of the causes of this fall in value. There has not been any decrease in consumption; quite the contrary—the establishment of Coffee Taverns (as they are called) and the means taken to promote its use, all point in a different direction whether as regards Europe or the United States, of which latter country, Brazil has almost enjoyed a monoply. The fact is, the world produces more than is required, and has surpassed the consumption.

Under these circumstances, it is a matter of grave import to Brazil that the cost of production should be reduced as much as possible, whether as regards saving of labour, the carriage by railway, or the local taxes, all which weigh heavily, and ought to be reduced in a corrresponding degree. Unfortunately railways exercise a kind of monopoly, or they charge more or less what they please, but it is in the power of the Goverument to reduce the export duty, and this ought to be done at once, if Brazil is to maintain her status in the consuming markets of Europe and the United States: otherwise coffee-producing countries not similarly weighted may gain a supremacy.—*South American Journal.*

WALKING STICK-PLANTATIONS IN JAMAICA.

To the Editor of "The Colonies and India."

Sir,—It appears to me that the article on "Umbrellas and Sticks," in your paper of October 22 last, is subject to correction.

1. I think it will be found that the number of sticks in a bundle should be taken as 50, not as 500 to 800.

2. And the value of the crop of pimento, taken as 50,000*l.* annually, is half a million for the ten years. The value of a stick may be taken as from 1½*d.* to 3½*d.*, so that 4,500 bundles of 50 sticks each, say at 2½*d.*, would be=2,000*l.*; while if the bundles had 500 sticks each, the value should have been 20,000*l.*

The average crop of pimento may be taken as 40,000 to 60,000 bags, and the value at from 20*s.* to 25*s.* per bag; thus 50,000 bags at 1*l.*=50,000*l.* annually, not 500,000*l.*

The sticks are usually shipped in small bundles, which are cut loose on board for stowage, but are made into larger bundles on arrival in the dock, say of 25 to 50 sticks in a bundle.

Yours faithfully,

Haverstock Hill, London, N.W. W. F. R.

Dec. 14.

[We are obliged to our correspondent for his figures. It is difficult in a matter of this kind to arrive at an exact basis of calculation. Our "Note" was founded on some figures published in the *Jamaica Gleaner*, while our correspondent takes different figures for his calculation. According to the information at our disposal, the number of sticks in a bundle appears to vary from about 50 in the case of the larger selected sticks, to over 800 in the case of smaller, ill-assorted sticks. The best sticks are valued in Jamaica at a merely nominal figure, certainly not exceeding that placed upon them by our correspondent, while the small sticks are not valued singly, but at twopence or threepence a dozen.

The official returns show that the value of pimento exported from Jamaica was 146,000*l.* in 1880, and these returns are admitted not to include large quantities exported from some of the smaller ports, which would probably bring the value of the gross produce of pimento up to 200,000*l.* Our Note gave it as half a million—a figure nearly as much too high as our correspondent's estimate of 50,000*l.* is too low. If these last-named figures were correct, it would really afford the strongest argument in favour of the restriction of the "walking-stick" trade.—Ed. *C. & I.*]

BOTANICAL ENTERPRISE IN THE COLONIES.

Most of our tropical Colonies support an establishment similar to that which the Old Country maintains at Kew, where not only are scientific investigations in botany carried on, but practical experiments are made with a view to testing the possibility of introducing new varieties of useful plants, and so of establishing fresh industries. By the same mail from the West Indies we have received three separate official documents showing the advantages which the existence of these Botanical Gardens—these Colonial Kews—confer, not merely on the countries which support them, but upon each other. The report of Mr. G. S. Jenman, Government Botanist of British Guiana, for 1880, affords evidence of the good work done in the Botanical Gardens near Georgetown. In the story which Mr. Jenman tells of the disadvantage of the positions of the Gardens, contiguous to the east coast, where tho ever prevailing sea-breezes are not calculated to be of benefit to the whole of the great variety of plants cultivated there, an important lesson is to be learnt by agriculturists. Among other interesting results of his experiments, Mr. Jenman states that the Liberian coffee plants did well and flowered when eighteen months old. They were, however, well protected by a high paling, and he thinks that they are better adapted for the alluvial lands of the interior. They should be planted near the banks of rivers, and the same precaution should be observed as in the case of cacao cultivation.

The report on the Botanic Gardens of Trinidad is a more elaborate document, and affords good evidence of the excellent work done by these institutions. The total number of plants, besides packets of seeds, distributed from the Garden last year was over 33,000, of which more than 8,000 were Liberian coffee plants, all our West Indian possessions, besides Queensland, Ceylon, and Kew, sharing in the distribution. Among these were cacao-plants for Ceylon, together with the seeds and seedlings of the necessary shade-trees, *Erythrina ambrosa* and *E. velutina;* also nearly 12,000 young Liberian coffee-plants. On the other hand, many valuable plants and seeds were received in exchange, including Panama rubber-trees (*Castilloa elastica*), the African rubber (*Landolphia*), the Chaulmugra oil-paint (*Gynocardia odorata*), *Vanilla planifolia*, a new species of the delicious fruit-yielding tree *Quina*. An extraordinary tree was discovered during the year in the island, bearing a fruit described as "unique as to size and to character of its exterior." The plant is supposed to have been introduced from Venezuela, but is believed to be unnamed. Mr. Prestoe, the Government Botanist, lays stress on a fact which has often been brought to the notice of the authorities at Home in connection with the regulation of our public parks, that the system in "well-kept grounds" of removing all fallen leaves and branches from under the large trees is inimical to their welfare, depriving their roots of the nourishment and protection from the heat of the sun which, in a state of nature, the leaves afford.

The nutmeg plantation in the Gardens has been very successful, the trees having yielded every year over 20 lb. of nutmegs each, of an average value of 2*s.* 6*d.* per lb. This crop is equivalent to a yield of 60*l.* per acre per annum, allowing only 30 female trees to the acre. A batch of these trees only 15 inches high when planted in August 1878, were 5 feet in height and stoutly branched at the end of last year. Mr. Prestoe's account of his experiments with the Liberian coffee tree, though too long to be quoted here, should be read by coffee planters all the world over.

A pleasing feature in this most interesting report is the little paragraph devoted to a notice of the birds observed on the Government lands. Mr. Prestoe says that there was not only a marked increase in the number of the ordinary kinds of birds, but that toucans, "cookoos," trogans, shrikes, grebes, or "thrushes," and others were unusually numerous.—*Colonies and India.*

MR. SCOTT BLACKLAW ON BRAZIL.

We publish a further contribution to our knowledge of our great rival in coffee-growing, Brazil, from the pen of their well-informed authority, Mr. A. Scott Blacklaw. He enforces what we already were aware of, that the three great factors in the enormous extension of coffee cultivation in Brazil were the high prices which prevailed for the article a few years ago; the large and rapid extension of railway facilities in the coffee districts, and the concentration of slave labour, as well as all available free-labour on the one pursuit. In addition, Mr. Blacklaw, who speaks as an eye-witness of the scenes he depicts, gives us a graphic but revolting picture of the revival of the slave trade, not on the ocean it is true, but round the coasts of Brazil. Most of those who had slaves in the northern districts, who could no longer make fortunes by cotton growing, sold their slaves to the coffee planters of the south. Even Mr. Blacklaw, who in his day has worked slaves, writes of the "horror" excited in his mind by seeing gangs of human beings driven to market and subjected to examination like brute beasts. He saw evidence which convinced him that not only the divine law for all humanity but the Imperial Emancipation Law of 1871 had been evaded by slave-owners who had *forbidden their slaves to marry.* If we in Ceylon are suffering from fungus and short crops as a providential visitation, and if, owing to the action of Brazil, prices have now fallen to an unremunerative standard, we shall not have to answer, when inquisition for blood is made, and punishment awarded for keeping back the wages of the poor—we shall not, in the day of account, have to answer for buying and selling droves of women and gangs of boys between 10 and 15, as if they were mules or oxen. What with abundant slave labour so procured, in violation of laws divine and human, and a slovenly system of culture, described as "letting the trees grow," on vast areas of fertile land, Brazil has beaten us, and, we suspect, ruined herself in the race. For, with reference to Mr. Tytler's vaticinations of revolution, let it be noted that, by the process described by Mr. Blacklaw, the division of interests between free north and slave-holding south, in the Empire of Brazil, is now nearly as complete as was the case in the northern republic, before the Titanic contest commenced in which the crime of human slavery was wiped out in blood. Vengeance for iniquity may be long delayed, but come, ultimately it must, and, if at the preaching of a second Jonah, there is not a repetition of Nineveh repentence in the case of Brazil, a baptism of blood seems inevitable. In any case, what we now know of Brazil, and what we have just heard about the heroic death of the rash but gallant Brownrigg,—fighting to the last against coward and caitiff odds,—is surely enough to cause us to vow, or renew our vows, that our best

will be done to remove from God's holy earth not only the slave trade but the institution of human slavery.

THE ANDAMAN ISLES AND PLANTING.

(Written by a Naval Officer for the "Ceylon Observer.")

Although the Andaman Isles have been the property of the Indian Empire during the whole of the present century, it was not till 1859 that an English settlement was formed there. About that time, the necessity for establishing a Penal Settlement began to force itself upon the Indian Government, and it was finally decided that the most southern of the Andaman Isles should be selected as a place of imprisonment for convicts sentenced to long terms of confinement. The islands at present scarcely pay their way. This arises from the fact that so very little of the convict labour is remunerative in the sense of bringing back money to the Exchequer, whilst the outlay of money for new machinery, victuals, and salaries of the officials is, of course, a considerable item. An attempt on a pretty large scale is, however, about to be made to establish Government plantations of tea, coffee, cinchona, and other plants, for which the islands are very suitable, nearly all of them being now grown by the convicts in small quantities. Communication with the island is by a fortnightly steamer from Calcutta. This steamer is guaranteed by the Indian vessel is allowed to convey six tons of cargo free for the use of the officials and troops in the settlement. The aborigines of the Andaman Islands are probably the lowest of the human race. It is a somewhat peculiar fact that such a race, distinct in itself and having no affinity or similitude whatever to any of the neighbouring races, should be residing on a group of islands in the Bay of Bengal. It is only in the immediate neighbourhood of the settlement that the Andamanese are even approachable. In the northern islands of the group it is not safe to land, as they receive inquisitive people with showers of poisoned arrows. The Chief Commissioner of the Andamans has on several occasions tried to land in these other islands, but has had to abandon the attempt, the attitude of the people being so threatening. The Andamanese, men and women, scarcely ever attain a greater height than five feet. They wander about perfectly naked, and have no houses, simply living in the jungle, and their food is the roots of trees and fish Like most barbarous natives brought into contact with civilization they are dying out rapidly, and threaten to become, before very many more years, totally extinct. Diseases contracted from the convicts have had a terrible effect on them, thousands having died from the diseases thus spread. Some attempts have been made to civilize these wretched people, but they have not been very successful. A school has been established at Port Blair for the education of Andamanese children, but the number under instruction is very small, and the seeds of barbarism seem to have been implanted so deeply in the natures of these youngsters that, even after receiving a civilized education, the greatest difficulty is experienced in preventing them from returning to what is, apparently, their natural state. These people are wonderfully adroit in the use of the bow and arrow. Their arrows are tipped with a sort of steel hooping; and, as their bows are very large, and the arrow has a proportionately great velocity, any one struck by one of them in a vital part would have but a poor chance of recovery. Attempts have been made times without number to conciliate the fierce tribes inhabiting the northern islands, but without success. Their habits are nomadic, and they are no doubt aware that closer ties with a civilized power would soon end in its natural result—their extinction. The Nicobar islands, 300 miles to the southward of the Andamans, of which they are a dependency, are inhabited by Malays. No convicts are at present kept there, but it is intended at some future date to utilize them as an outlet for the criminals of India. The same steamer that runs to Port Blair also proceeds to the Nicobars, from whence there is a large export trade in cocoanuts. There is no doubt that the Andamans, extremely fertile as they are, have a great future before them—say in fifty years hence when the thousands of convicts who will have passed through them by that time have settled down on the soil, and cultivated the vast tracts of land which are at present covered with jungle. The harbour of Port Blair is spacious and well protected; the climate is cool, tempered as it always is by the sea breezes which blow continuously all the year round, and there are more disagreeable spots on the face of the earth for a military man to spend a year in than the Andaman settlements.

COFFEE PROSPECTS.

(Robert Von Glehn & Sons' Monthly Coffee Circular.)

January 11th, 1882.

The stocks of coffee in Europe have increased during the past month about 11,000 tons, and prices have still further declined:—Middling plantation Ceylon coffee, which we then quoted 77s to 82s, is now barely worth 72s to 77s; and good average Santos, which was then worth 60 fr. in Havre, is now quoted 56 fr. per 50 Ko. It cannot be denied that some failures in Bordeaux, of firms but slightly interested in coffee, have contributed largely to accentuate the decline in prices. Our opinion is that the alarm which appears to be felt as to the financial position in Havre is excessively exaggerated, if not entirely unfounded, as, owing to the admirable system for advances on produce carried out by the Bank of France, no large losses are likely to remain long unpaid, and no large quantities of coffee are likely to be forced for sale at one time; the future course of the article must therefore be studied on its own merits.

We venture to maintain our opinion [as regards Rio] that the receipts will be smaller, and may even fall to such a point as will revive the lifeless markets of Europe and America.

Now one of the most important questions in forming an opinion as to the future course of prices, is, what can the shipments from Rio during these same six months of the present year amount to? We have seen above that the eminent Rio firm, from whom we have so often quoted, estimates the available quantity of coffee for the seven months from 1st December 1881, to 30th June 1882, at 2,063,400 bags, and deducting what we now know to have been shipped in December, viz., 320,000 bags, we get as available according to this authority, for the six months, from 1st January to 30th June 1882, 1,743,400 bags, or more than 300,000 bags less than were shipped during the same period last year.

For reasons stated above, we, however, think the deficiency will be greater, and it is possible that Rio shipments to Europe alone, which, during the last six months, have been nearly 100,000 bags less than in the same period of 1880, may, during the next six months, fall below those of the same period of 1881 by 300,000 bags.

Scarcely less important in forming our opinion of the future course of the market is the question:—"What quantity of coffee can Santos send us during the next six months?"

The Santos crop of 1881-82 is variously estimated from 1,500,000 to 1,800,000 bags, but taking it at the average of these two figures, viz., 1,650,000 bags, and deducting the shipments of the first six months of the season, viz., 735,000 bags, we find available, for the six months from 1st January to 30th June, 1882, 892,000 bags.

It looks, therefore, at present as if the shipments from Santos during the next six months were likely to be largely in excess of those during the same period of last year.

If the present Santos crop does not, however, much exceed 1,500,000 bags, which is the estimate of our own Santos correspondents, and if the Santos planters hold back rather more coffee than usual, the quantity that will be shipped to Europe during the next six months may after all not be so large.

It must, however, be remembered that Messrs. Bradshaw and other eminent authorities estimate the 1882-83 or following crop at 2,000,000 bags. Santos coffee is not likely, therefore, to be less plentiful for some time to come than it is now, and we doubt the wisdom of paying a premium for future and distant delivery of this kind of coffee, as is at present being done in the Havre market.

From the smaller coffee producing countries there is no feature of importance. The native Malabar crop is said to be large, but is held back by the natives, who are not likely to take present value until forced to do so. The Manila crop is said to be small and early. The visible supply of Java coffee to Holland is the same as last year, viz. 796,000 bags, against 735,000 bags on 1st January last year.

The Costa Rica crop is reported large, but of inferior quality.

From St. Domingo there were reports of an insurrection, which it was thought would interfere with the production of coffee, but as very good Haiti coffee is selling in Havre at 48 fcs.—about 34s per cwt.- we conclude the report is not believed. No change in the crop estimates is advised from Ceylon, but the bulk of the crop is coming to London.

The quality of the Wynaad and Coorg crops is superior to that of recent years. The Neilgherry on the other hand is inferior.

CEYLON TEA IN THE LONDON MARKET.

(Special Report for "Ceylon Observer.")

4, Guildhall Chambers, 33, Basinghall Street, Loudon, E. C.

13th January 1882.

DEAR SIR,—The Indian tea market contiuues very firm, though without material alteratiou since the holidays. Prices, as compared with this period of 1880, are higher for common, slightly higher for medium, whilst for fine and finest they are considerably lower. The low prices which prevailed so long in 1880 and during the greater portion of 1881, although disappointing to the grower and importer, have had the satisfactory result of largely extending the consumption. The increase of 5,000,000 lb. for the past year is very remarkable, following, as it does on the large advance of 1880 on 1879 of 6,364,000 lb. The liquors now most sought after are those possessing dark, clear, colour with fine flavour and not those of lightish colour with some pungency. Ceylou tea imports show some improvement, more attention evidently being given to the manufacture than hitherto. With regard to manufacture, it cannot be too strongly urged upou producers that it will be a ruinous mistake to resort to coarser plucking, in consequence of the high range of values paid here during the past few months for common makes. The prices realized were due in a very great measure to good quality, resulting from fine plucking and not so much to scarcity. If coarse plucking be resorted to, large quantities of poor liquoring tea will result, which will soon become as unsaleable and low in price as China teas now are. It would be difficult to see to what a low average price Indian teas will siuk, should the very serious mistake be made of sacrificing quality to quant ity. On the other hand, planters must not rush iuto the opposite extreme and make too large a proportion of fine or high priced grades. It will be as well to bear in mind that the largest consumption of tea is of kinds under 1s 4d, per lb., and tho next up to 2s. Brokeu sorts have sold much better than whole leaf at the same range, as the liquors being stronger and darker are more useful for mixing purposes. Tea in half chests fetches only the same price as when packed in chests. Boxes of about 20 lb. are not much in favor with the trade, though very useful to retailers. It should be noted that the weight of each package should not in the least exceed 28 lb. gross; otherwise a heavy loss on account of draft (1 lb. per package) will be incurred. As advised in a late letter, it will be well if planters will send their tea in as large breaks as possible, leaving the bulking to be done here, if the lots are small. We give below the result of sales of Ceylon tea this week in public sale:—

HUTCHISON & Co.

THE INSINCERITY OF BRAZIL IN REGARD TO THE SLAVE TRADE AND SLAVERY.

We publish a further contribution to the history of slavery in Brazil and the action of the Government (controlled by slaveholders) in regard first to the slave trade and then respecting emancipation. A more disgraceful exposure of systematic deceit has seldom been made, and as British subjects we have the right to express special indignation at the manner in which our statesmen have been betrayed and trifled with. It is certainly no new discovery that the existence of human bondage in a country blunts the moral feelings of the community, while, of course, the government only too truly reflects the character of those on whom its existence depends. There can be no question, we believe, of the *bona fides* of the Emperor personally, but all the revelations now being made by the honest *Rio News* and by our correspondents show how greatly we erred in giving credit to any considerable portion of the leading Brazilians for sincerity in the loud professions they have made of desiring to free their country from the blot and the curse of slavery. We read, recently, a letter from a Brazilian addressed to a French journal, in which he lamely attempted to defend the action of his country. Having a bad case he resorted to the attorney policy of "abusing the other side." He pointed to the degraded condition of many of the French peasantry. We are perfectly familiar with this form of argument or rather attempt to divert attention from the real point at issue. It was the favourite *tu quoque* used by the slaveholders of the United States when anything was said against their "institution" of human "chattels." Mrs. Tyler, the widow of President Tyler, used it, as she though', triumphantly. "Look at home!" she said, "and correct the destitution and degradation which prevail among your 'lower classes.' —your 'mean whites.'" No doubt that is a duty, but it is the very class who demand the liberation of the slave who do their best for degraded freemen. But our poorest are FREE: free to carry their persons and their labour where they choose; free to marry and free to keep their wives and their children to themselves. They cannot be "sold South." They are not inevitably doomed by law to the condition of brute beasts, as is the case in Brazil. If the great nations of the world agreed to regard the stealing of human beings from Africa and the traffic in them as piracy, why should a distinction be made in favour of a system of internal slavery and sale, by which, day by day and hour by hour, human beings are deprived of their inalienable rights—as the constitution of the United States puts it—of "life, liberty, and the pursuit of happiness"? He who knew human nature best of all said: "The poor ye have always with you." All freemen may not be able to secure happiness, but the chance is afforded them, which is denied to the poor slaves of Cuba and Brazil. The former country has suffered the penalty of her violation of human rights, and we cannot doubt that unless Brazil repents and makes all the restitution she can, her turn will come. Meantime, as in society men who forcibly appropriate

what does not belong to them are ostracized if not actively punished, we cannot see the propriety of treating Brazil, Spain, Egypt and other slaveholding countries as if they were respectable, clean-handed units in "the comity of nations." It is time we spoke of Brazil as she deserves to be spoken of. The fact that she is the greatest coffee-producing country in the would ought not to blind us to the connected fact that she is the greatest criminal against the laws of human nature and the Lord of human nature.

"THE TROPICAL AGRICULTURIST."

An old colonist writes from the mother country by last mail :—

"The success of the *Tropical Agriculturist* was so evident and so certainly assured from its first issue, that I have hitherto not thought it necessary to say one word in its favour, and I only write now to briefly record my candid opinion that it has more of the elements of permanency about it than, perhaps, any publication ever issued from the Indian press—not excepting the Government *Gazettes*. In all probability, it will live as long as any of the products, regarding which it records information so interesting and valuable.

"May it live as long as the Bogaha itself! Meanwhile, find my subscription for two years enclosed. The only suggestion I have to make is to implore you not to 'improve' or alter the work in any shape or form down to its fine classic cover. Let us have it uniformly the same for the next half century at least."

THE ESTATES PURCHASING AND PROSPECTING COMPANY, which lately started into existence, is, we are glad to learn, to be followed by another Company which the force of circumstances is bringing into existence. It has for some time been a matter for serious consideration how gold, known to exist in large quantities in the pyrites is to be extracted. The appliances for this process do not exist on the various mines, and are too expensive and elaborate to be undertaken by each separate concern. The representatives of the various mines at home have resolved to assist in starting a Company for smelting works, for the reduction of these pyrites and the extraction of the gold, silver and copper found in them. The various Mining Companies could obtain their ore treated at a central factory, where scientific and expensive smelting works will be erected and conducted under skilled management. Should such a Company come into existence, we hope it will follow the wise course adopted by the Estates Purchasing Company, and secure a local agency and an Indian direction.—*South of India Observer.*

NUTMEG CULTIVATION.—We have received from Mr. W. Ferguson a copy of the "Journal of the Indian Archipelago" for October 1848, containing a paper called "Some Account of Nutmeg Cultivation, by Thos. Oxley, Esq., A. B., Senior Surgeon of the Straits Settlements." This appears to be a full and thoroughly practical essay. One paragraph we may copy here :—

The nutmeg tree shows flower about the 7th year, but the longer it is before doing so, the better and stronger will it be. I cannot refrain from a smile when a sanguine planter informs me with exultation that he has obtained a nut from a tree only 3 or 4 years planted out,—so much the worse for his chance of success, too great precocity being incompatible with strength and longevity. The best trees do not shew flower before the 9th year, and one such is worth a score of the others. This will be evident when it is stated that I have seen several trees yield more than ten thousand nuts each in one year, whereas I do not believe that there is a plantation in the Straits that averages 1,000 from every tree. This very great disparity of bearing shews plainly that the cultivation of the plant is not yet thoroughly understood, or greater uniformity would prevail, and I think it clearly enough points out that a higher degree of cultivation would meet its reward. It is not quite safe to cut down the male plants upon first shewing flower, as they many times show perfectly female flowers the following year, and in that case are generally the strongest and finest trees. But there is some indication of this in the first mode of flowering. When the racemes are many times divided and have numerous flowers, there is no chance of its becoming entirely female, but where there are only two or three flowers on a raceme there is a fair prospect of its doing so. The tree has not been introduced into the Straits sufficiently long to determine its longevity, but those introduced and planted in the beginning of the present century as yet shew no symptoms of decay.

We shall submit the essay for Dr. Trimen's judgment before republishing it in the *Tropical Agriculturist.*

THE HARVESTING OF THE CINCHONA BARK.—'Have you any knowledge of the Caulfeild bottle process?' was the question put to a mercantile firm not long ago. We suppose that, effective and important as it is, the principle is as simple as that on which boys deprive alder twigs in the Highlands of Scotland of their bark taking the bark off and putting it on again unbroken in the manufacture of whistles. They used to beat the alder bark all round with the handles of their knives, and this loosened it. The same effect in a far better and more scientific manner is, doubtless, produced by the friction of the polished surface of a bottle rendered ponderable by being filled with sand. The beating process often broke the bark, which the rubbing is not likely to do. If Mr. Caulfeild really invented the idea, it is much to the credit of his sagacity. Even if he had previous hints, which he adopted, he deserves the gratitude of cinchona growers. Cinnamon is peeled when there is plenty of juice between the wood and the bark. Possibly the friction of the knife in the process of removing the outer bark may cause the inner to separate more easily. But we never saw or heard of any beating or rubbing process to induce the more easy and unbroken removal of cinnamon bark.

INDIAN AGRICULTURE.—Sir George Couper, in his address to the Talukdars of Oudh at the close of the Agricultural Exhibition last Saturday, departed somewhat from the customary empty formalities and platitudes of such occasions, and gave these wealthy landlords some very wholesome advice as to their duties and responsibilities in the important position they occupy. It was a plain talk full of good sense and sound admonition. He counseled them first to make greater exertions for increasing the value of their estates, by introducing improved machinery, better seed, more manure, and more extensive irrigation arrangements. Then he passed to what he styled far the more important division of their duties, that pertaining to the improvement of the welfare of their tenantry, in which he assured them that not only Her Majesty's Government but Her Most Gracious Majesty herself were deeply interested. He bade them take note of the widespread assertions that their tenantry had been unduly harrassed and grievously oppressed by the exactions imposed, and warned them that if this were so and were not speedily mended it would become the duty of the Government to see what legitimate means could be provided to alter this state of affairs and check the degradation of agriculture, He exhorted them to feel a kindly sympathy and take a warm personal interest in the welfare of their tenants. We trust these words will produce a good effect, and we hope they will be properly followed up. It is one of the best signs of the times that the rulers are more fully awaking to the vast importance of greater efforts to improve the condition of the many millions of patient toilers committed to their care.—*Lucknow Witness.*

Correspondence.

To the Editor of the Ceylon Observer.

BEES AND THE FERTILIZING OF COFFEE.

Kent, 22nd Dec. 1881.

DEAR SIR,—One of your correspondents, in an *Overland Observer* which has lately reached me, ridicules the idea of bees being serviceable in fertilizing the coffee tree during the blossoming season, by carrying about the pollen of the flowers, while collecting honey. He even doubts that bees frequent estates for any length of time, and thinks that they may be only seen for a few hours on the occasion of their swarming in the jungle. I am not prepared to say whether they are useful or not in spreading the pollen, not being acquainted with the sexual construction of the flower, but I well remember that, in the year 1858, while on a visit to the late Mr. Nietner, of the Fernlands estate, he pointed out to me the very great number of bees which were busily engaged in collecting honey all over the estates. He also called my attention to the bee-eaters, which hovered in considerable numbers in the air, attracted by their insect prey. It was in the month of March, and there was one of those glorious blossoms which give the appearance of the trees being thickly covered with snow—a sight which often gladdened the heart of planters in those days, but which, alas! is seldom seen now. The bees remained for several days, and, to the best of my recollection, Mr. Nietner, who, you well know, was an able naturalist, expressed the opinion that they were doing good service. In consequence of the great destruction of forest in coffee districts, bees seem to have disappeared. I, therefore, hail with satisfaction the prospect of the domestic bee being introduced, to take the place of the wild species, which have been driven from their haunts by the advancing steps of cultivation. I have no doubt that many old planters could corroborate my statement as to the presence of bees and bee-eaters all through the blossoming season. My own experience extends from the year 1846, when forest abounded in almost every district of the Central Province.

I have read with much interest Mr. Marshall Ward's final report upon leaf-disease, and regret to find that he has arrived at the conviction that there is no cure, and that all that can be hoped for is that the disease may be kept in check by the judicious application of manure and the use of lime and sulphur. Let us hope that the introduction of new products will save the island from the hard times with which it is threatened as far as coffee planting is concerned. I am inclined to think more of cocoa than quinine, as commanding more general consumption.

J. P. G.

BRAZIL PRETENDING TO ABOLISH THE SLAVE TRADE AND EMANCIPATE THE SLAVES. BUT ONLY PRETENDING.

Dollar, Scotland, 12th Jan. 1882.

DEAR SIRS,—We may have been very far wrong in our former opinions as to the near collapse of the coffee plantations in Brazil. We have always been right, however, in asserting that it is on the *labour question* that the future of the coffee enterprise depends.

The cultivation up till now has been almost entirely carried on by slave labour. Free labourers have been employed in the felling and clearing of forest land for coffee plantations. The bullock-drivers and muleteers were generally from the same class, and building-contractors of which there were a great many when estates were being extended, also worked with free labourers. These labourers were all of the *creole* race, descended from ever so many mixtures of the Portuguese colonist and the Tupy Indian fellows whose idea of life is to spend half of it holiday-making, to work as little as possible, and even for that little to receive payment a year or two years in advance. A good many masons and carpenters are Portuguese, Germans, Italians, and Spaniards, who may have been formerly employed on the railways, and are very migratory individuals. On some estates, there are families of all the above nationalities who cultivate a few thousand coffee trees as so much per year, or so much per bushel of cherry coffee picked off the price of coffee land they treat. The planter has to supply each family first with a good house costing £60 to £80; second to give them a large paddock planted with artificial grasses and fenced, so that will mules and hungry work-bullocks may not go astray; third to give the family a piece of good land, although at an elevation that could not grow coffee (owing to frost) to grow Indian corn for colonists' pigs and animals, beans, rice, potatoes and other necessary vegetables for food for his household (some colonists grow on this patch cotton and sugarcane as well). Last but not least in importance the head of the family will be also given a sum of money to clear his account on the place where he was formerly employed, which advance is often lost. So that, all things considered, independent of the advance, a capital sum of £100 at least would be absorbed for each family. Free labor of this sort is not tasteful to those who have been accustomed to work with slaves, and nearly all who have tried it lose money and throw colonization adrift and take to the slaves. The slaves then being the Brazalian planter's mainstay, let us see how the institution of slavery stands at the present day, and, even at the risk of repeating what I have often written before, let us notice some of the legislative enactments relating to slavery in Brazil. Commencing from the time that the civilized world began to interest itself on behalf of the slave, we find that in 1825 a treaty was made between Great Britain and Brazil for the suppression of the slave trade. The Empire was then but three years old and had been recognized by the British Government, through the announcement of Mr. Canning, in the House of Commons, in that year, as an independent state, and, elated with its newly found liberty, Brazil was to follow the example of other nations. There might have been an intention to stop the shameful traffic. The laws of the country, however, were not made to punish Brazilian subjects for engaging in it until 1831. All slaves entering into the country after that date, 7th November 1831, *were declared free*, and persons introducing them were to be punished by the criminal law for reducing free men to a state of slavery.

This law remained a dead letter, for the slave trade was carried on with the connivance of all parties in Brazil, both official and unofficial, for many years: some assert up to the time of the rupture with Great Britain in 1861; say thirty years. There is what an American writer of some distinction, Capt. Codman, who made a voyage to Brazil in 1847, describing when the trade was in full swing:—

"The number [of slaves] annually imported now cannot be ascertained: but I know that, while we were in Rio, (thirty days) four thousand were landed in its immediate vicinity from five small vessels. We are not informed how many were landed on other parts of this extensive coast at the same time. It is scarcely possible to conceive that one of those vessels of two hundred tons could have brought one thousand and five negroes safely, having had on board, probably, on leaving the coast about twelve hundred—sixty per cent being the usual allowance given to death. Who can imagine anything more horrible than their confinement for thirty days, while crossing on the warmest latitudes of the earth, stowed with the nicest calculation of a stevedore in that vessel's hold living and dying packed together!"

"The slavers are now so closely watched on the African coast that an owner makes his calculation to lose one vessel out of three; and, if successful, the speculation is made in throwing overboard cargo to escape detection."

The law of 1831 having been openly evaded, was easily replaced and from the pressure of the Russell Government in 1847-52 caused the Brazilian Government to make legislate in earnest for the suppression of the slave trade, and on 4th September 1850 a second act was passed,

This law was similar to the one of 1831, although defining more particularly who should be considered parties, principals, accomplices, &c., and declaring the trade piracy. Like it, it declared that the blacks thus illegally introduced, should be returned to their native country, and that they should be put out to service for a term of years in order to earn as much as would pay their return passage. This term of year, was not to exceed fourteen. That this law was passed at the instigation of the British Government, I can gather from a series of lectures delivered by a distinguished Brazilian in 1873, where the lecturer gives the following lament :— "Notwithstanding the measures adopted in this law, which ought to convince England of the good intentions of the Brazilian Government, she [England] still maintained the Aberdeen Bill promulgated in 1845."

I find that this called "the Aberdeen bill" subjected Brazilian ships and Brazilian subjects to the judgment of British tribunals, if they were *suspected* of carrying on the traffic in Africans.

The subject was discussed some two years ago about the time that an Abolition Society was formed in Rio de Janeiro. The right of the Brazilians to hold as slaves negroes brought into the country, after the passing of these laws, was (two years ago) stoutly defended by some of the ablest men in the Imperial Parliament, and amongst the advocates in favour of this illegal bondage, was the Secretary of State for Foreign Affairs in the last Cabinet. Our leading journal in Rio de Janeiro declared then that, if the law of 1850 were carried out, over 500,000 human beings now held as slaves ought to be free, and that, by the law of 1831, nearly a million Africans and their descendants are at present illegally held in bondage. I have been informed by many people that it was partly owing to the evasion of these laws that the troubles began with Great Britain in 1861. Although the affair of the stealing of the cargo of a shipwrecked vessel and supposed murder of the crew on some of the southern coasts was the main cause of quarrel, yet the outcome of the settlement in 1864 was the passing of a law on the 24th September of that year, declaring all negroes free who were imported since the passing of the abovementioned laws.

This law, like all the others, wrung out of Brazil at the instigation of a foreign Power, was also not heeded; and, again, dust was thrown in the eyes of Great Britain by the passing of the so-called Emancipation Law of 1871.

The draft of a scheme of emancipation was first promulgated and discussed both in Brazil and Europe in 1867. By it, slavery was to be abolished entirely in the year 1900. I have, to this day, great difficulty in convincing people in this country—who remember the discussion—that by the law, as ultimately passed, all who were slaves at the passing of the law remained in bondage until releasedby death.

I say dust was thrown in the eyes of the people of Great Britain: first by promulgating the draft of a law giving a stated number of years when slavery was to cease entirely, and then passing an act four years after leaving out that most important clause, and, second, in making people believe that the fund established under the new law would soon free all. The decrease at the end of ten years *including deaths* is only 2½ per cent, as shown by their own returns, which I shall show to you further on. A.S.B.

COFFEE PULP AS MANURE AND LEAF-DISEASE.

Nuwara Eliya, 17th Jan. 1882.

Dear Sir,—Has it never occurred to any scientific planter that the use of coffee pulp, as a manure, might be injurious to the health of the coffee tree ?

What plant, or animal, can naturally be expected to thrive fed on its own refuse ? And anything more *damp* or *sour* than old coffee pulp cannot well be imagined. In my opinion, the cause of leaf-disease must be in the tree itself, and that trying to cure diseased *leaves* is simply beginning at the wrong end.

I may be "all out" in thinking that the use of pulp has anything to do with the existence of what is called *Hemileia*, but, failing science, we must trust to some lucky *guess* for a cure.—Yours truly,

IGNORAMUS.

[Caustic lime should be added to the pulp.—Ed.]

JOTTINGS FROM COORG.

Jan. 17th, 1882.

Dear Sir,—As a subscriber to your valuable paper(the *Tropical Agriculturist*), which, by the way is—though in many instances unsuited to South of India planters, as our systems are so different—thoroughly appreciated here by all who read it. As a subscriber, I say, I do not think I should let this month pass without letting you know how we are getting on here "over the water." This year has been a most exceptional one. In fact, I think I may almost say we have at last got our long-looked-for "bumper," and heaven knows it is wanted in the present state of the coffee market. Most estates are getting 10 and 20 per cent over their estimates, and all, in the bamboo district at any rate, slightly over. This pleasant state of affairs is, I think, greatly accounted for by the late and unusual rains we have been recently getting, between four and five inches in November ; and about one and a half inch ushered in the new year with cold mists and sharp east winds This, of course, will not seem at all strange to you in Ceylon, but it is almost unprecedented here, and has kept our heavily laden trees in good heart, and most estates have a very fair show of wood for this year. Pruning and manuring are now in full swing, and most of us hope to have our coolies paid off by the end of next month. The little cinchona we have looks well ; several nice fields of succirubra and pubescens of the last two years' planting is about all we can boast of at present. Nearly every estate is now going in for it, though none do so entirely, except one near Mercara, which was bought from Government several years ago. The little bark which has already been sent home has, I believe, fetched very fair prices, and there is no reason why it should not continue to do so, as our climate and soil, especially in the Ghauts, is very fairly suitable for it. It is generally planted here in the coffee rows, three trees of coffee to one cinchona. It then serves a double purpose. One or two have small plots of Ledgeriana Calisaya brought from the Neilgherries, but nothinglarge. Clearings look well everywhere ; no leaf-disease to speak of, and little or no borer showing yet. It is a great thing crops are so good ; something to liven us up on our estates, as our gay and festive Town of Mercara is, as usual, as "dull as ditch-water." In fact, the drive or ride in alone requires all the patience of Job to stand, without imperilling your soul, as you are in imminent dread of either your springs breaking, or your nag going dead lame owing to the good(?) condition of the roads. Our executive engineer having discovered a novel method (for India) of making the roads passable—a method, I think, for its deep thought and ingenuity deserving of great credit—namely the laying down of long stretches of metal in the middle of the road without the slightest attempt to bind it, and to prevent traffic along the sides and to enable the road to get into good order in a cheap way, large boulders and trunks and trees are placed on the unmetalled portion regardless of the risk to human life and limb, to say nothing of that to your horse's legs : and this is done, now of all times, when our coffee is being despatched to the coast and Bangalore, but perhaps that is a part of the plan. I must not, however, encroach further upon your valuable space and have only done so at all in the hope it may induce other of my brother planters to use your journal as a means of thoroughly ventilating any moot point, and to assist one another in the cultivation of our common staple, coffee.—Yours &c.,

CHERRY RIPE.

LIBERIAN COFFEE AT A HIGH ELEVATION.

Shawlands estate, Lunugala, 21st Jan. 1882.

Dear Sir,—As you wish for information with re-

gard to the elevation at which Liberian coffee will grow and flourish. I may mention that I have a few trees here, now four years old and bearing heavily. One tree in particular, which ripened a few hundred cherries last year, has now a load of over 3,000 cherries on it, by computation. The cherries are growing in clusters all round the stem of the tree, where you generally see suckers. The elevation is 3,100 feet.

Those trees have had no special care taken of them and the soil is not particularly good. They have had leaf-disease as badly as the Arabian coffee in their vicinity, but have suffered less! Notwithstanding all this, I do not believe Liberian coffee will ever supplant the Arabian; and this seems to be the general opinion.—Yours faithfully, G. H. HALL.

CINCHONA CULTIVATION.

22nd Jan. 1882.

DEAR SIR,—Perhaps some of your numerous correspondents can give some useful information regarding what should be done to a clearing of cinchona officinalis under the circumstances I now proceed to mention.

It is say four-and-a-half years old, and the larger portion of it is seeding and flowering heavily. Would pruning up moderately and cutting off blossom, as far as a cooly could reach, be the right thing to do, or would it be better for the trees to be allowed to continue as they are and shed the seed?

From Mr. Owen's hook, I cannot quite gather whether he recommends pruning under these circumstances or not, though he certainly does not with trees that remain without blossom.

Does the mere fact of blossoming denote that the tree is likely to die sooner than one which has none, both looking apparently healthy at the same age, four-and-a-half years?

Lastly has it not been the general experience in Ceylon, till now, that officinalis trees at that age, and even younger, have tended to seed heavily at the same time without the bark being in any way deteriorated by it, whether grown in a very suitable climate or not. It seems, from what little I have seen of officinalis, to be almost its nature to try to reproduce itself at that age. Is it the case in India, where they have much older trees than many in Ceylon?—Yours truly, ENQUIRER.

COFFEE LEAF DISEASE.

Colombo, 23rd January 1882.

DEAR SIR,—As I gather there is an impression abroad, that the results obtained at Gangapitiya are greatly neutralized by the supposed fact that an adjoining untreated estate is equally free from leaf disease, I think it necessary to correct this idea. A glance at the map will show that Gangapitiya is surrounded and immediately adjoined by Gangawatte, Ambacotta and Lower Rajewelle, with which it has been compared. On the other side of the river is some native coffee, heavily diseased. Then about three miles farther down the river comes Maliaberietenne, the visiting agent's report of which has just been shewn to me by Messrs. Whittall, stating that it was likewise considerably diseased. Then, still farther down the river at the very end of the district away from the bulk of estates, are Henegahawelle and Victoria, which are now reported to be comparatively little affected. I know nothing of the past history of these estates and whether like Gangapitiya they have for the past four years suffered severely from leaf disease during October, and again during January. It is sufficient for the purpose of the results of my experiments to have compared Gangapitiya with the immediately surrounding estates, *on every side*.

I am beginning to realize that every fact I bring forward to testify the usefulness of the treatment I have recommended is being unjustly discredited and distorted. I have devoted, to the neglect of my interests elsewhere, nearly the whole of my time for the last 18 months to the pursuit of these experiments, I have also gone to considerable actual expense; I have left nothing undone that could be done, and no one, I venture to say, would have retreated with a better grace had failure resulted. But, instead of failure, the results fully justify the opinion that with some modification the treatment might result not merely in a mitigation of the disease but in a cure. I have been endeavouring now to arrange for the continuance of my experiments during the next season, being willing to devote still more of my time to it, but I find that speaking of the past and present, not only are the results of my experiments not accepted on their absolute merits—but they are subjected rather to an under-current of adverse criticism which is based upon inaccurate and non-existent data,—and owing to this I am unable to obtain such a measure of success as I consider necessary. I think therefore that I had better retire now from the further direction of these experiments, and I must leave the coffee industry to arrange for their continuance under some other guidance. I am tired of meeting nothing but unjustified disbelief and opposition. But I challenge those who are responsible to absent proprietors and mortgagees to fold their hands and do nothing.

Surgeon-Major Shortt has testified to the value of carbolic acid as a remedy against leaf-disease. Mr. Morris has done the same. Mr. Marshall Ward has admitted that carbolic acid is a remedy against leaf-disease, he admits that a great deal might be done with it were it not for the fact that it is injurious to the trees. I don't know whether those interested will even allow that I have disproved the existence of this fact, but I claim to have proved that carbolic acid can be used against leaf-disease with perfect safety; I claim to have proved that it can be used on a practical scale and on this basis alone I now call on the Government and on those responsible to vested interests to continue the experiments taking the advantage of my experience as to time of application, etc. There are many to whom I am obliged for moral and actual support during the past year, but they are too few to justify my devoting another year to this matter; for nothing less than absolute success at at least half-a-dozen estates in different districts would, I feel assured, rouse the coffee industry of Ceylon from its present despairing apathy.

EUGENE C. SCHROTTKY.

THE WILD VANILLA.

Theobroma, Mirigama, 24th Jan. 1882.

DEAR SIR,—Walking through the jungle here, I came across an orchid, which, to my unscientific eye, looks very like vanilla. I send you by rail a few cuttings. I have been unable to procure the flower or fruit. The pod, as described by a Sinhalese man, exactly resembles the vanilla.—I am, yours faithfully,

R. H. L.

[W. F. furnishes the following note:—"The plant sent by your correspondent is the Vanilla Moonii, Thw. It was long ago discovered by Moon, and included in his Catalogue of 1824, as the Vanilla aromatica? Moon, p. 60. It is quite a common plant in various parts of the Western Province, and flowers and fruits freely, every part bearing a strong resemblance to that of the cultivated vanilla, but the fruits are not aromatic. It festoons trees profusely with its pendant stems, and is so like the cultivated vanilla plants that a person not aware of the existence of this indigenous species is liable to be deceived by it. It is pecu-

liar to Ceylon, and Dr. Thwaites has named it after Mr. Moon, the first discoverer of it. Another species, Vanilla Walkeriæ, Wight, almost leafless, and having beautiful white flowers, resembling polished silver, with stems and fruits resembling those of the vanilla, is equally common in the Western Province."]

LEAF DISEASE AND CARBOLIZED POWDER.

Colombo, 25th January, 1882.

Sir,—We notice that reference is made in last night's *Observer* by a Matale planting correspondent to the supply of carbolized powder. Be good enough to allow us to rectify a wrong impression which appears to be current regarding our position in the matter.

We are agents for Messrs. Calvert & Co., and sell their various preparations of carbolic acid. Their 15 per cent carbolic powder is sold by us at R21·50 per barrel of 200 lb. as frequently advertised in your columns. It will be thus seen that the essential element weighing 30 lb. is combined with 170 lb. of material on which likewise freight has to be paid in addition to import duty. At Mr. Schrottky's suggestion we undertook to get out the acid (which is admitted duty free) and prepare a powder here containing the same percentage of acid though on a somewhat different base. This saving of 85 per cent of freight and the whole import duty enables us to sell 200 lb. of this locally prepared carbolized powder, at R12·50, making a very appreciable reduction in cost,—a material point in connection with the purpose for which the powder was intended.—Yours faithfully, LEWIS BROWN & Co.

COFFEE LEAF-DISEASE:—MR. SCHROTTKY'S EXPERIMENTS.

January 25th, 1882.

Dear Sir,—The planting community do not seem to realize that in my concluding notes, I have spoken with excessive moderation of the results of my experiments: it seems entirely forgotten that I have practically proved that leaf-disease can be successfully kept in bounds by carbolic acid vapour through all the variety of seasons of *a whole year* in the middle of a district where leaf-disease is almost chronically present. Let me recall the facts ascertained:—Speaking of the bulk of estates, leaf-disease in the Dumbara Valley is more or less prevalent during nearly the whole year. The periods of most severe attacks are September, October (south-west monsoon), and December, January (north-east monsoon,) and sometimes also during March. This applies specially to Gangapitiya estate, which (when I commenced my experiments) I was assured was about the worst place for my experiments, for it suffered usually even more severely than the rest, and certainly when I took it in hand it was as diseased as it could be. Gangapitiya is the only estate where the treatment was systematically carried out in the early part of the year and the disease had practically been got under by the end of May. We have spared no expense and trouble at other estates (particularly at Pallekelly where though we commenced at the same time, the treatment was suspended during what we now know the most important time of the year) in trying to gain on the fungus at a later period, but unsuccessfully. The fungus later on appears to grow almost quicker than one can kill it. Speaking now of last year, the attacks of leaf-disease during the S. W. monsoon in the Dumbara Valley were, one can say, less severe than usual, but still the disease was prevalent to a large extent. On my inspection of the district early in October, I found Pallekelly only partly affected; farther up the valley towards Gangapitiya the disease became worse and in estates immediately adjoining Gangapitiya, the disease was prevalent in a bad form. It had commenced, I was informed by the managers, at the end of June, and had increased steadily, and by one of these managers I was informed at the time that he did not believe a tree could be found on his estate that was free from disease. Gangapitiya was almost absolutely free from the disease with the exception of a field immediately to the leeward of a native estate, which had been neglected for a time, as every cooly was wanted to pick crop. When the north-east monsoon commenced, the valley began to recover, ample rain fell and everything looked luxuriant during November. Disease commenced to show again at the latter end of that month, and in beginning of December there was not a tree, nay, scarcely a leaf to be found in the estates immediately surrounding Gangapitiya, that was not diseased. At Gangapitiya it had been a case of a *continued, unabated* fight: a hundred times the fungus tried to establish itself, a hundred times it was prevented. The manager, in my absence in India during the S.W. monsoon, wrote to Messrs. Whittall & Co., "Leaf disease continues to crop up in places here and there, and I apply the powder immediately wherever I detect it." The disease was most severe during the middle of December, and up to the beginning of January, Gangapitiya remained unaffected. This closes *the whole year*, for our experiments in the Dumbara Valley were commenced in the beginning of January 1881, and it has been proved by the results at Pallekelly Estate that the fungus has no chance against the carbolic acid vapour at this time of the year. For want of material we had to abandon the struggle at Gangapitiya end of December, and the fungus is evidently endeavouring to obtain a footing now; we cannot prevent it; but the experiments are complete, the 12 months are over. A not unnatural qualification of the success of these results has been the statement that two estates at the very end of the district, appear now to be almost equally free from leaf disease. I have of course given full attention to this. I find that these estates are exceptionally situated, and that their past history essentially differs from that of the bulk of estates in the Dumbara Valley and from that of Gangapitiya estate more particularly.

EUGENE C. SCHROTTKY.

GARDEN PESTS.

Kahagalla, Haputale, Jan. 25th.

Dear Sir,—Can you or any of your readers tell me how to get rid of the small black slugs? There are so many of them in my garden that nothing can grow properly. DEW.

[The following paragraph taken from the *Australasian* today would seem to meet the case of our correspondent. —Ed.]

The *Konigsberger Land und Forstwirthshaftliche Zeitung* contains a short and interesting account of an experiment in killing insects and mildew in plants with a solution of carbolic acid. One part of carbolic acid was mixed with 20 parts of water, and left standing 24 hours, after which it was well shaken. A coating of oil and fat formed on the surface, which was carefully removed, so that nothing but water was left. The mixture was poured over a bed of radishes and cucumbers, which were badly mildewed, but the plants were destroyed by the first and second experiment. But the quantity of water was afterwards increased to 100 parts, and the mixture was successfully used for the smallest and most delicate plants. It was poured over trees, rose-bushes, and peach trees, and was most efficacious in destroying all kinds of insects. A small quantity was also poured over an ant-hill, and the insects forsook their nests with such rapidity that they left their eggs behind —a circumstance almost unknown in the annals of ant history. A small cherry-tree, the ripening fruit of which

attracted the ants in such great number that it was gradually dying, was saved by a narrow ring of the solution being made round the roots, which by being renewed every four or five days effectually kept the intruders away.

BRAZIL: ITS CONDITION AND PROSPECTS:

No. 2.

Dollar, 29th December 1881.

DEAR SIR,—A second great cause of the extension of coffee cultivation was *the high price of coffee.*

Simultaneously with the rapid extension of the railway syste in Brazil came a rise in the price of coffee. From 1868 to 1878, and notably in the years 1873 74-75 and '76 the price of the article was such as left large profits to the Brazilian coffee planter. During these years, fortnues were made as quickly from coffee-growing as they had been made from cotton a few years previously. Those who had coffee estates extended them. Those who had made a little money at other occupations rushed into coffee land. If enquiry were made as to the antecedents of many of the most prosperous coffee planters in the Province of Saõ Paulo, you would find this one had begun life as a cart driver. From driver, he gradually became owner of bullocks and carts. That one was a muleteer who gradually got a pack of mules of his own; worked amongst them, himself and his children, aided, perhaps, by some of the half Indian poor labourers. The railway constructors bought up his mules at three times the original price of them. Let me here remark that all removal of earth from railway cuttings and the forming of embankments are done by small mule carts. A third was what you would call a jungle felling-contractor, who worked along with his own free labourers half Indian like himself. With the rush into coffee land, the price for felling jungle rose. A fourth was a sawyer and contractor for squaring timber for building purposes, whose knowledge of the timber trade he turned to good account by supplying railway sleepers at so much a thousand. All these and others who had made a little money noticed the way in which poor families were made rich from the profits arising from the high price of coffee, and, being accustomed to have charge of labourers and work amongst them, made successful cultivators of coffee on the Brazilian system (of only letting the trees grow): and these were the best men for working the free *camarada*, with which he made his start, and continued until he was rich enough to buy slaves. These gradually became the large Fazendeiro we now see them. Reports of success, as they always are, were much exaggerated; so much so that a great many people who knew little of agriculture or of the management of either free or slave labourers got affected with the coffee craze; bought land; and planted it with coffee.

We have noticed that the sugar and cotton planters of the South, who could not prosper in face of low prices and heavy export duties, turned their attention to coffee. In the Provinces north of Rio de Janeiro, however, the land was not suitable, nor was the climate fitted for the growth of coffee as a commercial pursuit. This brought about the third great cause of coffee extension in Brazil.

The Exodus of Slaves from North to South. The sugar planter in the North reasoned thus:—"Why should I continue in a branch of agriculture that gives me no profit? I have still a large capital lying on my slaves, and, owing to the large demand on coffee-growing in the South, my slaves will fetch double the value I am accustomed to put on them if sold there. I am not to leave my old home. I don't know anything of coffee planting. Besides the institution of slavery is tottering; it cannot, in view of the working of the law of September 1871, last long. I'll realize while the price of live property is high, and invest the proceeds in Government bonds, and with the six per cent they give me I'll live quietly." We must be just, however. There are a great many good, able, and well intentioned men amongst them; and the planters in the north do not all do this. Many of them do consider the misery that such a course subjects the poor slave to. They know the slave has a particular liking for the country and district where he has been born and grown up, that, in spite of the captivity in which he is held, the ties of affection bind him to the old plantation, and so fast that even freedom can scarcely separate him from so many old people he is accustomed to call grandpapa and grandmamma; from the large number of uncles and aunts and the dozens of cousins with whom, when they were children, before being turned on to the field-gang, he used to sport and play; to puddle in the stream in the dry season and roll in the mud together in the wet; to hide from the old cook in the orange grove at meal times, or even to stand a pommelling together from the same aged individual (whom he loved none the less afterwards for it) for denying any knowledge of their only garment, while they know some parts were left on the guava trees, and others on the garden fence. They know the habits of the negro well, and that, were the old African, who but ten or fifteen years before had been torn from his kindred in his own land, but had now, through the softening influences of time, almost forgotten the lights, the village burnings, the slave hunts, and long marches which he had experience of in the "Great Dark Continent," could not without a pang be separated from the friends he had made in later years. All honour to those, who, out of commiseration for the slave, held to his plantation and tried to improve his position by adopting a better mode of cultivation by means of the plough, and by the erection of improved machinery, extracting a larger percentage of juice from the cane. A large proportion of the planters in the North, however, sold their slaves.

The Portuguese slave-dealer, who had a few years before been driven into forced retirement, saw his occupation revived, and under much better conditions. *The slave trade* was renewed with vigour. There were no British cruisers that his ship had to evade in leaving port; no risk to run of his cargo being damaged in ill-ventilated ships, while crossing a wide ocean; and no chance of being chased and of the cargo being thrown overboard to prevent his ship being taken as a prize. The buying was now done openly and quietly. The transport by sea was in clean, airy, and swift steamers, flying the flags and under the protection of the various civilized nations of Europe. The landing was not effected in a rock-hidden bay—of which there are numbers between Rio de Janeiro and Santos—but in the open harbours of Rio de Janeiro and Santos, and along with European merchants and their families and pleasure-seekers from all parts of the world. Railways carried the slave gangs at once away from the feverish sea-coast to the interior, where they were soon disposed of for large prices to eager coffee planters. I did not intend entering into the sentimental part of the subject, but I cannot help looking back with horror at the remembrance of the large gangs of slaves I have seen at the railway stations in the interior of São Paulo. I noticed that gangs of boys from 10 to 15 years were readily bought up. There were often rows of women with their children. In many cases, a sale was effected before they left the railway station, if a medical man were procurable. Many of this profession are *specialists* at examination of "niggers." The fee for medical examination is high as the value at sale is considered. Outside of the medical profession, exports are

often called in, the same as a farmer amongst ourselves will trust the opinion of an experienced neighbour in the examination of a horse, in addition to that of a skilled veterinary surgeon. The number of women without husbands and children without parents among these shows that either the law of 1871 is not regarded, as far as relates to separation of families, or that, owing to that law, many slave-owners do not allow slaves to marry. It has been by such a trade that the planters of the provinces of Rio de Janeiro, Minas Geraes and Saõ Paulo have been able to pick the large coffee crops from the numerous new plantations opened in late years.

We now see that railway extension, the high price of coffee in the United States and Europe, and the removal of slaves from the sugar and cotton plantations in the North to the coffee-growing provinces of the South, are the three principal factors in considering the question of the large production of coffee in Brazil.

The most important part of the question, however, for the Ceylon coffee planter is to find out how long this is to continue, and, as I before observed, this is the most difficult of all. No doubt it hangs entirely on the lahour question, and that leads to the perplexing point of how long slavery is to last.

Mr. R. B. Tytler, in a letter to your valuable paper, the *Ceylon Observer*, as far back as 1852, writing on the subject of the large production of coffee in Brazil as it then affected Ceylon—when Brazil was giving little more than a third what it gives now—quoted an authority, showing that the slave question was then embarrassing the landed-proprietors; in 1871 the slave holders themselves thought the law passed that year was to bring them to speedy ruin. I myself, when writing you eight years ago, thought slavery could not last many years, and in 1875 I prophesied that the crop picked that year was the maximum of Brazil's capabilities. We have all been wrong in our conjectures. The signs of decay are very indistinct, but such as these are, I shall notice in a future communication.

P. S.—I have no doubt annoyed you by giving you these pieces in scratches, but you can please yourself about publishing them as they arrive or altogether. With the compliments of the season.—I am, yours very truly, A. SCOTT BLACKLAW.

COFFEE IN SOUTH TRAVANCORE.

South Travancore.

DEAR SIR,—As regards the statement of coffee exported from the Malabar Coast given in the January *T. A.*, allow me to remind you that this part of Travancore has two ports—Quilon exports even more coffee than Colachel—Colachel will only export about 11,000 cwt, again this year, whilst Quilon will export over 14,000 cwt. P. B. P.

EXPERIMENTS IN THE MANURING OF COFFEE.

Yoxford, Dimbula, Feb. 1st, 1882.

DEAR SIR,—In sending you the following somewhat lengthy notes of my manuring experiments, I am actuated mainly by the desire of adding to the general stock of information on the subject of manuring, and, if possible, leading planters in general to adopt a more scientific system of experiment than is customary. Some will no doubt be inclined to dispute the correctness of my conclusions, but it must be considered that the laying down and watching of such a series of experiments is in itself a sort of training, qualifying one to judge more accurately of the results than those who have not laid themselves out for a similar course of self-instruction.

The experiments were laid down in a field which had only borne one fair crop since it was first planted in 1871, at an elevation (4,300 feet) which appears to he above the line of highest crop production on this side of the country, and in a soil of only fair average Dimhula quality, which had never been manured previously. So that it can hardly he said that the results are due to the superior climate or soil of this estate over the district in general, with the exception, perhaps, of the one plot, of which after-mention will be made, and which comes in usefully to compare the value of season with manure. I would warn those who may read this report with any interest that, if they make use of the mixtures apparently most successful here, without any reference to the soil or climate they have to deal with, the result will in all probability he disappointment. The principles, however, of right application are to be gathered, but it is only hy experience gained from careful experiment that any certainty of result can be expected to be attained.

How far further experiment may modify the present results time alone will shew; one year's trial cannot be expected to lead to decisive proof.

The experiments which follow, were laid down at the end of July 1880, a period which, I have since come to the conclu-ion, was too late for the best results at the elevation before mentioned.

The plots are parallel numbered from one to ten.

No. 1.—No manure ground forked. This plot is full of boulders of gneiss, which cropping up above the coffee and retaining the warmth, appeared to give the trees a sort of artificial climate considerably superior to any of the other plots.

No. 2.—Cattle manure 25lb. with ½lb. hones per tree.

No. 3.—Complete manure containing nitrogen, phosphoric acid, potash and lime.

No. 4.—Hughes' mixture, as recommended, castor-cake ½lb., hones ½lb., superphosphate ¼lh.

No. 5.—No manure.

No. 6—Manure without potash, *i.e.*, containing all the ingredients of No. 3, except potash.

No. 7.—Manure without lime.

No. 8.—Manure without nitrogen, beyond that contained in ½lb. bones (steamed).

No. 9.—Manure without phosphoric acid.

No. 10.—Complete manure No. 3 applied 6 weeks later than to the other plots.

In comparing the results, the condition of the coffee on the different plots at the time of application must be taken into consideration. Plots 1, 2 and 5 were superior coffee in good heart; next came plot 10, then plots 6 and 9; and, lastly, plots 3, 4, 7 and 8, which were thin and comparatively poor. The results were :—

Plot 1	... ...	Cwt. 7¾	per acre.
,, 2	... ...	,, 7¾	,,
,, 3	... ...	,, 5½	,,
,, 4	... ...	,, 2¾	,,
,, 5	... ...	,, 3	,,
,, 6	... ...	,, 4	,,
,, 7	... ...	,, 4¾	,,
,, 8	... ...	,, 6¾	,,
,, 9	... ...	,, 4¾	,,
,, 10	... ...	,, 4	,,

The comparison between plots 1 and 2 is interesting, as shewing apparently that *season* is equal to the best manuring. For further comparison, plot 1 is of little value, as in such a year as last, which was unfavourable for high coffee, it gained the advantage of a sort of artificial season by reason of the warmth retained by the boulders above-mentioned, which was so great for a short time as to cause the leaves of the trees to droop and look as if they were going to die.

Leaving out No. 1, therefore, I take No. 5 as the standard of comparison, still, however, bearing in mind the difference in the condition of the different plots

at the time of application. Plot 2, as compared with plot 3 at the time of the laying down of the experiment, was in good heart, plot 3 being at that time thin and weak. The effect of the manure on plot 3 was very marked as regards the formation of wood, but, owing to the late application, it failed to mature its new wood in time for the early blossoms, which practically gave me my last year's crop. The difference is about 2 cwt. an acre, which may therefore be taken as the difference in value between the condition of plot 2 and plots 3, 4, 7 and 8 at the time the manure was applied. The next point that strikes the attention is the superiority of plot 8 over plots 3, 4 5, 6 and 7. To what is the superiority attributable? To me it appears to be in the absence of nitrogen beyond what was to be found in the bones. The growing period seemed to be extended on the other plots beyond its proper length, for I noticed at the time of the early blossom that the trees seemed to have a greater inclination to form wood in the plots to which nitrogen had been added than on plot 8, in which as I have said, there was no nitrogen beyond what was contained in the bones. I may add that I see the same tendency exhibiting itself again this season, which, I believe, only a continued spell of dry weather can counteract.

The total failure of the manure in plot 4 is remarkable, but I believe it to be attributable to the same cause and to the fact that the nitrogen in the castor cake only became slowly available, continuing to act so as to cause the wood to go on growing at a time when growth should have been checked.

Potash appears to exert a favourable influence on each of the plots to which it was applied, though in plot 9, in which it is in excess, the benefit gained seems to bear only a moderate proportion to the amount used, *i. e.*, it would appear that beyond a certain percentage in a manure any excess is of no gain to the tree.

Lastly, plot 10, compared with plot 3, seems to show that time of application is an important factor, making, indeed, all the difference between profit and loss, for the gain on plot 10 over plot 5 is only 1 cwt., or say R50, whereas the manure cost R9·50 applied.

I do not seek to draw any further deductions from this one year's experiment, as, owing to the season, the differences are not sufficiently marked.

I sum up the results of this one year's trial as regards the question, does manuring pay?

There was a profit on plot 3 of R21·50, after deducting the cost of manuring; on plot 7 of R20; on plot 8 of R89, while on plot 2 the gain was R106·50. Plots 4, 6, 9, and 10 show a loss.

If the manures had been applied at an earlier period, I am inclined to think that the gain on plots 3, 4, 7, and 9 would have been greater.

Last year, the experiments were laid down in June, and it will be interesting to see if the above conclusion is borne out.—I am, dear sir, yours faithfully.

Wm. D. BOSANQUET.

The Cedars of Lebanon.—We have received from Mr Eldridge, Consul-General at Beyrout, a copy of the regulations lately issued by Rustem Pasha for the guidance of travellers and others visiting the Cedars of Lebanon. These venerable trees have now been fenced in, but, with certain restrictions, they will continue to be accessible to all who wish to inspect them. In future, no encampments will be permitted within the enclosure, except in the part marked out for that purpose by the keeper, nor may any cooking or camp fires be lighted near the trees, a regulation that has been rendered specially necessary by the partial destruction by fire of three of the largest cedars. Lastly, no animals will be allowed to enter the enclosure, and the keeper of the ground has orders to hold the dragomans and tourists' guides responsible for any infraction of the regulations.—*London Times.*

179

A Quinine Manufactory is in a fair way to be established in Colombo; a lease of the piece of land adjoining the Slave Island Ice Mills has been taken for a period of ten or fifteen years and no time will be lost in going to work. One point on which some doubt has been expressed is whether the temperature of Colombo is not too high for the purpose of manufacturing, and whether Nuwara Eliya would not therefore be a better site for the purpose; but no doubt the present promoters know what they are about.

Coffee.—It is true that the finer qualities of our Coffee maintain their position fairly well—R47 f. o. b. equal to 92s per cwt. in London, is still the quotation here; but the fall in respect of medium and low qualities is certainly very great. R26 now offering for "Garden Parchment" is rather a change! For certain Ceylon marks we know there are buyers for English and Continental houses who, year by year, must have their supply of the best coffee, and who care not if it costs a good deal more than the ordinary market quotation. But granted that the bulk of our Ceylon produce is far superior to either Brazil or Java coffee, and that in past years it was all taken off, it is strange, with three short crops now, that the much more limited supply of our high-class coffees should not be in better demand.

Spores.—A M. Miguel has been making a careful examination of atmospheric dust. He finds in the air two varieties of spores. These spores are the seeds of plants, and are so small as only to be seen clearly under the microscope. Of the first variety there are about 30,000 or 40,000 contained in a cubic yard, the number varying somewhat according to the weather, and are, for the most part, not injurious to health. Of the other kind, however, there are found only about 100 in the cubic yard, and some of these, if taken into the system, may produce serious effects. During rainy weather the first variety may increase in number, so that a cubic yard of air will contain 200,000 of them, while during a drought the number falls to only 4,000 or 5,000. The second variety almost disappears during rainy weather, but may double in number during a drought. So it seems that much of the disease in the world is connected with the existence of atoms so minute that a microscope is required to render them visible.—New York *Hour.*

Leaf-Disease (?) on a Mantis.—A correspondent writes:—"Talking of leaf-disease and its hosts, one would have imagined that at least they would have been confined to the vegetable kingdom. But, examine the mantis I enclose and let your eyes answer whether or not the unfortunate insect was not suffering from an attack that might have been calculated to deprive it of its wings in a week or so and it not prematurely departed this life. Seriously it seems to me a remarkable example of how nature adapts itself to circumstances in many cases, for its support and protection. This specimen was caught on my back in a clearing, and not in the jungle I had lately passed through, whence I had doubtless settled on me! So I am unable to identify the tree or shrub it was on; but must conclude that it was suffering from a disease of which its natural appearance, the spots and markings on this mantis' wings are a true delineation; and it would be interesting to know by what subtle process the malady, in appearance, develops itself. Is it another illustration of the means Jacob employed towards a different end among the sheep and the rods and branches of his father-in-law? Perhaps, when we have a better understanding with Nature—if such are certainly curiously blended—and we [illegible] and entomological authority seems that "the diseased spots of the wings of the praying mantis is probably due to natural decay from the old age of the insect, and not from the attacks of any insect parasite." [illegible]

THE TEA TRADE.—The custom house returns show that large supplies of tea continue to be shipped to London and Melbourne from Madras and the Coast ports. In November last the shipments of tea from Beypore aggregated 16,682 lb; from Calicut 1,705 lb and from Madras in December 6,005 lb. Of the latter quantity, 5,000 lb were sent to Great Britain, 975 lb to Bombay and 30 lb to Melbourne.—*Madras Standard.*

CUPREA BARK.—In *Comptes Rendus*, p. 593, Oct. 17, M. Arnaud describes a new alkaloid which he has obtained from a dark red-brown bark with a resinous fracture, imported from Santander, and which may be presumed to form part of the recently imported China Cuprea. He finds the bark to contain 0·8 per cent of cinchonine and 0·2 per cent of the new alkaloid. He obtains it by treating the bark with milk of lime, drying the mixture, exhausting with boiling alcohol, treating the resulting extract with hydrochloric acid in excess and crystallizing. The hydrochlorate of the new alkaloid is less soluble and crystallizes out first, the hydrochlorate of cinchoniue remaining in solution. This alkaloid he has named cinchonanime. It appears to occupy an intermediate positiou between quinanime and cinchonine, in having two atoms less hydrogen than the former and two more than cinchonine.—*Pharmaceutical Journal.*

GOLD IN CEYLON.—We have within the last few days had a second visit from Mr. Harvey of Australian gold-mining repute, who called here on his way from Melbourne to Southern India with a party of miners from Victoria, whose services he has secured for one of the Wynaad Gold Companies, with which he is connected. His visit to the gold fields of India will be brief, probably for not more than two months, as he has other work in view elsewhere. Mr. Harvey has not changed his opinion of the value of the auriferous deposits in South India. He continues to speak of them as formerly, as being of a varied character—a portion exceedingly rich, a portion of indifferent quality, and another portion as likely to prove worthless. The great difficulty in the Wynaad is the absence of good roads, and Mr. Harvey is decidedly of opinion that a much smaller percentage of the precious metal will pay in Ceylon than in India, in consequence of our having such excellent roads in all directions thereby lessening the cost of transport, and facilitating access to any gold reefs that may be discovered. During his recent stay in Colombo this gentleman examined a large number of quartz samples submitted to him, the produce of different districts, and although the greater portion of these were pronounced by him as cold and valueless, there were others which immediately struck him as giving promise of some practical results. These samples bore a strong resemblance to the gold-yielding quartz of Southern India, having that peculiar colour about them which betokens the presence of ore of some kind, in many cases sulphur with appearances of copper. But of course an examination with the eye is not sufficient to pronounce upon the probable value of a small sample, and when Mr. Harvey was requested by one Colombo firm to pay a visit to a district from which a very promising sample had been taken, he pointed out the necessity first of a further exploration of the locality, so as to expose a certain depth of the reef, to enable him to come to something like a conclusion on the subject. Mr. Harvey left by the Bombay steamer for Tuticorin whence he will proceed to the Tambracherry estate, for which property he is chiefly acting, and for which he is taking the miners engaged in Australia. During his absence of six weeks or two months, explorations will be made in several localities with a view of enabling him, on his return in February, to give something like a practical opinion on the value of the samples raised; and we may add that Mr. Harvey thinks it extremely probable that gold may be found in Ceylon which, with our advantages, may be worked to a profitable account.—"C. Times."

COFFEE.—We find that the consumption of coffee has been fairly maintained, and on the continent demand has steadily increased in a most healthy manner to such an extent that if the heavy supplies could but be arrested, no doubt stocks would in time assume reasonable proportions. But in the face of continued large imports, and of the almost total disappearance of the large class of middlemen or dealers who were formerly of great use in acting as intermediaries between the importer and the retailer, and so helping to steady the market, there is no escape from present depression. An impression naturally arises, that some "bear" influence is at work helping to intensify what otherwise would be an ordinary fall in the coffee market; and should this be the case, the ultimate result may be a rebound in prices as sharp as the present fall.—"C. Times."

THE BENGAL GOVERNMENT'S PROFITS ON CINCHONA.—The Calcutta *Englishman* says that the Bengal Government, like the private trader, find cinchona a paying speculation. The last official year the Government turned out 9,296lb. of its well-known febrifuge, at an average cost of R9-3-10·625 a pound, and a total cost of R85,921-6-3. They had also in hand from the former year 3,726lb. By sales to the public of the febrifuge, seeds, and plants, a return of R56,436 odd annas and pies was obtained, and a further sum of R32,340 from the sale of yellow bark in London. Thus public sales of the produce of the cinchona establishments more than paid for the expenses incurred. In addition, however, to the produce sold, febrifuge valued at R90,880 was disposed of to the Medical depôts of Calcutta, Bombay, and Madras. Had quinine, for which this febrifuge was substituted, been procured in the open market, the quantity needed would have cost the public purse, it is estimated, R5,50,000. The sum saved the Government in a similar way since thefebrifuge was first substituted for the more expensive drug, is further calculated to have amounted to 16 lakhs.

SUCCESS OF MR. SCHROTTKY'S PATENT PROCESS OF INDIGO MANUFACTURE.—From the Calcutta *Englishman* just received, we take the following, and we commend the facts of the leading Bengal journal to the critics of Mr. Schrottky's work here, who, writing from Calcutta, endeavoured to prejudice local authorities:—

The experiments that have been carried out in Tirhut during the past indigo season with a view of testing the value of Mr. Schrottky's patent process of indigo manufacture, seem to have been thoroughly conclusive as to its success.

At Harsingpur Factory the result of a series of trials was an average excess of dry produce of from 17½ to 39½ per cent. from the patent, as compared with the ordinary, process. At Dhoolie Factory the result was an increase, in favour of the patent process, of 21 per cent.

"At other factories," to quote the patentee's account of the results obtained, "the Patent Process was chiefly tried with the view of ascertaining whether it would improve the colour, but in the majority of cases, an increase in quantity, where quality of plant was the same, could be shown, which, however, did not always appear as an increase in the number of presses; the gain lying chiefly in a much thicker paste, and hence larger sized cakes. At Barowlie Factory, for instance, the produce was, before the use of the Patent Process, 10 presses from 12 vats, The "Mâl" or paste being very thin and difficult to press, cakes averaging 2¾" to 2¾" thickness. The first day of the Patent Process the "Mâl" changed entirely its character; it became very thick and pressed easily. The number of presses were the same, *but the cakes ranged from* 3¼" to 3½" *thickness.*

It also appears to be beyond doubt that the use of the new process leads to a decided improvement in the quality of the indigo manufactured, the difference in the valuations being in many cases twenty rupees per maund in its favour.

New Industries.—I see in your paper inquiries about tapioca and dried banana or plantain, made in the island. Both these articles have been, from time to time, made, of course, in small quantities, by my father, the Rev. F. Asbury, of this place (Manippay), and supplied especially to American friends here. He holds a prize-certificate of the committee of an agricultural exhibition held years ago in Madura, Southern India, for exhibiting the best tapioca; rope made of plantain fibre; collection of gums; etc., etc.—*Cor.*

Moyar Coffee.—The annual meeting of this Company was held on Dec. 21st, Mr. Hall in the chair. The chairman stated that that was the first meeting of the Company since they parted with a considerable portion of their land to the Devala Moyar Gold Mining Company. He had to express the regret of the directors that they had not a more favourable report to present to the shareholders in a financial point of view, the result of the last year's working, instead of a profit, having been a considerable loss, owing to a bad season for the coffee crop and the smallness of the price obtained for the coffee in this country. Whilst they expected twenty-five tons of coffee from last season's crop, they only secured fourteen tons. The three estates held by the Company covered an area of about 2,600 acres, but the extent of the coffee plantations was not very large: and about 200 acres were under cultivation, and another 100 acres were planted out last year, and 50 acres had been cleared for planting, so that altogether they would have about 350 acres under cultivation at no distant date. They were also planting out cinchona, one of the products likely eventually to give good returns. Up to March 31st last they had planted out 97,000 plants, whilst previously they had not more than 20,000. They had recently a good supply of rain water, which had done the plants much benefit, and in future it was expected they would be enabled to obtain all the water they required from the river for the purposes of irrigation. It was expected that the next season's coffee crop would amount to forty tons. The report was adopted. —*Overland Mail.*

Egypt is pronounced by competent authorities too dry for Jute; the Western Province of Ceylon is the spot for the requisite vapour bath. A humid atmosphere must be a *sine qua non* for its fructification, then I am afraid that such practical experiences will bar its progress. I think the climate of Egypt is too dry for such an undertaking to prove profitable, and that none but a similar climate to that of Bengal with its constant moist atmosphere—a species of vapour bath—its alternate showers and sunshine during the period of the growth and maturity of the plant—will bear good and profitable results in my humble opinion.—*Cor. of Dundee Advertiser.*

Cinchona Bark.—At the public sales held on the 20th instant, 5,742 packages were offered, as follows:—South American, Columbian, Pitayo, &c., 2,893, Cuprea 2,377, Carthagena 263; East Indian, Nilgherry district, 122; Ceylon, 87. The market during the past fortnight has been the most active on record, prices advancing day by day, the rise from the lowest point being from 40 to 50 per cent., and even more in some cases. At and immediately after the public auctions, 3,500 packages were sold, and the total sales for the fortnight, many of which are not reported, are computed to be not less than 10,000 packages. For some time, owing to the enormous arrivals of Cuprei, prices receded until they were so low, that they were reported to be considerably less than the cost of production. This, coupled with the assertion that supplies of Cuprea had nearly run out, appears to have induced some speculators to operate largely for a rise.

Sulphate of Quinine.—The price of best English brands has been advanced from 4s to 10s per oz., but manufacturers will only take orders for small quantities, and it shortly probably before long we shall have again to quote a further rise.

Indian Tea in Russia.—The *Statist* is informed by Messrs Gow & Wilson, who have made inquiries of the British Consul at St. Petersburg, that Indian tea does not find purchasers in Russia owing to its alleged rough flavour. The few merchants who have ventured to import have had to dispose of it mixed with China tea, and a well-known merchant, who imported a large parcel of Indian tea last year, being unable to find purchasers, ultimately reshipped the consignment, incurring a considerable loss by the transaction. The quantity of China tea imported into Russia, overland and by sea, in 1880, was about 28,800,000 lb. The duties on tea, according to Article 75 of the Russian Customs Traff, is—1. Flower, green and yellow 22 robins per pud. 2. Ordinary black tea; stalks, and brick tea, 15·40 roubles per pud, both payable in gold. No distinction is made in the tariff between China and Indian teas. There are two circumstances which we should think are adverse to the sale of Assam teas. One is the fact that Assams, being "tippy" teas, the duty on them would be the higher rate, and the second reason is that these teas are more pungent and rasping than Darjeeling, Kumaon, and Kangra Valley teas, which, though fine, would, in most cases, pass at the 15 rouble 40 copeka duty. The difference in duty would be great consideration to the Russian dealer. The Russians are extremely particular in the choice of teas; but, if a high class delicate quality were introduced, the present prejudice against Indian descriptions would be overcome, just as it has been in this country.

Red Rust in Wheat.—Mr. R. A. Perkins, of the Experimental Farm, Millicent, near Mount Gambier, South Australia, speaks of red rust as follows:—"This fearful pest first made its appearance in this colony about the year 1853 or 1854. Many will remember the year 1854 to their cost. Since then it has been more or less prevalent, and much valuable time and expense has been wasted in experiments and researches to try and find an antidote for red rust, but none of those tried have proved a sure remedy, although some are of great value. First—It has been proved that soft fluffy-strawed wheats are the most susceptible to red rust, so it behoves every farmer to sow none but what will grow a strong glossy straw. Second—Manure and Pickle.—I have tried a great number of different sorts of pickle, and the best results have been obtained from salt and lime, and the worst from bluestone. I consider that we require a stimulating pickle, of which I find lime and salt far the best. Glue and charcoal, saltpetre, sulphate of soda, and many chemical mixtures, have been tried with varying results, but none have proved of any permanent value. I have made a great many experiments, and may mention a few that have been suggested by Mr. Sabine in a paper read before a commission appointed by the Royal Agricultural and Horticultural Society to inquire into the subject of red rust:—1st.—New seed treated with bluestone. 2nd.—Old wheat treated with salt and lime. 3rd.—New wheat treated with salt and lime. 4th.—Old wheat treated with bluestone. The results of these experiments have always been in favour of salt and lime. The old seed is, I believe, of some value; the plants are stronger and more vigorous and healthy, which is of great importance, and it is an acknowledged fact that a strong, healthy, early crop has the best chance of yielding a good harvest. When those facts are acknowledged, it behoves every farmer to sow nothing but strong healthy wheats. Those most suitable are, as tried by me:—First, Oregon; second, Red Tuscan (old), White Tuscan; fourth, Nonpareil. These are of strong growth and hardy nature. I find all those sorts of a soft fluffy straw are most liable to rust. I have the noted Dufiance and other sorts, which I hope to be able to give a good account of next season."—*Sydney Mail.*

CINCHONA.—A paragraph has lately gone the round of the papers to the effect that Mr. Cross, who has been for some time in Ootacamund examining and reporting upon the Government Cinchona Plantations, had informed Government that the greater part of the Cinchona propagated by Government and sold to the public as C. Succirubra (red bark) was really the comparatively worthless variety known as C. Micrantha or the grey bark of commerce. This statement, put forward by so high an authority, naturally caused some anxiety to those planters in Wynaad and elsewhere who had obtained their plants and seed from the Government Plantations. We are now authorized to state that His Excellency the Governor, who is himself a most able and experienced botanist, aided by Dr. Bidie and other experts, went into the question most fully, during his recent visit to Ootacamund and after hearing all that Mr. Cross had to say in favor of his peculiar theory, has arrived at the most positive conclusion that Mr. Cross is mistaken, and in fact, that there is no evidence to support his theory, while everything goes to show that the variety which has been so widely distributed by Government is neither more nor less than it purported to be, viz, the common C. Succirubra or red bark. A practical planter to whom we mentioned the result of the investigation remarked "What does it matter whether they call it Succirubra or Micrantha? We know that it fetches a good price in the London market, and if it *is* Micrantha, why we'll plant Micrantha, that is all."—*South of India Observer.*

VEGETATION IN THE DEHRA DOON.—In a letter, under date the 8th November from the Dehra Valley, Captain J. F. Pogson writes as follows :—This is a wonderful place for Horticulture. All the large old houses have gardens, and tree plantations, and *these*, as a rule, are *botanical gardens*, though the proprietors seem quite unconscious of the fact. On Saturday, I went for a walk and stood at a gateway, astonished to behold an avenue of "keloo" trees, (*Cedrus Deodara*), with "Cheel" (*Pinus sylvestris*,) "Kyle" *P. longifolia*, Cypress and Juuiper (Himalayan,) in full growth in the immediate vicinity of maugoe trees, plantains in full fruit, papaya in ripening fruit, with the large bamboo, Loquat and Lichee. The hill blackberry growing as a weed under jacktrees (kuthul) of Bengal, and guavas. As for forest trees with which the magnificent roads are shaded, I have yet to learn their names. What I have yet come across I do not know, for such a jumble of trees from all parts of the world growing in defiance of all laws, and nations on the subject I never expected to see. I have come across *Ficus elastica*, American aloe, and adjacent something very like pineapple. Lord Hartington should come here, and imagine himself in a mighty "*Chatsworth*," with the cover (glass-roofing) taken off, and then perhaps the improvement of Indian Agriculture, Horticulture, and forest tree culture would be taken up in real earnest in place of being experimented upon. En route from Saharunpore, I passed through miles of forest growing as if the height of forestiug consisted in seeing how many forest trees could be packed within a given space not sufficient for the growth of half-a-dozen trees. Some day I will visit the forest and measure the number of trees to be found within a radius of twenty yards.—[Any one who has journeyed to the Doon viâ Saharunpore will recognize the truth of Capt. Pogson's description. Conspicuous in forests of sal and Sainé, are scandent *bauhinias* with foliage of enormous size. The Doon is 2,000 feet above sea-level lying under the shadow of the Himalayas, and the climate seems suitable for a meeting-place of the vegetation of "the abode of snow," of temperate and of torrid zones alike. Appropriately therefore is this place the site of the first College of Forestry in India—the first we believe in the British dominions.—ED.]

A SUBSTITUTE FOR COFFEE has lately been discovered by two gentlemen at Akyab, for which they have applied for a patent. It is the seed of a plant called in Burmese *dannaythee*. It is grown as a weed plentifully all over the province, and it is thought, if cultivated, would doubtless produce larger and finer seeds. They are very small usually, but, for the cost of picking and shelling them, a plentiful supply can be had. The seeds, after being well roasted and ground, produce a slight aroma of coffee, and with pleuty of milk and sugar form a palatable drink, although Mocha is generally preferred.—*Madras Mail.*

THE COTTON INDUSTRY THRIVES APACE (says the *Bombay Gazette* in its annual review). Every year adds to the numbers of our spinning and weaving mills. The mill property of Bombay, which became depressed of 50 per cent. below par in consequence of the late famine, has now, in spite of occasional fluctuations, risen to par value and a little more, and 30,000 operatives find profitable employment in the industry. The ordinary Hindoo labourer, the representative of the Deccan ryot, has occupied this field of industry almost entirely, and here it is that the Hindoo woman appears conspicuously as a helpmeet to the family and as a breadwinner. The Mahomedan element in the mill industry is small compared with the Hindoo, and it is not easy to tempt the Mahomedan hand-weaver to relinquish his independence and join the operative class in the large mills that are worked by machinery. As far as can be seen at present, the capital which has been embarked in the mill industry of Bombay is comparatively safe and sufficiently remunerative to attract native capitalists, especially the Bunniahs and the Bhattias. [When are Messrs. de Soyza and Rajapakse to try a cotton mill in Ceylon?—ED.]

CULTIVATION OF THE GRAPE VINE IN CASHMERE.—The subject that next came before the meeting was the culture of the Grape in Cashmere for the manufacture of wine, as alluded to in a letter from Monsieur Ermens, the Director of Agriculture to His Highness the Maharajah. The following are extracts from the letter :—Cashmere is essentially a wine-growing country, and the richness of the soil is admirably adapted for vine cultivation. His Highness the Maharajah engaged me specially for the cultivation of the vine as well as for the manufacture of wines and spirits. I arrived in Cashmere in 1876, and selected the Shirmencha slope as the most suitable for vine cultivation, because the soil appeared to me suitable, and also because of the certainty of procuring water for irrigation purposes. In Europe water is no great object ; but in India the soil dries up so quickly that water is indispensable. I began by planting in 1877, and the cuttings all came from France and from the best districts, the names of which are as follows :—Margaux, Tabernet, Sauviquion, Cabarnet Franc, Malbec, Merlot, and Verdot. These are the fine varieties of vine, the wine of which is known in the trade as Margaux, Chateau-Lafitte, &c. The other cuttings come from Chateau-y-queem in two varieties, the Semillion aud the Sauviquion. The grapes of these are of a very fine quality, and yield a superior class of wine, Chateau-y-queem being, as you are aware, the finest white wine in the world. You will notice that I have taken cuttings from the best vines, and I have been highly successful, as on the 3rd year, I gathered lots of grapes and made an abundant harvest—a thing not to be done in France under five years. The wine made has lasted and been found excellent. This wine will have acquired all its flavour in 1883, and then be sold in the open market at a low price, compared with French wines sold in India. [If all this turns out to be correct, then India may be added to the wine countries of the world. But the quality of the wine when matured has yet to be tested. As population increases in Australia, we suspect it will beat the world for cheap as well as good wines.—ED.]

BRITISH HONDURAS.—Every endeavour is to be made to foster the fruit trade between Belize and New Orleans. The planters are constantly adding to the area under fruit cultivation, and the trade promises eventually to assume immense proportions. For want of roads, the mahogony trade is coming into standstill, though there are inexhanstible supplies of it in the forests of the interior.—*Colonies and India.*

AGRICULTURAL AND HORTICULTURAL SOCIETY FO INDIA.—TEA CULTIVATION IN THE ANDAMANS.—Read a letter from Major Protheroe, C. I. E., Officiating Commissioner of the Andamans, of which the following is an extract :—

"You will be glad to hear that the tea experiment in Port Blair, begun a few years ago, has so far been successful, and that the hybrid variety of tea, the seed of which was supplied by you from, I think, Assam, flourishes in those islands, flushes well, and the tea prepared from it has been highly valued by experts. The China and Assam varieties of tea have not, however, succeeded so well as the hybrid."

OUR LABOR SUPPLY upcountry is, in many cases, embarassingly deficient even on estates which have never been behind in the payment of wages. Instead of from 100,000 to 200,000 immigrants, as in former years, the arrivals in 1881 were only 53,000 and the departures exceeded this figure by 10,000. This is a sad and significant sign of the times, but, as there is "a tide in the affairs of men," so there must be ebb as well as flow. Even now we look for the "good time coming" for employers of coolies as well as coolies themselves.

THE HYBRID CINCHONAS ON THE NILGIRIS.—A correspondent writes :—"Colonel Beddome has changed his opinion regarding these hybrids so often that I cannot place much reliance on what he writes. I am able to deny emphatically that Mr. Cross found either of what we call hybrids in the *original* planting of 1862. True there are a few there in 1862's planting *now*, but they were in the nursery in 1870. Mr. McIvor's report for 1875 first mentious these trees and it is not likely that, if Mr. Cross introduced one or both of them in 1861, they would have passed unnoticed for 14 years. All the analyses up to date shew that, what we call Pubescens, is equal to, if not better than, Officinalis, and the growth,—therefore the weight of bark,—is infinitely superior even on grass land."—*Madras Mail.*

MR. H. C. BURY, a well-known Uva pioneer and the proprietor of valuable plantations in Haputale, is a passenger home by an early steamer, after a short visit to the Central Province. Mr. Bury is on the whole well pleased with the appearance and prospects of coffee in the premier district. He is delighted with cinchona cultivation more especially at an elevation of 5,000 feet and upwards. The one great drawback is transport, and if it had not been for the absolute necessity to the Government themselves now, of extending the Namuoya line to Haputale, he and other proprietors would devote all their energy to the promotion of a low-country Hambantota line with a curing establishment at that port. Such a railway, the Government, of course, will not now allow, and we have pointed out to Mr. Bury, advantages in direct communication with Colombo, even though the line only start from the top of the Pass. The over-hill line will certainly be a first-class work at the money allowed and once made, no flood or landslip need be feared such as have been experienced all round the Uva lowcountry on the Halpe, Hambantota and Batticaloa roads during the burst of the north-east monsoon. If only the "twenty five miles' section" were commenced to settle all doubts!—Mr. Bury successfully experimented with Cinchonas some ten years ago in Haputale, and we must hereafter refer to his experience in this industry to encourage his successors of the present day.

THE ERYTHROXYLON COCA.—The Madras Museum is in receipt of some samples of this plant, which is a native of Peru and Equatorial America. The leaves possess very powerful stimulating and sustaining properties, and are eaten for this purpose by mountaineers in the localities where the plant grows. It use enables them to carry heavy burdens, and the leaf has also the property of assuaging hunger. Its is now being introduced on the Continent of Europe, where the leaves are used as the ganja leaves are used in India.—*Madras Mail.*

SHEVAROY, Jan. 27th.—The crop, which is very late this season, is now being despatched to the coast. The quality on the whole appears to be good, increased attention being paid to the washing of the coffee—a defect pointed out by the jurors of the Sydney Exhibition as applicable to all Indian coffee. The quantity as anticipated is lamentably small, falling in many cases far below estimates, and in all below the average Trees are, however, in good heart, and estates have never looked so well as they do at the present moment. Eight rupees per bushel of dry parchment, delivered in Yercaud, has been accepted for a small parcel on Pondicherry account.—*Wadras Times.*

WHITE-ANTS AND LIVING TREES.—Most books on gardening state that white-ants will not eat anything that has life in it. The Forest Report of the Punjab, however, states that, during last year, two of the Eucalyptus trees at Changa Manga, some 60 feet high, were blown down; when it was found that white-ants had eaten up the greater part of the supporting roots. The Conservator fears that damage of this kind will seriously interfere with the raising of Eucalyptus on a large scale. The report does not show, however, whether it was quite certain that the roots had not dried up and become dead *before* the trees fell down?—*Pioneer.*

THE COFFEE CROP IN SOUTHERN INDIA.—The coffee crop is expected to be late this year. The late spring rains brought the blossoms out a little after time, and the dry weather generally that succeeded did not contribute to develope the berry. In some localities it is abnormally small, but the bean shows compact and firm. The crop will probably be characterized as light and small. Most estates are short, and even this limited outturn was menaced during the year. If prices rise, working expenses may be recovered; if not, the outturn will leave many of the estates with an increasing debit balance. The gold industry has thrown coffee back considerably, but beyond a temporary depression, this product will assert its superiority and remunerative character before long.—*Indian Agriculturist.*

SCORPION STING.—When cases of scorpion-sting were brought to me, I used to follow the old plan of treatment, viz., incision of the part stung, touching the part with Liquor Ammoniæ, and then the application of a paste of Ammoniæ Carbonas and Ipecac to the same part. After reading in your paper the different reports of Liquor Potassæ as an antidote to snake poison, I gave the Liquor Potassæ a trial in scorpion-sting, and the results were so good, that I now give all my cases the benefit of the latter treatment. I invariably give internally 30 drops of Liq. Potass, and touch the part with Liq. Potass. Both the Ammonia and Potash plans of treatment were successful. I find, however, the Potash superior. The Liq. Potassæ when applied, gives less pain, and the patient is almost immediately relieved of the agonizing pain of the sting. I may mention that I gave some Potass to a Missionary Priest, as very often cases are brought to him. He had one severe case, that of a boy. When first seen the boy was bad, he was given the benefit of the Liquor Potassæ plan of treatment, and the relief was immediate.—"R. A. J." in *Madras Mail.*

BERRIES AND SPIKE.

TO THE EDITOR OF THE "MADRAS MAIL."

Sir,—A forward spike early in December is no phenomenon. Year by year we have it, and about X'mas a blossom is usual. This blossom, as a rule, produces ripe cherry in August. During the month of November 1880, my estates had a blossom which yielded some 500 bushels of cherry picked in the following May. This year, a blossom came out at the same time, from which we expect at least 1,000 bushels.

I am of opinion that very early blossoms do not affect the general blossom to any appreciable extent. Moderately early blossoms do, and are, so far as my experience goes, favourable to the production of good crops. In February 1873, I had a blossom which resulted in an extremely good crop; early in January 1879, a very successful blossom that gave at least two-thirds of a good crop. During this season my estates blossomed six or seven times between the 7th January and 30th May, but, as before stated, the bulk of the crop was from the January blossom: all these blossoms ripened crop about the ordinary time.

Wynaad, 23rd Dec. Bamboo.

THE NEW ALKALOID IN CUPREA BARK.

(*Pharmaceutical Journal*, 24th December 1881.)

From the Report of the meeting of the Chemical Society, which took place last week, it will be seen that Mr. David Howard read a paper describing the results of his observations respecting a peculiar alkaloid existing in the bark known in commerce as cuprea bark. The details there given leave no doubt that the alkaloid observed by Mr. Howard is the same as that referred to by other observers in the papers published in this Journal last week, and it is interesting to note this simultaneous and quite independent confirmation of the existence of a peculiar alkaloid in the bark in question.

From a letter just received from our valued correspondent, Dr. Hesse, in Germany, it appears that the new alkaloid has also been noticed by a friend of his in Stuttgart, who at first regarded it as cinchonidiue, though he was unable to obtain any evidence of cinchonidine being present when the bark was operated upon in the ordinary course of manufacture.

From what is known of the new alkaloid in cuprea bark, it is not very difficult to explain how this happened. In the ordinary course of analysis the new alkaloid would be distinguished from quinine by its comparatively sparing solubility in ether, and the fact of its forming a tartrate of sparing solubility might readily lead to its being taken for cinchonidine. But in the process of manufacturing of quinine sulphate, these chatacteristic features of the new alkaloid and its salts would not be of any influence in pointing to its presence. The determining circumstance in that case would be the sparing solubility of the neutral sulphate, and as that is a characteristic which brings the new alkaloid into close resemblance with quinine, it would have the effect of masking its presence in the course of manufacture and even of leading to its being overlooked if the quiniue sulphate containing an admixture of it were tested by the method of fractional crystallization.

From these considerations it will, moreover, be evident that means are now furnished for accounting for some of the discrepancies that have occasionally been observed to obtain between the results of analysis and of manufacturing operations in regard to cuprea bark. It is not likely that in a well-conducted analysis of that bark the new alkaloid would be returned as quinine; but in the course of manufacture it might well happen that the new alkaloid would be ob ained as a sulphate, together with the quinine, thus augmenting the yield of quinine sulphate, apparently in disagreement with the result of analysis. And if the amount of the new alkaloid be on the average only as great as that indicated by Mr. Howard, viz., ·35 per cent, or about one-tenth part of the quinine, the effect of its presence would be sufficiently remarkable, while in cases such as that referred to by Mr. Whiffen, where the new alkaloid amounts to 0·8 per cent, the possible difference between analytical and manufacturing results would be rendered still more palpable in the same way.

Dr. Hesse remarks in his letter that under the rade name of "cuprea bark" are comprised a variety of different kinds of bark corresponding in texture and colour, though perhaps in no other respect, and that sometimes this name is applied to bark which has not even the copper-red colour which was originally one of its distinctive features. A pale coloured bark of this kind is mentioned by Dr. Hesse as having been examined by Professor Körner, who obtained from it a peculiar alkaloid forming finely crystallizable salts, which will form the subject of a communication before long. Besides this, the bark examined by M. Arnaud, and from which he obtained cinchonamine, seems to be of the same kind, viz., similar in texture and colour to true cuprea bark and coming from the same district, but differing from it in containing more cinchonine and the new alkaloid described by him as cinchonamine.

AGRICULTURAL ITEMS.

It is of no use to apply remedies to the fowls to get rid of lice if the house is not rid of them. The house should be cleaned out thoroughly, every loose thing pulled out and well scrubbed with hot lime wash. The roots should be well greased all over, and then, but not until then, apply remedies to the fowls.

Water glass, soluble silicate of soda, has been used by the Germans for keeping eggs. This a clear liquid, of the consistence of syrup, and when smeared over the shell soon dries into a thin, hard, glossy coating, entirely impermeable to the air.

A DAIRY MAXIM.

If milk and butter you would have—
A right delicious treat—
Keep churn, and bowls, and milking pails
Most scrupulously sweet.
With boiling water, day by day,
Cleanse each with utmost care;
Then rear them at your doorway,
To dry in open air.

—From "Twenty Golden Rules," by F. R. (G. Bradley, Huddersfield.)

Experience has proved board floors for poultry houses to be injurious to the fowls. No amount of cleaning can keep them free from vermin and bad odours. Clean, dry earth is the proper flooring for hen houses. It should have an under strata of solid, packed earth. This should be scraped at least once a week, and again sprinkled with road dust mixed with air-slacked lime.—*Sydney Mail.*

EFFECT OF MANURES ON CROPS.

(*Field*, 19th November 1881.)

Year by year the work done in experimental agriculture increases rapidly, and the results obtained, which generally refer to the effects of manures on certain crops, are published in the monthly and weekly periodicals. But part of this work, over which much trouble and time has been expended, is in a great measure lost to the agriculturist; for, soils, climates, and local conditions varying greatly, if the experiments are repeated exactly, disappointment follows,

and labour and money are lost. It is therefore necessary, in order that the experimental results obtained by others may be made use of, that the modifications in the original plan which ought to be introduced, and which are determined by the locality, should be discovered by independent experiment in each district. We do not despair of the discovery in the future of some plan whereby agriculture will be regulated by rules other than those of thumb and chance.

It is not proposed to enter here into an account of the various disturbing influences which render the modifications referred to necessary, but rather to lay before our readers a few facts, which may simplify their labour should they at any time venture to repeat on their own land the experiments of others. What we are about to say is rendered all the more necessary by reason of the method so frequently adopted in the description of experiments as to the amount of manures employed. We read that 42 lb. of phosphoric acid, or that 3 cwt. of superphosphate, were applied per acre. We doubt very much if these statements produce any definite impression on the minds of many who have read such a report. How are they to discover the number of pounds of phosphoric acid in a "super?" or will 3cwt. of some super which they have bought be as good as that which is described in the experiments? It is an answer to these questions which we now give. Of course, if we are told that so many shillings' worth of 22 per cent superphosphate have been used, there is then no difficulty in doing likewise; the difficulty to be overcome is when we are told to use as much of a manure as shall contain a certain weight of some one constituent.

In superphosphates, phosphoric acid, as is well known, exists in two forms, as the soluble and the insoluble phosphate of lime. The analyses, a copy of which can generally be obtained at the time of sale, state (1) the percentage of "soluble or dissolved phosphate," by which is to be understood the amount of insoluble phosphate, or bone earth, rendered soluble in the process of manufacture. A second entry (2), which is explanatory of the first, is sometimes made, which states the actual amount of phosphate of lime (chemically termed monocalcium phosphate) which is soluble in water, and its percentage is always lower than that of the first. One more entry (3) may be found, namely, the percentage of insoluble phosphate of lime, or that part of the original material which has escaped alteration during the manufacture. To calculate, then, the amount per 100 lb. of the super of phosphoric acid contained in either 1 or 3, it is only necessary to multiply the percentages by 0·46, in 2 the amount is found by multiplying by 0·607. The products from 1 and 2 will be the same, as the two substances are identical, the first being a technical term, the second the chemical term. Care must therefore be taken that both figures are not employed in the calculation. As an example, we quote the following analysis:—

	Per cent.
1. "Soluble phosphate" (equal to bone earth made soluble)	21·84
2. Soluble phosphate, monocalcium phosphate..	16·39
3. Insoluble phosphate..	5·56

Multiplying the percentages of 1 and 3 by 0·46, we find that 1 contains 10 lb, and 3 contains 2½ lb. of phosphoric acid, though not in the same state of combination. If 2 be multiplied by 0·607, the same result is obtained as when 1 is multiplied by 0·46. Of course, if the manure be wholly insoluble, as in the case of bones, there can then be no doubt as to which factor to employ.

Nitrogenous manures being also largely employed, either as sulphate of ammonia, nitrate of soda, or raw bones, it is necessary to show how it is possible to translate a given number of pounds of nitrogen into sulphate of ammonia, &c., or *vice versâ*. The analyses state, besides the phosphate of lime, the percentage of ammonia which can be obtained from the bones. To calculate the amount of nitrogen to which this percentage is equivalent, divide by 1·214; or, supposing that it is desired to know how much pure sulphate of ammonia will contain the same weight of ammonia, then the ammonia in the bones must be multiplied by 3·88, and its equivalent in pure nitrate of soda will also be obtained by employing the multiplier 5.

In the same way we may calculate the quantities of guano which are equivalent to known weights of sulphate of ammonia, &c. The only other manure to which we need specially refer is kainit, which contains at least 24 per cent. of sulphate of potash. Multiplication of the percentage of the sulphate by 0·44 gives the amount of potash present. By the aid of these figures we hope that some of our readers will be able to understand, and to appreciate more thoroughly, the experiments which have been carried on for years past by such earnest workers as Messrs Lawes and Gilbert, and others.

FORESTRY IN MOUNTAIN DISTRICTS.

(*Field*, 26th November 1881.)

Whilst the legislation of this country is feeling its way towards some remedial measures in reference to the increasing injury arising from floods, it may interest our readers to learn that so far back as the years 1860 and 1864 the French Government passed laws in reference to the planting and turfing of mountain districts with the view of preventing the formation of torrents. We are indebted to M. P. Demontzey (who holds the important position of Conservateur des Forêts) for this information, together with a vast mass of details as to the carrying out of the necessary works. M. Demontzey is well qualified to be the author of a practical treatise on the replanting and grassing of mountains, and the work is certified by the Ministers of Agriculture and Commerce.

The French Government, having the advantage of a Forestry Department, are more alive to the necessities of assisting proprietors to make improvements. We proceed to give a brief outline of the objects sought and the results. The laws to which we have referred have two branches—one of encouragement, the other of restriction. The former consists in the powers given to the State to stimulate proprietors, by grants of money and material, to replant and renew unproductive soils or exhausted pastures, of which the actual condition would contribute either to the formation of new torrents or the extension of existing ones. This measure is applicable to all mountain regions. It is essentially preventative in its action, having for its final aim the maintenance and protection of the soil by a series of replanting or regrassing, which the law has named *optional*, and which are thus useful to the general interest, as well as advantageous to proprietors. The means of coercion give the right to improve in the name of public utility similar works called *obligatory*, of which a preliminary inquiry has proved the imperious necessity. The one is for prevention, the other for cure where the malady exists.

The object of these two laws may be thus described. On one hand, to prevent the formation of torrents by the consolidation of the soil on mountain surfaces, a result obtained by optional planting and turfing, and even sometimes by obligatory turfing. On the other hand, to suppress the effects of actual torrents by obligatory works of both kinds. Finally, to obtain and maintain by the results of these two primary effects the regulation of torrential rivers and the protection of valleys below.

The observation of scientific men led to the conclu-

sion that torrents, which rend the mountains and destroy their valleys, are one of the most powerful auxiliaries of those inundations increasingly frequent in the plains, and that the primary cause of the formation, as also of the extension of torrents, was the removal of trees. M. Surell established this theory in his "Études sur les Torrents des Alpes," and demonstrated the following propositions:—

1. The presence of a forest on a soil prevents the formation of torrents.

2. The destruction of a forest leaves the soil a prey to torrents.

3. The development of forests causes the extinction of torrents.

4. The fall of forests redoubles the violence of torrents, even causing them to be reformed.

It was admitted during the discussions of the law of 1864 that in special cases the forest might be replaced advantageously, at least in part, by the close vegetation of a grassy sward. These principles being established, it was necessary to go to work gradually, and above all to carry out a series of experiments of such duration and extent as would secure unimpeachable evidence. Moreover, the laws being declared tentative, the funds supplied were only sufficient for preliminary experience. It is now more than sixteen years ago since the work was commenced. The numerous studies which have resulted, the valuable observations that have been made, and, lastly, the undeniable and living proofs obtained, have victoriously silenced all objections. M. Demontzey tells us that in the higher regions of the Alps, the classic ground of torrents, one can see now numerous forests of resinous trees suitable to the climate, showing vigorous growth, not only in the basins of reception of primary torrents attacked by these works, but even on their steep banks, fixed and protected for ever; whilst these torrents themselves, once so formidable, have become streams not only harmless but most valuable, inasmuch as they supply good and abundant water for irrigation. The earlier chapters treat of the description and formation of torrents; their effect in the heart of the mountain, description of preparatory operations, and action of dams. This portion of the work is well and numerously illustrated, and a careful study of the drawings will assist in understanding the various means adopted to alter the character of torrents and prevent their mischievous character.

The next portion of the work treats of planting. The object to be obtained is a woody vegetation which possesses the following conditions:—

1. Roots so powerful as to inclose the soils with their numerous rootlets as in a net, so making them more porous and protecting them against being washed away.

2. To afford a sufficient cover to shelter the surface from meteorological influences.

3. To furnish humus more and more abundant, valuable on one hand to fertilize the soil, and thus increase the growth; and on the other, to furnish the retardation and the regulation of rain water or snow falling on the surface.

4. To maintain, without momentary and perpetual interruption, these salutary effects, and develop them by the use of lime.

Useful information is afforded as to the selection of trees. A mixture of Alpine and silver fir with oak seems to have done best in the climate of the Alps. Corsican and Austrian pines are also favourably mentioned.

The necessary preparation of the surface for the reception of either the seed or the young trees, and which is required to a greater or less extent, according as climatic conditions are favourable or unfavourable, are described at great length. The various modes of executing works of planting and growing are carefully described, these works having been obligatory. The details as to optional works, assisted by grants from Government, are given with great minuteness, and, to some extent, are but a repetition of information previously given.

INSECT-DESTROYING APPARATUS.—The cotton-worm, Colorado beetle, and other insects injurious to the cotton-plant, may be destroyed either by sprinkling solutions of various chemicals, such as London purple, over the plant, or by dusting the foliage with various poisons in the form of dry powders. A number of appliances for showering the plants with the solutions or powders have been introduced, but none have been constructed upon so large and complete a scale as some new machines, shown at Atlanta for the first time. The largest of these sprinklers is automatic in action, may be easily moved by one horse or mule, and will thoroughly drench every plant in twenty rows at the same time. It consists of a horizontal triangular frame of wood and iron, supported on three wheels,—one guiding-wheel in front, and two trailing-wheels behind,—a tank for the liquid, and a sprinkling device of novel form. On top of the frame is erected a wooden tripod, or derrick, and from the centre is suspended, near the top, a barrel for holding the solution. A rope, pulley, and small windlass are also provided for lifting the barrel to its place. A rubber pipe extends from the bottom of the barrel to the rear of the machine, where it divides into branches —each branch hanging down behind the machine and between every second row of plants. Thus, if there are twenty rows of plants to be sprinkled, there are ten branch pipes. The elevated position of the barrel gives a good head to the streams, and the motion of the apparatus over the ground keeps the solution agitated and prevents the mixture from clogging the pipes.—*Century Magazine.*

THE KEEPING OF BEES.—The bee, an insect properly known by few, and more often erroneously exciting fear, offers through its unsurpassable industry and its productiveness an inestimable branch of industry. Above all, as surpassing in diligence and divers other qualities, as well as in bodily attractions, the "Italian bee" deserves mention. These bees are so harmless that it affords indeed pleasure to handle them, and really astonishing are their efficiency and their care of the gathered honey. The queen is of a golden yellow and extremely fertile, the former quality having also reference to the ordinary bees, making it a sight worth seeing to watch the various hues showing when the insects fly about in the sunshine, so much so as to attract even the stranger's attention and make him their friend with a little closer inspection. Their significance and profitableness cannot be underrated. Many hundredweights of American honey are annually imported at a comparatively high figure, which expenditure might be saved in cultivating the trade here. Many people besides would find both bodily and mental recreation in devoting their surplus time to a few hives, and have as compensation their table furnished with a slice or two of the beautiful honey so conducive to health. Considering the employment in a more material light —*i.e.*, the way of making a living by it—its advantages are obvious. There is no necessity of buying or renting land, as with the farmer, for either grain-growing or cattle and sheep raising purposes. The bees fly about looking for their food, simultaneously bearing fruit to the orchard and flower-garden, and thereby benefiting the fruit and flower grower. The little attention hitherto paid to the matter has caused it to remain in an inefficient, unremunerative state, which to remedy I have brought with me a number of Italian queen bees. I should be happy to enter into correspondence with any one taking an interest in the matter, with a view to turn it to account, and beg to add that the annual profit arising out of the undertaking, if properly and carefully managed, would soon exceed £200 sterling.—WILHELM ABRAM, Bee-farmer, Care of German Consulate, Sydney.—*Sydney Mail.*

BRITISH PHARMACEUTICAL CONFERENCE.

RESULTS OF EXPERIMENTS MADE UPON THE BARKS OF CINNAMON AND CASSIA, ALSO UPON THE OILS EXTRACTED THEREFROM.

*By J. Woodland, F.L.S., F.C.S., etc.**

Wishing to ascertain, if possible, the substance which causes an iodized decoction either of cinnamon or cassia to lose its blue colour, I made experiments upon the known constituents of the drugs with the result of finding that the volatile oils possess the property of absorbing iodine to a considerable extent, which peculiarity the other known constituents of the drugs seem to lack, and as far as the experiments made at present determine, the oils are the only constituents having that decolorizing power.

The oils of cinnamon and cassia both take away the blue colour imparted by iodine to a decoction of starch, and that of the former drug possesses this property to a much greater extent than is the case with that of cassia, although not in any constant proportion, the amount of iodine that is absorbed by the oils being dependent upon the age of the sample in an inverse ratio, as the greater the age of the oil the smaller is the quantity of iodine solution absorbed by it. This decolorization is more especially seen when the oil and iodine are dissolved in the same medium, such as rectified spirit or carbon bisulphide, but if the oil be diffused in water, and iodine solution with starch paste added, although the decolorization takes place quickly at first, yet after a time it proceeds but slowly, owing to the imperfect contact of the reacting agents. Iodine also dissolves in both of the oils, more quickly in that of cinnamon, and if the iodine be in excess, it imparts to the solution in oil of cinnamon a rich red-dish-brown colour, whilst the more slowly formed solution in oil of cassia has a dull greenish-brown colour, with a very slight appearance of red after shaking.

The quality of cinnamon or cassia bark being dependent upon the amount of oil contained therein, it occurred to me that samples of these barks might have their value approximately determined by treating infusions or decoctions of them with a standard solution of iodine, and accordingly experiments were made which show that although the quality of a bark of cinnamon or cassia can be quickly ascertained, the total amount of oil will not be indicated on account of the time taken by the oil to absorb the iodine. Decoctions of commercial samples of the powdered drugs were made, 1 gram of each been taken, and four of them absorbed a decinormal solution of iodine in the following quantities:

Cinnamon.	Cassia.
No. 1 took 6·9 c.c. to impart a coloration.	No. 1 took 3·7 c.c.
No. 2 took 4·5 c.c. to impart a coloration.	No. 2 took 2·1 c.c
No. 3 took 4·9 c.c. to impart a coloration.	No. 3 took 3·3 c.c.
No. 4 took 11·8 c.c. to impart a coloration.	No. 4 took 2·3 c.c.

The iodine solution was added until after shaking well, a distinct colour was seen in the froth. Of the four samples of cinnamon, numbers 2 and 3 were poor ones, as there was not much odour emitted by them, and from these and other experiments made, a sample of an average quality ought, if 1 gram be boiled with water and then cooled, to take at least 6 c.c. of a decinormal solution of iodine to colour the froth. Cassia bark requires a much smaller amount of iodine to colour the froth, first, on account of the oil not absorbing so much as before-mentioned, and, secondly, on account of the bark containing a smaller percentage of oil.

In ascertaining if there is any other ingredient or principal in the cinnamon bark which absorbs iodine, great difficulty was experienced in expelling the whole of the volatile oil, for after boiling the powder with a strong solution of salt for four hours, the odour of the oil was still perceptible, and the decolorizing properties still evident. Hence I conclude that a considerable quantity of this ingredient must be left behind after the distillation of the bark with salt water, as I am informed is the process in Ceylon,* and I should like to have the experience of anyone who has witnessed the operation, there or elsewhere, related.

After trying various chemicals, I found that litharge liberates the oil to the largest extent, and also the most quickly, but as with the others, incompletely, although whether its action is chemical or physical, I am not prepared to say. The oil was finally got rid of by boiling the powdered bark for a considerable period with a strong brine, afterwards with a small percentage of slacked lime to convert the residue of the oil into cinnamate of calcium, and on acidifying one portion slightly with acetic acid and adding iodized starch, the colour was not removed, and no odour was perceptible on heating; through the other portion carbonic anhydride was passed, to convert any slaked lime into the carbonate, which was then boiled, and to the cool decoction iodized starch added with a negative result. These experiments lead me to suppose that the oil is the ingredient that alone possesses the decolorizing property, but what compounds are formed beyond that of hydrolic acid when the oil and iodine combine I am not at present able to state.

The same difficulty was experienced in attempting to exhaust the drug of its oil with benzol, carbon, bisulphide, chloroform, ether, rectified spirit, and alcohol, although, they were used both hot and cold, as the residue when slightly heated invariably gave off the odour of the oil, and a decoction bleached iodized starch paste.

It having recently come to my knowledge that oil of cassia is substituted for oil of cinnamon, a few experimcuts were performed, by some of which a distinction can be made between the two oils. If nitric acid sp. gr. 1·36 be added to oil of cinnamon (1 part of the latter to 2 of the former), and the mixture shaken, a bright orange-coloured liquid is first obtained, upon the surface of which floats an orange resinous substance which slowly becomes deeper in colour until a beautiful cherry-red colour is visible, by which time it has changed to a liquid that floats on a lighter coloured substratum, which also in a short time becomes nearly of the same tint, bubbles then commence to appear, and shortly afterwards spontaneous ebullition occurs with the evolution of nitrous fumes, and vapours of benzoic aldehyde; by the time this ebullition has ceased, the amber coloured liquid commences to clear itself and finally a clear amber liquid is left, with orange globules floating on the surface.

Upon oil of cassia nitric acid sp. gr. 1·36 has quite a different action, as after mixing 1 part of oil of cassia with 2 of nitric acid, a dirty green supernatant resinous mass (slowly turning brown) is seen floating on a yellowish liquid, and no further change is undergone; if a large excess of the acid be added after the first addition, the resinous mass changes to a deep reddish-brown, and the substratal liquid takes a cherry-red colour. The same reaction occurs if a large excess of nitric acid be added to oil of cassia at first, but in neither of these cases is there any

* Read before the British Pharmaceutical Conference, 1880

* As in the case of the Sikhim Cinchona bark. [illegible]

spontaneous ebullition or evolution of the nitrous fumes and benzoic aldehyde vapours.

If oil of cassia be mixed with oil of cinnamon the reaction with nitric acid takes place as with oil of cinnamon, but more tardily, according to the amount of cassia oil present, and at the end of the process a *turbid* subnatant liquid is seen instead of a clear one, as is the case with pure oil of cinnamon.

Spirit of nitrous ether can also be used to distinguish between these oils, as it forms a clear solution with that of cinnamon, but a turbid one with that of cassia.

Distinction can also be made between the powders of cinnamon and cassia, for on shaking cinnamon powder with iodine water, a greenish brown colour only is seen, whilst cassia powder treated similarly imparts a black colour. A better way, however, is to make a decoction of the powder and, when cold, add tincture of iodine in excess, when on shaking well in a test-tube the froth of the cinnamon decoction is distinctly yellow, and that of cassia grey or black, and if cassia powder be mixed with cinnamon, the characteristic froth of the cassia can be distinctly seen.

A vote of thanks was passed to the author of this paper.

Professor Attfield hoped that the author would continue his experiments with the view of ascertaining the special conditions under which this substance would absorb iodine. The absorption of iodine by essential oils was a matter involved in a good deal of obscurity. The amount absorbed appeared to depend a good deal on conditions, and if Mr. Woodland would look into those conditions, it was possible he might be able to give a good method of distinguishing between these substances.

Mr. Brady said with regard to the employment of salt water in the distillation of oil of cinnamon he had seen a statement to that effect, in Pereira's 'Materia Medica,' and it had been repeated elsewhere, but he did not think that salt was employed generally in Ceylon.* In the only distilling establishment he visited, not only was salt water not used, but the distilled water was used again and again, for a manifest economic reason.

Mr. Greenish said he had heard Mr. Brady state that there were several kinds of cinnamon,—eight or ten; he should like to know whether the particular kind of cinnamon used in these experiments was noticed, because naturally it would have an influence on the result.

Mr. Brady said the different kinds were merely planters' varieties; he did not think anyone could define them. A planter would be able to tell the different sorts, but he did not think there were even commercial names for them.

Mr. Greenish asked if there were any mode of distinguishing them.

Mr. Brady replied certainly not except by an expert. It was more like commercial sorting than botanical separation.

Mr. Greenish said probably it would have an influence on the result of the experiment.

Mr. Brady said practically oil of cinnamon was made by the poorer planters, usually half-caste Portuguese, who would not take the trouble either to cultivate the shrub properly or to prepare the bark for sale as fine cinnamon, and it was quite a question whether growing the finest cinnamon really paid the planters so well as using it in the rough condition as chips for distilling the oil.

* We remember making enquiries at the instance of the late Mr. Henry Mead, and we were distinctly informed that salt never was used.—Ed.

ON RED (CINCHONA) BARK.

By John Eliot Howard, F.R.S., F.L.S. *

In order to present more definitely the results of recent information on this subject, together with some suggestions for discussion at the Conference, I must (in some sense) begin at the beginning and show what I mean by "Red Bark."

The limitation of the genus Cinchona to those plants which have capsules dehiscent from the base towards the apex seems to me most correct and natural. I think my friend, Professor Karsten, has done good service to quinology, not only by the magnificent and unique plates and descriptions, in his splendid volumes, of the *Cinchona cordifolia* and *C. lancifolia* (for instance), but also of the lesser known group which he includes to my regret under the same head of Cinchonas (*Cinchona, sectio Hiterasca.*)

These have capsules variously dehiscent, though in other respects closely allied to the Cinchonæ. I have recently met with specimens of the bark of two of these, together with leaves and, in one case, very well preserved capsules, evidently of the *Cinchona pedunculata*, Karsten. The other I referred, with less certainty, to another of his species, *C. undata*, Krs.

I was informed that neither of these barks, when examined by Dr. Paul, manifested any trace of alkaloid. Is not this a reason (if confirmed) for the limitation of the term *Cinchona* to those plants which, having the capsules dehiscent from the base, also possess the medicinal properties from which the name is derived? To these alone it seems properly to belong.

When we come to the definition of species, the difficulty of discrimination increases so much that some (even of those who are interested in the cultivation) seem inclined to throw up the whole subject in despair, and to believe in unlimited hybridity and change, instead of that exact fixedness of type which, at all events since the researches of the early Spanish botanists, have marked the South American species.

Pavon especially was very careful in his selection of specimens, so that out of forty-one sorts which I possess of his collection, I am able to recognize at least twenty-eight as met with in commerce and as like as if they came off the same trees.

I have thus found amongst the barks of commerce, the bark of most of the species described by Pavon and his associates, and by Mutis and Zea, exactly reproduced with every minute feature. I have had the satisfaction of cultivating many, and of receiving specimens from the native habitats and the adopted countries of many others, and my conclusion is that fixity of type is the rule, and variability the exception. I do not deny that this latter occurs (through hybridity) in India; but I agree with the late Dr. Weddell in thinking that there is not usually much opportunity for this in South America. I can add that Dr. Weddell's specimens are admirably true to type.

Even in India the probability is that many of the variations observed are connected with the following characteristics, observed first by the Spanish botanists, and which I will now briefly explain.

All the different species of Cinchona (so far as observed) exist under different, slightly varying *forms*, of which it seems impossible to say that any one is the original species and the others varieties. For instance, I have now, growing from seeds gathered by the diligent collector, Robert Cross, two forms of the *Cinchona cordifolia*, from two different localities; one of which, from a place called Coralis Inza, possesses the true cordate form of leaf as represented by Karsten in his plate of *Cinchona cordifolia*; the other though equally in its marked characteristics the "hard Carthagena" or "cordifolia" bark of Mutis, does not

* Read before the British Pharmaceutical Conference.

yet show one leaf true to the type. The Coralis Inza form is much richer in quinine, and has consequently (at my recommendation) been transplanted by Mr. Cross to India, where I hope it may prosper, and perhaps be found useful.

Having premised these observations, I now come to the question of "Red Bark," of which the true species is, as defined by Pavon, the *Cinchona succirubra*, so named by this botanist from the peculiarities of the *juice*, which he defines as follows:—

"In arboreum corticumque amputatione succum lacteum primum profluit; postea in colorem intense rubicundum transmutatur, unde *cascarilla colorada* nomen oritur."

That is to say, it is named "Red Bark" (in Spanish as above), from this peculiarity in the juice. True Red Bark is, as I have shown in my 'Illustrations of the Nueva Quinologia,' the product of *Cinchona succirubra* of Pavon. But *C. succirubra*, like other species, exists under somewhat different forms, as will be seen by examination of the specimens I send to illustrate the subject.

One source of variations is connected with the *macho* and *hembra* forms of the same plant; that is to say the preponderence of the male and female elements in the flower, attended, as well shown by Dr. Weddell, with correspouding changes in the rest of the plant. The colour of the flowers, for instance, varies in its intensity. Another contrast between different forms is found in the perfectly glabrous or subpubescent under surface of the leaf. This, as defined by Pavon, and as found generally in India, is perfectly smooth. As defined by Klotsch, it is *foliis subtus puberulis*, judging (as he did) from a specimen of Pavon's in the Berlin Museum.

These differences, apparently trivial, are nevertheless important to the cultivator; the pernicious effects of the rapid oxidation of the cinchotannic acid I have explained in the 'Nueva Quinologia,' so that we may fairly say, the more truly *colorado* or *red** the bark, the less probability there is of good results in the alkaloids. I send for the Museum small specimens—(A) of Pavon's own collection; of the genuine Red Bark (B) in commerce; and of the more resinous sort (C), which I have described in the above work, as they used to be imported from South America; fetching a high price, but useless to the quinine manufacturer, containing in each case about 2 per cent of alkaloids, the most predominant, cinchonine and cinchonidine. The truest Red Bark in India will come to this by age. The state of degeneration which I have described (at p. 14, *sub voce C. succirubra*) was believed, by Mr. Broughton, to have set in during the continuance of his observations, and I have recently had the opportunity of examining specimens, carefully selected by Mr. Cross from the Government Gardens at Ootacamund, which present the much more mature bark as exhibiting the true characteristics of genuine Red Bark, both in physical characteristics and in the nature of the alkaloids it contains.

I have forwarded specimens of these (D), No. 19 and No. 20, as sent by Mr. R. Cross, with the following information:—

Analysis of No. 19.

Quinine ·91 per cent = sulphate of quinine 1·21 per cent.
Cinchonidine 1·43 per cent.
Cinchonine 3·84 per cent.
Amorphous alkaloid 1·14 per cent.

Analysis of No. 20.

Quinine ·86 per cent = sulphate of quinine 1·15 per cent.
Cinchonidine 2·05 per cent.
Cinchonine 3·66 per cent.
Amorphous alkaloid 1·06 per cent.
On these barks I have remarked thus in a recent report to the Marquis of Hartington:—

"Both these are most characteristic specimens of Red Bark, and the produce well illustrates the mistake, which I have constantly pointed out, of the excessive cultivation of this species. The bark of such trees can only be made serviceable by *'renewing'*; otherwise the oxidizing process goes forward to the ultimate destruction in old trees of almost all the alkaloids."

In the same report I have particularly contrasted with the above, Mr. Cross's No. 18 (E) as follows:—

"Under No. 18 I find valuable information. This is called 'Red Bark,' but is indeed, not Red Bark at all, but, as described by the Spanish botanists, 'cinnamon-coloured bark' (*acanelada*). According to these authorities, when the trunk is wounded a clear juice flows out, which changes to a *golden colour*." (See my 'Nueva Quinologia' under head of *C. coccinea, vulgo cascarilla, serrana scanelada y Pata de Gallinazo.*)

Truncis incisis, succum crystallinum exudant, postmodo in aureum colorem convertitur.

"Under similar circumstances the *C. succirubra* yields a milky juice which changes to an intensely red colour...It is rightly named by Cross, *Pata de Gallinazo.*"

I published information on both these barks in 1862, and my work was sent out by the Government to, I suppose, all the stations, but apparently we have these *two* species still united under the designation of *C. succirubra*. I know not to what extent the species prevails in India, but it is satisfactory to believe that it is a much better sort for cultivation than that with which it is confounded, as is shown by the following analysis of (E)*:—

Quinine 2·27 = quinine sulphate 3·03 per cent.
Cinchonidine 3·21 per cent.
Cinchonine 3·17 per cent.
Amorphous alkaloid ·93 per cent.

But we have not only *two* but *three* species confounded under the heading of *C. succirubra*, as I have convinced myself by comparing together the specimens which I send, together with information from Mr. R. Spruce, the collector of the seed for India, also from the late Mr. McIvor, and from examination of specimens of bark from India and also quite recently from St. Thomas.

This is the *cuchicara* or "pig's skin sort" of Red Bark, little valued in commerce of old, the appearance being against it, but apparently of greater value than the true Red Bark as regards contents in alkaloid. See specimen (F) and analysis.

Analysis of Bark from St. Thomas.

	Quinine Sulph. Per cent.	Quinine. Per cent.	Chinchoni-dine. Per cent.	Cinchonine. Per cent.	Amorph. Per cent.
Large quills ...2·86	2·14	3·26	2·49	·89
Medium quills..2·31	1·73	3·16	2·23	·91
Small quills ...1·83	1·37	2·00	1·34	1·00

I will give in an appendix the remarks written by Mr. Spruce himself on inspection of the *C. erythrantha* of Pavon (as represented in my illustrations of the 'Nueva Quinologia'), which he says is probably true cinchicara.

According to Spruce the *C. conglomerata* and *C. umbellulifera* of the 'Nueva Quinologia' are probably allied species.

The propagation of so many millions of trees of what is called *C. succirubra* in India, without all cautions and in neglect of all the information I have been able to reproduce from the careful Spanish botanists, impresses on my mind very strongly the inquiry *cui bono* as to any information I am giving now and might be able to render hereafter.

* The redder the worse.—Ed.

* So that we ought to cultivate that with [illegible] *coloured bark* and not the deep red.—Ed.

† Mr. Howard, a quinine maker, objected to *C. succirubra* altogether.—Ed.

I reflect, however, that amongst the private cultivators there are some who gladly avail themselves of the best scientific information they can obtain; and who will find in the end that they have done well to attend to the careful discrimination of the species, and also of the forms of the species, and in giving their attention to the cultivation only of those most adapted to their purpose.

From the observations of Mr. Spruce I do not suppose that it is easy for an unpractised eye to discriminate between these species when not in flower; but Mr. Cross writes to me that he alone saw the tree in its native *habitat* and collected the plants at the foot of a precipice when in company with the son of a cascarillero. It is, at all events, rather late now to attempt any separation. The seed of the different species has been put by the collectors into the same bags, so that all is uncertainty. The Jamaica sort seems to me to represent very perfectly the subpubescent type of a true *C. succirubra*, according to the specimen described by Klotzsch. It is, moreover, richer in alkaloid than the average Red Bark of the East Indies, which for the most part (but not without exception of better qualities) must belong to the glabrous type.

I have, now growing, a plant of a kindred sort, the *var. pubescens* of McIvor, and am not disinclined to think that it may be (after all) one of the cognate species as mentioned above, instead of a hybrid. If I can succeed in getting it to flower, I shall perhaps be able to solve the question.

Professor Trimen, Director of the Royal Botanic Gardens, Ceylon, says in Report for 1880:—

"I have also received from the Government plantation at Nediwuttum, Nilgris, a Wardian case with some young plants of the kind called* *C. officinalis, var. pubescens* by Mr. Howard, but considered a hybrid by the late Mr. McIvor. Owing to the remarkably careless packing these were nearly all dead on arrival, but a few have survived and are doing well. They possess much the appearance of *C. succirubra* at present."

I am informed by a private cultivator in Ceylon that it forms a handsome tree, differing in its mode of growth from *C. succirubra*. (See Appendix.)

Another planter tells me he has of this sort, which he identifies with the tree in my possession, not less than 300,000 plants in various stages, from which he expects great results.

I must now draw to a conclusion this I fear, rather prolonged paper by suggesting as a subject for discussion, what is the difference in therapeutic efficacy between pharmaceutical preparations of *C. succirubra* and *C. officinalis?*

It is probable that in future these will almost exclusively be made from the barks grown in India, and at present the former seems to be the most recommended.

I cannot believe that the medicinal effect will be the same in both cases. I have before stated that the astringent principle shows an entire divergence in the two different barks as tested by various reagents. I am not aware that either in one case or the other any medicinal inquiry has taken place. The same observation may be made as to the remaining constituents of the *C. succirubra* and the *C. officinalis*, in the former case much more complicated than in the latter.

The supply of cultivated bark from South America will probably go entirely into the hands of the quinine manufacturers. This may also be the case with the best of the *C. officinalis*, but much of what is cultivated is of an inferior description.

I will not add anything respecting the relative constituents in alkaloids, but conclude with an observation of Lord Bacon (quoted by Dr. Kentish, one of the early writers (1784) on Peruvian bark), that mankind are far too apt to contemplate nature as if from the top of a tower, without descending to the investigation of details.*

Practically, however, the substitution of theory for scientific investigation is sure to lead to very unsatisfactory results.

In the present instance we have the following confusion:—

When "Red Bark" is spoken or written about, it may be the produce of—

(A). *C. succirubra.*

a. Glabrous form.

β. Subpubescent form.

or—

(B). *Coccinea*, Pavon. (?). *Pata de Gallinazo.*

or—

(C). "Pubescent" sort of Howard.

or—

(D). *C. conglomerata*, Pavon., *casc. colorado*, producing, according to Cross, the *morada* sort of Red Bark, of which I send specimen [G].

or—

(E). *C. erythrantha*, Pav. (?) *casc. cuchicara.*

APPENDIX.

[*Remarks written by R. Spruce on my Quinologia. 'Notulæ ad Quinologiam novam Spectandæ, R.S.'*]

Cinchona.

"*C. coccinea*, Pav., *Pato di Gallinazo* (Ecuador).—Plainly the true *Pata di Gallinazo* of the Quitensian Andes, and seen by me in the very same localities (Chillanes, Guaranda), also in valleys of Pallatanza and Alausi. I could not distinguish it by the leaves alone from the *Cuchicara*, growing along with it, but the Indians say they can always tell it. Its bark has some commercial value, that of the *cuchicara* none. The two agree in the very stout leaf veins, the corymbose inflorescence and the *dull scarlet or brick-red colour of the flowers*, quite different from the red or roseate hue of the flowers of most other cinchonæ.

"*C. erythrantha*, Pav., compared with the *Pata di Gallinazo* by Pavon himself, is probably *true cuchicara*. The *acute venation* and the locality (hill forests of Guayaquil and Jaen) seem to confirm this view.

"*C. conglomerata*, Par.—Except for the elongated panicle, this much resembles a pubescent form of the *cuchicara.*"

APPENDIX.

[*Extract from 'Nueva Quinologia,' C. succirubra*, p. 14.]

"In the red bark it is to be remarked that the brick-red colour, which as Ruiz observes, is not found in the growing plant, but in the dried bark, is really an excretory product of vegetation, a part used up and brought by contact with the air into a state in which it can no longer be serviceable to the living plant and from which it degenerates by a still further degradation into *humus*, as we have reason to conclude, both from following out the above experiments on the changes of colours to their last result, and from observing analogous changes in the bark itself as it verges towards its latest stage. The pieces of flat red bark possessing the finest colour are generally remarkable for their specific lightness, having a texture analogous to that of wood that has lost its firmness by incipient decay. Indeed, it is by a process of *ercmacausis* that the red bark acquires its colour;

* I simply suggested it being called "*var. pubescens*," looking upon it as a *hybrid*. It is quite unlike *C. officinalis*. It would be better to call it (simply) "Howard's sort."

* Solent autem homines naturam tanquam ex prærálta turri et à longe despicere, et circa generalia minium occupari: quando, si descendere placuit, et ad particularia accidere, resque ipsas attentius et diligentius inspicere, magis vera et utilis foret comprehensio.—L. ii., cap. 1.

the cinchotannic acid in which it abounds having become oxidized and changed into cinchona red, and under these conditions the alkaloids also appear to undergo some corresponding alterations. They are now implicated with resin, which appears to have also become oxidized so as to act the part of an acid, and is with difficulty separated; the chlorophyll has disappeared. Kinovic acid is still present; gum, which contributed to this so-called resinous character and was abundant in the bark of the smaller branches, has undergone a decrease. But the most remarkable feature is the altered conditions of the alkaloids themselves. Quinine, which formed a considerable portion of the whole, is now greatly diminished, cinchonine and cinchonidine remaining much the same. The total percentage has undergone no diminution, and an alkaloid, quinicine (?) which was either entirely absent from the smaller quills, or present in a feeble proportion, now appears in notable quantity.

"This was the result of my observations on South American barks up to 1862, I then thought the total percentage of alkaloids had not diminished with age. The quinicine (?) I found associated with aricine(?) or perhaps the quina (?) of Batka."

The chief part of this troublesome and noxious residuum I now suppose to be paricine (1881.)

Correspondence as to the New Species.

In order to show at once the importance and the difficulty of this investigation, I add the following letters, which complete the history of the subject up to the present time.

I have written to India for more precise botanical details.

Description by a Planter of the Pubescent Species.

"This tree has a very thick stem and the bark also was very thick. The foliage of the tree forms a perfect pyramid; the branches dropping down and then turning up at the ends. The leaves are of a dark green colour, rather round at the ends and very pubescent on the under side."

Analysis of Bark.

3·50	1·19	0.24	0·35

or equal to sulph. quinine 4·67 per cent.

(From Mr. McIvor's Letters.)

"*Ootacamund, Dec.* 10, 1873.

"This bark is taken from a hairy leaved variety of *C. officinalis*. It is a tree of wonderful growth. It produces enormously thick bark and the tree is not injured by wind. The tree from which I now send you the bark is only five years old. It is 26 ft. high and has a stem of 16 in. circumference at the ground, and the bark now sent you is taken in a strip from the stem to the height of about 13 ft. from the ground.

"This tree grows at least twice as fast as the *C. succirubra*. The bark of this variety which I sent to Dr. de Vrij was taken from a tree grown at a high elevation, and from a N. W. exposure. The bark now sent you is taken from a tree growing at a low elevation with a N. E. exposure. Dr. de Vrij found the bark of this species to yield 10·67 of total alkaloids with 4·72 of crystallized sulphate of quinine.

"If under all conditions this bark be found to yield this amount of alkaloids, and especially quinine, it is certainly the best plant we can grow, being hardy and of rapid growth and perfectly free from canker and other diseases to which the *officinalis* and especially the *calisaya* are liable. I therefore sincerely hope that you will be able to confirm Dr. de Vrij's results, and if this occurs in the two barks taken from different positions and elevations it will establish the value of the species beyond doubt. As the matter at present stands, the extraordinary vigorous habit of growth and hairy leaves, leave on my mind the impression that it is a species of rather doubtful quinine-producing qualities. I shall therefore be very glad if you are able to confirm Dr. de Vrij's results."

My analysis was as follows:—

Sulph. Quinine	6·00	per cent.
Sulph. Cinchonidine ...	5·00	,,
Cinchonine	0·60	,,
Amorphous Alkaloid ...	0·60	,,
	12·20	

Thus rather beyond Dr. de Vrij's results.

"*Ootacamund, April* 30, 1874.

"Allow me to thank you very much for your letter of the 20th February last, and your kindness in having made the analysis of my hairy leaved variety of *C. officinalis*. This plant is, I believe, a true *officinalis*, but as it had the aspect of a bad quinine producing species, I received with some doubt the several previous analyses I got of this variety, and therefore troubled you to examine its bark. I am now quite confident that this will be one of the most profitable varieties we can grow on the Nilgiris, and our cultivators here will, therefore, be much indebted to you for the information your letter contains.

"There are two strong growing varieties very much alike, the one having a very smooth leaf, the other (your *pubescens*) a hairy leaf. The two plants, a few yards off, look quite identical. They are so in habit and vigorous growth, and it was two years ago [therefore in 1872] that my attention was attracted by the hairy leaved variety, on all occasions on which I tested or got it tested, yielding a much larger amount of quinine and total alkaloid than the other.

"No doubt the specimens sent you, and to which you refer, were of the smooth leaf growing variety. It is to be regretted that your *pubescens* (which I think is very well named), produces so much cinchonidine; but as this alkaloid is rising in the market and in public esteem, in a few years this objection may diminish, but 5·50 of quinine is, I concluded, a bark that will always command the attention of manufacturers.

"Although *C. pubescens* is a mere variety, still, it comes true from seed, and I have not noticed any seedling of the hairy variety produce the smooth leaved variety, so closely allied to it, or *vice versa*."

"*Ootacamund, June* 27, 1874.

"I had great pleasure to receive your letter of the 29th ult., and will have much pleasure in sending you dried specimens of the *C. pubescens*, and the kindred smooth leaved variety, as soon as I am able to get them. At present the plants are out of the flower and we are in the middle of our rains and enveloped in mists. The *pubescens* is, I think, intermediate between *C. succirubra* and *C. officinalis*, but partakes more of the *officinalis* type. It is a much more robust growth than either, and in all situations far outtops the *succirubra*. I send you a few seeds which, I have no doubt, you will find come up quite true, as it does not vary very much when raised from seed, when the plants from which the seeds are collected are kept separate from other kinds.

"I take the liberty of again sending you some bark of *C. pubescens*. The bark is the narrow strip left on the same tree from which I took the bark sent to you in December last. If not giving you too much trouble, I would very much like to know what this bark yields; the more, as Mr. Broughton and Dr. Bidie have been trying to impress on the Government here, that mossing does not improve the bark on the trees generally, but that the renewing bark drains the alkaloids from the natural bark adjoining, i.e., that the alkaloids in the natural bark are transferred to the renewing bark.

"I do not believe this to be the case; but if it is so, in any degree, the bark now sent you will show ex-

actly to what extent this takes place, as the narrow strips of bark were surrounded on all sides by renewing bark. I send a small specimen of the renewed bark, also taken from the same species as the barkseut you."

[The strips, like the original bark, presented the appearance of thick fine bark, and gave even a better result than those gathered seven months before, thus completely dispelling the transference hypothesis.]

The analysis was as follows:—

Sulphate of Quinine	6·94
,, Cinchonidine	4·48
,, Cinchonine	0·20
,, Quinidine	0·14
Amorphous Alkaloid	1·14
	12·90*

Mr. McIvor continues:—

"This theory of the transference of alkaloids has been got up, I believe, to impress on our Goverument the disadvantage of mossing, but even if the alkaloids are transferred we would not lose anything. But the transference of any material once deposited in one part of a vegetable tissue to that of another part is unknown. A notable example of this is found in the graft. Here two plants differing in their nature are placed in the closest combination, yet in the experience of upwards of two thousand years, and with almost every species of plant, the stock has not been found to communicate to the graft, or the graft to the stock, in the minutest degree, any of those subtle influences on which depend the size and flavour of a fruit, or the colour of a flower, both the stock and graft retaining through their existence their respective qualities; though the stock is built up by the sap elaborated by the leaves of the graft, and the graft supplied with its nourishment through the roots of the stock. Moreover, if the alkaloids are transferred, they are not transferred in the same conditions, especially so in red barks, as we find renewed red bark very rich in quinine, and this on trees where the natural bark contains scarcely any quinine."

"*Ootacamund, August* 16, 1875.

"Of *C. pubescens* we planted on private plantations 20 acres last year, and this year we planted out 60 acres of this plant on the Kartary estate.

"I have another seedling raised with the same batch of hybrids, which promises to be better than *C. pubescens*, at least, so far as I have been able to ascertain, it yields nearly 10 per cent of sulphate of quinine; but I shall send specimens of this variety and of the bark also. We have only a few plants of this kind, and I overlooked it in my investigations of last year. It is not unlike No. 3 of De Vrij's analysis, but has a more oblong leaf."

I did not receive the above-mentioned specimens, and consequently am without the means of identifying the three sorts mentioned above.

The tree which Mr. McIvor sent me proved to be quite different in the bark, and I judge of no value. Some mistake had occurred and this threw me off the scent and led me to give credence to the theory of hybridization which is easily called in (like some other theories) to satisfy minds that do not desire the labour of really fathoming difficult questions.

It will be seen by what follows that the theory of hybridization must be set aside, in this case at least.

I do not find any further reference in letters from Mr. McIvor except in one received after his return from Ceylon, which journey led to his lamented decease. In this letter he speaks of its coming true from seed.

(From Colonel Beddome.)

"*The Nilghiris, June* 24, 1881.

"We have a very valuable species here in what Howard calls *officinalis* var. *pubescens*. There are two varieties, one quite glabrous on the under surface of the leaf, known here as *magnifolia*, and the other very downy, called *pubescens*. They were both supposed to be hybrids of Nilghiri origin; but they are no hybrids. I find them in our oldest plantations. Cross says he recognizes the glabrous one as the "*Pata de Gallinazo*" of the bark collectors on the Chimborazo, and that he found it at a much higher elevation than *succirubra*, and it grows here at a much higher elevation than *succirubra*, growing splendidly at over 7,000 feet, where *succirubra* will not grow at all.

"Two bales of this sold last month in England at a higher price than any *officinalis*. It was the best we have sent home. There is another distinct species that I cannot name. It has its leaves very hairy on both surfaces, like *Paludiana*, but the flowers differ from that species, and it has an extraordinary bark, very rough and corky. There are only five trees of it in our 1865 plantations. Cross says it is the true *crispa* of the Loxa neighbourhood," and that *he only* has ever collected it, and that he sent the seed of it here with *officinalis* seed in 1863, but that McIvor said it had never germinated. There are two trees here known as *officinalis* var. *crispa*. One is a very narrow leaved form, which is easily recognized, but not, I think, of any worth. The other is said to be known in Ceylon as "crispa," and is only a smaller-leaved form of ordinary *officinalis* and quite runs into the type.

"I think on the Nilghiris at elevations above 5,000 feet, every species and variety should give way to the Urutusinga var. of *officinalis*, and to the species and varieties we call *magnifolia* and *pubescens*. They are both of splendid growth and both have a very high percentage of quinine. The Calisayas all die out here, and so do the Grey Barks. They certainly require a lower elevation, but even in a warmer climate our long drought may be too trying for them."†

(To be continued.)

WHICH KINDS OF CINCHONA BARK SHOULD BE USED IN PHARMACY?

By E. M. Holmes, F.L.S.‡

The cinchona barks, cultivated in Java, India, Ceylon, and Jamaica, etc., have formed for some years a regular article of commerce, and are now generally acknowledged to be superior in quality to those imported from South America.

These barks are not recognized by the pharmacopœias, and they cannot therefore be legally used in pharmacy. This is the more to be regretted because it is well known, at least to all who are conversant with the cinchona trade, that the South American barks obtainable in retail commerce at the present time, although closely agreeing in appearance, and even in some external characters, with the descriptions given of the official barks, are often comparatively worthless.

Pharmacists are consequently placed in the undesirable predicament of being compelled by law to use inferior bark when better is obtainable. It therefore appears to be a suitable subject to bring before the Pharmaceutical Conference in order to obtain from representative pharmacists as well as from experts in bark analysis, a consensus of opinion and an amount of practical information which should have some weight in leading the framers of future pharmacopœias to remove this anomaly.

The points on which I venture to express an opinion, and on which it appears to me that discussion is necessary, are as follows:—

1. It is desirable that cultivated cinchona barks should replace the uncultivated barks in medicine and pharmacy?
2. What variety can most advantageously be used?

* And yet Mr. Moens got very poor results.—Ed.

* Rather the *Crespilla ahumada* which should be Pavon's *C. decurrentifolia*.—J. E. H.

† Why should the grey barks (micrantha), &c., be cultivated?—Ed.

‡ Read before the British Pharmaceutical Conference.

3. The advantages of uniformity of strength of preparations of cinchonas.

With regard to these points I have the following remarks to offer for consideration.

It is evident from recent papers in journals devoted to pharmacy in this country, the Continent, and the United States, that it is practically impossible to obtain in retail commerce at the present time, with regularity and certainty, cinchona bark of uniform quality, for the following reasons:—

(*a*). The South American cinchona and allied trees are not wholly known to Europeans, and many worthless kinds exist, which bear so strong a resemblance to official bark as to mislead the purchaser, and possibly even the collector. These inferior barks are known to be mixed, either intentionally or otherwise, with the better kinds, so that it has become necessary to analyse all the South American barks that come into the market.

(*b*). The demand for good cinchona bark, *i.e.*, such as will yield a large percentage of quinine, easily separable in the crystalline state, is so great that the whole of the available material practically passes into the hands of the quinine manufacturers, while the inferior or "druggists'" barks find their way into the hands of the retail purchaser.

(*c*). The wholesale dealer is often compelled by the requirements of his customers to purchase barks of fine appearance and moderate price, rather than of superior quality. On the other hand, the cultivated cinchona barks are not mixed with false barks, but there is at present, and probably will be for some years, difficulty in obtaining good qualities of yellow and pale barks, the supply of these not being as yet equal to the demand for them for the purpose of making quinine, while several hybrid species, yielding inferior bark, are not unfrequently sold with those of good quality, and cannot be distinguished by external characters, except by experts. But one variety of cultivated bark, *Cinchona succirubra*, is easily obtainable in almost unlimited quantity, and of very good quality. This is due to the following facts. The tree grows at a lower elevation, and, being hardy and easily propagated, is cultivated over a much wider area than the others, and is consequently met with in larger quantities in commerce. Owing to the comparatively large amount of red colouring matter it contains, it is less sought after by quinine makers, and the supply of bark is therefore likely to increase instead of decrease.

It would appear therefore desirable that the cultivated cinchona barks should replace those of South America for the following reasons, viz:—

The larger average yield of alkaloids.

Their freedom from false barks.

The increasing supply which tends to render it easy to obtain bark of good quality.

With respect to the variety of cinchona bark which can be most advantageously used in medicine and pharmacy, that of cultivated *C. succirubra* seems to be the most suitable, as already suggested by Professor Flückiger, since it can be procured of good quality, contains all the cinchona alkaloids (except aricine), is less liable to be mixed with hybrids, and is more easily distinguished by its external characters than any other species.

It may further be suggested that as every cinchona bark which comes into the market is analysed before being sold, it would be an additional guarantee if the retail purchaser could be furnished by the wholesale druggist with a statement of the percentage of alkaloids in the label of the packages he purchases. Pharmaceutical preparations made from the renewed bark of *C. succirubra*, thus guaranteed as to the percentage of quinine it contains, would probably give most satisfaction to the medical profession.

Lastly, with respect to the strength of Pharmacopœia preparations of cinchona. If the red bark were accepted in future pharmacopœias, the fluid extracts, if made according to the British Pharmacopœia, would, in all probability, deposit some of its active constituents, and it might be desirable to ascertain from the experience of those present whether this is the case with the fluid extract made according to the United States Pharmacopœia, which is only one-fourth of the strength, and of which one part represents one of the bark. With respect to the decoction, it is well known that the process of the British Pharmacopœia may be repeated two or three times with the same bark, and that it will not then be exhausted. The Norwegian formula for acid decoction in which sulphuric acid is added may exhaust the bark more completely, but would not be admissible where it was desired to give ammonia with the decoction. Neither the decoction nor the infusion of cinchona possesses any advantage over the fluid extract, as the bark does not contain any volatile oil or aromatic property likely to be driven off by evaporation, and it would be a boon both to the patient and the dispenser if these preparations could be replaced in medical practice by such active preparations as the tincture or fluid extract.

The simple tincture of cinchona in the British, United States, French, and German Pharmacopœias is in the proportion of 1 to 5, and the compound tincture 1 to 10 in the British, and 1 in 8·6 in the German, and 1 to 12·5 in the United States Pharmacopœias. An approach to uniformity in strength of these preparations, therefore, depends in some measure upon the framers of the forthcoming United States Pharmacopœia. The introduction of the metric system into pharmacy is apparently only a matter of time, and it is a subject for congratulation, therefore, that the constituents of some of these preparations, except in the compound tincture of continental pharmacopœias, bear decimal relations to each other. The present meeting offers an opportunity for suggestions being made as to whether a greater uniformity of constituents in the compound tincture is either possible or advantageous. The British formula contains saffron and cochineal, and the German and five others cinnamon and gentian, but these ingredients are not contained in the British and United States formulæ.

CINCHONA BARK FOR THE PHARMACOPŒIA.

*By W. de Neufville.**

In a paper published by Professor Flückiger (*Pharmaceutische Zeitung*, see also *Pharmaceutical Journal*, April 30, 1881, p. 903), he has made several statements with regard to the superiority of East Indian cinchona bark over that of South America for pharmaceutical purposes, and he proposes the substitution of East Indian bark for the calisaya bark, which has been hitherto recognized as official bark.

Whilst appreciating the ability with which Professor Flückiger has treated the subject, I on the other hand cannot but think that much can be said in favour of still maintaining the use of South American for official purposes.

The first statement of Professor Flückiger, that flat calisaya (or the yellow bark of the British Pharmacopœia) is more scantily and less regularly imported than formerly is scarcely in accordance with fact, for the supplies of flat bark have so considerably increased during the last years that the drug trade has not been found capable of absorbing them. Professor Flückiger also points out that in consequence of the geographical position and the political situation of Peru and Bolivia, calisaya bark could neither be had uniform nor in sufficient quantity. But just in these two respects calisaya offers advantages compared with most other sorts. For instance, calisaya is shipped pretty regularly during the whole year, and I do not remember any time during the past five years that the supply of calisaya bark in the European markets has not been ample for the demand. Notwithstanding the political difficulties to which Professor Flückiger refers, the shipments of calisaya have pretty regularly taken place during the late Peruvian war, and the northern

* Read before the British Pharmaceutical Conference.

districts of South America which Professor Flückiger regards as been more favourably situated in this respect are, on the contrary, subjected to much greater irregularities, and at times have altogether failed in their supply, owing to the revolutions, and, more important still, to the fact of the frequent drought of the Magdalena and other rivers.

Replying to the statement that it is not likely that the planting and cultivation of cinchonas will be undertaken in Bolivia and Peru, I can only say that the cultivation of the cinchonas has already been commenced in those countries, and the trials which have been made have so far furnished satisfactory results that already for the past two years the produce of these plantations has been sold for high prices in the London market, thus proving the good quality of the bark.

It cannot be denied that of late the importations of flat bark have not at all been rich in quinine, but Professor Flückiger attaches less importance to the contents of quinine so long as there exists a sufficient percentage of other alkaloids, and of these flat barks on an average contained over 2 per cent, as per the analyses made of the last arrivals of flat bark. It is true that most Indian barks are richer in the amount of total alkaloids, but here the question arises, are the druggists capable of extracting the alkaloids out of the Indian bark? and I am inclined to doubt it. It is a known fact that the Indian barks at first offered great difficulties to the manufacturers of quinine, and even at this date there are manufacturers who for this reason will not work Indian bark. As a druggist's bark this objection applies more forcibly. On the other hand no bark works easier and better than the American calisaya, and this fact ought to bear weight to prevent its abandonment as an article of the official materia medica. It is not, however, to be forgotten that India sends us a great many barks very inferior in quality, and it is a very difficult matter for the druggist to discriminate between the poor and rich kinds of bark. Druggists, indeed, are very apt to favour a "showy" bark, which in fact may be very poor in alkaloids. This remark applies very forcibly when Indian barks are concerned. On the other hand the quality of calisaya bark, more especially flat bark, is easily judged from external appearance. In addition to this, druggists have been perfectly acquainted with the character of this kind of bark for many years past.

If, after all, the *flat* American calisaya is to be abandoned on account of its not being sufficiently rich, why not adopt the American calisaya *quill*?

Calisaya *quill* has the advantage over all kinds of Indian barks of being much easier to extract, offering greater facilities for distinguishing the quality, arriving regularly during the whole year, and being better known to the druggist than any other barks, and is to be had in all grades from 2 per cent up to 6 per cent of crystallized quinine sulphate, besides a good proportion of the other alkaloids.

As to the non-applicability of bark from the districts of Colombia for druggists' purposes, I am quite one with Professor Flückiger, and with the opinion that has been expounded by others competent to treat on the subject, so that nothing remains to be said by me on this point.

Votes of thanks having been passed to the respective authors of these papers,

Mr. Wellcome said that it had been clearly shown that the percentages of alkaloid in *Cinchona succirubra* would differ very greatly according to the conditions under which it was grown. This was also true of other valuable varieties of the cinchonas, for when grown at low altitudes, or under other unfavourable conditions, the percentage of quinia was smaller, and the proportion of lower alkaloids was likewise liable to variation. He did not think any one variety of bark could be justly adopted as an officinal standard. The quills which had been referred to last should certainly not, because there was no one variety which was more frequently intermixed with inferior grades, which were very difficult to distinguish except by assay. It would seem that the officinal standard that could be adopted would be any bark yielding upon assay a certain fixed percentage of total alkaloids, of which a certain fixed percentage should be quinia. The value of the lower alkaloids—particularly cinchonidia—had been more fully appreciated in India and America than in England. In reference to the new bark, *Cinchona cuprea*, mentioned at the Conference last year, some light had been thrown upon it by the reports of Dr. Robbins, of New York, who had recently returned from a visit to the Columbian Forests. This *Cinchona cuprea* seems to be an exception to the general rule, not only in its appearance and structure, but also in the fact that although it is grown at low altitudes, it is a valuable quinia bark, yielding about 2 per cent of quinia. It is reported that this yields little or none of the lower alkaloids. With reference to the fluid extract of Cinchona of the United States Pharmacopœia, he might say that in the experience of American pharmacists it had proved very unsatisfactory. It precipitated very freely and was not generally in favour—the compound tincture being the preparation more generally used. With regard to the process suggested by Dr. de Vrij last year, he did not know how far it had been successful, but it would be interesting to have some information upon the subject from those who had given it a practical test.

Mr. Brady called attention to the dried specimens which Mr. Howard had sent to illustrate his paper, and invited those interested to examine them.

Dr. Paul said there could be no doubt that at the present time there was a need for alteration in the selection of bark used for pharmaceutical purposes. He gathered from the paper which had been read, that there was some little difference of opinion as to the direction in which that change should be made. The officinal yellow bark and the flat calisaya bark were almost invariably worthless, so far as the presence of quinine was an element of value. The flat calisaya bark of commerce now really contained nothing more than a little cinchonine—1½ to 2 or 3 per cent, and was not at all equal to the character given in the Pharmacopœia, and it required to be replaced. Dr. de Vrij and Professor Flückiger were very enthusiastic in recommending a total substitution of the Indian barks for the South American, but that was a step of a somewhat extreme character. There were many reasons for approving of the introduction of Indian grown bark, both crown bark and succirubra. They were now very largely imported, and the amount of total alkaloids in them would range from 5 to 10 per cent. In the better kinds of crown barks there was a very large amount of quinine, while in the succirubra the cinchonidine preponderated. They were already finding a large application on the Continent for pharmaceutical purposes, and the greater quantity of Indian bark used pharmaceutically was sent from India. At the same time, as Mr. de Neufville had pointed out, two new kinds of bark came to this country from Bolivia and the northern parts of South America, which were very excellent barks for pharmaceutical uses. They were mostly of the character of quill calisaya, yielding 2½ to 4 per cent of sulphate of quinine. There was an abundant supply of them, and there was no reason why they should not be adopted. He thought the most desirable course to take would be not to exclude the South American bark, but to alter the kind of bark to be used as an officinal bark, and to supplement that with certain kinds of Indian grown bark.

Mr. Groves said there seemed a tendency, in some quarters, to value Peruvian bark almost exclusively according to the proportion of alkaloids it contained. This doubtless was reasonable on the part of the manu-

facturer, but the medical man had often other objects in administering bark than giving the mere alkaloids. These could be obtained in a state of purity from very inferior sources, but the cinchotannic acid and bitter extractives were only yielded in quantity by certain barks of good quality. He therefore thought it desirable to adopt for the natural preparations (liquid extract, tincture, decoction, infusion) of cinchona, a bark such as the Indian succirubra, recommended by Mr. Holmes, which abounded in these non-alkaloidal principles, and which might, according to the desire of the prescriber, be reinforced by the addition of one or more of the cinchona alkaloids derived from ordinary commercial sources.

Dr. Paul did not wish to be understood as suggesting that the value of bark should be judged by the relative amount of alkaloid, but there could be no comparison between flat calisaya, which contained no alkaloid at all, but cinchonine and none of these extractive principles and another bark which would contain both.

Mr. Cleaver remarked that Mr. Howard in his paper invited discussion on the therapeutical value of different kinds of bark; but that seemed a difficult subject, and one they could not go into without medical evidence.

The President said it was not their business.

Mr. Cleaver said with regard to the employment of these barks in pharmacy, the great discrepancy showed that pharmacists ought to require that each bark should be sold with a guarantee. If they would pay a decent price, he had no doubt that they would find wholesale druggists who would supply them with bark containing a fair proportion of alkaloidal matter. Most of the wholesale druggists either had analyses of the barks they bought, or could get them, and would be very pleased to supply intending customers with analyses of the barks they wanted.

POTATO DISEASE EXPERIMENTS IN SCOTLAND.

Mr. James A. Gordon, of Arabella, Easter Ross, N.B., repeated this year again the experiments, which, as noticed in *The Field* at the time, he conducted last year, in order to ascertain the disease resisting and yielding properties of several new varieties of potatoes. The soil was good loam, and the climate of Easter Ross is far above the average of Scotland. Mr. Gordon endeavoured to grow some new varieties from the seedling, but none of them satisfied him except a new sort of Victoria, which is proving remarkably well. It is a capital cropper, resists disease wonderfully, grows a fine uniform kind of a tuber, and is highly appreciated on the table.

The ground for the different trials received the same treatment and manuring in every way, and the sets were deposited in the first week of May. In addition to about 16 tons stable dung per imperial acre, the manures applied consisted of 2½ cwt. each of bone meal, kainit, and mineral superphosphate, 1 cwt. Peruvian guano, and ½ cwt. sulphate of ammonia. The crop was good and comparatively disease-free, as the following results show:—

	Marketable.		Diseased.		Undersized.		Total weight per acre.	
	tons.	cwt.	tons.	cwt.	tons.	cwt.	tons.	cwt.
Champions	9	0	0	13	3	0	12	13
New Seedling Victoria	10	0	trace		1	0	11	0
Magnum Bonum	7	10	trace		0	15	8	5

Last year the different sorts stood in the same relative order as above in regard to weight per acre. The yield this year, though good, and above the average of the country, is slightly under that of 1880.—*Field.*

NEW ZEALAND BOTANIC GARDENS.

The twelfth annual report of the Botanic Garden Board of New Zealand has been issued, from which it appears that the gardens are in a somewhat starved condition, and that the powers that be do not fully appreciate the importance of a botanical garden as a centre for the introduction and diffusion of useful and ornamental plants.

New Zealand has special facilities, in its climate and position, for becoming the head centre for the cultivation and diffusion of the plants of the southern hemisphere; and in the material interests of the colony, as well as for scientific purposes, it is greatly to be wished that more energetic efforts could be made in this direction.

"A further advance has been made in the preparation of the ground for the systematic collection of plants intended for the use of botanical students; but, until the Board can feel justified in spending a sum of about £70 on it, this most desirable addition to the gardens must remain in abeyance.

"From the share of the Californian seeds, imported last year by Government, that was placed at the disposal of the Board, about 2,700 young trees have been raised. From last year's stock 479 trees have been distributed to various public institutions for planting their grounds.

"The keeper of the gardens was sent in April last to the Tararua Mountains, and, with a small expenditure of about £5, succeeded in obtaining a fine collection of live alpine plants from an altitude of 5,000 to 6,000 feet, among which were several novel or rare species.

"A valuable collection of plants, hitherto almost unknown in the live state, has also been obtained for the gardens by the taxidermist to the museum, who accompanied the "Stella" on the annual trip to the Auckland Islands, in March last.

"The Board has been indirectly the means of introducing to the colony a consignment of Japanese fruit and foliage plants, which will, it is expected, prove of great value, as being suitable to the climate. It was represented to Government that Mr. Tiffin, of Napier, was about to visit Japan on a horticultural expedition, and that it would be a good opportunity for getting Japanese plants for distribution selected by a thoroughly competent and enthusiastic collector. The suggestion was cordially entertained, and, as a result, in April last, twelve cases were received, containing 1,800 plants, of which the following is a list:—50 Oranges, 1,000 Persimmons, 300 Kiakie, 100 giant Chestnuts, 150 Maples, 200 Bamboos."—*Gardeners' Chronicle.*

OIL OF ANDA-ASSU.*

(*Pharmaceutical Journal*, 5th Nov. 1881.)

Johannesia princeps, Vell. (*Anda Gomesii*, Juss., *Anda brasiliensis*, Raddi., *Andicus pentaphyllus*, Vell.). is a large tree of Brazil, belonging to the natural family Euphorbiaceæ, growing along the coast on sandy soil, but also much cultivated in the interior. It has numerous spreading branches, digitate leaves, with five entire oval-lanceolate leaflets, each with a petiole, and all attached to a common petiole having from two to five glands at the point of insertion of the leaves. The flowers are pale-yellow, in irregular terminal panicles, the male flowers on stalks, the female sessile. The fruit is a nut over three inches in diameter, almost heart-shaped, or indistinctly four cornered. The kernel is oval, somewhat compressed, with two prominent and two rather indistinct corners. Martius states that the shape of the nuts, as they appear in the market, is so different that probably several species are the sources of them. The seeds, of which there are two, seldom three, are about the size of a small plum, somewhat kidney-shaped and covered with a firm, dark-brown epidermis. They have an agreeable almond-like, or hazel-nut-like flavour, and contain a fatty oil.

These seeds are known in Brazil under the following names:— [illegible], [illegible], [illegible]; [illegible]; *purga de [illegible]* (in Rio de Janeiro and S. Paulo); *coco de purga*, *purga dos Paulistas*; *fruta de [illegible]* (in Minas). They have been used from ancient times as an effective purgative, and have particularly been found

* From *New Remedies*, September 1881.

useful, even by European practitioners in Brazil, in affections of the liver, jaundice, and dropsy. They have also been found valuable as auxiliary remedies in menstrual disturbances and in scrofulous affections.

The ordinary dose for a male adult is two seeds, which may be increased to three, or even more with caution. They are best administered in form of emulsion, or combined with starch or sugar, and mild aromatics, whereby their effect is rendered less harsh, and the tendency to vomiting which sometimes occurs, is diminished. The oil of the seeds is also used as a purgative, but it is much less effective than the seeds themselves; an ordinary dose is about 40 drops. It is also used for burning in lamps, and has the peculiar property of being a very rapidly drying oil, for which reason it is much sought after by painters and artists. The shell of the fruit is astringent, and is sometimes used for stupefying fish. After being roasted it is held to be a sovereign remedy in diarrhœa brought on by cold and exposure.

Dr. Jorves,* of Rio de Janeiro, obtained very satisfactory results with the oil, in 1860, having used it in a case of cirrhosis with dropsy, in the dose of two teaspoonfuls in a cup of coffee. Dr. Fazenda also obtained very good results.

SUGAR-PLANTING IN THE MALAYAN PENINSULA.

A few particulars as to the administration of a sugar estate in Province Wellesley. The one consisted of 695½ orlongs (an orlong being equivalent to 240 ft. square, or 1¼ acres), and 523½ orlongs were then under cultivation. This area was divided in forty-nine fields, all of which were divided and surrounded by a continuous series of narrow canals, along which punts conveyed the canes from the fields to the mill, brought firewood for the furnace, carried manure to the young plants, and sugar and rum to the landing place for shipment to Penang in transit to England. The rum, however, requires no punt, the puncheons floating and being pushed through the water by wading coolies. Drains traverse the fields longitudinally; and when unproductive, cultivation is frequently suspended in some fields, and these in a few years become covered with jungle, but they are often cleared and tried again. I found that the cost of one year's working of this estate was calculated in dollars and cents as follows:—Salaries, &c., $2,593·19; wages, $21,525·15; manure, $8,317·25; firewood, $2,192·58; freight, $76·10; brick lime, $435·18; timber planks, $361·45; attaps and attap buildings, $383·68; oil and grease, $263·35; coppersmith, $290·72; tools, $142·40; small stores, sundries, &c., $395·01—total, $36,276·06.

The Kling is a drudge, who does not object to be driven; the Javanese will know what they are expected to do, and have a task set them; but the Chinaman contracts. One with a knowledge of agricultural work, a little capital, and some assistance that way from the planter, engages a number of men to work on the estate, he paying their wages, and receiving a contract price for all work done. The prices paid were then, for first banking, $2½ or $3 per orlong; for second banking, $6; cutting canes, $6; weeding, $1; breaking banks, $4; trashing, $1; and breaking new land, $10 per orlong. They are very industrious, useful, and cheerful, but still remain "heathen Chinee"—they will cheat if possible. These men use the big toe as an opposable thumb; and where a British carpenter, when planing a small piece of wood, would hold it steady with his hand, these men effect the same purpose with the toes. I found that the wages of those carpenters on the estate averaged one month, 40, 33, and 25 cents per day. As woodcutters they live in the jungle, and then numbered about thirty. They split the wood into logs some three feet long, and stack it five Chinese feet high, and were paid at the rate of $1 for every Chinese foot in lenght, the stack measured. How these men exist in the dreary dismal swamp in which their work is carried on, or how they resist the malaria, is difficult to imagine. Some fall victims to crocodiles, one being taken from his shallow canoe while I stayed there, and the skull of that identical crocodile now hangs above me as I write.—*Field*.

* *Monit. de la Pharm.*, 1881, 26.

TROPICAL FRUITS.

(*Field*, 17th December, 1881.)

Amongst the tropical fruits exposed for sale in London, I have often wondered at never having seen that prince of fruit, the mango. It is grown extensively in the West Indies, but whether it arrives at the same perfection there as it does in the East, I know not; but as the fruit, if plucked when it has arrived at maturity and packed carefully in cotton-wool, will take ten days to ripen, I am astonished it is not imported, for it would arrive just fit to eat. Col. Hastings Fraser, a few years ago, brought some home from Secunderabad, a journey of twenty-one days, and they were in such perfect order, that he was enabled to present some to Her Majesty the Queen. Now, of all the fruits I know, I consider none equal to a first-class mango. There are, of course, mangoes and mangoes. There are some fifty varieties, and none but those which have been grafted are fit for the table. Those from Goa, Malwa, Bombay, and Bangalore are the most esteemed, and plants can be procured in any quantity at Bombay, and could be easily transported to England and grown in a hothouse; indeed, if I mistake not, I saw in the *Illustrated London News* or some other paper, a few years ago, that a mango tree at Chatsworth, the Duke of Devonshire's palatial residence, was then in fruit; but whether it came to perfection, or has borne since, I do not know. But I should think it could be easily reared in a suitable house, and grafted trees seldom exceed 10 ft. to 12 ft. in height. In Burmah and Assam the trees are not grafted; a few are in the latter country, but none in the former; but in both countries the fruit is scarcely eatable, owing to a beetle being found inside almost every mango. Although the Burmese do not graft, they improve the fruit by stripping off the greater part of the bark, leaving only sufficient to keep the tree alive; thus the sap is retarded, and the mango loses that turpentine smell and flavour, which renders the ungrafted fruit barely eatable. The latter, too, is very stringy, but a graft mango can be scooped out with a spoon, and should be destitute of a single fibre.

Mangoes, like most fruits to be perfect, should be allowed to ripen on the tree; but this in India is almost impossible, owing to almost every creature, whether two or four legged, or winged, preying upon it. Moreover, as it arrives at maturity the fruit requires support, as from its weight, with the slightest wind, it is very apt to fall. Thus very often the best description of fruit is supported by tiny openwork bamboo baskets. The tree covered over with netting, and watched day and night; but it is well worth all the trouble, for, as I have said, a good mango is certainly the best fruit I ever ate.

Many other Eastern fruits might with advantage be introduced into England; for instance, the custard apple. It grows in any soil, and the jungle round Secunderabad is composed almost solely of it. It grows wild; yet when picked ripe off a bush at early dawn it is delicious. When cultivated it grows to a large size and has fewer stones. The very best are obtainable at Bombay. It will grow readily from the stones; whether it is ever grafted I do not know.

Another curiosity, and a fruit much talked about, is the Durian. Europeans who have got accustomed to it declare there is no fruit like it. I agree with them, but not in their sense; for, whilst they mean it in a complimentary sense, I mean just the contrary—for a mor

fœtid smell and taste I never came across. The common jack fruit is bad enough, but a Durian is the quintessence of all the rotten jacks in the East. They say it should be eaten out in the open air, sitting in a tubful of water; yet, for all that, those who have overcome their first dislike prefer it to all other fruit, and in Rangoon and Moulmein, where it is scarce, it fetches large prices. I should think it could be grown under glass in England very easily. It requires a damp heat, and takes five years before bearing fruit. The mango (grafted) will bear in its third year, but should not be allowed to do so until the fifth or sixth, as the fruit is then much finer.

The Tipparie, or Cape gooseberry, is a hardy bush, bearing a small fruit encased in an outer skin, which dries and shrivels up when the fruit is ripe. This shrub grows wild over the Neilgherry Hills—indeed anywhere where the seed is thrown down. It is subject to considerable cold during the winter at Ootacamund, and I believe it would live through an English winter in the southern counties, certainly it should in Jersey. Conserve made of it is delicious, far better than from any English fruits of the same class, whilst the fruit itself is not only exceedingly nice, but very wholesome.

F. T. P.

OLIVE CULTIVATION IN ITALY.

(*Journal of the Society of Arts*, 25th Nov. 1881.)

Mr. Schuyler Crosby, the United States Consul at Florence, states that the greatest care and attention has been for years bestowed on the olive tree, and great efforts made to make it yield, when young, the expenses of its cultivation, and every known means to effect this result have been tried without success. Calculations, from year to year, of the cost of planting, value of land, expenses of cultivation, gathering the berry, &c., made by the most experienced and enthusiastic of farmers in Italy, show conclusively that, even under the most auspicious circumstances of climate and weather, the tree does not yield a profit to the grower, under thirty and sometimes forty years. In Tuscany, an old proverb runs thus: "The chestnut trees of my grandfather, my father's olives, and my own vines." Hill sides, with a southern exposure, are almost always chosen for planting, either from the seed, branches, or the roots. Along the Mediterranean the olive tree does not thrive well when planted on the plain, and at a certain distance from the sea suffers much from a saline deposit on its leaves, which, if not washed off, by a timely shower, renders the tree for a long time unproductive. The tree is an evergreen, retaining its foliage at all seasons of the year. It dreads damp air, and thrives best in fresh earth, which retains a certain amount of humidity, and does not become arid; for this reason, calcareous soil, which does not undergo either extreme of climate, is the best adapted to its cultivation; it flourishes even in the cavities of the stoniest hills and mountains, and its roots will thread the smallest crevices of a rocky hill-side. To this quality of earth or soil is attributed the wonderful prosperity of the olive tree in certain parts of the Pisan and Lucchese territories, where it is absolutely planted in the calcareous rock, which being cavernous and spongy, retains just sufficient humidity to nourish, and not injure the roots. It is said that the olive tree never dies, and that the most neglected and withered plants, with no earth to be seen round its roots, and showing no signs of vitality, may, by means of abundant manuring, by filling in earth round the roots, or by transplanting the roots into new ground, be reclaimed, and again made productive. The berries are generally gathered in November, just before they become ripe, and when a grape-coloured tint appears upon the surface; though some growers insist upon the advantage of permitting the crop to remain on the tree until January or February; the objection to this delay, however, is that the fruit gathered so late in the season, not only produces an inferior quality of oil, but also seriously damages the prospects of the next year's crop. The berries are gathered as far as possible by hand, the peasants using ladders which will reach the highest points of the tree, great care being taken not to strike or even shake the limbs—shocks being hurtful to the tree, and are apt to seriously injure the young and tender branches, which are precisely those which will bear the next year's fruit. After the olives are gathered, they are carefully placed on wooden racks in order to let them lose a certain amount of humidity, and constantly moved about to keep them well ventilated and prevent fermentation. In extracting the oil, great care must be exercised in the pressing of the olive, which must be gradual and slow; for, if done with too much haste, as is often the case when steam is employed, the oil is sensibly deteriorated. If an oil of a very superior quality is required, great care is always taken not to crush the stone, or even to bruise it. The process of extraction varies according to the quality sought to be obtained, whether for the table, for burning, or for industrial purposes. The oil expressed from the fruity portion of the olive, when obtained by gentle pressure, and without the agency of heat, is called virgin oil; it is an exceedingly thin liquid, translucent, mutuous to the touch, and of a colour that varies between a faintly greenish and amber tint; its taste is sweet and pleasant, and it has a slight olive odour; when of only recent preparation, it is somewhat turbid, but after a short repose it becomes transparent, and deposits a blackish sort of dreg, composed of the fatty principle of oil, mucilage, and azote. Next, after virgin oil, the result of cold and gentle pressure, and which always retains the taste of the fruit from which it is expressed, and which serves as a condiment for food, and as a preservative of comestibles, such as the olive itself, the tunny fish, sardines, &c., come other qualities known as ordinary oil, lamp oil, and, lastly, "olio d'inferno," used for machinery and industrial purposes, and probably so-called from the amount of heat and torture it has been subjected to in the process of manufacture. The ordinary oil is made from the second application of the screw, when the pressure is brought to bear upon stones, kernel, and every part of the berry; even boiling water being used as an agent to assist in the increase of the yield of oil. When the mass of paste refuses to yield any more oily matter to the press, it is placed in large troughs of clean water, and kept moving as long as it furnishes a single drop of oil. This pasty mass, called "sanza," is then moulded into blocks, and sat apart to dry, when it is much sought after for fuel for manufacturing purposes. Thus, from the moment the fruit is consigned to the press-room to the end of the process of extracting the oil—even to the feeding of the furnaces of the workshops—not a single particle of the olive has been allowed to go to waste. The process of clarification of the oil is effected naturally, by letting it stand for a certain time, during which the substances held in suspense are gradually deposited at the bottom of the receptacle. The oil is first placed in wide, low vases of earthenware, thickly glazed, and allowed to remain four or five days, after which the contents are drawn off, leaving the deposit behind. The more frequently the oil is separated from the deposit, the finer will be the quality. The oil, however, frequently holds these substances for a long time in suspension, when it becomes necessary to have recourse to filtration, in order to accelerate the depuration and clarification. The filters used in Italy and also in France are formed of heavy mats, with a double bottom, which is perforated with conical-shaped holes, forming so many funnels, into which pieces of clean carded cotton are lightly placed. For the first few days the oil passes perfectly limpid through the cotton, and then an accumulation of the residuum of the funnel causes to flow. Several layers of loose straw are then placed at the bottom

vat, and these are sprinkled with well-washed animal charcoal, in rather coarse grains; in this case the charcoal deprives the oil during the passage of a certain amount of impurity, while the renewed clean cotton in the funnels does its work so well, that the oil reassumes its wonted clearness. It is then put up in kegs and barrels, and is ready for home consumption or exportation.

EFFECT OF MANURES ON CROPS.

(*Field*, 3rd December 1881.)

In a former article (*The Field*, 19th November,) having stated that the effect of manures on crops in various localities was not always the same, as the conditions were certain to be different, we then merely alluded to those conditions, but now propose to call attention to some of them at least.

It is true that but little is as yet known concerning the full effect which they are likely to exert, and we do not propose to enter fully into all details as far as they are known, for that would be impossible in the space at our disposal; but our intention is rather to point out the principal influences at work, so that those who take an interest in the subject of experimental manuring may be the better enabled to draw conclusions from such results as they may obtain practically, after allowance has been made for the effect of the locality. The extent to which allowances should be made is at present unknown; and it will only be by repeated trials that the necessary corrections will be discovered. First, all the constituents for plant life must be present in the soil. This we may consider as an axiom concerning which there can be no dispute; but more than this is requisite, the plant food must be in such a condition that it can be with ease absorbed or assimilated. This latter condition does not always obtain; it is quite possible for two soils to be almost identical in chemical composition, in so far that each constituent is present in the two soils in the same quantity; but still one of the soils may be fertile, the other not so. This difference is due to a want of similarity in the arrangement of the constituent parts. In one case they are combined, so as to be readily dissolved by water, and thus rendered accessible to the plant, whereas in the other the arrangement is otherwise.

A fertile soil will not require manuring to any great extent, and it is doubtful whether the addition of much manure would be productive of any corresponding gain. The time when a great gain by manuring occurs is, as is well known, after the soil has been exhausted by a former crop, when certain of its constituents which were soluble have been removed, and then either a fresh portion must be rendered soluble, or manures must be added. In the latter case the same end is attained, and in a shorter time. The improvement of the soil is therefore due to cultivation and manuring; but the extent to which this occurs is largely dependent upon properties inherent in the soil, and also upon external influences. Granted that the soil of the locality is normal in composition, whether it be a clay or a sandy loam, that it is not absolutely deficient in any one constituent, there are then three distinct physical properties of the soil which most probably have a definite though indirect influence on the action of manures, and these properties are—porosity, colour, and character of the surface. We have said "indirect influence" as being in opposition to the direct influence of the constituents of the soil upon the manures. The time which elapses after the land has been thoroughly wetted before it becomes fit for working is largely dependent upon porosity, which, so long as it is not possessed in too high a degree, is of great value. A soil which is too porous is said in common parlance to be "hungry;" then the manure, instead of being retained, is readily washed down and out of the reach of the plant; on the other hand, want of porosity causes a soil to be wet, and then aeration cannot take place, the very substances which compose the soil do not become altered and rendered soluble, and the excess of vegetable matter is not decomposed. However, a wet soil has one redeeming feature—when once warm, it retains its heat much longer than if it were dry.

The colour and character of the surface are, as a rule, of great effect, dark coloured soils being warmed by the heat of the sun quicker than those lighter colored, and the presence of vegetable matter, which produces the dark tint, appears to retard the cooling; hence the changes in the composition of the soil, which require a moderate temperature, will proceed more rapidly in a dark soil, and the presence of small stones on the surface is likewise useful, as it prevents the soil below from cooling too rapidly at night.

From what we have just said, it is evident that the lay of a field is of great importance, as the amount of heat received from the sun on a southern slope is not only greater than that received by the same area on the level, but the above physical conditions to which we have cursorily referred, make themselves felt, which would not be the case were the field on a northern slope.

We must not omit the influence exerted by the shelter of trees, whether for good or evil. In many parts of England, more especially in the north, trees and hedgerows have been reduced to a minimum, under the supposition that the land in the neighbourhood will become drier. Such a supposition is no doubt true, as under the lea of large hedges the land has not much opportunity of getting rid of superfluous moisture, and the precipitation of the rain by trees, if a fact, is reduced in quantity. But, on the other hand, trees and hedges contribute a considerable amount of shelter from the wind, reducing the evaporation of water from the surface, and consequently the temperature of the earth. However, it becomes a question to be decided by experience, whether dryness probably accompanied by a lower temperature of the soil is or is not preferable to a moister condition, but with less movement of the air, accompanied by a slightly higher temperature. This last state of affairs has been tried for some time, and it remains but to hear the opinions of those who are working under the new system; for our own part, we are inclined to think that the old method, with better drainage, would be preferable.

Such, then, are some of the various physical conditions of a soil which can be judged of by the eye, and which will tend to produce a variation in the results obtained by manuring different soils with the same quantities of manure.

We can hardly conclude this article without mentioning one or two chemical conditions which are only indicated by analyses of the soil. Superphosphate added to a soil deficient in lime is but of small value, as, instead of being fixed by the lime which ought to be there, and retained for the plant's use, it passes away too readily in the drainage. A highly ferruginous soil is likewise unsuited for the application of a superphosphate, because the iron present fixes the superphosphate in such a form that it becomes of no use to the plant.

It is almost needless to state that the proportions of those manures which are already well represented in the soil might be reduced, were our knowledge in a more advanced state. At present we are only in possession of a few facts, which tend to show that the addition of manure to soil already well supplied is unaccompanied by a corresponding increase in the yield.

GINSENG ROOT, AND ITS DIGGERS.

BY GUY LA TOURETTE.

(*Oil and Drug News.*)

The American ginseng (*Aralia quinquefolia*) is one of the most graceful and beautiful plants that adorn the

United States' forests. It has a fleshy perennial root, varying according to age, from an inch to eight or nine inches in length. From this root springs a straight stalk, terminating in three and sometimes four petioled leaves, each with three divisions. From the point of divergence of the petioles rises an umbel, covered with minute whitish flowers that develope into large green berries, containing seeds, turning a rich glossy scarlet when fully ripe. The root, the only part of the plant of commercial value, is of a faint salmon colour without, nearly white within. It has numerous fibrous rootlets that serve to attach it firmly to the soil, and also to diminish its value, for there is a fashion even in ginseng, and just now a large smooth root without fibre commands a higher price than any other, and as that dug in Minnesota, and in certain counties of the State of Pennsylvania, fulfils these requirements, it is eagerly sought after by dealers.

About the middle of May, or earlier in favourable localities, the tender green stalk of the ginseng (popularly called "sang") shows itself above the ground, and the "sangers," as the diggers are called, who have been impatiently awaiting its appearance, begin operations. Whole families, generally the lowest of the poor whites, migrate to the forests and mountains for the season, that, commencing then, ends about the middle of October, when, the berries having ripened and fallen, the plant turns yellow, withers away, and is indistinguishable from the other undergrowth. These sang-diggers are such a peculiar race that they deserve more than the brief notice I can here bestow upon them. It is true that many respectable people dig ginseng *en amateur* but "sanging" as a profession is not considered the thing at all. Sangers are the most "ornary" sort of people, and anyone familiar with the byways of southern phraseology will understand the force of that deformed adjective.

In West Virginia a curious tribe of them, unable to read or write, moving about like gypsies, have apportioned out the State among themselves, and although closely akin, and bearing identical names, resent an intrusion upon their respective territories in the most vigorous manner. Their wants are simple: bread, meat, coffee, tobacco, and some cheap articles of clothing suffice for them, for they live from hand to mouth. It has been suggested that these "sangers" are hibernating animals in winter, and it would be well for their immediate neighbours if they were so; for reduced as these "almost" gypsies are to the greatest straits for the barest necessities of life during the cold weather, it inevitably follows that other people's granaries and smoke-houses undergo a mysterious depletion at times, for your true sanger dislikes work, and will evade it as sedulously as a tramp, but when the ginseng period arrives behold a change! The much-despised sanger emerges from his obscurity, and, sack slung from the shoulder, and sang-hoe in hand (an implement not unlike a small coal-pick), betakes himself to the mountains. The country storekeeper, who has frowned upon his efforts to obtain credit during the winter, is now anxious to be considered one of his best friends, and spreads infinite webs of flattery to secure his custom. The sang-digger is called lazy and shiftless; but I confess that, wandering among the mazes of the wild hills and mountains, by the side of rocky, foaming trout streams, and through the cool wind-swept forests in pursuit of one's livelihood is far more agreeable to one's senses and feelings than hoeing corn on a blistering hillside during the dog days, and even for those who do not have to dig ginseng for a living there is a strange fascination in the search for the plant that cannot be fully understood except by those who have experienced it.

Ginseng root is sold green to the country stores, which offer prizes for the heaviest root [illegible] m, and for the greatest number of pounds [illegible] any [illegible] person during the season. The price paid varies with the season, all calculations being made upon the basis of dry "sang." Thus in May and June the root is light, taking between four and five pounds of green to make one of dry, in July and August between three and four, and in September and October, when the root is matured, two to three. As the great exporters will only buy it when flint dry, and perfectly free from all other roots, care must be taken to prevent fraud on the part of the sangers, whose consciences do not apparently trouble them when they mix poke, angelica and other roots with the ginseng. A more innocent way of practising imposition is to soak the green porous roots well in water before selling, and sometimes (but not often) to insert fine shot in the larger roots. It is quite needless, I suppose, to say that the storekeepers, who pay in goods for all they buy, are able by a judicious making up of their wares to avoid any positive loss in these transactions.

As soon as the root is bought it is dried, either in the sun or in kilns built for that purpose, or steamed, and then quickly evaporated—a process that renders it beautifully clear like amber. When prepared in this way it is known to the trade as clarified ginseng and brings a higher price, but owing to the risk attending this method of preparation, it is generally dried in the state in which it is dug, and the faster this can be done the better it is for the merchant, for ginseng dried rapidly does not lose so much in weight as when allowed to dry slowly. All attemps at the artificial cultivation of ginseng on a large scale have hitherto been without success; the growth of the plant from the seed is slow and uncertain, and the spontaneous supply has until recently been great enough to meet all demands, so that no very determined efforts have yet been made to grow it by the inhabitants of the States where it flourishes. The East India Company sent a party of scientific men to the United States some years ago, who, after making a series of experiments with the plant for a period of six years, declared it an impossibility to rear ginseng in a state of artificial cultivation. Many old diggers and merchants also say so, but one old digger with whom the writer has an acquaintance does raise annually quite a quantity for the market, and therefore what he had accomplished on a small scale, with care and patience, could be done on a larger under like condition; and as the demand is now in excess of the supply, and China is depending more and more every year upon the United States for the root, it naturally follows that those who shall first successfully grow ginseng will find it a very remunerative business, until the secret of its culture shall become wide spread, when the price must necessarily decline.

And so by the superstition of a semi-civilized race an otherwise inconsidered weed becomes an article of great commercial value, gives occupation and a livelihood to numbers of people, and adds materially to the wealth of the United States.

ROYAL AGRICULTURAL SOCIETY'S JOURNAL.

FLAX FARMING—NARROW-GAUGE LINES FOR PLANTATIONS

LINSEED AND COTTON CAKE—DRAINAGE WATER.

(*Field*, 17th December 1881.)

The second part of vol. 17, second series, recently issued, contains much interesting and valuable matter, including three articles on Continental farming by Mr. H. M. Jenkins, the editor, reprinted from his able report on the agriculture of the Netherlands to the Royal Commission on Agriculture. The first is on flax farming in the Netherlands, which follows a long and important article on the modes of culture and preparation of flax as practised in Ireland and on the Continent, by Michael Andrews, Secretary of the Flax Supply Association for the Improvement of the Culture of Flax in Ireland. This writer describes the result of his own experiments as to an improved mode of watering, viz., by securing a uniform temperature. This is effected by

placing the steep vats in chambers heated by steam pipes, the water being introduced into the vats at the required temperature, and this maintained by heating the surrounding atmosphere of the chamber—in other words, simply by creating an artificial climate. This process has been very successful; the fermentation is in full vigour in twenty-four hours after the commencement of the process, and continues uniformly for some days, when it gradually subsides as the operation approaches completion.

It may not be generally known that the artificial processes for separating the fibre from the woody matter of the stem have not hitherto proved successful. The use of chemicals has proved injurious to the quality of the fibre, and this has also been the result of both Schench's and Watt's processes. The former introduce steam into the water and the vats; the latter into close chambers in which the flax was placed. It is satisfactory to learn that the cultivation of flax has been attended with considerable success in Ulster, and it is quite certain that the linen manufactured at Belfast has of late years been largely developed. In the Netherlands the principal centre of flax farming is the Island of Ijsselmonde, immediately opposite Rotterdam. The island itself has long since been *flaxed out*, but some of the inhabitants, who are known as flax farmers, either hire land for the purpose of growing the crop, or else buy the crop at harvest time; the former plan is most popular, and from £8 to £11 an acre is paid for land ready for sowing, all further expenses being borne by the flax farmer. The crop in a good season is estimated at from £18 to £20 an acre. Nearly 50,000 tons are grown annually.

The report of the judges on the Derby Prize Farm Competition, which we conclude to have been written by Mr. Clare Sewell Read, is a masterly production, and will bear comparison with even Mr. Little's very able and eloquent report of last year. The utility of these competitions is two-fold. The occupiers in the district are stimulated to increased exertions, and the brushing up does them good; and the reading public have an opportunity of becoming acquainted with farm practice in different localities. Such papers as those which have recently appeared not only describe the particulars of each competitor's practice, but give a general account of the leading features and special characteristics of each district traversed, which is most interesting. Milk is the sustaining product; corn and meat growing, though ever so well done, realises a miserable percentage, but those farmers who produce milk can show a solid profit that is highly satisfactory. As regards statistical facts, grass is increasing, corn land diminishing. There are now 11,000 head more horned stock than in 1871; but, alas! 40,000 less sheep, attributable almost entirely to the ravages of disease. The milk trade is of comparatively recent growth, but it has latterly made such progress that over-production is to be dreaded. The Midland Railway, which carried 1,000,000 gallons in 1872, now convey four times as much, and it is thought that not half as much cheese is now made round Derby as formerly. With such excellent management as was found on the competing farms, there is no fear of damage to the land from milk sold; but of course there is always the possibility of an equivalent not being returned, and then pastures would speedily suffer. Decorticated cotton cake is generally given, and an outlay of from 50s. to 60s. per acre in purchased food is not uncommon. The farmers are very attentive to their business; hence one great secret of success. Rents are high, and in some cases either outlay must be made or a reduction given. The judges were much impressed with the energetic, enterprising, and successful management of the late Mr. Carrington, who had laid down large areas of land to grass and drained, and at his own expense. Mr. Carrington had every possible confidence, and laid out his money without any security whatever, further than the custom—not even having an agreement. The judges say:—

Little did we dream, when we first inspected these farms, that a tenancy which had endured for centuries would be so sadly and suddenly terminated in a few days. There was no son old enough to carry on the work, and the dying man directed his executors to relinquish all his farms. A large share of the tenant's capital must be left in the land, and the chief part of the tenant right must be left to the justice and generosity of the landlord. We trust that an amicable settlement may be arrived at, and that those splendid new pastures may not be ploughed up as the executors' last resource.

The judges remark upon the terribly neglected condition of arterial drainage, which has greatly aggravated recent flood visitations, which, especially along the course of the Trent, has proved so disastrous. Shallow drainage on clear soils at near intervals has proved more successful than deep drainage. This is now universal experience.

The paper by W. H. Delano, C.E., on "Secondary or Narrow Gauge Railways for Agricultural Purposes," embracing a description of the Duke of Buckingham's line made in 1871, which appears to be very successful, will attract attention, inasmuch as the subject is one of considerable importance. As such roads are to be feeders for the line of railways, it seems very desirable that, whilst carrying special locomotives lighter than railway engines, the gauge should be the same, so that reloading would be avoided. In many parts of the country the sides of the highways have vacant space sufficient for a single line of rails. If such land could be utilized, one great cause of expense—viz., the cost of land—would be obviated. Mr. Delano describes various foreign enterprises of this nature, nature of the concessions, regulations, &c.

Dr. Voelcker's report on "Further Experiments on the Comparative Value of Linseed Cake and a Mixture of Cotton Cake and Maize Meal for Fattening Bullocks," confirms the experience of the previous season's work, viz., that the mixed food is the more economical. These facts should certainly lead to a modification of ordinary practice. In one case two lots of three beasts, the results were very remarkable. "In the cotton cake and maize meal lot the increase, amounting to 49 lb., was obtained at an expense of £10 9s. 8½d. in purchased food, or at a cost in purchased food of 5½d. per pound increase in live weight; whilst in the case of the three bullocks fed on oil cake, the increase of 40 lb. was obtained at a cost of £14 2s. 9½d. in purchased cake, or at the rate of 8¾d. per pound."

Messrs. Lawes, Gilbert and Warrington contribute a most valuable paper on rainfall and composition of drainage water, collected at Rothamsted, in which the injurious influence of wet seasons in washing nitrates from the soil is clearly proved. On this occasion attention is confined to the amount and composition of drainage water from unmanured fallow land. We are promised a further paper as to the influence of cropping on the loss of nitrates.

CINCHONA CULTIVATION IN JAMAICA.

The Government of Jamaica appear to be very desirous of encouraging the cultivation of cinchona, and they have made arrangements for the grant, under certain conditions, of a limited extent of land, at a nominal price, to any person who may be prepared to embark in the undertaking. Further particulars of the progress of cultivation have been received since those already printed in this *Journal* (vol. xxix, 240, 455). The demand for seeds and plants is said to continue to increase largely, as the new industry brings into productiveness regions which in many cases were unsuited for coffee or provisions, and which were a burden on

the owner. Mr. D. Morris, the Director of Public Gardens, writes in his last report:—"As indicating the value of cinchona planting in the Blue Mountains—taking 379 trees which occupied an area of less than 120 square yards—it was estimated that if they yielded on the average one pound of dry bark per tree (young trees at the Government Plantations yielded 1½ pounds per tree), each tree would be worth at least 5s; this would give £91 15s as the value of 379 trees on an area of 120 square yards, one-fortieth of an acre. Under ordinary conditions it would not, however, be advisable to plant the trees so closely as this, but the value of an acre of land planted with trees even at one-half the above rate, would amount to more than £1,890. Large as this sum may seem, it appears that with the precious Ledgeriana bark, grown by the Dutch in Java (a few plants of which have just been introduced to Jamaica), the yield per acre, as quoted by Mr. J. E. Howard, F.R.S., is estimated, from actual sales, at £2,000 per acre."

Three kinds of cinchona are now well-established in Jamaica, viz., *C. officinalis*, *C succirubra*, and a variety called *C. calisaya*, which is supposed to be a hybrid between the other two. The *ledgeriana* is a variety of *calisaya*. Seeds of the *C. officinalis* for cultivation at elevations above 4,000, are supplied by the Government at 5s. per ounce, of *C. succirubra* at elevations between 2,500 and 4,000, feet at 3s. per ounce. An ounce is sufficient to produce 20,000 seedlings, which will plant five acres. Boxes of seedlings may be obtained at a guinea per box, and plants are obtainable at from 40s. to 60s. per 1,000.—*Journal of the Society of Arts.*

GRAFTING.

Some time since we directed attention to autumn grafting of all kinds of trees. Whether practical effect has been given to the suggestion in this colony, we know not. Probably not, for it is a matter of great difficulty to get people out of their old grooves. We notice in the *Gardeners' Chronicle* that at Iowa the system of winter grafting is advocated and acted upon; and the remarks are so very sensible and to the point, and so peculiarly applicable to the circumstances of this colony, that, with additions to suit, we deem it advisable to give a brief *résumé*. The peculiarities of our climate during the early spring months are such as, unless in very favourable situations, to make grafting a mere matter of speculation. It may be either too wet or too dry. The wind may be hot, or the weather may be, as of late, alternately hot and very cold, all combining to materially affect the union between scion and stock. The method adopted by the Iowa college is to graft early in the winter, store the grafted plants in sand, placed in a humid cellar or other close house; leave them till the following spring, and plant out into the proper positions. The covering of sand and the humid atmosphere will have caused the union to be perfectly complete, and then all the plant will have to do is to grow when planted out in the open ground. In the covering of the incised parts, our Iowa friends somewhat alter the usual method. They advocate first placing the clay compound on the scion, and then covering with a grafting wax compound, spread on some fine muslin. The material they use is white resin, linseed oil, and wheaten flour,—a composition that does not harden, and therefore may be applied without warming. In consideration of our short winters, which generally are not very severe, even in the coldest parts of the colony, these etceteras might be dispensed with. That is, presuming the ties perfectly cover the incised parts, and are then planted in sand, the exclusion of air will be quite sufficient to allow the granules from both scion and stock to form and unite. We recommend both amateurs and gardeners to try the method next season, and we firmly believe that it will be found a perfect success. The process should be extended not only to fruit trees, but to other classes of plants. Thus the camellia, with which we so often hear of failures, might be tried. In fact, all plants that are propagated by this method might be experimented on.

Vines.

It appears that Baron von Mueller has been applying for seeds of American grapes, with the view of getting stocks phylloxera proof, and that the species sought after are the vulpina, æstivalis, cordifolia, and labrusca. If these, as is stated, are more or less liable to the attacks of the phylloxera, they will prove but of little use for grafting purposes, as it should be borne in mind that the severe winters in America must act in a measure as a check; but in this colony or in Victoria, where the frosts are so slight as to scarcely cake the surface of the ground, they will be as equally prone to phylloxera as the varieties already attacked. Again, as most species of American grapes are very prolific in growth, and may be multiplied by the hundreds of thousands either by cuttings or layers, plenty of stocks, without troubling the seedling process, could be obtained in one season wherewith to try experiments. In the matter of training vines, we noticed specially one idea; that was, to let the rods attain a sufficient height, and then gather the tops in and tie up in a bunch. This system certainly would do away with expensive stakes, but could only be adopted in situations that are not exposed to puffs of hostile wind. Another question presents itself: Do vines require stakes at all? We grow them on what is known as the currant-bush system, and if this plan were carried out in its integrity the vines should be self-supporting. Thus the shoot should be nipped off one eye above the bunch, and by a series of nippings the present allowance of useless rods might be entirely dispensed with, and the plant present what it is intended to form—simply a dwarf bush.—*Australasian.*

COST OF COCONUT AND CINNAMON CULTIVATION IN CEYLON.

I suggested to my Colombo friend that if he were an American, instead of a Sinhalese, by birth, and had some capital to invest, he would probably look about and find twenty more fathers of boys or girls, of his own nationality, religion, and social status, and pool say £500 each. This would give a joint capital of £10,000, with no interest to pay. They would then find a thoroughly competent native manager; and by giving him besides his salary, a certain share in the profits, identify his interests with their own. They would buy of Government a block of 2,000 acres, of which 750 would be planted with coconuts, 750 with cinnamon, and the other 500 held as a reserve. Roads would be opened, and the estate either marked into twenty plots, one for each shareholder, or if it were to be managed as one estate, then twenty good building plots would be laid out at the centre of the property, and a village formed. Some time ago I got the native manager of just such an estate to sit down with me and make the calculation I am now going to lay before you. It was an estate that had failed in the hands of an European capitalist. He was an absentee, his manager cooked the accounts, the kanganies cheated the manager, the coolies stole products from under the noses of both, and so it at last came under the hammer and into native hands. There were several partners and a good practical man to manage under their personal supervision. The result was that within five years the estate paid for itself, and now the owners can

meet the market, whatever it may be, and still make money. The manager's figures may be faulty—I cannot vouch for them—but at least I have had them endorsed by several native estate owners of my acquaintance, whose signatures are known at the Madras Bank and the O. B. C. Here they are:—

Investment of a capital of £10,000, contributed by 20 proprietors in sums of £500 each.

Dr.	£	s.	d.
To purchase of 2,000 acres of coconut and cinnamon land, at R15	3,000	0	0

	£16,713	0	0

In the 15th year the income will be

For Cinnamon	£3,225	0	0
,, Coconuts	3,600	0	0
—Cor. of Ceylon *Times*.]	£6,825	0	0

[The figures look too good to be true. The market for cinnamon is not very promising, while coconuts were never cheaper than now. No allowance is made for part of the land turning out unsuitable for cinnamon or coconuts after planting, as in the case of the Horrekelly estate: 2,000 full-grown coconuts per acre is, we suspect, a good average yield for a property of 750 acres, and therefore we would put £2,500 instead of £3,600 as the full income from this source. So with cinnamon, £1,000 off the above income would be a safer estimate, but even then the investment offers a very encouraging return.—Ed. *T. A.*]

CAWNPORE EXPERIMENTAL FARM.

The report on the operations at the Kanhpur experimental farm during the past year records the results of some very interesting experiments with manures and agricultural implements and machinery.

Of the manures employed five belonged to the nitrogenous class, *viz.*, indigo plant; hemp plant; cattle-dung; cattle-dung in combination with gypsum, and poudrette; and three, *viz.*, bone-superphosphate, bone-dust and ashes of cattle-dung, were non-nitrogenous. The crops to which the manures were applied were wheat and barley and sugarcane.

In the case of the wheat and barley the result was to show the immense superiority of the nitrogenous over the non-nitrogenous manures, the former producing in every case a marked increase in the yield, and in every case but one, that of cattle-dung in combination with gypsum, an increase of the net profit, while the latter either increased the yield in so slight a degree as to lead to a diminished profit, or actually diminished the yield.

Among the nitrogenous manures, again, the greatest increase in the yield was produced by poudrette; but green soiling, which came very near it in this respect, produced a slightly better pecuniary result. Next to green soiling and poudrette, came cattle-dung as regards increase both of yield and net profit. Among the non-nitrogenous manures the best results were obtained from ashes of cattle-dung, with an increase of grain of 56 per cent, but a slight decrease in net profit per acre; while bone-superphosphate gave an increase of yield of 39 per cent, with a net pecuniary loss on the cultivation, and bone-dust gave a small increase in yield of grain with a decrease of straw and a diminution of net profits to the extent of R2·2·4 per acre.

Hemp was found equally efficacious with indigo as a green manure, and in one case, in which two areas, each 200 square yards, the one green soiled and the other fallow, were put under wheat, the manured plot gave a better outturn, by 73 per cent as regards grain, and 24 per cent as regards straw, than the fallow. Experiments were also made with gypsum alone; but the results were conflicting, 360 lb. per acre in one case increasing the yield by 45 per cent; and 100 lb. and 200 lb. per acre actually diminishing the yield in two other cases.

The experiments on sugarcane were made with cattle-dung, guano, and guano followed after an interval of 12 months by bone-superphosphates. The best result was obtained with the last named, the outturn per acre with 6 maunds 24 seers superphosphate being 2,584 lb. of sugar, and the net profit R94·4·3, and with 3 maunds 32 seers superphosphates, 1,591 lb. of sugar, with a net profit of R44·11. The next best result was obtained with cattle-dung, 260 mds. per acre, producing a yield of sugar of 1,964 lb. with a profit of R56·10·3, and 130 mds. per acre, producing a yield of sugar of 1,542 lb. with a profit of R39·8·5. Guano alone, in the proportion of 12 mds. 35 seers to the acre, gave a yield of 2,554 lb. of sugar, with a loss of R23·0·9, and in the proportion of 3 mds. 18 seers per acre a yield of 1,848 lb. of sugar, with a profit of R10·12·10.

Some interesting experiments were carried out with different forms of winnowers, an English instrument (by Deli), a farm-made instrument and the ordinary native method being tried in competition. With a high wind the results as regards both time and economy was in favour of the English winnower, which winnowed 100 mds. of grain in 18h. 58m. at a cost of 15·4 as., the native method coming next, and doing the work in 28h. 37m. at a cost 18·7 as, while the arm-made winnower took 32h. 16m. to do the work, at a cost of 21·1 as. In a calm, on the other, while the English winnower did almost equally

well, the time being 20h. 50m. and the cost 16·9 as. the native method was altogether out of the race, the work occupying 51h. 41m. and costing R4-3-8, and the farm-made instrument did the work in about twice the time and at 50 per cent greater cost than the English.

The experiments with the windmill, one of the American Kewance pattern, show conclusively that it cannot compete with the common native *dhenkoli* worked by hand. In the first place the minimum velocity of wind necessary to work the windmill with any efficiency is four miles an hour, and the number of months during which the average wind velocity in the North-West Provinces comes up to this is small. In the second place the efficiency of the windmill, with even a four mile breeze, is less than that of a *dhenkoli* worked by two men, while its daily cost is greater. It should be noted, however, that the windmill was a very small one, its efficiency with a 6 mile breeze being only about ·026 H. P. Possibly, a larger mill would give a better comparative result. —*Englishman.*

INDIAN PLOUGHING EXHIBITIONS, CUDDAPAH AND KURNOOL.

From L. R. Burrows, Esq., Acting Collector of Cuddapah, to the Secretary to the Board of Revenue, dated 12th September 1881.

I have the honor to forward, for the orders of the Board, copy of a letter from Superintendent of Government Farms, proposing to send some men and ploughs under the direction of an Agricultural Instructor for exhibition in this district. I shall be very glad to arrange a series of exhibitions in different parts of the district and to invite the principal agriculturists to inspect the ploughs and their work. The exhibitions might easily be made very interesting by putting the best ploughs of local make in competition with the Madras ploughs. Cultivation in the neighbourhood of Cuddapah is of a very high class, and I feel sure that if there is any real advantage to be gained by using Madras ploughs or any implements of a different kind from those now in use, the cultivators about here will not be slow to make the change. I understood from Mr. Robertson, with whom I consulted personally, that funds were available under the Board's orders for the purpose in view.

From W. R. Robertson, Esq., M.R.A.C., Superintendent, Government Farms. I have estimated the salary of the Instructor at R45 per mensem, which with R15 batta will bring up the allowance to that sanctioned for an Agricultural Instructor. We cannot offer less emoluments, for the work is only temporary and the districts remote and not specially favored as regards climate, &c. I have entered in the estimate a sum for the hire of cattle; probably only a portion will be required. If the same cattle are used throughout each district, the owners will, of course, expect payment when the land of other cultivators is being ploughed by means of the cattle.

Resolution—The Board observe that the experiments in Trichinopoly were unsuccessful, but that those in Bellary, at the cusbah at any rate, were of an encouraging nature. The proposed expenditure is sanctioned on the understanding that the Collectors will stop the experiments if not satisfied with their progress.

FEEDING PROPERTIES OF THE "REANA LUXURIANS."

Read—the following letter from W. R. Robertson, Esq., M.R.A.C., Superintendent, Government Farms, 182 to the Secretary to the Board of Revenue, dated Saidápet, 19th August 1881.

In continuation of my letter, No. 481, of the 14th of May last, embodied in the Board's Proceedings, No. 966, dated the 2nd June 1881, I regret to have to report unfavorably of the seed of the *Reana luxurians* as a food for stock, not because of the grain being innutritious, for this is a point on which I can offer no decided opinion, the grain not yet having been analysed, but because of the difficulties experienced in preparing the grain as food, and the unwillingness of stock to eat the grain when prepared. The latter perhaps is not an unsurmountable difficulty, for stock generally refuse a new kind of food when first offered. But the difficulties experienced in preparing the grain for use as food are, I fear, fatal to the prospects of the grain being used as such.

2. I have tried various processes in preparing the grain—

(1.) A quantity of the grain was placed in cold water and allowed to soak for 56 hours. At the end of this time the grain was almost as hard as when first placed in water, while it had increased only about 10 per cent in volume.

(2.) Half a measure of the grain was boiled for 6½ hours. At the end of this time the shell was perfectly hard, though the inner portion was soft; still it was quite impossible that the grain could be masticated by any animal. After boiling the grain measured 6½ ollocks, which was an increase of 62 per cent. It appeared to be useless to continue the boiling process longer. The boiled grain, when cold, was offered to several sheep, all of which refused to eat it.

(3.) Half a measure of the grain was placed in a stone mortar and was beaten for two hours with a heavy pestle, but none of the grain was crushed.

(4.) Half a measure of the grain was placed in a powerful corn-crushing mill. The grain in passing through the mill was partly crushed, but only very imperfectly, and it was necessary to pass it seven times through the mill to get the grain powdered; and this was only a rough coarse powder. This powdered grain was offered to a number of sheep, but again it was refused.

3. Under these circumstances, it is not, I think, necessary to go to the expense of analysing the grain. I enclose a sample, should the Board deem it necessary that further trials should be made with the grain.

4. I fear, however, the grain has but little to recommend it as a food for stock. Its hard, flinty husk forms fully 30 per cent of the entire grain, while the inner portion is tough and waxy, and, I should think, very indigestible. Maize has many more claims, and those of a much stronger character, on those who are desirous of introducing a better food-grain into this country either as food for man or beast; and maize could be successfully cultivated wherever the *Reana luxurians* could profitably be grown.

Resolution—Submitted to Government with a file of the previous printed correspondence. The Board fear that there is little prospect of utilizing the grass or the seed derived from this plant.

MR. ESPEUT, F.L.S., ON CULTIVATION IN JAMAICA.

(*Field*, 31st December 1881.)

If any one will contrast the data I have given in previous letters, which experience is every day proving to be inside the results actually obtained in fruit cultivation here, with the figures given on page 489 of your issue of the 1st of October (No. 1,501) of orange

planting in Oregon, he can scarcely fail to see the great advantages Jamaica offers over that belauded portion of the United States—not a British possession, be it observed.

The letters recently published in the *Times*, though rather *couleur de rose* in some respects, give a very good idea of Jamaica as it now is.

If ever there was a time when this beautiful colony should attract the attention of capitalists and enterprising young men from the mother country, it is now. When the Panama Canal is accomplished, the position of Jamaica will be materially benefited, and opportunities which now offer will not be offering then of obtaining land cheap.

As you were so good as to allow me to allude to the plans I have adopted for aiding the intending colonists with small capital, will you kindly let me say that experience has proved the wisdom of altering the previously stated terms? At first I proposed to give the land, and materials for a cottage, free of rent for five years, on the condition the land was planted in chocolate for my benefit, I finding the seed and paying taxes and rates. Now it is found mutually more satisfactory and agreeable that I should plant the chocolate myself; and instead, receive one-third of the annual nett profits of the banana cultivation, after the capital is wholly repaid, as rent for the land and house, &c.

One gentleman who took up 100 acres of land and commenced planting it in bananas in July, 1880, expects to get back the entire capital expended before next April, and thereafter to hand me £500 a year, or £5 an acre, as my one-third of the profits. Of course, I do not wish to make people believe this result will always follow in *any* part of Jamaica; but I certainly do believe that in this district, and especially on lands near any tramway or shipping place, the capital will be repaid in two years, and the return from bananas will give a nett profit for three years of 50 cent per annum on the outlay. I have 400 acres in cultivation on these terms on this estate, and have dozens of enquiries, local and from outside Jamaica, for lots from the 2,000 acres of suitable land which I am prepared to devote to this system. It may be said, if the thing is so good, why do I not keep it all in my own hands? The reply to this is, that my hands are full, and that I have still other and sufficient land for all the capital I can devote to this particular cultivation, having regard to the heavy outlay for up-keep of over seven miles of tram lines, a large sugar estate, and a daily increasing chocolate cultivation.

I thank you very much for the space you have so kindly given me on this and previous occasions, and once more advise those who think of settling abroad to look at Jamaica before they decide on going elsewhere.

W. Bancroft Espeut.

Spring Garden, Buff Bay, Jamaica, Nov. 10, 1881.

OSTRICH FARMING IN SOUTH AFRICA.*

At a time when industries are languishing at home, and hands are idle for lack of employment, many might do worse than turn their attention to the new and thriving industry which has sprung up at the Cape, in the domestication of ostriches, which are farmed for the sake of their plumage. Mr. Arthur Douglass is the author of a very interesting work which describes the rise and progress of the new enterprise, which dates no farther back than 1867. Already, in the Cape Colony a capital of not less than £8,000,000 is employed in this new method of farming, while the export of feathers during the past year amounted to 163,065 lb. weight, valued at £883,632, or £5 8s 4d per lb.; most of this product having been derived from tame birds. The value of a really good ostrich feather had long been known in the market, but not until within very recent years was the idea carried out of taming and rearing birds, whose half-yearly crop of feathers might be made to yield almost their weight in gold.

Ordinary farming knowledge avails nothing in the rearing of the ostrich. On the Cape Coast cattle, unless they are native, are subject to fatal attacks of liver complaint, and only a small percentage of the calves can be reared. Horses fall off in condition, and the insects of the district blister and destroy the teats of cows. Farther inland it is not so bad, and on the more congenial grassy lands some fairly extensive stocks of sheep are kept. Yet here also they are liable to diseases of divers kinds, and heavy mortality has been experienced in raising them. Mr. Douglass ascribes much of this to overstocking, and allowing old, sickly, and inferior sheep to breed. With the ostrich also great care is required to avoid over-stocking, and so give the herb-seed a chance of reproduction. He favours for this purpose letting half the farm lie idle six months. The man who is able to own land should, he says, always have two large camps for each troop of birds, if he would keep an eye to the future; whilst the needy man on hired land can move to another farm on the expiry of his lease, and thereby avoid the inevitable consequences of over-stocking.

What capital is required? In the course of an interesting chapter on this head, Mr. Douglass states that with a few hundreds of pounds an excellent start may be made on the 'halves' or partnership system. But, above all, he advises the would-be ostrich farmer to obtain, as a preliminary to business, at least two years' experience of the colony. Otherwise the emigrant is almost sure to invest his money foolishly. Far better is it, in the opinion of the author, to obtain, if possible, letters of introduction from the relatives of well-to-do people who may be living at the Cape, and pay a premium of £100 to cover cost of board and lodging during the first year, and be prepared at the same time to engage in any kind of work.—*Australasian.*

PROPOSED CURE FOR THE PHYLLOXERA.

Many years ago the important silk-producing industry of the valley of the Rhone was threatened with ruin. A mysterious disease seized upon the silk-worms, and resisted all the efforts at its cure, until at length M. Pasteur, who was even then engaged on those studies upon fungi and fermentation which have since rendered him so famous, demonstrated that the pest was caused by a living parasite, and devised means of stamping it out effectually. Few modern researches have been more suggestive or more fruitful in practical results than these of Pasteur. Our knowledge of the vast amount of mischief to health and industry caused by the lower fungi, and particularly by bacteria, has been rapidly increasing, while, happily, the power of successfully destroying these has increased in scarcely less rapid proportion; witness the improvements in wine-making, the still greater advance in the art of brewing, and, best of all, that revolution in surgery effected by the introduction of antiseptic methods. Of late years the vine-growing districts of France have been steadily invaded by a serious pest of a widely different kind, the *Phylloxera vastatrix*, an insect belonging to the same family as the common green aphis of the rose, and endowed with the same power of rapid sexual multiplication. In spite of all remedial measures, the insect is still spreading, and thus constitutes a serious danger to the wine supply of Europe. Soon after the establishment of the Phylloxera Commission of the Academy of Sciences, M. Pasteur threw out an ingenious suggestion, clearly derived from his early experience o

the silk-worm disease, to destroy the invader by innoculating it with a parasitic fungus; thus reversing the principle of all the previous applications of our knowledge of these organisms by treating them as allies instead of enemies. Unfortunately no experiments were made, and the subject was forgotten until last year, when Professor Hagen, of Harvard, published an account of his experiments on the destruction of obnoxious insects by the application of the yeast fungus. He concluded that the yeast cells entered the body of the insect, there giving rise to fatal disease, and accordingly recommended the application of yeast to the phylloxera, Colorado beetle, &c. Such results as these, on the one hand confirming the old belief in the efficacy of yeast as a means of destroying greenhouse pests, and on the other at variance with all experience as to its mode of life, could not but stimulate inquiry. The subject was soon undertaken by a distinguished Russian biologist, Elias Metschnikoff, who has shown that the disease-producing fungus of Hagen was not the yeast itself, but was merely associated with it as an impurity. He has succeeded in cultivating several species of fungi parasitic upon insects, notably one which he terms "green muscardine" (*Isaria destructor*) and in tracing their entire life-history. By cultivating the green muscardine apart from insects upon a suitable nutritive fluid, he has been able to obtain a considerable quantity of spores, and thus feels justified in recommending the cultivation of such fungi on a large scale, and the dissemination of the germs in places infested by insects. The subject is at present engaging considerable attention in France, and experiments are being made, of which we shall doubtless know the results in the course of next season. In the meantime it is impossible not to await with interest and hope this application of a new method.—*From an article on "Recent Science" in the November number of the "Nineteenth Century."*

SUGAR GROWING IN MACKAY, NORTHERN QUEENSLAND.

After careful inquiry and comparison of results, I am justified in setting down 1 ton 12 cwt. of sugar per acre as a fair average yield per acre from the canes all around. With advantages such as exist, especially in the climate of Mackay, this yield, though favourable as compared with other Queensland sugar districts, and highly profitable in itself, is below what might reasonably be expected, and probably much under what better cultivation and appliances will make it in course of time. Only in two instances have I observed manure to be applied. At Fouldeu, Mr. Walker uses superphosphate of lime manufactured on the premises; while Messrs. Hewitt and Co. apply stable manure on a part of their Pleystowe plantation.

The crushing season begins in June and finishes about the middle of December, and during this time not more rain falls than is sufficient for nourishing the young canes—on an average about 17 inches. In some of the plantations these are put in the ground almost as soon as the old canes are cut down and the ground ploughed up. The cuttings are taken off near the top of the cane, and placed in a slanting position in the ground, in a way which leaves only a joint exposed above the surface, but in very dry weather even this is covered up—a work in which the kanakas have become expert. There is another way in which the young canes are allowed to grow—that is, by rattoons, as it is called, the cane stumps being left in the ground, from which the next crop springs up, the earth being ploughed up so as to leave the stumps just covered. In general this process is permitted to go on for three years before the stumps are ploughed up for re-planting; it saves a great deal of labour, and though the canes are not so vigorous as those which grow from plants, yet the stumps continue for three years to give a tolerably fair crop. In some cases they will yield a profitable crop for a longer period—even for five or six years; but it is considered safer not to let the time exceed three years.

It is remarkable to what a height the canes grow in well-cultivated and well-drained land. I have seen a crop standing in some places as high as 12 and even 15 feet above the ground; and once, on the ridges of the Pioneer, witnessed the singular spectacle of two men on horseback becoming invisible to each other at a short distance whilst riding among the canes. When the cultivation is good there appears to be no difference in this respect between the rich level alluvial soil of the Pioneer and the dark soil on the hillsides; both at the present time are equally prolific, but in a very wet season the hills would probably have the advantage.

It is said that 11,000 tons of sugar will be the probable yield for the present year, but in comparison with the land unoccupied the district has barely been scratched, and it has been estimated on a fair calculation, what may seem at the present stage an exaggeration, that no less than 250,000 tons of sugar per annum will be produced in the district when all the land is tilled with skill and care. Be that as it may, there is an immense tract of land yet open to the selector, but unfortunately, just as people are becoming anxious to take up land, the Government have withdrawn it from sale. When it is thrown open again, the rush for it will be enormous, judging by the number of inquiries which are made at the Mackay land office. The conditions are similar to those of New South Wales, and it is probable that in the Mackay district every selection will be contested for at auction.

Cane-growing seems very catching; nearly all who can embark in the enterprise; sugar-growing and cane-planting are the principal topics of conversation in the town and in the country, and all the small farmers, of whom over 200 are said to have settled down, who formerly grew maize and tried their hand at cotton, have abandoned those industries for the more lucrative one of growing sugar-cane, which they dispose of to the millowners for about 11s. per ton. —*Australasian.*

THE CULTIVATION OF CASUARINAS.

TO THE EDITOR OF THE MADRAS MAIL.

Sir,—I must crave a small space in your paper to enable me to make a few remarks on the estimate framed by "B." for planting six acres of land with casuarina trees, as published in the *Eurasian and Anglo-Indian Advocate*, and reproduced in your issue of the 20th July last.

"B." does not provide for the expense of forming a fence or hedge for the plantation to protect it from the ravages of cattle, &c. No plantation can thrive without a proper fence, and this should be the first thing attended to. The American aloe or corkopilly plant, is well adapted for this purpose, but will require watering the first year, especially the latter plant. Both will repay their cost in the third or fourth year, and be a source of revenue as long as the fence is kept up; the only thing to be taken into consideration is, the first outlay. "B." also omits in his estimate the assessment of the land, and the interest on the capital to be laid out; but I may mention here, that Government grant waste land free of assessment for twenty years for the planting of topes.

The soil should be of a loose sandy nature. These plants thrive best on such soils, on the sea coast, on re-claimed salt marshes, and on the slopes of the banks

of rivers. The items for ploughing and manuring are superfluous, but the forming of furrows and ridges with the aid of a plough, will facilitate the planting in straight lines, and expedite the work. The plants will require watering at least two years, and not one year only, or rather for nine months in the first year, and seven in the second year. By transplanting early in August, the plants will, if well watered, take firm root, and spring up quickly during the cold months of October, November and December, without being watered. The loss of 630 trees to every acre of land should not have been dreamed of. Such a mode of cultivation must be condemned as a very slovenly one. Spare plants are always retained in a bed ar two to replace those that die away, so that the full complement of 3,680 plants may be calculated upon. It would be more accurate to say that the plants will take five years to come to maturity, not four. An acre of the best description of dry land in this district is assessed at a little below Rs.2-8. The cost under his head need not therefore have been doubled to Rs.20 per acre. The assessment of land suited for casuarina plants never exceeds Rs.2 per acre. I have no means of framing an estimate for planting a fence for six acres of land, but as I have said that it will pay for itself, any inaccuracy under this head will be immaterial.

The suggestion to plant castor oil beans on the ridges between the casuarina plants must commend itself, as it will afford shade to the young plants, and prevent the moisture being absorbed by the sun. A common, or butter bean may, with advantage be set at the foot of the castor oil plant, for its beans. The return from these two latter sources is not brought to account in the following estimate.

Following the estimate of "B." as close as possible, for planting six acres of land, mine would be as follows:—

24,000 plants at Rs.5 per 1,000	Rs.	120
Planting and first watering at 12 As. per 100	,,	18
Forming ridges with the aid of a plough ...	,,	9
Assessment at Rs.2 per acre for 5 years ...	,,	60
Watering for 1st year	,,	600
Watering 2nd year	,,	300
Cost of fence or hedge	,,	100
Cost of watching and sundries	,,	444
		1,651
Interest on Rs.1,651 at 12 per cent. for 5 years	,,	1,580
Total cost ...	,,	3,231
Sale of 21,780 (plants 3,630 plants per acre) at 8 Annas each	,,	10,890
To be realized from fence in the shape of fuel or fibre	,,	100
		10,990
Deduct gross expenditure	,,	3,231
Net profit	,,	7,759

"B." having omitted three very important items in his estimate, namely, the assessment, cost for fencing, and interest on the capital, his estimate for the cost of raising the plantation is insufficient. As the want of funds will hamper any undertaking, it is essential that an estimate of the probable costs should be as accurate as possible.

Yours &c.,
Nellore. W.

TROPICAL FRUITS.

(*Field*, 24th December 1881.)

Sir,—In last Saturday's *Field* F. T. P. expresses his wonderment at never having seen the mango exposed for sale in London. Let his surprise now cease, for I saw some only a fortnight since at a fruiterer's in Oxford-street, at the corner of Holles-street. Judging from the view I got of them through the window, I should say they were the "pucka" Bombay article, and in by no means bad condition. I have eaten several kinds of mango in Java, and the best is still inferior to the Bombay fruit. The fruit sold in Singapore and Penang, and known as the Manila mango, is simply consolidated turpentine in taste.

The flavour of the Durian is a matter of—not taste, but habit. I have eaten a good many, and cannot really say I like it. Those Europeans who really long for the fruit are such as have lived a long time in the country, among the natives. I always understood that the Malays value the fruit for its supposed aphrodisiacal qualities; but I met with a direct practical argument against this in the fact that the Europeans who praised the fruit most were some Roman Catholic missionaries, one of whom had been thirty years in Malacca.

F. T. P. has evidently never tasted the mangosteen.

E. T. S.

(*Field*, 31st December 1881.)

Sir,—I have to thank E. T. S. for his notes on tropical fruit. But how came mangoes in Oxford-street at this time of the year? for the fruit ripens in India in May and June. There is a variety which sometimes bears fruit in September and October, but it is scarcely fit to eat, and I must avow, if I was astonished before at not having seen mangoes for sale in London, I am doubly astonished to hear that they were exposed for sale a fortnight ago.

I know the mangosteen well, but it is a fruit which will not keep any length of time. To get it in perfection it must be taken ripe off the tree and eaten there and then. The fruit has been introduced into India. I saw numbers of trees in a garden between Vizianagram and Rajahmundry. The trees bore fruit plentifully, but it was quite different from the mangosteen of the Straits, and not fit to eat; I see no reason why it should be introduced into England. The lichie is also a delicious fruit, which might with advantage be introduced into our hothouses. The loquat, if I mistake not, has either been grown in England, or can at times be procured there; but it is a fruit I care little about. Good fruits in India, except in the hills, Cashmere, and Afghan, are very scarce. In the Straits and China there are many varieties, but I do not think much of them with the exception of the lichie and mangosteen.

The grapes at Aurungabad, near Jaulwah, were, some thirty-three years ago, when I first went to India as a "griff," the finest I ever ate, and as cheap as dirt; but since the railway they are sent to Bombay, and the same care in their growth is not now taken as in days gone by. I have eaten as fine peaches grown in the open air in Assam, as the very best hothouse ones in England.

Perhaps the vendor of the mangoes in Oxford-street would explain where he got his fruit at this time of the year, and what is their price? F. T. P.

Sir,—I venture to think that F. T. P.'s surprise will, so far from ceasing, be greatly increased by E. T. S.'s letter, in which he says that he saw some mangoes for sale "only a fortnight ago at a fruiterer's in Oxford-street, at the corner of Holles-street." I have lived for upwards of sixteen years in various parts of the Bombay Presidency, of which four were spent in Bombay itself, and I can assure E. T. S. that the good folks of that city would be extremely surprised to find mangoes growing there in November. The mango tree flowers from January to the end of February; the mango showers, which are popularly supposed to knock off the surplus stock of fruit, and to usher in the hot weather, usually occur about March 10, and the fruit is in season, as a rule, throughout May and the first few days of June. A few are to be found in the market towards the end

of April, but they are not of the best quality, and it is generally considered that the first shower of the S. W. monsoon is the end of the mango season, as it is believed that a mango on which rain has fallen when ripe or ripening is ruined. Certainly they rot and spoil very quickly immediately after the monsoon begins.

The real difficulty about getting mangoes home, is—apart from the fact that first-class Afoos mangoes usually cost in Bombay two annas (or threepence each)—that, once they are plucked, they ripen very rapidly, and have to be eaten to save their lives. They are occasionally sent home, and the most successful experiment of the sort I know was made by a gentleman closely connected with one of the lines of steamers trading between Bombay and Liverpool. He entrusted five dozen to the captain, who, after a voyage of twenty-seven days, delivered the crate containing the precious fruit the day after arrival in port. It was found that only twenty or so were fit to put on the table, and this though they had been gathered hard and green, packed each fruit separately in a distinct compartment of the case, which itself was kept in the ice room of the steamer. Under these circumstances, it is hardly surprising that the Bombay mango at least should not be frequently found in the London market. It seems a pity that E. T. S. did not ask the Oxford-street fruiterer where he had got his mango from. They assuredly could not have been Bombay fruit.

T. D. M.

Cheltenham, Dec. 25.

OSTRICH FARMING.

Having lately arrived from the Cape Colony, I think it would not be out of place to give as briefly as I can my personal knowledge and experience of its progress in the Cape Colony. My first experience in ostriches and ostrich feathers was in 1869, and from that year to June, 1881, I have never been out of that business. During 1869 to 1872 the feather market, sales weekly, averaged £2 500 to £3,000. In 1871 ostrich farming created a great sensation in the colony, and a great many people who can afford to buy birds did so, price being no object so long as they could be obtained, £350 to £450 was paid for a pair of birds—that was the time when the pioneers of the enterprise made such rapid fortunes. The feather market was increasing in quantity month by month, and in 1874 to 1875 the sales realised £7,000 to £8,000 weekly. It was thought then that the feather trade was getting overstocked, but that prognostication was not to be realized, for in 1876 prices began to advance; in 1877 to 1878 (prices you will find at foot of my letter). From 1879 to June, 1881, the average weekly sales on the Port Elizabeth market amounted to £18,000, leaving out the large number of parcels which changed hands privately. I have myself sorted feathers in four months to the weight of 3 tons. It is very tedious work, and most difficult, especially when you have to sort so many different farmers' produce in classes for shipment. There are also large ostrich auction sales in the colony. I have seen myself as many as 150 pair sold in one day, and on an average including young birds, they realised £70 per pair. In fact, ostrich-farming for the last eight years has been, and still is, paying better than any other farming enterprise known. I often think the more feathers are grown the more are wanted. I know personally many men who have cleared all live stock off their farms on purpose to raise money to buy ostriches, the interest upon their outlay being so great. There are also large Ostrich-farming Companies whose shares are at a good premium. The shares were taken up by all classes, and a great number of mechanics invested part of their savings, knowing the profits of the enterprise. It was said some years back that ostriches would not live here or there, but I have bought feathers from farmers where it was said they could not thrive, and good ones too, but I must say that where what we call in the Cape Colony prickly pear and aloes grow is generally a good place, as they generally grow in low-sheltered lands where the soil is very light. In farming the birds if you want full flesh on your feathers and bright colour you must be near the vegetable growth. If you don't give your birds vegetable food with other food when you pluck them you will find the fleshy part of your feather thin and wiry, your coloured one, especially the cock bird's rusty-looking which depreciates their value. That is the reason the wild feathers are so uneven of late years. The country they are now running in is far up, and the hunters don't care about following them. The country has and does suffer much with droughts, and when they are tempted down their feathers are then in flesh, poor butted, and overgrown, but if they could get a good supply of green food their feathers would be full, fleshy, and everything you could wish for. About three years ago I sorted a large lot of wild feathers, about 1,600 lb. in weight, which was forwarded to my late employer from one of his stations in the interior; and out of all that quantity I could not get more than 60 lb. of prime feathers, all the others were more or less wiry, overgrown, and faulty. Mr. A. Douglas's farm is in the heart of a splendid farming district, with sheep, goats, and cattle on it, and towards the Kowie there are some splendid agricultural lands. I have the pleasure of knowing his farm, and have been upon it three or four times. He has on his farm prickly pears and aloes. There is another large ostrich-farmer at Adelaide, about seventy miles from Grahamstown. He also farms Angora goats, and produces some of the finest hair exported from the colony. As I have repeatedly said, the secret in ostrich-farming is practical knowledge and care of your birds. I have travelled part of the west and almost the whole of the eastern province amongst ostrich-farming, and always got the best feathers from a care-taking farmer and where they have had green food. A feather-sorter can tell as soon as he looks at a feather whether the birds have been cared for or neglected in some way or other, even if he has never seen the bird.

Notwithstanding the short time I have been in Victoria, I feel confident that ostrich-farming must prove a successful enterprise under practical management. I will give you as a guide what profits can be obtained from one pair of birds in twelve months. I buy a pair of birds, for which I give £300. If they are good, and the feathers up to the mark, their plumage at the very lowest would fetch £50. The hen begins to lay; she lays, we will say, thirty eggs, but often many more, you hatch per incubator. Say we get only twenty-five chicks, they are worth £6 10s. a month old, and every month they increase in value. You won't sell, but keep them until they are twelve months old, they will be worth £20 each. Twelve months' return—1 pair birds, £300, 12 months' feathers, £60, 25 birds, at £20 each, £500 £560. On the same scale in five years they realised £2,800, less original value £300, or £2,500 in all. You must also bear in mind there are all the chickens' feathers to be reckoned on, and the first, second, and third brood are laying and producing, and also being plucked, and their feathers sold. Many men in the Cape have in that small time fortunes out of one pair of birds. If a made Company should form for ostrich-farming, the public would see profits accruing from the enterprise. Birds would be in demand, which would fetch high prices here in consideration of saving expense and risk of shipping. On that ground a Company would soon recoup itself for all expenses and increase greatly the value of the shares.

PRICES OF FEATHERS.

In 1873 to 1876 the market steadily increased and in face of great supply, prices were unchanged.—*Australian Paper.*

HORTICULTURE IN LOWER BENGAL.

(Asian.)

THE PEA (*Pisum sativum*).

Probably to the cultivation and improvement of no other vegetable has so much attention been given as to the Pea. This is fully demonstrated by the immense number of varieties now in cultivation. Take, for instance, the catalogue of any first-class English seedsman, and we shall probably find upwards of a hundred kinds enumerated, and even this total would not embrace half the number of varieties grown in England. It must however, be admitted that an immense number of these are but synonyms of others; as an example it may be mentioned that some of the oldest and best varieties, such as Veitch's Perfection, or Langster's No. 1, which are the kinds principally grown by market gardeners at home, are known under ten or twelve different names. In England these are divided into three sections, that is, early medium, and late varieties, the sowing of which extend over a period of about six months, that is from December to May. Here, however, where our season for sowing is limited to about six weeks or two months, it is certainly unnecessary to grow a large number of varieties even for a large garden; a selection of four or six good sorts will be amply sufficient. I append a description of a few of the many new sorts, and also a list of the most popular of the older kinds; a selection from this may be made with every confidence of a good return, they being all well-known and tried varieties.

The Pea delights in a rich, deep, light soil, one that has been well-manured, for the previous season's crops suits it best. Should however the soil be poor, it may be enriched with a good dressing of very old cow manure, or leaf mould, which, when possible, should be applied a month or two before sowing. On no account use fresh or half-rotted manure; this being too stimulating in its action, causes an unnatural production of stem, to the detriment of the crop, and frequently also causes the plants to become infested with mildew.

The first sowing may be made about the middle of September on raised beds, commencing with the dwarf early varieties, and, where space is available, this should be followed by successional sowings at intervals of a week or ten days up to the end of November. Before sowing, the seed should be steeped in water for three or four hours, and then allowed to dry for about the same time before being planted. The dwarf kinds may be sown in rows about eighteen inches apart, and the seeds about one inch apart, covering them with about an inch of soil. The taller growing sorts require a space of at least three feet between the rows, and should be planted two inches deep. As soon as they are about six inches high they should be staked, planting the sticks so that they cross each other at about six inches from the top, where they should be firmly tied together. The situation best adapted for the Pea is one where it receives the full morning sun, but partially shaded during the remainder of the day.

THE RADISH (*Raphanus sativus.*)

The Radish requires a free, open, soil, well enriched with manure. In fact, to grow them to perfection, it is nearly impossible to make the soil too rich. Sowings may be commenced early in September, and continued at intervals of about ten days up to January, though the produce of sowings made during October will invariably be found the best. The seed is best sown in drills about five inches apart, and after lightly covering with soil, the beds should be well beaten down. This insures the roots forming of a good shape. As soon as the plants are large enough, they should be thinned out to a distance of four inches apart in the rows. If the soil is fairly rich, and the plants kept liberally supplied with water, they should be ready for drawing in about three weeks from the time of sowing. Care must also be taken to keep the soil well stirred about the plants. There are now a large number of varieties, but these differ more in form and colour than in quality, for, when well grown under the same conditions, but little difference can be discerned in their flavour. There are also two indigenous varieties which grow to an enormous size, and are much eaten by the natives. These are, however, so coarse and inferior in quality to the English varieties that they are not worth cultivating in the garden.

SAGE *(Salvia officinalis.)*

This can only be grown as an annual in this country, and then with but a moderate amount of success. The seed should be sown in pans or boxes in October, and kept in a cool, sheltered place till the plants are ready to be put out. They should then be transplanted into a bed of light, rich, soil, a shady situation being selected for them, the plants will then continue growing freely till April, when, as the heat becomes more intense, the plants will gradually dwindle off, and those that survive this trying ordeal invariably succumb to the first heavy rains. If grown in pots a few plants may occasionally be kept through the year but with extreme difficulty. The plant known as Bengal Sage *(Meriandra bengalensis)* is entirely distinct from the preceding, especially in flavour, although it is used as a substitute for it; this is propagated by division of the roots.

SALSIFY *(Tragopon porrifolium.)*

SCORZONERA *(Scorzonera hispanica.)*

Neither of the above can be cultivated with any degree of success in Bengal, owing to the shortness of our cold season, both of the plants requiring a long time to mature their roots which is the part used.

SPINACH *(Spinacea oleracea.)*

Although there are two distinct varieties of Spinach which in Europe are cultivated at different seasons in this country, they must be grown at the same time; and, as their produce so closely resemble each other, it is hardly necessary to grow more than one of them. Preference should be given to the round-seeded variety, being quicker in growth and more tender than the other.

Sowings may be commenced in October in drills about twelve inches apart, in any good garden soil which has been previously well manured. Sowings should be made at short intervals up to December to keep up a continuous supply. The plants must be kept well supplied with water, and an occasional dose of liquid manure will also have a beneficial effect.

Savoy Cabbage.

This, like all of its class, delights in a deep, rich, well-manured soil. It should be cultivated in the same manner as recommended for the Cabbage. The dwarf varieties, such as "Little Pixie" and "Tom Thumb" are decidedly the best. These should be planted out in rows about fifteen inches apart with the same distance dividing the plants in each row. They should be liberally supplied with water through the whole period of their growth.

The Tomato.

Probably there is no part of the world with a climate better adapted to the cultivation of the Tomato than that of Bengal from October to March, and yet it is a plant that has been much neglected here. Only two kinds are seen in our bazaars, namely, the Small Red varieties, which in this age of vast improvements should long ago have been consigned to oblivion, especially when we might have in the place such fruit as "The Trophy," "Acme," "Carter's Greengage" or "Nisbet's Victoria." The cultivation of the Tomato here is extremely simple. Seed should be sown at the end of August in a seed-bed sheltered from heavy rain. The plants will be ready for putting out early in October; they should be planted in well-manured soil in rows three feet apart, with the same distance between the plants. When practicable a bamboo trellis should be placed along each row, about three feet high, to which the plants may be trained. In England it is customary to pinch out the point out of each shoot to induce them to set their fruit. Here, however, this is quite unnecessary, and require no care beyond an occasional watering and tying up.

Turnip (*Brassica rapa.*)

A rich deep, mellow soil, with a fair amount of moisture, is the most favorable for the Turnip, although any good soil, well dug and manured, will grow them well. Sowings should be commenced in September, and continued at intervals of a few days up to the end of November. They should be sown in drills about twelve inches apart, and as soon as the plants are large enough should be thinned out to the same distance in the rows. The plants must be kept free from weeds, and the soil frequently loosened around them. They must also be kept free supplied with water and occasionally drenched with liquid manure.

The Silk Industry.—The prospects of the newly established silk industry in the Dun appear to be highly satisfactory. Messrs. Lister & Co., of Bradford, who have been connected with this work for some time, took over the business from Government in February last, and from that time all direct connexion of Government with it ceased. This in itself is a good sign. A piece of waste land has also been granted the firm for the cultivation of mulberry trees, and some 20 acres have been planted. The agent of the firm, Mr. Lepper, also has done much to encourage the ryots to take to the rearing of silk worms; and it is said the operation is becoming very popular. It furnishes employment to women and children when there is little else to be done, and the prices to be obtained leave an ample margin of profit for the expenses incurred. A maund of cocoons are estimated to cost the cultivator R12 all told; whereas the firm reaps a profit after giving even R30 for the same quantity. The industry is encouraged further by the distribution of medals and rewards, though these inducements will probably not be needed much longer. As Messrs Lister have announced their intention of buying up all the cocoons that are offered, the ryots of the Dun have happy prospect before them. The difficulty at present appears to lie in obtaining a sufficiency of mulberry trees.—Calcutta *Englishman.*

Barking Cinchona.—As to the desirability of covering the interval left after the removing of bark, I wrote to the *Times* in October, and I still maintain what I said then, that a great deal of money and bother might be saved by leaving the intervals exposed. Of course, a proper time must be chosen to bark in, that is during cool, cloudy weather, when there is neither too much sun or rain. The plan has been tried already to a small extent and with tolerable success. Some of the trees died from exposure, but the greater part renewed their bark splendidly, with no dimension in their percentage of alkaloids.—Officinalis. —Cor. of *Ceylon Times.*

The Effect of Light is shown by a reference to the alpine flora of Switzerland, in which the larger proportion of red, pink, and blue flowers in spring is remarkable. H. Muller attributes this to the greater transparency of the mountain air, and consequently more intense light. On this account and because of the spring being a month later than in this country, the alpine spring flowers are brightly coloured. This explanation is confirmed by Siemens's experiments with the electric light (*Nature*, 1881, vol. xxi, No. 535). Mr. Buchan, however, who bases his results on the whole of the British flora, considers that on the average the blue flowers blossom considerably the earliest (*Proceedings Edinburgh Botanical Society*, 1876).—*Pharmaceutical Journal.*

Tonic.—In the *American Journal of Pharmacy* for October, Mr. F. B. Meyer contributes an inaugural essay on *Parthenium integrifolium*, Lin., a plant of which the tops have been used for several years in some sections of Indiana, with good results in the cure of fever and ague. The herb yielded to petroleum benzene a dark green, waxy, slightly bitter substance, which treated with ether and water gave very bitter crystals, soluble in both liquids, and which gave a beautiful deep red colour with ferric chloride and did not reduce Fehling's solution. The infusion of the drug, with the addition of a little spirit to preserve it, is the form in which it is used in medicine. The liquid preparations of the drug have an agreeable orange-like odour.—*Ibid.*

Lantanas.—Thanks to the industry of Continental raisers, the garden varieties of this useful plant have greatly increased of late. Doubtless the old Lantana Camara was the type from which the first departure was made, and now as a result we have varieties of spreading and compact growth, tall and dwarf, large flowered and small flowered, and of many varying tints of colours. A large number of these are of great value for decorative purposes, and there are indications that the Lantana is rising in public favour. Objection has been taken to them on account of their strongly scented foliage, the peculiar tone of which is not grateful to most people, and hence, as Mr. B. S. Williams observes, they have been much neglected. But they have qualities of a high order which more than counterbalance this defect, if it can be termed so. For three or four summers past Mr. Barron has successfully demonstrated their great usefulness for bedding and pot purposes; indeed, for the former use they are attractive, durable, and particularly pleasing. The dwarf varieties are best adapted for bedding, but they are also most useful for pot purposes. As specimen plants for exhibition they are very effective, and it is not unusual at some country shows to see in August fine specimens of the rich-coloured Lantanas, such as Le Grenadier, grown into large plants, covered with healthy foliage, from amid which rise numbers of large trusses of bloom. Fine fresh specimens of Lantanas are far preferable to the stale Allamandas, Dipladenias, Ixoras, &c., one too often sees at shows at the end of the season. The Lantana can be had in bloom for the space of some eight months in the year, and the plants are rarely, if ever, attacked by insects—recommendations of no mean order.—*Gardeners' Chronicle.*

THE SWEET POTATO.—Specimens of this (obtained in Convent-garden) seem to be very much more watery and soft than those we have had in America. It is strange our American friends do not send some mealy and good samples of it, for it is an excellent vegetable in its best state properly cooked. We believe it is only in the warmer soils in the States, where it is in its best condition as regards texture, but know very little of the vegetable which cannot be successfully grown in our own country.—Ex.—*Field.*

A NEW SANDAL-WOOD.—M. Pierre describes in the *Bulletin de la Société Linnéenne de Paris*, 1881, p. 290, two species of Sandal-wood growing in Cochin-China, and forming large trees, the timber of which is used for ornamental uses, while the oil derived from it is used for medicinal purposes. When rubbed or burnt it emits an odour of Sandal-wood, on which account it is employed as incense in the temples. The two species are called respectively Epicharis Loureiri and E. Bailloni. —*Gardeners' Chronicle.*

FRUIT IN COLOMBO: MANGOSTEENS AND RAMBUTANS.—A correspondent gives the following hints for the growth of these fruit-trees:—"I send 4 mangosteens and 5 rambutan plants. You ought to have holes of about 24 inches diameter and 6 or 8 inches deep for them, at about 18 or 20 feet apart. Cattle manure is the best you can give them. I need not tell you that you ought to keep the plants covered during sunny weather and during the heat of the day only. They are both slow-growing plants; more especially the former, but after the third or fourth year, when they are, or rather will be, about a foot and a half high, they get on rapidly. I suspect that the growth in Colombo will be even slower than it is here (Kalutara).

CULTIVATION OF USEFUL PLANTS IN COSTA RICA.—In a report from San José, Costa Rica, it is stated that besides Coffee, which will always be the principal article of export from the country in consequence of the soil being so well suited for its cultivation, Beans, Corn, Rice, Sugar, and Cocoa are also grown for home consumption and but for the costly conveyance to the port would be more largely cultivated for export. The only new features to be observed under this head is the cultivation on the coast of Bananas and Cocoa-nuts on each side of the railway between the river Sucio and Limon which in time promise to be articles of considerable export, the want of a railroad hitherto for conveying the fruits to Limon having to a large extent prevented their cultivation.—*Gardeners' Chronicle.*

WYNAAD AND ITS GOLD MINES.—Devalah, Feb. 6th — Since my last commuuication, I have gathered some information respecting certain Mining Companies here, which may not be uninteresting. It is apparent that, when crushing does begin, it will be continued steadily, and by more than one Company. The South East Wynaad Company will soon commence the work of getting out the gold. Some trial crushings were, I believe, made at Richmond the other day, by Mr. Cooper. One hundred and eighty-two tons of quartz were crushed, and the yield is said to have been an ounce of gold per ton. This Company is about erecting a second mill, which speaks well, as Mr. Cooper would not surely have incurred the expense of this additional machinery, unless he had some very tangible reason for doing so. The "Phœnix" is attracting more than ordinary attention. The Australian machinery and mill, which Mr. D. Grove has imported, is now being erected, and is generally admitted to be the best in the Wynaad. The "Phœnix" will employ water (of which there is an abundance), as the motive power. Of quartz, the shareholders of this Company need have no fear, as there is no limit to it, and the character of the stone is considered very good. Mr. Grove appears sanguine of success, which is encouraging.—*Madras Mail*, Feb. 9th.

HARVESTING CINCHONA BARK.—An experienced cinnamon planter writes *in re* rubbing cinchona bark to facilitate peeling:—"Among the instruments that go to the outfit of every cinnamon peeler is a stick about six inches long, and one inch more or less in diameter, of the hardest wood he can obtain. This is used for rubbing the cinnamon sticks, to free the bark from the wood, as only the finest sticks, cut in the nick of the time, can be peeled without rubbing more or less."

SOUTH WYNAAD, 29th Jan.—I have been listening to some spirited discussions lately on the subject of pruning. The good old school, we know, recommends the use of the knife with great severity at this time of the year. "Cutting up his Tote into hat pegs" was the expressiou used as descriptive of the system in all its ancient rigour. Later experience teaches some of us that severe pruning is a mistake, that the trees are shaken by it, and weakened rather than strengthened by the immediate and entire cutting off of all the old wood from which crop has lately been removed. Indeed, enthusiastic disciples of the new school eschew the knife altogether. Leave on all the wood they cry; don't worry the trees just when they most need rest; wait till the monsoon, and let all handling out be done then at once—done with sufficiency and without the exaggeration of the hat peg system. In thinking the matter over, it seems that the new theory is a sensible one. Several planters are trying it; whether with good or bad results we must wait for the future to shew us. The cry, *in re* miners, is: "Still they come." What with miners and railways, and telegraphs, a new era is dawning for Wynaad. I know the European influx is already raising bazaar prices; and, before long, we must have domestics kidnapped, for at present they are as hard to catch and to keep as eels. They regard the unsophisticated miner as lawful and undisputable prey, and they scorn the very idea of going into the service of old residents, who, (as a cook naively remarked to me) "know too much, therefore poor man nothing can make in their service." Any decent servant could get almost instant employment at high wages in Wynaad now a days.—*Madras Mail.*

JAMAICA.—We have received from Mr. D. Morris, the well-kuown Director of the Botanic Gardens in Jamaica, a valuable contribution to the controversy respecting the labour question in Jamaica. Mr. Morris, who is one of the largest employers of labour in the Blue Mountain district of Jamaica, and whose opinion is the more valuable having regard to his experience in Ceylon, says that, compared with India and Ceylon, there is practically no labour difficulty with regard to coffee and cinchona cultivation, and that with an increase in population during the last ten years equal in proportion to that of the United Kingdom, the labour difficulty is likely to be felt less year by year. Mr. Morris has no object to serve in describing things otherwise than as he finds them. The truth about Jamaica will gradually make itself known amid the conflicting statements which her friends and her detractors make concerning her. All that the colony wants is a fair field and no favour. It is no use to try and shirk difficulties; but at the same time the advantages of the colony ought to be better known than they are. If a number of energetic and practical men with capital could be induced to take up their residence in the island, and do for it, under its present condition, what the old planting aristocracy did under its former circumstances, the colony would soon emerge from its present backward condition. Even the climate is not generally understood. In the hills life is most enjoyable, and the climate most salubrious. During the last two years only two cases of yellow fever have occurred in the island, and those were among sailors at Kingston Harbour. This simple fact should remove a thick cloud of misapprehension.—*Colonies and India.*

THE "BEARS" AND COCONUT OIL.

A merchant writes with a copy of the Annual Report of of Messrs. Rose, Wilson & Rose, dated January 2nd, as follows :—"See the enclosed report :—

Coconut Oil.—The position of the market during the past year was most unsatisfactory, as will be seen by prices, which declined to an extent never before experienced, and most ruinous to importation. The few fluctuations that did take place were maintained for no length of time and were generally followed by greater depression. The import was 10,645 tons against 12,307 tons same time last year, far in excess of our requirements. The deliveries notwithstanding the extremely low value show a decline. This is owing to the large importation of Copra, the greater portion of which is taken for abroad, where it is admitted free of duty, whilst oil is liable to a duty of from one to six pounds per ton. In January the market opened at £31 10s for Ceylon, and in March had declined to £27 10s. A slight improvement then took place but only lasted for a short time, as in August as low as £26 was accepted. This stimulated the demand, and speculators stepping in, there was a rapid rise until £29 was touched in September, from which there was a gradual decline to the present quotation. In July, large "bear" sales were made for shipment during the last four or five months at as low as £26 15s to £27, which could only be covered afterwards at a loss, and with a rising market in Colombo, as high as £29 to £29 10s, was freely paid here in August for those shipments. Cochin did not vary so much. Opening at £33, it steadily declined to £29 15s in August. In September the price had risen to £31 5s, at which it remained steady for some little while but again declined to £29. Mauritius.—The stock being held off the market until within the last month or so, little business was done in this description. The opening quotations are—Ceylon spot £25 10s in pipes and puncheons, January-February delivery £26; Cochin £29 Mauritius £26 to £26 5s in hogsheads. Copra oil £25.

"Is not this what I told you long ago, and it appears it has been recognized at home. Is it not a shame that an article in which, perhaps, only second to coffee, the island is most interested in, should be depreciated in value to such an *unprecedented* extent, mainly through 'bear' sales by people who worked for a fall. This should be fully exposed for the benefit of merchants at home? It is now pretty well certain that we shall have no larger supplies for another three months at least, and yet the makers or dealers have only been getting prices such as might have ruled with the largest supplies of nuts."

The case is certainly one deserving of all publicity, and very probably we shall by-and-bye find that coffee has been worked on by 'bears' just as coconut oil is now shewn to have been.

FARMING IN DAKOTA, UNITED STATES.

(*By an ex Ceylon Colonist.*)

We have been favoured with permission to publish the following extracts from the letter of a gentleman formerly resident for some years in Ceylon:—

Ontario, Dec. 18th, 1881.

I went up to Dakota in the spring to have a look around and help with the seeding.

So I have been here in Canada, doing the watch-dog during the summer. Before I forget it, I will at once ask you to find out, if you can, from Mr. Sumps, about the rattans he uses in his work. A firm here in Woodstock wants to get them out direct, instead of dealing, as they do at present, with firms in New York, who, they say, take advantage of them. They would like to find out about the different qualities, where they are procurable, how they are generally sold, by weight or length or what, and anything else about it you can find out. I wanted them to give you a run up to Madras, if you thought it necessary, to find out there, but they did not think it worth while till they heard more definitely. This, I thought, would have made a nice holiday trip for you, but it may come yet.

I think I must tell you some of my ideas of Dakota.

Dakota, I may tell you, is about 400 miles from E. to W. and between 800 and 900 miles from N. to S.: quite a respectable little bit of country. This is all divided into counties, at least so much of it as is surveyed, but there is still lots of it wild. These counties are generally about square or oblong, varying from 25 to 50 miles in either direction. These again are divided into townships (corresponding to parishes) of 6 miles square, and contain 36 sections of land, each one mile square. Thus, you will see, that the country is all divided off like a draught board, with roads crossing one another every mile. So much for the divisions. Now for the land.

The Red River is the eastern boundary of the territory and the town of Fargo is on the Dakota side of the river. It does not look much of a place in the woodcut, but it is growing amazingly, and now numbers between 4,000 and 5,000 inhabitants. The land of the Red River valley is considered to be the finest out, for grain-growing. It is just about as flat as can be, all up the valley for about 8 or 9 miles on each side of the river, and then it rises a little, and for 20 or 30 miles further west it is very similar; only higher and drier. In the summer, this does not make any difference, but in spring it is an advantage to get grain sown as early as one can. This last spring was an exceptionally late one, and many of the farmers near the river did not get any crop. When I was there, I saw some miles with the water one to two feet deep, and the seeding was then almost over at our farm. What made the spring so late was that there was an unusually heavy fall of snow during the winter, and it did not thaw out till near the end of April. Every other year that my brother has been there,

they have commenced seeding about the beginning of April. Farther west again than the land I have described, there is flat land and bluffs; all good for farming. I can hardly describe to you what the bluff land is like, but will try. Can you imagine as if some mammoth moles had been at work, and gone over the ground so that their molehills were all over, and these molehills, from ten to thirty feet high, and many of them running into one another, and you have about as good an idea as I can give you, till you see it for yourself. West of that again the land is varied, both bluff and flat interspersed.

Now, as to soil, it is something different from any I have seen elsewhere. In colour, it is a nice chocolate brown; in depth from ten or twenty feet near the Red River to about a foot less or more some forty miles west. Below that, the subsoil is mostly clay; some places stiffer than others. The ground dries wonderfully quickly after a soaking, and, in the spring, when the frost is coming out of it, the seed can be sown whenever the frost is out deep enough to harrow. I found the seed drill often scraping through the upper surface of loose soil on the frozen place below. The frost usually penetrates four or five feet, and this thawing out gradually keeps the land just moist for the young grain, and ensures the good start it gets. When I was seeding, the dust was blowing on the surface, and it was frozen land six or seven inches below; it dries off so quickly.

As to the weather, in summer it is much the same as we have it in Ontario, but not quite so variable. Usually the autumn is very dry and favourable for harvesting work. This was an exceptional season, as there was a good deal of rain just after the grain was cut and bothered farmers in their threshing. They just cart it to the threshing machine from the stook, and shift the machine to various parts of the field usually twice a day.

The winter comes on a little earlier than in Ontario: usually about the beginning to the middle of November, when frost sets in and ploughing ceases. It continues till the end of March, or the middle of the month, when the snow which lies all winter quickly melts, and the seeding begins in a few days after. The winter weather is rather colder than we have it in Ontario, but is not so variable. Indeed, the whole season the thermometer is seldom above freezing point, but the atmosphere is so dry that the cold is not much felt. Ten degrees of frost in Scotland is more felt, owing to the moisture in the air, than fifty degrees is in Dakota. It is even better in that respect than we are here, and strange to say, when the cold gets so intense as that the air is as still usually as in a house. Sometimes they have what they call "blizzards" that is (blows hards) when the wind sweeps across the prairie in a gale, and generally accompanied with snow, when it is not always safe to go any distance. There being no fences to guide one, and the snow falling preventing one from seeing many yards around, people have wandered for miles, often passing within a hundred yards of a house and not knowing it, and sometimes perishing. That is one of the drawbacks to the otherwise "paradise"; the other, and I think the only one, is the water. All the ground is impregnated with alkali which gives the water a peculiar flavour, which those who taste it first seldom like, but most folk get very fond of it. During the month I was there I got to enjoy it. Now the wells are usually dug 50 to 80 feet deep, and kept well pumped out, and then the peculiar flavour is hardly perceptible. It then has just a slightly sweetish flavour. At the depth I mention an abundant and never-failing supply of water can always be had. Then there is this to be said in favour of it, that it is very wholesome. My father always enjoys much better health up there and for sometime after his return than at any other time, and attributes it to the water. Now, that, I think, is all about the place, as a place. I will next try and tell you what is done there, and how it is done. Well, it is a grain-growing place, almost no stock being kept so far, but, as the country gets settled, mixed farming, of both stock and grain, will be adopted. Wheat is the chief product; next oats and flax seed. There are no fences or very few, so that owners of stock are responsible for any damage they may commit on any other property. What fences there are are made of wire with wooden posts, and they are the most suitable, as the snow does not drift behind them, as any other fence.

Farms are mostly about 320 acres in extent, though many are much larger. Four and five thousand acre farms are common, and our next neighbour, who is the largest wheat grower in this continent, or may be in any, had this season about forty thousand acres in crop.

In the spring, whenever it is possible for the frost seeding wheat begins, and in about a fortnight it is usually all in. Next comes sowing oats, which may be done anytime in the next month, but the sooner the better. Generally the oatland is plowed after the wheat is sown. When these are done, the hurry of the spring is over, and other general work on the farm goes on till haying, when the winter's supply is made, and generally stocked in the place it is cut. This hay is cut off the prairie, the natural grass, which is very sweet when cut green. To get a good crop of hay, the first time on the prairie, it is burnt over in the spring, which takes away all the hard wiry grass of the previous season. It is no trouble to burn it off, as throwing down a lighted match is all that is needed, before the new grass has started. In a week after, it is as beautiful as a braird of wheat, and grows very fast. As the country gets settled, of course, farmers will have to sow grasses on their own farms, but, at present, there are many sections uncultivated, held by speculators in the eastern states, and anybody who likes cuts hay on them. The way they do it is this. A man starts and cuts round with the mowing machine as much as he thinks will suffice him, and all within the cut he makes is considered by others to be his hay. This prevents any disputes, and, of course, the early bird usually picks out the biggest and fattest worm. In the fall, to protect the stocks from fires, they plough round them, about forty or fifty feet from them, two or three furrows, and ten or fifteen feet further two or three furrows more, and, on a still day, they set fire to the grass in the belt between them. This forms an impassable barrier to the fires, either in fall or spring. The same thing is done round houses that are out on the prairie. Flax is sown any time before the beginning of June, but there is not very much grown. If the farmer has any more prairie land than he wants to crop, it is broken up, that is, plowed for the first time before the middle of June, and plowed again in August for a crop the following year. The first plowing is usually about 3 inches deep, cut off and kill the sod; the second is about 5 inches deep. The plows are quite different, but I will tell of them again. Next comes harvest. The grain is all cut and bound with machines that do it in one operation; the band is either of thin wire or twine. Each machine is able to do from 150 to 200 acres a season, and is drawn by three horses. A gang of men to stook follows the machines, and the grain is cut all before threshing begins. This is begun as soon as possible, and is done by portable machines, driven by a portable steam-engine of 6 to 8 horse power. A gang of 24 to 30 men is needed to run the threshing machine, and a day's work is from 800 to 1,400 bushels of wheat, more of oats.

Threshing is done in the fields, and the grain is taken off at once to the railway station and put into

the warehouse, or, elevator, as it is called, and sent off as soon as possible.

In winter nothing is done but feeding the stock of horses, and cleaning the seed grain for the following season.

A windmill is generally on every farm, and is used for grinding up the horse-feed, and pumping water. They are made self-regulating, so that if the wind blows very strongly they go more slowly, or even stop altogether. The only trees are along the sides of rivers, in a strip of half-a-mile or so on each side, and that is all the wood there is for fuel; but there is lots of coal in the west and north-west of the State, which is being made available for the market by means of railways. There are no lack of railways, or will soon not be, as several competing lines are stretching all over just like a spider's web, and all of them have far more traffic than they can manage at times.

Land is procured in various ways. If a foreigner wants to get a farm, and yet *not* to become an American citizen, he must buy from another man or a corporation, such as a Railway Company, such as the Northern Pacific R.R. To enable this railway to build their track through what was then a wilderness, the Government granted them the half of the land on each side of the line twenty miles wide, that is forty miles in all. That was through the *territory*, which has not yet been incorporated into a State. Through a State, the grant was only half that width. That strip is all surveyed and marked off into sections of a square mile each, just like a draught board, and the black squares are granted to the Railway Company, while the white ones remain the property of the State. This is to prevent speculators buying up large blocks in one piece, to the disadvantage of the country being settled. Lands of that class before mentioned can be purchased from $4 an acre upwards to $12, if unbroken by the plow, according to location and quality. Eight to ten dollars is a common price anywhere within a few miles of a station for first-class land; cheaper further back. If improvements have been made, the price may go as high as twenty-five dollars an acre, but fifteen to eighteen is an average price near railways. Of course, it is only within ten to fifteen miles of a railway that the land is being largely cultivated. Lands of the foregoing class can be bought by a man in any quantity, according to his purse, but, as for the lands belonging to Government, one man can only get at most 320 acres, and then on certain conditions.

First the purchaser must become an American citizen. There are three ways of getting this land: by taking up land as a homesteader, by pre-empting land, and by taking up a tree claim. One man can choose two of these three methods, and take up 160 acres or less on each of the two ways, or he can take one only at 160 acres. Homesteading is the cheapest. A man takes a quarter section 160 acres of Government land goes to the registry office and files a claim to it, paying only a fee of three or four dollars. He must live on this land four years out of the next six, and, at the end of the six years, if he has done so, it becomes his, and he can get the title deeds made out, costing about $15 to $20; that is all he pays. Pre-empting the man gives notice the same way for another quarter section; paying the fee, he has to live on it for six months of the next year, and then can buy it from Government for two dollars and a half an acre. In taking up a tree claim the quarter section is selected, and notice given in the same way, and the man requires to plant one-sixteenth of it, ten acres in forest trees, keep this in order for eight years, so as to form a small plantation of trees, and if he does so, he, at the end of that time, can get the title deeds by paying the fee of $15 to $20. So that, you see, a man with comparatively little capital can take up 160 acres as a homesteader, 160 more on a tree claim, and, if he can struggle through the first three years, at the end of eight years, he is the possessor of 320 acres, and an American citizen, or he can homestead and pre-empt, or pre-empt and take a tree claim. Even if forced to sell sooner, his claim to the land brings a fair price, though he has not got his title-deeds.

I think that is about all I can say about the country, except that like all newly peopled districts life is much rougher than in the older districts, but a very short time serves to shake down the different atoms to their bearings, and even at first they are quite as law-abiding as further east. No one thinks of carrying weapons there any more than where I am at present.

Farming there has been made a science of quite as much as anywhere else, and economy is looked to as a first item. If it is economical to buy a machine, it is got, or the reverse, and credit can always be had till after harvest.

Now, as to whether you would like it as a place to settle or not, I would not take it on me to say. I think you would. And there is one thing of which I am certain that money can be made at it. Taking the experience of my father for the last eight years, I can say that any one investing in a farm can have the money he put in all out again in that time (eight years) if fortunate in good crops and good prices every season, even in five or six years and would also be the owner of the farm, stock and buildings, which would be worth 50 % to 100 % what he invested. In the Company my father is in there was a sale of a portion of the property, which realized more than the original investment, which was divided among the shareholders, and what remains is so increased in value that the original shares of $100 each are worth $200, and giving a dividend this year of 8 per cent, besides paying off a lot of borrowed cash. Now they were very unfortunate the second year, losing all their stock implements and buildings, which were insured only to a small extent, and that crippled them for two years very much.

For several reasons I could not wait there this season, but I am going to make a start next spring, if all's well, on 3,200 acres, which I hope to make a good thing of. Here is a calculation, based on my father's experience, shewing how a man with £2,000 capital could buy a section 640 acre one time, paying it by annual instalments of $1,250 a year, interest at 7 per cent, and clear himself in 6 years, casualties excepted, and have all paid for:—

		$
First year, no crop.		
Contract to break and replough 160 acres		720
Erect buildings &c.		2,000
Interest 450 taxes 30		480
		3,200
Second year, first crop.		
Stock and implements and granary	3,270	
Wages, harvest expenses &c. (700)	1,680	
1st instalment and interest	1,700	
Taxes	50	
		6,700
		9,900
Crop 150 ac. wheat=3,000 bushels @ 80 c.		2,400
		7,500
Third year, second crop.		
Stock and implements.		2,960
Wages and harvest expenses &c.		3,035
		13,555
2nd instalment and interest		1,615
Taxes		70
		15,240

Crop 450 ac. wheat=900 at 80 c.			7,200
			8,040
Fourth year, third crop.			
Implements		400	
Wages and harvest expenses &c.		4,200	
			4,600
1,250	365 70		1,595
3rd instalment, and interest and taxes			
			14,235
Crop 600 ac. wheat 12,000 bus. at 80 c.			9,600
			4,635
Fifth year, fourth crop.			
Wages, harvest expenses &c.		4,200	
1,250	185 70		
4th instalment, interest and taxes		1,505	5,705
			10,340
Crop as last year			9,600
			740
Sixth year, fifth crop.			
Wages harvest expenses &c.			4,200
Last instalment 1,400 int. 100 taxes 70			1,570
			6,510
Crop 600 ac. as last year			9,600
		Profit	3,000

Recapitulation.

At the end of fifth crop (casualties excepted) you have 640 acres of land which originally cost you ...		6400
Buildings cost		2700
Implements and stock cost		5,660
		14,760
Also the original capital of £2,000 which has not been taken at all into the calculation, but used as working capital, say equal to		9,000
Profits at end of last year		3,000
		26,760

Shewing how £2,000 may in six years be increased to $26,000. The property would readily sell at the valuation I have put on it, viz. $14,000.

Now you see what a man may do buying the farm at $10 per acre. You can see what a settler on Government land may do, getting 320 acres for next to nothing, if he has only a little capital. I do not think I need say any more, as figures shew better than any explanation I can give you.

There is a great exodus from the Eastern States and Canada, both to Dakota and to Manitoba. The land in the latter place is just as good, and chances would be equally good there but for the fact that the railways there have fallen into the hands of a monopoly that take the thick of the cream off, and a Tory Government we have in power here do all they can to help them. But for that I should have gone to Manitoba, which is under the British flag.

This winter in Canada promises to be a very mild one. Here we are within a week of Christmas, and not a particle of snow on the ground. We had a few days sleighing a month ago, but it has been mild weather ever since, and ploughing was going on till a week ago, when we had just frost enough to stop it. I feel such a difference this winter in being able to stand the cold. Last winter I felt it very much, but that was in being run down so before I came.

THE POSITION OF THE COFFEE TRADE AND ITS PROSPECTS.

Amongst a perfect avalanche of Price Currents which last mail has brought us, are Patry & Pasteur's, Rucker & Bencraft's, and von Glehn & Sons' annual reviews of the trade in colonial (perhaps we should say tropical) produce, in which coffee takes a prominent place. The figures confirm what has already reached us as to accumulated stocks in European markets, and the enormous increase in the quantity of coffee Brazil is able to send into the markets of the world. The latter, however, is the great factor in the severe depression which is likely to affect us so seriously. Whether we take the actual figures for the calendar year 1881, or those estimated for the season which began with 1st July 1881 and will end with 30th June 1882, the result is much the same: an export of seven millions of hundredweights, besides the local consumption of, say, 600,000 cwt., the latter being equal to the total of our estimated crop. The exports in 1881, in round numbers, were:—

From Rio	5,200,000 cwt.
,, Santos	1,660,000 ,,
Together	6,860,000 cwt.

Ceará and other places making up the round seven millions. The estimate for season 1881-82 is even worse, in consequence of Santos being expected to export two million cwt. of coffee, much of which competes with our Ceylon plantation. We scarcely see why Rio, which exported 254,000 tons last season, should be estimated at only 235,000 for the present, but, even so, the figures are:—

Rio	4,700,000 cwt.
Santos	2,000,000 ,,
	6,700,000 cwt.

Other ports would make up the 7 millions. But Rucker & Bencraft, whose estimate the, above i t adds—

At the present time the 1882/1883 crops in Rio and Santos promise to be enormous, some saying that Santos alone will give 2,000,000 bags. It is estimated that the crops together will total not less than 6,000,000 bags, or say 353,000 tons.

The equivalent in cwt. of 353,000 tons is 7,060,000. Messrs. Robert von Glehn & Sons, who have recently had a passage-at-arms with Kern, Hayn & Co. of Rio, take a more hopeful view of the prospects of the coffee trade, because they doubt the capability of Brazil to export the large quantities estimated in other quarters. We quote as follows:—

The stocks of Coffee in Europe have increased during the past month about 11,000 tons, and prices have still further declined:—middling Plantation Ceylon Coffee, which we then quoted 77s to 82s, is now barely worth 72s to 77s; and good average Santos, which was then worth 60 fr. in Havre, is now quoted 56 fr. per 50 Ko. It cannot be denied that some failures in Bordeaux, of firms but slightly interested in coffee, have contributed largely to accentuate the decline in prices. Our opinion is that the alarm which appears to be felt as to the financial position in Havre is excessively exaggerated, if not entirely unfounded, as, owing to the admirable system for advances on produce carried out by the Bank of France, no large losses are likely to remain long unpaid, and no large quantities of coffee are likely to be forced for sale at one time, the future course of the article must therefore be studied on its own merits.

On the other hand we hear that two gentlemen who recently visited Ceylon *en route* from Rotterdam to Java stated that dealers in Havre had speculated for a rise and had stocks of Brazil coffee equal to 1,300,000 cwt. The Dutch gentlemen added, as their *opinion*, that coffee would not again touch 70s. for three years to come. Our readers can judge for themselves. Messrs. von Glehn make a long statement

to support their shorter estimates of coffee from Rio. They do not believe that 1,500,000 bags *could* be kept upcountry, and add:—

We are by no means convinced that the quantity of old coffee remaining upcountry is so large, and we venture to maintain our opinion that the receipts will be smaller, and may even fall to such a point as will revive the lifeless markets of Europe and America.

We wish we could share this hopeful view. Regarding Santos, the price current we are noticing states:—

The Santos crop of 1881-82 is variously estimated from 1,500,000 to 1,800,000 bags, but taking it at the average of these two figures, viz., 1,650,000 bags, and deducting the shipments of the first six months of the season, viz., 753,000 bags, we find available, for the six months from 1st January to 30th June, 1882, 892,000 bags.

It looks, therefore, at present as if the shipments from Santos during the next six months were likely to be largely in excess of those during the same period of last year.

If the present Santos crop does not, however, much exceed 1,500,000 bags, which is the estimate of our own Santos correspondents, and if the Santos planters hold back rather more coffee than usual, the quantity that will be shipped to Europe during the next six months may after all not be so large.

It must, however, be remembered that Messrs. Bradshaw and other eminent authorities estimate the 1882-83 or following crop at 2,000,000 bags. Santos coffee is not likely, therefore, to be less plentiful for some time to come than it is now, and we doubt the wisdom of paying a premium for future and distant delivery of this kind of coffee, as is at present being done in the Havre market.

The stocks of Brazil coffee in the United States were 15,000 tons in excess of last year,* while in the United Kingdom, Holland, Hamburg, Trieste, Havre, Antwerp and Marseilles, we get an excess of 36,000: together 51,000 tons over the stocks at the end of 1880. To this has to be added the large stocks in the two Brazil ports, and then we can understand the heavy fall which has taken place in prices. Amongst hopeful facts we note that the deliveries of coffee at Havre rose from 43,459 tons in 1880 to 54,877, or more than 11,000 tons excess, in 1881. But it is in the United States that the great increase of consumption is shewn which has prevented worse consequences and at an earlier date than have occurred. The increase in five years has been from 134,000 tons to 195,000, an excess of 51,000 tons, or in cwt. 1,020,000; the actual consumption last year by the forty-five (?) millions of people being 3,900,000 cwt. The deliveries for the past two years have in fact exceeded the imports as in the case of Indian tea in Britain. Here are the figures for advancing consumption in the United States:—

1877	...	134,500 tons
1878	...	144,000 ,,
1879	...	180,000 ,,
1880	...	174,000 ,,
1881	...	195,700 ,,

The contrast, in the case of the United Kingdom, is deplorable. Our population has increased to about thirty-four millions, but the consumption of coffee has gone down from 15,000 in 1879 to 14,300 tons in 1881. We are in truth now 100 tons below the figure for 1873. Those who place faith in the impudent fallacy that the mixing of chicory with coffee helps instead of hindering the sale and use of the latter will do well to listen to what Messrs Patry & Pasteur have to say upon the subject. They represent the use of coffee as being abandoned, because those who wished to drink the genuine article despaired of obtaining it:—

From the above figures, it will be seen that the trade in this article in the United Kingdom has been smaller than in any of the previous ten years, both as regards import, export, and we may even say consumption, if we bear in mind the increase of population which has taken place in the last eight years: and even the consumption of chicory in 1881 shows a slight decrease on that of 1880; but no one in the trade will be surprised at this, as it is the natural result of the unchecked and unprincipled adulteration going on under Government sanction and protection; and the impossibility which exists in many places for consumers to procure anything but a vile mixture under the name of coffee, is probably driving many of them to give up the use of the article altogether.

The gentlemen who were responsible for "burking" the "Adulteration Memorial" in the Planters Association may well take shame to themselves after this.—Continuing their review, Messrs. Patry & Pasteur write:—

Prices have declined considerably during the past year, and they are now lower for Ceylon and East India, both plantation and native, than at any time since 1871, As compared with this time last year, the decline upon plantation coffee is 10s per cwt., on Rio 11s per cwt., on Santos 14s per cwt., and 4 cents on Jaua in Holland.

The deliveries for consumption in the principal European ports are estimated at 369,600 tons in 1881, against 348,800 tons in 1880, and 375,500 tons in 1879, and in the United States at 194,000 tons, against 174,000 in 1880 and 180,000 in 1879.

Taking these figures as reliable, the total consumption of Europe and the United States in 1881 amounted to:—

Europe	...	370,000 tons=7,400,000 cwt.
United States		194.000 ,, = 3,880,000 ,,
Together	...	564,000 ,,=11,280,000 ,,

The consumption in Australasia, &c., and in coffee-producing countries will raise this figure to over 700,000 tons=14,00),000 cwt. We had received a letter from a planter questioning the figures quoted from the *Statist* with reference to Java crops. But we see no reason to doubt their correctness. In the 11 years 1871 to 1881, the exports from Java have fluctuated greatly. In 1871 the total was only 32,000 tons, of which 446,000 bags were government and 60,000 private growers' produce. The very next year the export rose to 68,000 tons, made up of 986,000 bags government and 99 000 private,—the proportion of the latter being very little over 10 per cent of the whole. This proportion was largely increased when the big crop of 1876 came. Of the 96,000 tons exported that year, 240,000 bags were private against 1,286,000 government. Each bag, no doubt, contains about a pikul, for the total number of bags was 1,526,000, while the equivalent of 96,000 tons in cwt. is 1,920,000. Java, therefore, has never come closer to the round two millions than within 80,000 cwt.; while Ceylon did not, in her best year, 1869, go quite 70,000 cwt. beyond the round million. In 1880 the Java export went down to 49,000 tons from 94,000 in 1879, a fall of more than one half. Last year, however, there was a recovery to 82,500 tons, the proportion of private (notwithstanding the policy of the Dutch Government, in opening estates on the best mountain ranges and forbidding the presence of

* Patry & Pasteur, on the contrary, show 17,700 tons nly of stocks against 19,000, or 1,300 tons decrease!

private planters on the same range with a government estate, lest the produce of the latter should be appropriated!*) had risen to 325,000 bags against 1,051.000. Private growers are, evidently, at length, making head way in the Dutch colony. But while Java in the 11 years has not appreciably increased her production, if we take the averages of the first six years and the concluding five, and while Ceylon has gone down from 46,000 tons in 1871 to only 22,700 in 1881, the progress of Santos has been steadily onwards. When Java gave her great crop of 96,000 tons in 1876, Santos gave only half the quantity; but in 1881 Santos had risen to 71,000 tons against Java's 82,500; while in 1882 the port of the district of São Paulo is likely to export 2,000,000 cwt. (bags of 17 to the ton rather!), or probably equal to the aggregate exports of Java and Ceylon. We expect only 600,000 cwt., and, judging by the past, Java is not likely to greatly exceed 1,400,000. If the English and Dutch colonies thus compare with one port in Brazil, what is the contrast with the whole empire? Its *exports* are equal to half the whole produce of the world, besides the 60,000 tons retained for home consumption. In every sense Java and Ceylon, but especially Ceylon, have been exposed to unfair competition. Java, no doubt, grows coffee by compulsory labor, but there is a wide difference between feudal serfdom, qualified by benevolent laws, and the inhuman slavery which has enabled Brazil, temporarily, to win by so many lengths in the race. To continue our extracts from Patry & Pasteur's review :—

Stocks in the European ports on 1st January are 36,000 tons in excess of what they were a year ago, and in the United States 2,000 tons less.

The new Ceylon crop is expected to exceed the previous very short one, and estimates point to a total of 33 to 35,000 tons. British India will probably send rather more than the previous season. Costa Rica and Central America have generally good crops. The Java crop of 1881, which will form the bulk of the supply for 1882, is a good crop; but the growing one, which has been suffering from drought, will probably be smaller. The all important crops, however, are Rio and Santos, and from those countries, full supplies must again be looked for. It is estimated that the shipments from Rio, from 1st January to 30th June next, may amount to 110,000 tons, and from Santos to 35,000 tons. The growing crops, so far, promise well from both countries, especially from Santos.

With the heavy stocks now held in Europe, it appears, therefore, that we shall have abundant supplies of coffee during 1882, and it would seem as if the lowest point had not been reached yet.

In the period under review the fall in prices has been in sympathy with the enormous production of Brazil. Ceylon plantation has gone down from 125s in 1873 to 75s at end of 1881, and our readers are aware of the further fall to 67s; since partially recovered. Native Ceylon has fallen from 110s to 50s (now 44s!); Java has fallen from 66 cents in 1873 to 33½ at end of 1881; Rio afloat from 83s in 1869 to 42s at end of 1881, and Santos from 84s a float in 1874 to 44s.

We must take comfort in the certainty of enlarge consumption and in the proverb that when things are at their worst they are sure to mend.

* A curious reversal of the position of the planter in Ceylon, at which, when in Java, we could not help feeling amused.

PRODUCTION OF CINCHONA BARK.

The following paragraphs occur in James Cook & Co.'s cinchona bark report, dated 8th December :—

According to the returns just published, there were under cultivation near Darjeeling in 1879 on Government account 2,174 acres cinchona, containing about five million plants, also in the Nilgiris about 1,100,000 plants, and in Burma nearly 100,000 more. On private account there were about 1,800 acres planted in the Darjeeling district, as well as a considerable extent of land in the Nilgiris, of which the produce is sent to England for sale. That of the Darjeeling Government estates is all used for consumption in India, but in spite of this the importation of quinine was for the years ending 31st March :—

	1875-76	1876-77	1877-78	1878-79	1879-80
Lbs	3,925	4,648	5,025	5,940	7,409

The export of bark was :—

Lbs	26,992	72,452	286,944	227,179	459,286

In Ceylon, cultivation is extending, but on some estates the progress made is not so satisfactory as could be wished, the plants dying out. In Java the crop for 1880 is said to have been fully 100,000 lb.

Board of Trade returns of bark, 1st January to 30th November :—

COFFEE LEAF-DISEASE :—MR. SCHROTTKY'S EXPERIMENTS.

We are told that a good many proprietors are now preparing to give a trial to Mr. Schrottky's mixture. When Gangapitiya estate was last visited by Mr. Schrottky, accompanied by several gentlemen, interested in the experiments, the opinion was expressed that the immunity from leaf-disease, which that estate had enjoyed during June-December, might probably to some extent be due to an exceptionally dry South-west monsoon, while adjoining estates, that had greatly suffered during the larger part of that time from the disease, might have had more rain. It was stated at the time that with regard to immediately adjoining estates, there had been no difference of rainfall. It was however, so easy to attribute the successful results of the treatment to some such natural cause, that, without careful enquiry, this mere probability of difference in rainfall has, we hear, been spoken of as an ascertained fact, and Dr. Shipton, for instance, writes of it as being a great qualification of the results obtained. The following details supplied by Mr. Schrottky seem to dispose of the argument in that direction :—

"SUMMARY OF DAILY WEATHER REPORTS: GANGAPITIYA ESTATE, AGAINST AMBACOTTA AND GANGAWATTE ESTATES.

June 1881.

9	days showery	9	days drizzle and showery.
1	,, rain	1	,, rain.
20	,, fine	20	,, fine.

July.

4	days showery	5	days drizzle.
27	,, fine	26	,, fine.

August.

10	days showery	6	days leaf drizzle.
		5	,, showery.
21	,, fine	20	,, fine.

September.

6	days showery	5	days drizzle and showery.
24	,, fine	25	,, fine.

October.

13	daye rain and wet	6 days	showery.
		7 „	rain.
18	„ fine	18 „	fine,

Ambacotte and Gangawatte are two immediately adjoining estates, where leaf-disease, as usual and in common with the bulk of estates in Dumbara, had been showing up since July, being particularly bad in October and again at the end of December, during all which time Gangapitiya was almost absolutely free. The estates nearer Kandy, Pallekelly for instance, get a little more rain during the S. W. monsoon than the estates above referred to, but so far from the greater rainfall having resulted in a greater show of leaf-disease, there was on the contrary in October last less at Pallekelly than furthor up the valley. We would again draw the attention of planters to the facts established by Mr. Schrottky's experiments, viz. that leaf-disease can be successfully checked during all the seasons of a year, and that given the commencement of the treatment at a favourable time of the year and systematic continuance, the disease can practically be kept out of an estate as long as the treatment is continued, though surrounding estates may keep up a continual supply of spores.

The treatment being compared by Mr. Schrottky, at an early stage of his experiments to a weeding, the reapparance to some extent of leaf-disease at Gangapitiya, after the discontinuance of the treatment, affects its merits as much or as little as the reapparance of ordinary weeds affects the merits of weeding. Gangapitiya has again been visited by Mr. Schrottky a couple of days ago, and, though leaf-disease has been found prevalent, the estate maintains its superiority over adjoining estates; there has been no leaf-fall and no dying-back of wood has taken place. Mr. Schrottky says that leaf-disease throughout the valley, rainy weather notwithstanding, is passing away.

Since the above was written, we learn that the weather reports from Henegahawella have been examined. This was one of the estates at the end of the Dumbera district, the immunity of which from leaf disease in December was supposed to qualify the results obtained at Gangapitiya during the last South-west monson. Counting from the beginning of June to the beginning of October, we learn that the days on which rainfall is reported from Gangapitiya aree double those reported from Henegahawella!

THE TEA-PLANTING ENTERPRISE OF CEYLON.

Out of a very apparent and tangible evil, good has undoubtedly resulted in the case of Ceylon as a planting colony. Had it not been for the persistent ravages of leaf-disease, we very much doubt if our planters would ever, as a body, have been persuaded to turn their attention to the cultivation of any other product eave the one staple, coffee, and a country dependent for its prosperity on any one product would always have been in a very hazardoue position. The persistency of the fungus has changed all that, and, though we are far from concealing the overshadowing importance of coffee even now, yet there is, we suppose, no district and no planter today without an interest in "new products" which interest will steadily increase season by season, if not month by month. Leaf-disease may be said to have done its work, and if any faith is to to placed in "cycles," it ought now to leave us; but, even if it does, the low prices for coffee bid fair to accelerate and intensify the process of substituting new products for the old staple. Among the former—cinchona, cardamoms, cocoa, Indiarubber, Liberian coffee, wax-plant—few are as promising as tea. We have frequently remarked that the western and the greater portion of the central divisions of Ceylon were evidently intended by nature for a tea-growing country. "Leafage" is the predominant characteristic of the vegetation, and the constant humidity and the almost uninterrupted monthly rainfall—often so adverse to blossom and fruit-formation—are just the conditions in which the tea-plant ought to rejoice and bring forth flushes more abundantly. The fact is being generally recognized, but the scarcity and comparative dearness of seed have hitherto prevented that "rush" into tea-planting, which under more favourable circumstances we should probably have witnessed. Nevertheless, that a great deal more has been done than is generally understood may be inferred from two facts mentioned to us the other day "at the kraal" by Mr. Elphinstone:—the tea seed sold from Horagala estate alone last year realized R16,000, and the area planted with tea on this gentleman's group of properties now aggregates 1,500 acres. Of course a great portion is young, not yet in bearing, but the shipments from this quarter alone in 1882 ought to equal 100,000 lb. For the current season we shall be disappointed if the total exports fall short of 500,000 lb., no great quantity when compared with the millions from India or the hundreds of millions from China, but nevertheless a quantity which affords good promise of the greater things to follow.

The planting of tea—even if there be no special "rush"—is sure to go on rapidly in Ceylon. Every Indian planter of experience who has seen our plantations, convenience of transport, and mode of working labour, has acknowledged the great advantages we possess. The latest testimony has come from Mr. Cameron—an old Assam planter and proprietor, who is for a time watching the tea production and preparation on Windsor Forest estate. This gentleman has had to do, in days gone by, with the establishment of several Assam Tea Campanies, and, be speaks in terms of unqualified approval of the prospects of our local enterprise. He is prepared to do all in his power to convince English capitalists and authorities on tea that Ceylon is destined to be a tea-producing country of very considerable importance. Both in the lowcountry and far up on the Adam's Peak range, there is virgin forest land well adaptrd for the cultivation, while a good deal of cleared land that ought never to have been opened with coffee, is still capable of being profitably utilised for the sister plant.

We need not refer to the fair prospect of increasing demand and remunerative prices for Indian and Ceylon teas the only condition in our case being improved preparation, for which machinery no less than close and skiful attention is required. The latest evidence of this fact is contained in a communication from a Ceylon resident now in England, who is well qualified to look into the matter, and the results of whose investigation are deserving of the careful consideration of our tea planters. He writes:—

"Since my arrival in England, I have taken advantage of every opportunity to ascertain the opinion

held regarding Ceylon tea, and find that those who have used it object to its peculiar herby flavour. Some of it, which I procured in Glasgow, had that flavour very strongly, and was not nearly equal in quality to that which I used in Ceylon. For some little time past I have been attending at the Customs here and have had an opportunity of learning the opinions held about it by practical men. While all speak highly of its purity and strength, they seem all to be of opinion that it is not nearly so well cured and prepared as China tea.

"Mr. Exall, the tea analyst at the Customs, is of opinion that, in curing Ceylon tea, the process of fermentation is not properly and sufficiently carried out, the leaf not being sufficiently exhausted and the essential oils, which he considers unpleasant to the taste and unwholesome, not being sufficiently destroyed and removed. The official tea examiner at the St. Catherine Dock Warehouses holds very much the same opinion, but attributes the objectionable flavour partly to a supposed difference between the variety of tea grown in Ceylon and that grown in China, or to a difference in climate and soil. So far as I can ascertain, Ceylon teas seem to realize in the market here a considerably higher average price than China teas, but they are hardly known under their own name, and appear to be used almost entirely for mixing with and bringing up the strength of weaker China teas. Would it not be to the advantage of Ceylon, if its tea took a higher place in the market and became known under its own name. It is quite evident that it is not liked by consumers, because of its herby flavour, but it is equally evident that it is valued by dealers for its strength and purity. If the opinions I have quoted are correct—and they are, I think, those of men thoroughly well able to judge—the Ceylon planters can work out the matter for themselves by making careful experiments in fermenting, noting the time occupied in the process, the temperature in which it is carried on, and the colour of the leaves. My own knowledge of the subject is imperfect, but, perhaps, the suggestions I make may be of some use."

Recalling the process through which the "curing" of coffee in Ceylon was brought—in the course of a score of years, by the combined application of planters and engineers—to a pitch as near prefection as is possible, we feel confident that in a much shorter time the same experience will be realized in the case of the sister staple, and that, as far as "preparation" is concerned, Ceylon tea will yet be at the top of the market.

THE CINCHONA PLANTATIONS OF SIKKIM.

Colonel R. H. Beddome, late Conservator of Forests, Madras, has reported to the Madras Government, that he has paid a visit to the Darjeeling Cinchona Plantations. He met Dr. King, the Superintendent, at Sureil, on a spur of Senchal, about 14 miles from Darjeeling, and about 1,200 feet above the plantations, where the Doctor resides whilst on duty in Sikkim, and he spent six days in going over all the different plantings and the factory with the Doctor and Mr. Gammie, the officer in charge. The Colonel states :—

The planting hitherto has all been carried on in the valleys of the Rungjo and Ryang rivers, tributaries of the Teesta, at elevations between 2,000 and 3,800 feet. All virgin forest at these elevations had been cleared for hill cultivation (called here joom-chena) prior to the commencement of the cinchona plantations, so they have all been opened out on what we call secondary forest, or kumeri land; and I was rather disappointed to find that there had nowhere been any attempt at the high cultivation pursued on the Nilgiris, and that weeding was only attended to for the first two or three years. The planting, with the exception of some 200 acres of young "Ledgeriana" lately put down, is in patches over a considerable area (about 2,400 acres); the number of trees is as follows:—

Succirubra	...	...	4,320,000
Officinalis	...	..	25,000
Magnifolia (of Naduvatam)		...	200,000
Calisaya and Ledgeriana		..	400,000
Carthagena	...	...	150
Micrantha	...	...	500

The soil where planted is in all cases a friable surface soil with a gritty subsoil of either gneiss or mica-schist, and the planting is in patches, because clay like subsoils have been avoided; also localities where the mica-schist crops up to the surface, and places where a certain rank grass (*Saccharum cylindricum*) grows which have by experience been found quite unadapted to cinchonas.

The growth of the succirubra is certainly more rapid than with us at Naduvatam on the Nilgiris, and is quite similar to that on the Tinnevelly hills at 3,000 feet elevation. In one portion of the planted area—the slopes below Rungbee bungalow—I saw many trees about 50 feet in height, and one was measured 55 feet high and 29 inches in circumference breast high. They, however, are deficient in leaf and branches and want the fine heads that our Nilgiri trees possess, besides being of less girth and will probably be short-lived in comparison. The system of harvesting the bark is almost entirely that of uprooting; and, as this is generally carried out by thinnings in the different areas, not a clean sweep; most of the older plantations have a thin bare appearance which would be ruination in our wind-blown localities, but in these protected valleys in Sikkim there is little or no wind. Coppicing has been carried out over some 50 acres, and the trees in all cases seem to have reproduced splendidly. Mr. McIvor's system of stripping has, however, been a complete failure, not, Dr. King informs me, from the trees not being able to renew their bark, but owing to the ravages of ants, who eat off all the young growth directly it begins to renew; this system is therefore never now attempted. The Java scraping method has been tried on a few succirubra trees and with success.

The most interesting feature of my visit was the discovery that Dr. King's "Sp. ignota," called "hybrid" in some of the reports and generally known by this latter appellation to the subordinates, is exactly the same as the Magnifolia of Naduvatam (Mr. Cross's pātā de gallinazo). It grows here with a strong healthy habit and its value has been* fully recognized, and it is now intended to discontinue growing "Succirubra," and plant only this "Pata" and "Ledgeriana," the former at the higher elevations, the latter at the lower. This Pata is being grown almost entirely from cuttings, as it not supposed to come true from seed. I saw many seed-beds of it in which about half the plants appeared to be this broad-leaved form and the other half were said to be "Officinalis"; the typical "Officinalis," however, in these Sikhim plantations is of very poor growth and very spindly in habit and it has been acknowledged that the climate does not suit it and it is scarcely at all propagated now, whereas the narrow-leaved forms like "Officinalis" from "Pata" seed appear to be of much stronger and better growth as they

*Dr. King and Mr. Gammie recognizing it as a very distinct form some 8 years ago, and it has been largely propagated since.

mature; I suspect therefore that there is some mistake and that analysis and further experience will prove them to be varieties of the "Pātā" and not really "crown barks." Mr. Gammie recognizes two different forms among the broad-leaved glabrous "Pātā" trees; these, to me, were quite undistinguishable. There is also a sprinkling of the downy variety which we call "pubescens." I would again urge upon your Government the importance of a most careful investigation into the chemical value of this species, both as to the glabrous and the downy varieties ("Magnifolia" and "Pubescens" of the Nilgiris); many individual trees of each should be analyzed to find its largest and smallest percentage of quinine, and both natural and renewed bark should be analyzed. In my first report on the Nilgiri plantations, I have stated that it will be far more profitable in every way than "Succirubra," and I have since found that this is the opinion of nearly every one in Ceylon and in Sikkim, and it will probably in time oust succirubra entirely from all localities except very low elevations, but it is necessary to be cautious and have very complete analyses. It will probably be best to grow it entirely from cuttings, when we have ascertained our best individuals or varieties by analysis, but I should recommend also very careful experiments with seed.

Dr. King has been most successful with "Ledgeriana;" his original trees were all from a pinch of Nilgiri seed, sent by Mr. Badcock from the packet which Mr. McIvor received from Mr. Money. Last year and this year a continuous block of 200 acres with a southern aspect has been planted out with the seedlings from some of the original trees and the plants appear the picture of health. There are four well-marked varieties, the best of which called by Dr. King, No. I, is not, I think, now represented on the Nilgiris. Dr. King has promised to send seed of all to our plantations, and I trust that we may succeed with them better than hitherto, if ground is opened out at a lower elevation, as contemplated and sanctioned.

Ledgeriana is grown from seed, as cuttings are not found to root well; but bottom heat has not been tried.

The uprooting system may be all very well in Sikkim as there is a very large area available for planting and fresh land can be taken up each year, and uprooted areas lie fallow for a good many years before they are replanted; it should never be advocated for our limited areas, as I am convinced any attempt to replant the same ground just after uprooting would always be more or less a failure.

None of the Sikkim bark is sent to England; it is all made into a febrifuge in a factory on the estates. This febrifuge appears quite similar to what is now sent out by Whiffen as Quinetum, and is said to be quite as efficacious as quinine, and it is much cheaper and very easily made. It is prepared entirely from "Succirubra." The bark is first dried in sheds open at the sides, then by artificial heat, after which it is ground in a bark-mill or pounded, and then steeped in Commissariat barrels for three weeks, three supplies of water being given acidulated with muriatic acid, and run off into tubs where it is precipitated by the addition of caustic soda, then filtered, the liquor running to waste, and the precipitate remaining on the filter: this is then dried in a drying house (heat about 100°) and pounded, again dissolved in water with sulphuric acid, animal charcoal being added for decoloration, then again filtered, and to this solution a dilute solution of caustic soda is added, the precipitate being collected as before in a filter and again dried and pounded when it is ready for use, and costs R9-3-10½ per pound, which calculates for the cost of the bark and the establishment, &c. The whole process appears to be very easy and simple and does not really require any special knowledge of chemistry, so that if there is the objection, I believe, to our red barks being thrown into the English market, I think Government should consider whether a similar febrifuge should not be made on our plantations. Mr. Gammie has also made very pure quinine from "officinalis," "Pātā" and "Ledgeriana" barks, and there appears also to be no difficulty or secret about this, though it is only an experiment as yet; it costs much more and the bark has to be boiled, but it cannot cost more than R30 per pound. It is now to be made on a large scale.

The annual rainfall at the Sikkim Cinchona Plantation is about 120 inches.

The Madras Government remark in an Order of the 6th January:—"This interesting account of his visit to the Cinchona Plantations at Darjeeling completes Colonel Beddome's inspection reports on the Cinchona enterprize as carried out in this Presidency, in Ceylon and in Bengal, and the paper will be forwarded to the Secretary of State and communicated to the Government of India, the Ceylon and Bengal Governments, and to the public, in continuation of the previous reports. Colonel Beddome's renewed proposal for a special analysis of the "Magnifolia" and "Pubescens" varieties, formerly dealt with on 29th August 1881, will now be attended to by the Conservator under the terms of G. O., 13th December 1881, passed upon the despatch from the Secretary of State replying to the first-quoted proceedings. The suggestion regarding local manufactnre was negatived on the Cinchona Committee's report (24th February 1879), and is not compatible with the new arrangements made by the Secretary of State for manufacture at home. The Government take this opportunity on Colonel Beddome's resignation of his office to thank him for the very valuable services he has rendered for many years both to the Forest Department and to Botanical science generally."

DISAFFORESTMENT IN SIKKIM.

In connection with the Cinchona Plantations at Darjeeling, Colonel Beddome remarks:—

"It is very sad to see how all these grand Sikkim valleys have been denuded of all virgin forest between an elevation of about 1,000 feet from the foot up to nearly 6,000 feet. In 1848, when this portion of Sikkim became British territory, these valleys were nearly all one continuous forest. The Nepalese then were allowed in and they cleared in every direction for maize, murwah (ragi) and other hill cultivation; they stopped their destruction at about 6,000 feet in elevation as the climate there is too cold and bleak, and a belt at the foot of the mountains was left as unhealthy and too hot. Reserves are now formed by Government in the forests above 6,000 feet, very cold situations, where the growth is very slow, and also in the unhealthy forests at the foot; but Government did not recognize the necessity of reserves until it was too late to form them where they were of greatest value and most required. All the country now between 1,200 feet and 6,000 feet has been turned into poor secondary forest with such trees as Mallotus, Macaranga and Eurya (the same genera which appear with us in similar places although different species) or poor scrub, or in many places grass lands with very rank large species of grass. Similar destruction has gone on in British Bhootan until within the last year or two, that country having been one sheet of splendid virgin forests about eight years ago. There was no grass land proper on these hills prior to the clearings for hill cultivation; the country was all one continuous forest. No one could now possibly visit any of the valleys in British Sikkim without at once acknowledging how important it is that the State should form Forest Reserves."—*Madras Mail.*

CEYLON "COCOA" AND ITS PREPARATION.

Kurunegala, 11th Feb. 1882.

Dear Sir,—To many planters and proprietors resident in lowcountry districts where cocoa is "king," it is, perhaps, time that the process of cocoa curing should be ventilated.

The planters in this district now beginning to cure their first samples, not knowing whether the process they follow is right or wrong, hope to call forth some criticism by explaining the method pursued, which is as follows :—

Having taken the beans out of the pods, they are heaped up on some matting, placed over wire netting raised off the floor ; the beans are then covered over with plantain leaves (the ribs of which have been previously removed), and above this earth and sacks are heaped. The heap is then left to ferment for four days, after which the coverings are taken off and the beans well stirred. Then the heap is covered up, as before, for four days longer ; the beans are then washed lightly by hand and dried in the sun.

We beg to forward for your inspection a sample oured after the above method, and should be greatly obliged by your ascertaining whether the sample is of any appreciable value in the market.—Yours faithfully,

COCOA CURER.

The above letter comes from a planter in an out-of-the-way district, and he accompanies it by a sample of "cocoa "beans which we at once submitted to competent authority for an opinion. The result is very gratifying. Our mercantile friend, who was not told the name of the planter, his estate or district, writes :—

"The sample of cocoa which you have just sent me is, I think, the finest I have yet seen of Ceylon growth. The majority of the beans are bold, well filled out, have a thin fragile husk and the contents are of the rose-brown colour which appears to be so much liked by chocolate-makers. I do not consider it quite dried enough for shipping, and I should, of course, have the few unripe beans, also the broken beans picked out ; the result would then be a sample finer than the Amba, Raja, and Palli marks hitherto shipped. With regard to value it is impossible to say what it would fetch in the London market, but if previous sales of abovementioned marks are any guide, I should say a fancy price of over 110s. for a small parcel. The market has never yet been tried with a large shipment of Ceylon growth."

No doubt our planting correspondent has something to learn yet in reference to preparation, but he is on the right track. Mr. J. Holm in his little pamphlet on "Cocoa and its Manufacture" (which every planter ought to have) writes :—

The seeds have to undergo a peculiar progress, called "curing," before they are fit for use by the manufacturer. This process is one of great delicacy, and requires much experience and skill to conduct it successfully. Upon it depends in a very great degree not merely the preservation of the cocoa, but the development in it of a fine flavour. There are two modes of conducting it. The simpler one is merely to place the cocoa seeds, when taken from the pods, in heaps in the sun, and these are stirred at intervals. A sufficient quantity of the pulp in which the seeds are imbedded adheres to them to supply enough moisture to give rise to a moderate amount of fermentation, which ceases when the nuts are sufficiently dry to be packed. The other mode is by "claying," that is, the nuts are placed in holes or trenches dug in the ground, and covered with clay or sand ; they are stirred at intervals, and great care is taken to prevent the fermentation which arises from proceeding too violently. When it has reached its proper point, the nuts are spread upon a platform or upon mats until perfectly free from moisture, when they are placed in bags.

THE CHEAPENING OF QUININE.

The decline, by about 25 per cent., in the wholesale price in London, of sulphate of quinine, during the year 1881, was chiefly attributable to the large increase in the output of Nilgiri bark. The Government undertook to cultivate cinchona in the hope of thereby making quinine abundant and cheap, and their success has stimulated private persons to plant cinchona on a large scale. From 1860-61, when the Nilgiri plantations were commenced, up to the end of 1879-80, the outlay of the Madras Government was, inclusive of interest, R18,61,476, and their receipts were R15,99,626 leaving a balance of capital due of R2,67,850. The Government had to pay heavily at the outset for their experience, and if they had to go over the same ground again, with the knowledge they now possess, they would probably be able to effect a considerable saving in their outlay. But the money spent on tentative operations has not been lost and the public have been freely admitted to the benefit of the information the Government have obtained of the best methods of cultivation. So recently as the end of 1875-76 the outlay of the Government amounted to about 13 lakhs, and their receipts to less than 2 lakhs. But since then there have been the following gratifying comparisons between expenditure and revenue :—

Year.	*Expenditure.*	*Revenue.*	*Profit.*
1876-77 ...	R 1,18,742	1,18,960	218
1877-78 ...	,, 1,34,228	3,71,071	1,36,843
1878-79 ...	,, 1,44,179	4,30,908	2,86,729
1879-80 ...	,, 1,56,708	4,89,731	3,33,023

If the receipts were as good in 1880-81 as in 1879-80, then the Government have already had the satisfaction of recovering all their outlay, with interest thereon, and of possessing estates which yield a nett revenue of 3½ to 4 lakhs a year, with a steadily rising tendency. But, though making a very handsome thing out of their own estates, the Government encourage competition by their free sale of seeds, and in 1879-80 as much as 1,711lbs. of seed were distributed. They have 847 acres under cultivation, and at the end of 1879-80, there were 677,350 plants in permanent plantation. Colonel Beddome reports that in the Sikkim plantations there are 4,945,630 cinchona trees. He does not mention the amount of bark that is obtained at Sikkim, and, strange to say, the very bulky Administration Report of Bengal for 1880-81 makes no allusion to cinchona. The bark that is obtained at Sikkim is all made into a febrifuge in a factory on the estate. This febrifuge "is said to be quite as efficacious as quinine, and it is much cheaper, and very easily made." The cost is R9-3-10½ per lb., or about 9 annas per ounce. We are not aware of a census having been taken of cinchona trees in Government and private estates ; but it is well known that year by year the area of cultivation is increasing both in Madras and in Bengal, so that we may confidently expect to see quinine brought in a short time within the reach of those poorest of the poor, who, in this more or less fever-stricken land, have the greatest need of the medicine.—*Madras Mail.*

CINCHONA : A REVIEW.

The Cinchona Planter's Manual. By T. C. Owen. (Colombo : A. M. & J. Ferguson. London: J. Haddon & Co., 3, Bouverie Street, 1881.)

It is not every day that we are called upon to review works printed on such distant soil as Colombo. Here is one, however, to which it is worth while calling our readers' attention, for it is a highly praiseworthy attempt to produce an exhaustive practical treatise on the cultivation of cinchona trees in Ceylon and (for the greater part of the volume applies elsewhere equally well to any climate in which quinine bark can be grown.)

In learning the results yielded by cinchona cultiv-

ation in Ceylon, in reading of cinchona tree growing side by side with the coffee shrubs, and in being reminded how apt the former are to "sporting," or hybridization, a curious physiological suggestion raises itself in our minds. Remembering what we were taught in our youth, that the coffee and the cinchona both belong to the very natural and well-defined family of the *rubiaceæ*, we are tempted to enquire what might be the effects of the pollen of the cinchona on the stigmates of the coffee flower; and *vice versa*, what influence the pollen of the coffee might exert if transported into a flower of any of the cinchona. Shall we some day find quinine or cinchonine in our Ceylon coffee berries, or caffeine among the "total alkaloids" of the Ceylon cinchona barks? Good black coffee is the nearest approach to sulphate of quinine in intermittents, as was well proved at Ghent in 1829, when the latter fell short during a violent epidemic; and at the present time it is not unusual, in malarial districts, for the physician to administer a pinch of sulphate of quinine in a table-spoonful of strong coffee decoction. Again, the "sporting" tendency of the cinchona trees has been so keenly observed in Ceylon that some of our most eminent botanists are "at loggerheads" with regard to the existence of several species, and only those observers who are actually on the spot, and eye-witness of the phenomena, can possibly realize the gradual transformation of the hybrid varietics, their divergence from the original species, and their return to it under certain given circumstances. Whether coffee and cinchona can be crossed at all, and to what extent, is a problem for the future, but it is natural to conclude that a soil and climate so eminently suited to the one must prove equally suitable to the other. This appears to be beyond all doubt, since the Ceylon experiements were first started by Keir, Dundas & Co., in the year 1868.

But even under these advantageous circumstances, no success can be looked for by the planter who is ignorant of the botany, physiology, and agricultural chemistry of the cinchonæ; and to guard against such an undesirable state of thigs, Mr. Owen has written: "The Cinchona Planter's Manual," which is at once an exhaustive and popular treatise upon the subject, and a work which we can confidently recommend to all who are interested in this important enterprize.

Analyses of the barks taken from different kiuds of trees, grown in different circumstances, and analyses of the soils are numerous throughout the work, and prove of the greatest value in enabling us to form an opinion upon the cinchona cultivation in its present state and future prospects. We are particularly interested in the experimental trials of manure which have been carried out during the last few years. Here we see very clearly that sulphate of ammonia and guano both increase, to a slight extent, the yield of total alkaloids, but that a much greater increase is obtained by the use of farmyard manure. The difference is so considerable that it proves conclusively our utter ignorance as to the manner in which manures act upon crops in general, and how much we have yet to learn upon this important subject; nor do the analyses of soils help us much in the elucidation of this difficult problem.

We have said enough, however, to show that Mr. Owen's volume is well worth perusal, and if it should be read as much as it deserves to be, a new edition will soon be called for. He has condensed a mass of highly useful information into a very small compass, and no cinchona planter, either in India or South America, can fail to derive some benefit from the author's meritorious efforts.—*Messrs. Burgoyne, Burbidges & Co.'s Monthly Report.*

DOMESTIC INDUSTRIES IN INDIA.

Those who favour the scheme for establishing land banks in India will be gratified to see the marvellous development of similar institutions in Germany, as shown in the latest official returns. Herr Schulze-Delitzsch reports that, at the end of last year, there were 3,250 co-operative associations of all kinds at work, and of these 906 were "people's banks." 1,144 associations, including these 906 people's banks, have published their balance-sheets; from which it appears that they have over one million members, and that the business done by them during the year exceeded 100 millions sterling. The report is also important, with reference to this country, as showing the impetus given by co-operative Societies to those domestic industries which experience shows are indispensable to the maintenance of a thriving peasant proprietary. In Germany, and also in Belgium, where the small proprietor is most prosperous, he does not look solely to agriculture for a livelihood; but he has auxiliary means generally in the shape of some industrial pursuit, such as weaving, mining, fishing, straw-plaiting, clock-making, wood-carving, glass-blowing, pottery, &c. And in this way he and his family fill up their leisure time, especially in winter, when field work is slack; and make a comfortable addition to their agricultural earnings. In Japan exactly the same thing may be observed, each agricultural village having some hereditary industry in which by long practice they have acquired exceptional skill: thus in one village all the people are occupied in making fans, in another umbrellas, in a third wooden clogs, pottery, or lacquer work; and so on. Now in Germany these industries are supported by no less than 1,355 co-operative societies, having for their object to purchase in common raw materials and instruments of trade; to facilitate manufacturing operations; and to provide for the sale of the articles produced. And thus Prussia, which fifty years ago depended almost entirely on agriculture, has now developed important industries, and exports from her rural districts metals, cottons, woollens, silks, chemicals, glass, pottery, wood-carving, tobacco, sugar, &c. Unfortunately in India this happy process has been reversed; and the raiyat is gradually losing such auxiliary means of support as he formerly possessed. In his Indian tour Mr. Caird noticed how in every village men were "standing idle in the market-place," not because they were unwilling to work, but because there was nothing for them to do when their field work was completed. Foreign competition and other causes have killed off the ancient domestic industries for which India was once so famous, so that the whole burden of the population is thrown back upon the land; and this burden the land is altogether unable to support. It appears therefore that side by side with agricultural banks, vigorous efforts should be made to establish industrial associations, having for their object to revive ancient domestic industries, and to introduce into each district such new industrial pursuits as are best suited to the locality and the character of the people. Any local efforts in this direction will no doubt receive the support and approval of the Government. And the present time seems a favourable one for action, looking to the revived taste in Europe for all articles of Indian manufacture.

—I have &c. W. WEDDERBURN.

Ahmednagar, Jan. 30th.

COFFEE IN LONDON.

It is extremely difficult for any one engaged in the coffee trade to keep up his spirits just now. It would tax the powers of a Mark Tapley to be jolly under such circumstances. Firms, who have been in the habit of selling Cey-

lon coffee direct to the Continent, find their occupation gone, and it is pretty much the same with the export houses who execute orders on the spot. There is literally nothing to be done and men sit idle in their offices, or wander in and out of the commercial sale room, their faces growing longer with each foreign telegram posted on the board, and every fresh report from the auctions going on up-stairs, for they all tell the same tale of the utter want of confidence, and consequent decline, because supplies are in excess of the demand. For the moment at least the pessimists have it all their own way, and nobody has a good word to say for coffee. You will have noted that even Messrs. Patry and Pasteur express the opinion that we have not reached the lowest point, and it would be cruel deception to say that there are any strong or well-defined hopes of a speedy reaction. The latest telegrams from Brazil put down the probable available supply thence from 1st July, 1882, to 30th June, 1883, at 7,000,0000 bags divided in this way:—balance remaining in the two ports on June 30th next 1,000,000 bags:—next seasons crop from Rio 4,000,000. and from Santos 2,000,000 bag, as however, Messrs. Kern, Hayn & Co. pointed out in their December circular, it is too early even in the middle of January to form trustworthy estimates and it is obviously impossible to tell how much will be left on hand when the current season closes. There is plenty of time I take it for bad weather, to upset all present calculations, but still it is tolerably certain that nothing has occurred so far to mar the prospects of a crop equal to the one now coming forward, and that it is manifestly in excess of consumers' requirements. At the same time there is this gratifying feature in the situation so far as Ceylon growers are concerned; notwithstanding the exceptional depression, fine colory plantation sold yesterday as high as 113s and it may be taken for granted that the higher grades of your staple will still maintain their value, though middling and ordinary qualities are dragged down by competition with foreign sorts, and the present quotations for the low grown begin at 54s for small. Such a wide range of prices is entirely without precedent, but it is after all quite natural under the circumstances. Ceylon proprietors at home, are encouraged to hope by the latest advices from your side, that they may be recompensed for a bad market, by a big crop next season, whilst the outlook in regard to cinchona, tea and cocoa is very satisfactory. It is worth noting that the consumption of cocoa has gone on steadily increasing in this country during the last 22 years from 1550 tons in 1,859 to 4,865 tons in 1881 and during the last three or four years all descriptions of Indian Peas, with which Ceylon is included, have grown in popular estimation with amazing rapidity.—"C. Times" Cor.

PRODUCTION OF QUININE.

The *Laboratoria* (a Barcelona journal) gives the following figures as the annual product of the various quinine makers in the world, but does not state the source from which they are obtained:

	Kilos.
North America	20,000
Howard, London	10,000
Whiffen, London	3,500
Jobst, Stuttgart	9,000
Bohringer & Sons, Mannheim	9,000
Brunswick Chininfabrik ...	6,000
Zimmer, Frankfort ...	6,000
F Koch, Oppenheim ...	1,500
Pelletier, France	4,000
Taillandier, France ...	3,000
Schissmann, France ...	1,000
Dufour Fratelli, Genoa ...	3,000
The Lombard Factory, Milan	40,000

We learn from an American journal that,—"The Lombard Factory is a limited company, with a capital of 4,000,000f. in shares of 500f. It is under the direction of Mr. Alexander Bohringer. The factory stands on a space of 8,300 square metres, and the whole superficial floor space is 130,000 square metres.'

The above table gives a total of 116,000 kilogrammes or about 255,200 lb. of quinine, which is singularly close to the aggregate of the estimate we embodied in the last edition of our "Handbook and Directory," although the details differ. Our calculation was as follows:—

MANUFACTURE AND CONSUMPTION OF QUININE.

Manufactured in	lb.	Consumption.	lb.
United States ..	63,000		
Germany	56,250	United States ...	88,000
Italy	45,000	Germany, Holland & Belgium ...	30,000
France	40,000	Italy	22,500
England	27,000	France	20,000
India	12,500	Russia, Austria, Turkey & Greece	40,000
	243,750	India	17,500
		(Other countries, Japan, Brazil, Africa, and Australia, &c.) ...	25,000
			243,000

India is however left out of the Barcelona estimate, and, if we iuclude the cheaper alkaloids in our reckoning, we suppose 300,000 lb. would be a fair estimate of the world's manufacture at the present moment. If we take 2 per cent of quinine as about the average obtained from the bark worked up, this would give 15 millions pounds' weight of bark per annum required by manufacturers. Here again we are in close approximation to the estimate we ventured to compile a year ago of the probable consumption of Cinchona Bark for all purposes:—

IMPORTS AND CONSUMPTION OF CINCHONA BARK.

United Kingdom and British Colonies import about 9 millions lb., but consume only ...	3,500,000 lb.
India (manufactures fr m local growth apart from quinine, &c., imported)	500,000 lb.
Europe, Continent of, through Holland and France (5¼ million lb.) chiefly	8,500,000 lb.
United States	6,500,000 lb.
Other Countries (Brazil, Africa, and rest of Asia)	1,000,000 lb.
Increase within next few years	1,850,000 lb.
Total...	21,850,000 lb.

Thirteen millions of pounds was the estimate in 1880 of the quantity of bark utilized for quinine, the rest being required for bark preparations by druggists, by brewers (in Germany especially) as a substitute for hops, and as a dentifrice. Before we go further we may ask how many trees of an average description would be wanted for this yield of quinine, if cut down and rooted up on plantations, and how many if scraped only? But the practical value of such an enquiry is interfered with when we remember the sometimes enormous quantity —hundreds of pounds' weight of dry bark—got from a single full-grown tree in the South American forests as compared with the 5 lb. to 25 lb. of bark per tree harvested in Ceylon and India. A reference to our London Commercial Letter today will however shew that the steady diminution of the supply of bark from South America is already freely anticipated, and it is manifest that if it depended on Ceylon, India and Java to supply even half the present total of requirements for all purposes—or ten millions of pounds

of bark per annum,—the strain on the planted area would be very great. The supply, in fact, could not be kept up. There is room therefore for a vastly extended cultivation of cinchona.

The scope for the extended consumption of quinine and the inferior cinchona alkaloids is also enormous. A leading Loudon Veterinary Surgeon has said that if quinine were only half its present price, he would never prescribe a "ball" for a horse without an appreciable quantity of the valuable tonic. As a substitute for opium the merits of quinine have yet to be pressed on the notice of European philanthropists as well as on that of the millions of Chinese. The other day, an American visitor told us that his companion across the Pacific to China, an experienced Shanghai Missionary, was carrying back to his adopted country as the greatest earthly blessing he could give to the people he laboured amongst, in the rural districts, a basketful of quinine pills! The efficacious and precious febrifuge is almost unknown in China, and largely as a substitute for opium, the whole of the present production of the world might be absorbed if only it were brought within the reach of the people and at a price within their means. That the Chinese can afford a good round sum is evident from the ten millions sterling which is at present paid by them on account of "opium" to the Indian Government. It would be well if all who are interested in the welfare of Ceylon and India as well as of China, would endeavour to give a practical turn to the agitation against opium, by adding to the negative object of "Anti-Opium Societies"—namely, the putting down of the opium traffic—the positive recommendation to encourage the substitution of quinine; and just in the same way we must do our best to turn the influence of the powerful British Anti-Slavery Society against the false Brazilians; while we should like to see the united influence of every coffee-growing country directed to the overthrow of the present iniquitous system whereby "coffee" mixtures are ruining the consumption and market for pure coffees in the United Kingdom.

Here then are three great movements which are sure of success sooner or later, and which Ceylon colonists and their friends at home may do a good deal to foster and to agitate in support of. The one to encourage the substitution of *quinine* for *opium* in the trade between India and China has only to be mentioned to secure universal approval, and it may be pointed out that it is not in China only, that such substitution is required. In the Fen districts of England and in the low-lying portions of Essex, Middlesex and Kent, the consumption of laudanum among people suffering from chronic ague is large beyond the conception of most people, many country apothecaries confessing that they sell the soothing though deleterious extract, by the wineglassful to hundreds of customers every Saturday night. We should urge the example of the good American Missionary in China who goes among his people with a basketful of quinine pills as worthy of being copied by the philanthropic and charitable in all the ague-stricken districts of England and civilized Europe, and we may then anticipate with confidence the day when a doubled or even quintupled production of bark will enable the febrifuge to be issued at a rate which will ensure consumption in quarters where as yet, this most valuable of febrifuges, is entirely unknown.

When the present mail left England, we observe that a Deputation against the Opium Traffic with China, with Alderman MacArthur as its head, was about to wait on Mr. Gladstone. We must endeavour to induce Mr. MacArthur as a friend of Ceylon, to consider the suggestion we have thrown out about quinine; as well as to take up the question of Slavery in Brazil and that of Coffee Adulteration. We might then well regard the worthy ex-Lord Mayor as "M. P. FOR CEYLON" (just as Mr. Fawcett was named "M. P. for India"), and surely never did an ill-used, badly-governed Colony, stand in more need of a Parliamentary Representative.

MR. CHRISTY OF LONDON ON CALISAYA SEED.

We received by a recent mail, an envelope containing a few seeds, with the following letter and extract:—

DEAR SIR,—I send you by this post a few seeds of the cinchona just to hand this week. I gave the *Gardener's Chronicle* in Dec. a letter upon the same subject that I sent to you. The gentleman who sends us this seed speaks of the woods that yield the cinchona from which Ledger is supposed to have taken his specimens, as "wild cinchona."

We think the most of it will go out to Ceylon and India by the mails this month, as it is all bespoken.—Yours truly, THOMAS CHRISTY & Co.

I send you a slip I had printed today, which is a translation of a letter.

Coca.—I know of one contract that is being made for 2,000 lb. weight of green leaves. The gentleman left last night who is to collect them in Peru. They are going to be made into extract. The green leaf only keeps good for five months.

— —

CINCHONA SEED.

Translation of Letter received 19th February 1882 by T. Christy.

I can now advise you that the seeds that are sent you proceed from trees of calisaya, similar to those of which I left you samples of the bark. I cannot tell you exactly if they proceed exclusively from either the "Morada," "Zamba Morada," and "Verde," but it is probable that the greater part is of the latter, and that it is mixed with the other kinds, as the "Verde" is the one which most abounds. As to choice quality among these several classes, you may take it that they are more or less equal. "Morada" and "Zamba Morada" produce more quinine, but the "Verde" recoups me, as it possesses alkaloid in smaller quantities, but bark in larger, so that you can classify it as equal to the others in value.

The cinchona, called "Ledgeriana," is just the same as those which are represented by the samples of bark which I left with you; the only thing different being that these samples are from cultivated trees, which contain twice as much quinine as the wild trees from the woods, which Mr. Ledger classifies as "Roja Morada," and "Naranjada;" but these significations vary only according to the districts from which the bark is cut. With the best faith you can dispose of the seed as being the very best which exists among calisayas, and, if necessary, state that it is "Ledgeriana," which is identical with these calisayas.

From analysis given, there is no doubt that the alkaloids are very greatly increased by cultivating the trees, as, in the wild state, the bark scarcely ever gives more than

three to four per cent of quinine, whereas the cultivated trees yield nine to ten per cent.

I have ordered some seed to be collected from the wild trees in the woods, and it shall be sent you with next shipment.

The present mail has brought the following further communication :—

DEAR SIR,—I enclose you a slip, which I have had printed this evening, and it carries the matter of cinchona seed as far as Mr. Holmes could get it done in time for today's mail. No doubt, with your experience in Ceylon, you will be able to follow it further. I shall send you any information that I can gather.—Yours truly,

THOMAS CHRISTY.

The barks will be sent to Howards and others who may be able to throw any lights on the matter.—T. C.

Pharmaceutical Society of Great Britain, 17, Bloomsbury Square, London, W. C., January 27th, 1882.

Messrs. Thos. Christy & Co.—Gentlemen,—In reply to your enquiry respecting the leaves, barks, and seeds of cinchona forwarded to me, I may say that I have carefully compared them with specimens in the Museum of this Society, and the barks correspond well with the finest specimens of cultivated Bolivian Calisaya here.

With respect to the leaves and fruit, so far as I can judge, the "*Calisaya morada veluta*" is the *Cinchona Calisaya Bolivina sub. var. pubescens* of Weddell's Notes (Transl. p. 44), and the *Calisaya verde* is, so far as I can ascertain, Weddell's *Cinchona Calisaya oblongifolia*, and the tree concerning which Markham ("Travels in India and Peru," p. 270) gives the following account :—"I have been assured by Gironda and Martinez that there are three sorts of Calisaya; the *Calisaya fina* (*C. Calisaya a vera*, Wedd.), the *Calisaya morada* (*C. Boliviana*, Wedd.) and the *Calisaya verde*. They also told me that the last-named tree was a very large one, with leaves wholly devoid of any red colour on the nerves, and habitually growing very far down the valleys and even in the plains. A tree of this variety supplies 600 or 700 lb. weight of bark, whereas the *Calisaya fina* yields only 300 or 400. Gironda declares that, in the province of Munecas, Bolivia, he saw one that furnished 1,000 lb. of tabla, that is to say, of the bark, of the trunk, and lower branches."

These remarks confirm the statement made in the copy of the letter forwarded with the barks, viz., that it pays better to cultivate the *Calisaya verde* than the *Calisaya fina*, or in other words, that, although the *Calisaya verde* yields only 6½ to 9 per cent of pure Sulphate of Quinine (while the very best Ledgeriana yields 13 per cent, and other specimens not more than 6 per cent, yet, as the *Calisaya verde* yields twice the amount of bark that the *fina* or Ledgeriana does, this is equivalent to from 13 to 18 per cent of Quinine in the *Calisaya verde* morcover, from the fact that the *Calisaya verde* is a more vigorous tree than the delicate Ledgeriana, and will grow at a lower elevation, it is obvious that it can be cultivated to a much greater extent and may be extremely valuable for grafting the Ledgeriana upon.

I am not aware that the *Calisaya verde* (*Cinchona Calisaya oblongifolia*) has as yet been introduced into India, and I think you are to be congratulated on having succeeded in obtaining seeds of so valuable a Calisaya.—I am, gentlemen, yours very truly, E. M. HOLMES.

THE WAX-PALM OF BRAZIL.

Doubts have been freely expressed as to whether the seeds of this plant *(Copernicia cerifera)* sent out to Ceylon by Mr. Scott-Blacklaw would germinate; but this doubt should now be set at rest by Messrs. Auwardt & Co., who write :—

"We beg to enclose for your inspection a couple of the wax-yielding palm seeds which we put in a flowerpot just to test them about a fortnight ago, and you will see that they have sprouted."

The seeds in question have sprouted splendidly. Dr. Trimen is trying some of the seed at the Peradeniya Gardens, and recalling all we are told about the tree and its uses :—its delicious fruit, its leaves used for hats and clothing, the wood for building, the roots medicinal, besides the all-important wax which is so easily collected and utilized :—we certainly trust this "new product" will receive a fair trial in Ceylon. Our native friends with land to plant up ought more particularly to give it a trial.

A PLANTER'S ORGAN : "THE TROPICAL AGRICULTURIST."—We have read with much pleasure a new monthly publication, which made its appearance at Colombo on June 1st last, in connection with the *Ceylon Observer*. It contains a great deal of useful information for planters. It contains capital articles on various details of coffee planting, also numerous paragraphs dealing with cocoa, cinchona, sugar, and other tropical products. The magazine supplies a distinct want and ought to succeed. It can be ordered through Mr. Gall's book store, Harbour Street.—*Gall's Jamaica News Letter.*

INDIAN TOBACCO.—The export of tobacco from India is steadily increasing. Five years ago the exports were valued at less than 9 lakhs; in 1880 their value had risen to over 14 lakhs. Mr. J. E. O'Conor, in commenting on the tobacco trade, in his latest review, expresses great satisfaction with the tobacco and cigars of Poosa, and the Madras cigars also he finds to be improving. It is known that in the estimation of the London agents and merchants the Indian leaf only requires the labour of skilled curers to compete successfully with the produce of America and the Manilas. —*British Trade Journal.*

HAPUTALE, 13th Feb.—The weather up here is now everything that could be desired and estates hereabouts never looked in better heart or more capable of giving a heavy crop than they do at present. Down the Pass, on the Haldummulla side, they have had a little wind, but the trees will quickly respond to the present favourable change in the weather and autumn blossoms promise to be good. Old Kahagala is a *perfect picture* and the surrounding estates are equally good —so good in fact does coffee look in this particular quarter that it puts cinchona quite into the shade, and that is saying a good deal for Haputale cinchona, like its coffee, is not to be surpassed anywhere in Ceylon. Leaf-disease is conspicuous by its absence.

CINCHONA BARK SALE.—Messrs. Robinson & Dunlop disposed of the following lots of bark by auction today (Feb. 10th). Considering that quinine is reported to be lowering in price again, the result is very successful.

Correspondence.

To the Editor of the Ceylon Observer.

NEW FIELDS OF ENTERPRIZE: THE SOUTH SEAS.

Na Songo Plantation, Upper Rewa, Matailuntan, Viti Levu, Fiji, 21st November, 1881.

Sir,—Noting, in nearly every issue of the *Overland Observer* which comes to hand, the publicity which you give to "new fields for emigration," I have taken the liberty of forwarding you by this mail two letters, from a gentleman in the New Hebrides group, which, I think, may be of considerable interest to planters in Ceylon to peruse, and which may probably result in one or more planters turning their attention to that quarter, where everything seems to be to the advantage of the planter, with the exception of hurricanes.

Planters in Ceylon will be glad to hear that coffee is still doing well here in Fiji, and that little or no leaf-disease is to be seen. Some of my oldest coffee, about nineteen months old, which I topped at 3 feet 6, two or three months ago, had a magnificent maiden blossom last month, which set splendidly, and which I reckon at five or six cwt. to the acre.—Yours truly,

Wm. LAING MALCOLMSON.

Rathmoy, Sandwich Islands, August 21st, 1881.

Wm. Laing Malcolmson, Esq., Fiji.

Dear Sir,—Your letter requesting information about this island, and its capabilities for coffee-growing, reached me a couple of days ago. I will preface my remarks by saying that I am a coffee planter, but in a very small way, and all the experience I have ever had with the plant has been since I came here. To try the capabilities of soil and climate for that article, I put in one acre at the back of my house, on jungle land, and at an altitude of about 500 feet above sea-level, and about three-and-a-quarter miles distant from the coast. I planted this purely for experiment, and it answered admirably. In 22 months from the time the seed began to come up in the nursery, I was picking my maiden crop of beautiful, well-developed coffee (the seed came from Ceylon). I did not weigh my crop either then or since, but I put it down in my own mind that the yield (first) was from 3 to 4 cwt. to the acre. The following year we were visited with the most severe hurricane yet experienced here, and the coffee trees, at the time it came, were 5 feet high, beautifully shaped, and *covered* with blossom. The acre was white, like a field of snow. You may guess the effect; the trees were nearly all blown flat, and, when they were put straight and carthed up comfortably, I found that, from the sheer force of the wind, all, or nearly all, the primaries were killed. I broke them off, and at the time, not knowing what to do with it, I just left it to itself, the consequence being that it threw out a lot of shoots, suckers and gormandizers, and so it has been going on ever since, totally neglected, with the exception of cleaning the ground now and then. It has since every year continued to give very fair crops, more than I ever could have expected, and the trees, although, as I tell you, a *mass* of shoots and gormandizers, are *perfectly healthy*, not a symptom of leaf-disease or anything else. So far my experiment has been a great success, and, you will admit, a very severe test. The only wonder to me has been that it has survived at all.

In October last year, I commenced felling and clearing at Sea-view, distant three miles back from my house, at three-and-a-half miles from sea coast, altitude 1,500 feet by aneroid, *heavy* jungle land, and commenced putting out nursery plants of 15 months old in February, for experiment sake again. I put out about half an acre of whole plants, which then had two to three pairs of primaries out, but while doing so, a burst of sunshine came out, accompanied by very strong wind, and, of course, down went all the tender tops and leaves. Although feeling very much disposed to take my knife and cut them down to stumps at once, I left them. They recovered amazingly, and they are now fine plants, well shaped, about, or a little over, four feet high, and budding out blossom for a maiden crop (some have blossomed). With the exception of a scale, which is identical with the scale on orange trees, and is on many of the plants in the jungle here, there is no disease of any kind; they are a beautiful, rich dark green, and growing fast. All the plants of six acres, which I put out in the early part of this year, I cut down to stumps, and find it the safest way. The shoots from those are now about 2 feet high with 2 or 3 pairs of primarics. This will convey all the information, I think, you require on this head. This scale only comes on an odd plant here and there, and only on the green and tender parts, and does not appear to affect either the growth or the health of the plant. Can you tell me anything about it? There is plenty of land on the island everywhere, well adapted for coffee, but the streams of water unfortunately are few and far between. On my property there are 3 running permanent streams, and so far I am well off, for they are suitable for pulping &c.; and adjoining my land and for miles beyond there are two splendid streams, and thousands of acres of coffee land, a little stony and broken, perhaps, but magnificent coffee land, in a valley, well sheltered, and all jungle; but I know of no other part of the island where it is so. Certainly, I have not travelled about much beyond my own limits, but I am in my tenth year of residence here. All or any of this land can, I believe, be purchased from the natives, at the rate of say 2/6 per acre, paid for in trade. The general altitude of what I call coffee land may be put down, I think, at about 1,500 feet, and the mountains which back it up on the east and north-east (the prevailing wind quarter) may be, or look like, 1,500 feet more. What may be on the top of those, in the shape of available coffee land, I know not. I get abundance of rain at Sea-view. Scarcely a week passes without showers. In fact, drying and burning off is often difficult. The general temperature may be put down at, in the shade, in summer from 80° to 86°, and in winter from 60° to 70°. This is at Sea-view. On the low coast land it is several degrees higher. I have a thermometer at each place, and sometimes keep record, and compare notes, but I have seldom tried it in the sun. I have no hesitation in affirming that I do not think there is a more suitable coffee climate and soil in the world. The soil varies both in depth and colour. Some is black, rich, loose mould for several feet down, and the subsoil chocolate; and, in others, more reddish than chocolate. In others, I believe you could go down 20 feet through rich, black, soil, and, in odd places, patches here and there, you will come in 18 inches on a mineral-looking tenacious red clay; something of the aluminum style. I dig all my coffee holes 2 feet each way. I can give you no idea what it costs to bring an acre of coffee to maturity here, but I should say it could not be done in any part of the world cheaper. I do not want to tell you things I know nothing about. *Labour* has to be imported from other islands in this group. The Sandwich natives, or any others in the New Hebrides, will not work on their own island. Labour costs at the rate of say £6 per annum, with every expense added; wages only £3 per head. Cost of procuring them from £5 to £7, food, clothing &c., making up the sum. Term of servitude,

3 years. Cost of returning to their homes, 10s. to £1. Free trade, and no taxation. The latter is what will tickle you Fiji people. Title to land good, if properly bought from the proper owners, and paid for in full. All the labour I have came to me under "the stars and stripes." I am a subject of Queen Victoria. Labourers can be obtained here, if a man has the cash ready to pay for them. Direct communication with Sydney can only be had twice a year by missionary schooner "Dayspring" and for letters only. They will not carry anything else for a planter, even if he pays for it. Sydney is distant about 1,200 to 1,300 miles, and New Zealand a little less. New Caledonia is about, I think, 400 miles or 2 to 3 days' sail for a schooner. Captain McLeod is an old and very regular trader between this and Noumea, and his schooner makes trips every two months, from and to Noumea and Sydney; there is a large steamer, the "City of Melbourne," twice a month. We are *subject* to hurricanes about January and February every year, and they happen, and are of about the same strength as those you have in Fiji, neither more nor less. The island of Sandwich, or any other of this group, is not so healthy as Fiji. There are fevers here sometimes, but, if a man is *temperate* and *works hard*, there is nothing here to injure him. This unfortunate island has in some way got a much worse name and reputation than it deserves. Every malady under the sun here is called fever and ague. If a man kills himself by emptying a gin bottle, people will have it that it is fever and ague that has brought about his collapse. No man, who comes here with a determination to succeed, and erects his dwelling on the high lands, need be more afraid of Sandwich than any other place, and that is the truth. Any one who is afraid to meet it had better not come. I have seen too much here of that sickening rubbish. If you, or any of your friends, are desirous of settling here, the best way would be for you or one of them to come over in one of the labour vessels, and see and judge for yourself. I will be happy to give you or them accommodation and all the assistance in my power in arriving at a true comprehension of Sandwich and its belongings; and, as far as coffee is concerned, as you know very well, to a man of experience, seeing is believing.

Mr. Leefe of Fiji has been over a large portion of my coffee land, and, if you can drop on him, he can describe it to you exactly. I trust I have told you all you wish to know. I cannot think of anything else, which would enlighten you now, but upon any question you may address me in the future, I shall be most happy to give you all the information in an honest way, neither exaggerating nor concealing, and I will conclude this by saying that I believe with all my heart in the success, ultimately, of coffee-growing in Sandwich, and, if I did not, I would not remain a day longer in it.—I remain, dear sir, yours truly,

ROBERT GLISSAN.

P. S.—I forgot to add that Captain McLeod has about 15 acres of coffee planted on his estate in Villa Harbour or South West Bay, on the southern end of this island. I saw it about two months ago, and it was looking very healthy and well, although badly and carelessly planted; it was then about 15 months old. There were also a few trees about 5 to 6 years old, all jumbled together in what had been an old nursery. They had never been pruned or attended to in any way, but they were looking blooming, and laden with ripe fruit. All are growing about ¼ mile from the salt water and at about 200 to 300 feet altitude. Unfortunately there is no stream of water *there* for pulping &c. Latitude of Sandwich 17·30.

Rathmoy, Sandwich Island, New Hebrides Group,
September 10th, 1881.

Wm. Laing Malcolmson, Esq.

Dear Sir,—I wrote, in answer to your letter, about a fortnight or so ago, and sent it in to the harbour, to Mr. Salisbury, to forward by first opportunity offering. I do not know whether it has left there yet. On considering the matter contained in your letter, about the probability of some of your Ceylon friends coming here to settle, if my report of the place proved favorable, I think it as well to lay a proposition before you and them, which might greatly tend to confirming that inclination, and it is as follows:—If I could meet with a Ceylon man of good sound coffee experience, I would be glad to enter into partnership with him, giving up to him all the management of the coffee plantation. To make the matter clear, I hold somewhere about 10,000 acres of land here, 3,000 of which is first-class coffee land, and on which are three running streams of water. I have about 6 acres of coffee already planted out, the greater portion of which is at this moment in flower for a maiden crop. I have about 10 acres more cleared and burnt off, and about two-thirds of that pitted or holed, ready for favorable planting weather, and hope to have 10 acres more cleared and ready for planting next February, the rainy season. I have 4 different nurseries, containing something like 8,000 plants over a year old, and have another nursery in the middle of my clearing containing 26 beds of 4 × 60 feet each, or, as I estimate, about 40,000 plants, planted this year, and which are all up and throwing out their second leaves. This gives me an unlimited supply of plants to carry on with. I have put up a nice comfortable three-roomed cottage at Sea-view, and there are huts for the men also; there is a large quantity of tools for the men, and carpenters' tools also. In fact, there is everything needed both on Sea-view and Rathmoy for the efficient and separate working of both places—everything but pulpers and machinery for working up the coffee. I have 33 head of labour, 23 of which have nearly 2 years yet to serve, and 10 recently got, which have their 3 years of time to serve. I am also going to receive 20 more at the end of this year. In fact, I may just broadly state that the whole place is formed and in good working order. I will take a partner for a half share in the whole estate of 10,000 acres, and all working implements on the place, for everything but my own personal property. If he pays me in cash the sum of three thousand pounds (£3,000), I will then place to the credit of working expenses of the estate £1,000, against the same amount placed by my partner, and together work the property, share and share alike in every way. I will carry on maize-growing down at Rathmoy with a separate gang of labour, to cover all the labour expenses (which I am at the present time doing) and each gang can be made available at times of push at either place. The maize pays well here, and the ship comes to the Corn House and takes it away *whenever* it is ready for shipment, and I have gathered crops here giving a yield of 80 bushels to the acre. So that I deem it advisable to continue the maize-growing for a few years with the coffee. I have received many offers (and favourable ones) of partnership here, but would not take any one that was not experienced in coffee culture.

It is, as you know, a very different thing for a man to come to a settled place and home, with everything ready-made to his hand, to settling down on new ground in some lonesome spot, with labour, tools, buildings and in fact *everything* to provide, and any person joining me would do so under most favourable auspices. If you know of one to do this, let him first come and visit the place and judge for himself, and do nothing in the dark, and if it is to be done, let it be done quickly.

I may tell you, that I have years ago secured the best, most convenient, and most valuable land in my neighbourhood, and, previously to settling here, I made two trips of inspection from Queensland, and

took good care to establish myself in what I considered the best locality. The title of my property is good, as I paid the natives every pennyworth asked for it, and my deeds are well drawn out and all property witnessed there can be no possible doubt of its security. Although the greater portion of it was purchased 9 years ago, the natives all round acknowledge my right to it, and there has never been the slightest dispute of ownership. I have beautiful creeks of fresh water on Rathmoy also, and a large extent of as fine sugar land as there is in the world. My chief reason for proposing this arrangement is that I find it rather too much to be continually shifting myself about between Rathmoy and Sea-view.—I am not so young as I was 20 years ago, being now in my 47th year and the continual separation from my wife of a week and a fortnight at a time is very unpleasant and lonely for both. There can be no harm done in proposing the matter to some of your Ceylon friends, and, if they deem the thing advisable, they can come over at once, or communicate with me without loss of time. So now, as I think I have laid the matter before you in an intelligible form I will say good-bye for the present and remain, yours truly,

Robert Glissan.

COFFEE LEAF-DISEASE: MR. STORCK'S MODE OF "PATENT EVAPORIZATION."

5, Laurence Pountney Lane, London, E. C.,
12th January 1882.

Dear Sir,—I have been reading the last *Overland Observer*, and have perused with much interest Mr. Storck's letter of 20th October 1881, in which he states that the cure he avers to have discovered for "leaf-disease" is a system of *permanent vaporization*.

All concerned must agree that Mr. Storck is fully justified in withholding his secret, until he has obtained a well-secured guarantee (in which the Governments of India and Ceylon should unite with the coffee planters of both countries) for a reward, which should be commensurate with the immense interests it would benefit, if Mr. Storck's process proved a success; a stated time, however, to be named to thoroughly establish this point of a successful remedy.

I would suggest either of the following as the most suitable forms of reward. Either that the two said Governments should alone give the reward; or that a patent, free of expense, should be granted to Mr. Storck for his process, to extend over a given number of years, and that all planters availing themselves of it should annually pay a certain moderate fee of so much per acre.

If the process proved successful, an ordinance should then be passed making it compulsory that all coffee planters should make use of it, until such time as the disease had completely disappeared. All abandoned estates and gardens should have the coffee rooted up and burnt. This also should be made a "*sine qua non*" by law; and if natives neglected to use the remedy, their gardens should be treated in like manner.

By such means alone, if we believe in such men as Thwaites, Abbay, Morris, Marshall Ward, and Storck, could the pest be thoroughly stamped out.—Yours faithfully, WILLIAM SABONADIERE.

LOCAL MARKET FOR TEA.

Dear Sir,—With reference to your correspondent's letter of the 6th inst., which appears in your paper of yesterday, respecting a local market for tea, I should recommend your friend "A." and several owners of small blocks to send down their tea to some one in Colombo, and make a small depôt here. I shall be glad to be of service to them in rendering them every assistance, and I might possibly give them a fair idea of the value in the London market I expect to receive very shortly samples of Ceylon tea, and, having a knowledge of tea-tasting, acquired in a London dealer's office, I may be of use to them.

I have orders already, but cannot hit upon the quality I want.—Yours truly, B.

COFFEE STATISTICS.

Deyeucwatte, Passara, 24th Jan. 1882.

Dear Sir,—On reading the *Statist's* article on coffee production and trade of the world, it occurs to me that there is an error in the Java statistics, "96,000 tons being the highest, and 42,000 tons the lowest; the former being reduced to cwt. 1,920,000 (one million, nine hundred and twenty thousand cwt.), and the latter only 840,000 cwt. (eight hundred and forty thousand cwt. exported).

I do not like to trust the printer's devil with figures only, and therefore give the quantity in brackets in writing, for even that wonderful book of *Tropical Agriculture* by Simmonds is misprinted, giving the outturn of coffee of the world at one million cwt. *instead of ten million cwt.* (Look it up for yourself, Mr. Editor.)†

Your own statistics of the coffee production of the world were usually ten million cwt. something like as follows:—

Brazil	5	millions
Java	2½	,,
Ceylon	1	,,
Other coffee producing countries including India	1½	
or *ten million cwt.*‡		

Now, we find Brazil pouring into the market during the current season 1880-81, crop of six millions four hundred and eighty thousand hundredweights, viz. from Rio ... ... 5,080,000 cwt.
From Santos ... ... 1,400,000 ,,

Total Brazil ... ... 6,480,000 ,,

Ceylon crop being only half-a-million or less by forty thousand hundredweights, and less than half the outturn of 1872 and 1873.

It would be interesting to discover whether the Java statistics are correct or not, because, at present, they point to a decrease of two-thirds, or say over a million cwt. on the average. So far this fact would show *Java a greater sufferer from leaf-disease and short crops in proportion to Ceylon.*‖

Both the abovenamed countries have the advantage of Ceylon in being enabled to extend cultivation as railway extension progresses and woe to the Ceylon Government for not taking greater care of *her staple product*.—I remain, dear sir, yours faithfully,
HENRY COTTAM.

LOCAL MARKET FOR TEA.

February 6th, 1882.

Dear Sir,—Will you permit me to ask, through the medium of your valuable journal, whether a local market can be found for small lots of carefully manufactured tea I ask, as owners of small blocks of tea planted on hill do not care to export small quantities, as, I believe, small lots do not usually pay to export. You, who know everything, may be able to give us a hint.—Yours truly, A.

[Our correspondent should try the local storekeepers.—Ed.]

* We have answered this by anticipation. The figures are correct.—Ed.

† Simmonds' book has a number of gross errors.—Ed.

‡ Our last Handbook gave 11 million cwt. as the quantity exported, the producing countries consuming three millions more.—Ed.

‖ Apart from leaf-disease, seasonal influences and other circumstances tell on Java crop.—Ed.

NEW FIELDS OF ENTERPRIZE: BEWARE OF SHARPERS.

Badulla, 8th February 1881.

Dear Sir,—I enclose the copy of an extract from the *Scottish American Journal*, dated 15th December 1881, which, I think, ought to be widely circulated through every paper. Some of the young men referred to were, for some time, in Ceylon, but, thinking they could better themselves in another part of the world, and seeing such an advertisement as that referred to below, at once jumped at such an opening, and were shamefully deceived. This system is not only confined to America; as I have heard of similar cases having been connected with Ceylon, where young men paid large premiums, such as £100 per annum, to learn their work and another £100 for their board. Such cases of extortion ought to be exposed. Any man, after six months' planting experience, is surely worth not only his board but also a small salary.—I remain, dear sir, yours faithfully, A NOVICE.

PEELING CINCHONA AND CINNAMON BARK.

Koslanda, 12th Feb. 1882.

Dear Sir,—In your issue of the 9th, I observe a note on peeling cinchona with the help of a cinnamon-peeler's stick for rubbing the bark, so as to facilitate the peeling.

From my experience, it is undoubtedly a fact that this stick is necessary in peeling cinnamon, but it is no help whatever in peeling cinchona.

I tried both the cinnamon-peeler's knife and the rubbing process with cinchona, and found the stick utterly useless, to say nothing of the damage it did the bark; but I strongly recommend the knife to cinchona planters, if they really go in for barking and making pipes *à la mode*.

Cinnamon, as a rule, will not peel all the year round, but I never found it the case with cinchona: so the stick for rubbing is not necessary, even if it were a success.

I tried it simply for curiosity sake, and found that the rubbing, although gently applied, damaged the bark to a great extent.

I also observed that cinchona will not peel after 36 hours (from the time it is cut), and the only remedy in a case of that kind is to steep the sticks for an hour or two in water.—Yours faithfully, H. J. C.

KAPOK, COTTON, COTTON TREE, SILK-COTTON.

Dear Sir,—I fear these terms have got somewhat mixed, and some have added to the trouble by confounding the Sinhalese word 'kapu,' for the common cotton, with 'pulun,' the Sinhalese for the silk-cotton. The following may prove of interest to your readers:—The red-flowered silk-cotton tree not uncommon from the coast up to the Kandyan country is, I believe, truly indigenous to Ceylon, and is the 'katu (thorny) imbul-gaha' of the Sinhalese, and in the *Flora of British India*, 1, p. 349, the following botanical names are given for it:—*Bombax malabaricum, heptaphylla*, and *Ceiba salmalia malabarica*, and *Gossampinus rubra*, whilst Maxwell 1. Masters, who has elaborated this order, calls it "cotton tree." From 'Bombax' comes 'bombastic,' inflated, puffed up, &c. The woolsack is said to be in some way connected with this. I think Masters is wrong in calling this the "cotton tree," and leaving the other without a common name. One of the generic names, *samalia*, is, I think, derived from the Malayalim name of the tree under which Rheede figured it in his *Hortus Malabaricus*. The cotton of this tree is scant compared with that of the next tree. There is a very common drug sold in the bazars of India and Ceylon, and which is used for the same purpose as shark-fins, rat-tails, &c., in fact as an aphrodisiac, and known as 'madana-kamapu' in Tamil. 'Madana' means intoxicating, 'Kama,' the goddess of love, 'pu,' flower, which I have never seen identified with any known plant. Several years ago I had some of this drug soaked in warm water, to which some soda was added, and I discovered that the drug was composed of the young unexpanded flower-buds of this tree. [Indian compilers, writers, plagiarists, please copy!]

2nd.—The tree commonly known in Ceylon as the silk-cotton tree, very common near gardens and cultivated grounds, is remarkable for its green bark, and the regular manner in which its branches spring from the trunk in equidistant threes forming angles of 120° with the trunk when the trees are young. It is, also, like the other, remarkable for having its flowers and its cottony pods on when the tree is bare of leaves. The flowers are generally white, and when in young bud they are a favourite food of the flying-foxes, *Pteropus Edwardsii*, which infest the trees in the evening. The Sinhalese name of this tree is 'pulun (silk-cotton) imbul-gaha,' and it is the cotton from this tree which is so much used in Colombo and on the coast of Ceylon for stuffing pillows, mattresses, &c. It is to be had in Colombo for 12 to 16 cents a lb., but not quite free of seeds. The contents of one good ripe dry capsule of this tree when opened out will fill a beaver hat. The two trees produce silk-cotton, the staple of which is too short to be woven, but I think this one should be called the cotton tree in preference to the other. I am away from my books and do not know the meaning of the Sinhalese word 'pulun' always used for the cotton from the tree, but it is never confounded with the 'kapu,' the produce of a species of *Gossypium*, none of which is indigenous to Ceylon. I do not think the 'pulun imbul' tree is indigenous, as I never saw one truly wild.

In *Fl. Brit. Ind.*, 1, p. 350, the following names and synonyms for this tree are given:—*Eriodendron anfractuosum* and *A. orientale*, *Bombax pentandrum* and *B. orientale*, and *Ceiba pentandra*.

From all I know about this tree, I think it is likely to have been introduced into India and Ceylon from the West Indies. W. F.

Mr. Storck and Coffee Leaf-Disease.—We shall not fail to call Mr. Storck's attention to the letter of Mr. W. Sabonadière, which appears on the previous page: the latest reference we have seen to the subject is contained in the following paragraph in the *Madras Mail*, in which a quotation occurs we had not seen before:—

Mr. J. R. Storke, a coffee planter in Fiji, has been experimenting with coffee leaf-disease *hemileia vastatrix*. He makes two important announcements—first, that the disease may be contracted, under certain conditions, by the Liberian coffee plant; and second, that he has discovered a means of "infecting a tree, a run, a plantation, or a whole province, and of curing it again at will." He gives no details of his method of cure, but invites personal investigation on his estate at Upper Rewa, Fiji.

Fibre.—A Report has been issued on the materials in India, suitable for the manufacture of paper. Several fibre-yielding plants are mentioned; amongst others, various species of the plantain or banana tribe. Trade returns show a large and continually increasing delivery of hemp from the Philippine Islands. The quantity is estimated at 20,000 tons, valued at half a million sterling. M. Léotard says there is no doubt that the Manilla hemp plant, *Musa textilis*, grows as well in British India as other species of the plantain or banana tribe. Further British India could, in a space of two years, supply London market with all that it could take of hemp fibre.—*Madras Mail.*

ABOUT PERAK.

Mr. Dean's very able report on the State of Perak enables me to condense what I have to say, and all who wish for details should procure it. As he says, the country is one mass of heavy jungle, with perfect soil, for Coffee, Cinchona, Tea, and Sugar, suitable elevation for each being easily obtained, from sea level, up to 8,000 feet. From 150 000 to 200,000 acres are available, and numerous rivers, which are being cleared, will afford all necessary means of transport, until railway are opened. It is it present the intention of Government to open about eight miles of rail, from the proposed post of this place, and afterwards twenty-three miles to Kwala Kangsas on the Perak River. I may say the work will not stop until it has opened up the whole State. Land is to be had for $2 per acre, and no doubt capital would be treated with on easy terms if it was shown the work of opening up would be carried on with energy. The rainfall varies above this; at an elevation of 3,200 feet, about 300 inches fell during the past twelve months. From all accounts this must have been an exceptional year, and this place is known to have the greatest rainfall in the State. About 20 miles to the South-east and at the same elevation the rainfall was 80 inches. The average rainfall for the State may be taken at 75 inches. The young Coffee, Cinchona, and Tea that I have visited will compare most favourably with the best district in Ceylon and those who have not, as yet, lost their all, should pay this place a visit. There is a good resthouse here, and one is being built at Kwala Kangsas. Travelling by boat, with short walking trips to inspect the soil, &c., on the hills would be the best way of seeing the country. This can be done, as the mountain ranges are not so continuous as to make it necessary to cross them. Labour will have to be imported, for which the permission of the Indian Government has been obtained, and, I conclude by saying there is nothing to be done here, at present, without capital, but it is expected the war debt will be paid off this year, and when it is, Government intend spending money freely in opening roads, &c., &c. Then, no doubt, there will be employment for experienced men, accustomed to Tamil coolies.

C. H. CAULFIELD.

Taiping Larut, Perak; 14th January, 1882.—*C. Times.*

SUCCESSFUL EXPERIMENTS IN TEA PLANTING.

[I send you a copy of the *Glasgow Herald*. It contains a letter by a Glasgow grocer, S. Cranston, mentioning a very successful method of preserving tea seed, and other points of interest.—*Cor.*]

SIR,—We are indebted to Mr. Richard D. Cruickshank, Indian tea merchant, Glasgow, for the following particulars of his experiments and experience as a grower of Indian tea seeds for exportation to the different localities in India, Ceylon, Fiji Islands, &c., and we have no doubt they will be read with interest by every one connected with the tea trade, and especially by the Government officials and capitalists who are engaged in various undertakings which are intended to open up the vast tracts of India, by bringing them within the reach of commercial enterprise, and thus tend to develope the resources of the Empire. The difficulties which Mr. Cruickshank encountered may best be realized by a few quotations from Colonel Money's Prize Essay on Tea Cultivation, which states, with the clearness of an acknowledged authority, the conditions and circumstances under which the propagation of the tea plant in India was begun upon scientific principles. It is matter of history that the early efforts of the East India Company were directed solely to obtaining seeds and plants from China. The opinion of the most experienced Indian planters of the present day is, that all this trouble on the part of the East India Company was not only useless, but positively injurious; and when the Government was doing its best to foster cultivation by distributing China seeds and seedlings gratis; it made a mistake, the harm of which it will take years to undo. Colonel Money begins his essay with a laconic truism, "Nothing was known of tea formerly when everybody rushed into it; and not much is known even now." Speaking of the varieties of plants, he says:—"These are many, but all arise from the species which was discovered some forty years ago in Assam. The indigenous tree has a leaf nine inches long and more; the leaf of the China bush never exceeds four inches. The indigenous 'flushes,' that is produces, new tender leaf (from which only tea is manufactured) much more copiously than the China, and this is in two ways: first, the leaves are larger, and secondly it flushes oftener. The infusion of tea made from indigenous species is far more "rasping" and "pungent" than what the China plant can give. A pure specimen of either is rare, and it is very difficult to rear successfully the pure indigenous. The China is much hardier when young. The plants between indigenous and China are called "hybrids;" they were in the first instance produced by the inoculation, when near together, of the pollen of the one kind into the flower of the others. Now there are very many varieties of the tea plant—a hundred, or even more—and no garden is wholly indigenous or wholly China. Had China seed never been introduced into India, a very different state of matters would have existed now. The cultivation would not have been so large, but far more valuable. The Indian tea is vastly superior to China, and commands a much higher price at home, but it is still very inferior to what it would have been had not China seed been so recklessly imported and distributed over the country—it will never be possible to undo the harm then done. Another difficulty was the transport of seed to any new localities, for nine times out of ten a large proportion failed; and again, the enormous cost of tea seed in those days, 200 rupees a maund (about 80 pound weight), 500 rupees a maund at least, deducting what failed, was its real price. This item of seed alone entailed an enormous outlay, and was another difficulty ten cultivation had to contend with. It was, however, a source of great profit to the old plantations, and principally accounts for the large dividends paid for years by the Assam Company. The seed of indigenous hybrid, and Chinese is like in appearance and cannot be distinguished. Thus, when seed formerly was got from a distance, the purchaser was at the mercy of the vendor. The tea flower (the germ of next year's seed) appears in the autumn, and the seed is ripe at the end of the following October or early November. It thus takes one year to form, and when picked the mass is still in capsules. It should be laid in the sun for half-an-hour daily for two or three days, until most of the capsules have split. It is then shelled, and the clean seed laid on the floor of any building where it will remain dry. Sunning after shelling is objectionable. The sooner it is sown after it is shelled the better. If for any reason it is necessary to keep it—say a fortnight or three weeks before sowing—it is best kept towards germinating in layers covered with dry mould. Put if to be kept longer, leave it on the dry floor, as above, taking care it is thinly spread, and collected together, and respread every day to turn it. For transport to a distance it should be placed in coarse gunny bags, only one-third filled, if the bags shaken and turned daily during transit, a journey of a week will not very materially injure the seed. For a long journey it is best placed in layers in boxes, with thoroughly dry and fine charcoal between the layers, and

sheets of paper here and there to prevent the charcoal running to the bottom. In round numbers, one maund of tea seed contains, say 30,000 seeds. If you get 8,000 to germinate with seed that has come a long distanee you are lucky. After a two months' journey 3,000 is probably the outside which will be realised.

This state or condition of the Indian tea plantations at the time when greater intelligence and careful study of climate, soil, and situation were beginning to attract attention, must have rendered it a difficult task to procure really fine seeds of a pure strain from the indigenous stock; and the condition of the gardens to which Mr. Cruickshank turned his services affords an abundant corroboration of Colonel Money's deliverance. When he first joined the Company the seeds he gathered were only the size of a blackberry (currant), and they brought only £25 per annum to the Company; but by careful cultivation and experiments, extending over the short space of two years, he raised seeds the size of a boy's marble, weighing ten times heavier than those with which he began his task, and in three years their revenue from seeds alone was £1,600 per annum, with the prospect of a large increase upon that sum. This statement seems almost incredible, but what follows renders its acceptance quite easy and natural. The number of litigations arising out of sales of bad seed must be patent to everyone who is connected with India, and here is one case out of many which came under Mr. Cruickshank's personal observation:—1,600 pounds of seed were delivered, weighing 500 seeds to the pound, which gives the enormous number of 800,000 separate seeds; they were carried from Assam to Cachar, and were five months in transit, and after being duly planted, and when the time for the plants to be appearing had come, it was discovered that not one seed had germinated. Mr. Cruickshank himself saw these seeds planted under instructions from the agents, and payment was to be made upon the percentage that germinated. All these seeds cannot have been bad at first; but such a result speaks volumes for the carelessness and ignorance of probably both the seller and the buyer. This fact almost suggests the story of "wooden nutmegs." It is a noteworthy fact that many planters have acted on Colonel Money's advice and have rooted up and cleared from their gardens every bush grown from China seed, and have replaced them by sowing indigenous seed. Great difficulty having been experienced in packing the seeds, so that their germinating power might be preserved unimpaired, even for one month, or until they could be conveyed from the gardens to Calcutta, Mr. Cruickshank tried the experiment of having them packed in strong loamy soil which had been thoroughly dried in the sun and broken up by passing through a fine sieve and hermetically sealed, and found that there was no particular loss sustained in their germinating power by keeping for six months, in fact, he has kept some seeds for fourteen months by this method. He recommends boxes to hold 20 pounds of seed as being the most convenient for carriage, and less liable to breakage and damage to the seed. On the principle that one accomplished fact is better than a dozen theories, it is interesting to note that Mr. Cruickshank has asked us to exhibit in our window seeds and plants of his own growing, and they have been examined and admired by thousands. Mr. Thyne, of Buchanan Street, was struck with their robust, healthy appearance. The seeds from which this plant was grown were gathered by himself on the 1st of November, 1879, and were preserved by the abovenamed method and brought home, and were planted in the hot-house at Garscube, near Glasgow, on the 20th of June, 1880, and every one of the seeds germinated, and their progeny consists of a beautiful hardy plant (or rather six plants or stems), standing three feet high, and bearing a vigorous foliage, many of the leaves measuring nine inches long, and it is still sending out fresh shoots, the bright pale green of the younger leaves contrasting with the darker tints of the older growth. To the non-professional mind the questions arise—What are the virtue of the two methods as practised by Colonel Money and by Mr. Cruickshank? and what is the action on the seed, the one method contrasted with the other? Charcoal packing cannot exclude the air, and Colonel Money seems to advocate as much air as possible, provided it be dry, cool, and in the shade. Is it possible that the charcoal absorbs some virtue from the seed, or absorbs the natural moisture from the seed, and thus renders it too dry to germinate when placed in soil at the end of two months, except to the very small extent of 10 per cent? These gentlemen, experienced planters both, are agreed upon the treatment of the seed up to the point of packing for transport—but here they differ widely. Mr. Cruickshank uses strong, loamy soil that has been dried in the sun, and hermetically seals the box, which shuts out all air from the seeds and retains in the seed whatever moisture may have been left in it when the drying process was completed; and the percentage of the seed that germinated is 100 as against 10! One could not look for so large a percentage from Mr. Cruickshank's method if his seeds has been planted in the open (in India); but he would be disappointed if at least 50 per cent did not germinate after a long journey and six months' keeping, because he has realized 80 per cent of seedlings by his method from seed sown in the open after keeping them for three weeks covered with dry mould. It would thus seem that tea seeds are prone to decomposition, and the point to be overcome is to arrest this tendency until after the seeds have been sown. That excluding the air has this result is partly proved by the fact that of two seeds of equal virtues, one planted at the depth of a foot from the surface, does not germinate for a long time after the other, planted at the depth of one or two inches. But the interesting and valuable fact remains that Mr. Cruickshank's method has preserved the germinating power for six, eight, and fourteen months, while Colonel Money's system appears to be capable of preserving this germinating beyond two months, and then only to the extent of 10 per cent. Of course, we cannot touch on the vicissitudes that attend the young seedlings after they have germinated, for here this comparison naturally ends. We may, however, state that Mr. Cruickshank brought home orchid roots by the same method, and with a like success. These facts are doubly interesting when we read that the growth of tea is now being experimented upon in America and many other countries, other than India and China, and in commencing a new industry it is well to get the best material to work with. This seed has the reputation of being the finest strain in Assam, and the parent plant was planted by Bruce, "the pioneer of tea in India," on the northern division of the great "Assam Tea Company's Gardens" at Jaipur, near Makkum Petroleum Springs, 550 feet above the sea level, and just on the British frontier. The Assam railways "guaranteed by the Secretary of State for India in Council" will have their terminus at Makkum—the prospectus of which was advertised in the *Herald* recently, and shows that the company was formed for the purpose of working coal, timber, petroleum, and iron in Assam, and for establishing a service of steamers on the Brahmapootra River, as well as the railway from the river (near Dibrugarh) to the Makkum coal-fields near the Dehing River. A few miles up the river Dehing forests of indigenous tea are found, so that this district may be considered the *habitat* of the plant. An acre of this class of plant will yield from 800 to 1,200 pounds of manufactured tea per annum when the plant comes to its maturity, and if properly manipulated will bring 3d per pound more than the ordinary hybrid or China varieties more commonly grown. The value of this seed is fifteen

times that of China seed, and the demand is so great that orders have to stand over for years. This method of preserving and packing seeds for export is calculated to have a wonderful effect on the prosperity of Indian tea planters, for they have now the assurance of an established fact that seed can be packed so as to keep for a length of time sufficient to carry them to any part of the world that may be found suitable for their growth. Owners of good stock can derive a large revenue from their seeds, while their less-fortunate brethren may take heart, and, by purchasing good seed, they may safely calculate on a larger outturn per acre, and the finer quality of the manufactured tea will soon recoup them for their outlay for seed and loss of time and ground rent. While the new plants are coming to the leaf-bearing stage, the experiments that are now being carried on in California and Australia (and suggested for New Zealand by letters in the *Herald*) will be watched with interest, and, should they prove successful, they may be the means of helping to solve that vexed problem of Chinese labour by providing a new industry eminently suited to the deft fingers and natural occupation of the yellow man. If we are not taking up too much of your valuable space, we should like to touch on a point which is suggested by one clause of Colonel Money's—namely, "The Indian tea is vastly superior to China tea, and commands a much higher price at home." This is no doubt quite true, and from a planter's point of view it cannot be denied; still we should like to record our opinion after 20 years' experience in Glasgow, where we have had many opportunities of noting the public taste, and it is well to look at the question from all sides.

That the Indian plant is more prolific and fetches a higher price is a fact which goes to show that planting from Indian seeds has a double chance over China seeds of turning out a profitable undertaking. Indian tea commands a higher price because it is much stronger, and is, therefore, valuable for giving body to a mixture of China teas; but this high price is very often out of proportion to its real value in the pot—the value is fictitious on account of their beautiful appearance to the eye, being in reality what the Highlandman said of his daughter, although he meant the reverse—"She was bonnier nor she was better."

Strength of body and toughness is a *sine qua non* in a piece of iron or steel, but is not absolutely so with regard to tea. Tea is drank under the belief and hope that it will have an exhilarating and invigorating effect upon the system—which it undoubtedly has if properly infused and used in moderation. Now, the great bulk of Indian, and especially Assam, teas are usually strong, thick, dark, and pungent, and these qualities are often so decided as to render them nauseous to the palate of ladies and delicate people; but these very properties commend them to the working classes, who "like something to grip the mouth." In China tea these characteristics are not so marked; but it possesses a finer flavour, and a more refreshing and exhilarating quality than the Indian, and these are virtues of no little moment. Given a sample of Indian (Assam) tea costing 2s 6d on the London market, and a sample of China tea at the same rate; an infusion of one ounce in a large teapot of each tea will yield liquors vastly different. The Indian sample will be very strong, rasping, and dark, with a flavour that is not pleasant to nine out of every ten people, a weaker infusion simply tones down, but cannot remove the unpleasant taste and flavour. On the other hand, the China sample will be of a moderate strength, with a soft, silky feeling on the palate, a pleasing colour to the eye, with a most agreeable flavour to every palate—except one that may have been rendered less susceptible to a delicate, delicious impression by reason of much smoking and drinking. In short, it may be said that Indian tea satisfies the palate very quickly without giving much refreshment to the system, while China tea refreshes the system without leaving any depressing sensation or a feeling of over-satisfaction. Judged by its effect on the human system, and not by its price on the market, we beg humbly, and with considerable diffidence, to contradict so exalted an authority as Colonel Money by declaring our opinion that "China tea is vastly superior to Indian tea."

At present it is well-known that India teas are not much used by themselves, very few people relish them alone, and they are almost solely used for mixing with China tea. Now, we venture to think, and give the suggestion for what it may be worth, that if the Indian planters could or would produce a "self tea" (one needing no mixture), combining the body and fullness of the Indian tea along with the refreshing qualities of the China tea, they would give an immense impetus to the increasing consumpt of the Indian product at the expense of the Chinese, thus supplying ourselves from our own empire, at the same time promoting the well-being of the native population. Some of the Darjeeling teas of recent years have been approaching this style of a "self tea," but the fine ones are (in our opinion) too dear; and the medium and common ones are often raw in taste, and slightly herby in flavour, something like the smell of new hay—a very pleasant flavour in its own place, but the breakfast table is not that place. In the preface to the first edition of his prize essay, Colonel Money states that "up to the last, at every visit to plantations other than his own, he has taken notes and learnt something—if rarely nothing to follow, something at least to avoid."

The writer of this letter has learnt much from Colonel Money's able essay, and much from personal intercourse with Mr. Cruickshank; and the copious notes which he took and received during many conversations with Mr. Cruickshank have enabled him to string together a number of facts which cannot fail to interest many readers of the *Herald*; and in this hope he begs to subscribe himself, sir, your obedient servant,

Stuart Cranston.

FLOWERS FOR THE TROPICS.

(From *Sutton's Tropical Garden Guide.*)

(*Continued from page* 736.)

Loasa.

A very beautiful climber.

Linum Grandiflorum.

A beautiful annual of slender growth. It thrives better in a well-manured border than in pans. Sow in October.

Lobelia.

A useful and beautiful annual, suited for pot culture, hanging baskets, bedding or edgings. Light sandy soil required, with plenty of moisture. Sow in October, and prick out when large enough to handle.

Lupinus.

A good old-fashioned showy flower. Sow 3 or 4 seeds together after having soaked them in water to render germination easier. Sow in October, and do not transplant.

Mesembryanthemum.

This beautiful annual is highly appreciated in India, the flowers, when open in the sunshine, being of great beauty. Sow in October in shallow pans filled with good soil, and transplant as soon as ready.

Malope.

Sow in October where the plants are to remain, as they seldom thrive after transplanting.

Marigold.

Sow in any good soil, and transplant to the places where they are intended to bloom when about 2 inches high.

MARTYNIA.

A free flowering plant, bearing very handsome large flowers. Sow in October on good rich soil; the plant will begin to flower 7 weeks after, and continue in bloom for a long time.

MIGNONETTE.

Sow in October, in patches in the open ground, or in pans in which the plants are to flower. On no account transplant, and if it is wished to prolong the blooming period, do not fail to pick off the flowers before they begin to form seed-pods. A sandy soil is best, but Mignonette will succeed in any garden with a little care. Liquid manure once a week will be useful.

MIMULUS.

This beautiful plant should be in every garden. Mix with sand to sow, to ensure regularity, the seed being very small. Prick out into pots, which should be kept in pans of water, as it is almost an aquatic. Plenty of silver sand should be mixed with the soil.

MYOSOTIS (FORGET-ME-NOT).

Must be cultivated as an annual, as it does not survive the hot season. Sow in October, and, if possible, keep the pot in a pan of water, to ensure perfection of growth.

NASTURTIUM.

Very little care is necessary in the growth of these beautiful flowers in Southern India, but in the North-West Provinces frost must be provided against by covering at night. In Bengal the seed should be sown in October and the ground kept well watered.

NEMESIA.

A very profuse blooming dwarf annual. Sow in October.

NIGELLA.

An annual with large flowers, which are surrounded with Fennel-like foliage. Sow in a damp soil in October. Does not do well when exposed to the sun.

NEMOPHILA.

A very pretty little annual, producing a profusion of flowers; should be grown in every garden. Must not be sown earlier than the middle of November, or the seed will not all germinate.

NOLANA.

A hardy trailing plant, bearing large and beautiful flowers. Very effective in pots, when the stems should hang over the sides. Sow in October. Will not bear transplanting.

NICOTIANA.

A highly ornamental plant, with showy delicate-coloured flowers. Sow in October, and transplant when large enough.

ŒNOTHERA (EVENING PRIMROSE.)

Sow at the beginning of the rains in a bed or pot of fine soil; prick out 3 inches apart; by the end of the season they will be fit to move to permanent quarters, where they will bloom well throughout the cold season.

OXALIS.

A dwarf but strong plant suitable for pots or rock-work. Sow in October.

PANSY.

Sow in pots about the middle of the rainy season to bloom about Christmas and continue flowering till February.

PEA, SWEET.

Sow in October, in circles at intervals along the border. When 9 or 10 inches high, sticks should be given to support the plants.

PETUNIA.

A very showy plant. Although really a perennial must be cultivated in India as an annual. Fresh seed should be ordered each year, or the plants speedily revert to their original type. Sow in October, and transplant when 3 inches high.

PERILLA.

Chiefly attractive for its rich bronze foliage; the flowers are not showy.

DOUBLE POPPY.

A free flowering annual and very effective. The Pæony-flowered variety is best. Sow in October on light rich soil where the flowers are required, as Poppies will not transplant.

PHLOX DRUMMONDI.

A very beautiful annual: no Indian garden should be without it. Sow in gumlahs, from which, when 2 inches high, plant out into small beds or clumps. Self-sown plants should be destroyed, as they are inferior to those produced from English seed. Sow in October or in January, to bloom in pots during June and July.

PLATYSTEMON.

A beautiful plant of trailing growth; will not bear transplanting. Sow in October.

PORTULACA.

By far the most brilliant and dazzling of all the annuals. Sow in the open ground in good rich soil, and great care should be taken that the spot chosen be not shaded by trees. Portulaca looks best in clumps, edgings, or circular beds. Sow in October.

RHODANTHE.

A beautiful annual, very useful for pot culture. Requires frequent shifting from one pot to another, with plenty of well-rooted manure. Sow in October.

SALPIGLOSSIS.

A highly ornamental annual, with a great profusion of delicately pencilled flowers. Sow in October; plant out when an inch or two high, to bloom about the end of April.

SALVIA.

A useful tribe of annuals, especially valuable for bedding.

SANVITALIA.

An exceedingly handsome dwarf growing plant with small oval leaves, thickly studded with daisy-like flowers. Sow in October.

SAPONARIA.

A handsome free-flowering annual, well adapted for bedding or sowing in clumps. Sow in October.

SCHIZANTHUS.

A very pretty annual when in full bloom, but of rather straggling habit. Sow in October, in light, sandy soil.

SCABIOUS.

A showy border plant, bearing large heads of flowers. Will not sometimes flower same season; but if not, keep till next cold season. Sow in October.

SILENE.

Very attractive, and remarkable for its fresh-looking foliage. Sow in October.

SPHENOGYNE.

The foliage and flowers of this beautiful annual are very attractive. Sow in October, and transplant 3 or 4 together in the open border.

STOCK (TEN-WEEK).

These usually succeed well in India, but in the immediate neighbourhood of Calcutta, just before the blossom develops, the plants are liable to be injured by a minute insect. Sow in open ground in October, and protect from the sun and rain. Some persons transplant when 2 inches high, but we think the best plan is to allow them to remain where sown.

SUNFLOWER.

This well-known annual thrives in India, producing very large flowers. Sow in July.

THUNBERGIA.

An elegant climbing annual. Sow in October.

TROPÆOLUM.

The seeds should not be sown till the cold weather has set in, as the young plants cannot endure the heat. It is a remarkably pretty creeper and should be trained to a trellis.

VERBENA.

A very attractive plant, well adapted for bedding. Sow in October.

VIOLA.

Strikingly handsome and beautiful flowers, which blossom well in the cold weather. Sow in October, and shelter from the sun and rain.

VENUS'S LOOKING-GLASS.

A profuse-flowering dwarf annual. Sow in October.

VIRGINIAN STOCK.

This pretty annual is well adapted for edgings or for planting in clumps, as the profusion of flowers renders it exceedingly attractive. Sow in good rich soil in October.

VISCARI.

A beautiful and profuse flowering annual, most attractive when grown in beds or clumps.

WHITLAVI.

A very beautiful annual, well suited to Indian gardens. Useful for borders. Sow in October.

ZINNIA.

This beautiful annual is useful for bedding purposes or for planting 3 or 4 together in a border. Sow in pots in July.

A NEW ALKALOID IN THE BARK OF CINCHONA CUPREA.*

BY B. H. PAUL AND A. J. COWNLEY.

In operating upon the cinchona bark that has lately been much employed in the manufacture of quinine, under the name of *Cinchona cuprea*, we observed some months ago the frequent occurrence of a crystallization from the ethereal solution of the alkaloids extracted from the bark. As this bark had never been found to contain cinchonidine, it seemed at first sight probable that the crystals thus deposited from an ether solution of the alkaloid might be quinidine, which is almost always present to some extent in cuprea bark. Further examination of these alkaloid crystals showed, however, that they did not consist of quinidine, but of an alkaloid which resembled quinine in forming a sparingly soluble sulphate, as well as cinchonidine in forming a sparingly soluble tartrate, though it differed from quinine in being crystallizable from an ether solution and from cinchonidine as well as quinidine by the mode in which it crystallized from ether.

There seemed, therefore, every reason to conclude that the cuprea bark contained an alkaloid which had not previously been isolated, and the probability of this being the case was consistent with the long observed peculiarity of the quinine sulphate obtained from this bark, as regards crystalline form or rather the texture of a mass of crystals. We consequently proceeded to separate a sufficient quantity of this alkaloid for studying its history more completely. This was, however, a work of some difficulty, since the sparing solubility of the sulphate did not admit of any satisfactory separation by the method of fractional crystallization, and we were constrained to have recourse to the plan of crystallizing the alkaloid from ether. By this somewhat tedious process we have obtained a small quantity of it, from which we have prepared some of the salts, and now give the following details of the characters of them and of the alkaloid.

The alkaloid is sparingly soluble in ether, crystallizing from it in long thin plates and sometimes in needles.

The sulphate resembles quinine sulphate in its sparing solubility in water, thus differing from the sulphates of cinchonidine and quinidine. It crystallizes out in needles.

The tartrate resembles cinchonidine tartrate in regard to its comparatively sparing solubility in water.

In the absence of any method of effecting a definite separation of this alkaloid, it is difficult to form any correct estimate of the amount present in the bark, and we have good reason for thinking that the amount of it varies considerably in different samples. Sometimes no indications of its presence are to be detected, and we are of opinion that this was generally the case with the earlier importations of cuprea bark. At any rate, it is only within the last four months that we have noticed the occurrence of this alkaloid, and then only in some samples. In certain instances, when there is much of the alkaloid present, its behaviour simulates that of cinchonidine, so much as to give rise to the conclusion that the bark contains that alkaloid, as well as quinine and quinidine.—*Pharmaceutical Journal.*

NEW ALKALOID FROM CINCHONA.

BY W. GEORGE WHIFFEN, F.I.C.

In the examination of the bark known as *Cinchona cuprea*, which has been imported from South America in large quantities during the last two years for the manufacture of quinine, I have repeatedly noticed the presence of an alkaloid differing apparently from the known cinchona bases.

Having lately collected a quantity of this substance for examination, I found it to be a previously undescribed cinchona alkaloid having great similarity to quinine.

It occurs, I believe, in greater or less extent in all the cuprea bark, and I have found from ·1 to ·8 per cent in samples recently analysed.

If the impure quinine, as obtained from a bark containing the new alkaloid, be dissolved in ether, there will be found, on long standing, massive groups of prismatic crystals. These crystals are collected and washed and recrystallized several times in ether to purify from traces of quinine.

As thus prepared the alkaloid is very soluble in alcohol even when dilute; the solution is strongly alkaline to litmus. When freshly precipitated the alkaloid is soluble in ether, from which it crystallizes in stellar groups of fine tabular prisms, having a pearly lustre. It is also considerably soluble in dilute liquid ammonia. It is not decomposed by cold oil of vitriol, nor by concentrated nitric acid. Sulphuric acid and potassic bichromate produce with it a deep green coloration.

So far as I have been able to examine them, its salts closely resemble those of quinine. The sulphate crystallizes from a solution in boiling water in pearly white needles, which taste intensely bitter; it is rather more soluble in cold water than sulphate of quinine, but far less soluble than sulphate of cinchonidine.

The cold saturated solution in water is precipitated by Rochelle salt, but is not precipitated by the cautious addition of potassic iodide. Chlorine water and ammonia produced an emerald green coloration like that formed by quinine and quinidine. With excess of acid its solution is fluorescent even when very dilute.

The most characteristic reaction is its action on polarized light. The solution of the sulphate in acid rotates the ray to the left more powerfully than sulphate of quinine, the relative angles obtained from efflorescent salts being thus represented:—

Sulphate of cinchonidine	(*a*) j	135°
Sulphate of quinine	(*a*) j	196°
Sulphate of new base	(*a*) j	221°

I have prepared specimens of this alkaloid for combustion analysis, and hope shortly to publish its ultimate

* The data contained in this paper find confirmation from the observations of Mr. Whiffen, recorded in the following paper, which was received at the moment of preparing for publication.—ED. *Ph. Journ.*

composition; meanwhile, on accont of its similarity to quinine and of the great action it exerts on polarized light, it may be distinguished by the term "ultra-quinine."—*Pharmaceutical Journal.*

TROPICAL PRODUCTS AND THEIR USES:

CASTOR-OIL—BEES—ALKALOIDS—PARSLEY AND MILK—CUPREA BARK.

(*Pharmaceutical Journal.*)

A curious statement is made in the *Bulletin de la Société d'Horticulture d' Orléans*, that the castor oil plant is an excellent remedy against flies. Those that alight on the leaves and suck the sap are said to fall down dead, their bodies becoming white. The castor oil plant is easily grown, and the experiment is worth a trial, although it is quite possible that the observation is a mistaken one.

In a paper recently read at the Linnean Society, Sir John Lubbock showed that bees have a preference for blue colour, and explained the fact that there are so few blue flowers by supposing that all blossoms were originally green and then passed through white or yellow, and generally red, in becoming blue, changes which may be observed in certain flowers during the development of flower-buds, *e.g.*, Boraginaceæ.

Some experiments by Herr Karl Hock (*Archiv*, Nov., p. 358) point to the spectroscope becoming available in the detection and recognition of alkaloids and other vegetable principles. Thus if digitalin be dissolved in concentrated hydrochloric acid and warmed, a greenish yellow liquid is formed that gives an absorption band in the blue at F. If sulphuric acid be used instead, a brown red solution is produced that gives two dark lines, one strong one in the green at Eb, and another rather fainter in the blue-green before F. If a few drops of Erdmann's mixture be added to the sulphuric acid solution, a third intense line is produced in the yellow at D. Delphinine, treated with sulphuric acid, gives a distinct band in green-yellow at D¾ E. Cubebin, amygdalin and salicin all form, with sulphuric acid, red solutions which are easily distinguishable from one another by their absorption bands. Other substances that have been found by Herr Hock to give characteristic absorption spectra of dark lines under similar conditions are belladonnine, solanidine, morphine, narcotine, codeine, papaverine, cryptopine, quinine and strychnine.

Dr. Stanislas Martin, in the *Bull. de Thérap.*, remarks that fresh parsley leaves used as an external application act most efficaciously in arresting the secretion of milk. For this purpose freshly plucked leaves are used and renewed several times a day as fast as they begin to fade. He states that they were used for this purpose by the Roman matrons of old, and are still used by women in the East, who renew a cataplasm of the leaves three times in twenty-four hours.

In August last mention was made in these columns (p. 179) of the fact that Herr Skraup had questioned the existence of homocinchonidine as a body distinct from cinchonidine, and had attributed the differences observed by Dr. Hesse to an overlooked admixture of quinine. Dr. Hesse has since replied, and whilst admitting that the sample of alkaloid supplied to Herr Skraup was slightly impure, denies entirely his conclusions. According to Dr. Hesse cinchonidine occurs in several South American cinchona barks, especially in those from *C. lancifolia* and *C. tucujensis*, and also in East Indian barks from *C. succirubra* and *C. officinalis*. In consequence of the enormous number of plants of the latter two species now under cultivation, it is probable that a considerable quantity of this alkaloid will come into the market in a few years. On the other hand homocinchonidine is found in the latter two species only seldom and then in traces, although it occurs in considerable quantity in South American red bark. In many respects the alkaloids closely resemble one another; under similar conditions they crystallize exactly in the same form, but whereas cinchonidine melts at 200° to 201° C., homocinchonidine melts at 205° to 206° C. Both alkaloids when dissolved in alcohol or chloroform under similar conditions rotate polarized light equally strongly to the left, though in acid solutions they differ. Much the same may be said of the hydrochlorates, both as to crystallization and rotatory power. But if 2 parts of the hydrochlorate be dissolved in 240 parts of hot water, and 1 part of Glauber's salt dissolved in the least possible quantity of water be added, the sulphate of cinchonidine forms crystalline prismatic needles, which when dried in the air, though they slightly effloresce, retain five molecules of water several months, whilst the sulphate of homocinchonidine forms delicate clusters of needles, which when dried in the air shrivel up and lose nearly all water of crystallization. The difference in the sulphates is said to be perceptible to the touch and taste. At 22° C. homocinchonidine sulphate is the best soluble in water, at 30° it equals cinchonidine sulphate in solubility, and as the temperature rises it becomes increasingly the more soluble of the two. Both bodies yield cinchotenidine upon oxidation, and Dr. Hesse thinks probably their difference is dependent upon the position of the hydroxyl groups.

According to a statement in the *Monthly Review of Medicine and Pharmacy* (December, p. 374), an examination of samples recently received in the London and New York markets as "cuprea" bark, seems to indicate that the number of bales of *Cinchona nova* held in stock, but called cuprea bark, is a not inconsiderable element in determining the price of quinine, and that the real stock of bark available for manufacturing purposes is considerably less than the monthly stock summary shows. It is not easy to understand this statement. It would be difficult to confound two cinchona barks so utterly unlike in their external characters, *Cinchona nova* being thick and marked with transverse fissures, caused by the shrinking of the bark in drying, and its inner surface distinctly fibrous, while cuprea bark, on the contrary, is a thin bark, externally resembling the false yellow bark of Para, the periderm being coarsely cracked longitudinally, the derm also cracked longitudinally, with occasionally concave depressions, and the inner surface smoother than any other known cinchona bark. It may further be noted that the bark is occasionally described as "*Cinchona cuprea*," which would indicate that such was the botanical name of the tree yielding it. This is an error, the tree not being known to botanists in this country, neither Mr. Howard nor the Kew authorities having as yet seen specimens of the leaves and flowers of the tree. Although it is quite possible that the name *Cinchona cuprea* may be given to it if it prove to be a new species, it is premature to call the bark other than cuprea bark, or *cuprea* cinchona bark. There are apparently two or three varieties of the cuprea bark in commerce, but none of these in the least degree resemble *Cinchona nova* (*C. magnifolia*), and evidently all belong to the same group or section of the genus as the typical cuprea bark. Nor does there appear to be any record of the cuprea bark appearing in the London market in 1857, although Mr. J. E. Howard noticed a somewhat similar bark in 1853.

CINCHONA.—In accordance with a suggestion of Colonel Beddome, the Government have sanctioned the expenditure of a sum not exceeding R1,000 for the experimental trial of various patent manures. It is understood that valuable artificial manure can be obtained from the firms on the West Coast, Mr. W. Rowson, Assistant Superintendent, Government Cinchona Plantations, Neddiwuttam, having proposed "that our soils be sent home for analysis, and that suitable patent manure be procured from England." The Government have replied that no analysis of the soils need be made at present.—*Indian Agriculturist.*

TROPICAL AGRICULTURE IN CEYLON: "LOWCOUNTRY PRODUCTS."

No. I.

A "PEOPLE'S PARK" WANTED FOR COLOMBO—HENARATGODA GARDENS.

"Kew Point," in Colombo, still preserves the memory of the first Botanic Gardens established during the British period in Ceylon, and, much as we appreciate the taste with which the police quarters in Slave Island have been built and the grounds around them laid out, we yet could wish, for the sake of residents in the capital of the island, as well as that of the multiplied visitors we may soon expect, that something more than the name and a few noble trees had come down to us of this generation from the Ceylon namesake of the great and justly celebrated Kew Gardens. It is true that others, besides Prince Soltykoff, have characterized Colombo as one great botanical garden; and no doubt numerous and varied drives over excellent roads lined with elegant cocoanut palms, and through richest green foliage of breadfruit, jak, cadju, bamboo, mango, cinnamon and other luxuriant trees and plants, brightened and rendered doubly cheerful by the primrose-coloured *pisonia*, the crimson "shoe flower," and in its season the truly grand "flamboyant tree" of Madagascar, are "beautiful exceedingly." Still we cannot help wishing that here, in Colombo, we could shew in a special garden or park, such as visitors to Calcutta, Bombay and Madras and the other leading cities of India at once seek, collections in a conveniently limited space of all the leading plants of the tropics, with the additional attraction of a select zoological family, ranging from the gigantic elephant to the minima deer, from the eagle to the sun-bird, and from the thirty-feet long alligator down to the three-inch green lizard: not forgetting "the praying mantis" and the stick and leaf insects. We trust that one speedy result of the concentration here of practically the whole steam navigation of Ceylon and much of that of the Eastern world will be to free Colombo from the reproach of possessing nothing more closely approaching a "People's Park" than the pretty but, as yet, scantily furnished expanse in the Cinnamon Gardens, of which the really handsome Gregory Museum is the central object. Until recently, a visitor who wished to see a systematic collection of plants, indigenous and introduced, had perforce to travel to Peradeniya, seventy miles upcountry. Doubtless the traveller would find his reward in roaming amidst the contrasted culture and wilderness, bounded by a noble river, of the "Royal Botanical Gardens of Ceylon," with its medium climate. If a sight of sub-alpine forms and a view of some of the grandest and most beautiful scenery in the world were desiderated, the journey had, as it still has, to be prolonged to Nuwara Eliya and Hakgala, the latter looking out and down on the forested mountains, the prairie hills and the rice-terraced valleys of Uva. With the attention paid to such "lowcountry products" in late years as Liberian coffee, cacao, cardamoms, caoutchouc trees, &c., came the demand for a strictly tropical branch of the Gardens over which Dr. Thwaites so long presided and where Dr. Trimen now reigns. Economic rather than æsthetic principles guiding the choice of situation, an exceptionally rich piece of forest ground was chosen, not at Colombo or near it, unfortunately, but within half-an-hour's drive or walk from the Henaratgoda station, sixteen miles from Colombo, on the line to Kandy. Here can be seen a rich grove of indigenous forest, alive with clouds of the great frugiverous bat called in popular parlance "the flying-fox;" and the visitor might ask the intelligent Sinhalese in charge whether he has observed any cases, such as undoubtedly occurred at Madras when trees the resort of those curious animals were denuded of leaves, of death amongst the big bats from sun-stroke! But the visitor will need the time between 8 a. m., when his train arrives from Colombo, and 10, when the down train from Kandy passes Henaratgoda, to examine the varieties of Liberian, (so-called) "Arabian," West Indian and other varieties of coffee; of cocoa from Carraccas and Trinidad, with fruits ranging from deep red sprinkled with gold to palest white; also cardamons, indiarubber trees of several species, and many other interesting plants. As the garden is bounded on one side by a swamp, some of our aquatic plants can be examined, and just outside the garden is one of the noblest objects in the vegetable kingdom, a talipot tree in flower. A good look at this tree in its dying glory of a pyramid of primrose-coloured blossom surmounting a massive column and springing immediately from amidst leaves of deepest green and of vast proportions will well reward a visit to "The Henaratgoda Tropical Gardens."

In travelling to Kandy by the railway line and without the trouble of alighting, if only a good look-out is observed areas cultivated with "new products" may be noticed. Cinnamon does not, of course, come under this category, and strictly we cannot include the manioc or cassava plant, with which experiments have been tried since the days of Bennett, if not from an earlier period. If only the markets for cinnamon and tapioca could be extended, Ceylon could grow any quantity of both products. But the new products to which we specially wish to attract the attention of our traveller are the gigantic coffee of West Africa "Liberian coffee," and the cacao (cocoa) of Central and South America and the West Indies. Both are rapidly making for themselves new homes in Ceylon, and a glance can be obtained of very fine specimens of both on "Liberia" estate, a few miles on the left hand going up beyond the station of Polgahawela (the Cocoanut Tree Plain), where the trains meet, and which is 45 miles distant from Colombo. "Liberia" is and always will be notable as the scene of the first attempt on an extensive scale to cultivate the coffee of Liberia in Ceylon. About two years ago Mr. W. Forbes Laurie, the enterprising proprietor, organized a party, of which Dr. Trimen, then only just arrived, formed one, to visit this splendid property, and a full account of the visit and of what was then observed on this splendid and most promising estate appeared in the *Observer* at the time. On that occasion the party was numerous enough to induce the railway authorities to attach a passenger carriage to a goods train which dropped

the visitors opposite the estate, those bound for Kandy or returning to Colombo being picked up by the afternoon trains. Isolated visitors would have to face a long and hot walk along the line from Polgahawela, or a ride which, in either case, could not be accomplished under at least a couple of hours, and as the return to the station would occupy about the same time, very little time or energy would be left for looking at the estate with its splendid blossom, and fruit-laden coffee bushes, interspersed with cacao trees with their long leaves and large pods. Owing to this disadvantage of position with reference to a railway station, visits to this the first Liberian coffee estate in Ceylon, must be much more "like angel-visits, few and far between," than the spirited and hospitable owner could wish. Much more manageable, in the interval between the arrival of the morning train from Colombo at Polgahawela, about ½ past 9 a. m., and the passing down of the afternoon train from Kandy, about 4 p. m., is a visit to the younger but equally successful plantation of Udapolla, which can be easily reached in a bullock hackery drive of half-an hour or less from the station. For most part of the way the journey is over the main road to Kurunegala, and the road opened to connect the estate with this highway and so with the railway, is short and easy, its terminus revealing a scene, well worth seeing by those who believe in Liberian coffee or cocoa; but still more worthy of attention by those who are sceptical because either of absolute ignorance of what has been accomplished, or of an exaggerated idea of the effect of preliminary difficulties, some of which were and are formidable enough, but which intelligent perseverance, observation, experience and skill have in this case conquered as they will in others. Our introductory matter has taken up so much space, that we must defer until tomorrow the details of our pleasant and profitable visit to the Messrs. Leechman's Liberian coffee and cocoa estate Udapolla, on the possession of which they are to be congratulated, and the flourishing condition of which we consider of good augury to enterprize in Ceylon. For the present we would simply add that, amongst the sights to be seen in travelling along the line, the traveller to Kandy should not by any means miss a good look at the successful experiment by Messrs. Leechman & Co. in planting up a portion of an old Arabian coffee estate with Liberian plants. Those plants, fresh, flourishing, and most promising, can be seen as the train emerges from the darkness of the long Moragala tunnel, on the right hand side of the line, just before the carriages cross the rocks of Wyrley Grove and run almost sheer over the celebrated Kadugannawa Pass road. The constructors of the road and even those who made the railway had no idea that Liberian coffee and cacao would rank, as they certainly will, amongst the important and profitable products of Ceylon.

No. II.

CULTIVATION BETWEEN COLOMBO AND POLGAHAWELA—CEYLON COMPARED WITH JAVA.

The country through which the railway runs between Colombo and Polagahawela is almost a perfect flat, the rice swamps being diversified only by low laterite knolls, on which the habitations of the natives are placed, but in such dense groves of coconut, areka and talipot palm, with jak, bread-fruit, cadju and other trees, that only a few of the houses can be observed from the line. While the vegetation generally presents an air of rich luxuriance, the amount of low undergrowth, in the shape of guava, lantana, &c., in the immediate neighbourhood of houses, suggests the idea of untidiness, and the European traveller feels inclined to ask: "Why do the people not clear and keep clear the space about their houses?" The Sinhalese cottagers would reply that, besides not seeing any advantage in unnecessary labour, they know that to clear and keep cleared of subsidiary growth the spaces near their houses would simply deprive them of a readily available store of small timber for firewood and other purposes. The intermixture of palms and trees of ordinary leafage on the knolls, contrasting with the sheets of water, the emerald green expanses of rice, or those which, as is the case now, are yellow for the harvest, is often very picturesque, and long before the great bulk of the Allagala mountain looms out beyond Polgahawela all feeling of monotony is dissipated by the appearance of the lower ranges of hills rising over the Mahaoya. The perfectly flat "paddy" fields for about forty miles along the railway beyond Colombo form a great contrast to the terraced rice fields seen in Java *en route* from Batavia to Buitenzorg; while the pretty terraces in the Dekanda valley form just a minute specimen of the vast terraced hill-valleys between Buitenzorg and Bandong, the latter the capital of the Preanger Regency. Some of the walls of the Java terraces are seven, ten and more feet high, cut in soft, greasy, brown volcanic soil which is as rich in the sub-strata as on the top. We have no such soil to shew in Ceylon, but neither have we to combat, in the case of fallows, such a fearful array of alang-alang. "*Alang*" is the Malay form of our Ceylon word *iluk*, and the doubling of the name is in accordance with the genius of the Malay language when an intensified form of good or evil, size, prevalence, or luxuriance, has to be expressed. If we possess not the fertile volcanic soil of Java, neither does our soil produce such expanses of a grass so difficult to extirpate as the "alang-alang," nor is a village in Ceylon likely, with its 100 inhabitants, to be suddenly overwhelmed by a mud avalanche, as happened in the Dutch colony, the other day on the side of Merapi—the Mountain of Fire. *Our* predominant element is water, and there is plenty of it for the husbandman's buffaloes to luxuriate in. Amongst the strange sights in Java, apart from the spectacle of a Malay or Javanese ploughman sitting on his plough to give it a better hold of the earth (a thing we never saw done in the soft mud fields of Ceylon), one of the most peculiar is the prevalent flesh-colour of the buffaloes. On first seeing the animals we experienced somewhat of the same revulsion of feeling produced by the appearance of a white man in a state of nudity, in a country where it is the custom of the dark-coloured races to walk about almost clotheless. We really felt as if the pink-skinned buffaloes had left home without their

apparel, and after laughing ourselves out of this idea, we came to the conclusion that they were *albinos*. But not only were their eyes, like their frames, perfect in strength,—the pink-skinned animals were by no means exceptional, "few and far between," but almost as numerous as their dark-coloured congeners. Our good friend Mr. Moens told us that the light-coloured buffaloes were, if anything, the stronger. But the most curious fact of all is that animals of both colours are produced whether the parents be both dark; both light; or one dark and the other light. The question then is how was it that such a departure from typical colour originated and how is it perpetuated in Java (which once was joined to the Himalayas), while in Ceylon, and we believe in India, a pink buffalo is as rare as a white elephant. If any reader can tell us where this phenomenon has been discussed and solved we shall feel indebted to him. But there are much greater divergences from Ceylon conditions in Java, although the one island is just about as far south of the equator as the other lies north of "the line." We brought acorns from Java which for size amazed beholders here, and no doubt the four indigenous oaks of which Java can boast, while Ceylon has not one *true* oak, are sylvan memorials of the far-back geological period of union with the Himalayas. But why is it that Java with a climate as tropical as ours, is able to breed not only a race of ponies famous for bottom and speed (we can see them rushing over Marshal Daendel's mountain roads, three abreast, and sending the sand flying into the traveller's face!) but elegant and fleet blood-horses. Attached to Mr. Kerkhoven's large tea estate at Sinagar are stables accommodating a couple score of as fine racers and saddle horses as could be seen anywhere, the manure (which is most carefully conserved) paying much of the cost of keep. The rich soil, no doubt, produces rich grasses, and equally certain it is that the "paddy" grown in the rich volcanic soil is proportionally rich in nitrogenous properties. Travellers along the railway line can now see the rice fields being regularly reaped by means of sickles. Possibly owing to a government regulation, forbidding the removal of the straw from the soil, in the paddy fields of Java, which probably cover as large an area in the Preanger Regency as the whole rice cultivation of Ceylon, sickles are not used, only sharp knives by means of which a few inches of the straw below the head are cut off. The women perform this operation, as well as the subsequent one of tying the heads together in equal sized bundles, with feminine neatness and dispatch. Two bundles are slung, one on each side of a pingo, and in this way cooly loads of paddy are carried to market or store, the grain adhering so closely to the stalk, that but little is lost. In travelling, our driver, when he wanted to feed his ponies, purchased a couple of these bundles, from a travelling cooly or at a wayside boutique, and the animals ate grain and straw, without pounding or preparation, finishing off with a draft of water, and then recommencing their gallop. At this rate we shall not get to Udapolla today, and, as we are going to see Liberian coffee and cacao, we may as well dispose in advance of our Java reminiscences of these new products. We had the advantage of the guidance of Dr. Treub, who is in charge of the Culture Gardens as well as the Botanical Gardens at Buitenzorg, in our visit to a large private plantation of cocoa,* as well as to the Government Culture Gardens, where, besides coffees of all possible species and varieties (including some with copper-coloured leaves), we were shewn fruit-bearing Liberian coffee trees under shade and in the open and also extensive nurseries of this plant. Dr. Treub, in view of a controversy which had raged as to the question of shade for the African coffee (the rule in Java, for Arabian coffee having been shade, even up to considerable elevations), requested our special attention to the comparative or contrasted appearance of the Liberian trees in the open and those grown under shade, both as to leafage and fruit. Although we fully share the orthodox Ceylon belief that shade is unnecessary, we felt compelled to say that not only were the trees under shade in this case superior in both respects to those in the open, but that never in Ceylon had we seen finer Liberian coffee trees. Dr. Treub seemed very much gratified at this latter concession, and, as regarded the shade question, he proceeded to state that the then head of the Culture Department, who had succeeded van Gorkom, had thrown the authoritative weight of his opinion against shade in the cultivation of the new coffee. "The result has been," said Dr. Treub, "that millions," and then correcting himself he substituted "hundreds of thousands of plants were lost, before shade was resorted to for this as for the old coffee." All we could say was that evidently, notwithstanding almost equal conditions of latitude, there was something in the climate of Java which rendered it essentially different from that of Ceylon, and that the planters in each colony must act on the results of their own experience. On the mature Liberian coffee trees, as well as those of the other varieties, we had to look carefully before we could detect a single trace of the fearful fungus, *Hemileia vastatrix*, but the case was very different when we came to examine the young Liberian plants in the nurseries. They were closely planted in the rows (one possible condition of comparative debility and liability to disease), the foliage was close to the ground, and the soil, as well as the plants, was copiously watered at least once a day: perhaps more frequently, for there had been a three months' drought. Our readers will see that here were all the conditions favourable for the vivification and virulent action of the spores of *Hemileia*, if they were present. Present they were with a vengeance for, on turning up the leaves of the nursery plants at Buitenzorg, we had a repetition of what we saw eleven years ago on an estate in Ceylon, the owner of which, after thirty four years' residence in the island, invested all his life's savings in coffee culture, only to commence a deadly struggle with "leaf-disease," the result of

* Correctly written [illegible]; but sometime ago we intimated in the [illegible] that, for the sake of uniformity, we should adopt [illegible] pronunciation in Ceylon for cacao, ... the name of the palm, by way of distinction, "coco." This form has been adopted in our Directory.

which has been that in the ten years only one really good crop has been harvested: 2,200 bushels being the substitute for 8,000 due under old conditions, in the season now closed. Having previously seen Arabian coffee trees in Java about three to four years old, in a plantation about 1,500 feet above sea level, shaded by trees of *Albizzia Molluccana*, rather badly affected with leaf-disease, we feel justified in saying that *Hemileia vastatrix* is as certainly present in the Dutch colony as in Ceylon; and if it never acts with such fatal virulence in Java as it has done here, the cultivators will owe their comparative immunity, first to favourable conditions of soil and possibly of climate (the atmosphere being in many places so permeated by sulphurous gases that our silver watch turned black during our travels); and second, to the diligent and intelligent use of the plenteous stores of sulphur at their command, and the lime which can also be obtained. Shelter will be more or less given by the shade trees. The great merits of the *Albizzia* for shade is its rapid growth into a grand tree, "its leaves turning down at night, so as to permit a free fall of dew." We are using the words of a Dutch friend. The chief demerit of the tree is its brittleness, so that great branches sometimes do not need wind or anything beyond their own weight to send them crashing down, destroying the coffee or the cocoa below. Of this peculiarity of the tree we had full proof when we visited the cocoa plantation at Buitenzorg, in company with Dr. Treub, whom it was then our turn to question as to the comparative effects of shade and full sunlight on cocoa pods. We felt regret and depression to see so many thousands of pods, which ought to have been beautifully red, presenting a funereally black appearance from the action of a species of blight, of fungoid origin, we believe. We attracted Dr. Treub's attention to the fact, which he could not deny, that in spaces to which full light had been admitted by the fall either of whole trees or large branches of the shade trees the proportion of healthy pods was far greater. He admitted that this cocoa blight was a serious visitation, so early in the history of the young industry, and stated that the Government had arranged for considerable importations of *Cacao alba*, which was believed to be blight proof. Specimens of the red and white varieties, in a perfectly healthy condition, we saw in the hot open (it *can* be hot there) at Udapolla: and, although Liberian coffee has not been equally fortunate, yet the badly affected trees were but rare exceptions to the rule of an undulating expanse of trees rich in dark-green foliage and laden with fruit. Out of a great variety, certain trees, the seed of which is specially selected for sale and propagation, seem able almost entirely to resist the fungus, while their yield is exceptionally good in number as well as size of cherries. Of the latter we brought a few with us to Colombo, and a dozen, in a pretty dry state, weighed 3¼ ounces; while a single specimen measured round 3¼ inches by 2¾. If trees of this coffee, planted 700 to an acre, yielded only an average of 2,000 cherries, and single trees have given from 5,000 to 6,000 (enough to fill a bushel), the result would be 14 cwt. per acre of clean coffee. Half this yield would pay exceedingly well, but the whole or more is likely to be gathered at Udapolla. The mucilaginous matter is more in proportion than in the small coffees, so that from 100 bushels of Liberian "cherries" is obtained only 25 bushels of "parchment." That quantity of parchment, however, yields cwt. 5-1 of clean coffee.—But here we must stop for today.

No. III.

THE KURUNEGALA ROAD—UDAPOLLA ESTATE—LIBERIAN COFFEE.

In proceeding from the Polgahawela railway station to Udapolla estate, the traveller cannot but be struck by the luxuriant growth of the coconut and areka palms and the jak and other trees which line and shade the road to Kurunegala. A village is passed through, the inhabitants of which looked well and cheerful. In certain years and at certain seasons, however, they, like most of the dwellers in the region at the foot of our mountain ranges,—the "Terai" of Ceylon,—suffer a good deal from "jungle fever." No doubt liability to this depressing affection is one of the most formidable obstacles to extended cultivation over large tracts of fertile soil in the lowlands of Ceylon,—along the banks and on the deltas of such rivers as the Mahaoya. So strongly did this objection offer itself to a planter of whom we once enquired why he did not try an experiment with lowcountry cultivation, that he emphatically said he would have nothing to do with a pursuit so risky to the health and life of Europeans, not to speak of the native labourers. If such a principle were generally acted on, much of the world, notably Africa, would never be opened to culture, commerce, civilization and Christianity. Not only are there large areas of healthy land in the lowcountry of Ceylon, but even in the Seven Korales and along the banks of the Mahaoya a fair degree of immunity from sickness can be secured by the adoption of sanitary measures and the taking of occasional charges. On Udapolla salubrity has been secured by shifting the bungalow site from a low situation to a breezy knoll, and Mr. Jardine, the able and intelligent superintendent, looked hale and hearty, as he conducted our party round the estate, pointed out the varieties of trees, and dwelt on the ascertained characteristics of each. He confirmed what our own experience had previously taught us, that imported seed had given not one or two but about a score of types of African coffee. Some are as objectionable as others are superior. On the latter, dense and dark in foliage, unaffected by the fungus, with the primaries springing from the stem close above the ground and every branch and twigs as well as the stem, covered with fruit in all stages and shewing blossom, flags were being placed, so that the fruit of such selected trees might be separately gathered and prepared for the nurseries or for sale. We have spoken advisedly of fruit on the stems and branches, for, in the case of the Liberian coffee, clusters of blossom and fruit appear on the bark, after the fashion seen on jak and bilimbi trees. It is also, as yet, impossible to say how frequently the same wood will bear fruit, so that pruning is

more sparingly resorted to than even was the case in former years in Haputale, where the same wood bore three times in succession. As our readers are aware, the general rule with Arabian coffee in Ceylon is that when secondaries have borne a full crop they must be removed by the pruning knife to make room for their successors. Not only is there no pruning of the Liberian coffee trees, but even handling is confined to the removal of one shoot, when two start from the same "eye." The eccentric mode of growth, *towards the stem*, of the secondarics of this species of coffee, was a trouble to the owners of this estate as it has been to others, and as it was felt that the knife, if too freely used, would simply result in denudation of the trees, Mr. Jardine, was allowed *carte blanche* in the treatment of the errant twigs. He has successfully adopted the expedient of tying the secondaries with strings of unravelled gunny, on the principle of

"Just as the twig is bent, the tree 's inclined."

No doubt this system of altering the natural direction of growth involves time and trouble, but the number of trees per acre is not so great as in the case of Arabian coffee, nor are the shoots so numerous, and fruit is borne so copiously by all ripe wood, that the trouble and expense are amply repaid. At the commencement of the Liberian coffee enterprize, not only was shade deemed absolutely necessary, even after the trees had grown up, but such preposterous distances apart as 12 × 10 and even 12 × 12 were recommended and the advice acted on. Experience on Udapolla, extending now in the case of the oldest trees to three years and eight months, has led to the decision that the best distance apart is secured by 7 × 8. On an estate so planted, at least 700 good trees may be expected to give an average of 2,000 cherries each, the result being 2 cwt. *of clean coffee* from each 100 trees, or 14 cwt. per acre, as we have already stated. That such calculations are justified experience proves. At the commencement of the present season, Mr. Jardine, determined to be on the right side, estimated only 1,100 bushels from Udapolla. That quantity had actually been gathered before our visit, so that to that, extent, we saw this splendid property at a disadvantage. The estimate of the season's yield had been raised to 2,000 bushels, but a gentleman who took part in the visit, a planter of long experience and the head of one of the leading Colombo firms, declared that in his opinion there were 2,000 bushels then on the trees. He meant of this season's fruit, apart from that at all stages, which would constitute next season's crop, and which closely covered the younger wood and the ends of branches and twigs. It is a peculiarity of the Liberian coffee that although it is affected by seasons, in one of which it has generally three "big blossoms," yet it is almost always, like the orange tree, shewing blossom and fruit in all stages. This characteristic and the fact that the cherries of this species of coffee do not, in many cases, put on the rich ruby red which distinguishes the mature "palam" of the Arabian coffee, have led many to doubt if the fruit would properly ripen : indeed the belief that it would not and could not ripen has been advanced as a fatal objection to this new product. But not only were we assured that the fruits are perfectly ripe when only of a pale yellow hue ; we had the convincing proof of the pulper in action. Apparatus and appliances, for the preparation of this exceptionally large coffee, being as yet somewhat imperfect, it is true that children were employed to recover about 2 per cent of the parchment beans from the mass of cherry skins ; but this was not due to any want of ripeness in the cherries. As to the quality of the coffee, all we can say is that we have seldom drunk a better flavoured infusion than that contained in the cup served to us at Udapolla. A gentleman high in local society has told us that twice were his guests served with Liberian coffee without its origin being revealed, and that they were loud in its praise ; and we know that more than one critic, who was fond of protesting that he could, under any circumstance, detect the alleged coarser flavour of this coffee, mistook the beverage when supplied and imbibed for the product of best Arabian. So strong is prejudice or tradition that the Messrs. Leechman have actually been compelled to prepare this coffee specially for the American market, so that it may have, instead of the greenish blue hue of well ripened and properly prepared beans, the dirty yellow colour, which the unripe and badly prepared coffee originally received from Liberia had accustomed consumers to expect ; just as the same yellow colour is desiderated in "best Mocha" coffee. Our friends are doing their best to imitate the outward signs of badness, but they warn their correspondents in America that, if sourness is the result, the preparers must not be blamed. We feel confident that well ripened and well prepared Liberian coffee will, ere long, assert a position on its own merits, just as Indian tea has done.

The mistake of too wide planting having been discovered, its correction here, as elsewhere, has been effected by quincunxing as well as planting between every two trees in the rows in which they are widest apart. Of course, all these trees will not be permitted finally to crowd each other. The inferior trees—those which send up long stems before they think of primaries, and others which, although dug about and manured, shew a special predisposition to leaf-disease and a "shuck" condition—will be rooted out. Over a considerable surface, however, cocoa trees, equivalent to 70 acres if planted apart, are interspersed among the Liberian coffee and look exceedingly well. As yet these plants are perfectly free from any trace of disease, and a few are bearing at a rate which gives promise of most profitable returns. It is now evident that, so luxuriant is the growth of the cocoa trees, they will require considerably more space than the Liberian coffee : 12 × 10 or even 12 × 12 being, in their case, probably not too wide apart. Those interested in the estate say : "Even if leaf-disease affects the Liberian coffee as disastrously as it has acted on the Arabian, we can fall back on the cocoa." But although leaf disease is attempting its "level best" against the beleaguered coffee, and has been successful in shaking and denuding a few weakly trees, the vast majority of those we saw covering the undulations of Udapolla (from 200 to 500 ft. above

sea level, with glorious views of the plains of Seven Korales and of the hills and mountain ranges from Belgoda to Kirigalpotta and Totapela) were vigorous and fresh and evidently able to resist the attacks of the insidious fungus. A more beautiful sight can rarely be witnessed than this fine plantation of Liberian coffee, interspersed with cocoa trees, kept clear of weeds, no easy task in the hot lowcountry (with a rainfall of about 90 inches), by means of fortnightly weedings. When these were insisted on, the contractors, who received R1·25 per acre per mensem, grumbled ; but now that they see the advantage of keeping the weeds down by preventing them from seeding, they are more than reconciled to the frequent weeding. The most prevalent weed here and the most difficult to eradicate, we were surprised to learn, was a soft, succulent spreading plant, which the natives convert into curries. Europeans who have partaken of it so cooked declare it to be very nice. The native names are : Sinhalese, *kiri* ; Tamil, "*koli kurumban.*" We have heard of much worse weeds than this, which surely ought to be utilized by being sent to market? Having asked about the "topping" of these Liberian coffee trees, we were told by Mr. Porter that the best average height was 5 to 5½ feet, but that the altitude varied from 4½ feet in situations much exposed to wind, to 6 feet extreme in rich soil and good shelter. If the trees were allowed to grow higher than 6 feet, the pickers would need the aid of ladders, which are actually put in requisition in Java in the case of Arabian trees, allowed to grow at their own sweet will, and to become the hosts of luxuriant mosses, ferns, and orchids. We brought a dendrobium to Ceylon which we saw in full blossom at a height of 12 feet high in an old coffee tree which was at least 20 feet high and as thick in the stem as a man's thigh. We do not recommend the Java mode of cultivation, but we hope some planter will spare a few exceptioual trees, in order that the extreme height Liberian coffee can attain to may be settled. In very hot low districts, like that in which Udapolla is situated, rapid growth upwards is not likely to be so much the rule as in moist climates such as prevail at Kalutara and towards the Adam's Peak ranges. At Kalutara it has been already proved that the growth of secondary wood is more luxuriant than in the Seven Korales districts. Here at Udapolla the real danger will be that of trees exhausting themselves by enormous crops of fruit. Supplies of good manure will constitute the remedy, which indeed has already been applied with good effect. The contiguity of the railway station is a great advantage for the carriage of artificial manures from Colombo, while a good deal of old well-rotted cow-dung has been obtained from the natives. The manner in which the manured trees have responded to the application is most encouraging, as shewing that strength of tree and luxuriance of foliage can be preserved while large crops of fruit are gathered. We heard most encouraging accounts here of the great success of Scowen's transplanter, supplemented by a tin shield and cup, which effectually prevent the breaking of the cylinder of earth taken up around the plant, while *en route* to the field. By this means plants can be put out in any weather, only a few ferns being required in periods of drought. A plant was taken out of its hole and put down again to shew us the *modus operandi*. The hollow cylinder of the transplanter was put down over the plant and pushed by the handle to a depth of fully four inches. The instrument was then drawn up, and the plant came with it in the centre of a cylinder of earth. That portion of the earth taken up was carefully cut away with a sharp knife. The earth and plant were then pushed up by a wooden peg, over which the instrument was placed and pressed. The cylinder of earth, if carried any distance with the plant, would now be liable to break away and leave the roots exposed. Of course Mr. Owen's expedient of old newspapers converted into funnels might be at this stage adopted ; but what was actually used, as safer and more effectual, was an elastic tin shield, open on one side, so as to enable the operator to make it clasp the earth. As soon as this was done, a tin cup was put on underneath, and the plant and earth could be carried any distance. Hundreds of thousands of plants have thus been put out with scarcely any appreciable loss.

No. IV.

VARIOUS PRODUCTS ON UDAPOLLA—INSECT PESTS.

A visitor whose eye has been educated into an ideal of coffee by the characteristics of the Arabian (properly Abyssinian) species will be struck not merely by the comparatively enormous size of the foliage, generally, of the Liberian species, but by the robust stems and branches even of young trees, the exterior of the bark being much rougher than is the case with the ordinary coffee. Some excellent varieties of the new coffee, however, are distinguished by comparatively small and pointed leaves. All coffee blossom is beautiful, although evanescent, but there is a positive grandeur about both the blossom and the cherries of the gigantic species. The period for the two or three great blossoms is between December and May. Although there is more or less blossom and fruit all the year round, yet the period between July and November is comparatively quiescent : the resting time of a coffee which sleeps with its eyes open. As may naturally be supposed, the Liberian trees grown at low, hot elevations, like that of Udapolla, come into bearing at an early stage ; but it is as yet impossible to fix the limit of altitude for the profitable cultivation of this extraordinary plant. A gentleman who accompanied us on our visit stated that he had grown plants at Pussellawa (at from 2,500 to 3,000 feet elevation), which, at the same age, were taller and bore more cherries per tree than any of the Udapolla trees, fruitful as these were. He referred to a few isolated plants, however, which had probably received special attention. We have attempted, without success, to acclimatize the Liberian coffee in a valley 4,900 feet above sea-level in Dimbula : the plants live but refuse to grow. About 2½ years ago, however, we gave a New Galway planter a couple of plants for trial which were about a year old at the time. They were recently reported to have blossomed and matured fruit at an elevation of 4,300 feet ! This, we suppose, is the extreme height yet in Ceylon

at which the coffee of Liberia has flourished and fruited, and we should be glad to receive full information as to shelter, exposure to morning sun, mean and extremes of temperature, &c. Our readers will remember that Dr. Thwaites put his ban on any attempts to obtain a hybrid between the Arabian and the African coffees, such as has proved so valuable in the case of tea culture in India—the hybrid between the large indigenous Assam tea and the small China being superior to the native Assam in robustness and to the China in size of leaf and strength of liquor. Why a process which has resulted favorably in the case of tea should be objectionable in that of coffee, we have forgotten if we ever had the reasons explained to us. Amongst the notes of our visit to Udapolla, we find the remark, with reference to the doubts expressed as to the cherries ripening, that no difficulty was experienced in pulping even after the heat of May and June. As those are the months when cinnamon grows near Colombo is peeled, because of the south-west monsoon rains and the consequent flow of juice between stem and bark, we take it for granted that at 45 miles north-east from Colombo there is a perceptible difference of season and climate. In going to the estate almost at right angles to the railway, the 47th milestone from Colombo by road via Ambepussa and Alawwa, and the 11th from Kurunegala, will be noticed, and attention will be attracted to the nice wicker granaries by the roadside, erected over pedestals, and the lower portions of the wicker work plastered with clay. Here the paddy growers store their grain. And this reminds us that in Java the women not only reap the grain but perform the operation of planting, which in the Dutch colony is most scientifically and carefully regulated. The seed is germinated thickly in nurseries at corners of fields, and when the men, with their buffaloes, cattle and ploughs, have prepared the earth for the young plants, companies of women make their appearance to conduct the planting. Each removes a bundle of plants about 4 to 6 inches in height from the nurseries, arranges the roots straight together, and chops off from 2 to 3 inches of the tops of the young blades. The plants are thus uniform in size and start fair, in the rows in which they are placed, those rows being as straight and as equidistant, while the spaces between the plants in the rows are as regular, as is the case in the most careful coffee planting. In Java, the Government have an important Culture Department presided over by a high civil servant, every young gentleman who joins the service spending the first six months of his residence in the colony at the Culture Gardens at Buitenzerg, not only reading books on agriculture and listening to frequent lectures, but taking part in the practical work of growing sugar, coffee, cocoa, cassava, rice, &c. The peasantry are not only taught but we believe compelled to adopt what is deemed the best method in cultivating the great staple article of food, rice, as well as other products, indigenous and exotic. The two large volumes which Mr. Van Gorkom, the late director of the Agricultural Department, has just published (in Dutch, we regret to say) are proof of the great interest taken by the Dutch Colonial Government in all branches of agriculture and the importance they attach to "new products" as well as old staples. We hope, shortly, to be able, by means of translations, to give our readers the benefit of some of the information which the learned and able Dutchman has collected regarding cultures so diverse as cassava and coffee; sugar and indigo; rice and cinchona. And this reminds us of what we were told at Udapolla, that, in the Kalutara district, *calisaya ledgeriana* plants are flourishing at so low an elevation as 200 feet (on Geekianakande estate), the refuse of the *citronella* grass from which the essential oil has been extracted being used as manure for the cinchona plants. We shall be curious to learn the subsequent history of those plants and especially the results obtained by analysis of the low-grown bark. We were struck with the different growth on Udapolla of seedling Ceará rubber trees and those grown from cuttings. The former shot up about a dozen feet, before commencing to form "heads"; the latter sent out primaries close to the ground, and the whole habit was bushy and squat. A large number of *suriya* trees *(Thespezia populnea)*, which had been grown along the paths, we found uprooted. It was explained to us that the trees failed to grow straight and injured the coffee near them. Trees which had been spared in one portion of the grounds, where shelter from wind was required for a separate patch of cocoa trees, shewed the same tendency to early blossoming and seeding in this forcing climate as did the other plants grown. The timber of the suriya is so valuable for coach-building and other purposes, that we suspect a regular plantation of the trees would, in from the fifth to the fifteenth year, yield a large return to the planter. Trees grown from seed are doubtless superior, and plenty of seed can be obtained. By close planting a straight habit in the trees could be secured. *Cassia florida*, the *wā* of the Sinhalese, yields excellent firewood for railway purposes in four years from planting out; and this and perhaps some other trees could be combined with a plantation of suriyas. We were amused at the details of an experiment which Mr. Jardine had tried with a fast-growing shade tree (Jonah's "gourd"), *Palma Christi*, the castor oil plant. All was serene until one morning in the course of his rounds the superintendent was horrified to see almost bare stems, except that they were covered with multitudes of caterpillars which had already eaten up the leaves. We suggested that the "poochies" had been produced by the *tusser silk moth*, but our friend said he was too anxious to exterminate the creatures, with the plants which had attracted them, to glean any information as to their identity. Happily none of them seem to have shewn an inclination to taste the foliage of the coffee and cocoa plants. It is impossible, however, to predict what enemies introduced products may have to encounter. Not only have the cockchafers of Ceylon discovered that the tender rootlets of coffee are preferable to those of the patana grasses as food for the grubs; but suddenly and mysteriously a fungus, previously so latent that even science was ignorant of its existence, discovered that

the leaves of the coffee plant were good for food and to be desired, and we all know the fearful result. *Oïdium* and *phylloxera* may have been introduced to Australia with the vines which were imported from all vine-growing portions of the earth: from the forests of the western world as well as from the sunny plains of France, the slopes of the Swiss mountains, and the banks of the Rhine and Moselle. But purely indigenous was the plague of locust-like grasshoppers which we found so prevalent on the largest vineyard in Victoria, perhaps in the world, that opened in the valley of the Yarra by an enterprizing Swiss, Mr. de Castella, and named "St. Hubert" after his patron saint. The St. Hubert wines and the names of Castella and Rowan are now known all over the world, the Emperor of Germany's special prize at the Melbourne Exhibition having been awarded to them by the German Commissioner, who ranked the Australasian light wines with those of his own country. But over the 250 acres of vines, which (with cellars, presses, &c.) had cost, we were told, £80,000, the grasshoppers were devouring. The insects were so numerous that we could not walk through the vines without treading on them; 200 turkeys which Mr. de Castella had just turned in were making but slight impression on the enemy, and we were actually told that the insectivorous shrikes known locally as "magpies" were dying from the irritating effects of the serrated wings and legs of the grasshoppers they had swallowed. The visitation was reckoned a very serious one; but probably creatures which we saw swarming in the fervent heat of January may have been killed off by the wintry frosts of July. In any case, it is not only coffee planters who have to contend with insect and fungoid plagues. In Victoria the heroic but we fear ineffective remedy is being tried of eradicating all the vines in the Geelong district, because *phylloxera* has there appeared. We have noticed the discovery made by the cockchafer beetles of Ceylon that the rich rootlets of coffee are as food preferable for the nurture of their *larvæ* to the roots or stems of poor, innutritious grasses. But Professor MacCoy, the Professor of Natural Science in Melbourne University and Director of one of the best filled and most interesting Museums out of Europe, has in his Prodromus of the Natural History of Victoria recorded a case still more singular. Noticing a plate of *Agarista Glycine*, the Vine Day Moth, he wrote:—

> This species received its specific name from Lewin observing that in New South Wales the larvæ fed on the leaves of the leguminose plant the *Glycine bimaculata*. In this colony, however, is is generally called the vine-moth, from one of the most extraordinary changes of habit ever recorded in any insect. In the early days of this colony, before the introduction of the vine, the larvæ of this insect fed on the *Gnaphalium luteoalbum*, which is a very common weed, but since the planting of vineyards the *Agarista glycine* has increased enormously in numbers, and *has totally abandoned its original food to devour the leaves of the grape vine*, never now touching the former, but thriving and multiplying beyond measure on the foliage of so totally dissimilar a plant, that if the perfect female Day-moth be guided by ordinary instinct to choose that plant on which to deposit its eggs on which the larvæ might find suitable foliage for food (the perfect insect not only being deprived of jaws fit for eating leaves itself, but being separated from the foliage-eating larval stage of its existence by the intervening pupa stage, in which feeding, motion, and the senses are all stopped), it is not possible to conceive or understand how the egg-laying Day-moth could have gained such knowledge of the properties of the vine as would induce it to abandon the natural food (not of itself, but) of its larvæ, and to put its trust in a foreign plant of which one might suppose it could know nothing.
>
> There are two or three broods in the year, the first brood of larvæ appearing about the end of October, or when the vines begin to come into leaf, and after a few weeks enter the pupa state, about the beginning of December, the moth coming out about the end of December, while the larvæ figured, descended into the earth, formed their earthen cocoons beneath the surface at the end of March, and the perfect imago came out on the 18th of May.
>
> I cannot understand Lewin's statement and figure of a light cocoon of thin silk attached to twigs of trees for this species, for in this colony it invariably forms a slight cocoon of earth below the surface of the ground.
>
> The injury done to the vines in the extensive vineyards of Victoria by the larvæ of this species is enormous, and seems to be increasing. Their numbers are altogether too great to be dealt with by any other means but hand-picking, and there are not hands enough in the country yet for that as the children by law must attend school. The acclimatisation Society acclimatized the Indian Minah in the hope that, besides destroying the grasshoppers and locusts (which they do admirably), they might diminish this pest also; but they have unfortunately developed a taste for eatnig the grapes, and do not seem to like the larvæ of the *Agarista*. Before the new school law, children used to be employed thinning the numbers of the larvæ in an unpleasant but effective manner, by cutting each one across with a pair of scissors as they walked along the rows of plants, instead of delaying to pick them off. Even this sharp and decisive proceeding is too tedious to keep down their numbers, and, to add to the difficulty, the fowls even will not eat them, nor any other creature as far as I know. The only suggestion I can make is to employ hand-pickers, at the time of the approach of the first brood of caterpillars, when the vines come first into leaf. Each one killed then prevents the formation of multitudes, as well as gives strength to the plant by their present removal. The next object of attention should be to kill all the moths of the first brood found on the wing, the figure here given rendering the right one easy of recognition, and this for each one killed will destroy myriads of eggs which would form the second brood.

The above extract proves that "there are more things in heaven and earth" (and in the insect world) "than are dreamt of in our philosophy"; and that we are not alone in suffering from the attacks on our enterprize of enemies, minute and yet so formidable as almost to set man's industry and skill at defiance. But as we do not believe that fungi or insects will destroy the young vine industry of Australia, so neither do we believe it to be the settled design of a benevolent Providence that the leading and long-established enterprise of Ceylon should succumb to the attacks of *Hemileia vastatrix* and grubs. The pests have had their cycle, and we again look for "a good time coming."

Before closing these discursive notes, we cannot help attracting the attention of travellers along the railway line to the very large flocks of the small stork (paddy-bird of the English and "*kôkâ*"—from the note it utters when rising,—of the Sinhalese) now to be seen feeding on Darwin's most recent heroes, the earth-worms, in the newly-ploughed rice-fields. We have seldom, if ever, seen so many "kôkâs" together before. Then about five miles on the left, before reaching Polgahawela, there is, just under a low hill, surmounted by a large pointed boulder, a glorious group of fully a dozen talipot palms in blossom We trust Mr. Skeen, or some other enterprizing photographer, will not fail to perpetuate this group in a series of plates.

In reference to the remark respecting the favourite transplanter used on Udapolla, we find a correction is required. The fitting complement to Scewen's transplanter, which is the one chiefly used, is found in a tin envelope and ring contrived by Mr. L. W. Davidson, manager of Culleden estate, Kalutara. This envelope is, as we said, a single piece of sheet tin cut to the size required, which opens out to clasp the plant and ball of earth when released from the transplanter, the envelope being secured by a ring slipped over the end. In practice this has been proved to be a most convenient and successful mode of working, and Mr. Davidson's envelopes and rings are likely to become general favourites. Not only for Liberian coffee and cocoa, but for cinchona, the transplanter and envelopo will be used with full confidence that they will save the life of many plants which, under ordinary circumstances, are either killed off through the shock of being pulled up, or from a break in the 'planting' weather, or through the water settling round the stem. Against each of these evils careful transplanting with a ball of earth is found to be a wonderful safeguard.

No. V.

LOWCOUNTRY ESTATES—LEARNING BY EXPERIENCE.

We feel it a simple duty to add a few "more last words," in order to do justice to the gentleman who originated the Liberian coffee estate at Udapolla, and to whom its success is mainly due. Mr. R. Porter is a first-class Visiting Agent, and Mr. Jardine is a model Manager, and to both Udapolla owes much of good service. But, from first to last, Mr. Wm. Carey Leechman has been the life and soul of an enterprize which we are glad to believe will liberally reward him for his indefatigable exertions, and the firm to which he belongs for their liberal outlay on the "new products" cultivated on Udapolla. We speak from personal knowledge when we say that Mr. W. C. Leechman put forth the whole energy of his nature, and spared himself neither in bodily fatigue, exposure to heat and disease, nor mental anxiety, in order to make the experiment the success which, in less than four years, it has assuredly become. The soil is fairly good, and it responds to culture, especially good drainage, which has been found essential, although for a large portion of the year the climate is distinguished for a high degree of heat. We should think that in some of these lowcountry estates, where not so much masses of rock or large boulders are scattered over and in the soil, but manageable stones or fragments of rock, *underground drains* might succeed? The danger, of course, would be choking up in exceptional rain-storms, although gratings might obviate this objection. If any experiment in this direction has been tried, we should be very glad to learn the result. On looking at our few rough pencilled notes, we find that the very best trees, which resist leaf disease and yield in great abundance "cherries" of the largest size, are distinguished by dense dark foliage, the leaves being not only sharp pointed but "crinkly." Seed gathered from such selected trees are sure to give immensely better results than the imported seed, which Mr. Wm. Leechman, above most men, was successful in germinating, resorting to the expedient of spreading the seeds on coir mats and keeping them steadily damp until the cotyledons began to appear. Perhaps Mr. Leechman will admit that in some cases he was only too successful. To illustrate our meaning, we may mention that we once visited a medical man who, by constant care as to temperature, &c., had undoubtedly prolonged, by many years, the existence of his wife, who was suffering from a bad form of heart disease. In reply to our natural remark, "What a blessing to humanity has medical science become," he replied: "In many cases the benefit is questionable: the feeble and diseased, who used to die, are kept alive to grow up and marry and perpetuate their infirmities." We thought of this, when we heard that the few weakly trees on Udapolla owed their origin to imported seed which only Mr. Leechman's unremitting care compelled to germinate, and which, being imperfectly ripened and formed, gave, of course, trees after their own kind. Planters are now able to go to work at an immense advantage over Mr. Leechman and others of us, who had to depend entirely on imported seed, some lots of which were all bad and many of which yielded only tens of plants for thousands of seeds. Those commencing now can fill their nurseries with not only seed from selected trees but the select seeds of the produce of selected trees: seeds like those of the cherries we carried away as specimens and which (the cherries) weighed over a quarter of an ounce each. The modern planters, too, have the benefit of accumulated experience in the correction of such ideas as that 12×12 or 10×10 or even 9×9 feet distances apart were necessary and shade essential for the new coffee. A proper use of Scewen's transplanters supplemented by Davidson's envelopes has proved that even the expense of temporary shade for plants put into the field in dry hot weather may be dispensed with. Trees planted 7×8, and, therefore, at the rate of over 700 to the acre, may be expected to yield on an *average* (as already stated) one hundredweight of clean coffee for every fifty trees. As 5,700 cherries have been gathered from one tree on Udapolla, the rate of bearing mentioned, and which is calculated on only 2,000 cherries to a tree, is likely in some places to exceed the figure we have mentioned. We wrote without our notes when we represented Udapolla as being free from insect plagues, after Mr. Jardine had smitten the castor oil plant "poochies," hip and thigh. More than thirty years ago, when the scale insect on coffee was as much a *bugbear* as the fungus and grubs* are now, a Mr. Young announced a cure for bug by colonizing the coffee with red ants, which had been observed preying on the scale insects. (The probability is that the ants only *tapped* the insects for the sake of their juices.) The obvious objection, in view of the almost nude state in which the coolies worked amongst the coffee bushes,

* A gentleman just returned from an upcountry tour told us this morning that he saw sixteen grubs taken up with the roots of one tuft of grass.

was that the remedy would be worse than the disease. And so the ant(i)-bug discovery was laughed out at court. But the existence of nests of red ants on coffee bushes is no more of a laughing matter than is an attack by a black snake on the nest of a "laughing jackass," the subject of a most animated group shewn in the Queensland Court of the Melbourne Exhibition and now re-deposited in the interesting museum which all visitors to Brisbane ought to see. The plucky fight even to the death in defence of their young made by the great kingfishers against the formidable reptile is a grand study; the stuffed specimens having all the animation of life. That and more may be said of the red ants which haunt some of the Liberian bushes on Udapolla, and which from it has been found most difficult to dislodge them. We should think that applications of lime, or lime and sulphur, sulphur fumes, or carbolic acid, would prove effectual. Probably there is attraction other than the dense foliage of the coffee bushes, but this matter we failed to investigate. Perhaps information as to the possible existence of nectar-yielding insects on the bushes, or some glutinous exudation on the stems or branches may be forthcoming from the intelligent and observant superintendent. We must not forget to say that the holes on Udapolla are 20 inches wide and deep.
