The Tropical Agriculturist

[Vol. I containing Numbers I to XIII.]

THE

TROPICAL AGRICULTURIST:

A

MONTHLY RECORD OF INFORMATION

FOR

PLANTERS

OF

COFFEE, TEA, COCOA, CINCHONA, INDIA-RUBBER, SUGAR, TOBACCO, CARDAMOMS, PALMS, RICE,

AND OTHER PRODUCTS

SUITED FOR CULTIVATION IN THE TROPICS.

[ISSUED ON OR ABOUT THE 1ST OF EACH MONTH.]

COMPILED BY

A. M. & J. FERGUSON,

of the "Ceylon Observer."

"It is both the duty and interest of every Owner and Cultivator of the Soil to study the best means of rendering that soil subservient to his own and the general wants of the community; and he who introduces, beneficially, a new and useful *Seed, Plant,* or *Shrub* into his district, is a blessing and an honour to his country."—SIR J. SINCLAIR.

A. M. & J. FERGUSON: COLOMBO, CEYLON.

AND SOLD BY:—LONDON: J. HADDON & Co., 3, BOUVERIE STREET; NEWTON & ESKELL, HIGH HOLBORN. ABERDEEN: W. WESTLAND. MADRAS: HIGGINBOTHAM & Co. CALCUTTA: THACKER, SPINK & Co. BOMBAY: THACKER & Co. (LIMITED). SINGAPORE: J. LITTLE & Co. PENANG: D. BLAZE & Co. JAVA: JOHN PRYCE & Co., BATAVIA. MAURITIUS: C. W. HALL. PORT LOUIS. NATAL: ROBINSON & VAUX. DURBAN. AUSTRALIA: GORDON & GOTCH. JAMAICA: JAMES GALL. TRINIDAD: "CHRONICLE" OFFICE. BRITISH GUIANA: "ROYAL GAZETTE" OFFICE.

1882.

☞THE FIRST VOLUME, 1881-82, including 13 Monthly Numbers, making 1088 pages, is now ready, with an exhaustive index, title, &c., handsomely bound in cloth, gold lettered. Price £1 2s. or R13·50 credit ; and £1 or R12 cash. Carriage extra. Too heavy for post.

PRINTED AT THE "CEYLON OBSERVER" PRESS : COLOMBO, CEYLON : 1882.

NOTE.

The object held in view in commencing the "Tropical Agriculturist" as a monthly periodical is sufficiently explained in the Introductory Note to the first Number. We have merely now, on the completion of the first annual volume, to express our thanks to the large number of readers and contributors throughout tropical planting lands—East and West—as well as in Ceylon and Southern India, for the support rendered, and to express the hope that the second volume and succeeding volumes of this publication may be found even more generally useful than the one now closed.

A. M. & J. FERGUSON.

Colombo, 5th June 1882.

[N.B.—On account of the Index having been stereotyped, perfect agreement between the different parts has not been possible; and for the same reason some errors in figures have had to remain uncorrected. Readers using the Index are therefore recommended to refer to the different catchwords of the subject sought for: *e.g.*, if information is required on Indian Tea in the United States, reference should be made to the words "America," "Tea," and "United States."]

INTRODUCTION.

We have already announced that our "HANDBOOK OF INFORMATION FOR CEYLON" published this year is the last bulky volume of the kind that will be issued from our press.

In future, we trust to present annually a compact DIRECTORY volume with every-day information which is needful to the planter, merchant, civil servant, &c. This will necessitate the exclusion of papers bearing on planting subjects such as have occupied a prominent place in successive Handbooks during the last twenty years. The difficulty has always been to find space for the information which we would fain publish for the benefit of our readers. Almost every issue of the Daily and Weekly *Observer* contains information which the planter would be glad to preserve in a convenient form for reference, and we have been frequently pressed to supply this want by an issue separate from the Directory. There is also a great deal of information bearing on the cultivation of new and old products to be found in Home and Colonial periodicals which we should like to make generally known, but for which it is impossible to find space in the pages of an ordinary newspaper.

It is to provide a fitting medium for all such literature that we have determined to publish "THE TROPICAL AGRICULTURIST." This will be issued monthly, and, as may be observed, in a form suitable for easy reference, and for binding in either half-yearly or yearly volumes as may be desired.

Prefixed to each issue a table of "Contents" is given which is of little more than nominal value, but at the end of every half-year a thoroughly useful and complete Index will be appended, so as to make the information under each topic, or respecting each product, readily available.

The publication will be made as soon after the first of each month as possible. Our present preliminary issue, which we distribute gratis to the number of 2,000 copies, cannot be taken as a fair specimen of what will follow either in respect of contents or punctuality; indeed the second issue is, at this date, almost ready for publication. It will be our endeavour to find a place in these pages for everything bearing on the practical work of a tropical planter, our space being no more restricted than our will to serve our constituents. It will be observed that our contents on the present occasion include papers and much useful practical information on the following among other subjects:—

The Cultivation of Cinchona, Tea, Cacao, Liberian Coffee, India-rubber, Tobacco, Vanilla, Fig, Aloe, &c.; on the Preparation of Tea; Adulteration of Tea and Coffee; Manuring of Plantations; the use of Lime; the Coffee Leaf Disease; on Apiculture and Ceylon Bees; Tea and other Products at the Melbourne Exhibition; Planting in Natal, Jamaica, &c.

In our second and third numbers we shall endeavour to find space for the portions of the past letters of the Commissioner at Melbourne for Ceylon, which Tea planters and merchants would wish to keep by them. We shall be glad to receive suggestions from any of our readers for the benefit of our new venture. We have endeavoured to make the subscription as low as possible to *Observer* subscribers, an average issue of from 70 to 80 pages being guaranteed monthly.

"OBSERVER" OFFICE, 24th June 1881.

"THE TROPICAL AGRICULTURIST."

FORM OF ORDER.

TO THE PUBLISHERS,
"*Ceylon Observer*" *Office*, COLOMBO, CEYLON.

1881.

DEAR SIRS,—Please enter my name as a subscriber for "THE TROPICAL AGRICULTURIST" (monthly) at eight rupees per annum (being a subscriber to the Daily or Weekly *Observer*), or at twelve rupees per annum (not being a subscriber to the *Daily* or *Weekly Observer*).

Yours truly,

NEW AND OLD TROPICAL PRODUCTS.

From a recent Price Current of Messrs. Lewis & Peat of London, we transcribe a list of products from India, Africa and China, with the quality and quotations specified, in order to indicate the wide field offered in the requirements of the home market for the operations of the Tropical Planter. A considerable number of the articles named is not the subject of proper, systematic cultivation at all, and yet their quality and value could not fail to be improved by receiving the attention of the trained Agriculturist. The following table may therefore afford useful hints to planters on the look-out for new and profitable products to cultivate in their forest-land or open fields: —

IMPORTED FROM BOMBAY AND ZANZIBAR.	QUALITY.	QUOTATIONS. 1881.
ALOES, Socotrine and Hepatic	Good and fine dry	£6 to £12
	Common and middling part of	£3 10s to £6 10
BEES' WAX, white	Good to fine	£6 10s to £7 10
yellow	,, ,,	£4 5s to £5 5s
CARDAMOMS—		
Alleppe	Fair to fine clipped	5s 3d to 5s 9d
Mangalore	Bold, bright, fair to fine	7s to 8s
Malabar	Good to fine plump, clipped	6s 9d to 8s
	Middling & stalky	4s 6d to 6s 6d
CHILLIES, Zanzibar	Good to fine bright	100s to 105s
	Ordinary and mid.	90s to 95s
CLOVES, Zanzibar and Pemba	Good & fine bright	1s 0½d to 1s 1d
	Ord. and mid. dull	11d to 1s
Mother	Fair, usual dry	2d to 2½d
STEMS	,, fresh	3½d to 3½d
COCULUS INDICUS	Fair	7s 6d to 8s 6d
COLOMBO ROOT	good to fine	40s to 45s
	Ord. & mid. wormy	35s to 38s
EBONY WOOD	Fair to fine	£4 to £9
GALLS, Bussorah & Turkey blue	Fair to fine dark	55s to 70s
green	Good	45s to 50s
white	,,	40s to 45s
GUM AMMONIACUM—		
drop	Small to fine clean	30s to 45s
block	dark to good	20s to 30s
ANIMI, washed	Picked fine pale in sorts,	£17 to £21
	part yellow & mixed	£14 to £ 17
	Bean & Pea size do.	£8 to £13
	amber & dark bold	£11 to £15
scraped	Medium & bold sorts	£7 to £10 10s

IMPORTED FROM BOMBAY AND ZANZIBAR. (*Continued.*)	QUALITY.	QUOTATIONS.
GUM ARABIC, picked	Pale bold clean	50s to 62s 6d
	Yellowish & mixed sorts	40s to 48s
	Fair to fine	40s to 50s
ASSAFŒTIDA	Clean fair to finc	50s to 80s
	Sightly stony & foul	15s to 35s
KINO	Fair to fine bright	£4 10s to £6
MYRRH, picked	Fair to fine pale	£6 to £9
Aden sorts	Middling to good	£4 to £6
OLIBANUM, drop	Fair to fine white	57s to 68s
,,	Mid. to good reddish	50s to 55s
pickings	Mid. to good pale	27s to 32s
siftings	Slightly foul to fine	20s to 24s
INDIA RUBBER	Mozambique, fair to fine sausage	2s 2d to 2s 4d
	,, ,, Ball	
MYRABOLANES	Good to fine pale picked	10s to 12s
	Ord. to fair pt. burnt	6s to 9s
NUX VOMICA	Thin to fine plump	8s to 13s
ORCHELLA WEED	Picked clean flat leaf	30s to 45s
	,, wiry Mozambique	55s to 70s
SAFFLOWER, Persian	Ordinary to good	5s to 30s
SAPAN WOOD	Clean to good bold	£7 to £10
SANDAL WOOD Logs	Fair to fine flavour	£40 to £65
,, Chips		£20 to £30
TURMERIC	Split bulbs	7s 6d to 9s

IMPORTED FROM CALCUTTA, CAPE GOOD HOPE.		
CASTOR OIL, 1sts	Nearly water white	3½d to 3¾d
2nds	Fair and good pale	3½d to 3¾d
3rds	Brown & brownish	3¼d to 3¼d
CUTCH	Good dark clean	20s to 34s
GINGER, Bengal, rough	Fair to good	19s to 20s
Scraped	,, ,,	22s to 25s
INDIA RUBBER Calcutta	Good to fine	1s 8d to 2s
	Com. foul & mixed.	6d to 1s 6d
Rangoon	Fair to good clean	1 s 6d to 2s
Madagascar	Good to fine pinky and white	2s 3d to 2s 4½d
	Fair to good black	1s 11d to 2s 1d
INDIGO, E.I.	Ord. to good shipping Bengal	5s 6d to 7s
	Ord. to g ood Oude	3s 6d to
LAC DYE, superior, DT, T, AB, &c.	Superior	6d to 10d
Native and inferior, rejections	Common	½d to 2d

(*Continued on page 71.*)

(From April 1 to April 9.)

THE MADRAS GOVERNMENT AND THE CINCHONA BARK MARKET.

The Managing Director of the Scottish Trust and Loan Company of Ceylon deserves the thanks of our cinchona planters for coming forward in so timely and practical a manner to endeavour to stop what has become a serious and undoubtedly an improper interference on the part of the British Government with private enterprise :—

CINCHONA BARK FROM INDIA.

Scottish Trust Loan Company of Ceylon, Limited,
123 Bishopsgate St. Within,
London, March 2, 1881.

SIR,—As a matter of great interest to the planters of India and Ceylon, I beg to draw your attention to the following remarks:

The circumstances under which the Government of India commenced the cultivation of the cinchona plant are well known to all, and their success in obtaining a febrifuge for their army as well as for the population of India, is in the highest degree commendable.

They are now, however, far beyond this point, and whilst the planters of Ceylon, struggling against adverse seasons and a dire pest, which has seized their plantations, added to the competition of overwhelming slave-grown crops from Brazil, and adulterated concoctions here, are looking to the future of their cinchona plantations to aid them in their troubles, they find the Government of India, unfettered by want of capital, and the wide difference that lies between private parties and a mighty Government, sending such ever-increasing quantities of cinchona bark into the London market as fill them with anxiety for the future.

The steamer "Eldorado" just arrived has 196,000 lb. of Government bark on board as one shipment or 20,000 lb. in excess of the aggregate shipments from Ceylon for the current season.

If the Government of India is to compete in the English market with private enterprise, an unpleasant outlook for the Englishmen whose welfare depends upon their labour in the torrid zone—let both sides be equal—the Government of India paying a high price for their lands and labour, eight to ten per cent for their money, no assistance from Government Chemists and collectors and the multitudes of advantages which they can indirectly obtain from being the paramount power, and we shall then not feel ourselves over-matched.—Yours truly,

THOMAS DICKSON,
Managing Director.

Mr. Dickson intends to send a copy of the letter to the London papers, and he is anxious to follow up this protest by a memorial and deputation to the Secretary of State for India and the Colonies, provided the Ceylon planting and mercantile community take the necessary action. There can be no doubt that the case against the Madras Government—by far the worst offenders—is a very strong one, and we may expect in any movement of this time to find allies in unexpected quarters. It is not generally known that the Madras authorities, in shipping their bark to London, have entirely departed from the understanding which prevailed at the time the cinchona enterprise was commenced in the Nilgiris. The full intention of the Home Government was to produce bark in order to manufacture on the spot a febrifuge which would be available for the mass of the population. So soon as Mr. McIvor proved the cultivation to be a success, an analytical and manufacturing chemist, Mr. Broughton, was sent to Madras, just as Mr. Wood was detached on a similar mission to Sikhim. Mr. Wood was encouraged in every possible way by the Bengal authorities, and the consequence was that he established a successful local manufacture, which continues under his successors, to absorb all but an insignificant proportion of the bark cut; while, in consequence of the bad treatment received by Mr. Broughton and his consequent disappearence, the Nilgiri bark has been regularly shipped to the London market to compete with the produce of private enterprise. At Sikhim they now manufacture 200 lb. of febrifuge weekly, absorbing nearly 300,000 lb. of bark per annum, while the Nilgiri crop of bark may be said to be all exported. Mr. Clements Markham has most consistently and urgently protested against the mistaken policy of the Madras Government, and Ceylon memorialists would find in him a strong supporter of their petition. From Mr. Markham's "Chinchona" book lately published we quote sufficiently to shew how strong a case he makes out against the practice which Mr. Dickson attacks :—

"No correct judgment could be formed of the financial result of the Nilgiris enterprise until the factory [Mr. Broughton's] was in full work, and turning out 800 pounds annually, or more. The ingredients, except acid and caustic soda, were obtained in the country, and their cost was small in comparison to the work done. But the outlay, as regards labor and many other items, is the same whether the out-turn is large or small, so that no reliable calculation could be made as to the real cost, until the factory was working up to its full power. Moreover, experience would have suggested improvements in the arrangements for pressing the bark, for preventing loss of alkaloids, and other details. Unfortunately this hopeful experiment, so fraught with benefit to the people of the Madras Presidency, was cut short prematurely, and before a fair trial had been made.

"A Committee was appointed by the Madras Government to report upon the financial result of the manufacture before any correct conclusion could be formed. In their report, dated November 28th, 1874, they submitted a calculation by which it was made to appear that the 'amorphous quinine' was produced at a loss. In the years 1872 and 1873, the quantity produced was 445 pounds. By arbitrarily charging the factory with £2,500 for the bark, and £583 for the cost of working, and interest on plant and buildings, they made out that the 445 lb. cost £3,083, and they placed its value at £1,500. By these figures they made out a loss of £1,583. Their calculations are misleading. It was quite premature to attempt any calculations at so early a stage. The legitimate profit from the sale of bark to pay off the capital charge would, in a few years, have secured a net result obviating all pretext for charging anything for the value of the bark against the factory, while the actual charges would have been lowered by improved arrangements, the results of experience. The capital charge, with interest, has now actually been paid off, and the only legitimate charge against a factory, is, therefore, the cost of cultivating the bark. The cost to the Government of producing one pound of bark, as proved by experience in Sikkim, ought not to be more than 5d; and the factory would as soon as it was in full work, have turned out one pound of the febrifuge at a cost of six shillings, as in Sikkim. So that the febrifuge could have been sold, at a profit, for less than 1 rupee per ounce. But the whole system of manufacture would eventually have

become more economical in proportion to the increased production; and Mr. Broughton had certainly made a most promising beginning of a useful work.

"The Committee's Report had a most disastrous effect. Mr. Broughton resigned his appointment, and left India in December 1874. His place has not been filled up. All attempts at producing a cheap febrifuge for the use of the people were at once put a stop to. The great objects of the enterprise were abandoned. The Nilgiri plantations have, especially since Mr McIvor's death, been sadly mismanaged. The only object has been to obtain harvests of bark to sell at a profit in the London market, without regard to the renewal of gaps, and to keeping the plantations up to a proper standard. There has been undue destruction of valuable trees. I have reason to fear that there has been miserable waste and havoc, to secure large present results, without regard for the future.

"Yet the trees remain, though in diminished numbers, and flourish. The work can be taken up where it was unwisely dropped, at any time, when a future Government is better advised. The good work cannot be altogether undone. A scientific superintendent of the plantations, combining chemical knowledge, like Mr. Moens in Java, is urgently needed. There have been checks and disheartening delays. But the plantations are still safe. Sooner or later the broken continuity will be restored, work in the right direction will be resumed, and the great object of the enterprise will be finally secured here, as elsewhere.

"Meanwhile the whole interest of the experimental manufacture centres in the Sikkim plantations, where more enlightened views have prevailed during recent years, and where the true object of cinchona cultivation is understood and appreciated.

"After this, it only remains that those concerned—and particularly Ceylon planters—should begin an agitation in order to see a stop put to the present shipments of bark from the Government cinchona plantations on the Nilgiris at an early date.

The above was written on the receipt of Mr. Dickson's letter. Strange to say before it appears in print we receive information which almost supersedes the necessity for the complaint and protest. The *Madras Mail* of the 30th March, contains the following important intimation:—

"CINCHONA.—As a great deal of Cinchona is now being raised by private enterprise, the attention of Government has recently been directed as to what would be the best means of dealing with their own plantations, so that they may not compete with private enterprise. It has been decided to send the bark to England, not to be sold in the market, but for the manufacture of alkaloids for use in India. The work has been undertaken by a London chemist, who has had the good fortune of coming across, in the process of extraction of alkaloids, two other alkaloids which are cheaper, and just as efficient febrifuges as the quinine now used."

We cannot understand why, if all the bark is to be utilized (as it ought to be) for the medical department of the Indian Government, it should be thought necessary to get the febrifuge manufactured at home. Probably the Madras authorities are determined not to follow the example set in Bengal, and will plead that better manufacture with complete extraction of all the alkaloids will more than compensate for the cost of freight of bark. That is their look-out, however. We have no doubt eventually that local manufacture will be established on the Nilgiris as at Sikhim. Meantime all that our correspondent and the Ceylon planters require is the assurance that no more bark from the Indian Government plantations will be sold in the open market.

COFFEE MARKET REPORTS.

The market reports received from London seem, in some respects, to read conflictingly. But between the estimates of Messrs. Rouse & Co. and Messrs. Rucker & Bencraft in respect of the coming Brazil crop, there is not much discrepancy. The difference in their estimates is not more than 100,000 bags. Although the next Rio crop is expected to be less by 900,000 cwt., yet it must be noted that in Santos coffee, the kind which is chiefly sent to Europe and competes with plantation, there is an anticipated increase of 600,000 cwt. The statistical return of Messrs. Rouse and Co. for the three chief coffee-producing countries is as follows:—

BRAZIL.

Exported 1st July to 28th February.	1880-81.		1879-80.
	Tons.		Tons.
Rio to Europe	71,500	...	41,000
,, the States, &c.	98,500	...	90,500
Total.....	170,000	...	131,500
Santos to Europe.....	38,200	...	33,200
,, the States	10,000	...	8,300
Total from Santos ...	48,200	..	41,500

The Rio crop now coming forward is estimated at about 4 million bags (=237,000 tons), and Santos 1¼ million bags (=74,000 tons). The Rio crop of 1881-2 is expected to be about 3¼ million bags (=193,000 tons), and Santos 1¾ million bags (=104,000 tons).

CEYLON.

Exported 1st October to 6th March.	1880-81.		1879-80.
	Tons.		Tons.
Plantation	11,200	...	16,100
Native.....	1,000	...	1,000
Total.....	12,200	...	17,100

The present crop will, it is stated, be only about 20,000 tons, or 13,000 tons less than the small crop of last season. Of Plantation East India the advices continue equally unfavourable.

JAVA.

THE GOVERNMENT CROP.

1880.	1879.	1878.
618,000 bags*	1,260,000 bags	826,300 bags
or	or	or
36,700 tons	74,800 tons	49,000 tons

* Latest official estimate."

Messrs. Rucker & Bencraft report under the same date, 10th March:—

"COFFEE.—Our surplus European stock on the 1st instant was 17,500 tons against 25,300 tons on the 1st of February. The stock itself has rather increased during the month, but in nothing like the same proportion that it did in February last year, hence the great improvement visible when the past and present year's stocks are compared together. Our readers will remember that last year the European stock ran from 84,700 tons on the 1st of March to 116,660 on the 1st of May, and that then for some months it remained about steady. It is hoped and believed that the improvement made in the relative position will be increased, and the more sanguine

ones affirm that before very long our surplus stock will disappear altogether. To put Coffee in Europe on a better foundation, it is necessary that not only should the surplus disappear, but that a very decided deficiency should be apparent, as it must ever be remembered, when comparing this year's statistical position with that of a year ago, that the stocks in May, June, July, and August last year were unhealthily large. As regards the current Ceylon crop many of our friends advise us that the total will be even less than is expected. There can be little doubt but that the smallest crop known for many years is now being shipped. It is therefore with great satisfaction that we note that the crop for next season promises to be a good one. The last Dutch sale was, say ½ to 1 cent below valuations. Good ordinary fetched say 35½ to 36½ cents, or say 1½ to 2 cents under the prices paid at the last sale. Such a low price has not been known for ten years. Stocks in Rio and Santos are fairly heavy, and the daily receipts in the former port are for the time of year unusually large. The estimates for the 1881-82 crops are about 3,200,000 bags from Rio, 1,500,000 bags from Santos, 200,000 bags from Nord, giving a total of 4,900,000 bags. The market on the spot is very quiet, and the auctions daily are in favour of buyers. Privately business recently has been of quite a retail character."

As of still greater interest to our planters, we give prominence to the monthly coffee report of Messsr. Robert von Glehn & Sons. This firm makes the probable deficiency in the coming, as compared with the last, Brazil crop equal to 1,200,000 cwt., and shews altogether a total deficiency of coffee crops in 1881-82 of 2,270,000 cwt. :—

"LONDON, March 7th, 1881.

Since the date of our last circular, prices of coffee have declined as follows :—

Middling Plantation in London from	92/6 to 90/ ...	say 3 per cent.
Good ordinary Jamaica in London	from 56/ to 53/ ...	6 per cent.
Rio Coffee in New York 13 cents to 12 cts.		8 ,,
Good ordinary Santos Coffee in Havre	70 cents to 65 cts.	7 ,,
Haiti Coffee in Havre	67 ,, ,, 62 ,,	8 ,,
Santos Coffee in Hamburg	60 ,, ,, 57 ,,	5 ,,
Java Coffee in Holland	38 ,, ,, 36 ,,	5 ,,

The causes of this decline are not far to seek. Hopes had been confidently entertained that during the present half year the receipts of coffee at Rio and Santos would fall off, and that under the influence of small stocks in New York and reviving trade, the bulk of these reduced receipt would be taken for the United States Markets. These expectations have not been realized and during the last five week receipts of coffee have amounted at Rio to 14,950 bags per day, against 5,223 bags per day in February last year and against 13,650 bags per day during the last 6 months of 1880; at Santos to 4,450 bags per day against 800 bags per day in February and against 3,327 bags per day during the last 6 months of 1880; and moreover so far from the United States taking more, they have taken less than their usual share of the supplies of Brazil coffee, in consequence no doubt of the stringency of the New York money market, and the shipments to Europe have therefore increased in proportion, causing a temporary glut of this kind of coffee in the European markets. There have not been wanting, besides, the usual exaggerated reports of the future supplies which always accompany times of depression. Take as an example the letter signed "Common Sense" in the *Shipping and Commercial List of New York*, in which the writer predicts that "we shall enter upon the crop of 1882 with a surplus of over 3 million bags of Brazil coffee," and states it as his opinion that the price of fair Rio in New York should fall to 10½ cents before 1st July. We will not class with exaggerations such as this the opinion expressed by some of the Rio firms, that receipts will continue up to 30th June at an average of 15,000 bags per day, and we advance with some hesitation an opinion contrary to such authorities, but we do not believe the Rio receipts will continue on so large a scale, and we know that our opinion is shared by the most competent authority on this side of the Atlantic.

As regards the future of the Coffee market, we think there are unmistakeable signs that we are approaching the turning point. In the first place, present low prices are evidently everywhere stimulating consumption; witness the increase in the deliveries for the month of February.

From London 902 tons Plantation Coffee, against 504 tons in February, 1880.

From Holland 87,000 bags coffee against 64,000 bags in February 1880.

From Havre 85,799 bags coffee against 56,535 bags in February, 1880.

From Trieste 11,130 quintals against 9,150 in February 1880.

Secondly the large crops of 1880-81 are rapidly coming to an end, and our stocks in Europe show it is true an excess over last year of 20,000 tons, but the crops of 1881-82 do not promise to be anything like so abundant as those just coming to a close.

The following statement shews the difference between some of the principal crops of coffee just coming to a close, and the new crops :—

Crop 1880-81.	Estimated crop 1881-82.	Deficiency.
Rio ...4,570,000 bags	3,200,000 bags	—
Santos 1,356,000 ,,	1,700,000 ,,	—
Brazil...5,926,000 bags	4,900,000 bags	60,000 tons
Java ...1,259,960 piculs	618,000 piculs	38,000 ,,
Ceylon 31,000 tons	25,000 tons	6,000 ,,
Manila 90,000 piculs	70,000 piculs	1,250 ,,
EAST INDIA—		
Plantation 10,000 tons	4,000 tons	6,000 ,,
Native 7,000 ,,	5,000 ,,	2,000 ,,
	Total	113,500 tons

Allowing for exaggerations and increase of production of coffee in some of the other countries of growth, from which returns are not so easily obtained, we contend that we have enough before us to show conclusively that the production of coffee has not outstripped the consumption of the world.

NEW GALWAY.—Some days ago I saw a note of yours in re "Tea from Uva," in which you said you thought the tea referred to would be *the first* shipment from Uva. The first shipment from Uva, I believe, was from this (New Galway) district. In the beginning of 1880 or late in 1879 New Cornwall sent some. Early in 1880 Warwick sent some to England. I also sent a packet to Ireland, and this year Warwick has sent some more. We have had a fine blossom out for the last few days, and some nice showers to set it. Cinchona same as last. Tea, a few trees dying out. No other new products. Can you suggest any that would pay at this elevation? Elk fearfully destructive to cinchona and grass. Elephants, a few seen now and again. There are some cheetahs in the neighbourhood. Occasionally we hear of a bullock or cow being killed. I caught a cheetah a short time ago, 7 feet 6 inches from tip of nose to tip of tail. Bug is gone on the hills and will nae come back again (I hope). Leaf disease, none to speak of. Grub, catch 'em if you can. Railway, a long time coming. General prospects, fair.

CEYLON AT THE MELBOURNE EXHIBITION.

COFFEE AND TEA AWARDS.

PROSPECTS OF CEYLON TEA IN THE MELBOURNE MARKETS.

Melbourne: March 14th, 1881.

DEAR MR. BRUCE,—When I telegraphed and then wrote to you the result of the jury awards respecting Ceylon coffee, as communicated to me, I could not doubt that ere the departure of the mail for which I am writing the full details would have been published, so that we might see how we compared with India, Fiji, &c. As yet, however, there is nothing made public regarding coffee or cinnamon. You in Colombo, therefore, will have known the awards for Ceylon coffee some three weeks before those awards are made public in Melbourne. I have heard the delay in publication attributed to the loss by a juryman of some papers, but I am assured that no alteration is likely to be made in the awards as communicated to you. It is possible that in to-morrow's paper the coffee and cinnamon awards may appear, or at any rate in the *Argus* of the 16th, so as to enable me to see what the comparative position of Ceylon is as regards coffee.*

The proof of the tea awards having been brought to me for correction I was able to telegraph to you "Tea 36 awards, 11 being Firsts." I now forward a copy of the *Argus* of March 10th, in which the thirty-six awards are underscored. Enclosed you will find separate list of Ceylon awards and synopsis:

MELBOURNE INTERNATIONAL EXHIBITION, 1880-81.

TEA AWARDS.

Jury.—Messrs. D. Gibson, J. Everard, W. J. Cowderoy, A. Harvey, W. Pitt Brown, and E. S. Harley.

ORANGE AND FLOWERY PEKOES.

First Order of Merit, Ceylon.—Keir, Dundas & Co. Loolecondera Estate, Upper Hewaheta:

Do do do
Do do do
Do do do

The Ceylon Company (Limited), Koledenia Estate,

Third Order of Merit, Ceylon.—Keir, Dundas & Co., Loolecondera Estate, Upper Hewaheta; G. H. D. Elphinstone, Windsor Forest Estate; Mackwood & Co., Galbodde Estate; Keir, Dundas & Co., Loolecondera Estate, Upper Hewaheta.

PEKOES.

First Order of Merit, Ceylon.—Haldane and Anton, Calsay Estate, Dimbula; A. J. Stork, Blackstone Estate.

Third Order of Merit, Ceylon,—A. J. Stork, Blackstone Estate; P. R. Shand, Dunedin Estate; Mackwood & Co., Galbodde Estate.

PEKOE SOUCHONG.

First Order of Merit, Ceylon.—Keir, Dundas & Co., Loolecondera Estate.

Second Order of Merit, Ceylon.—P. R. Shand, Dunedin Estate.

Third Order of Merit, Ceylon.—Mackwood & Co., Galbodde Estate; G. & W. Leechman, Agrawatte Estate; Ceylon Company, Hope Estate; Ceylon Company, Sogama Estate; G. H. D. Elphinstone, Windsor Forest Estate.

SOUCHONG.

Second Order of Merit, Ceylon.—Keir, Dundas & Co., Loolecondera Estate, Upper Hewaheta.

Third Order of Merit, Ceylon.—Mackwood & Co., Galbodde Estate; G. & W. Leechman, Agrawatte Estate; G. H. D. Elphinstone, Windsor Forest Estate; Ceylon Company, Koledenia Estate.

BROKEN PEKOES.

First Order of Merit, Ceylon.—Keir, Dundas & Co., Loolecondera Estate; Ceylon Company, Sogama Estate.

Third Order of Merit, Ceylon.—Mackwoods & Co., Galbodde Estate; C. S. Armstrong, Rookwood Estate, Deltota; Mackwood & Co., Galbodde Estate.

CONGOU.

Third Order of Merit, Ceylon.—J. A. Smith, Lonmay Estate; Keir, Dundas & Co., Loolecondera Estate.

MIXED TEAS.

Third Order of Merit, Ceylon.—T. C. Owen, Oonoonagala Estate.

BLENDING AND PACKING.

Second Order of Merit, Melbourne.—Ceylon and Foochow Company.

COLLECTIVE EXHIBITS.

First Order of Merit, Ceylon.—Keir, Dundas & Co., Loolecondera Estate, Upper Hewaheta.

Second Order of Merit, Ceylon.—Mackwood & Co., Galbodde Estate.

India takes 35 First Orders of Merit, Ceylon 11, Japan 1, Melbourne 1 (blending and packing).

India takes 77 Second Order of Merit, Ceylon 3, Japan 2, Melbourne 1 (blending and packing).

India takes 104 Third Order of Merit, Ceylon 22, Japan 14.

India exhibits 339 samples, 216 awards; Ceylon 78 samples, 36 awards; Straits Settlements 1 sample; Japan 35 samples, 16 awards; Melbourne and China 54 samples, 2 awards.

COFFEE.

Jury.—E. S. Harley, W. P. Brown, M. Benies, J. Hutchens, R. W. Wilson.

FIRST ORDER OF MERIT.—Ellembellary Estate, Madras; Cootamundra Estate, Madras; Hillgrove Estate, Madras; Nedembally Estate, Madras; Seaforth Estate, Madras; Glenvan's Estate, Madras; Inglewood Estate, Madras; Stanes and Co. Estate, Madras; Balmadies Estate, Madras; J. T. Baker, Yakkabendakelle Estate, Ceylon; Lee, Hedges, & Co., Ceylon; Colombo Commercial Company, Ceylon; Whittal & Co., Ceylon; Mackwood & Co., Ceylon; Loolcondera Estate, Ceylon; Courthope, Bosanquet & Co., Ceylon.

SECOND ORDER OF MERIT.—Waverley Estate, Madras; Hallacarey Estate, Madras; Chowdikadu Estate, Madras; Eliza Estate, Madras.

THIRD ORDER OF MERIT.—Sussex Estate, Madras; Goatfel Estate, Madras; Thottullgalla Estate, Ceylon; Delmege, Reid, & Co., Ceylon; Langdale Estate, Ceylon; Kintyre Estate, Ceylon; Tillicoultry Estate, Ceylon; Armitage Bros., Ceylon.

PURE PLANTATION GROUND COFFEE.

FIRST ORDER OF MERIT.—R. Harper, Melbourne; Parson Bros, Melbourne; J. F. M'Kenzie and Co.; Gregg and Co., New Zealand.

ESSENCE OF COFFEE.

FIRST ORDER OF MERIT.—Dunn and Hewett, London; A. Elder, Edinburgh; E. Delacre, Brussels.

ROASTED COFFEE.

FIRST ORDER OF MERIT.—Parsons Bros., Melbourne (Ceylon Plantation, Peaberry, Jamaica, and Java.)

SECOND ORDER OF MERIT.—J. F. M'Kenzie and Co., Melbourne (Ceylon plantation); R. Harper, Melbourne (plantation and peaberry).

CORAL AND SHELLS.

HON. MENTION.—Ceylon Government, coral and shells.

* 15th March. The coffee awards are in to-day's *Argus*.

MINERALS, ROCKS, AND FOSSILS.

Jury.—O. R. Rule (chairman), George Foord, H. Y. L. Brown, Jas. G. A. Stitt, and R. H. Bland; Norman Taylor, expert.

Second Order of Merit.—W. A. Fernando, Ceylon, plumbago.

Third Order of Merit.—Delmege, Reid and Co., Ceylon, plumbago; Armitage Brothers, Ceylon, plumbago; A. C. Dixon, B. Sc., F.C.S., Ceylon, collection of rocks, minerals, gems, &c.

Fourth Order of Merit.—A. M. & J. Ferguson, Ceylon, plumbago, enclosing quartz, showing what care must be taken to separate foreign matter.

CHEMICAL AND PHARMACEUTICAL PREPARATIONS.

Jury.—C. R. Blackett (chairman), M. Galloy, H. Brind, P. R. Challen, Sydney Gibbons, W. Johnson, J. Kruse, J. Robertson, S. H. Roberts, J. G. A. Stitt, R. G. Wilson, Dr. Renzio, and Baron von Muellcr; expert, Geo, Manley Hopwood.

MEDICINAL OILS.

Third Order of Merit.—D. A. T. Dessanaika, Ceylon, medicinal oils.

MEDICINAL BARKS, &c.

First Order of Merit.—Botanic Gardens, Calcutta. collection of cinchona barks; Government of Madras, Madras, cinchona bark, jalap, &c

Second Order of Merit.—E. H. Cameron, Ceylon, cinchona barks; Lee, Hedges and Co., Ceylon, cinchona bark; Mackwood and Co., Ceylon, cinchona bark; T. C. Owen, cinchona barks.

Third Order of Merit.—Botanic Gardens, Brisbane, collection of medicinal and other barks.

VEGETABLE SUBSTANCES USED IN TANNING AND DYEING.

Honourable Mention.—Dissanaika, Ceylon, tanning barks.

SUMMARY.

10	1st awards.	
2	2nd ,,	
22	3rd ,,	
1	1st ,,	for general collection.
1	2nd ,,	do

In all 36 awards.

From the latter it will be observed that, out of the 36 awards, the teas exhibited by Messrs. Keir, Dundas & Co. obtained 11 (including the collective award) or very nearly one-third of the whole. Of the 6 First Class awards gained by this firm, 4 were for special teas classed as "orange and flowery pekoes." They also, of all the exhibitors from Ceylon, obtained the only First Class award for what I suppose I am right in regarding as our staple tea:—pekoe-souchong. For souchong they obtained a Second Class award, and, for broken pekoe a First. Besides their four First Class awards for the special or fancy teas, orange and flowery pekoe, Messrs. Keir, Dundas & Co. obtained two Third class awards for the same class of teas. A Third Class award for congou makes up 10 direct awards, to which must be added an additional or collective award for general excellence. With 11 awards in all, of which 7 are First Class, Messrs. Keir, Dundas & Co. take first rank not only amongst Ceylon exhibitors but also in comparison with India and all comers. This must be gratifying to those immediately interested, especially to him who may be regarded as almost the pioneer of tea growing and tea manufacture in Ceylon,—Mr. James Taylor.

Next in order to Messrs. Keir, Dundas & Co., tested by number of awards, come Messrs. Mackwood & Co., who received 6 Third Class awards and a collective award for general excellence, or 7 in all. One of the awards for orange and flowery pekoe, one for pekoe-souchong, one for souchong, and two for broken pekoe. To these 6 Third Class awards is added a Second Class award for general excellence. If any person is inclined to undervalue Third Class awards, I may say that one of the jurymen told me that the standard of marks set up was so high that admittance to the Third Class involved a very severe ordeal. Following Messrs. Keir, Dundas & Co. and Messrs. Mackwood & Co. in number of awards comes the Ceylon Company (Limited) with five awards, Of these two are First Class: one for orange and flowery pekoe and one for broken pekoe. Two Third Class are for pekoe-souchong, and one Third Class for souchong.

Fourth on the list as regards number of awards comes Mr. G. H. D. Elphinstone with three Third Class awards. One was for orange and flowery pekoe, one for pekoe-souchong, and one for souchong. I hope this result will not be disappointing to Mr. Elphinstone and to the practised Indian planter who superintends the manufacture of his teas. With reference to the whole of the awards the composition of the jury must be kept in view and the tendency in Melbourne to judge teas largely by outward appearance. One juryman said to me, not with reference to Mr. Elphinstone's teas, but as accounting for the number and class of awards for Ceylon teas generally, that some of the teas were "out of condition." As the teas were in good order when tested by Messrs. Moody and Sibthorp, any change for the worse, if it has occurred, must be attributed to delay and exposure, the result of Mr. Everard's pig-headed obstinacy in so long resisting the presence of Mr. Brown. Had I known at the first all I know now, I should have protested against the appointment of Mr. Everard as juror and especially against the samples being taken to his office and lying there during the long delay which his obstructive action involved. Mr. Sibthorp, in the official letter in which he requested the executive to add Mr. Brown to the jury on tea (of which Mr. Everard was really chairman, Mr. Gibson being chairman of the general jury which took in tea, coffee, &c.) stated distinctly that Mr. Everard could be objected to as agent for Japan tea, and that the objection would only be waived if Mr. Brown's presence was allowed. Mr. Brown was then allowed to act. I have nothing to say against Messrs. Cowderoy, Harvey, and Hurley, except that they are naturally swayed by the traditions of the Melbourne tea market. This person wasted the time of the jury at one sitting for an hour by personal abuse of me, and he has favoured me with a characteristic letter, because of my efforts to get justice done to Ceylon. I have not replied to Mr. Everard, and I only mention him and his animus now, to say that, considering all the circumstances of the case, we have only reason for surprise that the jury

awards for Ceylon tea are so favourable as they stand. Of course the previous verdicts of tea-tasters and analysts will not be forgotten.

Next to Mr. Elphinstone comes Mr. A. J. Stork with two awards, one of which is First Class for pekoe and one Third Class for the same kind of tea. They evidently know how to prepare fine tea on Blackstone estate.

Messrs. Leechman & Co. are the recipients of two Third class awards, one for pekoe-souchong, and one for souchong, regarding which my remarks already made as to the standard insisted on should be noted.

Windsor Forest, Gallebodde, Agrawatte, and Blackstone, are all situated in the old and rainy districts of Dolosbage and Ambagamuwa.

Mr. P. R. Shand received two awards, one of which was Second Class for pekoe-souchong, and one Third for pekoe.

The other Ceylon exhibitors on the list obtained each one award, that against the name of Calsay estate in Dimbula (Messrs. Haldane and Anton) being First Class for pekoe.

Mr. C. S. Armstrong obtained a Third order of merit for broken pekoe. This gentleman must have learned the secret of having made the kind of tea which pleases the eye of the typical Melbourne broker, for I heard but one chorus of admiration of the appearance and especially the *packing* of a consignment of Rookwood tea sold on the 8th of this month by Greig & Murray. The verdict was that the packing was greatly superior to Indian. Whether the prices will satisfy Mr. Armstrong's expectations, I do not know, but they are considered good with reference to the present state of the market. I believe the bulk was purchased by Mr. Walker a dealer who has laid himself out to sell Indian and Ceylon tea. He most strongly believes in the superior quality of the latter. He has asked permission to distribute specimens in the Ceylon Court, permission which of course, I shall be only too happy to grant. I enclose the leaf of the catalogue in which the Rookwood teas are described and the prices at which they sold are noted.

SALE OF CEYLON TEA.

Under instructions from the Importers. Ex R M. Steamer, from Ceylon, Season 1880-81—Rookwood:

44 quarter-chests Ceylon pekoe souchong 20 lb., blackish well made wiry leaf, very brisk strong rich malty flavor 1/1½.

40 quarter-chests Ceylon pekoe souchong 20 lb., even twisted blackish even leaf, strong ripe rich malty pekoe flavor 1/1½.

20 half-chests Ceylon broken pekoe 44 lb, handsome small very even leaf pekoe tips, rich and full ripe brisk pekoe flavor 1/3½.

7 quarter-chests Ceylon broken pekoe 25 lb., small even handsome wiry leaf pekoe tips, rich full strong and pungent pekoe flavor 1/5.

6 half-chests Ceylon broken tea 21 lb., fairly twisted brownish black leaf, strong brisk full flavory 1/2.

44 quarter-chests Ceylon pekoe 21 lb., wiry small handsome pekoe leaf, choice full ripe strong malty pekoe 1/6.

12 half-chests Ceylon fannings 44 lb., small even reddish brown open broken leaf, pungent strong brisk flavory /9½.

On the 1st of this month occurred a sale of Ceylon tea by no means so encouraging:—

61 half-chests of pekoe-souchong sold at 1s 1d per lb.
19 ,, souchoug 11d ,,
1 ,, congou 7d ,,

Mr. Moody shewed me a specimen of the tea which realized only 7d and he predicted a low price. The leaves resembled beans with loose tissue. I said: 'It is very hard: *that* tea is made from good Assam hybrid, the flush of which is large. The liquor is probably good." The reply was: "No matter: tea of this appearance will not suit this market." I have little doubt the tea will be sold at a large profit by the cutters and mixers.

Mr. J. A. Smith of Lonmay estate, it will be seen, obtained a Third award for congou.

Mr. T. C. Owen obtained a similar award for what the jurors have classed as "mixed teas." Whether Mr. Owen's tea was really a mixture of different teas, or merely a "one kind" tea, I do not know, but one day it was remarked to me:—"The more teas are mixed the better. If several teas, each of which may have an objectionable flavour, are blended, the result is a tea which takes greatly with consumers." It has, therefore, been recommended that persons or firms in Ceylon should lay themselves out to purchase and mix high and low grown teas and teas of different flavours and qualities. One of the brokers controverted this view and said the mixing could be much better done here. But the motive for this opinion is obvious and I agree with Mr. Moody. I have no doubt some of our merchants will soon try the experiment of buying and blending teas. Brokers and dealers in London and Melbourne may offer objections, but the taste of the consumers must rule in the end. As tea grows in Ceylon from sea-level to 7,000 feet, there must be large scope for a judicious mixing of the delicate mountain teas with the ranker produce of lower levels.

The general result is that for 78 exhibits of tea Ceylon has received 36 awards, or not far short of 50 per cent. Of the awards 11 were First Class, including 1 collective award; 3 were Second Class, including 1 collective award; while 22 were Third Class. Of course the fact will be noticed that the majority of the awards are Third Class, but that still means, according to a member of the jury, a high order of merit in the tea. Considering that tea manufacture has been carried on in India for well nigh half a century, while our enterprise, as a serious matter, does not date back more than a fifth of that period, and considering also that on this occasion India from the Brahmaputra to Cape Comorin, sent the best specimens of her produce, I think we ought to be if not contented yet encouraged by our "good second" position.

India sent no fewer than 339 samples of her best teas to the Exhibition and the awards were 216, in the proportions of First Order of Merit 35
Second ,, 77
Third ,, 104

For First Class awards in proportion to total samples, Ceylon is considerably ahead for India:—one-seventh against less than one-tenth. In Second Class awards India scores victor. In the proportion of Third Class awards to total exhibits, the two countries are about equal. Ceylon, therefore, considering her comparative youth, has come in a *very* good second to India.

The total exhibits of tea you will see, was 507, China not being directly represented at this Exhibition. Japan is and very efficiently by my good friend Mr. Tokio. Japan tea ("Oolongs") seems to be as much appreciated in Melbourne as in the United States, judging by the awards, which are in the proportion of 16 to 35 exhibits. But of the awards only one was First Class and one Second, while 13 were Third Class.

The China teas were, I believe, shewn by Mr. Gladstone of the Oriental Tea Company, which Company obtained First and Second Class awards for "blending and packing." The unmixed China teas ("pure and simple") seem to have been shut out because not exhibited by any one directly connected with China. Mr. Gladstone is to protest, and I do not see why his protest should not be successful. If so, according to his information, five of the China teas will be classed for first awards. * You will see that Melbourne blended

*15th March: See remarks in to-day's *Argus*.

teas and China teas numbered together 54 samples. The Straits sent one sample which does not seem to have obtained an award. Java did not shew. At the next World's Show all the world's teas and especially those of the mother country of tea, China, ought to be exhibited. The Straits, Fiji, and the tropical regions of Australia, are sure to compete, but what with soil, climate and *labour supply* (this above and beyond all), it will go hard if India and Ceylon do not hold to the high rank they have attained.

A considerable proportion of the Ceylon teas which have received awards are high-grown, in Upper Hewaheta, Dimbula, Pussellawa, &c. In looking over the Indian list of awards the proportion of high-grown teas, in Darjeeling, the Nilgiris, Kangra Valley, Kumaon, &c., is still more striking. Of the eight teas from India which obtained First Class awards for orange and flowery pekoe, four were Darjeeling teas and one a Nilgiri tea. Of the collective First Class orders of merit, only one was given for low-grown Assam and Sylhet teas, while high-grown tea obtained three: two Darjeeling and one Ceylon.

While, therefore, plenty of good tea can be produced at low elevations, the result of these Melbourne Exhibition awards ought to afford encouragement to those who possess tea estates at such high elevations as those aronnd Darjeeling and Ootacamund in India, and Nuwara Eliya in Ceylon. The Calsay pekoe which gained a first order of merit was grown at an elevation of about 7,000 feet. Mr. Elphinstone, with tea culture exteuding from sea level to nearly 7,000 feet on Oliphant, ought to be able to send perfect mixed and blended teas into the markets of the world. And so with others in Ceylon, for whose tea enterprise there is I believe, a great future.

But tea from the same estate and prepared under the same superintendence is far more capricious than coffee. Climatic changes have much to do with this, as tea is specially sensitive to atmospheric influences. But, following the case of Java with its rich volcanic soil, the question arises whether the sudden fall in value of tea from the Terai and Dooars estates in India may not be owing to the same cause: a *deficiency of iron* in the soil? Iron is not a fertilizing substance, but the ferruginous clays of Dimbula &c., which are fatal to cinchonas, seem to suit tea well: better than soils which are apparently richer, finer and deeper. I suspect Col. Money's preference for rich-soiled low insalubrious places for tea cultivation is liable to large qualification. I hope the Ceylon press will publish the whole of the Indian awards, so that tea growers may be able to test the correctness or otherwise of the inferences I have drawn, as well as to learn lessons which do not present themselves to me at present. Through the courtesy of Mr. Moody, of Messrs. James Henty & Co., I am able to forward several copies of the pamphlet in which he has embodied in a clear and convenient form the whole of the tea awards. [Distributed as far as possible to Tea exhibitors.]

The "Ceylon and Foochow Company, Melbourne," which figures for second order of merit under "Blending and Packing," is, I understand, Messrs. Mackenzie & Co. under another title. That title clearly indicates that our fine Ceylon teas are used to improve those obtained from China, and the compliment ought to be appreciated by Ceylon tea growers. In truth, the result of the Exhibition awards but faintly indicates the growing favour with which Ceylon tea is now regarded. Of course there are dissentient voices,—some interested and prejudiced and others of honest people whose tastes require to be educated in a right direction. Most sincerely do I trust that this Melbourne International Exhibition and my own efforts in connection with it may result in securing a ready and profitable market for Ceylon teas amongst the specially tea-drinking colonists of these great and advancing lands of the South. Commerce is progressive, but some of its branches are stringently conservative. Of this we have had strong proof in the recent refusal of brokers and dealers to bid for the Syndicate Indian teas at Sydney and Adelaide. But this kind of passive resistance to change for the better will ultimately give way before the efforts of men like Mr. Moody of the firm of Messrs. James Henty & Co., of Melbourne I have before me as I write a catalogue of a sale which Messrs. Greig & Murray are to hold on the 18th, "under instructions from Messrs. James Henty & Co., Agents for the Calcutta Tea Syndicate in connection with the Government of India, and R. A. Sibthorp, Esq., Commissioner." This catalogue includes 3,026 half-chests of the teas of Season 1880-81, "from the celebrated districts of Assam, Cachar, Darjeeling, Chittagong and Kangra Valley." The collection is so large and so well assorted with reference to this market, that I feel confident the teas will go off with good competition. There are lots to suit small as well as large dealers. For instance 5 quarter chests Assam pekoe of 20 lb. each; 5 similar packages of pekoe souchong; 20 half chests of Cachar orange pekoe of 50 lb. each; 39 chests of Cachar broken pekoe of 96 lb. each; 15 half chests Cachar pekoe of 45 lb. each; but the great bulk of the teas are in those 38 lb. packages which Mr. Moody so strongly recommended as the most suitable for this market. The lots of such half-chests run from 20 to 60. This sale of exclusively Indian teas will rival in quantity the great sale of Foochow teas which took place a few days ago. Much of that tea was of very low quality, while the Indian teas, presented in quantity never before paralleled in Australia, are all pure and good. At twice the cost of the low quality Foochows they will be comparatively cheap, looking at the quautity and nature of the extract they yield. That good teas *can* be obtained from China, I have repeatedly admitted; but there can be no doubt that the bulk of the Foochow teas (especially this season) are inferior and rubbishy. In buying Indian and Ceylon teas, the Australians will have guarantees involved in the fact that the producers and manufacturers are their own countrymen, honest and reliable. Even if slowly at first, therefore, yet none the less surely will the rapidly increasing population of Australia take the bulk of their teas as they now do their coffees from India and Ceylon. In this and in other directions, the bonds of union will be drawn closer between the great colonies of the south and Britain's widespread eastern possessions.

15th March.—Coffee having been mentioned above, I may now say that the coffee awards have, at length, appeared in this morning's *Argus*. Considering the efforts made by the planters of Southern India to send numerous and carefully prepared specimens of their very best produce to this Exhibition, I am not surprised to see "Madras" leading, with 9 First Orders of Merit against 7 awarded to Ceylon. Madras estates get, in addition, 4 Second Class awards, against none of that class for Ceylon. Madras figures for two Third Class awards, and Ceylon for 6. I take it for granted the Ceylon press will republish the whole of the coffee awards from the *Argus*, including those given to Melbourne dealers for Ceylon plantation coffee, which, when counted, tend to more nearly equalize the positions of Ceylon and India. On what principle the coffees exhibited by Messrs. Delmege, Reid & Co. and Messrs. Armitage & Co. were ranked Third Class, I cannot say. I only know that in a letter addressed to me by Messrs. Delmege, Reid & Co. they stated that the produce of Langdale, Kintyre and Tillicoultry estates, which they got ordered out from London for the purpose of this Exhibition, sold in Mincing Lane at 112s per cwt. Taking the awards as I find them, it appears that Southern Indian coffees obtained of

First Class awards	...	9
Second ,, ,,	...	4
Third ,, ,,	...	2
	Total ...	15

This was out of a much larger number of total exhibits than Ceylon sent. For her more limited number of exhibits, Ceylon obtained

First Class awards	...	7
Third ,, ,,	...	6
	Total ...	13

Over and above this number of awards, Ceylon can claim the principal credit for the coffees which obtained awards as follows :—

"PURE PLANTATION GROUND COFFEE.

FIRST ORDER OF MERIT :—R. Harper, Melbourne; Parsons Brothers, Melbourne; J. F. Mackenzie & Co., Melbourne; and Gregg & Co., New Zealand."

Largely, if not exclusively, the coffee for which the above awards was given was plantation Ceylon,

Then we get:—

"ROASTED COFFEE.

FIRST ORDER OF MERIT.—Parsons Brothers, Melbourne (Ceylon plantation, peaberry, Jamaica and Java).

SECOND ORDER OF MERIT.—J. F. Mackenzie & Co., Melbourne (Ceylon plantation) R. Harper, Melbourne; (Plantation and peaberry."

Ceylon ought to get credit for the vast majority of the above awards given to the leading Melbourne importers of and dealers in coffee; and it is more than probable that from Ceylon coffee was obtained the

"ESSENCE OF COFFEE,"

for which awards were given, thus :—

"FIRST ORDER OF MERIT.—Dunn & Hewett, London; A. Elder, Edinburgh; and E. Delacre, Brussels.'

As Fiji is not mentioned in the list of awards in the *Argus*, I cannot help thinking the list is incomplete, I certainly understood that at least one First Class award was given for Fiji coffee. Before the 22nd, the day on which the Marquis of Normanby is formally to deliver the awards, complete lists will, no doubt, be available. Meantime, I copy the Ceylon awards as they appear in to-day's *Argus* :—

FIRST ORDER OF MERIT.—John F. Baker, Polwatte mills (coffee of Yakkabendekelle estate); Lee, Hedges & Co.; Colombo Commercial Company; Whittall & Co. Mackwood & Co.; Loolcondera; and Courthope, Bosanquet & Co.

There are thus seven First Class awards, instead of six as I was led to telegraph. Loolcondera estate does not seem to have been included in the list furnished to me originally. It is well to have a correction to make on the favourable side. To continue copying the Ceylon awards :—

THIRD ORDER OF MERIT.—Thotulagala estate; Delmege, Reid & Co.: Langdale estate; Kintyre estate; Tillicoultry estate; and Armitage Brothers.

As Mr. Harley, who, in effect, judged the coffee, was also judge of the cinnamon, I expected the awards for each to be published simultaneously. But as nothing is said of our old staple bark, I turn to our new. I told Mr. Blackett* that I was disappointed to get only Second Class awards for our Ceylon cinchona barks, but he assured me that the quantity as well as the quality of the Indian barks left no other result possible. The awards for Medical Barks appeared in the *Argus* of the 8th, with the result that India obtained two FIRST ORDERS OF MERIT, thus :—

Botanic Gardens, Calcutta, collection of cinchona barks.

Govt. of Madras, Madras, cinchona bark, jalap, &c.

SECOND ORDER OF MERIT :—

E. H. Cameron, Ceylon. cinchona bark.
Lee, Hedges & Co.. do.
Mackwood & Co., do.
T. C. Owen, do.

You will thus see that all the cinchona barks exhibited in the Ceylon Court obtained Second Class awards, being ranked second only to the fine and extensive exhibits from British Sikhim and the Nilgiris.

In the same paper you will see the awards for minerals, rocks and fossils. I regret that a First Class award was not given to Mr. Fernando, and I have written to this effect, attracting special attention to the enormous block of pure plumbago exhibited by him. As matters stand the awards to Ceylon exhibits in this class are :

SECOND ORDER OF MERIT :—

W. A. Fernando, Ceylon plumbago.

THIRD ORDER OF MERIT :—

Delmege, Reid & Co., plumbago.
Armitage Brothers, do.
A. C. Dixon, B. Sc., F. C. S., collection of rocks, minerals, gems, &c.

FOURTH ORDER OF MERIT :—

A. M. & J. Ferguson, plumbago enclosing quartz, shewing what care must be taken to separate foreign matter.

I am sorry to see exhibits in the Third Class which I hoped to see higher up, but I suppose our Ceylon plumbago was compared not with any exhibits of the same mineral but with the large, complete and valuable collections of more precious minerals in the Exhibition. I need scarcely say that I did not expect any award for the piece of plumbago enclosing quartz. Mrs. Guille used the language, when shewing the specimen, which the jury adopted. I feel that Mr. Dixon's collection of Ceylon rocks and minerals deserved recognition in a higher class, but we cannot get all as we could wish. For medicinal oils you will see that Dassenaike Mudaliyar obtained Third Order of Merit, and also "honourable mention" for tanning barks. The Government of Ceylon also received "honourable mention" for an exhibit of hal resin.

In the *Argus* of the 10th, in addition to the tea awards, you will find a Fourth Order of Merit awarded to the Ceylon Government for printing; while "special collections of books" are "commended," thus :—

Government Agent, Kandy, Ceylon, styles and books.
A. M. & J. Ferguson, ,, printed books.
Rev. C. Alwis, ,, printed book.

For walking-sticks there seems to have been no First Class award. Wijeynarayane, of Ceylon, therefore comes first with a Second Order of Merit.

In the Melbourne *Argus* of the 12th are the Fine Arts awards, with reference to which I may say that I could not obtain recognition of the plumbago elephants sent by Messrs. Fernando, Delmege, Reid & Co., and Armitage Brothers, as sculptures. As a yellow primrose was nothing more than a yellow primrose in the eyes of Peter Bell, so the model of an elephant in our Ceylon carboniferous mineral was merely "black lead" to the Melbourne jurors. And the Melbourne exhibits from Ceylon did not include any pictures except the Kandian specimens of scenes from Hindu mythology. Our photographs atoned for all. In that branch of the Fine Arts, however, represented by "general furniture" you will see under SECOND ORDER OF MERIT :—

D. F. de Silva, Ceylon, carved ebony stand and brackets.

A mistake has been made here, which I have brought to the notice of Mr. Newberry with the repeated expression of my hope that the elaborately carved ebony couches may receive the recognition they deserve. The carved ebony chairs exhibited by

* Chairman of the Pharmaceutical Jury.

Don Andris of Galle have secured a Third Order of Merit, while Mr. Sumps' rattan lounging chair and tea-poy are awarded the Fourth Order of Merit.

In the *Argus* of the 14th you will see that Mr. Kyle's exhibit of Breakwater concrete receives honourable mention. I drew special attention to his plan of and report on the breakwater, which, as I wrote long ago, I submitted to Sir Wm. Jervois, &c.

Under "Building Stones," honourable mention is made of "Graves, Cotton & Co., Ceylon." This is a mistake which I must get adjusted. I suppose that really honourable mention has been awarded to the breccia or cabook, or both, sent from Ceylon.

In the *Argus* of to-day (15th) you will find in addition to the coffee awards "honourable mention" made of the Ceylon Government for an exhibit of "coral and shells." The Fiji Court opposite us has, in addition to lovely shells, a most exquisite collection of corals. But the only exhibit in the nature of coral which stands in the Ceylon Court is the so-called "black coral" sent by an Italian who believes that the true red coral exists in deep water off Ceylon! I must see whether a mistake has not again been made.

I see that "honourable mention" has been made of the collection of African elephants' tusks made by Mr. Chirnside and Mr. Adams. The latter I met at their really grand exhibit case a few days ago and had a long talk with him about the African elephants and their wealth of ivory. He told me that the mounting of the truly magnificent tusks cost many hundreds of pounds, and I can well believe it. The beautifully white ivory is rich with gold carving, and two tusks form the frame of a unique mirror. There is one tusk which a powerful man would soon tire of carrying. Our poor yellow tusks compare unavourably with this superb trophy of ivory, but I think "honourable mention" ought to be awarded to Mr. Templer's elephants' skulls. I have written to that effect.

I have spent the best part of two days going over, copying and commenting on the numerous and on the whole gratifying awards received by exhibits in the Ceylon Court and published during the fortnight, since last mail left. To-morrow morning, it is probable, the cinnamon awards will be published, so as to enable me to indicate their nature, and then little more can be expected. As matters stand, our comparatively limited collection in the Ceylon Court has received, I believe, not less than 120 awards, and a very fair proportion of these are First Class. I have considered it only honest to put up *all* the awards, low as well as high, and Sir Herbert Sandford said he wished others acted on the same principle. With the array of award cards, of a good size and printed in colours, the effect of the Court is quite striking, and before we commence to dismantle I may, perhaps, decide on having one more photograph taken. I feel pretty certain that no Court of its size in the Exhibition has secured so many awards, and few Courts of any size. Mr. Dawson has been always ready to give information to visitors and jurors, and Mrs. Guille since she joined the Court as caretaker has done excellent service, not only in arranging and keeping everything nice but also in giving information to visitors and jurors, her knowledge of French and German being particularly acceptable to the numerous foreigners at the Exhibition. I have felt that very frequently I could be of more use to Ceylon out of the Court than in it, and it is only just that I should acknowledge my obligations to the Assistant Commissioner and to Mrs. Guille.

Through some mistake on the part of Mr. Caire I have not yet received the additional sets of photographs you asked for, but I hope to send all by next steamer.

Trusting that the intelligence respecting awards, &c., will be acceptable to the Committee, as well as to the Government and people of Ceylon, believe me, yours truly,

A. M. FERGUSON

AWARDS FOR COFFEE, TEA, AND CINNAMON.

Melbourne, 16th March 1881.

DEAR MR. BRUCE,—In this morning's *Age* appears the report of the sub-jury on tea which I enclose. As regards sample 528 the probability is that it was lost by the breakage of the bottle in transit from Mr. Newberry's office to Mr. Everard's. The fact that special attention was drawn to this sample—Mr. Taylor's underfermented tea—shews that it was dispatched from the Ceylon Court and its disappearance probably deprives Mr. Taylor, Messrs. Keir, Dundas & Co., and Ceylon, of an additional First Class award. I have consulted Mr. Moody about sending in a further sample of what remains of this tea, but he thinks it better, in view of all circumstances, not to move further in the matter. You will see what the jury say about teas getting out of condition, and no doubt the tea exhibits have suffered materially by delay, first in the appointment of a jury and then in the conduct of the major part of the sub-jury under the influence of one of their members. You will see that the number of samples of teas submitted to the jury was really 823, the largest number, I suppose, ever shewn at any Exhibition. Notwithstanding delay, exposure and their consequences, I think the position attained by Ceylon is most encouraging. Of the fine quality of our teas there can be no doubt. The great point is *care in preparation*.

With reference to the shifting of the coffees exhibited by Messrs. Delmege, Reid & Co. and Messrs. Armitage Brothers from the second to the third class since the original memorandum was furnished to me, enquiry will be made. I have reason to believe, however, that class was decided by size of bean. The coffees in question were good in colour and bloom, but smaller in the bean than others.

As I anticipated, this morning's *Argus* contains the awards for cinnamon, and, as I expected, Ceylon here stands beyond competition. As regards Ceylon exhibitors, this is the order in which they appear:—

CINNAMON.

FIRST ORDER OF MERIT.—S. Rajepakse, Mudaliyar; J. F. Drieberg, Ekelle Estate.

SECOND ORDER OF MERIT.—H. D. Silva; Lee, Hedges & Co.

I suspect it was the smallness of the exhibit sent by Messrs. Lee, Hedges & Co., which shut it out of the First Class. Mudaliyar S. Rajepakse's cinnamon was in full bales of all sorts, from Third to Very Superior.

I am sorry that Mudaliyar Jayetilleke's vanilla did not obtain recoguition (Mr. Vollar's was spoiled). But the Mauritius samples were large as well as fine. Succulent vegetable matters are so apt to get "out of condition." Mr. Bawa's preparation of coffee and milk was sour when opened.

You will see that the Government Agent of Kandy gets a second order of merit for seeds, and that Messrs. G. & W. Leechman receive honourable mention for their enterprise in seuding a living coconut palm.

This, I suppose, about exhausts the list for Ceylon, unless my representations about the collections of Dr. Trimen; the Government Agent, Jaffna (palmyra palm products); and Messrs. G. & W. Leechman (coconut palm products), are attended to. By next mail I may probably be able to send you a copy of the corrected and complete list (a long one) of awards to Ceylon.—Yours very truly,

A. M. FERGUSON.

The following is the report of the Sub-Jury No. 2 on Tea, consisting of Messrs. Everard (chairman), Cowderoy, Harvey, Brown and Harley :—

"The sub-jury appointed by sectional jury 31 to report on tea have concluded their labors, and have now to say that sample bottles of all teas on Exhibition, numbered from 1 to 823, were sent to the tea salesroom of Messrs. Everard and Co. the country and exhibitors of the teas not being disclosed until the whole of the samples had been tasted, and the awards made. We had some difficulty in deciding how we should give the awards, but we ultimately concluded to judge of each description of tea internationally, giving an award to the best of the various kinds of tea, and if we found afterwards any special exhibitors well up in all classes of tea, to give such collective exhibit a first award, &c. In going through the various exhibits we found several samples of China teas, but as we afterwards found they were exhibited by the Oriental Tea Company and the Ceylon and Foo Chow Company, but not being the manufacturers or producers, we were unable to give them any awards but it is only right to say that if such exhibits had been eligible we should have given first awards for Souchong, Congou, Pouchong, Oolong, yellow Pekoe. Tea consumed by natives and scented orange Pekoe, very fine. It is much to be regretted that official exhibits from China and Java were not made, as we could then have demonstrated the relative positions of all the tea-growing countries. We much regret that many of the samples had gone off in qualities and lost much of the aroma which would have remained in fresh drawn samples, and this probably causes some of them to be placed in a lower position in the awards than would otherwise have been the case. Where possible we have made allowance for this but many of the samples were out of condition from improper curing and other causes. One sample, No. 528, exhibited by Keir Dundas (Ceylon Court), and to which special attention was drawn, never reached us.—For the jury, J. EVERARD, chairman. Melbourne, 4th March, 1881."

CINCHONA.—We are informed that probably the experience gained on Summerhill estate, Nuwara Eliya district, will afford a satisfactory answer to the question, "Will cinchona grow successfully on the same land for the second time?" On this estate some 16,000 trees were cut down and rooted out last year and the land planted over again, the result being a growth so far which is very satisfactory.

COFFEE LEAF DISEASE.—We call attention to the opinions quoted by our London correspondent at first hand from Mr. Cooke, one of the great English authorities on Fungi. Mr. Cooke is much interested in Mr. Marshall Ward's work, more particularly as he is himself engaged in investigating a disease which has attacked the coffee in Venezuela and Porto Rico. We shall take care that Mr. Cooke is furnished with copies of Mr. Ward's further reports as they are published. Our Scottish correspondent has also some interesting remarks on the subject which will shortly appear.

DATE COFFEE.—In a paper received this morning from London, there is an account of a lecture by Dr. Richardson, in which he speaks in highly favourable terms of what is known as 'date coffee':—"The lecturer also briefly alluded to the date coffee, which has recently been thrown upon the market, and observed that it was undoubtedly a highly nutritive article of diet, and largely flesh-forming."—*Oor.* [The Company advertise the opinions of several analysts and medical men. but one question is what kind of samples were laid before these gentlemen, and another why be allowed to apply the term coffee to a mixture chiefly formed of dates?]

THE COMMERCE OF JAMAICA.

A Supplement to the *Jamaica Gazette* of Jan. 20 has been sent to us by Mr. Morris, containing the annual report of the Collector General, with accompanying statements of customs revenue, imports and exports, &c., for this West Indian Colony. With regard to import duties we learn that the amount collected in 1879-80 was £25,000 in excess of the previous year, the collection being the largest made since 1875-6: this result was partly due to the drought experienced at the end of 1879 and beginning of 1880, causing a large demand for foodstuffs. The severe storm of August 1880 occurred too late in the financial year to materially affect the collections for that year, but the current year will show a large increase in the importation of flour, meal, rice, saltfish, &c. The amount of export duties was in excess of the previous year by only £43, a decrease having taken place in rum, coffee, and dyewoods, as against an increase in sugar. The aggregate value of the exports was over 1½ million pounds, being an increase of £155,000 over the previous year and £170,000 over the average of the three previous years. Of the total amount £1,512,978 19s 3d the island is credited with £1,427,000 19s 11d, or an increase of 13 per cent, and foreign produce and manufacture with £85,834 19s 4d, or a decrease of 9·36 per cent. The principal articles in which increases have taken place are as follows :—

Articles.	Quantities.	Values. £. s d.
Beeswax ...	476 cwt.	462 2 9
Cocoa ...	1,151 ,,	4,286 13 6
Ginger ...	1,073 ,,	4,036 1 3
Honey ...	1,070 ,,	1,070 11 9
Pimento ...	38,699 ,,	66,174 14 9
Sugar ...	2,966 hhds.	82,420 3 7
Cigars ...	6,030 lbs.	3,489 10 0
Hides ...	230,272 ,,	2,356 6 10
Bananas ...	111,689 bunches.	5 660 17 6
Cocoanuts ...	2,384,607 no.	7,553 8 5
Oranges ...	5,184,732 ,,	5,090 10 3
Coffee ...	Decrease in quantity.	5,583 9 11
Rum ...	,, ,,	11,767 0 0

Among the articles which shew a decrease is lime juice 37,641 gallons of the value of £1,825 1s 7d. It will be noticed that coffee and rum show a decrease in quantity though an increase in value, the latter due to better prices. The decrease in coffee was equal to 574 cwt. A new item of export was cinchona, the total quantity shipped in 1879-80 being 23,981 lb of the value of £7,302 14s. It seems that the trade in cattle and horses with Cuba, which promised at one time to become an important item in the export trade of the colony, has been checked to some extent by a rise of 12 per cent and upwards in the market value of stock, and also by the enforcement of strict quarantine rules. The distribution of the export trade was as follows:—67·3 per cent to the United Kingdom, 20·1 p. c. to the United States, 5·2 p. c. to Canada, and 7·4 p. c. to other countries, the first and last showing a decrease, and the other two an increase, the latter being due to direct or additional steam communication. The fruit trade with America increases annually, and promises to form in a few years a large proportion of the export value of the colony. 74·5 per cent of the value of the total exports is made up by the four great staples, viz. sugar 32·9, rum 13·8, coffee 16·8, and dyewoods 11 per cent. Pimento amounts to 9·6, and fruits including cocoanuts 4·8 per cent, while all the other items together amount to 11·1 per cent of the total production. The export of annatto has risen from 22,435 lb. in 1876 valued at £560 17s 6d to 91,890 in 1880 valued at £1,531 10s. The export of beeswax has not varied much, 1876 showing 1,017 cwt. 3 q. 5 lb. of the value

of £6,042 11s 11d, and 1880 1,540 cwt. 0 q. 9 lb. valued at £6,468 6s 9d. The quantity of cocoa exported in 1876 was 469 cwt. 1 q. 27 lb. of the value of £1,286 11s 6d, while last year the amounts were 3,304 cwt. 2 q. 9 lb. and £10,918 6s 7d. We hope the export of this article from Ceylon (121 cwt. last year) will increase equally rapidly. Coconuts also show a considerable increase, the figure for 1876 being 1,840,315 valued at £5,520 18s 10d and for 1880 6,315,475 valued at £20,525 5s 8d. The export of coffee last year was 90,972 cwt. valued at £254,722 against 96,715 cwt. in 1879 valued at £249,138, there thus being as we have said an increase in value though a decrease in amount. The export of cinchona we have already mentioned: it remains to be seen whether this article will have such a rapid increase in Jamaica as has been the case with us. The fruit exported comprised bananas, limes, mangoes, oranges, pineapples, plantains and shaddocks. Of the bananas the number of bunches exported in 1879 was 132,832 and in 1880 440,642, the values being £13,283 4s and £38,556 3s 6d respectively. The export of limes is very variable, last year showing 1,210 barrels valued at £484, being a decrease as compared with 1878 but an increase of 100 per cent over 1877 and 1879. Mangoes also show fluctuations, though there has been a steady increase the last three years: the export for 1880 was 37,360 valued at £28 0s. 6d. The export of oranges also varied somewhat, though last year showed a large increase or any of the previous four years, the amount being 14,609,489 valued at £11,687 16s 10d. (In this connection we may mention a case reported in the *Trinidad Chronicle* at the end of last year where the captain of a small American vessel engaged in carrying fruit from the West Indies to the United States made an offer for 100,000 to 120,000 oranges to be delivered in ten days. The *Chronicle* commenting on this showed that the price to be paid for the quantity would only amount to a few hundred dollars, but hoped that as in the case of Jamaica a large trade would spring up.) Pimento shows a rapid increase during the 5 years, viz. from 391,952 cwt. in 1876 of the value of £39,973 12s 10d to 91,209 cwt. in 1880 valued at £145,570 12s. 3d. The value of walkingsticks exported was £652 8s, being an increase over any of the previous four years, though the number of bundles was considerably less. Tamarinds show a marked decrease in value, the 4,550 lb. exported in 1880 being valued at only £56 17s 6d, whereas 3,479 lb. in 1876 were valued £173 19s. The value of the cigars exported has increased greatly during the five years, the 2,633 lb. of 1876 valued at £282 15s having grown to 9,826 lb. in 1880 valued at £4,913. Of manufactured tobacco there was a very large decrease in quantity and value in 1880 as compared with 1879, from 135,051 lb. valued at £8,440 13s 9d to 35,271 lb. valued at £1,322 13s 3d. The woods exported comprise brazilletto, candlewood, [ebony, fusticwood, lignumvitae, logwood, and mahogany. The export of brazilletto has risen from 3 tons valued at £4 10s in 1876 to 197 tons valued at £394 in 1880. Of candlewood there was no export in 1877, 1878, or 1880, but there was a decrease in 1879 as compared with 1876 from 75 5-20th tons valued at £124 10s to 19½ tons valued at £19 10s. Ebony shows an increase over 1879, but a considerable decrease as compared with the previous three years: in 1876 the amount was 498 1-20th tons valued at £1,494 3s, whereas last year only 230 tons valued at £644 were exported. The amount of fustic wood exported in 1880, viz. 1,699 tons valued at £5,097, was only half that of sent out in 1879, the value having diminished in the same ratio. Lignumvitae which in 1876-9 showed pretty nearly the same figure, 71-85 tons, last year took a sudden bound to 953 tons valued at £632 10s. The figures for logwood in 1880, 46,325 tons and £159,821 5s, are almost identical with those for 1877, the amounts being greater in the other three years of the series. The value of the mahogany exported in 1880 was £277 5s, against £30 only in 1879: in fact there appears to be a regular increase and decrease each alternate year. The last article mentioned in the export table is yams, and these show a steady decrease in quantity from 1,014 cwt. 29. 26 lb. in 1876 to 269 cwt. in 1880, the value having decreased from £331 11s 11d to £80 14s. As the value of this article seems to have increased, however, this year may show an improvement in the figures.

The last statement appended to the Collector's report contains a précis of reports of the collectors of taxes on the condition of the trade and agriculture in the several parishes of the island during 1879-80. In the parish of St. Thomas, we learn the cultivation of chocolate for export has been commenced, and also an acre of Liberian coffee as an experiment. In St. Catherine also a commencement has been made in chocolate, oranges and Liberian coffee for export. Of the parish of St. Ann we read:—

"The result of Agriculture has been this year considerably checked by severe drought. It is remarkable that with seasons so detrimental to other cultivation the coffee crop now being gathered promises to be one of the largest known for years past. The Pens are in good cultivation and steadily maintain their value and breed of stock. An exportation of 133 head of cattle to Cuba has taken place during the year. The supply of fruit was plentiful until the Cyclone of the 18th August which destroyed many valuable trees and several Chapels, School Houses Wharf Stores and other buildings—this, together with the drought, has caused unusual scarcity in ground Provisions. The fruit trade with America is thriving.

"The regular trading of Steamers to the several Ports of the Parish has been of great advantage, although the Merchants complain of dull times and stagnation of trade. The lake near "Moneague" shows no signs of abating, although it does not continue rising it monopolizes a considerable quantity of grazing land." In the parish of Clarendon there was an increase in the export of coffee owing to heavy crops, but the prospects for the coming year were very discouraging.

CEYLON BEES:

COLONIES OF "APIS DORSATA," THE MOST WONDERFUL BEE IN THE WORLD, TAKEN BY MR. BENTON IN THE KURUNEGALA JUNGLE.

We are glad to say that Mr. Benton has at length been successful in capturing the "Apis dorsata" (Sinhalese "*Bambara*"), which he describes as "the most wonderful bee in the world." Mudaliyar Jayetilleke secured a party of Sinhalese bee-hunters who guided Mr. Benton to the Bambaragala, a mountain rock some 30 miles from Kurunegala in the jungle, and there, after a very interesting and exciting experience, which Mr. Benton will probably relate for the benefit of our readers, two colonies of the "*dorsata*" were secured. So much importance does Mr. Benton attach to his work here, now that he has seen this bee, a splendid honeymaker, that he is to postpone his departure to Cyprus for another fortnight, returning to Kurunegala to morrow morning. He has left specimens of the new bee in spirits which can be seen at our office. The Sinhalese were much astonished to see the way in which Mr. Bentou handled bees which, wrongly used or blown upon, are so savage that they will pursue the offenders for miles, and Mr. Jayetilleke declares that he has got more practical information about bees from Mr. Bentou in a week than he had from all other sources in many years.

Correspondence.

To the Editor of the Ceylon Observer.

"EMPTY IRON TIN, PRESSED DOWN CRAMMED FULL WITH COCKCHAFERS."

DEAR SIR,—"Just a line" to request your correspondent "Cockchafer" from Dolosbage to kindly inform us what his *empty iron tin crammed full* of cockchafers was composed of? When I was at Dimbula two years ago we never knew a man (even an Irishmau) who paid at the rate of sixpence for such an article. In this manner we cannot conceive how your correspondent (vide *Observer* 31st) was able to secure 600 beetles for the amount. As for the "boiling water ready at 4 o'clock in an asphalte boiler," we are ready to believe anything after the *empty iron tin* &c.
—Yours faithfully, NO COCKCHAFER.

WILD THYME AND COFFEE LEAF DISEASE.

Penryn, Cornwall, 4th March 1881.

DEAR SIR,—Enclosed are two slips about wild thyme. May not some use be made of it in connexion with coffee leaf diseae, growing it amongst the coffee, or otherwise?—Yours faithfully, F. CUMMINS.

THYMOL, THE NEW ANTISEPTIC AND DISINFECTANT.

Thymol, a newly discovered Crystal prepared from wild thyme, is pronounced by Chemists and Physicians to be far superior to, and stronger than Carbolic Acid, coal tar, or any other of the antiseptics and disinfectants hitherto known. It has been shown by Lewin & Bucholtz, to be about eight times as powerful as carbolic acid.

It has the very great advantage of being quite harmless, and possesses the delicious and fragrant odour of wild thyme.

Cornwall is certainly at its best in May. In autumn the light granite-sand soil is apt to be parched; and there is but little heather in the mining parts, so industriously is the surface soil "skimmed" for fuel. The furze mostly blooms twice a year; but its autumn blossoms are few indeed compared with the abundant glory with which it clothes all wild places in springtime. Then, again, the hedgcs in autumn are dry and brown; while in spring a Cornish hedge—a stone wall generally with a good core of earth—is not only a botanical study, but is something for a painter to pore over. In some of those hedges you may count a score of different kinds of wild flowers. Sometimes for miles they are covered not only on the sides but along the tops with primroses, set so thickly that the leaves are scarcely seen. Sometimes they are ablaze with foxgloves and red campion. The flowers are not of rare kinds. You look in vain for any orchis except the commonest, or for the large vetch and purple flag which now and then light up the gloom of a deep Devonshire lane. But what with patches of lichen, and three or four varieties of hawkweeds and ferns small and big, and flesh-coloured stonecrop, *and wild thyme* so abundant as to colour the whole face of the stone for many yards, a Cornish hedge in the spring is something not to be seen elsewhere. And all this, combined with a sense of freshness unattainable at any other season, you lose if you put off your Cornish trip till the usual time. You don't even have the compensation of better weather; for mostly—though last year was an exception—May in Cornwall is often drier than July. After the long wet of winter there comes a month or more of steady sunshine, when you may be sure of smiling seas and warm seaside nooks day after day. And if you miss the great catches of pilchards, you come in for mackerel whiffing, work in which you may take a personal share instead of only looking on.—*Chambers' Journal.*

"CINCHONA" AND "CHINCHONA."

28th March 1881.

DEAR SIR,—In his book on the Peruvian bark tree the author has exercised his right and spelt the Spanish-Latin name as he thinks it should be spelt, and surely no other English writer can be supposed to know better, for none have given so much time and study to the subject of chinchona in all its bearings. Nevertheless he must be aware, as those are who have been like himself among Spanish Americans, that the word is by them written and printed "cinchona," and this not out of mere whim, but on the recommendation of the Madrid Academy, than which there is no higher authority in all Spanish-speaking countries.

With regard to the pronunciation, I wish to point out that here in Ceylon you are at fault. As is almost invariably the case in adopting a word from another language, the English have again used a little license and given the word a sound to suit themselves, as when on the introduction into England of the Portuguese and Spanish wines Oporto and Xeres they made so free with the names as to call them respectively, Port and Sherry. The correct pronunciation in this case is "cin*ch*ona,"—ch being the same as in chick, chip, chum. This is a more important matter than the spelling, because if pronounced "cin*k*ona" for instance the word would be as completely disguised to the ear of a Spaniard as the word chaff would be to that of an Englishman if pronounced kaff (to a North Briton perhaps there would be no difficulty), and would certainly not be recognized by a
CASCARILLERO BOLIVIERO.

COFFEE AND GRUB.

Lindula, 31st March 1881.

DEAR SIR,—I must thank "A. L. C." for answering my queries respecting grub, but surely he has made a mistake in mentioning 6c. as a fair sum to be given per 100 beetles! Until I learnt the experience of others I had settled to give 12c. per bottle containing on an average 2,000 of the small speckled beetle or the small brown cockchafer, or 12c. per 100 of the large patana cockchafer (*Leucopholis pinguis*), or the stag-beetle. Perhaps it is to the latter "A. L. C." refers? I am glad to say that I am not yet much troubled with beetles or grub, but as they increase (as I fear they will) the pay will decrease in proportion.

And with regard to the enemies of this insect pest: the problem seems to be to discover what birds or animals (besides Sinhalese) take a delight in *chewing beetle*... so, as every little helps, I give my unqualified support to the green lizard (erroneously dubbed 'bloodsucker'), which at present swarms in thousands, and which is called in Tamil *ōnān, pacchōnthi, karattōnān,* or more commonly *karattān.* It is perfectly true that in the low-country a little speckled lizard plays havoc with the young shoots of cacao and Liberian coffee, and richly deserves, therefore, to be hunted to the death; but he is herbivorous, while, as far as my careful observatiou has gone, our green friend is purely carnivorous. I have often watched the latter creep up a petania or verbena plant and quietly gobble down a small beetle that had alighted to eat the flowers, but only last week had I the pleasure of seeing one with a beetle an inch and a half long in its mouth. And here I may draw Mr. Haldane's attention to the fact that the victim was one of the squeaking beetles, which I think he has not described. A friend (not a planter), hearing the other day that a blue-gum was black with beetles feeding on the resinous exudations, asked if there was any connection between the increase of grub and the introduction of eucalypti. I suppose I was correct in denying the soft impeachment?
KAROLY FURDO.

[There are no Eucalypti in the part of Maskeliya affected with grub, we believe?—ED.)

CINCHONA AND COFFEE CULTURE:—WEEDS.

Holmwood, Agra Patana, March 31, 1881.

DEAR SIR,—I have been much interested by Mr. McCall's letter on not weeding cinchona, as that has been my principle for about three years: except where the self-sown seedlings are so thick as to deserve care, I only pull out or cut down the largest weeds. Where the seedlings are thick they answer the purpose of weeds in covering the ground. Whether this is the cause or not, I lose very few trees by canker, and damping out, or whatever it may be called, and many experienced planters who have seen my clearings say they have seldom seen healthier or better cinchona.*

I would go even further than Mr. McCall, and not only allow weeds to grow but also sow such grasses as are adapted for mossing or covering. If a clearing is kept fairly clean for two or three years this grass would be ready when the trees were fit to strip. It would certainly prevent the very free growth of self-sown plants, but considering the millions now obtainable this would not involve the loss it might have a year or two ago.

I notice Mr. McCall writes: "Weeds are doubtless one of the greatest enemies on coffee estates," but I have been and always shall be of the opinion that if on the estates that have suffered so much from the grub those grubs had had some weed roots to eat there would have been fewer coffee rootlets devoured. —Yours faithfully, REGINALD W. WICKHAM.

SELF-FERTILIZED COFFEE FLOWERS AND THE RESULT?

Maskeliya, 31st March 1881.

DEAR SIR,—In event of the failure of the fine blossoms we are having this year, can it not be ascribed to the fact that our coffee is "self-fertilized" year after year, as well as to the weakening effects of leaf disease &c. &c. ? The following is an extract from a lecture delivered in Manchester in 1873:—

"A number of experiments, conducted with a patience and a philosophical power of observation which cannot be too highly praised, led Darwin to the conclusion that when a flower is 'self-fertilised'—i. e., when the ovules are fertilised by pollen from a stamen belonging to the same flower—the number of seeds produced is smaller, or their vigour is less, than if it is 'cross-fertilised'—i. e., impregnated by the pollen conveyed from a stamen belonging to some other flower of the same species; and that if this process of self-fertilisation is continued through several generations, the plant at length becomes altogether sterile. This fact, when fully established experimentally, Darwin crystallised into the aphorism now so often quoted, that 'Nature abhors perpetual self-fertilisation.'"

From this, one may infer, that if at any rate the flowers intended to produce seed for nurseries, had been "cross-fertilised," we should have had stronger and healthier plants in our clearings, and therefore less likely to be affected with the different diseases that coffee suffers so much from now.—Faithfully yours, SWADDY.

[In other words, we ought years ago to have tried experiments with new seed:—from Coorg (chick coffee), Liberia, Mocha and why not from the heart of Abyssinia, the home of the coffee plant?—ED. C. O.]

GOLD IN CEYLON.

Kurunegala, 1st April 1881.

DEAR SIR,—Just at this time when you receive information from different quarters concerning the existence of gold in Ceylon, may I be allowed to give you the following descriptive names of villages in Seven Korales, which signify that at one time or other they were connected with gold in some shape or other, such as Randeniya—two villages by that name—meaning gold meadowland village.

Ranwalagedara—Gold mine, or pit, house.
Ranawana—Gold forest.
Rangama—Gold village.
Ranmutugala—Rock of gold pearl.
Rangalepola—Place of gold rock.
Ridigama—Silver village.

It is a well known fact that in ancient times a certain king did actually make copper, silver, and gold coins, at the city called Dambadeni Nuwara, and some of the specimens of these coins are to be found in Seven Korales. It is by taking the name of this city that the present Government Agent of the Province recently named a Hatpattu called Dambadeniya Hatpattu. I write this in order to attract your attention to the existence of these descriptive and significant names given to villages from time immemorial, so that in case, as you suggest, experiments are to be tried in search of gold, one or two of these villages may be selected as the scenes of such experiments, for by their situation and nearness to the town of Kurunegala and Polgahawela railway station they can be conveniently and easily reached.—I remain, yours truly, A KANDYAN.

COCKCHAFER CULTIVATION:

BEETLE POWDER *vs.* DATE COFFEE.

6th April 1881.

DEAR SIR,—As many eminent English doctors agree that ground dates make excellent coffee, and as it seems clear that the British public will consume anything not absolutely dirt, that is sufficiently adulterated to suit their palates, there seems to be no reason why we should not turn the cockchafer plague into a lucrative business. The beetles are known to contain a large amount of phosphates, and as we cannot always get crops from the branches of the coffee why not take them in another form from the roots? I think "Melolonthine" would be a good name for the beetle powder. We ought, perhaps, to mix a little real coffee with it at first until the public taste is educated to the required standard.

I have not time myself to take out the patents, but shall be glad to give hints on feeding, collecting, pulping, &c., to any man of genius whose relatives have nothing to do, on condition I receive a certain number of "Finder's" shares.

To ensure the supply of a pure article, it would be best to do the entire manufacture out in Ceylon or the dishonest middlemen in London would tamper with it.—Yours faithfully, NO FRAUD.

[Mr. Benton found the Sinhalese of the North-western province, only less fond of eating the young broods of bees in the combs, than of the honey itself!—ED.]

CINCHONA.

April 7th, 1881.

DEAR SIR,—Your correspondent "Cascarillero Boliviero," writing in your impression of April 5th, lays justly stress on the general mispronunciation of one part of the above title word in the island; but he should remember that the language in Bolivia, as indeed he confesses, is not up to the perfect Castilian standard of the Madrid Academy.

It is only in the Spanish-speaking parts of South America and in the North of Spain that the *c* before *i* is pronounced like *ss*. in Castile, according to my information, the *c* before *i* has the sound of *th* in the English word *pith*; *therefore* the word cinchona enough to be pronounced "thinchoua."—Yours truly. VANTOSKY RENTON.

* Of what age now?—ED. C. O.

TEA PREPARATION.

Bunyan Estate, Maskeliya.

DEAR SIR,—The enclosed circular you may like to read over. It refers to "Kinmond's *improved* patent tea drying and green leaf withering machine"—and was sent to me on the subject of manufacturing tea, *without* the aid of charcoal. A machine like this has been in use for the last ten years (I believe) in Assam.—Yours faithfully, TOM GRAY.

From the *Indian Tea Gazette* we quote as follows on this subject:—Years ago, when I first mooted the idea that Tea could be fired without charcoal, it was scouted. It was said "The fumes of charcoal had some chemical and necessary effect." "The Chinese would not have used it from time immemorial had a substitute, and a cheaper one, been practicable." Such were the objections. It is now no longer a question. A great part, perhaps the greater part, of the Indian produce, is to-day worked with other fuel, and it is only a question of time when *all* of it will be so. It is generally admitted that tea prepared in Dryers, is more valuable than that fired over charcoal; and begging the question that the fumes of charcoal are *not* necessary (the old idea is very nearly exploded), it is reasonable that it should be so; for, if there is one thing certain in tea manufacture, it is that speed is necessary. Charcoal drying took on an average 45 minutes.—Tea is fired in the best dryers in 8 minutes. In respect of speed, Kinmond's dryer (which is the one I advocate) is certainly unequalled. When, as in large factories, 30 to 40 maunds of tea have to be made daily, it is evident that, *cæteris paribus*, the machine which will do most in a given time and given space must be the best. The great feature in Kinmond's Dryer is the fact that a *separate* blast of hot air is forced through the tea on each tray. In all other dryers I have heard of, the *same* hot air passes through each tray successively, and moisture is consequently more or less carried upwards through each. It is principally in this respect, and in the large quantity of work it executes, that I consider the excellence of Kinmond's dryer to consist. It remains only to give shortly the results of a long series of experiments with Kinmond's dryer. The valuations were made by more than one Calcutta broker:—

Class.	*Charcoal dried.*	*Machine dried.*
Pekoe.....	R0 11 0	R0 14 0
Broken Pekoe	R0 10 0	R1 1 6
Pekoe	£0 1 6	£0 1 10
Broken Pekoe	£0 1 5	£0 2 7

These were made from the same leaf, at the same time, with every care. In one of my gardens, after Kinmond's dryer was obtained, the teas averaged upwards of 2 annas per lb. more all round. The dryer can also be used for withering leaf, which it does effectually, but in my opinion no tea dryer is fit for that work, inasmuch as to do a large quantity takes far too much time. Artificial withering is only necessary when the weather is wet and cold, and the machine, to do it, should do a large quantity *at a time*. No tea dryer *can* do this. A machine fitted for that work has yet to be invented, unless Baker's wet leaf dryer, of which I have heard good accounts, but have not seen, would answer.

THE GRAPE VINE OF COLOMBO.—Those who are of opinion that the grape vine does not thrive in Colombo would do well to pay a visit to the residence of Mr. P. T. Sleyma Lebbe at the junction of *New Moor* and *Messenger's Streets*. The very sight of the bower will lead one to believe that Colombo is the natural home of the grape vine; but this belief turns to wonder and amazement when he looks at the hundreds of bunches of luxurious fruits to be seen all over.—*Jaffna Patriot.*

MANILLA HEMP.

At the monthly general meeting of the Agri-Horticultural Society of India held on Thursday, the 17th February, the following circular from Surgeon-General Edward Balfour on the subject of the Manilla Hemp plant was submitted:—

Mr. Liotard, of the Agricultural Department of the Government of India, has this year (1880) reported on the materials in India, suitable for the manufacture of paper. Several of the fibre-yielding plants are mentioned by him and, amongst others, various species of the genus *Musa*, of the plantain or banana tribe, many of which have been grown in the East Indies from the most remote times. At pages 54 to 58 he describes the introduction, in February 1858, of the Manilla hemp plant, direct from the Philippines, into the Madras districts, by Colonel (now Sir George) Balfour. Nevertheless, the import trade return of the United Kingdom show a large and continually-increasing delivery of hemp from the Philippine Island, now averaging yearly about 20,000 tons, valued about half a million sterling. I have ascertained from the London Produce Brokers, through Dr. Birdwood of the India office, that this important article is the true Manilla hemp from the *Musa textilis*, that the bulk of it is delivered in London, where it is made up into cordage and ropes for ships, especially for yachts' running rigging, being very light, strong, and clean, and also for clothes lines. But there is no doubt that the Manilla hemp plant, *Musa textilis*, grows as well in British India as other species of the plantain or banana genus, and that British India could, in a couple of years, supply the London market with all that it could take of Manilla hemp fibre. The prospects of benefiting British India by creating an export trade from it of the extent and value above indicated might well incite to considerable efforts to attain success. In 1861 to 1863 the Madras Revenue Board made continuous efforts* to secure the naturalization of the plants which Colonel Balfour had introduced, but their efforts seem to have been effectual only in the Wynaad, from which, by 1877, the Conservator of Forests replied that the Philippine variety had been introduced on several of the coffee estates, where it grows remarkably well, and no doubt is felt there as to the value of its fibre. Revenue and of the Agri-Horticultural Societies might The attention of the Boards and Commissioners of be re-directed to this plant.

The Secretary stated that *Musa textilis* was grown for several years in the old garden of the Society, but it did not progress satisfactorily, and the cultivation was eventually abandoned.

CINCHONA CULTURE.—We are glad to learn that Mr. Karslake, who recently returned to Ceylon, is taking out a patent for what he hopes will be a very simple and cheap method for renewing the bark of cinchona trees.

SALES OF CINCHONA BARK.—Cinchona bark is selling locally, at wonderfully good prices, the Oliphant bark, chips of officinalis trees (1·43 of quinine) realized R1 per lb. on Saturday, the probable London valuation being, 2s 3d or so per lb. Gallamudena bark (succirubra quill) fetched R1·12½.

COFFEE LEAF DISEASE.

I told you in my last letter that I hoped to receive through the kindness of a friend Dr. Cooke's opinion upon Mr. Marshall Ward's last report on his investigation into *Hemeleia vastatrix*, and I have this week been favoured with a letter written by that gentleman upon the subject which I am permitted to extract from. Dr. Cooke's high reputation as a botanist will give weight to the opinion he expresses, and its favourable character will no doubt be satisfactory to Mr. Ward, who, I hope, will give us the opportunity of reply on the points as to which Dr. Cooke is anxious to obtained further information The following is the substance of Dr. Cooke's letter to my friend :—

"I have read Mr. Ward's second report, as I read also his first one, with considerable pleasure and interest. I consider that the work he has done is, thus far, satisfactory, and I follow it with the more interest, because it seems in a fair way of proving, what I at the first strongly believed, but had to suspend on account of conflicting evidence, viz.—that the *Hemileia* was related to the *Uredinea*, a belief in which I have never completely lost faith—even when the evidence seemed the strongest in favour of its belonging to the *Mucosini*. I do not know Mr. Marshall Ward personally, but I should be glad to learn from him, how he interprets certain of the phenomena recorded by Abbay and Morris, especially as to spores being contained *within* the large papillate spores of the *Hemileia*. I find another species of *Hemileia* at the Cape of Good Hope, with the smooth sporcs as well as the rough ones, which I have figured in *Grevillea* and called *cysts*. I should like to know if any of the brown spots, with black pin points on them—bear any resemblance to a *Septoria*—and what is the nature of the black pin spots. I should always be glad to hear from him as he proceeds, as well as see his reports—as I have also been investigating, as well as I can at such a distance from the coffee disease of Venezuela and Porto Rico —which is, apparently, a different thing altogether." I trust that this opinion of Dr. Cooke, and the queries he has started, may assist in the correctness of conclusions at which Mr. Ward may arrive.—*Our London Cor.*

COFFEE PLANTING &c., IN NATAL.

The following extracts from letters from a former Ceylon planter to a friend in the Island have been placed at our disposal. In one letter the writer says :—

"My chief object in going to the low-country was to see the coffee and sugar estates, and to see how they cultivated them. Sugar is, as of course you know, the chief export from Durban, and this flourishes, but the present season has been so dry that it is feared that the crop will not be a paying one. The estates, as a rule, are not large, varying from 150 to 300 acres in extent (some are as large as 600) with a large reserve of bush. Mills are not erected on all estates, but only on a few, so that the planters only have to look after their canes, which they send when ripe to the mill nearest them to be crushed, the crusher taking a portion of the sugar in payment for crushing. I went over one of the largest mills and was very much interested in what I saw, but it is fearfully hard work on Europeans to have to stand for hours in the heat of the day in the boiling-house. Nearly all the labour on the estates I visited is cooly, who have an awfully easy time of it and are perfect rajahs in their way. The men commence work at sun-rise and knock off in the middle of the day for food (which appears to me absurd) and return to work until sunset. The women very seldom work, and seem to be quite agreeable to remain idle, as the absurd Government regulations for coolies compel superintendents to supply the wives of the men with rations whether they work or not. The rations which Government requires to be given to coolies consist of 10 lb. rice a week and in addition to this the estate has to supply them with ghee, 1 lb. per month, and also fish when obtainable. If you stop any of these rations they go to court and the poor cooly gets all his own way. I saw very little coffee, but what I did see seemed to me to be doing very well, but this was partially abandoned although it had a very fair crop upon it. The bean is much smaller and very irregular. The curing is done very badly and the light and everything mixed up together. I went to the mills at Amgeni, where most of the coffee is cured, but even there I was surprised at the slovenly way in which everything was done. I saw some coffee on a barbacue before it was milled, and donkeys were promenading about on it, so you may judge for yourself how things are done. For all this and in spite of the grub which I hear kills the trees, I firmly believe from what I have seen that with care and occasional manuring that coffee might be made to pay here. Dry seasons are against it certainly, and *that* is all, I fancy. I am leaving this for the coast again as soon as I can get a transport wagon to take my things down, as I am convined that this is not the place for me ; I mean *up here*. Cattle, horses and sheep are dying in this district from cold and poverty, and as instances of this, one farmer lost 100 calves from lung sickness and another about 500 sheep from cold ; this is not very encouraging."

A second letter is written from Durban, Natal, on 22nd November 1880. The writer says :—

"This mail I forward a paper to you, in which it shews that although coffee has to a certain extent been abandoned here, yet there is a chance of its being revived again. People here know next to nothing about it and do not seem to take any trouble, and yet expect the tree to do well without going in for cultivation. Their great idea seems to be to get large crops without any outlay, and if they do not get this in about four or five years time, they abandon the estates. Another drawback they say they have is the borer. As yet I have not seen any trees so affected, but surely there must be some remedy for this; and they also complain of high winds, but up to the present time I have not felt any wind nearly equal in force to that I experienced on ——— when the young clearing was blown on its broadside, trees, stakes, and every thing else. They know nothing of the numerous pests and drawbacks which you have to contend with in Ceylon or they would not cry out as they do. Natal, I fancy, is a very good place for coffee, as crop ripens during the dry season, and the way I propose to go in for it here is to plant up in small acreages at a time, and that in connection with other things which give a good and quick return, such as maize, potatoes, and vegetables generally. They tell me that the only way to render the cultivation of coffee profitable in Natal is to renew stem, branch, and occasionally the tree, after it has borne its fourth crop. This to Ceylon planters would seem an extraordinary proceeding and I cannot understand it at all. However, as your humble servant hopes to be one of the commission spoken of in the paper I shall endeavour to find out during the tour which I suppose will be taken through the country, something more definite on this subject. The other day I visited a farm near Pietermaritzburg, for the purpose of looking at some coffee, and although the trees are looking like abandoned coffee, yet they looked wonderfully healthy as far as the foliage was concerned ; and this after they had borne a very good crop, but a large proportion of this was light. This I have often seen

myself on neglected coffee in Ceylon. I was reading a report yesterday on coffee in Natal by a sugar planter who had gone in for it on a small scale, and in three years time from putting the plants in he got ½ cwt. au acre and the following year 9 cwts., then a short crop and abandonment following, although manure was easily obtainable, transport cheap, and labor moderately so. Theu coffee is called a failure; it is a disgrace when one sees fine trees abandoned for want of a little attention and experience. I pruned one of the abandoned trees at the farm near Pietermaritzburg which I spoke of, and although it was only roughly done, yet when finished it looked nearly as well as some of the young trees in the best part of ——— clearing. I am in communication now with the M. L. C. for this county, and although my Ceylon experience was short, still I hope I shall be able to turn it to good account out here. I have only been down a few days and expect to be running about from place to place for some time to come. By the time this reaches you your crop will be all in, which I trust has been a favorable one and that you have plenty of good wood for a *bumper* next year 1881. How is your cacao getting on?"

A third letter, dated 19th January 1881, from Verulam, County Victoria, Natal, speaks of the war, and the consequent rise of provisions. The writer then proceeds :—

"What will be the outcome of all this it is impossible to say, but added to all this there has been a regular plague of caterpillars along the coast, which has destroyed hundred of acres of sugar-cane and mealies. Cheerful state of thingsfor a young colony!

"As far as regards coffee, I took the tour I mentioned in my last letter and will now give you an account of what I saw and heard. I started from this on the 20th December and the following day I came to the first under cultivation. It was only a small place of about 25 acres, and the proprietor was a man of a peculiar temper and was not altogether anxious to give me any information. However, I learnt from him that he was merely experimenting with coffee; although he had several failures, he intended to try and find out some remedy. Amongst some of the fields, (which I may tell you were all in blocks of from three to five acres with wind belts of bamboo and mulberry) I saw trees from five to six years old bearing an average crop of from 8 to 10 cwt. an acre, but these trees were not pruned or topped. He informed me that these trees at three years old gave a crop of 4 cwt. an acre, and every year up to the present had given a good return, and that he could not grumble and that is something to hear from a man out here, where nine out of ten men are in a perpetual state of discontent. Before leaving this field he said he expected to see it all die out next year, as it always did, from what cause he could not say, but in my own humble opinion it was simple overbearing and inattention and lack of manure that killed the trees. However, I was silent on the subject. The next field this interesting individual took me to was one he was experimenting on. It was about 7 years old, and the trees he informed me were fast dying out, so he thought that by sawing off every primary and applying a little manure in the shape of some bog soil and shells from the beach it might have the desired effect; and really I was surprised to see the effects on the bare poles, which had shot out new primaries, &c., in all directions and looked very much like coming into bearing again, but it is impossible to say whether the experiment will repay him for his trouble. The aspect of the plantation was N. W., about five miles from the sea, and the soil a loose loam. If the proprietor had been a decent sort of a man he would no doubt have given me further particulars and encouragement. However, he finished up by saying he would not advise anyone to go in for coffee, so we parted. The next estate I visited was ———, the superintendent of which was ———, formerly the possessor of an estate in ———, and who knew ——— and all ——— districts well. Possibly you may have heard his name, but it is 39 years since he first went to Ceylon and has left it now some 20 years. Poor fellow, he is getting on in years and is somewhat reduced in circumstances. He is not fond of Natal and holds a very poor opinion of coffee planting in general here, and there he is right, I fancy. He has no coffee under cultivation, but goes in for mealies and arrow-root. The next estate I visited was, belonging to the Natal Land and Cultivation Company, which holds much the same position here as the Ceylon Company, Ltd., used to do with you. I was very much pleased with what I saw here, but the system of cultivation carried on was somewhat different to Ceylon. They have 700 acres altogether in cultivation : coffee, tobacco, and mealies. Coffee is planted here in fields of from 5 to 10 acre blocks, with wind belts of bananas (bamboos are not approved of). Mealies and tobacco are planted between the rows of coffee. The plants and trees which I saw looked very healthy and those fields in bearing were looking A 1. The superintendent expects to get an average crop of 8 to 10 cwt. all over. Here they only allow the trees to grow to 8 years, after which they root them up and put in fresh plants. On my enquiry what the cost of cultivation was per acre, the superintendent said he could not tell me, as money was no object and as it was the Company's show estate, when money was wanted it came. This does not give a private individual much idea of what bis outlay will be before he gets a return. After leaving ———, I went to ——— estate near ———. This place belongs to the same Company and the same system of cultivation is carried on, and in all cases the superintendent have gained what experience they have in this colony, and don't seem to care to listen to what others have to say on the subject. However, I am quite satisfied that coffee can be grown in Natal and be remunerative for a certain period, but as to cost of cultivation I cannot say anything."

The following is the paper referred to in the second letter :—

THE FAILURE OF COFFEE PLANTING IN NATAL.—MR. Crowder, M. L. C., having brought before the House his notice requesting a commission to inquire into the above, and as I have informed the hon. members, that I am quite willing to give evidence thereon, I think the general public will not be displeased if one of the oldest planters lays before them briefly, through the medium of your valuable columns, his experiences in coffee planting, leaving your readers to judge for themselves whether the experiment is worth repeating.

In the year 1860, on the Red Hill estate, I produced half-a-ton of marketable coffee : in '61 two, in '62 four, and in '63 thirteen tons. Mr. Middleton, on the Snaresbrook estate, was in advance of me as regards quantity, until 1863 when my crop exceeded his. By this time, Mr. M. and myself were favored with many visitors and intending planters anxious for information on the culture of coffee, and preparation of the berry for market.

Our principal guide was "Old Laborie's coffee Planter of St. Domingo." By following his instructions the foregoing large crops were obtained from a very small acreage, and coffee planting in Natal proved the most lucrative branch of coast enterprise. To be as brief as possible, a few years after the success of the enterprise was though to be almost beyond doubts. A disease appeared amongst the trees, causing the branches to die off at the joints; this disease seemed to encourage the borer, and so destructive did this

grub become that out of about 180,000 trees on my own and Mr. Gooch's estates scarcely one tree escaped.

The way the scourge works is by insinuating itself under the crown of the root and boring up the stem of the tree, emerging from the stem after slowly killing the tree, near the topmost branches in the form of a beetle. While in the grub or dangerous form, the creature is about an inch long, of a pale yellow or whitish color, armed with a pair of strong hard forceps or pincers, which he seems to bore with in the most scientific manner.

Unfortunately I stuck to the plantation much too long, having learnt at school that perseverance was a marvellous virtue. My friends advised pruning: I pruned. Not pruning. I didn't prune. Manuring: I manured. No manure: I abstained from manuring. Bone dust: I boned. Lime: I limed. Guano: I emptied on a certain plot of land the contents of a bag warranted as imported from Jehaboe. Delving: I delved and dug. Weeding: I weeded. Let the weeds grow: and I speedily obtained a luxuriant growoth. Catch crops: I let go my hold. I shunned tobacco and mealies. I drained. Irrigate; I could'nt.

What to attribute the failure to I know not, but conclude by adding four words:—"The acts of God."

GOLD AND PEARLS IN CEYLON.

Our Kandy correspondent sends us the following interesting extract from a local publication dated March 1854:—

In connection with the discovery of Gold in Ceylon, and the alleged existence of a Pearl Bank off Mount Lavinia, the following information may perhaps be of interest.

Gold is found only in the native or metallic state, but is generally more or less alloyed with silver, in proportions varying from a fraction to 72 per cent. When pure, its specific gravity is 19·25.

If is found sometimes in brilliant crystallized grains, but more generally in small irregular lumps or grains in veins of quartz or calcspar. It is also obtained from beds of micaceous specular iron, in the form of spangles; in decomposing blende, and amongst iron pyrites. It is, however, far more abundant in the sand of rivers, and in the alluvial deposits of loose gravel, sand, and mud, which in many regions are spread over all other strata.

In the East, Borneo, Sumatra, and many other islands of the Indian Archipelago, as well as Cochin-China and Siam, are known to possess productive gold mines. Of the productiveness of the Ceylon Gold washings little can as yet be stated; but it has long been known to the natives that Gold was procurable; and by the kindness of L. de Soysa, Esq., Modliar in the Translator's department of the Colonial Secretary's Office, the subjoined extracts from two ancient Sinhalese works on the geography and products of the Island are made public.

From these works, entitled Kadayimpotta, it appears that formerly the whole Island was divided into three great Provinces, called Māyā Ratta,* Pihitty Ratta,† and Ruhunu Ratta ‡. These were sub-divided, Māyā Ratta into 28, Pihitty Ratta into 14, and Ruhunu Ratta into 14 Rattas, or smaller Provinces.

In describing the various Rattas in the Province of Māyā Ratta, one writer mentions, among others—*Siduruwana*, of which he says, "This country is so called from the number of streamlets, lakes, and rivers which abound in it. There are lands in it sufficient for the maintenance of the four constituent parts of an army. There are also in it rice villages, Gem villages," &c. &c. The Buddhist Temple Lankatilleka Vihare is situated in this District.

From the same author the following notices are extracted:

Kururatta (Allootcoor Corle?). A Pearl bank is spoken of about 6 miles from the Coast.

Pehetigalle (Pittigal Corle?). In this division there is a mine of precious stones called *Sindeya*, also a Sea-port called Mahadampe.

Bēlligalle (Belligal Corle?) Gold, precious stones and pearls are found here.

Dewameratta (situated between two oyas, or rivers, in the Kornegalle District). Silver is here found in a cave.

Merisaru and *Mahavelliganga*. Several mines of precious stones.

The second author, writing in a more summary manner, declares that there were known to exist in Ceylon, at the time he wrote "64 silver and 16 gold mines, one thousand (i.e. a very great number) of Pearl banks, and 100 mines of precious stones."

* Maya Ratta, bounded on the north by the Dedro Oya; on the east by the Mahawelliganga and the mountains; on the south by the Kaluganga; and on the west by the sea.

† Pihitty Ratta, bounded on the west, north, and east by the sea; on the south by the Mahawelliganga and Dedro Oya rivers; it was also sometimes called Raja Ratta, as the ancient Capitals were situated in it.

‡ Ruhunu Ratta, bounded on the west and north by the Mahawelliganga, and Kaluganga (or Kaltura) rivers; and on the east and south by the sea. The mountainous portion of it was called Malayaa Ratta.

HOW TO START A TEA GARDEN AND MAKE IT PAY.

ROUGH ESTIMATE.

Cost of opening out, in the Debrooghur District, Upper Assam, a new tea garden of 200 acres—clearing and and planting 50 acres annually, and probable profit therefrom in the eighth year:—

FIRST YEAR.

	Rs.
Cost of 500 acre grant under 30 years' lease rules, value of timber, &c. (first instalment)	1,000
Clearing 25 acres by Teklas for buildings, and sowing at stake, at R16 per acre ...	400
Preliminary buildings. Temporary bungalow, out-houses, godowns and cooly lines...	600
Tea seed, for germinating beds, and for planting out at stake, 25 maunds, at R70 per maund	1,750
Importation of 55 coolies, at R100 per head landed on the garden...	5,500
Engagement of 10 local labourers under a two years' agreement, at say R25 per head...	250
Wages of 62 labourers at an average of say R4 each per mensem	2,976
Establishment ... { Manager, at R200 per mensem. Mohri ,, 10 ,, Native Doctor ,, 25 ,, Chowkidar ,, 6 ,, Syce ,, 5 ,, Waterman ,, 5 ,, Dākwallah ,, 5 ,, }	3,072
Loss on say 300 maunds rice, at R2 per maund	600
Garden stores, implements, &c., say ...	1,000
Cart bullocks and pony	500
Government fees, law expenses, &c., say ...	300
Station or steamer agent's salary at R15 per mensem	180
Calcutta agent's charges, say	500
Discount, feed of live stock, stationery, postage, and other contingencies, say ...	1,372
Total	..R20,000

RESULTS AT END FIRST YEAR.

Receipts ... Nil.
Debit balance ...R20,000.

It is a good plan to give all buildings to Assamese to execute, as they build far better and stronger houses than imported coolies can, on first arrival in the country.

The following are the details of the buildings estimated for :—

Temporary Bungalow for Managers ...	R	50	0	0
Cook-house	,,	7	0	0
House for servants	,,	10	0	0
Stables	,,	8	0	0
Small out-house	,,	5	0	0
20 coolie huts	,,	140	0	0
House for Mohri and Assamese... ...	,,	14	0	0
House for Native Doctor...	,,	7	0	0
Hospital	,,	10	0	0
Rice godown (strong and substantial) ...	,,	25	0	0
Stores godown	,,	10	0	0
Charcoal godown	,,	10	0	0
	R	296	0	0

This leaves a balance of R304 for thatch, and other contingencies.

Tea seed.—About 22,000 seeds go to the maund, and if the seed is at all good, about 18,000 will be found to germinate in the beds. We will assume that the garden is to be planted 4 × 4'. The number of stakes in an acre thus staked in an acre thus staked out, will be 2,722. As three seeds as a rule are planted at each stake, 8,166 seeds will be required per acre. But to make sure of such a number, at least 9,000 should be laid in the germinating beds. We would thus require for the 50 acres no less than 450,000 seeds, and calculating that only 18,000 will turn out good in the maund, 25 maunds of seed will be required. We have allowed R70 as the price of seed per maund. For this amount very good hybrid jât can be obtained from trustworthy sources. Excellent tea seed can sometimes be obtained from natives at a very much lower figure, but as they cannot be relied on or trusted in any way, it is better to obtain tea seed from some well known garden direct. We have made no mention of nurseries, as there would in all probability be a sufficient supply of seed over in the germinating beds, which, growing up into seedlings, would suffice for the few vacancies which might occur. If the 50 acres is carefully sown and well looked after, there will be no vacancies to speak of. If the Manager, however, wishes to transplant out seedlings the next season, in lieu of sowing seed at stake, nurseries would of course have to be made. This would add to the cost, and the price of the extra amount of tea seed purchased would have to be added to the estimate.

Labour Force.—It will be seen that we have estimated for 55 imported coolies and 10 local labourers, making thus a total of 65 labourers on an estate of only 50 acres. This will perhaps be found fault with, but we maintain that this amount of labour is by no means in excess of actual requirements. Moreover, that instead of the estate suffering a loss thereby it will eventually prove a positure gain. We all know the heavy losses sustained by gardens owing to insufficiency of labour. The 62 working souls employed on actual garden work, it must be remembered, includes men, women and children. There would most probably be about 37 men, 18 women, and 7 children (boys and girls). Taking into calculation the number likely to be daily on the sick-list amongst freshly-imported coolies, and the number of deaths likely to occur during the year, 65 souls are by no means an unreasonable number to start operations with. For such a number a *good* native doctor should certainly be engaged.—*Indian Tea Gazette.*

THE PROGRESS OF INDIA.

What, for instance, can be more significant than the extraordinary development of foreign trade which India has witnessed during the last fifty years, involving as it does a rise from 18½ millions sterling in 1834 to more than 122 millions in 1880? This advance—due, of course, mainly to the introduction of railways—is more rapid even than that extraordinary commercial development which has been experienced in recent years in the United Kingdom. The average foreign trade of the United Kingdom for the period 1816—20 was 84 millions sterling ; this had increased in the period 1871—78 to an average of 646 millions. Thus, while British trade increased between seven and eight-fold in the sixty-four years between 1816 and 1880, the Indian trade has increased nearly as much in the forty years from 1840 to 1880 ; and the figures of the present year, as is well-known, already indicate that its commercial progress will be even more marked than that of its predecessors. Great, however, as this progress has been, it is really insignificant when contrasted with the possibilities which the country affords. The 250 or 300 millions of people who at present inhabit India, are hardly yet touched by the great tide of industrial enterprise which is setting in towards its shores. The 7,000 miles of railway, which at present traverse the country, have, indeed, infused a new life into the commerce of these parts where their influence extends ; but vast areas are still untouched, and the great majority of the people still live the primitive life of isolated agriculturists, tilling with pain their native glebe, aspiring to nothing beyond the satisfaction of their humble daily wants, and unconscious of the innumerable opportunities of wealth which lie unused around them, The average agricultural outturn, for instance, 11 bushels per acre, is as nearly as possible identical with that to which Mr. Lawes, the great agricultural experimentalist of England, has succeeded in reducing a portion of his land by incessantly cropping it with wheat, without any manure, for a period of thirty years. It is, in fact, about the lowest, which a soil, exhausted by continuous, reckless and unscientific cropping, can be made to yield. Supposing a more generous and rational method of culture to be introduced and the average yield raised —as it unquestionably might be—to the English average of 27 bushels, we should have an addition to the world's supply of agricultural produce of three millions of bushels, available either for fresh population in India, or for the wants of foreign countries.—*Pioneer.*

GOLD IN INDIA AND AUSTRALIA.

The Government of India in analysing Mr. Brough Smyth's famous report remarked : "If we omit the altogether exceptional sample from Wright's Level which gave 24½ oz. per ton, and the picked specimens from the same workings which gave 25½ oz. per ton, we get 88 samples, yielding an average of 1 oz. 8 dwts. 22 grs. of gold per ton." That was the result of Mr. Brough Smyth's explorations in the Wynaad over a period of eighteen months. Let us compare these figures with actual mining results in Australia. The actual yield from quartz-mines in Queensland was about equal to Mr. Brough Smyth's average specimens in the Wynaad. The average yield in New South Wales for the same year was 1 oz. 5 dwts. 7 grains per ton. There is no lack of rich "specimens" in Australia as in the Wynaad, but experience has taught the Australian miners not to attach too much importance to specimens. The average yield of a mine over a period of time, is a far more certain indication of the value of land in the neighbourhood for mining purposes. With the

above figures before us, we may well ask ourselves what there is to justify the high prices that have been paid for mining lands in Southern India? This is a matter, however, that chiefly concerns speculators in England; if they are satisfied it is not for Indian landholders to complain.

The reports before us contain some useful hints for the managers of the companies that are commencing operations in our midst. The importance of having improved machinery is strongly insisted on. Though the gold-saving appliances in Queensland are acknowledged to be "the most modern and approved obtainable in Australia," yet, we are told, it has been demonstrated by practical assay that as yet, "only about 50 per cent. of the gold contained in quartz is obtainable by our appliances. In some few reefs, where the mundic is largely impregnated with sulphides, especially zinc and lead, and nothing like 50 per cent. of the gold can be obtained, even when the reverberating furnace is used." Indeed the importance of the proper treatment of tailings, and matter which has passed through the quartz-crushing mills, is becoming universally recognised. The Queensland report avers that one-seventh of the yield of gold in one district had come from the "pyrites works," the owners of which are supposed to have made large profits. It is worthy of remark that the total value of quartz-crushing machinery in Queensland, is put down at £270,000 only, a small sum in comparison with the capital that has already been raised for mining in India. But with this machinery, the yield of quartz-gold in the colony in 1879 was about 190,000 ozs., worth at £3·10s. per oz., about £650,000. The yield from alluvial mines (chiefly worked by Chinese) in the same year, was 98,815 ozs. The total yield of gold for the year was 288,556 ozs., valued at £1,009,946, the number of miners being 3,191 Europeans, and 5,621 Chinese; and the average earnings of each individual miner was £114. For the year 1878, the earnings were as low as £74.

From the same official documents. we gather the interesting fact, that the total Australian gold supply from 1851 to 1878 was £240,000,000. And yet gold-mining flags in Australia, though any quantity of auriferous land may be had for £1 an acre. "The want of means to carry on prospecting operations for the discovery of the new gold-fields, and the gradual exhaustion of those easily-worked deposits of our known gold-fields, have been the main causes of the decrease in the number of our gold-miners, and until new fields be opened, or the necessary capital and skill for working the deeper or more difficult deposits of our older gold-fields be forthcoming an increase of our gold-yield can scarcely be expected." Such is the opinion of Mr. Harrie Wood, the experienced Under Secretary for Mines at Sydney. It is some consolation to reflect that gold-mining in India will not languish for want of capital.—*Madras Mail* 28th, March.

CINCHONA BARK.

The local agent of the New Zealand Loan and Mercantile Agency Company has forwarded us the following interesting extracts on Cinchona, received from its London Manager, and which will doubtless prove of interest to our readers.

"The cultivation of cinchona bark in various parts of the world has of late attracted considerable attention here, and in view of the possibility of its being exported from Fiji, we have endeavoured to procure some information on the subject for your guidance. You will find it embodied in the enclosed copy of letter addressed to us by Messrs. White, Binnie and Co., produce brokers, of this city, and the results of an auction held here on 30th ult., and set forth in the accompanying copy of the *Public Ledger* of yesterday. We believe that the best variety of the "Quill" bark grown in Jamaica (under the direct auspices of the Government) is most successfully treated at an altitude of about 5,000 feet above the level of the sea, and that the first essential towards its healthy developement is a dry well drained soil of good rich quality."

Extract from White, Binnie and Co.'s Circular:—

"There are no statistics to show the increase in the production of Bark in the East Indies (commonly called Cinchona Bark), the statistics in London comprising about South America and East Indies. The increase has however, during the last five years, been very great, and has been largely stimulated by the unexpectedly high prices realised in the London market, where three years since as much as 15s 6d was obtained for good Government grown quills. The market here has fluctuated considerably from time to time, but the consumption of sulphate of quinine is now so large that notwithstanding the large supplies of Bark, price of sulphate, which used to vary between 5s 6d and 7s per oz., has, during the last three years, averaged double that money, and is even to-day 11s per oz.

"Of the South American Bark lately imported, a large proportion is of very inferior quality, with a low percentage of quinine, whilst the East India is generally of superior quality and is greatly in favor with makers of sulphate.

"The unit is percentage of crystallised quinine sulphate which the bark contains, e. g., 1 lb. (7000 grains) contains 98¾ grains or 1·41 per cent., at 1s 6d per unit=2s 1d per lb.

"A large admixture of alkaloid (Cinchonine) will depreciate the value and vary the price."

London, December 2, 1880. [*Fiji Times.*

GOLD IN CEYLON.

The following is Sir Samuel Baker's reference to the first discovery of gold in Ceylon:—

It has hitherto been the opinion of most writers on Ceylon that the precious metals do not exist in the island; and Dr. Davy in his work makes an unqualified assertion to that effect. But from the discoveries recently made, I am of opinion that it exists in *very large* quantities in the mountainous districts of the island. It is amusing to see the positive assertions of a clever man upset by a few uneducated sailors. A few men of the latter class, who had been at the gold-diggings both in California and Australia, happened to engage in a ship bound for Colombo. Upon arrival, they obtained leave from the captain for a stroll on shore, and they took the road towards Kandy, and when about half-way, it struck them, from the appearance of the rocks in the uneven bed of a river, called the Maha Oya, 'that gold must exist in its sands.' They had no geological reason for this opinion; but the river happened to be very like those in California, in which they had been accustomed to find gold. They accordingly set to work with a tin pan to wash the sand, and to the astonishment of everyone in Ceylon, and to the utter confusion of Dr. Davy's opinions, they actually *discovered gold!* The quantity was small; but the men were very sanguine of success, and were making their preparations for working on a more extensive scale, when they were all prostrated by jungle fever; a guardian-spirit of the gold at Ambepussé, which will ever effectually protect it from Europeans.

They all returned to Colombo, and, when convalescent, they proceeded to Nuwara Eliya, naturally concluding that the gold which existed in dust in the rivers below must be washed down from the richer stores of the mountains.

Their first discovery of gold at Nuwara Eliya was

on the 14th of June, 1854, on the second day of their search in that locality. This was found in the 'Vale of Rubies.' I had advised them to make their first search in that spot for this reason; that, as the precious stones had there settled in the largest numbers, from their superior gravity, it was natural to conclude that, if gold should exist, it would, from its gravity, be somewhere below the precious stones, or in their vicinity.

From the facility with which it has been discovered, it is impossible to form an opinion as to the quantity or the extent to which it will eventually be developed. It is equally impossible to predict the future discoveries which may be made of other minerals. It is well known that quicksilver was found at Cotta, six miles from Colombo, in the year 1797. It was in small quantities, and was neglected by the Government, and no extended search was prosecuted. The present search for gold may bring to light mineral resources of Ceylon which have hitherto lain hidden.

The minerals proved to exist up to the present time are gold, quicksilver, plumbago, and iron. The two latter are of the finest quality, and in immesen abundance. The rocks of Ceylon are primitive, consisting of granite, gneiss, and quartz. Of these the two latter predominate. Dolomite also exists in large quantities up to an elevation of 5,000 feet, but not beyond this height.

CULTIVATION OF TOBACCO IN INDIA.

A report of the tobacco operations at Ghazipur and Pusa during the year 1879-80, by the Officiating Director of the Department of Agriculture and Commerce, N. W. P. and Oudh, had just been published, which shows that the enterprise of Messrs. Begg, Dunlop and Co. bids fair to command success. The firm have farms and machinery both at Ghazipur and at Pusa; but the most important part of their operations is carried on at the latter station, in the district of Darbhanga. Of the 1877-78 crop 29,993 lb. were exported, 25,247 lb. to England and 4,746 lb. to Australia. This was an experiment, and one which, so far as Australia is concerned, is not likely to be repeated, it being found that there was no market there for the cured leaf, as sufficient tobacco of the class is grown in the Colonies, and sells at the low price of 4d per lb. In England, however, the Indian tobacco met with a more promising reception. The market was very dull, and the average price of the tobacco sold was not higher than 3½d. per lb.; but some of the best leaf fetched as high as 5½d. per lb. The result is regarded as decidedly hopeful in this way, that American tobacco of average quality was being sold at the same time at similar rates; and the Indian tobacco was the result of the first year's curing, and was not so good as it might have been. The firm is now able to turn out a far better class of tobacco; so the question of the Indian competing successfully with the American article may be regarded as practically solved. The extension of the trade with England is not being pushed at present, however; the promoters of the industry contenting themselves with first developing a local trade in the manufactured article—smoking mixtures, cavendish, cigars, &c. The whole of last year's outturn, amounting to 163,000 lb. of cured tobacco, has been kept for manufacture at the company's works at Pusa. Cavendish, golden leaf, bright smoking mixture, dark smoking mixture, honey-dew, cigars, and cigarettes are all made under the superintendence of the skilled European curers and manufacturers employed by the company. The tobaccos are sold at prices varying from R. 1-8 per lb. for golden leaf to 7 annas per lb. for black cavendish. The increasing demand for the Pusa tobacco is shown by a statement of monthly sales commencing April, 1879, and ending November, 1880. In the first month named the total quantity sold was only 223 lb., and in the last 7,620 lb. were disposed of. The description for which there is the greatest demand is black cavendish, large quantities of which are used by soldiers. The cigar trade, which was developed only in the year 18°0-81, is increasing daily; and in the four months from August to November last upwards of 200,000 cigars and cigarettes were sold, valued at R3,000. As soon as the Indian market is satisfied, the present operations sufficiently consolidated, the establishment properly trained, and cultivation extended, the firm hope to be able to produce enough tobacco of good quality both to meet the Indian demand and to make regular and large shipments of leaf to England.—*Bombay Gazette.*

COFFEE LEAF DISEASE.

(*From our Correspondent.*)

Aberdeen, 10th March 1881.

A paper on coffee leaf disease by Mr W. Bidie was read at the last meeting of the Linnæn Society. Plants grown from Ceylon seed suffer most, while those trees of Coorg origin and growth are least affected. A system of "renovation pitting" has been successfully tried: pits being dug at short intervals, wherein after judicious pruning all the affected leaves are buried, and this precaution seems to check the spread of the disease, particularly among the Coorg coffee trees." In reference to the suspicion of Ceylon seed being affected, I may tell you, a friend of mine, who is an authority as a cryptogamist, has been devoting a good deal of time lately to microscopic examination of cereals, in view of embodying all evidence obtainable respecting the probability of fungi being carried and propagated from the embryo of the plant. He has found the embryos of cereals to be infested with the mycelium of fungi (of some kind or other), and extending his examinations to other seeds he found a like condition in the embryo of dates, and in that of Ceylon coffee. This fact, as far as I am aware, has escaped the observation of Ceylon scientists.

I had a call the other day from the Professor of Botany at the Aberdeen University, and had some talk with him about Mr. Schrottky's experiments. He has no faith of good resulting from that gentleman's work in Ceylon, as foreign matter introduced into the circulation of the tree of strength sufficient to kill fungi will certainly damage the tree. There is no single instance of fungi being cured by a like mode of treatment.

CHINCHONA CULTIVATION.*

Like all the books written by Mr. Clements Markham, this volume is a piece of excellent workmanship in every particular, full and accurate in detail and arrangement, lively and perspicuous in statement and narrative. For all general purposes it exhausts the subject and enables any person of ordinary intelligence to understand the steps which gradually led up to the beneficent results which have already flowed from the successful introduction on a large scale into India, and the cultivation there, of trees producing the Peruvian, or Jesuit's, bark, famous as the best and speediest cure for tropical and other fevers. It was in March, 1852, that the Indian Government first proposed officially to introduce, if possible, into India the most valuable species of the large family of trees

* "Peruvian Bark: A Popular Account of the Introduction of chinchona cultivation into British India, 1860-80." By Clements R. Markham, C.B., F.R.S., with Maps and Illustrations and Index. (London: John Murray. 1880.)

growing wild on the slopes of the Andes, in Peru, Ecuador, and Colombia; and the late Dr. Royle, the reporter on Indian products, did all in his power to further the design; but no real progress was made. Early in 1859 the subject was brought before Mr. Markham by Mr. Henry Deedes, of the Indian Office. For other scientific purposes Mr. Markham had already visited the chinchona regions of South America, and had become familiar with the people, and master of their languages. In March, 1859, Mr. Markham proposed a plan of operations and laid it, with an offer of his services, before the present Lord Derby, then the first Secretary of State for India under the system of government which the year before had superseded the old Court of Directors. On the 8th of April (1859) Mr. Markham's proposals were accepted, and he was duly commissioned to carry them into effect. Mr. Markham left England in December, 1859, for South America, taking with him Mrs. Markham, who, it was arranged, should remain at a point near the coast to conduct correspondence, &c., while her husband and his party explored the forests east of the Andes. The "fellow labourers" of Mr. Markham, as he calls them, were:—In the capacity of coadjutors, Dr. Spruce and Mr. Pritchett;—and as assistants, practical gardeners, Mr. Weir and Mr. Cross. Dr. Spruce was a Yorkshireman, born not far from the pleasant village of Stillingfleet, which has the honour to claim Mr. Markham himself as a native. Richard Spruce is from Welburn, near Castle Howard, and very early in youth distinguished himself by his knowledge of the botany of the romantic neighbourhood of that village. He had, like his leader, already visited South America. In collecting the grey bark trees of Huanuco the services were secured of Mr. Pritchett, who had been for some time agent of the Ecuador Land Company. John Weir was a practical gardener obtained from Mr. Veitch; and Robert Cross was an able and painstaking Scotchman from Kew. Mr. Ledger was also associated with the expedition. Of all these fellow-workers Mr. Markham speaks in terms of the highest praise; and we are ashamed to say that as regards each of them he has to utter bitter complaints of the shabby and unjust treatment they received at the hands of the Indian and the Home Governments. The details given by Mr. Markham leave no doubt that the recompense awarded to these men for all their perils, their attainments, and their success was emphatically paltry, and very far below the justice of their claims. Will the time ever come in this country when scientific labours, even the most distinguished, will not be estimated by the officials of the Government on a scale suitable only to a mechanic or a footman? There are titles, pay, and pensions in profusion for military and diplomatic services more frequently pernicious than useful; but the scientific discoverer or explorer is more likely to meet with contempt than recompense by the "department" he serves.

In the course of 1861, after encountering great hardships and no small peril in the South American forests, considerable supplies of the desired specimens were landed in England and India. For the interesting narrative of these hardships and perils the volume must be consulted. The region selected for the first chinchona plantations in India was that of the Nilgiris hills—the highest mountain range south of the Himalayas—situated in latitude 11 deg. 10 m. and 11 deg. 32 m. N., and longitude 76 to 78 deg. E., and affording conditions of climate suitable for the new cultivation. Outside India the cultivation has become successful and is assuming large dimensions in Java, Jamaica, and Mexico. During the eight years 1867-75 the Government of India imported a total of 46,000 lb. of Peruvian bark, at a cost of £160,000, or, say, an average of 70s. per lb. Besides the Government imports there was a private annual import into India of 5,000 lb. of bark, making the total annual imports about 10,000 lb. weight, at an annual cost of about £40,000, or, say, 80s. per lb. The success of the Indian cultivation has already to a large extent put an end to this great outlay. The private cultivators of bark in Ceylon and India are already looking forward to the creation of a large market in China; in which country, by reason of cheapness and the superior quality of the article, it is expected gradually to supersede opium as a medicine in those vast areas of delta and swamp where rice is principally grown and from which fever is never absent. It is among the possibilities of a future not distant, that India may make some atonement to China for the evils of the opium trade, by substituting for the exports of that pernicious drug exports still more extensive of the bark and alkaloids of the Peruvian tree, which has the property of curing and preventing the most constant and fatal maladies of tropical countries.

Mr. Markham says with equal eloquence and truth that among the greatest of the benefits which this country can confer upon India is, by the aid of science and enterprise, to enlarge the field of useful products of which the diversified climates of the Peninsula are suitable. "By this means we shall leave behind us the most durable memorials of the benefits conferred by our rule. The canals and other works of the Moguls were in ruins before the English occupied the country; but the melons which the Emperor Akbar, the founder of the Mogul dynasty, introduced into India still flourish round Delhi and Agra." And Mr. Markham adds—but we trust with too small an appreciation of the stability of the Ganges Canal and the Vehar Reservoir—that, centuries after these mighty works have become, the one a river and the other a dry valley, the people of India will have cause to bless the healing effects of the fever-dispelling chinchona trees still covering the southern mountains with their luxuriant forests. We will complete the forecast by adding that in this distant time the hundred native castes and tribes of India will remember with reverence and gratitude the names of the two valiant Yorkshiremen, Markham and Spruce, and their fellow-labourers," as the men who accomplished their great work in the short space of twenty years 1859-1879. Mr. Markham gives reasons for spelling the word "chinchona" and not "cinchona," or "cinhona," as it was spelt by Linnæus, and the altered spelling has raised a botanical dispute. The title "chinchona" is given to the bark tree as a memorial of the cure of fever by its means in 1638 of the Countess Chinchon, wife of the Governor of Peru.—*Pall Mall Budget.*

LEAF DISEASE IN COFFEE.—A correspondent, writing on Leaf Disease in Coffee, says:—"Something might be found out of the manner the Arabs treat the coffee plant. Mocha is the king of coffees—either by climate or treatment—perhaps it is that arid climates grow the best. There remains no doubt of the plant being perfection. Doctors and botanists may advise a good deal to counteract influences, yet Arabia is the starting point, because it gives the best. Dent's Concession in Borneo in its most arid parts should give next to Mocha. English coffee growers must beware that the Spaniards in Manilla do not take to and surpass them in coffee growing. Anyone finding out the mode to dispense with fungus, I think must do so from Arabia. If anyone cannot be found here who has been in Mocha, by bringing one plant with fungus upon it, and taking it to Mocha in a week, perhaps he might find out the Arabs' secret, and from that add to his fortune in a treatise on the plant, and thus surpass those who cannot dispense with fungus. Of all the people who have gone to plant coffee, has one of them asked at Aden anything about it?"—*L. & C. Express.*

ARTIFICIAL POULTRY RAISING.

A prominent dealer in poultry, Mr. H. W. Knapp, of Washington Market, New York, gives a discouraging opinion of the probable success of chicken-raising by artificial means. He said recently when questioned on the subject:—

I went to France to study the matter, for if it can be made to succeed it will make an immense fortune, as it has already done in Paris. I was delighted at what I saw there, and the matter at first sight seemed to be so fascinating that I do not wonder that new men here are always ready to take hold of it. Even clergymen and actors are bitten with the desire to transform so many pounds of corn into so many pounds of spring chicken. The now successful manager, Mackaye, spent about a thousand dollars in constructing hatching machines and artificial mothers in Connecticut, but he found that the stage paid better, and his expensive devices may now be bought for the value of old tin. Enthusiasts will tell you that by the new discovery chickens may be made out of corn with absolute certainty. In Paris this has been done; but the conditions are entirely different here. There the land is valuable, and they cannot devote large fields to a few hundred chickens; the French climate is so uniform that the markets of Paris cannot be supplied from the South with produce which ripens or matures before that of the neighbourhood of Paris; the price of chickens is so high and labour so cheap that more care can be given with profit to one spring chicken than one of our poultry raisers could give to a dozen. Here we have plenty of land; the climate south of us is so far advanced in warmth, that even with steam we cannot raise poultry ahead of the South, and the margin of profit is so small that one failure with a large batch of chickens sweeps away the profits from several successful experiments. When persons wanted me to go into the project I declined, and was called an 'old fogey.' One man spent a fortune on the enterprise in New Jersey, and at first was hailed as a public benefactor. What was the result of all his outlay and work? He managed to hatch quantities of our chickens every February; but although he could fatten them by placing them in boxes and forcing a fattening mixture down their throats, he could not make them grow; they had no exercise; they remained puny little things, and another defect soon appeared—though fat, they were tough and stringy. The breeder sent lots of them to me, and they looked fat and tender; but my customers complained that they could not be young, for they were tough and tasteless, and that I must have sold them aged dwarfs under the name of spring chickens. It was found absolutely necessary to let them run out of doors as soon as the weather allowed it; and by the time that they were ready for market, the southern chickens were here and could be sold for less than these. The upshot of the business is that this breeder has sold out, and another man has now taken hold of a small part of his old establishment to try other methods of making it a success. As to raising turkeys in that manner, it will fail more disastrously than the chicken business. Size and weight are wanted in turkeys; and that reminds me, continued Mr. Knapp, that the newspapers ought to impress the country people with the necessity of improving their poultry stock; breeding in-and-in is ruining poultry; every year the stock we receive is deteriorating, and this is the cause. I could give you some striking examples from my experience of forty years in the business. Some years ago we poulterers thought that ducks were going to disappear from bills of fare altogether; they were tasteless, worthless birds, which people avoided. On Long Island a farmer made experiments in breeding with an old Muscovy drake, tough as an alligator, and the common duck. The result was superb, and has changed the whole duck industry. If the farmers of Northern New Jersey, the sandy country best suited to turkeys, would bring from the west a few hundred wild turkeys, we should have an immediate improvement. I see no such turkey now as we had twenty years ago. The breast is narrow and the body runs to length; it is all neck and legs, and can be bought by the yard. Rhode Island sends us the best turkeys, but they are not what they used to be. If, instead of attempting to beat Nature at her own game, the rich men who have money to spend would devote it to better breeding, there would be an improvement. I do not yet despair of seeing immense farms wholly devoted to raising better poultry than we yet have.—*Home and Colonial Mail.*

NEW AND OLD PRODUCTS:

CEYLON LOW-COUNTRY REPORT. LIBERIAN COFFEE; CACAO.

Western Province, 5th April 1881.

My last, in which I took a tone of dread for the life of the Liberian coffee plants in the field, was written on the day on which rain fell, and it was just in time, for a few days more would have settled a large percentage of them; as it is, a few have been scorched. 21 days is the measure plants of this size can stand, even when carefully protected from the fierce sun. Since the rain came the plants have been making rapid progress, but a fresh *clecking* of crickets have appeared. They have cut a few plants here and there, over the field, but they have settled most seriously to work on steep stony hillsides, of which there are several in the clearing, on which they have cut fully one-half within the last few days. The most of the plants so cut would grow again if not further interfered with, but they are always cut anew, when they develope a bud.

Nearly all the seed from Theobroma is up, and that from L. & Co. has three-fourths up in five weeks; that from C., S. & Co., that was sown a few days later, is just showing one here and there. I was much alarmed about the crickets in the sheds, when I found one morning twenty cut seedlings, within a few feet, but for a week past they have of their own accord entirely desisted from this work.

When the plants began to suffer from the drought I set all hands to improve the shade. The rain came just as the work was finished, and I set all hands to undo what they had been doing, and this is the third time the same thing has happened since Christmas. After a fortnight of dry weather the sun scorches the leaves, wherever exposed; after one heavy shower, the shade must be removed at once, else the leaves rot, and are riddled by minute insects, so that he who hopes to get up Liberian coffee in this climate needs to be ever on the alert. If, however, he once gets it up to 18 inches, his cares are over: in twelve months more he will have a tree six feet high with twelve pairs of branches, regularly graduated from two feet to two inches, and having several hundreds of fruits at various stages of development. As the best bunches of fruit are up to, and even over, 30, and 140 has been counted on 8 joints of a two feet branch, I begin to think the assertion that a single mature tree has given 30 lb. not such an awful cram after all. The author who gave currency to this statement, nearly 40 years ago, did not condescend to say whether the 30 lb. was in cherry, parchment, or marketable coffee—he left a wide enough margin for choice, so that with 600 trees per acre, and the crop reduced to 3 lb. of cured coffee, we have still 16 cwt. per acre. If some of the trees under my care make good their present promise four years hence, this

is by no means a wild estimate ; with good soil to start with, and skilful treatment in the mean time.

CACAO.

I have heard of such wonderful estimates of the profits of cacao cultivation, framed by those who are just beginning in the low-lands of the Western Province, that I think a slight sketch of my own three years' experience may be of service to them. I may introduce myself as a planter of over forty years standing, with a wide and varied experience ; but when I began cacao I knew no more of the habits of the plant than I had casually picked up from newspapers, and other publications, to which I had given no particular study : I had, therefore, almost a clean sheet to take my notes on.

It is just three years since I sowed my first seed, in bambu cylinders, filled with the best soil I could command. Most of them grew, and they were planted out, on land that had been trenched, rooted, and prepared for Liberian coffee nurseries, with the larger trees left as shade. Here they grew till the best plants were four feet high, and were getting their branches, when a belt that separated them from the clearing was cut down, and within a few days not a leaf remained on any of them. Some of them still live, and struggle to send out shoots from the stem, but the wind always defeats their efforts. The next batch of plants were put out, alternately with Liberian coffee, on land with a very easy incline to the west, the soil being a loose gravel, with much organic matter. This lot got on tolerably till the south-west monsoon opened, when they went the way of their elders. Those that remain alive are making a strong effort, but will no doubt be finished off by the wind, when it comes round to the S.W. Of course I have given up all attempts to establish a cacao field on that land.

On this place, I introduced 500 well-grown plants, in bambus, in July 1879, and before the end of that year not one in ten was left alive. They encountered three months of dry weather ; they were cut by lizards and crickets ; insects riddled the leaves ; white ants cut the taproots, just below the surface ; the wind stripped them ; and now at the end of 21 months I have not 25 of the 500 odd remaining. In November 1879 I sowed the whole field at stake, and surrounded each plant with a basketwork cylinder from 15 to 18 inches high. On the portion of the clearing that faces the S. W. the whole of them died out within four months, and three-fourths of those on the eastern side followed. At the end of May, last year, I put down seed at all the failures, but dry weather set in immediately afterwards, and they never even germinated. Finally I put down nearly 10,000 seeds in baskets in September and October, one-fourth of which were cut by lizards and crickets, almost as soon as they came up, and above 1,000 were cut the very first night after planting in the field. At the end of November last year the whole clearing was fully planted. Now, in April, one half of the spaces are vacancies. The number of plants for the place is is about 8,000. I have, first and last, used 25,000 seeds, and I have still upwards of 4,000 vacancies. My conclusion is, that, of all the plants I ever have had to deal with, the cacao is the most delicate, and has in this climate the most enemies. I by no means say that the evils to be encountered in getting up a field of cacao, in this climate, are insurmountable, for I have one field of ten acres, in which I have not at the end of five months absolutely lost ten per cent of my plants. I do not know whether cacao will, when more advanced, be able to resist the prevailing wind, on situations exposed to it, but, so far as my experience goes, it inclines me to the negative side of the question. In every situation that I have had to deal with, the young plant needs temporary shelter, but, so far as I have been enabled to observe, it is not benefited by overhead shade, except when very young. I certainly have seen benefit from placing a jungle branch with the leaves on, over the basket shield in hot weather. This plant does not take kindly to a soil where sand or gravel are the prevailing ingredients ; an alluvial flat, or a deep clayey loam, seems to suit it best.

White ants, I had always believed, touched no living plant, and it was only after obtaining the clearest evidence I admitted that the young cacao plant was an exception to the rule. It is ower true a tale that they have destroyed tens of thousands in the low-country, and will destroy hundreds of thousands more before all the projected plantations are complete. I do not know whether the gentleman who recommended steeped aloe leaves was in earnest. The aloe is by no means a common plant in Ceylon, and is a very slow grower, and nothing can be clearer than the utter impracticability of the plan where there is not an aloe plant within ten miles, or a drop of water to be found on the surface of 100 acres. As to the other enemies of this plant, the lizards and crickets breed most freely in a loose dry soil, and do not much affect clays, gravels, heavy loams, &c. There is no doubt that allowing the weeds to take and keep possession of the soil would moderate the ravages of both crickets and lizards on the cultivated plants, by affording them a wider field of choice, but it is an unsettled question, whether the gain in one direction might not be balanced by a loss in another ; so far as coffee is concerned, there is no question about the action of weeds. For myself, as the father of monthly hand-weeding on coffee estates, I will not be the man to make the experiment of burying young cacao plants in dirt, in the hope of benefiting them thereby. Seed must now come rapidly down in price, with so many trees coming into bearing at so many points of the country, and there will be little difficulty in maintaining nurseries at a moderate cost, to supply vacancies as they occur.

As to the minor insect enemies, I have observed about half-a-dozen species of caterpillar feed on the leaves, and several species of minute beetles ; then a small species of black ants bring the spawn of the white bug and establish it on the tender shoots of a thriving plant, but it generally succeeds in dismissing its unwelcome guest in a few days. Besides all those reptiles and insect foes, there is a large percentage of failure, for which I am still unable to account ; a plant of eight or ten inches suddenly ceases to grow, and sometimes remains for months, not dead, but sickly, and then suddenly dies off. On examination, there is no sign of insect action, either on root or stem. If this is an effect of dry weather, then why are other less advanced plants not affected in the same way ? I have had an ample opportunity this season of studying the effects of drought on the young coffee plants : all that were planted in the same kind of soil, and had grown equally, showed the same day the same signal of distress on the same day, but cacao shows no such uniformity of constitution ; a plant that has been cut when very small will fight to establish a fresh stem, through the whole dry season, and probably with success; while its next neighbour, that has met with no check, has been growing freely till it is above a foot high, suddenly drops its leaves ; sometimes renewing its growth when rain falls, but more frequently going off altogether, even after the advent of rain. I would be glad to learn whether this is common in the experience of other cacao planters, or if it is a special dispensation, affecting the soil and climate which I have to deal with only. The largest plant I have found the white ants dispose of was three feet high, but I have had cases of sudden death, of plants quite as advanced, for which there was no apparent cause. One plant that some time ago I remarked as a specially thriving one I found this morning with

all its leaves withered. Finding it was quite dead, I tried to pull it up for further investigation, but it retained too firm a hold of the ground for my strength. In February every plant drooped on the 21st dry day except the very smallest; in March it was the 25th day on which they began to complain. If therefore what I have stated of the cacao be the effect of drought it would appear that every cacao plant has its own constitution, and that while one gives up in a week another of the same age and treated precisely the same holds out three or four weeks and rapidly responds to the first shower. Mr. Fraser tells us that in Trinidad it is only the larger seeds in the middle of the pod that are used for reproduction. There may be something in that, but we who have been paying a cent each for our seeds naturally grudge doubling the cost by rejecting any.

NORTHERN QUEENSLAND.

(*From the "Mackay Standard."*)

COFFEE.

We could not perhaps do better than reproduce a few extracts from an article which appeared in a former issue of the *Standard* on this subject:—"Millicent, the property of Mr. Costello, is situated at about twelve miles distance from town. At the back of a compact homestead the cultivation begins, and here are found 25 acres of coffee, two or three years old in vigorous growth. It is growing on a spur running north from the mountain. Half the coffee is on the east side, the other on the west side of this spur. The land is the usual basaltic scrub, and we noticed that if possible the coffee looked more flourishing where the stones were most plentiful. William Sabonadiere in his well-known work "The Coffee Planter of Ceylon" sums up the characteristics of the soil most suitable for coffee culture as follows:—"A dark chocolate colored soil mixed with small stones under ledges of rock and bestrewn with boulders of granite." On Mr. Costello's selection these characteristics are found to perfection. The three-year-old trees have a fair crop of young coffee on them, and the two-year-old trees have already a very promising maiden crop. The trees are planted 6 × 8 feet apart, and the older ones are already topped to four feet in height. Although the entire crop is in a most flourishing condition those situated on the west side of the range are in a more vigorous condition than those on the east, being more sheltered from the force of the E. S. gales that the district is occasionally liable to. From the summit of the hill among the coffee one of those magnificent views for which the north side is so justly celebrated spreads out before us. To the east, like a panorama, the waters of the South Pacific glistening in the sunshine, and dotted with innumerable islands of verdant green, to the west and south the dense masses of the coast range and scrub land slopes of Blackfellow Mountain tower high above us. We visited Mr. Costello's coffee nursery where we found many hundreds of healthy young coffee plants ready for planting out when the proper season arrives. Highly gratified with our visit we started on our return after congratulating Mr. Costello upon the pluck displayed by him in his endeavor to introduce a new industry into the district. While on this subject we desire to draw the attention of farmers to the advisability of following Mr. Costello's example. The growth of coffee at Mackay is no longer experimental. The machinery required is inexpensive. The families of many of our farmers could do most of the crop gathering and the demand for coffee in the colonies will absorb all that can be produced for many years to come, while the duty of 4d. per lb. on imported coffee will offer that amount of protection to our producers until the Queensland market is supplied with Queensland grown coffee. That Mr. Costello may be considered the pioneer of coffee growing in Mackay does not admit of a doubt, and we trust he may reap the reward which he so justly deserves for his enterprise."

COCOA NUTS.

Whether it would be profitable to grow these on account of the copra we are doubtful, but there is a steady demand for the nuts in the South which will for some years render their growth a paying speculation. In this connection we may with propriety take the following extract from the columns of the *Australasian*. It forms, part of a special report upon this district which appears in that journal. "Barnes' garden is the sight of Mackay, and a very interesting example of the power of industry and perseverance, it is. Many years ago Mr. Barnes took up a selection on a tract of land that was little better than a salt swamp. Twenty acres of this have gradually been formed into the finest fruit, vegetable, and flower garden in Australia. Mr. Barnes supplies the whole of Mackay. He has reared 1,200 cocoa-nut trees, besides great numbers of apple, peach, and other English fruit trees, and bananas and date palms. He is famous for the enormous size of his pine-apples. Vegetables of every description are produced. A profusion of splendid flowers completes the beauty of a very remarkable spectacle. Bearing with us substantial proofs of the excellence of Barnes' garden, we rejoined the steamer which proceeded on her way through the most charming of Queensland waters."

DATE COFFEE.

(*Smith to Jones.**)

I hope 'twill ne'er be my fate, Jones,
To drink that stuff composed of date stones,
I never heard that juice of dates
Consoles, cheers or invigorates.
You might as well scrape mud from gutter,
And dub it "best prime English butter,"
As call *this* coffee: oh, 't is awful
That such a swindle should be lawful.
Some say 't is made of rotten figs, sir,
If that 's the case then "dash my wig," sir,
Your system 't will completely flummock
When you convey it to your stomach.
Others declare 't is made of raisin,
Which statement seems to me amazin';
For if you 'll list to me a minute,
I 'll shew there is no *raison* in it.
If made of rotten dates or figs, sir,
'T is only fit for feeding pigs, sir,
Then throw it to your swine and boars, or
Cocks and hens, but don't buy more, "sorr.'
We planters of this spicy island,
Whose business 't is to till and buy land,
We cultivate the coffee berries
Somewhat resembling English cherries.
True coffee can't be imitated,
'T were well to call *ours* "anti-*dated*,"
To shew that difference there be, sir,
'Twixt tweedle-dum and tweedle-dee, sir.

SMITH.

COLOMBO GRAPES.—Mr. P. T. Slema Lebbe has been good enough to send us a bunch of grapes the produce of his cultivation which was referred to in a paragraph in the *Jaffna Patriot*, copied into our issue of last evening. He informs us that the bower yielded over 120 lb. Having tasted the grapes we can testify that in the present hot weather they are very refreshing. The bunch sent us is 6 inches long and weighs 7 oz.

* The latter (Jones) has purchased a packet of "Date Coffee:" hence Smith's remarks.

(From April 10 to April 16.)

COFFEE MIXTURES AND ADULTERATIONS.

A planting correspondent in the low-country writes:—

"There appear to me two things that the Planters' Association ought to do about the Date Coffee:—

"1st.—Obtain a legal opinion, as to whether an injunction could not be got to prevent the Company from using the word 'coffee,' in describing their preparation of date stones. If they produce a beverage, that is cheap, palatable, wholesome, and nourishing, it is quite able to stand on its own bottom, and make a name for itself, but, whatever it may be, it is not coffee, and has no right to usurp a name which belongs to an article costing much more in production, and the value of which rests on qualities, which no cheaper produce can lay claim to. The English Parliament has legalized the sale of a mixture of chicory, because the grocers of Great Britain are a more important factor in elections than coffee planters, but the same privilege is certainly not extended to date stones, and the grocer interest is not likely to avail the Company, as it will naturally prefer the preparation it can mix at its own discretion.

"2nd.—A memorial to Mr. Gladstone, shewing that this new commodity avowedly comes into competition with a whole group of duty-bearing products, and praying that date stones may be placed on the same footing at the custom house as the tea, coffee, cacao, and chicory, it proposes to displace.* For once in a way, the coffee and chicory planters are in the same boat: a common foe should lead them to the same platform to fight for a common interest. The tea and cacao planters are less directly interested, but if this Company succeed in creating a taste for their trash, it will more or less affect the whole group, especially when the genuine commodities are loaded with a customs duty, and the spurious imitation enters free. The Company seem to be moving heaven and earth to push their wares on the markets; while the planters sit idly by, to watch but never act. We can have no hope of checking to any appreciable extent the fraudulent practices of British trading, which a high authority has declared to be the legitimate outcome of free trade, but when those practices touch our own interests at a vital point, nothing should be left undone that may possibly tend to our protection."

Our correspondent, and many more of our readers, will be glad to learn that the Chairman of the Planters' Association has taken up the question of memorializing the home Government on the subject of coffee adulteration and the sale of coffee mixtures, and that a result long pressed for in these columns will now be attained. We take it for granted that the draft memorial submitted by Mr. Wall to a Sub-Committee of the Planters' Association, after any needful amendment, will be unanimously supported throughout the country. We trust the Chamber of Commerce will either make it their own or take independent action to endeavour to secure the same end, namely, the restriction which the most ordinary fair play calls for in the case of the retail sale of coffee mixtures in the United Kingdom. We want both the local bodies to send home a petition annually until the present grievance is redressed. Coffee alone among colonial produce is placed at the serious disadvantage of having all kinds of legalized, but abominable, mixtures sold under its name in the United Kingdom. We do not see why the prohibition of all such mixtures should not be asked for. True, chicory and the trash of "dates" which is to be used for coffee pay the same customs duty (14s per cwt.) as the fragrant berry, but that is no safeguard against the most rascally deception which is openly and almost avowedly practised on the mass of the consumers. The working and even the lower middle classes are unable to protect themselves in buying the cheap and attractive coffee mixtures, so neatly and conveniently assorted. Then by degrees their taste becomes vitiated, until real coffee would positively be a strange and unpleasant drink to them. Chicory or some other powder they must have, and it becomes possible to palm off upon them 90 per cent of some wretched stuff to 10 of ground coffee. How is it to be wondered that the consumption of coffee in the United Kingdom should have gone back steadily, while tea has so marvellously increased, under these circumstances? Our Handbook shews that the consumption of coffee in the United Kingdom was 16,730 tons in 1847 against only 14,540 tons in 1880; while the consumption of tea in the same period has quintupled, the increase alone being equal to 72,500 tons. Forty years ago, in fact, coffee was drunk in the mother-country to the amount of fully 1¼rd lb. per head of population, while now the ratio is ·09 lb. Tea, on the other hand, from 1⅔rd lb. has gone up to nearly 6 lb. per head of population! Can any stronger evidence be required by Mr. Gladstone and his colleagues of the injurious effect of the iniquitous "Order of Council" which sanctions the sale of coffee mixtures? If it be the wish of the British Chancellor of the Exchequer and his Lords of the Treasury to suppress the consumption of coffee altogether in the United Kingdom, let them say so; but surely the present system of depraving the public taste ought to be stopped in the interest of everybody concerned.

Whether, however, the Home Government will consent to stop the sale of chicory and date mixtures of coffee or not, there is one reform which, if put as an alternative in the Ceylon Memorial, it seems to us, cannot possibly be refused at this time of day. We refer to the declaration on the label required on such mixtures of the proportions of each substance which they purport to contain. If this is done, it will open the eyes of the consumers to the small quantity of coffee they are really receiving in their mixtures, and, moreover, it will enable a check to be put on coffee, as on other, adulterations; for, should the proportion of coffee be found less on analysis than is declared, the retailer can, of course, be punished. Most heartily do we commend this movement to the support of planters and merchants. We have always thought it a reproach that the agitation commenced by Mr. Leake was not continued by his successors in the Association. Surely public men in Ceylon do not require to be told that here, as in the old country, if a grievance of long-standing is to be redressed, the efficacious mode of action is that which has been made memorable in Anti-Slavery, Reform, Free Trade, and so many more legislative victories, namely Agitate, AGITATE, AGITATE!

* It was expressly stated that duty is paid on the date stones.—ED.

THE INDIA-RUBBER ENTERPRISE.

Very great confidence is expressed in the future of the Ceylon Rubber enterprise. Not only does the growth of plants exceed all expectation, but the resulting produce is almost certain to be valuable if one may judge by what is said of rubber taken from other trees either indigenous or introduced years ago into Ceylon. We learn that a sample of rubber taken from a "Ficus" in the Matale district and sent to a London broker has been reported on most favourably as very suitable for commercial purposes, and worth 2s 3d per lb. All reports seem to agree that the demand is practically inexhaustible, provided rubber could be supplied a little more cheaply than at present, so many are the new as well as existing uses to which this product can be applied in British art, manufacturing and scientific departments.

On the other hand, the profitable nature of the cultivation of rubber trees to the Ceylon planters has been challenged for the following reason. It has been said that Ceará rubber trees to do them justice ought to be planted about 20 feet apart. That would give no more than a hundred trees to the acre; but it is felt that at least 175 trees can safely be planted. The yield of rubber per tree has been calculated at four ounces of marketable produce per tree per annum. This would amount to say 44 lb. of rubber per acre, which, at present prices, might be considered the equivalent of £5 gross. No great fortune to be made out of this amount certainly, even though, as is pointed out, the cost of cultivation and collection must be very small, a mere trifle. No new product, it may be said, leaves so small a margin as this one, if the yield of four ounces per tree is a fair estimate. It is on this point, however, that we require further information.

CEYLON TEA IN AUSTRALIA.

Our morning contemporary and a correspondent of his are rather sanguine in estimating the profit on the sale of Ceylon tea reported from Melbourne by last mail. Fault is found with us for speaking of it as "a poor sale." Of course we were contrasting the minimum 7d per lb. with the minimum of previous sales. Nevertheless, the average for nearly 4,400 lb. being 1s 2½d per lb., we are free to confess the sale was not so poor as we supposed. But it is a mistake to consider that all is profit between the rate at which the tea is delivered in Melbourne and the sale price. What about Melbourne charges? We have heard complaints that the charges on tea by agents "down South" are a caution and enough to run away with most of the profit on sales realizing no more than the one under notice. The rate of commission alone in Australian ports seems to be 7½ per cent against 2½ in London.

We most fully believe in the future of the Tea enterprise in Ceylon. We have said already, and we repeat the statement with the utmost confidence, that we can beat both Northern and Southern India in cheapness of production, while the average quality after further experience in preparation ought to be fully as good. Mr. Hay, of Dolosbage, an old Darjeeling planter, looks on a steady return of 400 lb. per acre per annum of tea as almost certain, and he is confident of placing the produce "f. o. b." in Colombo harbour at a rate nearer to 40 than to 50 cents per lb. There can be no doubt, therefore, that if care is taken to prepare tea suited to the Australian market, Ceylon should secure a full share of the business, and realize an average price for its tea nearer 1s 6d than 1s 2d per lb. The former rate after the deduction of all charges would leave a very handsome profit.

SIR SAMUEL BAKER ON BEES IN CEYLON.

If he has not already seen the book—and we think not—Mr. Benton will be interested in what the great hunter and keen observer, Sir Samuel Baker, has to say, in his "Eight Years in Ceylon," on bees:—

These people (in the eastern jungles,) lived upon sago cakes, pumpkins, wild fruits, and berries, river fish, and wild honey. The latter is very plentiful throughout Ceylon, and the natives are very expert in finding out the nests, by watching the bees in their flight, and following them up. A bee-hunter must be a most keen-sighted fellow, although there is not so much difficulty in the pursuit as may at first appear. No one can mistake the flight of a bee *en route* home, if he has once observed him. He is no longer wandering from flower to flower, in an uncertain course, but he rushes through the air in a straight line for the nest. If the bee-hunter sees one bee thus speeding homewards, he watches the vacant spot in the air, until assured of the direction by the successive appearance of these insects, one following the other nearly every second in their hurried race to the comb. Keeping his eye upon the passing bees, he follows them, until he reaches the tree in which the nest is found.

There are five varieties of bees in Ceylon; these are all honey-makers, except the carpenter bee. This species is entirely unlike a bee in all its habits. It is a bright tinsel-green colour, and the size of a large walnut, but shaped like the humble bees of England. The mouth is armed with a very powerful pair of mandibles, and the tail with a sting even larger and more venomous than that of the hornet. These carpenter bees are exceedingly destructive, as they bore holes in beams and posts, in which they lay their eggs, the larvæ of which, when hatched, feed upon the timber.

The honey bees are of four very distinct varieties, each of which forms its nest on a different principle. The largest and most extensive honey-maker is the 'Bambera.' This is nearly as large as a hornet, and it forms its nest upon the bough of a tree, from which the comb hangs like a Cheshire cheese, being about the same thickness, but five or six inches greater in diameter. The honey of this bee is not so much esteemed as that from the smaller varieties, as the flavour partakes too strongly of the particular flower which the bee has frequented; thus in different seasons the honey varies in flavour, and is sometimes so highly aperient that it must be used with much caution. The wax of the comb is the purest and whitest of any kind produced in Ceylon. So partial are these bees to particular blossoms, that they migrate from place to place at different periods, in quest of flowers which are then in bloom.

This is a very wonderful and inexplicable arrangement of Nature, when it is considered that some flowers, which particularly attract these migrations, only blossom once in '*seven years.*" This is the case at Nuwara Eliya, where the nillho induces such a general rush of this particular bee to the district, that the jungles are swarming with them in every direction, although during the six preceding years hardly a bee of the kind is to be met with.

There are many varieties of the nillho. These vary from a tender dwarf plant to the tall and heavy stem of the common nillho, which is nearly as thick as a man's arm, and about twenty feet high.

The next honey maker is very similar in size and appearance to our hive-bee in England. This variety forms its nest in hollow trees, and in holes in rocks. Another bee, similar in appearance, but not more than half the size, suspends a most delicate comb to the twigs of a tree. This nest is no larger than an orange, but the honey of the two latter varieties is of the finest quality, and quite equal in flavour to the famed 'Miel vert' of the Isle de Bourbon, although it has not the delicate green tint which is so much esteeemd in the latter.

The last of the Ceylon bees is the most tiny, although an equally industrious workman. He is a little smaller than our common house-fly, and he builds his diminutive nest in the hollow of a tree, where the entrauce to his mansion is a hole no larger than would be made by a lady's stiletto.

It would be a natural supposition, that so delicate an insect would produce a honey of corresponding purity, but instead of the expected treasure, we find a thick, black, and rather pungent, but highly aromatic, molasses. The natives having naturally coarse tastes and strong stomachs, admire this honey beyond any other. Many persons are surprised at the trifling exports of wax from Ceylon. In 1853, these amounted to no more than *one ton*.

Cingalese are curious people and do not trouble themselves about exports; they waste or consume all the bees'-wax. While we are contented with the honey, and carefully reject the comb, the native (in some districts) crams his mouth with a large section, and giving it one or two bites, he bolts the luscious morsel and begins another. In this manner immense quantities of this valuable article are annually wasted. Some few of the natives in the poorest villages save a small quantity, to exchange with the travelling Moormen for cotton cloths, &c., and in this manner the trifling amount exported is collected.

During the honey year at Nuwara Eliya, I gave a native permission to hunt bees in my forests, on condition that he should bring me the wax. Of course he stole the greater portion but nevertheless, in a few weeks, he brought me sevety-two ponnds' weight of well-cleaned and perfectly white wax, which he had made up into balls, about the size of an eighteen pound shot. Thus in so short a time one man had collected about the thirtieth part of the annual export from Ceylon; or allowing that he stole at least one half, this would amount to the fifteenth.

MR. BENTON ON BEE-CULTURE.

Of the importance of Bee culture, Mr. Benton has given us a new idea by the fact he learned in Java that wax is imported into Netherlands India, chiefly from Holland, to the annual value of two millions of rupees. The wax is chiefly used in dying the sarongs and other cloths of the people.

We call attention to the following interesting paper by Mr. Benton entitled

A PEEP INTO A BEEHIVE.

Light a piece of rotten wood or a roll of cotton rags and blow a few whiffs of smoke among the bees, then rap several times on the outside of the hive with a light stick and wait a few minutes for the bees to fill themselves with honey. A very little smoke will alarm the bees and with the drumming cause them to fill their sacs with honey. *When gorged with honey or liquid sweets, bees will not stiug unless forced to do so.* Some poor chap may have failed in getting sweetened up, so, on opening the hive, the cluster may be sprinkled with sweetened water. This they consider a great treat and by the time they have disposed of it are as harmless as so many flies. The buzzing which they make shows that they are as good natured as a compauy of fat aldermen just after dispatching a roast turkey at some friend's house. The combs may be taken out and haudled just as yon please, and the bees brushed and scooped about with little danger.

Three classes will be fonud to constitute a properous colony of bees during the summer season: A sertile queen, a few hundred droues and about twenty for thirty thousand workers.

The queen is the ouly fully developed femalc in the hive. The supervision of the hive and the laying of eggs is her office. She lays duriug the summer season from two tothree thousand eggs each day. A fertilc queen is about three-fourths of an inch long, has short wings, a slim, finely tapered body, and in the common bees, is a deeper black in color than the workers. The Italian queen has no yellow bands crossing the body, but is of a golden yellow color. The cells in which queens are produced are conical in shape and resemble a peanut in appearance. They usually project downward from the edges of the combs. About sixteen days elapse from the time the egg is laid until it comes forth a perfect queen. Five days after hatching, if pleasant, the queen flies out to meet a drone and pair. Aftcr pairing she returns to the hive and rarely leaves it during her life unless she is accompanied by a "first swarm." She lives four or five years but is not usually very valuable after her third year. If the queen be taken from a colony during the working season, the bees are thrown into great confusion, but they soou construct queen cells, place an egg or a larva in each, supply it with royal jelly, (the food for the queen larvæ) and thus cause it to be developed iuto a queen. Upon this one natural principle depend all of the various methods of increasing colonies by dividing them into parts and allowing each part to form a separate colony.

The droue bee is stouter aud larger thau either the queen or worker and similar to the queen in color. They appear in April or May and usually disappear during August. They have no sac within their bodies for carrying honey, no pollen-baskets on their legs and are provided with a stiug, consequently they are unable to assist in the labors of the hive.

The drones are the male bees and appear in the hives about the time young queens are being reared in order to impregnate them. When they have fulfilled this office they are then destroyed by the workers. But one drone is needed to impregnate each queen, but as bees (and nearly all winged insects) pair while on the wing and colonies in a state of nature are isolated, many males are produced that impregnation may be accomplished before the queen, in roaming about, meets with any accident.

Drones are produced in twenty-five days from unimpregnated eggs placed in large sized cells.

The Worker Bees, well known to every one, are undeveloped females having a sac within the body for carrying honey to the hive and baskets on the hinder pair of legs for carrying pollen—the yellow dust of flowers—which they feed to the young. Wax from which comb is built, is secreted by them under the scales of their bodies. It is secreted from honey the same as animals secrete fat from the food they eat. Eighteen or twenty pouuds of honey are required to produce one pound of wax, hence, if honey be taken out and the combs returned to the bees a great saving is made. Propolis or "bee glue" is a substance gathered by the bees from the trunks of trees, and is used in stopping all crevices in the hive and in varnishing the inside surface. About twenty-one days is the time required to produce workers from the eggs. The worker cells are small and when capped do not extend beyond the surface of the comb as do the capped drone cells. During the first two weeks of their existence they work iuside of the hive takiug care of the brood, etc. The workers live about two or three months duriug the honey season and from six to nine months at other times. As they drop off during summer their places are supplied by others, so that a whole colony, with the exception of the queen, is changed several times in a season. This is shown by substituting for a black queeu a fertile Italian queen. The young bees produced will have the yellow bands and in a short time the whole colony will be entirely changed.

A whole volume might be written about these wonderful little workers.

Ovid, Michigan. F. B.

—*American Paper*,

JAMAICA CINCHONA BARK.

Mr. Morris sends us sheets of the *Jamaica Gazette* containing the account sales of 180 bags of bark from Jamaica sold in London on 30th November 1880, together with a memorandum by himself on the results of the sale. These are summarized as follows:—

Species.	Gross Weight Shipped.	Deductions for Sample, Dust, &c.	Net Weight sold.	Average Prices on all qualities.	Total amount realized.
	lb.	lb.	lb.	£ s. d.	£ s. d.
Crown bark, *C. Officinalis*	7,791	930¾	6,860¼	0 5 6	1,889 17 7
Red bark. *C. Succirubra.*	6,314	801½	5,512½	0 3 1½	886 13 2
Yellow bark. *C. Calisaya?*	292	46	246	0 3 3	40 1 5
Total...	14,397	1,778¼	12,618¾	0 4 5	2,796 12 2

In explanation of the difference in price of this consignment as compared with the former one, the brokers write:—

"The reduction in price upon some of the marks as compared with previous consignments arises from the market having fallen 1s. to 1s. 2d. per pound; and also quinine is now offering at 10s. 6d. to 11s. per ounce, whereas in August last, (when the last consignment was sold,) the price of quinine was from 12s. 8d. to 13s. per ounce."

This bark was all from trees blown down or damaged by the hurricane of August last, and prepared so expeditiously that the whole was ready for shipment within six weeks from that occurrence. Sun heat alone was used for drying, Mr. Morris remarking on the superiority of this to drying in sheds. The qualities and prices of the shipment are shown in detail in the following table:—

Marks and Kinds.	Weight.	Rate per lb.	Amount.	Total Weight.	Total Amount.
Crown Bark,					
C. Officinalis.	lb.	s. d.	£ s. d.	lb.	£ s. d.
No. 2 Root bark	662	7 8	238 8 8		
„ 1 „ „	52½	7 0	18 5 9		
„ 1 Trunk „	790	7 2	283 7 1		
„ 2 „ „	388	5 6	106 14 0		
„ 1 „ „	3,902¾	5 5	1,056 19 10		
„ „ „ „	399¼	5 4	106 9 4		
Twig „ „	542¾	2 4	63 6 5		
Garblings „	163¼	2 0	16 6 6	6,860¼	1,889 17 7
Red Bark, *C. Succirubra.*					
No. 1 Root bark	188½	3 8	34 11 2		
„ 2 „ „	360	3 2	57 0 0		
„ „ „ „	873	3 1	134 11 9

Garblings „	288¼	2 11	42 0 9		
„ „ „	209¾	2 10	29 14 3	5,512½	866 13 2
Yellow bark, *C. Calisaya?*					
No. 1 Root bark	22¼	4 2	4 12 9		
„ 2 „ „	58¾	3 4	9 15 10		
„ 1 Trunk „	58¾	4 5	12 19 6		
„ „ „ „	35¼	4 2	7 8 10		
„ Twig „	71	1 6	5 6 6	246	40 1 5
	...		...	12,618¾	2,796 12 2

The average price for officinalis was 5/6 per lb. and of red bark 3/1½, against 6/7 and 3/11¾ for the previous consignment, but, if the fall in the market be taken into account, it will be seen that the relative prices have been maintained. The average price of the whole consignment was 4/5, being a fall of only 3d on the previous one. Mr. Morris quotes from *Colonies and India* a statement showing that the Jamaica red and crown barks went higher than the Ceylon and Indian, but whereas all the former bark was sold a good proportion of the Ceylon was withdrawn. At the end of his memorandum Mr. Morris states that the bark sent as C. Calisaya, but which Mr. Morris always considered as a hybrid has now been proved to be so, and will in future be sent on its own merits as the produce of the "hybrid variety." It realizes a better price than the red bark, and if it will grow at lower elevations than the crown its cultivation will be extended.

COFFEE MIXTURES AND ADULTERATION

We cannot believe that the Committee of the Chamber of Commerce will persist in refusing to join the Planters' Association in memorializing the home Government on this subject. The question is one which excites a great amount of interest throughout the country and estate proprietors will certainly feel that their Colombo Agents care little about their affairs if they decline to meddle in this matter. A correspondent writes:—

"I cannot but feel that we owe it as a duty, alike to the Government and to the coffee planters, to *show* how the prevalent practice of adulteration and admixture has affected the consumption! We had no such facts to show when previous representations were made. We could then plead the *unfairness* of the practice, and express a belief that the event of an increase of consumption *might* be due to this cause. But *now*, the further development of the evil, and of its formal though qualified legalization, prove clearly to have caused a declension of serious amount when increase ought surely to have taken place. If, then, it be granted that it is *proper* to point out the injurious effects produced by the practice, how could we consistently avoid asking for its prohibition? It seems to me that after pointing out the unfairness of a practice and its injurious consequences, we should simply stultify ourselves if we were *not* to ask for this manifest righting of a wrong! I believe that since the exposure of so much sophistication of tea from China the public mind has been much stirred, and the evil of adulterations generally has become much more fully recognized at home. Apart from the bugbear of *date coffee*, I think this time is opportune for such a representation as that contemplated by the draft memorial. I think we might well hope to get the order in Council amended in so far as necessitating a statement of the *proportions* of such mixtures as bears the title of "coffee mixtures."

CEYLON TEA.

2 Great Tower Street, London, 12th March 1881.

DEAR SIR,—We had a sample submitted to us recently of Ceylon tea the produce of the Sembawattie Estate, Yakdessa, and we are glad to notice a marked improvement in leaf and liquor.

The leaf is desirable, being blackish, fairly twisted and mixed with gold tip; the liquor, although lacking the fulness of some of the fine Darjeeling marks, is brisk and pungent. With care in the manufacture we believe this could be obtained, and the result would be a really valuable tea.—Yours faithfully,

GEO. WHITE & Co.

THE WAY TO CATCH COCKCHAFERS at night, according to Mr. H. Wright, is to hang a common estate lantern in a good-sized tin, at the bottom of which is a sufficient quantity of kerosine oil to kill the beetles, which, attracted by the light reflected from the tin, will precipitate themselves into the trap.

Correspondence.

To the Editor of the Ceylon Observer.

LIBERIAN COFFEE PLANTS.

7th April 1881.

DEAR SIR,—A very interesting article appeared in one of your issues regarding the use of seed from trees the flowers of which have been *self-fertilized*. It is pretty evident that leaf disease does not arise from any peculiar weakness of the coffee tree, but in independent of the injury and loss from the effects of leaf disease, the coffee tree has been allowed to degenerate, and this is probably one cause for young estates, in even choice virgin soils, yielding so poorly as compared with young clearings of olden times. It was a very common practice as soon as one estate was opened to plant out the next estate or clearing with plants grown from seed gathered from the maiden crop! It will be as well for those growing Liberian coffee to see that their plants are from trees a few years old—or still better grown from *imported* seed. In the face of all known rules and principles of planting and for the sake perhaps of a few rupees saved, a very bad practice is at the outset carried on and evil results must follow.

The rapidity with which plants from seed picked ripe and put into nurseries a few days after, is no proof that they are first chop. If the seeds are allowed to get partially dry and then put out, they will come up not "like beans," a thing most undesirable, but gently and with a firm appearance. Imported seed, when carefully packed, give a sufficiently fair result, and as plants from seed picked from trees grown on a *foreign* soil should be *treasured*.

AN OLD COVE

GOLD-PROSPECTING IN CEYLON:—TESTS, AND LOCAL EXPERIENCE.

Nuwara Eliya, April 11th, 1881.

DEAR SIR,—If your correspondent "Sore Fingers" will digest the "black sand" in dilute *nitro-muriatic acid*, decant it carefully and add a few drops of a solution of *proto-sulphate of iron*, he will readily ascertain the existence of gold by its being precipitated in a metallic form.

The dilute *nitro-muriatic acid* may be composed of 1 *part muriatic acid*, 2 *parts nitric acid*, 2 *parts water*.

The vessel containing the subject of the experiment should be placed in warm water.

The simplest way, however, is to wash the sand in a small pan with sloping sides and a flat bottom, passing it off gradually with the water, when, if the operation is conducted skilfully, whatever gold there may be will remain in the angle of the pan.

With regard to the "black sand" in question, it is very abundant in this neighbourhood, being found in streams and on and below the surface in every direction. I have hitherto found no gold with it, but this is not a thing to be surprised at, for gold is four or five times heavier than the sand and would naturally seek a much lower depth. If found together it would be owing entirely to some local circumstance, such as a light soil resting on a bed of clay or rock, or in watercourses where some rock or boulder has arrested the course of the stream forming a pool where heavy substances would sink and collect. This sand is—as far as I have been able to determine in the absence of some necessary tests and re-agents which I am awaiting—an oxide of manganese, probably the mineral *Psilomelane*, and may prove to be valuable.

I tested a piece of the supposed gold-bearing quartz from the Hog's Back tunnel the other day, but found no trace of the precious metal. The pyrites seemed only too pure. I may, however, have had a poor specimen to deal with, and I intend trying others which I have by me.—Yours faithfully,

W. FREDK. MAYES.

COFFEE LEAF DISEASE: THE RESULTS OF "VAPORIZATION" IN THE DUMBARA VALLEY.

(*Communicated.*)

The enclosed report will probably interest some of your readers as it introduces an entirely new feature into the results of my experiments.

Leaf disease was at its height in the beginning of January on the field that is here spoken of as well as on the surrounding coffee.

The treatment resulted at the time in a decided check of the spread of the disease, but in my opinion it had gone already too far and the treatment could have scarcely, constitutionally, benefited the trees much. For two months little or no leaf disease was observed but during the last eight days, it has again made its appearance in considerable vigour in that part of Pallekelly Estate; but the treated field is singularly free from it, of which I have satisfied myself personally. I can account for this difference in no other way than by concluding that the treatment did not only check the disease at the time being, but that it was also instrumental in preventing ultimately on the area operated upon, the growth of the various forms of this fungus which has resulted now in a fresh attack on the untreated coffee surrounding.

It will of course be necessary to corroborate the above by results elsewhere before we can fully accept this conclusion. Uredo-spores are now freely produced in the surrounding untreated coffee, and it will be interesting to note whether and in what space of time they will spread and germinate on the treated field.

EUGENE C. SCHROTTKY.

Mr. Vollar, writing to Mr. Schrottky, reports:—"Pallekelly, 9th April: I have much pleasure in stating that on close examination of the field that was treated by your process of 'vaporization,' some three months ago, I find that it compares very favorably with the adjoining untreated coffee. On the latter leaf disease is again showing up, while on the treated area it was difficult to find a leaf diseased."

THE TEA TRADE OF AMERICA.

The following remarks as to the tea trade of America, taken from a San Francisco commercial paper, may be interesting: The tea business of late years, and more particularly in 1880, has been sadly cut up and scattered, as almost every jobbing grocery now imports more or less for their own trade sales. During 1880 the steamers of the Pacific Mail Steamship Company brought us from China and Japan six cargoes, and the O. and O. Steamship Company eight cargoes, and the two combined brought us upwards of 120,000 packages, in addition to a much larger quantity in transit for Eastern cities. The O. and O. Steamship Company also chartered two sailing ships to bring tea for reshipment East by the Central Pacific Railroad. During the summer and fall the retailers formed a co-operative society for the purpose of importing for their own use an uniform brand and standard of teas for their retail city trade; how it will work is yet to be proven.

Although the bulk of the tea consumed in the United States is imported through the port of New York, the facilities offered by the steamers crossing the Pacific to San Francisco have diverted a portion of the traffic in that direction and a considerable part of the direct importations by interior importers have been received by that route. These direct importations naturally diminish the distribution from New York, while they supply a very important part of the consumption of the country, and this fact should not be lost sight of in estimating the trade of the year.—*Home and Colonial Mail.*

THE MANUFACTURE OF INDIAN TEA.

The following memorandum of instructions relative to the operations for season 1881, which, we understand, has been issued by a gentleman of experience for use on some large gardens in India may be useful to some of our readers :—

1. The hoe to be continually used throughout the manufacturing season in scarifying the surface of the land.

2. The spring shoots to be allowed to grow out about nine inches before commencing to pluck the leaves.

3. Plucking to be limited to the leading shoot or bud *and only two leaves* (this must be strictly adhered to), and the leaves or flush should not be allowed more than *eight* days to mature.

4. Withering to be done rather slowly, and avoid exposing the leaves to artificial heat.

5. Rolling to be done in the machine without much pressure, as the leaves will be all young and succulent.

6. Under ordinary conditions it will be unnecessary to allow the leaves to ferment, and they may be spread thinly upon the drying trays at once direct from the rolling machine.

7. The charcoal fires must be strong and brisk, so as to arrest the action of fermentation in the leaf.

8. The colour of the leaves after they have been infused for testing should be similar to that of a new bronze penny piece; this may generally be regulated by increasing or decreasing the fermentation of the leaves after the rolling operation. It is, however, impossible to get the proper bright colour on the infused leaf, unless the plants themselves are in a vigorous condition, and unless the leaves are plucked in a succulent state, say on the eighth day.

9. If the labour force is insufficient to cultivate the whole area under plant, and to remove each flush after it has been allowed eight days to mature, then special "nirricks" in boeing and plucking must be made, and liberal extra payment for the performance of extra work must be made. And if this arrangement should prove to be insufficient, then the worst parts of the plantation had better be abandoned for the time being, so as to enable the labour force to work the remainder in a proper manner.

It is utterly hopeless to expect to realise a profit by making nothing but "common teas," which, no doubt, are produced by want of cultivation, and by taking 12 to 14 days to remove each flush.—*Home & Colonial Mail.*

THE GOLD AND SILVER OF THE WORLD.

A lecture was delivered on Monday night at the London Institute by Mr. G. Phillips Bevan, F.G.S., F.S.S., the subject being the "Gold and Silver Mines of the World." It was replete with interesting facts and figures. Speaking of the early discoveries in the colony of Victoria, he cited Mr. Brough Smyth for the facts that three diggers at Forest Creek obtained in 19 days 360oz. of gold; a party of five cleared 2½lb. in a single day; another of four got 11oz. from sunrise till 3 p. m.; while another of three obtained £1,000 in 14 days. The same authority mentioned that at Ballarat, the head-quarters of the deep mining district in that colony, a party of six got 1,344oz. of gold for ten weeks' work, while in four months another gang earned £24,000. The winnings of 42 Ballarat companies up to the date of Mr. Smyth's writing were no less than £4,305,463, one of them—the Band of Hope—having washed 14,975oz. in 44 working days. Of colossal nuggets the lecturer mentioned the Welcome Stranger, weighing 2,280oz., 21in. long and 10in. thick, a lump of solid gold found by the merest chance, yet worth £9,534; the Welcome Nugget, which weighed 2,217oz., and was sold for £10,000; the Blanche Barkley, 1,743oz. in weight, and sold for £6,905; the Heron, weighing 1,008oz., which fetched £4,080. The Victoria goldfields now covered an area of 1,241 square miles, which in 1879 yielded 715,000oz., valued at £3,000,000. Queensland was traversed by a chain of gold rocks from north to south, and at least 4,000 square miles were being worked with all the experience gained from the failures of the sister colony. The yield for 1879 was over a million sterling. South Australia was more a copper than a gold country, but the goldfields of Port Darwin were being industriously worked by the Chinese. After mentioning South Australia and New Zealand, the present rage for speculation in Indian gold mines was touched on, with a due caution to perplexed investors. The Russian mines in the Ural range were interesting, both as having been probably referred to by Herodotus and as having enabled Murchison to forecast the success of gold mining at the Antipodes. Passing over to the American continent, the lecturer spoke of the gold fields of North Carolina and Virginia, the Californian discoveries and the rich silver mines of Nevada and New Mexico. He gave an elaborate description of the Great Comstock lode, the two mines of which had yielded in 20 years 363,671,605 dols. He spoke further of the immense wealth of the Arizona and Colorado silver mines, as well as of the Bolivian mine long known by the name Potosi, and of those worked in Peru, Chili, and Mexico. The European mines were the last to pass in review. It had been computed, Mr. Bevan said, that the grand total amount of gold produced during the historic ages was £3,517,093,500 and that of silver £2,826,250,000, making for both the precious metals together no less than £6,343,343,500.—*Home and Colonial Mail.*

MR. ANDERSON'S NEW BOOK.

Of coffee in New Caledonia Mr. Anderson thus writes :—"Sugar cane, rice, and coffee plantations are to be met with in various parts of the island. While in Fiji the notion is that the high land, 1,000 and 2,000 feet above sea level, offers the most suitable elevation for coffee planting, it is worth while to bear in mind that in New Caledonia, only a couple of degrees of latitude distant, the bushes are to be noticed on the flat land, and to all appearance thriving." Of coconuts in that island, he states that they are very abundant, but that from lack of a market for copperah, or intelligence, they are left to rot, and are chiefly used as food for pigs. He states the island to be rich in metals, especially nickel. Of the products of Fiji he writes that they are mainly bêche de mer, pearl and turtle shell. There is also sandal wood, but good quality of this is now scarce. Of your staple growth in Fiji, Mr. Anderson remarks:—"Coffee has been grown on sundry islands and seems from all accounts to have thriven at an altitude of 200 feet in a certain locality. It is supposed that on the high ground, 1,000 feet or 2,000 feet above the sea level, it ought to succeed well. After the doleful history of cotton, it would be a pleasure to hear of Fiji becoming a good coffee producing country. To start on a new speculation in a new colony like Fiji needs the pushing determination of men who can meet disappointment or success with a certain amount of equanimity. Before the coffee bushes produce, they are exposed to the vicissitudes of two or three years weather, and they are liable to be considerably damaged by heavy blasts of wind. In New Caledonia there are several coffee plantations on the low-lying land which to all appearances look thriving, but looking well and paying well are not necessarily inseparable conditions. The following is what our author writes relative to coconut planting:—"Many ex-planters and others are planting nuts with the hope of raising coconut palm estates. The trees take four or five years to produce properly. So

that patience is required. After they are in bearing order, there is no reason, should the demand for coconut oil be so great as at present, why the speculation should do otherwise than pay. The nuts ought to be planted at least fourteen feet apart. Roughly speaking 100 trees per acre can be relied upon. Reckoning upon 60 nuts for each tree, per annum, this gives 6,000 nuts per acre: that is about 1 ton of copperah. Many people might say this is below the mark: on the average it is not much so. The price given for copperah by the principal merchants in Levuka varies from £9 to £12 per ton." The estimate of the time for the trees bearing profitably—4 to 5 years—seems to me a mistaken sanguine one. I believe the pioneers of coconut planting in the Jaffna peninsula entertained the same delusive hope, and estimated their profits accordingly; but they were painfully deceived, for it was rare to find a tree attain a paying development under about twenty years, and it was no wonder, therefore, that the original planters of coconut estates in Jaffna lost their all before they derived paying returns from them. Mr. Anderson closes his remarks on the productions of Fiji as follows, and I would recommend his opinion to the authorities of Ceylon as an example:—"Were the future Government of the island to consider that the planters are the mainstay of prosperity—for if not they, who?—and if throwing aside all private hobbies and unbiassed opinions, they were to regard the interest of the planters as the interest of the country, time would not be long in deciding whether or not the isles of Fiji are to be considered as pearls of goodly value." These few extracts will convince your readers how much of interest to them they will find in Mr. Anderson's book which has special relation to their own experience; but, apart from that, the writer's remarks on the ethnology of the South Sea islands would alone fully repay its perusal.—*Our London Cor.*

REMEDY FOR RECENT COLD IN THE HEAD.—Rodolfo Rodolfi recommends, from personal experience, the chewing of two to three dried leaves of *Eucalyptus globulus*, as a soverign remedy for cold in the head and coryza, provided they are recent and not chronic. The effect is said to make itself felt decidedly in about half an hour.—*Pharm. Zeit.*

SOMETHING FOR MR. BENTON.—To-day (Saturday) a swarm of bees took up their abode in an old gin case at No. 4, Park Street. The gin case had been converted into a pigeon house; the pigeons, however, politely retired, and left the bees in undisputed possession. They are of the ordinary size, somewhat smaller, and darker than the ordinary hive bee at home. Whether they will remain and occupy the dove-cot has yet to be seen. At present they are all in and seem contented.—*Cor.*

DATE COFFEE.—There appears to be no end to the inventive genus of some people, and many of them seem to have made a 'dead set' upon coffee. We have had the celebrated pelatos coffee, which was simply baked acorns; more recently date stones have made their appearance in the London market under the title of *date coffee*. Yet another instance comes before us in the shape of "a preparation of fruit," under which name a foreign gentleman has obtained a patent for a preparation "closely resembling Mocha coffee." The fruit of the *Ceratonia Siliqua*, commonly known as carob beans or locust-pods, and vulgarly as Russian figs, is roasted and ground into powder, and is then mixed with a certain proportion of the roasted and ground seeds of *Vicia Sativa, i. e.*, tares. An infusion of this mixture may be use as a beverage, and if it is taken with a large quantity of imagination, it will closely resemble Mocha coffee.—*Planters' Gazette.*

(From April 18 to April 23.)

MANURES FOR COFFEE PLANTATIONS.

An important correction has to be made in our remarks on Mr. A. Ross's experiments with specially prepared artificial manures. Instead of R70 per *ton* being the cost, it should be, as most of our readers will have guessed, R70 per acre; but this is calculating on an application of not less than 1 lb. per tree, or fully half-a-ton per acre. This special manure, therefore, including cost of carriage and of application, is equal to R140 per ton; but, if it adds from 3 to 4 cwt. per acre to the crop ensuring a steady return of 5 and 6 cwt. per acre, Mr. Ross is right in saying that it will pay him well. It is a significant fact that more than one planter and visitor to the young districts have lately remarked to us that wherever coffee has been manured *there* the blossom has set satisfactorily. On one well-known Dikoya property, we believe, the experienced superintendent shews the difference between manured and unmanured coffee in this respect, on the same field. Nevertheless the proprietors who, at this time of day—after two most trying seasons—can face an expenditure of R70 per acre for manure are few and far between. In many cases within our knowledge, the total expenditure on estates which have been kept clean, has been reduced to R50 per acre. In other cases where similar rigid economy might be expected, the outlay has risen to R80, simply because, as the managers say, money so supplied so irregularly, that the labour force became comparatively disorganized, and it became impossible to get work done so exactly and steadily as would otherwise have been the case. This should be a warning to over-zealous agents and bankers: if the funds are to be supplied at all, far better to do so every three or four months, than delay for six, and even eight months, and so add twenty to thirty rupees to the cost of upkeep per acre. As regards manuring, it is evident that everything depends on the fitness of the particular application for the soil operated on. Until careful analyses and experimental stations in every district are established, a great deal of money must be wasted by planters, for it is not everyone who can arrange for analyses and the preparation of special manures on their own account, like the proprietors of Ventnure and Aluwihari.

THE HOT SEASON IN COLOMBO.

The correspondent who addressed us the other day, and his colleague who challenged the accuracy of our article, will be interested in the following return which has been courteously furnished to us from the office of the Surveyor-General:—

Maximum temperature of the air registered from January 1870 to April 23rd 1881.

In 1870	91.0	30th March.
1871	90.0	21st April and 9th May.
1872	90.0	13th and 14th May.
1873	91.0	1st May.
1874	91.5	19th April.
1875	95.0	3rd February.
1876	90.6	22nd April.
1877	94.6	16th February.
1878	93.7	13th April.
1879	90.5	26th January.
1880	90.8	26th and 26th April.
1881	91.2	7th February, 14 and 16th March, and on the 12th.
12	[1099.9	14th and 16th April.

Average—91.66

So that the average maximum temperature at Colombo in the shade is under 92 degrees. This will not seem very much to residents in India, or even Australia; but let them remember that the temperature with us never falls below summer heat, that in fact, the average of maximum and minimum is up to 81°—the highest so far recorded for any station on the world's surface (outside Ceylon); and yet Colombo is an exceptionally healthy city for European residents.

TEA PLANTING IN CEYLON.

We have received a letter from a gentleman on his way to manage a tea estate in Assam, in which he says :—

"I was much struck (in my rapid journeying through Ceylon by rail and short residence on a tea estate) with the capabilities of the island to produce tea, and with the lack of experienced tea planters."

He goes on to say that since seeing Ceylon his views have considerably modified, and he is desirous of procuring a berth at R700 or R800 a month, as a preliminary to investing on his own account. We have advised him to stick to India if he can get such a salary as this: not half that sum being at present procurable in Ceylon, although the prospect before tea planters investing on their own account is, we believe, exceptionally good. It is most satisfactory to learn on all sides how favourably impressed our Indian visitors are with the prospects of Ceylon as a tea-growing country. We travelled down by the Gampola coach this week with a young Assam tea planter, and he fully realized all our advantages in ready means of transport, full supply of labour, healthful climate, as well as suitableness of soil and climate in so many districts. The severe fever and epidemic cholera which carry off so many Assam labourers—each costing the planter a heavy bounty—have no parallels here. A beautifully regular and vigorous field of young tea (from 15 to 20 months old) on Helbodde estate, Pussellawa, attracted the attention of the travellers by coach and justly received commendation; a good deal of the land planted was patana.—The following extracts from the Tea Circular of Messrs. Layton & Co., dated London, 10th March, are deserving the attention of Ceylon as well as Indian tea planters :—

"INDIAN TEA.

"The chief feature is the large increase in the deliveries, it being remarkable that those of China Tea in the same period have fallen off very materially; buyers do not, however, appear to have been influenced in consequence, for while the public sales have continued moderate, and comparatively small, prices of common grades—perhaps in sympathy with China—show a slight decline; the only qualities for which the demand continues unabated are good and fine, these bringing fully former rates.

"Managers of gardens in India will do well to remember in the manufacture and preparation of Tea for the coming season, that although the article has hitherto deservedly —as compared with China leaf—taken root in the trade of this country, it is nevertheless patent that unless the inferior character and "washy" liquors are replaced, by hard pungent flavour, the result and average prices of next season must be again disastrous."

AGRICULTURE IN CYPRUS.—The *Homeward Mail* reports that an agricultural show will be held at Nicosia on Wednesday, Thursday, and Friday, April 27, 28, and 29. Prizes will be given for horses, mules, donkeys, camels, cattle, sheep and goats, pigs, turkeys, geese, ducks, and pigeons. The committee will also award prizes for wheat, barley, caroubs, potatoes, best samples of each vegetables (best basket of these in season), silk (best skeins), cotton (best sample), cheese (best sample), butter (best sample). An exhibition of agricultural machinery is invited, and merit will be awarded according as the funds will allow.

CEYLON AND INDIAN TEA AT THE MELBOURNE EXHIBITION.

By last mail I wrote you about the great sale of Indian tea—the greatest by far ever held in the Australian Colonies, including as it did 200,000 lb. weight—which was to be held at the instance of Messrs. James Henty & Co., on their own account and that of the Calcutta Syndicate. The sale has been held, and although the prices realized were somewhat lower than those obtained at the earlier sales the results are deemed very satisfactory and very favourable for the future of Indian (let us add Ceylon) tea in the Australian markets. Every "line" was sold, although some of the lots included large numbers of heavy packages, and as there were at least fifty purchasers of the teas they are sure to be well distributed. There is one dealer, Mr. Walker of Swanston Street, who sells only Indian and Ceylon teas, and who states that he has a large demand for the latter. Measures are being taken to establish another dealer in Indian teas exclusively in Collins Street, and in due time by such means as these prejudice will be overcome and a taste formed for pure first-class teas which must be gratified. Of course existing tastes have to be consulted, and many of the Darjeeling teas and those from Cachar, Kangra Valley, &c., are, equally with the Ceylon teas, fit for going into consumption on their own merits. Others must be mixed and blended. One of the great difficulties is about price. It is so difficult to get people to understand that a tea which yields 42 to 52 per cent of extract (Mr. Dunn has got the latter result from a Ceylon tea), soluble salts in proportion, is worth much more than a tea which cannot be made to give more than 30 per cent of extract, if so much. Preparatory to the sale, Mr. Moody diffused information as to the merits of Indian teas, including the following testimony from a source which even the most conservative of Melbourne dealers must admit to be valuable because beyond doubt spontaneous and disinterested :—

"THE TEA OF THE FUTURE.

"Under this head the *Anglo-American Grocer* gives the following interesting comments, which bear out, from a trade point of view, nearly all we have said on this subject :—

"Of all the articles of produce which claim the attention of our readers, we believe there are none that have shown the same remarkable expansion in their production, during the last score of years, as Indian tea.

"It will seem but as yesterday, to many of our country friends, when the London tea traveller first showed them a sample of Assam Pekoe. What excitement it produced! How speedily the kettle was boiled, and the new silver-tipped product submitted to the test. And how well it stood that test! Nothing approaching to it in strength had been seen before; little wonder, therefore that fancy prices were asked and easily obtained for it. With the enormous increase in the production—the present season being expected to turn out 45,000,000 lb.—prices have obtained a very reasonable level, and it is now the standing complaint of all Indian tea growers that their teas bring actually less than their relative value when compared with China tea of similar quality.

"It was in 1842 that the attention of the Indian Government was first drawn to the subject of tea cultivation in Assam; and seeing the immense benefit that would naturally result from the encouragement of the industry, they imported experienced cultivators and manipulators of leaf from China, who superintended the early efforts of the Indian tea growers.

"The tea plant grows naturally on the slopes of the Himalayas, and thrives best on a rich soil of decayed vegetation, with a humid atmosphere, and considerable heat. . . . The first ten or fifteen years of Indian

tea-growing produced scarcely a sufficient quantity to bring it commercially into use. But after 1860 it began to be used by appreciative consumers for the purpose of adding strength and flavour to China tea. The prices of the finer sorts ranged them from 4s to 4s 6d per pound, and there seemed to be such a future before tea of such excellence, that tea-growing became the speculation of the time. The next few years showed wretched results. The tea was badly made, and nearly half the crop had become sour when it reached this country. Prices fell to a very low point. Planters saw that they must improve the quality if they were to keep their position; and a steady improvement may be dated from 1870. Several grocers introduced Indian teas into their blends with excellent results; in many instances as much as one-half being Indian tea. We do not propose to offer any advice on the use of Indian teas; our object is rather to mark the steady development of the trade, and let our readers draw their own conclusions. A reference to the Cock returns for the present year shows an increase in the consumption of this tea of nearly six million pounds over last year, which fact alone is sufficient to establish the correctness of the heading of this article. We are informed that in many towns in the north of England and throughout Ireland, Indian tea is retailed alone, without any mixture of China tea whatever. This, no doubt, would be a bold experiment in some places, but if care be taken in the selection of the right sort, no doubt it would succeed.

We venture to think that the best results may be obtained from Cachar and Darjeeling teas mixed together. The Assam growths are almost too strong to drink alone; but every grocer finds, by experience, what suits his customers best, and acts wisely in giving them just what they like, and always alike. *A good plan, we should think, would be to mix three or four sorts of Indian tea together, say one heavy, strong, thick tea, another a brisk, pungent tea, a third of a juicy, full, soft, character, and the fourth, perhaps, a fine, flavoury, Darjeeling or Kangra Valley tea to give a distinctive tone to the blend.* These, of course, are mere suggestions on our part. We do not presume to lay down fixed ideas for carrying out what must in all cases depend on individual tastes; our object is to point out the wonderful popularity of Indian teas, and to suggest to all our readers the advisability of studying their character closely. We feel sure it is bound to be as our heading puts it—"The tea of the future," and the wisest course, therefore, will be for every tea-dealer to join the winning side, and realize in his own trade the truth in the old saying that "Nothing succeeds like success."

The writer in the *American Grocer* has gone wrong only in the statement that it was in 1842 that the attention of the Indian Government was first directed to tea cultivation. It is now certain that long before the era of the "discovery" of the indigenous tea in the jungles of Assam, by the brothers Bruce in 1826, the existence of an Indian tea was known to Indian civilians and others. The utilization of the plant was long hindered by Dr. Wallich's persistent opinion that the true tea was merely a camellia. But its true nature was placed beyond doubt and the attention of Government and individuals devoted to the enterprise much prior to 1842. The details I need not enter on. I may say, however, that he would be reckoned wild who in 1842 had ventured to predict that in less than forty years India would be successfully competing with China in the supply of tea to a great and advancing population in Australia. Ceylon also giving promise of taking her place in the same field.

10

(From April 25 to April 30.)

GOLD AND GEMS IN CEYLON.

We have received from Mr. Auwardt specimens of quartz from his property, Mount Pleasant, near Galle. In these there is no appearance of gold, but a good deal of black mica. In some samples previously furnished, Mr. A. C. Dixon discovered traces of gold. The professional reports of this gentlemen have also been laid before us, and we may extract a few passages to shew his opinion of the prospects of gold reef being found in the Southern Province near Galle. On the 15th December last, Mr Dixon wrote:—

"I have examined the specimens of gold, gems and bag of sand which I received from you on the 9th instant with the following result:—

a. The small nugget was pure gold and weighed over 6 grains.

b. The stones in the paper parcel were fragments of gems such as corundum, sapphire, garnets, tourmaline, zircon, &c.

c. The bag of sand contained fragments of the same mineral as *b*, abounding especially in garnets, I did not find any gold in the sample sent in bag."

On the 27th December after a personal visit, Mr. Dixon was able to say:—

"I saw the man who found the gold and examined the place from which he took it. I requested him to dig more and wash it in my presence, after which I examined the residue. I found no trace of gold in it, but numerous fragments of gems and quartz. I then followed up the ravine to its source with the expectation of finding a quartz reef from which the gold might have come. I found two small reefs crossing the ravine and took specimens from them. These I have examined and find only a sligth trace of gold not in quantity to warrant its working. There is evidence of the occurrence of gems in the vicinity. I saw several which had been taken from the opposite side of the hill, and judging from these they appear to be of as good a quality as the gems at Ratnapura but not so large in size. They were chiefly ruby, sapphire, tourmaline and cat's-eye. I have no doubt larger ones will be found. I spoke to your kangani respecting the quartz reefs and have no doubt that if they were broken into, it would set the matter at rest as to whether gold is to be found there in quantity worth working. From what I saw it did not appear to be so."

Again:—

"I have examined the specimens of quartz sent on the 17th March and find in it slight traces of gold at the rate of a few *grains* per ton. There is other metallic matter in the quartz, viz: iron as a sulphide. I have no doubt from what I saw when there that better samples will be sent you."

So far therefore search at Galle has been unsuccessful, although Mr. Dixon holds out encouragement of persevere in blasting for a reef. We trust Mr. Auwardt's further efforts may be crowned with success.

We learn that the result of Mr. Harvey's hurried visit to the Dolosbage, Matale and Ambagamuwa districts has been to leave matters very much as they were, save that certain out-crops of quartz were pronounced non-auriferous and that of other places an opinion was expressed favorable to investigation. Mr Harvey is a very high authority in the gold-mining world and is naturally, therefore, correspondingly cautious in the expression of his opinion. He was the first, it seems, to inspect and report favourably on the auriferous land belonging to the late firm of Messrs. William Nicol & Co. of Bombay, and his report led to the establishment of the Gleurock and other Gold mining Companies. His inspection of our hill region

was far too hurried to lead to definite practical results. It may, in one sense, be said to be premature, for Mr. Harvey would be the man to call in after some progress was made in the investigation, to give a decisive opinion on the value of quartz, and the nature of a reef. Planters will act quite rightly to make available representative specimens of the quartz which they have reason to suppose to be auriferous; but, as Mr. Harvey pointed out, the proper course in the case of Ceylon where gold has been found in the river beds and nowhere else (to speak of) as yet, would be to pan and wash in the river and follow up so long as gold was found, until at last it disappeared from the washings, and *then* to look right and left and all round for the matrix reef from which the gold had gradually been denuded. Now this is work appertaining to the Government of the country. It is impossible that private individuals can undertake this duty, and we think, therefore, there is good reason for calling on the Lieut-Governor to devote some portion of the surplus revenue from the Pearl Fishery to an investigation which may be fraught with important consequences to the revenue and prosperity of the Colony. It will be remembered that in 1854 an attempt to follow up the Mahaoya and Hingula in the manner described above, was frustrated by the advent of the south-west monsoon. Unfortunately this same rainy season is again close at hand. Mr. Harvey was greatly struck with the advantages presented to the miner in Ceylon in railway and road communication, water power, good climate, &c. He also expressed an interest in the gem-digging operations in the country and hazarded the opinion that much deeper mining both for gems and gold in suitable localities (as recommended by Sir Samuel Baker in the case of Nuwara Eliya), ought to lead to successful results. The bed of an ancient river, or the old bed of an existing river which has shifted its course, would probably be a favourite spot in which to operate for gold.

It must be remembered that Ceylon is one of the oldest geological formations. Geologists speculate on this island having been connected with Madagascar and the Malay Peninsula by land long since submerged. They still regard a belt commencing on the east coast of Africa and across Madagascar, Ceylon, Malay Peninsula and Borneo as the most likely division in which to find the remains of the earliest human beings or of the most advanced apes, on the earth's surface. Denudation of the rocks and reefs has therefore been going on in Ceylon far longer than in most countries, and the fact that very valuable gems and evidences of gold have been found so near the surface affords good reason for anticipating greater success from deeper mining.

Since writing the above we have seen Mr. A. C. Dixon on his return from the Rakwana district. The Rangwelleteane limestone with its supposed 90 per cent of lime is a delusion. The limestone Mr. Dixon saw is poor. Gem pits exist on Everton estate to the depth of forty yards, and Mr. Dixon saw finer stones—sapphires chiefly—than any he had previously seen in the island. Two or three were valued by the Chetty owner at over £200 a piece; but Mr. Dixon fully agrees that the proper localities have probably not yet been explored for the best gems, and he is likely to recommend a trial shaft in an old river bed.

CEYLON COCOA.

Our London political and commercial correspondents call attention to the fact of parcels of cocoa from Ceylon selling for 100s per cwt., an exceptionally high price, considering the state of the market at present. Mr. Tytler is to be congratulated on this result, since this cocoa came from his Dumbara properties. It is evident that Ceylon will beat the West Indies in the quality of its cocoa, provided care is exercised in the preparation. Since writing the above we have been favoured with the following letter from Messrs. Sabonadière & Co., who are agents for Ambecotta plantation, proprietors Messrs. Tytler and Heirs of T. C. Morton, while Pallekelly belong to Mr. Tytler alone (Messrs. J. M. Robertson & Co., Agents) realized the same price for its cocoa:—

To the Editor of the Ceylon Observer.

DEAR SIR,—We have much pleasure in handing you copy of sale prices and Broker's report on *Amba* cocoa per S. S. "Duke of Buckingham," shipped on this occasion by us in January last—details of *Palli* cocoa per S. S. "Almora," (shipped by Messrs. J. M. Robertson & Co.) belonging to same proprietors are also given. In forwarding us the report and result of sale, our London friends remark that, "The rates "obtained surprised the market—the highest valua- "tions before the sale being 80s. to 85s."

Yours faithfully,
p. p. SABONADIERE & Co.,
FREDK. NOONE.

Valuations and Prices of Cocoa
PER S. S. "DUKE OF BUCKINGHAM."

						in bond
Amba, A	15	Bags	valued @ 80/ to 85/	sold @		100/6
Do. B	5	,,	,, 70 —	,,	,,	80/
Do. T	1	,,	Chips and Triage	,,	,,	25/
	21	Bags Cocoa.				

PER "ALMORA."

Palli, 1	32	Bags valued @ 80/ 85/	20 Bgs. sld. @		100/
			12 ,,	,,	100/6
Do. 2	15	,, ,, @ 70 75	sold @		100/
T	3	Triage	... ,,	,,	60/
T	1	and chips	... ,,	,,	25/
	51	Bags Cocoa.			

Report on the above.—The sale of your cocoa per steamers "Almora," and "Duke of Buckingham" must be considered most satisfactory. The price of 100/ 100/6 for the bulk is quite a fancy one, and we must again remind you that if this cocoa comes in quantity, it is highly improbable that such sales can be maintained. There is little fault to be found with the cocoa itself; we think it rather better than last year's shipments: there being fewer unripe or pale berries.

The rose color of the bean itself is considered very good, whilst the light, fragile husk is much liked.

The price is the best proof how much the cocoa is liked.

True copy.
p.p. S. & Co.,
F. N.

GEMS AND LIMESTONE IN THE RAKWANA DISTRICT.

We learn from Mr. Shand, senior, that the Rangwelletenne limestone so well reported on by Mr. Hughes was found in the shape of boulders in the river, and that Mr. Dixon could not find any of similar quality for the good reason that all the best boulders had been collected and used up for estate purposes. There exists, however, a small bed of limestone not far away which runs through native property, and which, had the Superintendent of Rangwelletenne (Mr. G. D. Brabazon) not been absent from the district, he could readily have pointed out to Mr. Dixon. Altogether it is a pity that the geologist's visit to the district was not made known to proprietors generally beforehand. His attention

could have been directed to what is supposed to be the richest gemming land in the district, near the Everton ridge, and also on Batakande from which, last year, it is said, £9,000 of precious stones were sold, all taken from an area not exceeding 2½ acres! The old Everton pits which were sunk to a depth of 120 feet had to be abandoned by C. M. Hassana Marikar, because he had no means of pumping out an accumulation of water. It is very evident that there is room with modern appliances and adequate capital for a Limited Company to develop a very profitable Gem-digging industry in the Sabaragamuwa district.

CEARA RUBBER:—NO SEED TO BE GOT FROM SOUTH AMERICA.

A Colombo merchant writes:—"The following in reply to enquiries for Ceará rubber seed may be of interest:—'The last mail from South America brought news to the effect that drought had killed the plants for 150 miles, and that they have now to push many miles up the river to secure seed. None is expected in London for some time.'"

CINCHONA BARK SALES.

The sales of Indian bark reported by last mail, being the large quantities shipped by the S.S. "Eldorado" and "Kaiser-i-Kind," are regarded as most satisfactory, and a happy omen of what the future has in store for Ceylon and Indian planters. For the first time, the brokers report that the quantity of bark offered from the East was large enough to test the market, and the result was that nearly all the 2,400 packages were sold readily for prices reaching up to 10s 3d per lb. for "renewed crown"; while, out of 3,250 packages of South American offered simultaneously, only 600 found purchasers. The sale of the parcel by the "Kaiser-i-Hind" more especially calls for remark: it was as follows:—

	Bales.		Prices.
NCC natural crown	20	...	5s 0d
Branch crown	13	...	1s 11d
Mossed crown	6	...	7s 0d
Renewed crown	22	...	10s 3d
Natural succirubra	41	...	4s 0d
Branch succirubra	13	...	2s 6d
Mossed succirubra	8	...	5s 0d
Renewed succirubra	46	...	7s 0d to 7s 2d.

Upon this Messrs. Rucker & Bencraft remark;—

We particularly attract the attention of our friends to the sale of this latter parcel. Here we have not single packages, but important piles of natural crown at 5s, renewed crown at 10s 3d, natural succirubra at 4s and renewed succirubra at 7s to 7s 2d.

Prices, in face of the heavy supplies, were lower. It has undoubtedly been to the advantage so far of East Indian importers to sell practically to the highest bidder without reserve. But when such a heavy amount is put forward as at this sale, it becomes questionable whether the market is always capable of absorbing the whole quantity at full market rates, and it will be for the future to prove whether it is possible to continue the policy of immediate sale to highest bidder, when our East Indian friends are contributing no longer a few hundred packages per month, but instead as many thousands. We do not know anything about the analyses of this large shipment of bark, but it is generally questioned whether better prices would not have been obtained if it had been distributed over several sales, or at least had more firmness been shewn in holding it

We trust, however, that as regards the Government Gardens' bark, this is the very last consignment which will be sold to private manufacturers. We have the assurance from Madras that henceforth the bark is to be entirely used for manufacture on account of the Government as in the case of the Sikhim bark, with this difference: that Ootacamund bark is to be sent home to be manufactured in place of being used up on the spot. Our London Correspondent, in correcting the *Economist*'s deliverance on the question raised by Mr. Thomas Dickson, is wrong himself in supposing that the Ceylon Government is as great a sinner as the Indian in this matter. The Hakgala Gardens are of too insignificant proportions to be considered in any sense a rival to the planters, and all the bark harvested there, so far, has been exceedingly trifling. The answers to the questions in the following letter which appears in *Colonies and India* in reply to Mr. Dickson will be readily found in our Handbook:—

THE INDIAN GOVERNMENT EXPORTS OF CINCHONA BARK.

TO THE EDITOR OF "THE COLONIES AND INDIA."

SIR,—With regard to Mr. Dickson's letter I should wish to ask a few questions:

First. The Indian Government having created their plantations and supplied their wants, what objection can be made to their selling the surplus instead of allowing it to be wasted? [It is not the surplus, but *all* the Nilgiris bark that is sold.—ED. C. O.]

Second. Until the cost of introducing chinchona cultivation into India is recouped by the Government, have they not a right to reimburse themselves by the sales complained of? [The outlay has already been recouped.—ED. C. O.]

Third. In case of any emergency, such as an outbreak of fever in any district or the wants of an army in the field, should not the Government continue to extend their plantations, and meanwhile sell their surplus harvest as they are now doing?—I am &c.,

London, March 24. INDICUS.

Mr. Dickson is determined not to let the matter sleep, and it is well to make assurance doubly sure in the case of India, while most certainly the tendency of the Jamaica authorities (under the very energetic auspices of our friend, Mr. D. Morris) to develope a regular Government Cinchona Trading Company should be nipped in the bud. Experimental Gardens by all means; but, when it comes to planting hundreds of acres and to publishing special *Gazettes* with the detailed results of the sales of the Jamaica Government bark in Mincing Lane, it is time the home authorities were questioned on the subject. Mr. Dickson writes to us as follows:—

The Scottish Trust and Loan Company of Ceylon, Limited,
123 Bishopsgate Street, Within, London,
March 25th, 1881.

DEAR MR. FERGUSON,—I have sent you a copy of the *Colonies and India* in which my letter regarding cinchona appears, and also the *Jamaica Government Gazette*, to show you how eager the Colonial Governments, led on by specialists, are to become planters and traders and to copy the Indian Government.

If in cinchona, why not in sugar, tea, or any other produce? Every one interested in Ceylon and India who will give the matter a little consideration, will see the injustice, and one of the highest authorities, Mr. Clements R. Markham, writing to a friend says:—

"I saw the letter about Government cinchona sales,

and quite concur. Government very properly sold barks to repay expenses, and that being done, it has no right to trade; moreover that was not the object in introducing cinchona cultivation into India and Ceylon."

It is simply renewing the old East India Company's trading powers which were taken from them 50 years ago, and on a parallel with our old Government Cinnamon Garden affairs.

Unquestionably we can confine them to the limits I have mentioned, and restrict their trading powers, and I shall use my best endeavours to organize a deputation to some member of Parliament who will espouse our cause, and you and our friends in Ceylon must back us up. No time is to be lost unless we wish to be swamped.—Yours truly,

THOMAS DICKSON, Managing Director.

P.S.—I have stirred up many of the Ceylon houses here, who all agree something should be tried. I have brought the matter before Messrs. Matheson & Co. in hopes of securing the influence of Mr. Hugh Matheson, M. P., and also Sir Jas. Elphinstone.

I asked Sir David Wedderburn, but am sorry I did not succeed. I have just seen Mr. Magniac, M.P., of Messrs. Matheson & Co., who has kindly promised to interest himself in the matter, and is clearly of opinion the India Government have no pretext so long as we can show the plantations are self-supporting.

The statistics he requires are as follows :—

(1) What may be the annual production of the Government Gardens ? [360,000 lb. at Sikhim, all manufactured ; 250,000 lb. Nilgiris, all shipped and sold.—ED. C. O.]

(2) What may be the estimated requirements ? [Of bark by Government to make a febrifuge for the population, it is impossible to say.—ED. C. O.]

(3) Are they extending their plantations ?—[Very little.—ED. C. O.]

(4) Are their gardens still in debt ?—

[No : a source of profit.—ED. C. O]

Can you procure these, and we will then have it brought before Parliament, if not sooner ? [Refer to our Ceylon Handbook and Markham's new book for the latest and most authentic information.—ED. C. O.]

Copy of Letter from Mr. Markham.

"The object of introducing cinchona cultivation into India was to bring the febrifuge within reach of the masses of the people. It was right to sell the bark until all the capital outlay, with interest, had been recovered. This has been done, and the whole of the Government bark ought now to be worked up in India for the use of the people. I consider it a breach of trust, and an act of doubtful legality for the Goverment to continue to sell bark for profit in London Market.

"The Government cinchona plantations were not established for any such purpose. Their objects are to discover the best methods of cultivation and of harvesting to establish the best species to supply plants and seeds, and distribute them widely so as to extend the area of cultivation, and to manufacture very largely, the cheapest form of the febrifuge for the use of the people of India.

"Successive Secretaries of State, Sir Charles Wood, Lord Ripon, and the Duke of Argyll have adopted my views on this subject and impressed them on the Government of India and Madras.

"Certainly any one is entitled to quote my opinion : it is published, and is public property."

Mr. Dickson would do well to ask our late Governor, Sir Wm. Gregory, to interest himself on this question, and, perhaps, to call Lord Kimberley's attention to it. As we have already stated, Mr. Clements Markham is entirely with the planters in their claim. Sir Wm. Gregory's policy in Ceylon was based on the principles Mr. Markham laid down, namely,—Government gardens to supply seed and cuttings and to try experiments, while the cultivation for commercial purposes was left solely in the hands of planters. We feel sure that the House of Commons, if appealed to, would at once decide against the policy of the Madras and Jamaica Governments in growing bark to sell in the Mincing Lane market.

CEYLON COFFEE IN THE HOME MARKET.—An ex-Ceylon colonist writes :—"Your readers will be happy to hear that Ceylon coffee is the only one keeping up its price—some fine bold fetching 114s the other day, while some Jamaica *ditto* my broker shewed me only fetched 53s, which was worth 75s two months ago. In Brazil also there has been a heavy drop."

STRENGTH OF INSECTS.—At a meeting of the Maryland Academy of Sciences recently, Dr. Theobald showed a species of a beetle and gave the following figures : —Weight of beetle, 2 grains ; weight moved by it, 5½ ounces—2.640 grains, or 1.320 times the weight of beetle. A man weighing 150 pounds, endowed with the strength of his insect, should therefore be able to move 198,000 pounds, or nearly 100 tons.—*Madras Mail.*

LACQUERED TIN TEA BOXES.—Mr. C. P. Jones, of Baillie Street, Colombo, has sent for our examination a couple of Harvey Brothers & Tyler's patent portable lacquered tin boxes which have been used to a great extent by shippers of Indian tea. The boxes are imported to Ceylon in pieces, and are then hooked and soldered together. They are made in convenient sizes. The largest of those sent to us will contain 20 lb of tea, and costs R1·65 The smaller tin will contain 12 lb. Suitable representations of tea estates, and the processes of curing and packing tea, are portrayed upon them, giving them a very attractive appearance. We feel sure these will be well received if sent (filled with Ceylon tea) to Australia, as they will be handy for carrriage away from the centres of trade. The difference in cost of these over ordinary packages is equal to ½d. per lb of tea ; but the produce sold in these handy boxes sells for a better price and in fact the price of the box is more than repaid. Further particulars will be found in our advertising columns.

SCINDIA'S Paper Mill has at last been completed under the supervision of Mr. Cowasjee Wookerjee, who selected and brought out from Europe the machinery with all the latest improvements. The mill turned out really excellent paper several hundred yards in length, on the occasion of its first trial, which took place on the 9th instant. Yesterday (Thursday) Scindia, who had not previously been near the mill, held a special durbar in order to inspect the sample rolls of paper, which is here manufactured from karbi and rags and is pronounced to be of a superior texture. His Highness was much pleased to ascertain that the first European industry established in his territory had so far proved a complete success. The mill is to be visited by Scindia in State probably next week. Great praise is due to Mr. Wookerjee for the untiring zeal and energy he has shown in connection with this scheme, from which considerable results may be expected. The mill, indeed, promises to be a great success, especially as skilled European engineers and workmen have been employed to carry on the work.—*Indian Agriculturist.*—[When is a wealthy native like Mr. C. H. De Soyza, or Mr. Sampson Rajapakse, to establish a cotton or paper mill in Ceylon?—Natives carry on both successfully in India.—ED. C. O.]

Correspondence.

To the Editor of the Ceylon Observer.

NEW PRODUCTS IN UVA: CACAO AND LIBERIAN COFFEE ON PATANA-LAND.

Deyenewette, Passara, April 22.

DEAR SIR,—As you have done much to promote the success of new products, and always urged the necessity of railway extension to Uva, you will doubtless be pleased to receive by this post specimens of Liberian coffee and cacao grown on patana soil in Badulla district: the former raised from Polgahawella plants, and the latter from Pallakelly seed, and both three years old.

On some of the Liberian trees are hundreds of berries, and some of the cacao trees gave over forty pods. From some 200 pods gathered all about the size of the sample, an average of twenty-eight seeds was the result, all of which are growing in bambu pots except 300 seeds used by me in the manufacture of chocolate paste. After grinding the seed on a curry-stone and mixing cinnamon, cream, and sugar, it was very good, and only required vanilla to complete both flavour and colour to make the real thing.

It is about time you received another report on the progress of new products in Uva.

Trusting you will receive the twenty-five berries of Liberian and cacao pod in separate packets by this post, I remain, dear sir, yours faithfully,

HENRY COTTAM.

[The cacao pod is a good average specimen weighing 10½ oz., while the Liberian coffee cherries are splendidly healthy and full-sized. It is Mr. Cottam, hard-working persevering planter as he is who ought to have got a free grant of land, and not a capitalist so well able to buy for himself as Mr. M. H. Thomas. Indeed, we shall have a good deal more to say on the subject of this Uva grant, if Mr. Thomas does not voluntarily forego his claim to all but the first 100 acres. The House of Commons should hear of this matter otherwise. Meantime we wish every success to Mr. Cottam as a pioneer with new products.—ED. C. O.]

CACAO CULTIVATION.

Gang Warily Estate, Western Dolosbage.
23rd April 1881.

DEAR SIR,—Some time ago (9th inst.) "New Products" asked a few questions relative to cacao, and as no one has come forward—better late than never—I'll endeavour to answer them.

(1.) Where does it thrive best, in or out of shade? That will a good deal depend upon elevation. Over 2,000 feet I don't think shade necessary; but under that, I certainly think a light shade desirable; and, the lower the elevation, the more shade will probably be required. I find the jak tree answers capitally, and, for a light permanent shade might be planted about a chain (66 feet) apart, which would give ten trees to the acre.

Cacao under shade may take a longer time to arrive at maturity, and bear less fruit; but I believe that under shade the trees will be more lasting and the pods larger and the seeds of a better quality, at the same time yielding enough to pay well. I believe in cacao a good deal as a mixed cultivation; and I find it thrives well, both as plant and tree, under the combined influence of the shade of coffee (ten years old) and jak trees of about the same age. It does no harm to the coffee.

(2.) How many pods per tree are required to the cwt. per acre?

(3.) How many pods per tree, or cwts per acre will pay?

Fifty pods per tree is, I think, a low average and should give 1½ lb. of merchantable cacao. Taking 435 trees to the acre that is nearly 6 cwts. per acre; and this, at prices already obtained for Ceylon cacao, would pay handsomely. Planting and estate cultivation would be less; and merchants, charges &c. would be much the same as coffee. The 3rd and 4th years there would be a small crop, and the 5th and 6th years should more than pay working expenses. The 7th year the estate will be in full bearing. Twenty-five pods per tree should pay its way, one may calculate on crop lasting six months, a consideration, as less coolies would be required, and there would not be the same rush as with coffee.

(4.) What distance apart is considered most suitable? In decent soil, I say, 10 by 10 feet if cacao is grown by itself. This gives 435 trees to the acre.

Your low-country, Western Province, correspondent seems to be in the "dumps" about the cacao, and, I don't wonder very much, if he has planted in an exposed situation and in poorish soil, as I gather from his letter. Cacao requires for its wellbeing (1) good, freeish soil; (2) shelter from steady or gusty winds; (3) suitable elevation, with forcing climate, and good rainfall; (4) shade. To those (like above) who can't grow cacao as an even field I say plant the sheltered good nooks and corners (along with other products) with cacao. One or two hundred trees thus to the acre will always help to keep the pot boiling—the expenses against which will be only curing on the estate, and merchants' charges.

Your Western Province correspondent and others who are much troubled with whiteants should try cacao *stumps*, prepared the same as coffee stumps, but with more care. If the taproot is too long cut off a small bit with a sharp knife, but, do not do so if it can be avoided. It is a good plan to dip the tap root in any solution which is deemed likely to keep away whiteants, and encourage the growth of fresh rootlets. I have tried stumps myself successfully. They take upwards of a month to bud. They should be over six months old, but the proper time can be judged by the ripeness of the bark and thickness of the stem of the plant: the size of an ordinary pencil and thicker.

For plants to put out I recommend that the nursery should be made on poorish land, by which means the roots do not grow beyond control. Shade during weather which requires it with a temporary roof, or thatch, and remove the shade before planting in order to harden the plants, as is the case with cinchona. I find these tough little 'gentry' take to the ground and resist whiteants better than their more handsome and delicate brethren. Remove the plants as carefully as possible with a digging fork, and plant in continuous showery weather—not in a puddle of rain. Alternate sunshine and shower is the desideratum—shade with ferns, or branches which retain their leaves for a long time.

'Lastly, and in conclusion' (the part of the sermon, or lecture, we used to enjoy most) take care of the husks after you remove the seeds, as I note my pigs eat them readily, so they are likely to prove a not-to-be-despised addition to the pig food.

Mr. Tytler was to give us some hints about the *curing* of this interesting new product. I hope he will do so.—Yours truly,

JOHN DRUMMOND.

CINNAMON CULTIVATION IN THE HILL AND LOW DISTRICTS.

Veyangoda, 24th April.

DEAR SIR,—During the last few years planters, owing to the shortness of coffee crops, have given their attention to what is called new products. Amongst other things attention has been turned to cinnamon cultivation. A very great error has

been made in cultivating this product. Plants have been put out singly on one estate in the hill country on which I was resident. The visiting agent, on one of his inspecting visits, suggested a field on which the coffee had gone out, to be planted with cinnamon. I was asked to make enquiries in the low-country as to cost of plants. Clumps of plants were then selling at R30 per thousand; that was considered too high, and my P. D., who was resident on the adjoining estate, during one of his frequent visits to Ambagamuwa, purchased plants at R10 the thousand and planted them out singly, one in each hole. When next I met him, I pointed out to him the great mistake he had made. The plants would, I said, be fit for cutting in about three years Each stock would then put out a couple or so of suckers which in their turn will be fit for cutting in a couple of years. The clumps or bushes will thus be gradually pruned, and it would take ten or twelve years before the cinnamon will pay more than the cost of monthly weeding. My P. D. looked surprised and asked me why I hadn't told him so before. For the simple reason, I answered, that he had not consulted me. I have written so much, as I see from time to time advertisements of cinnamon plants for sale, and as a warning to planters not to put out plants singly. It will never pay, especially as the quality of the cinnamon grown on the hills is inferior and is known as Corle cinnamon. The best use to which such cinnamon can be put is to have it scraped into chips and sold for the extraction of oil. Cinnamon seeds are generally sown in the low country, in beds in which drills are made with the hand, and into which from 10 or 12 to a handful of seed is dropped. The more the seed the larger the clump, the sooner it will pay and the chances of the plants growing, as the outer ones protect the inner ones. It has been said in an old number of your Directory, in an article written evidently by that very able planter who now writes from the "Western Province," that it is next to impossible to make supplies good on our old estates. If the writer of the article in question were to visit the estate under Mr. Drieberg's charge at Ekelle, he would no doubt be agreeably surprised to see acres and acres of supplies flourishing, by Mr. Drieberg sowing his seed in handfuls in drills. Finally it will be impossible for planters up-country to put out plants in clumps, unless from nurseries on the estate, as the cost of carriage of so much soil with the clump will be ruinous.—Truly yours,

B.

INDIA-RUBBER SEED.—The Zanzibar correspondent of the *Times of India* writing on the 5th instant reports:—

On a recent visit to the mainland, Dr. Kirk, who is well-known as an enthusiastic botanist, has obtained specimens and seeds of the true India-rubber plant of the district, which will enable the botanical authorities in England to describe and fix the species. The seeds have been sent to the Indian Government at Calcutta, where the East African plant will be cultivated along with the plants already obtained from Brazil and Central America. As the East African India-rubber grows wild over upwards of 1,000 miles of longitude and extends far inland, no doubt many parts of India will be found suitable for its growth. The India-rubber plant has already been introduced at Madras by Dr. Kirk, who has also supplied the seeds from which plants are now being distributed to our tropical colonies from the Royal Gardens, Kew.

We have received several interesting communications on the subject of Rubber cultivation in Ceylon which will appear in an early issue.

CEYLON AT THE MELBOURNE EXHIBITION.

I have alluded to the vote of thanks accorded by the Pharmaceutical Society for specimens of Dr. Trimen's drugs. A copy of the local organ of this Society has been sent to me, in which you will find the following:—

Donations.—A special vote of thanks was carried to A. M. Ferguson, Esq., the executive commissioner for Ceylon at the International Exhibition; for a valuable collection of drugs, seeds &c., from the Ceylon Court for the society's museum. And also to Mrs. Guille, for the care she took in packing the specimens. Again, the President, in his address, stated:—

"The president of the Board of Pharmacy and himself, as president of the society, had issued a joint circular to the executive commissioners of all the courts at the Melbourne International Exhibition, asking for specimens of chemicals, drugs, &c, for the museum. Already they had received the most courteous responses, and from Mr. A. M. Ferguson, the commissioner for Ceylon, and editor of the *Colombo Observer*, they had received a numerous and valuable collection of dried specimens, arranged by Dr. Trimen, the eminent botanist, which it was intended to carefully preserve, as well as all other specimens with which they might be favoured."

Of course only portions of the specimens were given: the rest will go to Mr. Guillefoyle for his museum, or to other institutions.

Besides Mr. Blackett, Mr. Bosisto, M.P., is a leading member of the Pharmaceutical Society, and in the number of the periodical sent to me I find notices of the interesting exhibits of products of the eucalypti and other native plants which Mr. Bosisto shews in the Exhibition. While some of the eucalypti are of dwarf habit and useless for timber, the blossoms give food to bees so useful in this country. Hives are abundant everywhere, and so is honey. I rather wish than hope for the success of apiculture in Ceylon. We have enough of neither summer nor winter, I fear.*

An extreme contrast to the dwarf eucalypti are the great trees, the *tallest* by far in the world, of Fernshaw and Gippsland. *E amygdalina.* The leaves of *Amygdalina odorata* yield large quantities of essential oil which Mr. Bosisto was the first to introduce both in Australia and Europe, in the hospitals of which it is recognized

"As an antiseptic of great power. A few drops sprinkled on a cloth and suspended in a sick room renders the air refreshing; and for disinfecting and deodorising, a tablespoonful of the Oil added to two or three pounds' weight of sawdust, well mixed and distributed will speedily produce a purifying effect. It is also employed as a valuable Rubefacient in all Rheumatic Affections, as a Basic Odour in aromatising Soaps, and as a Solvent of Resins difficult of solution."

Then there is "Syrupus Rostrati":

"Prepared from the Inspissated Juice of the Red Gum Tree. A delicate mucilaginous astringent, employed in all affections of the mucous membrane, particularly in Diarrhœa and Chronic Dysentery."

But the great source of Bosisto's preparations is *E globulus*, "the blue gum," which is so great a success in South India and Ceylon, as well as in other parts of the world. To Mr. Bosisto it yields an essential oil, the effects of which are thus described:—

"Tonic, Stimulant, and Antiseptic. A small dose promotes appetite; a large one destroys it. In stronger doses of 10 to 20 minims it first accelerates the pulse, produces pleasant general excitement (shown by ir-

* Mr. Benton assures us that the alternate rainy and dry seasons here operate much as winter and summer do in temperate regions.—ED. C. O.

resistible desire for moving about) and a feeling of buoyancy and strength. Intoxicating in very large doses, but, unlike alcohol or opium, the effects are not followed by torpor, but produce a general calmness and soothing sleep. A strong cup of Coffee will at once remove any unpleasantness arising from an over-dose."

Then, from the same tree is obtained "Eucalyptol," thus described :—

"For Inhalation in Bronchial Affection. Quantity employed—From half to one teaspoonful with half a pint of hot water in the Inhaler."

Next comes the "Tincture," tonic, antiperiodic and antiseptic, "Eucalyptene":—

"The Tonic or bitter principle in an amorphous condition; employed in Low fevers in doses of one to three grains."

The "Liquor" is described as

"The Fever and Ague Remedy. Dose—For Ague and Dengue Fever 30 to 60 minims in half a wineglassful of mucilage and water, or glycerine and water, with the occasional addition of two minims of Eucalyptol every two or three hours during the paroxysms of Ague."

This would seem to be a fair substitute for quinine, which, however, it is not likely to supersede. Here, happily, fever of a malarious origin is rare. Next we have an antiseptic, emollient preparation, and then

"Cigarettes of Eucalyptus Globulus. Recommended for Bronchial and Asthmatic Affections, and also for the Disinfecting and Antiseptic Properties. Note.—The Cigarettes are numbered 1 and 2. No. 1 are without Tobacco: No. 2 contain a small quantity, and are recommended for general smokers."

There are two further preparations, thus described :—

"Ol.—Atherosperma moschata ess. The physiological effects of this Oil, in small doses, are Diaphoretic, diuretic and Sedative, and it appears to exert a specific lowering influence upon the heart's action. As a medicine it has been introduced into the Colonial Hospitals, and employed successfully in cases of Heart Disease. Administered in one or two drop doses at intervals of six or eight hours.

"Liquor Atherosperma mosch. Employed in Asthma and all affections of the respiratory organs."

"Dwellers in Ceylon will, therefore, see that the Australian gum trees are valuable for other properties than as quick-growing yielders of good timber.

From the Government of New South Wales I have received copy of an enlarged edition of Baron von Mueller's "Select Extra-Tropical Plants Readily Eligible for Industrial Culture or Naturalization; with Indications of their Native Countries and Some of their Uses." I anticipate reading this volume with the same interest and profit with which I have perused the published "Decades" of the Baron's great work on the Eucalypti. The book just received I can now only glance at, with reference to a few products in which we are specially interested and which can no doubt be grown in the tropical and even the subtropical portions of this wide-spread island-continent, if only cheap labour becomes available. Friends in Ceylon when they take into account the fact that the mean temperature of Melbourne is the same as that of Nuwara Eliya, 75°, will not be surprised to learn that at Berwick, close by, cinchona calisaya had not only grown but flowered "a ready five years ago." We need not fear the competition of this colony, however, and Queensland and Southern and Western Australia which have the proper climate lack the labour. The Baron states of *C. succirubra* that "It has been found hardy in Lower Gippsland and the Westerport district." The Baron adds :—"The best temperature for cinchonas is from 53° to 66° F.; but they mostly will endure in open places a minimum of 32° F.; in the brush scales of the Botanic Gardens of Melbourne, where years ago cinchonas were already raised by the thousand, they have even resisted uninjured a temperature of a few degrees less, wherever the wind had no access, while under such very slight cover the cinchonas withstood also a heat of a few degrees over 100° F."

With cinnamon the Baron seems to have tried no experiment, although he notes that Dr. Hooker found plants at 6,000 feet on the Khasya Hills, while Dr. Thwaites found the true *C. Zeilani um*, BREYN, "even up to 3,000 feet in Ceylon." Coffee, the Baron states, "has been admitted into this list, not without great hesitation, merely not to be passed. The cultivation within extra-tropical boundaries can only with any prospect of success be tried in the warmest and simultaneously moistest regions, frost being detrimental to the coffee plant." With reference to this I may add that coffee plants from Queensland shewn in the Exhibition looked very much "shuck," while specimens of tea plants were generally far more healthy. Queensland shewed even mangoes on several occasions and with "bananas" and pineapples she keeps Melbourne regularly supplied. * In Dunn & Hewett's case in the Exhibition cacao is shewn in every possible shape, and the attempt to represent a tree with blossom and fruit is fairly successful. But what is called a coffee tree is a miserable caricature of what, when healthy and free from fungus and grub, and covered with snow-white blossoms or ruby-red fruits, is a very beautiful object. May we yet see it in its pristine glory in Ceylon The Baron notices the Liberian species of coffee, but, strange to say, takes no notice of the fairly successful experiment to naturalize this plant in Queensland. That will yet be a great and rich colony, with its vast resources of soil and climate. I met Mr. Lukin Gresswell here a few days ago, and was much interested to hear his account of the great transcontinental railway he is engaged in furthering The idea now is that the Queensland section should reach the ocean at Port Parker, about 9 0 miles short of Port Darwin. But *all* these colonies are doing wonders in railway construction, lines of which will speedily connect the coldest regions of Australia with others where tropic heat ever reigns.

Mr. Lukin Gresswell holds that even in tropical Australia white men can labour and live, but this I doubt. The solution of the problem would seem to be Lieut.-Governors with paternally despotic "crown-colony" rule in the tropical latitudes, the lands being cultivated by Indian immigrants. This, and Sir Wm. Jervois's idea of Tasmania as the centre of the great Australian confederation, may yet be realized. But to return to the botanic Baron's book. Of the ubiquitous tea plant, which is said to grow in Japan so far north as 39° (or 32° farther from the equator than Ceylon), where a temperature of 16° F. sometimes exists, it is remarked :—"This evergreen and ornamental bush has proved quite hardy in the low-lands at Melbourne where in exposed positions it endures without any attention our night frosts as well as the free access of scorching summer winds." Again :—"The plant comes into plentiful bearing of its product as early as the Vine and earlier than the Olive. Its culture is surrounded with no difficulties, and it is singularly exempt from disease, if planted in proper localities." The Indian planters believe that they have chosen proper localities, and yet their bushes suffer not only from what the Baron himself calls "the very troublesome tea-bug of Asia, *Helopeltis theivora*," but from red spider and mosquito blight, while in Ceylon small moths do much mischief. The Baron, at the conclusion of his notice of "Camellia Thea," states :—"Seeds of the tea bush are now in many parts of Australia locally to be gathered from plan s distributed by the writer, and for years to come the cultivation

of the tea bush, merely to secure local supplies of fresh seeds, ready to germinate, will in all likelihood prove highly lucrative." This may be true, and the plant may be widely cultivated in gardens and hedges, but we need have no fear of the Australians for generations to come growing the tea they drink. Conditions of soil and climate exist here as well as in America, but cheap and plentiful labour is a *sine quâ non*. Cacao the Baron does not include in his book any more than cardamoms. On the whole, we, in Ceylon, are more likely to be successful in cultivating the eucalypts and acacias of Australia, about which this book gives much valuable information, than our Australian friends are to compete with us in the growth of purely tropical products.

CEYLON COCOA IN MINCING LANE.

Messrs. Rucker & Bencraft report as follows in their Price Current on the parcels of Ceylon cocoa referred to by us yesterday, and which it seems they sold :—

COCOA.—The statistical position is weak; stocks are increasing, and arrivals are heavy. At sale 7,200 bags went flatly, and prices were easier.

Our little parcel of Ceylon marks, Amba and Palli, fetched the fancy prices of 100s to 100s 6d. This cocoa is much liked, it has the true rose colour, and the husks are light and fragile. Stocks are :

1881.	1880.	1879.	1878.	1877.
59,471	26,941	17,737	25,614	26,539 packages.

Rather different are the remarks of Messrs. Wilson Smithett & Co., who are said to be leading authorities on cocoa :—

COCOA.—The auctions this week were again heavy, and importers shewing a disposition to sell a further decline of 1s to 2s was established. A parcel of 72 bags Ceylon realized an extreme price, and one that may prove very misleading to growers, as the quantity required for the special use (these went for coloring chocolate) is very small, and large importations could only rank with other growths, and sell at relative prices, say 70s to 75s per cwt.

But we notice that the same firm acknowledge to an increasing consumption of cocoa in France amounting for the first two months of 1881 to 1,910,028 kilos. against 1,562,523 in 1880 and 1,392,011 in the same period of 1879.

THE (CEYLON) TEA AND CINCHONA PLANTATION COMPANY (LIMITED).

We take the following from the *Home and Colonial Mail* :—

We have received a prospectus of the above project, the capital of which is £100,000 in £1 shares. The purpose for which the Company is formed is stated to be the "purchasing of estates and developing therein the cultivation of tea and cinchona." "It is also proposed to cultivate other valuable articles such as cardamoms, india rubber, cocoa, nutmeg, and vanilla, the soil and climate of the Southern Province of Ceylon being especially suitable for the growth of such products." "To inaugurate the business of the Company, the directors have arranged to purchase and take over certain properties, of about 2,335 acres in extent, in the Southern Province of Ceylon, locally known as Anningkanda and Panilkanda, at an average cost of about £6 5s. per acre." The estates are, the prospectus states, already partly planted with tea, cinchona, and cardamoms, the extension of which will be proceeded with vigorously.

The following contracts have been entered into: 1st. One dated the 25th of March, 1881, between Alexander Brooke, as vendor of the Anningkanda estate, with all the buildings, plants, trees, tools, machinery, and crops growing thereon, and David Baird Lindsay, as purchaser of the same on behalf of the company, and—2nd. One dated the 24th of March, 1881, between Edward Morton Rossiter, Richard Wade Jenkins, and William Charles McEntee, as vendors of the Panilkanda estate, with all the buildings, plants, trees, tools, and machinery, and crops growing thereon, and David Baird Lindsay as purchaser of the same on behalf of the Company.

The purchase money to be paid under these two contracts amounts to the sum of £15,000, of which £9,000 is to be paid in cash and £6,000 in fully paid up shares of the Company.

The directors express their belief that handsome profits will be realised by this venture for the reasons that they do not depend upon any one article of produce alone, and that labour is cheap and abundant in the district in which the Company propose to commence operations.

CYPRIAN BEES.

At the 10th annual convention of the North American Bee-keepers' Society the Rev. O. Clute read, for the author (Mr. F. Benton) a paper on "The Next Progressive Step," from which we take the following as of special interest to the gentlemen in Ceylon who purchased colonies of Cyprian bees from Mr. Benton as well as to others :—

I propose to try to accomplish a portion of the committee's work by presenting for your consideration a statement of the views entertained, after some years of experience with Cyprian bees, by prominent bee-culturists of Europe, so far as the latter have expressed themselves in the apiarian journals of the continent. The authorities I shall quote are such as are known to have had experience in cultivating this race of bees, and whose reputation is too well assured for any to doubt their having used care and having made great efforts to arrive at the truth. In 1868 the first colony of Cyprian bees were received just at the beginning of winter and did not survive until the next season. Another colony was obtained in 1872, and two more in 1874, since when other importations have been made. Apiaries of hundreds of colonies of Cyprians are now in existence in Austria; in Germany there are also large Cyprian apiaries, and the race is attracting much attention in adjoining lands as well as on this side of the water. The opinions expressed by foreign journals are, in the main, very strongly in their favour, and I am fully persuaded that our next progressive step is to introduce their cultivation extensively into this country.

A brief description of the Cyprians may not be amiss to many. The bodies of the bees are strong, slim, and wasp-like, the abdomen being quite pointed. They are to be classed, decidedly, among the yellow races; their whole bodies have generally a more golden or orange color than those of the Italians.

The Cyprian queens are perceptibly smaller than other queen-bees, their bodies being slender, in fact delicate appearing, very tapering, but long. The drones of the Cyprian race are strong, and have long, apparently stretched-out bodies.

In regard to the qualities of the Cyprians, Herr Cori says :—"This race exceeds all those thus far described. The bees commence brood-rearing earlier, have an active disposition, fly when the weather is cool, are extraordinarily prolific, and are diligent in honey-gathering. As regards their disposition to sting it may be said that it is not greater nor less than that of the Italians or of other races." The testimony of this man is well worth considering, for, holding a high position under the Bohemian government, he has for many years devoted a great deal of his time to the elevation of his favorite pursuit—bee-culture, in his native land, and has become re-

cognized in his locality as an authority in such matters. In 1875 he wrote as follows :—

"The Cyprians appear to be no particular friends to drones. At the second revision of my colonies in the spring during the latter part of May. I found in sixty-two colonies no ripe drone brood, and in only a few was any drone brood to be found, while from hives containing bees of other races drones had been flying for eight days. How long it was before my original imported Cyprian queen placed eggs in a drone comb, hung in the middle of the brood-nest ! Rather than comply with my earnest wish she allowed empty combs, usually so odious to the bees, to be placed between the sheets of brood, and yet this colony was very strong, the weather quite favourable, and I fed it more diligently than any of the others. Such a similar occurrence in all of my Cyprian stocks indicate that it is a peculiarity of this race to commence drone-rearing much later than others do. On the other hand, the killing of the drones takes place from two to three weeks later than with our other bees, but the making away with the drones then goes on rapidly. Indeed, we met with individual drones in February in colonies in good order and even those possessing good young queens. I believe, therefore, that I am not mistaken in assuming that a further peculiarity of this race is the wintering of individual drones. I found in none of my Cyprian stocks too great a multitude of drones ; on the contrary, in comparison with other races, there were rather less, than more. In the collecting of honey the Cyprians are very diligent ; they appear to be discreet in the occupation of the ready combs with brood and honey, and only after that to devote themselves with full zeal to the building of new combs. They begin the sealing of honey earlier than do other races of bees."

The best proof that can be adduced to show that the Cyprians have sustained the good reputation early given them by the Count, is found in the fact that from time to time, since the above was written, he has imported more from Cyprus.

One of the well-known and often-quoted bee-raisers of Northern Germany is Herr C. J. H. Gravenhorst, of Brunswick, not a breeder of queens for sale, but an extensive honey-producer, whose sensible articles in the old numbers of the *American Bee Journal*, form quite a fund of information. He says himself, in an article which I translated for the *American Bee Journal*, September 1877 : "After trying various races and concluding that the Italian was the best, I felt not the least inclination to procure and cultivate still another race." However, on the recommendation of some of his apiarian friends, he procured, in 1874, two Cyprian queens, and after three years' experience with the breed reported as follows :—

"The colony with the imported queen was especially diligent, gave a large return, and with the remainder of the stocks, was in good condition for winter. The wintering and development during the next spring left nothing more to be wished for.

"After having carefully observed the Cyprian bee—pure as well as hybrid—I have come to the following conclusions regarding the same :—

"1. The diligence of the Cyprian is at least equal to the Italians ; indeed, as regards economy within the hive, the former have the preference, because they are less inclined to build drone-comb. The same peculiarity is noticeable also with the hybrids.

"2. In their purity they are certainly more beautiful than the handsome Italians. Those who visited my apiary were always much surprised as strong stocks filled with these beautiful bees were opened, and masses of the insects rolled out so peaceably.

"3. When rightly handled, they are neither more nor less inclined to sting than the Italians."

In another place the same writer remarks :—

"It is a well-known fact that the most of the Italian colonies do not winter as well as black bees, and very often suffer by spring dwindling. This is not the case with the Cyprian bee. I have reared in three years many a Cyprian queen (not to sell with a few bees, but for my own use, and to sell in full Cyprian colonies in the spring), and every such colony wintered well, coming out strong in the spring.

"The Cyprian bee will not swarm as much as the Italian, and does not build as much drone-comb as the latter.

"I will not say the Cyprians work better than Italians, but it is certain my Cyprian colonies yielded me every year the greatest honey harvest. As to stings, it may be stated, they used them neither more nor less than the Italians."

Herr Dathe, the author of the very practical *Lehrbuch*, says : "The Cyprians are more inclined to gather honey than to swarm ; however, they are not as gentle as the Italians and are often so cross that they cannot be controlled by means of tobacco-smoke, resembling in this respect the Egyptians."

There seems to be two parties as regards the temperament of the Cyprians. Some say they are quite gentle bees, others that they are very ugly*—being almost unmanageable. This of itself would lead us to think that through some mishap the latter had been handling hybrid bees, which are well known as great hands to sting, and indeed, we find a large number of bee-keepers testifying that it is only when hybridizing has taken place that bees of Cyprian blood are cross.

Herr Guenther, of Gispersleben, Thuringia, is another noted and extensive breeder of Italian bees. who says the Cyprians are very diligent and prolific, but says they are exceedingly cross.

Herr Anton Lorenz writes :—"The Cyprian bee is diligent—where there is a chance to rob ; this proves its diligence, which we do not wish to disparage in the least, but its crossness exceeds all bounds. As some praise its good disposition, while others bring forward its inclination to sting, are we not to conclude that the race is not pure or not of the same sort, whether this be, as Herr Hilbert thinks, because some have Smyrnian blood in them, or because there are two kinds of bees on the Island of Cyprus, one of which is decidedly ugly."

I fully believe our next progressive step is to introduce and commence the dissemination of the beautiful, valuable bees of Cyprus. I have presented you with the views of the prominent apiculturists who have tested these bees on a large scale and for a number of years—some as many as seven years, and you see they are very generally agreed on all points but one, and that the majority report favourably regarding that point, while from our own experience with Italians we can easily understand how such a diversity of opinion might exist when in reality there existed no serious objection to the race of bees.

Perhaps we cannot, as that euthusiastic German, Herr von Natzmer, suggested to his countrymen, "annex Cyprus," yet I think when American bee-culturists fully realize how great is the benefit likely to result from the introduction of this race of bees, they will not be slow in turning to account all practical means at hand to aid in the work.

Lansing, Mich. FRANK BENTON.

NOTES ON LIBERIAN COFFEE : ITS HISTORY AND CULTIVATION (IN JAMAICA).

This is the title of a pamphlet by Mr. D. Morris, published by the Jamaica Government. Its purpose is to give the Jamaica planters the leading information on the subject Mr. Morris acknowledges his indebtedness to the book published by us in 1878. and, in fact, the whole pamphlet is largely composed

of information from that work and from our columns. We quote the following regarding Liberian coffee in Jamaica :—

In 1879, Mr. Jenman reported as follows respecting the Liberian coffee at the Castleton Gardens :—"There is a great demand for this coffee, which the garden is quite unable to meet at present. All attempts which have to my knowledge on the part of private parties to import either plants or seed have proved failures. Another small parcel of seed received some months ago from Kew Gardens, produced between four and five dozen plants. I shall still further extend the plots now in cultivation, that the Gardens may in time be in the position to supply plants in thousands yearly. I am glad to be able to report that the first few trees received have, this year, borne a small crop of fruit, which has recently been gathered and sown. Several applications for the seed have been made, all of which I have felt it my duty not to comply with. Ample means exist here for raising it successfully, such as private persons do not possess ; and, without question, it is to the interest of the colony that precautions should be taken to ensure a minimum of loss with the seed produced for the first few years. From the quantity given the first season it would be impossible to form even an approximate estimate of the ultimate yield of the tree ; nor, as its character under cultivation is as yet unknown to us by actual experience, could its merits compare with the common species be judged thereby. However, taking the circumstances connected with these particular trees into consideration, the yield appeared quite satisfactory. No record was obtained of the quantity produced by any or all the trees, as the berries were picked one by one as they ripened, to avoid the risk of loss by rats. Taking equal numbers of average fruit of the two species grown side by side on the same ground, the relative weight of the Liberian was as eight to three of the Arabian." The further progress of the Liberian coffee plants, at Castleton, is given in the following interesting remarks by Mr. Syme in his report for 1879-80:—

"LIBERIAN COFFEE.—Thirty plants of this species growing on the rather steep slope of the ravine above the aquatic tank are now from 4 to 10 feet in height, and bore this year a large crop of cherries. Over 7,000 plants have been raised from them. The parent plants were in flower when the hurricane swept over them thus blasting all hopes of a crop of cherries in 1880-81. Of the 31 plants put out in the old canefield by Mr. Jenman in April, 1879, five were uprooted by the storm. The others are now—say at twenty months old—from 3 to 5 feet in height with stout stems and fine bushy heads and in the best of health. Two or three produced a few flowers last August. This plantation has been extended during the year by an additional 86 plants, and the ground carefully cultivated—all have done well. No nurseries were planted with them, and they have had no protection from the sun or wind other than what was afforded by the adjacent hills and the bamboos growing by the river side. By thus planting in the open we may expect to have fruit from them at a comparatively early age. But for those who would plant this species extensively for profit it is advisable that the plants have both shelter and partial shade. Nevertheless, I am of opinion that on suitable soil with an annual rainfall of not less than ninety inches this species may be successfully cultivated without any special shelter from cutting winds of shade from the sun ; and that it will be equally well or perhaps better, the soil being suitable, if provided with shelter and partial shade in localities with an annual rainfall of not less than seventy inchcs. Thus there are large tracts of coast land in the Island that are well suited for the successful cultivation of this tree-coffee."

Hitherto, the number of plants placed under favourable conditions in Jamaica, have been too few to allow of an estimate being formed of the approximate yield per acre. The plants now at the Castleton Gardens were kept for two seasons in the uncongenial temperature of the Cinchona Plantation (5,000 feet,) but after removal to Castleton (600 feet,) they have made satisfactory and rapid progress. Recently they were described as "beautiful and much admired objects in their dress of stately dark green foliage, laden with the pure white bloom among which appeared the ruddy fruit from the previous year." During the year 1879-80 some seven thousand seedlings were raised from the produce of these trees, and the cultivation is being rapidly extended, both at Castleton and at the old Botanic garden at Bath. Another peculiarity of Liberian Coffee is dwelt upon which if found generally applicable to it, will greatly increase its value. The tree is mentioned as possessing the habit of sending its "strong tap-root far into the ground" and this characteristic is believed "will enable the Liberian Coffee to live and bear fruit in seasons of protracted drought, which prevent the setting of blossom on the ordinary coffee at low elevations."

We may naturally look forward to the quality of Liberian Coffee being greatly improved under cultivation both in the East and the West Indies ; but taking the opinion expressed above and assuming that Liberian Coffee will sell generally at 90s. per cwt., this does not, necessarily, involve a lower return for the capital and attention devoted to it. From its adaptability to cultivation in the plains, from its more robust and prolific character, and from the generally more economic treatment to which it is amenable, it is quite possible that its cultivation will prove even more remunerative than the high-priced varieties of Arabian Coffee.

THE EVIL WROUGHT BY THE PHYLLOXERA IN FRANCE AND THE REMEDY.

(*Pall Mall Gazette.*)

While nations during the last few years have been occupied in flying at each other's throats and doing their utmost to decimate their neighbonrs, a silent enemy has been making terrible havoc in France and other countries, causing to the former State nearly as great a money loss as that entailed by a tolerably long war. The name of this enemy, all the more deadly because it is so small as to be nearly invisible, is the phylloxera, and the mischief that has been inflicted by it on French interests may be estimated by the fact that in 1880 alone 92,000 acres of vineyards were utterly destroyed, and that the yield of wine and brandy, which was 83,836,000 hectolitres in 1875, was last year only 29,677,000. If we take one of the most productive wine departments in France —namely, that of Gard—we find that in 1865 there were 261,027 acres of vineyards, but that of these the phylloxera has absolutely destroyed 244,485, so that Gard now only possesses of her staple crop but 16,542 acres. The yield of wine has fallen away from 2,445,000 hectolitres to 139,640 in 1879, although a slight improvement was manifested last year. This means simple ruin to a large portion of the department, and a most serious loss to the whole State : while the numerous drinkers of claret, champagne, and brandy in this country are feeling their share of the loss not only in the scarcity of the articles, and the consequent rise in price, but also in the deterioration of the liquors, which is very marked in the case of the spirits. Nor is France the only victim, for wherever vineyards exist, as in Germany, Italy, Spain, Austria, Hungary, and even in Australia, we hear of this destructive little pest, defying all attempts at extermination, and driving the vineyard proprietors to the verge of insanity.

The magnitude of the evil may be measured by the magnitude of the reward offered by the French Go-

vernment—300,000 francs—to any person who shall discover a radical remedy. Chemists and savants have been active enough in devising nostrums, but the reward has not yet been claimed, although, collectively, several of the experiments have afforded partial relief in certain districts. The mischief of the phylloxera is that it seems to be wholly unaffected by changes of temperature : no summer, however hot, no winter, however cold, appearing to have any effect upon it. Indeed, one experimenter has gone so far as to enclose specimens in glass tubes and plunge them for a lengthened period into freezing mixtures, and yet the phylloxera has emerged triumphant and unharmed. Another of its peculiarities is, that it is preserved from the attacks of birds and insect-feeders by being able to burrow deeply into the roots of the vines, so that practically it has very few natural enemies to contend with. The treatment to which it has the most decided objection is that of immersion in water, and the flooding of vineyards has in consequence been in some districts the most efficacious remedy yet discovered. It is an easy one, when the character of the ground and the proximity of a river allow of its being applied ; but so many vineyards are situated on the steep slopes of hills, to which the water could not be brought except by a costly system of pumping and canals, that it would be practically useless in the great majority of cases. Of artificial remedies, the most efficacious appears to be the sulphur carbons, which kill the phylloxera more speedily than anything else. But, whether from the trouble or the expense, vineyard proprietors have been rather backward in using it, although every facility has been offered by the Paris and Lyons Railway Company to supply it at 45 f. per 100 kilogrammes, together with an injector, specially made for the purpose, at 40f. M. Dejardin, secretary to the Gard Phylloxera Commission, states that according to his experience the sulphur carbons do not answer alike in all soils, but only in those which, being very light, allow the vapour to thoroughly permeate every grain. The most radical treatment is, doubtless, the entire destruction of the vine and its replacement by American stocks. This seems rather paradoxical as it is from America that the phylloxera has been imported ; but notwithstanding this fact, the American vines are not injured by it. This is due probably to their comparatively new and robust growth, while the French vines, owing to their being a good deal worn out, or perhaps to some peculiar internal weakness, have fallen an easy prey. The latter supposition is the more likely, seeing that the phylloxera has been very destructive at Geelong in Australia, where the vines have not attained any great age. M. Girard, formerly president of the Entomological Society of France, does not share M. Dejardin's enthusiasm over the introduction of American vines, on the ground that enough is not yet known about their "idiosyncrasies," and that in all probability an entire change in culture will be necessitated, with a possible change in the quality of the wine. As a considerable acreage in Gard has been replanted with American stocks, whatever may be the ultimate result, a comparatively short period will enable the vine-growers to see how far the scourge will be kept at arm's length.

PERUVIAN BARK.

A popular account of the introduction of chinchona cultivation into British India. By Clements R. Markham, C.B., F.R.S. London : John Murray.

In this volume Commander [*sic*] Markham has supplemented the narrative previously published of the travels undertaken by him in connection with the enterprise of introducing the cultivation of Peruvian bark trees into British India and Ceylon, and has presented in a concise form a complete history of the undertaking, from its commencement in 1860 down to the present year. Although specially interesting to medical men and botanists, the author, writing in a popular style has rendered the work attractive to the general reader, and has placed before the public an amount of information in regard to the cultivation of the chinchona trees of South America, and of the manufacture of the inestimable alkaloid drug extracted from them, which will be recognised as being of a most valuable kind. The use of quinine and the relative alkaloids extracted from the cinchona tree has now become so indispensable, and has proved of such incalculable value in warm countries where fever abounds, that on this account alone a history of the enterprise by which its benefits have been secured ought to prove of great interest. We are informed that there are now 847 acres under cinchona cultivation in the Government plantations on the Nilgiri Hills, besides 4,000 acres of private plantations on the Nilgiris in Wynaad, Coorg, and other hill districts of Southern India. In British Sikkim the Government cinchona plantations now cover an area of 224 acres. The annual bark crop from Government plantations of Southern India alone is 490,000 lb. In Ceylon 5,578 acres were under cinchona cultivation in 1877. In 1879-80 the quantity of bark sold in the London market from British India and Ceylon was 1,172,000 lb. The East India source of bark supply is now the most important, but one as regards quantity, and by far the most important as regards quality. On the Nilgiris the whole expenditure has been repaid with interest by the sale of bark in the London market, and the Government is now deriving large profits of many thousands a year from the bark harvests. In Sikkim the true object of the undertaking has been better understood, and the plantations are utilised for the supply of a cheap and efficacious febrifuge to the people of India. In 1879 there were 7,007 lb. of this cheap febrifuge manufactured. Having given these general facts, the author proceeds to relate the history of the discovery of the virtues of Peruvian bark, of its first introduction into Europe, and of the opposition to its use. He then gives some account of the first botanical investigations connected with the cinchona genus, of the early trade and destruction of trees, and of the region of the Andes, where the trees flourish. His next object is to convey to his readers a correct general idea of the characteristics of a true cinchona, of the number of valuable species, and of the nature of the bark and of the febrifuge alkaloids which are extracted from it. Having also described each region of the Andes separately—where the valuable species are found, with some account of their discovery, and related the circumstances connected with the introduction of cinchona trees into Java by the Dutch, Commander Markham concludes with a lengthy description of the arrangements which he set on foot for the accomplishment of a similar object in India. In the course of his narrative the author directs special attention to the inadequate remuneration which his fellow-labourers, Dr. Spence, Mr. Pritchett, Mr. Cross, Mr. Weir, and Mr. Ledger received for their difficult and perilous tasks. He writes :—"They have laboured zealously and most successfully, and their task was one which called for special qualifications. Some have lost health, all have risked life and limb in the service of their country. They have nobly earned the gratitude of the Government and people of India. Cinchona cultivation is now not only self-supporting but remunerative. Recompense would not be paid from revenue provided by the tax-payers of India, but from the profits of work actually done by the very men who are now deprived of their due reward. It is unnecessary that I should give further expression to the indignation I feel at the injustice with which those have been treated who have done an

inestimable service to mankind. If the people of England, anh still more the people of India, are contented that this should be the requital for such service, there is nothing more to be said." The volume, it may be stated, is plentifully illustrated with maps and diagrams.—*Scotsman.*

CINCHONA.

(*From our London Correspondent.*)

The auction this week went off very irregularly, and the prices realized were moderate. There was great interest felt in this sale, because of the large quantity of Indian Government bark arrived by the "Eldorado" and "Kaiser-i-Hind." I give you the result of the sale of this importation, which was principally grown in the Government gardens at Ootacamund :—

TEA IN CEYLON.

A certain tea estate in Ceylon enjoys a reputation among Ceylon folks at home for splendid tea. I am in a position to tell that estate to exercise yet a little more watchfulness while tea is being put up for shipment. This estate has sent to England tea put up in bulk and in 2 lb. tins. The former—of which I have seen several cases—is uniform in appearance, excellent in quality and free from dust The same cannot be said of the 2 lb. tins, for, about a third of the number contained in one box are very much different from the remaining two-thirds. The third is a fine leaf, broken into $\frac{1}{8}$th to $\frac{1}{4}$th inch, very superior in quality, and although the appearance of the leaf is pleasing to the eyes of those skilled in teas it is too small to command its value from the general consumer. The two-thirds fall short of that estate's handsome clean leaf bulk cases, by being poorer in extract, flavour, and very dusty. The fault lies in packing tins of very different qualities into the same box. The retailer selling a sample tin cannot guarantee the others to be the same.—*Aberdeen Cor., April 1st.*

THE "TEA CYCLOPÆDIA."

This, according to the somewhat lengthy title, is "a volume of selections from leading and original articles, correspondence, and papers, regarding matters of permanent interest and value concerning tea and tea science, tea blights, soils, and manures, tea cultivation, buildings and manufacture, miscellaneous tea topics, tea statistics, &c., &c., &c., collected from the last eight volumes of the *Indian Tea Gazette*, and from several other valuable sources, and classified according to subjects, by the editor of the *Indian Tea Gazette*. Illustrated with colored plates on 'blights,' from drawings by S. E. Peal." The synopsis at the beginning states that

This Volume has, for greater convenience to readers, been divided into Parts, with separating half-titles. The first section treats of Tea Science, and the botany and chemical properties of Tea, as well as of the early history of the industry. The second section is devoted to a reproduction of the most valuable papers on, and correspondence and opinions regarding, "Tea Blights and Tea Pests," which have appeared in the pages of the *Tea Gazette* during the last four years, as well as in those of contemporaneous journals. The Third part is devoted to an exhaustive consideration of every point bearing upon Tea Cultivation and Manufacture for the past four years, arranged as nearly as possible under distinctive sub-heads. Part IV contains special reference to the principal Tea Districts of India, with incidental notes on the less important districts, while statistical tables of Indian Tea Cultivation, as far as published to date, are appended. Part V shows the countries, other than China and India, in which Tea Cultivation is now being carried on, or has at any time been attempted. Part VI refers to the discussions which have taken place regarding the opening up of new markets for Indian Tea, and of operations as far

as they have gone at present, or have been projected. Part VII is devoted to miscellaneous subjects of interest connected with Tea and the Tea Industry. Part VIII, the concluding part, contains Tea Reviews, for the past year, and valuable Tea Statistics for the past ten years.

The more important parts are printed in large type, and each column on each page has the subject set forth in capitals, so that the reader has little difficulty in turning up what he wants. A full index at the end completes the usefulness of this volume, which should be in every tea planter's bungalow, in Ceylon as well as in India.

THE JAFFNA TOBACCO TRADE,

Is the trade of Jaffna, whether we consider the extent of a land under tobacco cultivation or the amount of capital employed in it. As a matter of fact tobacco is more largely cultivated in the Northern Province than any other product. Extensive tracts of land are devoted to tobacco cultivation in all parts of the Province. To many in Pachellapallai, Wadamaradchy, Poonaryn and Illeppakadavai it furnishes the only means of livelihood. It is much to be regretted that there is no record of the area under cultivation nor of the quantity gathered in at each season. The Customs reports furnish us only with the quantity that is exported to India, the tobacco, which is converted into cigar or which is sent to the towns in the Island, being not noticed. There is however not the least doubt that the quantity of tobacco which meets the demands of the Island is very large.

In tobacco there is a greater variety than in any other article: but one feature common to the tobacco of the Province and which has been more than once noticed is that it possesses a flavour and strength seldom met with in tobacco cultivated in other parts of the Island. We cannot at present mention the names of all the species known here. The chief of them are *Illeppakadavai*, *Netheavaddai* and *Pokkan*, and these are considered very rich and form a large proportion in the tobacco that is used in the manufacture of cigars. Pokkan is also used for chewing purposes—but from its high price its use in this manner is limited only to the well-to-do classes.

Another circumstance connected with the tobacco trade and not generally known is that the tobacco exported to India is far inferior to that which is utilized for cigars. The tobacco for export is tied into sheaves containing 500 and upwards, rolled into bundles or chippams and sent off. The tobacco exported during 1880 is as follows :

January	...	.	...	cwt.	4,064
February	...	...	...	...	4,820
March	...	...	...	...	4,569
April	...	...	...	...	585
October	...	...	...	...	6,478
November		...	...	...	8,426
December		...	...	...	4,232

The total is cwt 33,174 We have no figures for the quantity drawn to meet the demands in the Island. It is a well known fact that a large supply is generally sent to Colombo, Galle, Kegalla, Gampola, and other places.

An impression exists in certain quarters that the tobacco trade has declined and that it is not so remunerative as it was a few years back. In our inquiries we have not met with a siugle circumstance to confirm it : and all that we have been able to ascertain shews it to be a wrong and unfounded presumption. There are more men engaged in the trade and the cultivatiou of the leaf is more extended now than in any period within our recollection.

In this connectiou it would be unfair not to mention the name of the gentleman who rendered material service towards the extension and development of this trade. We refer to Mr. Charles Morrison now Agent, O. B. C. Kandy. His energy and ability apart, during the time he presided over the affairs of the local Branch of the O B. C. he gave active encouragement to the trade, extended the business of the institution entrusted to him and relieved the traders from the necessity of borrowing money from the unrelenting Chetty who was the only capitalist then known in the land.

It is the opinion of experienced traders that the out-turn for this year will be very small compared with that of last year, the rain in January and February having prevented transplantation. The plants are still young and the crop will not be ready for market for a short time to come. A great disadvantage the tobacco traders suffer from is the stoppage of steam communication. This is a source of loss and incouvenience. The mode now adopted is to send it in sailing vessels to Negapatam and thence to Galle or Colombo by means of steamers.—*Com. Ceylon Patriot.*

COFFEE LEAF DISEASE.

LONDON, April 8, 1881.

I read with much interest Mr. Ward's last public reference to coffee leaf disease, and, I told you, I sent the lecture he read on the subject before the Planters' Association through the medium of a friend to Dr. Cooke. That friend has obligingly forwarded to me Dr. Cooke's remarks upon it, which I am kindly permitted to communicate to you. He writes :—"I have read over the account of Mr. Ward's lecture, but, as there is nothing new in it, nothing additional to his report, it hardly calls for special comment. All I can say is, that I think he is on the right track—that is—practical experiment, and I fancy that I go along with him in what he has said. Of course we must not force his analysis too hard. Most cordially do I endorse his last sentiment, viz.,—destroy every vestige of dead leaf from the surface of the ground, by burning them, and restoring in the *ash* the mineral constituents to the soil, but if all the leaves are carefully taken away, and so much potash &c., abstracted from the soil and not replaced, gradually the soil will grow so poor in the essential mineral constituents of the leaves that vigorous growth will become impossible. If the leaves are studiously picked up and carted away, without compensation to the soil for what is abstracted, the remedy will scarcely be better than the disease." I regret to say that Dr. Cooke's lecture on this subject read before the Linnean Society has not yet been published and I understand that even the author himself has not received a copy of it, so I am not in a position as yet to send you one. The delay by the Linnean Society in issuing copies of important papers like this is one that is strongly and adversely commented upon by all it members. I have not yet heard Dr. Cooke's opinion upon the note published by you relative to the appearance of a fungoid disease upon the coffee estates in New Granada. I am unwilling to tax Dr. Cooke's kindness too far, but I have asked my friend, if he should meet the former, to verbally ask his opinion as to the presumed similarity between it and the *hemileia vastatrix*. I have forwarded copies of your notice of this subject to several friends whose opinion on such a matter may have weight. The professor of botany to the Royal Veterinary college tells me that although there is doubtless an affinity between the two diseases, they appear to him to possess distinctly marked features of divergence. He also told me that he had not seen any future reference to the outbreak since the notice appeared in *Nature* that you quoted. He has also written me

with respect to Mr. Marshall Ward's lecture :—"I myself regarded the final remarks of Mr. Ward as *entirely to the point.* Practical men always look for miracles in remedies, which even scientists cannot produce." Mr. Leake writes me in reply to my query addressed to him on the New Granada subject : —"I know nothing of the new disease, never heard of it before. A green yellow Hemileia with a phosphoric smell must come straight from the old gentleman himself, I should think." Mr. John Brown, of the Uva Coffee Company, writes me: "I can give you no information about leaf disease in New Granada, but am anxious to know how it is progressing. I met a gentleman the other day who had been in conversation with a Brazilian planter, and got from him the assurance that there was no leaf disease in that large opposition shop. If I should hear anything you will be informed." Another gentleman connected largely with coffee, and who has travelled much, tells me in a letter in reply to one I addressed to him : "The disease is doubtless the *Hemileia vastatrix*, and consequently, as they don't manure in those parts, it must, as I have all along maintained, be owing to bad seasons." This is all the information I have as yet been able to collect on this interesting topic. If I should receive Dr. Cooke's opinion respecting it, I shall of course communicate it to you.—*Our London Cor.*

THE INDIAN GOVERNMENT EXPORTS OF CINCHONA BARK.

TO THE EDITOR OF "THE COLONIES AND INDIA."

SIR,—In reply to "Indicus'" letter of the 24th ult., I would state—

First.—The Indian Government created their plantations for the benefit of the masses of the people, and to bring a cheap febrifuge within their reach and the whole of the bark ought now to be worked up in India for the benefit of the people, and, not shipped for sale here for the purpose of showing flourishing accounts. To talk of a surplus of bark with millions of fevered wretches in India too poor to buy it is bitter irony, as the native press will doubtless show. The shipments are wrong morally and are wrong legally. For by everlasting laws the inhabitants of a country have the first claim upon the produce of the soil, and in the present case the produce is raised from their own taxes.

Secondly.—I have it from the highest authority that all the capital outlay with interest has been recovered.

Thirdly.—If the Government wish to be prepared for the emergency mentioned, selling their bark in London is in direct opposition. Better let the trees grow and improve until they are wanted or store their febrifuge until required, if they will not distribute it to the poor ryots; but they need not now fear any emergency, as there cannot be much under fifty thousand acres, containing many millions of Cinchona trees, planted by private enterprise in India and Ceylon.

I am, yours &c.,
THOMAS DICKSON.

123 Bishopsgate Street Withiu, London. April 2.

THE INDIAN GOVERNMENT EXPORTS OF CINCHONA BARK.

TO THE EDITOR OF "THE COLONIES AND INDIA."

SIR,—The question whether or not the Government of India should extend their cinchona plantations and offer the surplus bark in the best market, to the supposed detriment of planters in Ceylon, &c., might perhaps be put in another light than that presented by Mr. Dickson. In the case he puts forward, the planters are said to suffer from competition. But even if the Indian Government withheld from the European market the surplus bark they produce, is it to be supposed that private planters would not suffer from competition elsewhere? Would the Java planters who now produce the finest and most valuable bark in the world cease to extend their plantations? Would the Bolivians who are now *cultivating* the best cinchona trees, and who last year sent into the London market bark which sold at 14s. 6d. per lb., cease to compete against Ceylon? Ceylon can never hope, owing to the nature of its climate, &c., to compete with other districts in the most valuable kind of bark—viz. *Cinchona Ledgeriana.*

The plea of unfair competition is, therefore, childish. Planters must expect competition and be prepared to meet it by cultivating only the most valuable varieties that the climate and soil will permit of.

Secondly.—Any profit accruing to Government from the sale of cinchona by increasing the revenue should decrease the taxation. It therefore becomes a matter of whether a comparatively small number of planters shall make large profits, or whether thousands shall experience a decrease of taxation (other things being equal.)

Thirdly.—Quinine is still sufficiently expensive in this country to prevent the poorest from purchasing it for themselves in case of fever and disease. Competition will tend to remove this evil, and bring quinine more within the reach of the poor both in India and in this country.

Your correspondent "T. D." will find his sixth question answered in Mr. Markham's book on *Peruvian Bark* (1880), p. 440, where it is said :—

"It is true, therefore of the cinchona enterprise that, as a mere commercial speculation, it has paid off the whole outlay, including introduction of the plants, cultivation, and interest, and has become a complete financial success."

And again, "In 1880 the whole capital account had been paid of with interest, and the plantations began to yield a clear annual profit."

Those who complain of competition will do well to seek another market, and bear in mind the suggestion made by a writer in the *Pall Mall Gazette* of September 18, 1880 (quoted by Mr. Markham in his work), that "China will probably be hereafter among the largest and most constant customers for cheap febrifuge alkaloids from British India. From vast tracts of country in China where rice is cultivated fever is never absent. Opium is now employed as the medicine easiest to be had and cheapest. If cinchona alkaloids could come into competition with opium and obtain the preference by their lower price, the immense superiority of cinchona over opium as a febrifuge would produce a revolution in the Chinese consumption of the two drugs. By this process a solution would be found for the dangers and uncertainties of the large opium revenue of India and for the perplexing moral questions connected with it." To the above it might be added, although somewhat apart from the question at issue, that it probably only needs a different mode of preparation for the market to increase the percentage of morphia and decrease that of narcotine in Indian opium, and to thus bring it into competition with the Turkish and Persian opiums, with which the European and American drug market is almost entirely supplied, Indian opium being an almost unknown article on the Continent or in America.

London, April 5. I am, &c.,
CHEMICUS.

[Of course the chemists and home manufacturers will prefer the Nilgiris bark to be sent to the Mincing Lane Market to being utilized on the spot.—ED. C. O.]

INDIA, CROP AND WEATHER REPORT.

For the Week ending 12th April: General Remarks. —The reports disclose no material change since last week. The general health is fair, though small-pox still continues in parts of Northern and Central India

and British Burma, and is also more or less prevalent in places in Bengal and Assam. In the Cachar district of the last-named province cattle disease has again increased. There was more or less rain in parts of British Burma, in Assam, and in many districts of Western and Southern India. Elsewhere the dry weather prevailed for the most part, though there were a few showers here and there. In Bengal and the Central Provinces the harvest has been good, and in other parts of the country, with few exceptions, an average, or in some cases a full, yield has been obtained, or is expected.

Madras.—No rain in Kistna, Chingleput, Tanjore, and Coimbatore; general prospects good.—*Pioneer.*

CULTIVATION OF THE AMERICAN ALOE (AGAVE AMERICANA).

In our last issue we referred to the subject of the cultivation of the Rheea Plant on tea lands as a subsidiary to the tea plant. We mentioned how the fibres obtained from the plant *Boehmeria nivea* possessed qualities unlike those of any other material employed in textile work; the only difficulty that stood in the way of the extensive cultivation of the plant being, that no efficient process nor machine had been discovered suitable for separating, cleaning, and dressing its fibres. This difficulty, however, does not stand in the way of the American Aloe, so information anent the plant and the value of its fibre as an article of commerce will no doubt prove of interest to the readers of this journal.

The species *Agave Americana*, belongs to the genus *Agave*, of the natural order *Amaryllidaceæ*—the Amaryllis family. This plant is really not an *Aloe* at all (the African genus *Aloe* belonging to the Lily family), though very similar in habit to some species of that genus. Although it grows freely all over Northern India, and is now introduced generally throughout the country, it is a Mexican plant. The centre scape rises to the height of 18 or 20 feet, flowers in the rains, while the seed germinates in the capsules before they drop off. It grows in almost any soil, and requires very little care. It is supposed not to arrive at full maturity under one hundred years; but this opinion is an error, as the age at which it arrives at maturity varies, according to circumstances, from 10 to 50 or even 70 years. When it has acquired its full growth, it produces its gigantic flower stem and then perishes. The plant is useful in many ways. By making incisions in its stem a fermented liquor and favourite beverage called by the Mexicans "Pulque" is obtained, from which again an agreeable ardent spirit called "Vino Mercal" is distilled. "Pulque" is said to be a most wholesome drink, and remarkably agreeable when one has overcome the first shock of its rancid odour; it is said, moreover, to be an excellent application for gout and rheumatism. The dried flowering stems are an almost impenetrable thatch; an extract of the leaves is made into balls which will lather water like soap; the fresh leaves themselves, cut into slices, are occasionally given to cattle; the centre of the flowering stem, split longitudinally, is by no means a bad substitute for a razor-strop, owing to minute particles of silica forming one of its constituents; but the most useful part of the plant is the leaf, the fibres of which form a course kind of thread, which are called in England "Pita Flax." The natives make very good common cordage or rope with these fibres. Some samples of the fibre were sent to the Agricultural and Horticultural Society for "an opinion as to whether it could obtain any value as an article of commerce in the Indian or Home markets." Messrs. Cogswell and Robinson report on the samples as follows. —"With reference to the samples herewith alluded to in the foregoing memorandum, I beg to observe that the washed and heckled fibre prepared from the "Agave Americana" or common aloe, is about the best I have seen, being beautifully clean and well freed from the bark or outer skin of the plant, of good colour, there being but a very slight tinge of greenish, which it is impossible to thoroughly eradicate without extra steeping, or the addition of chemicals, to the injury of the fibre; it is of very great length and strength, and a really good commercial commodity, its value to-day (November, 1880) being about eight rupees a bazar maund. The sample unheckled I would value at about one rupee a maund less. The sample of combiugs, generally known as tow, could be used in this country for paper-making only, its value as such being about three rupees a maund; but in England, where spinning machinery can be applied to it, a good yarn might be produced. As a product of shipment thereto it is of greater value than being consumed locally for paper making; for the latter, I am of opinion, it is too good and costly, as jute tow, and such like fibres, are so cheap and plentiful in this market. —*Indian Tea Gazette.*

A PROFITABLE PLANTATION COMPANY

is the Darjeeling Tea and Cinchona Association, Limited, for which we have the report of the Managing Agents (Messrs. Schoene, Kilburn & Co. of Calcutta) to be presented at the fifth Ordinary half-yearly general meeting of the Company, convened for the 20th April 1881. We quote as follows:—

We have the pleasure to lay before you our annual report on the Company's affairs, and audited accounts to the 31st December 1880, shewing a profit on the past year's working of R187,892-13-4.

The estimated crop of bark, has, as we led you to expect in our report for the first half-year, been greatly exceeded, the total shipments of dry bark having reached 353,608 lb.; and although the results obtained cannot but be considered satisfactory, there is to us an element of disappointment in the excessive loss in weight in the drying process, during the past season nearly 4¼ lb. of green bark having been required to produce 1 lb. dry. It must, however, not be lost sight of that this loss in 1879 was below the rate usually expected. The gross average price realized in London for 290,192 lb. was 1s 10½d per lb. and 63,416 lb. still remain unsold.

The outturn of tea amounted to 1,251 lb. which fetched an averge price of Re. 1 and ½ anna per lb.; and the expenditure, under all heads, including the new cultivation and substantial buildings, R114,413-15-4 against an estimate of R97,000. The excess is accounted for by the large outturn of bark.

The result stands as follows:—

Proceeds of bark actually received ...	...194,178 lb.	R1,82,273	13	11
Bark sold but account sales not yet to hand...	96,014 ,,	,, 71,221	6	0
Estimated value of bark still unsold ...	63,416 ,,	,, 47,559	0	0
Excess realized over valuation of previous season's stock		,, 12,584	4	5
Tea and other receipts ...		,, 1,252	8	9
Balance from 1879 ...		,, 1,699	4	7
	Total	...R3,16,590	5	8
Deducting the outlay of ...		... 1,14,413	15	4
The amount at credit of the past year remains as..		...R2,02,176	6	4

Out of this sum you have already received R1,20,000 in ad-interim dividends to the extent of 60 per cent; and we now suggest that a final dividend of 40 per

cent on the paid up capital should be declared, making in all 100 per cent for the year.

The surplus balance of R2,176-6-4, we would propose be carried forward.

For further information we beg to refer you to the Manager's report annexed ; and, we may mention, that with the continued large consumption of bark, we think you may look forward to further satisfactory results.

The estimates for the current season are—

Expenditure	...	...	...	R106,000
Outturn of bark		...	...	300,000 lb.
do tea		...	...	8,000 ,,

From the Manager's Report we have :—

Cinchona Plantation.—From the 30th June, 301,611 lb. of bark have been packed and despatched, which, with 51,051 lb. cut during the first-half of the year, gives a total of 352,662lb., and shews an increase of 2,662 lb. over the revised estimate. At Namring the new clearances of calisaya and hybrid plants are looking exceedingly well. and will, I have no doubt, turn out a success. In nurseries, there are 134,000 plants, of which 50,000 are calisaya : these will be ready to be planted out at the beginning of the next rains, and as they are at present looking very healthy, I think there is every chance of their doing well. In addition to these, 2½ seers of succirubra seed have been placed in frames : this should, under ordinary circumstances, yield a very large number of plants, which in time will be put out 4'×4' on the land immediately under the Gielle tea estate.

Tea Plantation.—The quantity of tea made during the past season did not turn out so much as could have been desired. After the second flush, the bushes were badly blighted by green-fly, which very seriously affected the outturn : only 1,415 lb. of tea were manufactured, which however fetched good prices. About 60 to 70 acres of extensions will be made this year, to the West and South-west of last year's clearances, which will thus give a continuous block of 120 acres of new tea joining on to the 200 acres of tea that was planted three and four years ago. The seed is good hybrid, taken from well-known gardens in the Terai.

Labor.—From the end of October, coolies began to come in, in large numbers from the hills. The two factories of Boomong and Namring, mnstered between 800 and 1,100 coolies daily, during December and January, which is about 250 more than we were able to obtain at this time last year. Many of these are however only cold-weather coolies, who begin leaving about the end of February or beginning of March ; I hope to be able to retain between 500 and 600 coolies during the rains : this will still leave me rather short-handed, as the new clearances will require a very large amount of labor to keep them in anything like proper cultivation, in addition to which, barking has to be carried on during the whole of the rains. I shall do my utmost to keep as many coolies as possible.

SALT AS A FERTILIZER.—My experience in the use of salt leads me to the following conclusions :—It keeps the land cool and moist. It neutralises drought. It exterminates all soil vermin. It prevents potato rot. It glazes and stiffens straw, preventing clinkling and rust. It keeps the ground in such condition that the berry of all kinds of grain fills plumply, however long-continued the hot and dry weather may be.—*Country Paper.* [In a circular, issued in 1871, and also one in September, 1879, we clearly shewed by most conclusive experiments that salt prevented the potato disease. Why is it not used more extensively ? The Land laws, which empirics in the press, and wordy declaimers in chambers of agriculture denounce—do not clash with it. The true reason is—the cultivators are too lazy—indifferent. S. Downes & Co.]

SAWDUST.—The *Building and Engineering Times* point out that in America a very important use has been found for sawdust. By compression it is found to become sufficiently dense and compact to serve all the purposes for which the strongest wood is now required. It would seem impossible to obtain, even with the highest pressure, such cohesion as this ; but it is stated that the blocks of pressed sawdust are capable of standing a pressure of twenty-three tons to the square inch. This opens up quite a new market for sawdust, which has hitherto been a comparatively waste product. A more startling substitute still for planking has been manufactured from straw. It is asserted that the inventor can manufacture timber in any desired length from 12 feet and upward, and to 32 inches in width, at a cost competing with the better grades of pine.—*Overland Mail,* April 1.

WHITE ANT PEST.—Various remedies have been suggested and tried from time to time to check the ravages caused by white ants on tea estates, but none have proved effectual. Constant hoeing, kerosine oil, lime, charcoal have all been tried without avail ; mustard cake is recommended in the Journal of the Agricultural and Horticultural Society of India as a remedy. We are told that.—"Many years ago these insects caused much depredation on plots of sugarcane of foreign kinds in the Society's garden. Various supposed remedies were ineffectually tried, but only one had any real effect, and that was mustard cake. This was applied in the first instance simply as a manure for the cane ; but it had quite unexpectedly the effect of introducing the red ant largely into the plantation, and these completely destroyed their white brethren, so much so indeed that we were not troubled again by the latter."—*Indian Tea Gazette.*

COCA.—At a meeting of the Royal Botanic Society, Regent's Park, held last Saturday, Mr. G. J. Symons, F.R.S., in the chair, the candidates were balloted for and duly elected Fellows of the Society, and the names of nine others read for ballot at the next meeting. Upon the table was exhibited a fine flowering specimen of Erythoxylon coca, the "Coca" of South America, grown in the society's greenhouse. Professor Bentley said that, although in this country little was known of it, in South America its consumption was calculated at 40,000,000lb. per annum, and the natives considered it as much a necessity of life as tobacco in other countries. Marvellous tales were told of the power of the coca leaf in allaying hunger and stimulating and supporting the body in extraordinary exertions, more especially in that of climbing heights and travelling over mountainous districts.—*Home and Colonial Mail.*

DATE COFFEE.—A valued and reliable authority, who is always a long way in advance of the rest of the world, informs me that, as a set off to the Date Coffee Company, a firm of preserved fruit manufacturers intend to astonish us with something more delightful. Naturally, at the great marmalade works of this firm in Spain there are cartloads innumerable of orange pips, which have hitherto been a source of loss and vexation. It has, however, been suggested to these astute traders, by an equally astute Yankee, that they would make excellent "coffee!" The process is extremely simple. The pips are first thoroughly washed in running water, they are then dried for several days beneath the rays of a Spanish sun, and then very carefully roasted. The great difficulty is in the washing, which must on no account be over done ; but if it be properly accomplished, my friend says, the result is a beverage of the most delightful aromatic flavour, rivalling even the best Assam tea. Out of compliment to the inventor, who very appropriately is a vehement advocate of temperance, it will be called after him "Blank's Nectar."—*Home and Colonial Mail.*

(From May 2 to May 7.)

CEARA RUBBER CULTIVATION IN CEYLON.

We give prominence to several interesting and thoroughly practical communications addressed to us on this subject in answer to our remark on the uncertainty of the yield of produce from the fast-growing Ceara rubber in Ceylon. In the first place we have a sceptical planter asking; 'Will the planting of rubber pay?' and he gives au estimate which, if correct, looks very much like a decision in the negative:—

CEARA RUBBER, WILL IT PAY?

To the Editor "Ceylon Observer,"

Western Province, 22nd April 1881.

DEAR SIR,—I should very much like to ask a question through the medium of your valuable columns, and if you will permit me the space I will put it, and a few calculations besides. The question is, that with which I head this letter, viz., Ceará Rubber, Will it pay?

I am quite open to believe that it will, if anybody will be able or good enough to prove statistically that it has, will, and does. I of course mean, as a product *by itself*. I have taken some little trouble to go into figures in the matter, and the conclusion I arrive at is far from satisfactory to my mind, and unless some other calculation can be shewn with a better result, I greatly fear Ceará rubber is not to be the Eldorado that some may fondly anticipate.

We frequently see writers in the "Planting" column, speak of what a wonderful growth *has* been attained by Ceará, but what we want to see is an equally wonderful production of caoutchouc, but for this particular subject nobody will give us so much as a hint, even Dr. Trimeu in his "Notes on Some Trees Yielding India-rubber" only goes so far as to say that "in Ceylon it may be confidently *expected* that they [Ceará, &c.] will become a valuable source of revenue," but there is not one word to shew how this confident expectation will be realized. No doubt, if we had thousands of acres of Ceará growing wild, and had only to pay an occasional visit with a gang of coolies, armed with Mr. Wm. Smith's cinchona scraper, then Ceará would "become a valuable source of revenue," but otherwise I don't quite see it. I estimate as follows for one acre based on the following facts:—

109 trees planted 20 feet × 20 feet = one acre.

Each tree we may *expect* to give ½ a lb.

Vide Dr. Trimen's figures each lb is worth R1·25 in England.

Cost for the first three years will be as follows:—

Estimate for one acre of Ceará Rubber.

Purchase of one acre at upset price plus stamps, &c.	12·00
Felling and burning one acre of chena	12·00
Lining and holing	3·75
Weeding 1 acre for 12 months at 3s per month	18·00
Management	10·00
Purchase of seed and filling the same, 2 cents per seed	2·18
Contingencies 20 % on the above	5·78
Total for the 1st year	63·71

2nd year's expenditure:

Weeding at 2s per acre per month	12·00
Management	10·00
Contingencies 10 % on above	2·20
	24·20

3rd year's expenditure:

The same as 2nd year	24·20

Dr. Account		Current Cr.	
To 1st year's expenditure	63·71	By 1st crop ½ lb per tree = 54 ½ lb at R1·25 per lb =	68·13
To 2nd year's expenditure	24·20		
To 3rd year's expenditure	24·20	Balance to Dr. of 4th year	43·98
	112·11		112·11

To balance due 43·98

The above estimate gives nothing for cost of curing, roading, assessment, transport home, duty (if any) and interest on outlay, so not considering this the estimate must be considered as a very low one. As to the yield per tree I don't think we can well expect much more, till the tree is very much older, and allowing for the contingencies above, I think the estimate I have given as to quantity reasonable.

With regard to curing, Dr. Trimen speaks in his "Notes" of the purity of the prepared rubber being a matter of first importance," and goes on to say, that the milk should be passed thorough sieves, so that we may "confidently expect" that the preparation for the market will cost us something considerable. Then last, but not least, we have a vastly superior market to contend against.

If anybody "who knows" will be so good as to make his views public as to the paying question he will be granting a boon to them and also to yours faithfully,

SCEPTIC.

Very much to the point also is the series of propositions laid before us by Mr. Borron who has given considerable attention to this new product:—

To the Editor, "Ceylon Observer."

DEAR SIR,—In its avidity for new products, it is evident that the public would like to do a big thing in Ceará India rubber, but that its aspirations are checked by a scarcity of seed. It would be well, however, if our knowledge of the article was a little more complete, and your late leading article was well timed in preparing would-be cultivators for a possible trifling yield per tree and very low returns per acre. There are several other points, however, deserving of careful consideration:

1. We have been told that the demand for rubber is general and almost unlimited. If so, it is remarkable that while the total supply is comparatively not by any means large, yet the price seems to keep pretty steady at very moderate limits, so that it is strange the supposed large demand does not either increase supplies or raise prices. Perhaps some explanation may be found in the indestructibility of the substance enabling old used-up material to be again worked into new.

2. It is most desirable that our Botanical Garden Department should as soon as possible, by actual experiment, ascertain not merely the best planting distance for the trees, but also the probable average yield that may be reasonably expected, and the best mode of extraction. I note you adopt the distance suggested by Dr. Trimen, but I think general experience inclines to much closer planting. You mention 4 oz. per tree as the possible yield, but give no reasou for saying so. The mode of extraction mentioned by Mr. Cross, the collector, as adopted by the natives, viz., that "the outer surface of the bark of the trunk is pared or sliced off to a height of 4 or 5 feet," would, if it does not lead to the death of the tree, probably preclude the securing of a crop oftener than every second year.

3. The facility of propagation and successful growth in poor hard soils has evidently been much

exaggerated, and it would be well if the public were disabused on this point.

At an elevation of some 1,200 feet, with a high temperature and an annual rainfall of some 70 inches, I planted a seedling in good soil slightly manured. The plant grew most rapidly and well, attaining a height of some 25 feet in about 9 months. I planted another seedling in superior but unmanured soil, and in 4 months it was over 6 feet in height and blossoming. In poorer soil I planted 3 which in about 8 months had branched freely and were over 10 feet high In poor hard soil I planted 2 which, though healthy looking are now, at about 9 months old, only some 5 feet in height, while in very poor hard gravelly soil a plant of the same age was only a little over 3 feet in height and was sickly looking besides. Mr. Cross says;—"Dry hard gravelly wastes, if found to support any kind of bush, are also suitable sites." Again:—"On bare (!) or thinly covered portions of rock the cuttings might be laid down flat and a little heap of stones or any kind of débris about the size of a mole hill piled over each." I was foolish enough to sacrifice a tree to try this. Need I say, that after over a month's hot weather with some occasional good rains there are no signs whatever of a shoot, and the cutting seems to be perfectly dried up and lifeless. The ill success of this experiment did not encourage me to try the further recommendation of Mr. Cross, viz., that "holes might be made in stony land with an iron jumper, and a stout cutting put into each, and filled with pebbles." Such wild advice is almost enough to throw discredit upon Mr. Cross's other statements. As Mr. Cross, however, was only portions of two days in the Ceará rubber-growing distinct, the advice he tenders must be at second-hand, only, as by his own accounts the natives generally seemed very ignorant, one would have expected more caution from a scientific man.

4. In the future cultivation of this tree, one great difficulty and loss will arise from the ravages of wild pigs, which will grub up even fair-sized trees to devour the tubers on the roots. Of the few trees I have growing on an estate not specially subject to their attacks I have already lost two in different portions of the estate by their means, and one of the plants was over 10 feet high; while the other trees have only been secured by building walls round them. On a large scale I have had to fence in a cardamom clearing of about 140 acres to protect it from wild pigs, but India rubber hardly promises such returns as would justify so great an expenditure. Trusting that other rubber experimentalists will favor the public with their experiences.—I remain yours truly,

A. G. K. BORRON.

In answer to Mr. Borron's first remark, we may say that the consumption of rubber in the United Kingdom and Europe and North America has certainly increased very largely of recent years, but a still further reduction in price was the condition mentioned to us as preliminary to an almost unlimited demand. In 1874 the quantity imported into the United Kingdom was 129,163 cwt. worth £1,326,605, and in 1878 the import was equal to 149,724 cwt. valued at only £1,313,209. Moderate as the rate now is in the planter's opinion, the raw material is still too high it seems to admit of rubber being used so universally as it would be if large quantities could be got at a price nearer 1s than 2s per lb. This fact of lower prices being looked for, of course, strengthens the case of our correspondents in reference to the doubt cast on the question 'Will the cultivation pay?' On the second of Mr. Borron's points we most fully agree in the special need of the Director of the Botanical Gardens following up his useful paper of practical instructions with further notes, the result of experience which, at present, he alone has within his reach. Four ounces per annum were mentioned to us by a merchant, on the authority of Mr. Forbes Laurie, we believe, as a probable yield in Ceylon; but this point has yet to be practically settled, and that there are very diverse opinions abroad among men who have given attention to the subject, may be judged from the following from one who has consulted home as well as local authorities :—

"I think 4 ounces of caoutchouc per tree is *far* too little to reckon on, but Dr. Trimen will settle this point very shortly. In the meantime I may mention that the '*Chavannesia esculenta*' (a creeper in Burmah) gives 3½ lb. of rubber the 7th year, and can be tapped annually afterwards with the same result. The creeper is, I believe, a quick-growing one, but cannot surely equal the Ceará the growth of which 'passeth all understanding.' The trees at Peradeniya are planted close together and in *very* poor soil. If therefore the yield is less than some expect, the facts must be taken into consideration. Given a good soil, proper elevation, and so on, I believe the Ceara tree will yield from 1 lb. to 1½ lb. caoutchouc per annum after the 3rd year, but this is of course mere conjecture; the result has yet to be proved."

We trust Dr. Trimen will lose no time in determining, so far as he can, the yield from the Ceara rubber trees. According to Cross, the trees need be only five inches in diameter to be ready to tap, and, surely, those in Peradeniya must now be much larger. If the yield is only equal to four ounces per annum, most people will consider that Ceara rubber is not worthy of attention from the Ceylon planter, more especially in view of the large additional area covered with indigenous trees reported from the East coast of Africa. When Dr. Trimen does fix a day to tap, he ought to invite representative planters to be present.

THE AMERICAN APICULTURIST AND HIS HUNT AFTER CEYLON BEES.

Mr. F. Benton, our enterprising American visitor, carried away with him from the jungles of the Kurunegala district such a dose of malarial poison, as, we fear, must serve to remind him for a long time to come of the dangers attendant on tropical bee-hunting. Ignorant or sceptical of the risk of jungle fever, Mr. Benton walked long distances in out-of-the-way forests and villages; he climbed trees after the "Bambara" bee nests, and exposed himself to heavy rain in his eagerness to secure colonies and specimens of bees, of combs, &c., during the few days at his disposal. It was no wonder, therefore, that he was at length prostrated with a severe attack of malarial fever. We wished Mr. Benton to visit Nuwara Eliya to recruit, and, if possible, to see somewhat of the bees in that elevated region referred to by Sir Samuel Baker. To give an idea of the enthusiasm of this Western visitor in the pursuit of his object, we may quote as follows :—

"Kurunegala, April 16.

"I did not thing it advisable to join you on your way to Nuwera Eliya. My thanks are, however,

equally due to you. I intended sending a little review of Sir Samuel Baker's account of bees, there being, it seems to me, several important errors in it, but this morning one of our bee-hunters came in with the report that he had found *bambera* upon *bambera*, and I am off for his village, about seven miles away.

"Thus far I have obtained no additional colonies, although I have made very great exertions. I have seen many, but they were with one exception, in very inaccessible places on high rocks or trees. The single exception was a colony located within five feet of the ground and which I went after, but found that some one had smoked and burned away the bees and cut the comb for the sake of the honey, but a few hours before my arrival. The *bambera* I have in the frame-hives are doing well! working, &c!!"

Later on Mr. Benton was a little more successful and he returned to Colombo on Saturday, the 23rd instant, with some colonies of the "Bambara" (*Apis dorsata*) as well as of the small *Apis Indica*, and with a full collection of specimens of the combs, nests, bees of all kinds, &c.; but also, as we have said, with an alarming attack of jungle fever. All through Saturday night our American friend had what he called "a bad time," the most terrible experience in his life, and something to remind him of the dangers of a tropical jungle. Dr. White prescribed, and thanks to a vigorous constitution and the marvellous effect of repeated heroic doses of quinine, the fever was so far subdued by Monday morning as to enable Mr. Benton to fulfil his intention of starting back for Cyprus by the French mail-steamer. We hope to hear of his safe arrival there and complete recovery, and also of the safe arrival of his interesting charge, which will then probably be the first introduction of the *Apis dorsata* and *Apis Indica* to Europe. In any case Mr. Benton's expedition to Ceylon and Java will be fruitful in information of surpassing interest to apiculturists. Nor is it likely to be less fruitful of useful results to the East. The Cyprian bees introduced by him are flourishing well, we learn, with Mr. W. H. Wright (at The Aviary) and Mudaliyar Jayetilleke (Kurunegala). Both these gentlemen have acquired a great amount of practical information on bees generally, and as Mr. Benton said there is no valid reason why Ceylon should not develop an industry of considerable importance (especially to the natives) in Apiculture. As already mentioned Mr. Benton considers the rainy and dry seasons afford a parallel distinction to winter and summer seasons in temperate lands.

Mr. Benton is a capital example of the self-made, self-reliant, energetic American. It was very amusing to hear his quaintly original remarks on the dullness and unhandiness of the people about him in the jungle villages. When prostrated with fever he said he did not believe there was in all the N. W. Province anybody equal to tying a parcel properly;—he challenged a few to try but the rope came off almost as soon as the parcel was handled. "Now," he added, "I could tie that parcel so that it would travel a thousand miles without giving trouble!" A Western man and his health failing in the profession chosen for him by his father, Mr. Benton set to work, as an adult, to study and qualify himself as a school master, passing in succession as teacher in a Village, District and County School to the State Agricultural College (Michigan) where his position, curiously enough, is that of Professor of Germau, he having acquired a native's proficiency in that language, although his parents are of English descent. Apiculture he has taken up as a leisure study and employment. One brother he lost in the Civil War, while another is the well-known American artist, Mr. Dwight Benton, who resides in Rome.

Mr. Benton was very sorry to have to leave without completing certain work he had sketched out for himself in regard to our bees, and he intended writing a paper for the local Asiatic Society (which he had to take away unfinished), as also making some further contributions to our columns. One of these contributions—a preliminary sketch—which reached us from Kurunegala may be given as it stands, as follows :—

FROM FAR-OFF INDIA:

THE BEES OF CEYLON—APIS DORSATA, THE GREAT EAST INDIAN BEE.

From this, the bottom side of the world, I send greeting to all the bee-friends in dear old America. I shall present you here some very "big bee-yarns," yet all that I have not seen myself has been drawn from very trustworthy sources. [Two paragraphs headed respectively, "Off to the Jungles," and "Apis Indica (Mee Meso)," are omitted, their substance having been given in a previous article in the *Observer*.—ED.]

"DANDUAL MESO."

I did not see the bee which the natives call by this name, and which is smaller than that just mentioned, but a piece of its brood-comb which I secured is one-half an inch thick and shows hexagonal wax-cells, eighty-one to the square inch of worker-comb, while the drone-comb has twenty-five. The workers, then, must be about the length of those of *Apis Indica* but much more slender, being, in fact, quite wasp-like in shape, although the drones are no doubt quite as large, if not slightly larger, than those of *Apis Indica*. This bee is said to build a single comb which it attaches to the branch of some tree or to a horizontal timber of a building. I think, under favourable circumstances, it will, like other species of the same genus, build additional combs parallel to the first. Very likely it is *Apis florea*, said to be a native of Ceylon, India, China, and Borneo. It must have about the size attributed to that species; moreover. I found indications of but four sorts of real honey-gatherers in Ceylon, three of which I can identify as other species, and the native language recognizes four bees only. I would like to secure some of these bees, though I do not believe they are worth spending much time for. There is "bigger game in the bush."

THE TOM THUMBS AMONG BEES!

I have with me a small box containing a colony of very curious little bees with their equally curious queen and combs. These bees, called by the natives, *kana mee messo*, though belonging to the numerous family *Apidae*, are only distant cousins of our honey-bees, not being in the genus *Apis*, but that known as *Trigona*. The worker of this bee is but three-sixteenths of an inch long, has a large head and a small, blunt abdomen, the wings being longer than the latter. They are black, with one light colored ring on the abdomen, which is also light-colored underneath, stingless, very active, and gather pollen and honey. It is really amusing to see them come in laden with pollen, the pellets being larger in proportion to the leg of the bee, or even to its body. The strength of the individual workers is very great. The queen is dark yellow, and has an immense abdomen, her wings not being strong enough to lift her body into the air, when the ovaries are filled with eggs. The worker-cells of this bee are about half the size, and of the shape of short, plump, grains of wheat, and are placed in irregular bunches with passages between; the pollen-cells and the honey-cells are fully as large as good-sized peas, and each forms a group of its own. I found these bees in a small hollow tree in the jungle near Kalutara. They had built down from the hole of the tree a tube about a foot long, a half inch to three-fourths in some places in diameter, and composed of particles

of wood glued together with some resinous gum. Through this tube the bees entered, and it evidently served as a protection against some of their enemies. A nest of ants was located farther down in the same tree, but I noticed that these insects, so ravenous in tropical countries, avoided this tube. Another colony, which I found lodged in one of the hollow iron pillars in front of the village-inn in Kalutara, had built no such tube, the entrance hole being just large enough to admit one bee at a time.

But are these '*big* bee-stories'?" some one asks. Well, "from one extreme to the other," for now I will tell you what I know about the

GIANT BEES!

It was, unfortunately, only just before I was to re-embark (with the Cyprian and Holy Land bees I had brought with me), to continue my journey to Java, that I gained any satisfactory information about these bees. I had sought them in the forests and made inquiries among the natives everywhere I had gone, but had not found a single specimen. Then I visited the Colombo Museum, and though none were to be seen there, one of the gentlemen connected with it, Mr. R. Van Cuylenburg, very kindly introduced me to Mr. W. H. Wright, a retired planter and a lover of flowers, birds and insects, who had often seen *bambera*, the largest bee of Ceylon, which I fully believe is *Apis dorsata*, found also in India, Malacca, and many of the Dutch East Indian possessions. He told me they were not often found near the coast, but generally built their combs upon rocks or attached them to the branches of forest-trees. He had, however, been called upon to remove from the upper part of a hotel-window in Colombo, the principal seaport of Ceylon, a large nest of these bees. I remember to have read that a swarm once took up quarters in a coal-shed in Point-de-Galle, another seaport town. Thus, they do live in an inclosed space sometimes. "Why," said my informant, who is a highly esteemed citizen of Ceylon, "I have seen combs of *bambera* hanging down fully five feet from the branches of the trees. The natives climb into the trees and cut off the combs and let them down with ropes, smoking away the bees; and I have seen them load *thirty* men with the honey and wax taken from one *bambera* tree." Again he remarked, "When they swarm the air is black with them, and I have seen a stream of them as long as from here to the Museum." The distance indicated was nearly half a mile!

In Sir James E. Tennent's work entitled "Ceylon" is the following note: "A gentleman connected with the department of the Surveyor-General writes to me that he measured a honey-comb which he found fastened to the overhanging branch of a small tree in the forest near Adam's Peak and found it nine links of his chain, or about six feet in length, and a foot in breadth where it was attached to the branch, but tapering towards the other extremity. It was a single comb with a layer of cells on either side, but so weighty that the branch broke by the strain.'" I called on Mr. Wm. Ferguson, the gentleman here referred to, and found him a person of no slight scientific attainments, being a fellow of the Linnæan Society, and the author of several works on the botany of Ceylon. He confirmed the statements made in this note and added also that the swarm was close to the ground. Tennent also says: "I have never heard of an instance of persons being attacked by the bees of Ceylon and hence the native assert, that those most productive of honey are destitute of stings." I did not hear any such statement as is made above, but found that the natives had little dread of the ordinary bees, which do not often sting severely, and that the *bambera* was not feared as the various kinds of wasps. Tennent remarks: "Wasps are greatly dreaded by the natives." This is as I found it, and there is good reason for the dread, for some of these insects as well as the carpenter-bees, are immense fellows. The natives say that "seven *deboreh* stings will kill a man;" but I got eight, therefore———!* Then there is *cooroomineah*, "three stings from which are sure death." One more quotation, and then I will show you the point of these wasp yarns. Tennent says in a note: "At the Jan. (1839) meeting of the Entomological Society, Mr. Whitehouse exhibited portions of a wasp's nest from Ceylon, between seven and eight feet long and two feet in diameter, and showed that the construction of the cells was perfectly analogous to those of the hive bee." Now, the native words, *bambera* (the large bee) and *deboreh* (one of the large wasps) are used interchangeably by many who do not know the proper application of each; besides, many do not know the difference between these two insects, a fact not to be wondered at, especially as one species of the wasp so resembles the large bee as to deceive many who have often seen the latter. I was often shown nests of wasps when my interpreter, himself a native, had asked for *bambera* (the large bee). Of course although some wasps suspend their nests to the branches of trees and make hexagonal cells, "analagous to those of bees," their combs are built in a horizontal position, made of paper, and have cells only upon one side—the under surface, and it is needless to add that these insects are so fierce as to be untamable. Thus without further remarks the reader can see how natural it was that, through some travellers who did not take pains to ferret out the real facts of the matter, an error should creep into print and then into our bee publications. Such is, I believe, the origin of the story that the combs of *Apis dorsata* were built in a horizontal manner, and that the fierceness of these bees made them unmanageable, The description Mr. Wright gave me of the manner in which the natives secure the honey of these bees shows that no *great* fear of the insects under discussion can exist; moreover, there is in Mr. A. R. Wallace's valuable scientific works "The Malay Archipelago," a very similar account of the method employed by the bee-hunters in Timor. He says the nest of *Apis dorsata* was "on a horizontal branch seventy or eighty feet from the ground," to which the bee-hunter ascended "with his face, arms and legs completely bare," and after holding smoke under the combs "coolly brushed away the bees that settled on his arms and legs." "Several bees," says Mr. Wallace, "followed me at least half a mile and stung me severely." This is not at all strange, for Mr. Wallace says he remained under the tree until stung once, whereupon he "ran away *beating off the pursuing bees* with an insect-net and capturing them for specimens." He further states that he "is *inclined to think* that the best way is to make no attempt at escape, but only slow and deliberate motions;" and he "thinks a bee settling on a passive native makes no effort to sting." The italics are my own, and help to bring out the idea, which every bee-master will perceive at once, that *Mr. Wallace surely knew nothing of practical work with living specimens of the genus Apis*, however well able he might be to crack hard scientific names over dead ones. I not only believe *Apis dorsata* can be domesticated, but I also believe that, intelligently managed, that is in some manner which accords with its peculiar traits, it will be found to be little or no more dangerous than the other species of the

* Mudaliyar Samuel Jayatilleke, when he saw Mr. Benton, bare-handed and bare-headed, manipulating a colony of *bambaras* which had been placed in a frame bee-hive, and not receiving a single sting, said that 'he could scarce believe him an ordinary mortal' —ED.

same genus which we are accustomed to fear no more than we do our horned and hoofed servants.*

Now let us see if that horizontal yarn will shoot off in a perpendicular manner:

1st.—It is known that the combs are often five or six feet across, but being, as is also known, of ordinary bees-wax they would, especially in the heat of the tropics, break down through their own weight even if there were no brood, pollen or honey in them, and no weight of adhering bees to sustain. It is not reasonable, then, to suppose they are built in a horizontal manner, although the wasps' combs, being made of paper, withstand the heat and remain in their horizontal position.

2nd.—I have the assurance of Mr. Wm. Ferguson, F.L.S., that the comb he measured was built in a perpendicular manner.

3rd.—I have seen two preserved combs of *Apis dorsata*, and know that they could never have been built in a horizontal manner, nor could they remain long unbroken if their place of attachment were brought into such a position as to leave the sheets of comb horizontal.

4th.—Mr. W. H. Wright, who has seen many nests of *bambera* (*Apis dorsata*), says: "They *never* build their combs' horizontally, but *always* perpendicularly."

For my own part I have always believed that every species of the genus *Apis* built its combs perpendicularly. When, therefore, I heard this story about the combs of the great bee of East India, I concluded that, either the bee did not belong to the genus *Apis* and had been misnamed, or else that a mistake had been made in applying that story to this insect. I am now satisfied that the latter of these suppositions is correct; indeed, there is no doubt in my mind but that all these horizontal inclinations are exclusively attributes of our interesting, though none too distant, friends, the paper-making wasps.*

All the way from Ceylon to Singapore I pondered over the stories about these wondeful bees, and when our steamer entered that beautiful harbour, I at once sought eagerly for bee-trees in the surrounding country. The Malayans knew the large bees under the name *lebah besar*, but said that I must go to the adjacent mainland—the Malay Peninsula, because when these bees came upon Singapore island, the people drove them away with torches. But our steamer was to sail as soon as the China mail arrived, and it was not safe to venture far. so I did not find them. But upon visiting the Singapore Museum I was delighted to find there two combs of *Apis dorsata*. These were from Quedah, in the Southern part of Siam, just across the line from Malaya, and still in the Malay Peninsula. I had no rule with me, but with a stick I got the length and the breadth and with a strip of paper the thickness of one of the combs, also the length occupied by a certain number of cells, and these were measured when I reached the steamer. The length was three and one-half feet and the depth a little over two feet. The thickness of the brood-comb was one and one-half inches, and as near as my measurement will permit, I make out four and one-half cells to an inch, or twenty to the square inch. I shall make an accurate measurement of combs and cells of *Apis dorsata* as soon as possible and give the figures, for I cannot place great reliance upon the last two dimensions given here. Yet they agree with the estimate I made when viewing the combs; that is, I knew its cells had a greater diameter than the worker-cells of *Apis melifica*, but thought them not as large as drone cells of the species just named, although deeper, since I saw at once that the brood-comb was much thicker than even the drone-comb of *Apis melifica*.

With the measurements I have taken as a basis (and they cannot be *far* from correct), let us make a calculation First assume that the worker *Apis dorsata* bears the same proportion to its cell, as regards length of body, that the worker *Apis melifica* does to its cell, then we can say: the length of *Apis melifica* is to the length of its cell as the length of *Apis dorsata* is to the length of its cell; or, transposing these terms and substituting the known dimensions (given, for convenience, in eighths of an inch), we have the following proportion: 7-8th in.: 4-8th in.: 12-8th in.: x, the unknown term, x, representing the length of the body of the worker *Apis dorsata*. Working out the proportion, we find *Apis dorsata* to be very nearly seven-eighths of an inch long! Comparing in this manner the combs of the *Apis Indica* with the known dimensions of the worker *Apis melifica* and its combs, a result is obtained so nearly in accordance with the careful measurement I made of the worker *Apis Indica*, that I believe this method can be applied in obtaining the size of other members of the genus *Apis*, and that the figures I have given above as the probable length of *Apis dorsata* will prove not far from correct. It is very reasonable to suppose that the tongue of *Apis dorsata* bears a similar proportion to its body. as regards length, that the tongue of *Apis melifica* does to the body of this bee. Upon this supposition and with twenty-six hundredths of an inch as the average length of the tongue of *Apis melifica* if our figure seven-eighths of an inch represents very nearly the actual length of *Apis dorsata*, its tongue is forty-five hundredths of an inch long—over one-half longer than that of our common bees!

"What will these Great East Indian Bees do?" I don't know. Wait until I get them and see!

FRANK BENTON.

China Sea, off Banca Island,
February 10th, 1881.

Mr. Benton much regretted his inability to see or write to several friends before leaving, but the state of his health must be his excuse with all these including Mr. Jayetilleke, whose letter we quote from as follows:—

"Kurunegala, 1st May 1881.—I have just returned from the interior having had to attend the paddy rent sales, and was very much concerned and felt sorry to learn that Mr. Benton left this with an attack of fever during my absence, and more so not having had a single line from him, or any other person, as to how he is, and whether he has left Ceylon with his bambara bees. I thought you would be the best authority to write to and ascertain the fact. I am sorry Mr. Benton came too early in the season to secure the bambara bees, as this is only the commencement of the swarming season, and in a fortnight or so, there will be hundreds of bambara hives settled. He has gone to great risks in securing only one box of these, and I trust that he will succeed with them. The Apis melifica, or the Holy Land bees, are doing very well, and they are doubtless more industrious and fast workers and are more tractable than our common Ceylon bees. I have made one discovery which, if it results to my satisfaction, I shall communicate to you, which is that the Ceylon bees do not seem to approach vanilla flowers when in bloom, whilst the Cyprians are found continually amongst them, and I have an idea that, if they take to them, they might turn out to be good fertilizers, and save much trouble and labour in fertilizing them as is done at present. I am watching them carefully and have ceased operating on the flowers to discover if these bees will prove successful in carrying on this troublesome operation."

* Mr Benton proved this to be the case at Kurunegala.—ED.

COFFEE MANURING AND COFFEE PROSPECTS.

Mr. John Hughes is not inclined to let Mr. Tolputt have the last word in the prolonged controversy over the question of the best manure for coffee, whether it be one in which potash or nitrogenous elements chiefly prevail. The following communication arrives at an opportune time when the minds of many planters are specially set on the consideration of the best available manure to apply to their trees:—

79 Mark Lane, London, E. C., March 18.

John Ferguson, Esq., *Ceylon Observer*.

DEAR SIR,—I notice you have published some long letters from Mr. Tolputt.

If Mr. Tolputt will refer to my report (page 18), he will see that I by no means undervalue the importance of potash, but I maintain that 4 % potash equal to 8 % sulphate of potash will be found practically sufficient in a complete coffee manure, and that on soils already rich in potash a smaller quantity will do. I feel sure that planters will find it more permanently economical to make nitrogen in the form of organic matter, the dominant element of their manures. Thus, cake, fish manure (free from sand), and dried blood, aided by *small* quantities of steamed bone meal, or superphosphate, will be found to be the most economical manure for a shrub like coffee. It is no business of mine to convince Mr. Tolputt, and if that gentleman thinks proper to make potash the principal element in coffee manures and to waste money in expensive fertilizers of an exceedingly soluble nature, he can of course do so, but I shall continue to recommend planters to apply those manures which, from personal experience, I believe to be most profitable, and most suitable to the special requirements of their *soils*, *climate* and *situation*. I am glad to notice that the Ceylon Government has removed the duty from ground coral when used as a manure, for I believe it will be a most convenient method of applying lime to the estates.

If ground coprolites have been found to give good results in Aberdeen, it is not surprising that ground bones and ground coral (carbonate of lime), if applied in a stimulating climate like that of Ceylon, will certainly prove economical as a permanent fertilizer. In connection with this question of carbonate of lime as a manure applied either separately or in union with cattle dung, you may remember that at page 36 of my report I gave an analysis of some sea sand taken from Bude in Cornwall, and which I stated was used in large quantities every year, being mixed with cattle dung in the form of a compost. I send you a cutting taken from this week's *Farmer*, in which public attention is again directed to this use of carbonate of lime in the form of calcarious sand:—

Bude sea sand is becoming a popular article for land fertilization; its lasting effects are greater than those of other manures. By the analysis made by Dr. Voelcker, this material contains no less than 78·24 of carbonate of lime for every 100·00.

I am very pleased to hear you are likely to have a good blossom, and hope it may mature into a good crop.—Yours very truly, JOHN HUGHES.

But what is the use of manuring at all? will be the cry of planters after perusing the following very gloomy statements from an up-country report. This contributor begins by asking "What about the 'bumper' crop?" a remark at once unfair and unworthy of the writer, for he knows, or ought to know, that we opened the year by expressly discarding the word "bumper" from our columns, and neither by ourselves nor by a single correspondent has it since been applied to our prospects. These prospects were said to be better than any antic pated at the same period for either of the past two seasons, but we suppose our critic would almost deny this proposition now? He writes:—

"The splendid season we have had forced out very large blossoms everywhere up to about 4,000 feet, and even on considerably higher elevations in Dimbula. Bogawantalawa blossoms were poor. But the general cry is that they have not set. Is it the 'seasons' and 'weather' again? Too *dry* after the February blossom, too *wet* after the March one? Or must it be admitted that 'W. McK.' was right in seeing its *wood* in quite another light, from the roseate hue which so dazzled the eyes of 'Z'? Seventeen out of over a score blossoming seasons I have seen, were blamed for the difference between crops and hopes. Surely it is time now we admitted the Ceylon climate to be unsuited for *coffee*.

"You have surely been misled about that wonderful 'Venture' manure. You are advertising either the manure, Venture, or Mr. Ross; or some one seeks by your aid to shew mortgagees that we have only to follow in his footsteps to get paying crops for an indefinite time. I hear, however, that Aluwihare has actually fallen off in crops as much as any estate in Matale, certainly more than any estate which has received similar care and outlay. This too, in the last four years, while manures have been made from analysis, although perhaps not much of the Aberdeen manure went to Aluwihare. Venture gave much better crops per acre in 1876-'77 and 1878, than it did or will do in 1879-80 and 1881. During 1879-80, seasons were perhaps against it, but this manure had not been used previous to that time, or, at all events, did not affect the crops of 1876-77, nor perhaps of 1878. You say Mr. Ross finds that by manuring with this stuff (chiefly *bones and poonac*) he raises his crops from 2 or 3 cwts. to 5 or 6. But he did not get 5 cwts. in 1879 or 1880, and it is doubtful whether throwing in this crop the three years will average 5 cwts. Now, surely 'Venture,' *naturally* the finest estate in Dikoya, would have given at least *four* cwt. without manure during these three years. It is in its prime, being all under ten years of age, and most of it between four and eight years. The adjoining *old estate* of Lawrance, has averaged over three, during those years, without manure, or with only such stuff as pulp, &c. Norwood and Venture lie on either side of Lawrence. The first two estates were manured yearly up to last year, yet it was proved two years ago, that Lawrence, without manure, averaged much the same as Norwood, and within a cwt. or 1½ of Venture for the previous four years. Norwood and Venture had the advantage of *youth*. The difference in crops in favour of Venture did not more than cover the difference in expenditure.

"If coffee cannot set a crop in a good season, unless manured at a heavy loss during bad seasons, it is worse than worthless. All analysis of the tables of manures which you published lately from the Customs accounts shews that during the five years 1865 to '69, we used, on an average, £30,000 of manure yearly; from 1870 to 1874 £50,000 worth, and from 1875 to 1879 £140,000! Cattle manures too were made to a much larger extent during the last five years (1875-1879 than ever before. Yet, with this enormous increase of expenditure, and 80,000 acres of young coffee which has come into bearing since 1870, our exports go down to about three-fifths in the ten years, 1870 to 1880. Leaf disease has beaten us. We have spent more than we could afford from the crop returns in cultivation, without apparently arresting for a moment the backward tendency of exports. This too with a railway, with the export tax taken off, without the heavy loss

on rice which was a regular item in accounts 15 years ago, and with an increase of 40 per cent in prices for six years.

"When, oh! when, is the tide to turn? Can 'Z.' tell us?

"A great deal of manure was applied in 1879, and togeth r with that put out in 1880 all of which should be still unexhausted in the soil (since 1880 gave neither crop nor wood as of yore), the trees must be sitting in it. The quantity sent by rail in 1879, 225,000 cwts. is greater than that of any year previous to 1875, and in 1880 as much as 128,960 cwts. were sent up."

It is proving too much when the unwisdom of applying manure is attempted to be shewn. At this time of day it is surely unwise to condemn scientific cultivation; but no doubt the cause of comparative failure in a majority of cases in Ceylon, is found in the application of the manure not being guided by science. Our coffee planters have as much need as their neighbours who grow sugar in the West Indian Islands to lay to heart the lesson contained in the following article from the *Barbados Agricultural Gazette*:—

"It is somewhere recorded of an ancient planter that on being asked, by a younger member of the profession, what were the chief essentials in good farming, he replied, that there were three things which constituted good agriculture: the first was manure, the second was manure, and the third was manure. In fact, it is quite evident that this old gentleman, judging probably by the light of his past experience, had fully settled in his own mind, that *the* great and essential feature of successful farming was comprehended in that highly pregnant word *manure*. And who is there amongst us of a younger generation, that has given this all-important matter the most ordinary consideration, but must of necessity have come to the same conclusion—a conclusion irresistibly borne in upon the mind as the reaping of each crop discloses *results*, which, it must be confessed by candid persons, fall very far short (at least in most cases) of the *expectations* which had been formed, but which alas! were doomed to failure and disappointment. To the observant this repetition of failure, year after after, can scarcely be cause for wonder, when has been seen, perhaps with impatience, the composure (we had almost said obstinacy) with which men shut their eyes to what ought to be patent to the most indifferent and careless; and as long as this condition of affairs is allowed to exist, so surely will our planters make short crops, and become more and more heavily in debt to the merchants. English and Continental farmers have years ago discovered that they were unable to manufacture a sufficient quantity of so-called farm-yard manure to enable them to farm successfully, and had the good sense to largely supplement their own efforts in this direction by liberal applications of *natural* manures, like Peruvian guano and nitrate of soda, and *artificial* manares, as sulphate of ammonia, super phosphate of lime, and many others which we need not specify. But whilst our brother agriculturists have so promptly recognised the one thing n cessary to ensure satisfactory results, we in this island are only now, as it were, opening our eyes to the advantages to be derived by a more liberal treatment of the soil with manures suitable for restoring the elements of fertility to our much-abused and, at the same time, long-suffering servant. We say without hesitation that dame Nature, ever bountiful, and almost prodigal in her liberality, has bestowed upon men no greater gift than the soil which he cultivates with such niggard hand. Because man knows by experience its enormously recuperative power, he argues, if he give ths matter any consideration, that little help is needed from him, and *that little* he gives with grudging hand. Ought it to be possible for these things to be wr tten,—and in our own organ too? Truly it is not a gratifying task which we have undertaken, but the disease is a serious one, and requires a drastic remedy and though, by some, our criticism may be considered harsh, we would assure our readers that we write in no unfriendly spirit, only intent on bringing before them, with as much force and clearness as we can, the most easily attained means of producing the largest and most remunerative sugar crops, thus enabling us to compete, with some hope of success, with that ever-increasing production of sugar which is being carried on all over the world, and which, aided as it is by all the appliances which modern science and skill can devise, threaten us with great disaster, if not *extinction*. It is the opinion of some we know, that the great panacea for all our ills is improved manufacture of sugar, but whilst fully sensible of the advantages and greater profit, which have been proved to accrue from the introduction of improved processes of manufacture, there is no denying the fact that such alteration in our present system of manufacture, involves a greater outlay than most owners of Sugar Estates in this country are able, however willing, to undertake.

We believe it has been admitted by out-siders that our cultivation, (by which we mean the stirring of the soil, whether by means of plough, hoe, or fork; surface drainage, and the strengthening of the thinner portions of our fields by the addition of mould taken from deeper places)—leaves little to be desired, but we challenge any one to say that the beautifully prepared fields, almost garden-like in their appearance, have a proper proportion of *the great farmer*—manure.

Doubtless everything in this world is more or less relative, and to such as are content with a return of 1 hogshead or 1½ hogshead sugar per acre, we have only to say, 'Go on, and prosper in your mis-directed efforts.' But to those, on the other hand, who are desirous of securing better returns than they have hitherto done from their fields, we say, 'do not be satisfied with less than 3 hogsheads of sugar per acre with its accompanying molasses'—always remembering that although we in this country consider such to be a very heavy return, half as much again is ordinarily produced from an acre of land in countries where the soil has not become impoverished by constant cropping. Now although recent low prices seem insufficient to keep up Estates that are heavily in debt, it by no means follows that sugar cannot be produced to a profit in this island, as the following figures will shew:—It is thought that there are 80,000 acres of arable land, moiety of which (40,000 acres) grows canes for each year's crop, and produces about 40,000 tons (*nett*) of sugar, *and* 32,000 puncheons of molasses. Then it is generally admitted that the first ton of sugar can be produced at a cost of £14. and taking this ton of sugar, with its molasses, as worth £20 even at recent prices (say 21s. per cwt.) there is left £6 profit, or 42 per cent on the cost of production.

From these figures it follows that each arable acre, yielding a ½ ton of sugar annually, gives only £3 nett. and that at £100 per acre land yields an interest of only 3 *per cent.* Thus, while sugar in Barbados can be grown at 42 per cent. profit, a great many estates are only paying three per cent. To natives of this island fields of sugar-cane form so natural a feature of the country that probably few of us ever give more than a passing thought, as to whether the canes are high or low, good or bad; but the writer well remembers the comparison which he he formed in his own mind, on his return from his first visit to England, between fields of wheat, oats, and barley, on which his eye had been resting for many months, and our cane-fields Positively

the canes (the crop had but just begun) looked like a forest. By parity of reasoning it must become abundantly evident that high manuring is absolutely necessary to enable us to hold our own. We must not be deceived by illusory hopes of the English Government imposing countervailing duties on bounty-fed sugars. No—our strength lies within ourselves, and do not let us imagine that others will fight our battles whilst we look on with folded arms. Surely, it is in the power of each individual Manager or Conductor of a Sugar Estate, if he strive with might and main, to compound a fair quantity of really good pen-manure. We fear that many, by adding heavy and oft-repeated layers of mould to their manure heaps, flatter themselves that they are "making up" a fine lot of manure; but can there, we would ask, be anything more self-deceptive? Mould is not manure, and it is only by the judicious admixture of various materials, such as vegetable matter (whether in the form of sweepings, bush, or other litter) along with the dung and urine of *well-fed* animals, and a sufficiency (only) of mould to fix the ammonia and other gases which are liable to be given off in the process of decomposition, that a compound which will answer our expectations can be obtained. In the last leading article of this Journal the treatment of Stock was well and ably commented upon, and we heartily agree with the view expressed by the writer. When saying that Stock should be sheltered from the rays of the sun by day, and the chilling effects of the night dew, we only need to substitute the word 'manure' for 'stock,' and the remarks will apply with equal force. We confidently assert that all yard-pens should be *wholly* covered, and there can no doubt that field pens should, in part at least, if not entirely, be sheltered from atmospheric influences. It is curious to observe the inconsistency of men, who, while making a great point of almost instantaneously covering with a jealous care, guano and other artificial fertilizers, yet seem utterly unconscious of the great loss they sustain by undue action of weather on what they ought to guard with the most vigilant, and anxious care.

Having done all that can reasonably be expected in the making up of the best and largest quantity of farm-yard manure, there remains much yet to be done by having recourse to our chemists, with whose assistance great things can now be accomplished in the way of growing heavier crops than of yore. Time was when the application of artificial manures demanded the serious consideration of the Barbados Planter, for knowing little or nothing of their composition there was more or less of risk involved in the undertaking; but now that there are amongst us two Chemists of repute, why should we not, when any doubt exists as to the suitableness of any manure for our soils, make sure of what we are doing by having our soils analysed. We believe there should be, in most cases, *three* applications of Manure;—a priming in November in the cane-hole—the application from the farmyard, from October to December, *in the banks* —and the final touch in June, when the rainy season sets in.

Let us have improved machinery (Steam Mills if we can) but let us, even if to the neglect of other points, never fail to supply our fields with liberal applications of manure, and then, and only then, can we rest satisfied that we have achieved the highest aim in agriculture."

Mr. Ross's example in having his soils and manures analysed is, in our opinion, worthy of more general adoption. But, inasmuch as it is impossible for each individual proprietor to have this done systematically, we consider that the Planters' Associations and each District Committee, worthy of the name, ought to arrange for the establishment of experimental stations, through which so many conflicting theories and so much of contradictory evidence could be brought to the proof of practical demonstration.

COFFEE LEAF DISEASE.

Mr. Borron sends us a very outspoken, if a not very encouraging, letter on this subject. He finds fault with Mr. Marshall Ward for bringing forward his sulphur and lime experiment without giving all the facts of the case, apparently hinting that it was no more successful than those conducted according to Mr. Morris's directions; and he expresses once for all an opinion decidedly adverse to the repeated proposals of Abbay, Morris and Ward that planters should collect and destroy fallen diseased leaves. We believe that Mr. Borron has the majority of the planters with him in this decision, and that henceforward the thorough collection and destruction of the leaves must be put on one side as an impracticable operation.

SALT AND VERMIN.—A planter writes:—"I see it said *salt* is an unfailing remedy for vermin in the soil. If it be so, surely, in the face of the ruin wrought in many parts of the country by grub, the Government might relax somewhat their strict rules with regard to its sale. In one of the vermicide powders advertised in your paper, *poochics* seem to revel: 'They enjoy a day tied up in a packet' of it."

SULPHATE OF MAGNESIA.—The following correspondence has been handed to us for publication:—3rd December, 1880.—L. Nurse Bowen, Esq. Dear Sir,—We beg to forward you the following extract from a letter of Messrs. Cooper McCarine and Co., as it refers to the report of the Analysis Committee of the Agricultural Society, to which your name was attached as chairman.—We remain, sir, yours truly, (signed) Louis, Son and Co. "We thank you for a copy of *Planters' Journal*, and read with surprise the rough calculations of value of 'Ammonia Fertilizer.' It is certainly new to us to be told that Sulphate of Magnesia is not a Fertilizer! Why, we have had orders for it, and it alone, from planters in the West Indies."—Broad Street, 7th December, 1880.—Messrs. Louis, Son and Co. Gentlemen,—I have to acknowledge receipt of your note of 3rd instant, forwarding extract of a letter received from the shippers of the "Sulphate of Ammonia Fertilizer" to which reference was made in the report of the Analysis Committee of the Agricultural Society of this Island. On behalf of the Committee, I beg to state in reply, that "rough" as may be the calculations of the value of the Sulphate of Ammonia existing in this Fertilizer, it amounts to £25 per ton—exactly the price at which your firm, and many others, here, sell the guaranteed pure article. This is near enough for the Committee. With respect to the fertilizing properties of Sulphate of Magnesia, I admit profound ignorance on the subject, but would observe that when the Committee undertook this duty on behalf of the Agricultural Society, they adopted as a standard a tabulated form of comparative values of the fertilizing constituents of artificial manures by Anderson, Nisbet, Way, Hodges', the North British Agriculturist, and Dr. Voelker published in Richardson and Watt's Chemical Technology, and among these constituents Sulphate of Magnesia found no place. Nor do we find it in any fertilizers specially prepared for the sugar cane. Clearly then the planters here who have purchased this fertilizer have paid very nearly £6 per ton for an article, the existence of which they were ignorant of, and which they would never have purchased had they been aware of it.—I remain, gentlemen, very respectfully yours, L. NURSE BOWEN. —*Barbados Agricultural Gazette.*

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE LEAF DISEASE AND MR. WARD'S SULPHUR AND LIME EXPERIMENT: THE FINANCIAL IMPOSSIBILITY OF GATHERING AND DESTROYING DISEASED LEAVES.

DEAR SIR,—In Mr. Ward's lecture delivered before the Planters' Association, special reference is made to a certain sulphur and lime experiment, details being given of several highly satisfactory results. No mention, however, is made of any unsatisfactory consequences, of the possible existence of which even there is neither hint nor warning. And yet there *were* several adverse circumstances, apparently as resultant as the more favorable. If the birth of a new idea is hard to bear, if the revival of an exploded notion is yet more painful,—the suppression of some of the particulars of an important experiment is more unendurable still. Mr. Ward ought to know the danger of a half truth and to have realized that such a garbled narrative as his was only calculated to mislead the planters, and place himself in a false position. The community can afford patiently to await any theory or explanation that may be forthcoming, but meanwhile I think it is entitled to demand full details of this particular experiment with *all* its supposed results. I complain of no ideal danger. A proprietor has found fault with me for prematurely disposing of his stock of sulphur, and with a superintendent for the ill-success of his S. and L. application, though probably it was neither better nor worse than hundreds of others, while it will be more through good luck than good guidance if many estate owners have not been again seduced into further sulphur and lime expenditure.

Putting the sulphur and lime treatment aside, the most general urgent recommendation of science has been the collection and destruction of our diseased coffee leaves gathered as they fall. Mr. Ward says: "You will never get rid of leaf disease as long as you you allow the diseased leaves to remain on the ground as they are now. No specific can be successful so long as you leave the leaves there." I am afraid that on this point also the teaching of science and the experience of practice will be found incompatible. I have neither the means nor inclination to try this further recommendation, and must leave its trials to others who have; but so far, I think, I but express the opinion of many old and experienced planters, when I say that the risk of fire, and impoverishment of soil, the expense, the labor, and the time required for this treatment, if adequately carried out would be such that, if coffee badly affected cannot be made to pay without it, it certainly never will with it, and that it would be better to at once submit to the inevitable, than to be allured on by false hopes into a heavy and profitless expenditure. But further, if I understand Mr. Ward aright, the spores on fallen leaves on rocks or ground, anywhere, but under the living leaf, if left to themselves must die. They shoot their little tubes, which grow and fill and burst, and there 's an end of it. But if disturbed, as in the process of collection they must be, myriads will be diffused through the air, only to attach themselves to the living foliage of the surrounding trees, and run their full course once more. I do not say that the thorough and careful collection and destruction of the diseased leaves would not lead to a mitigation of the pest, but I feel no certainty that it would pay, which is the grand end and aim of the practical coffee planter.—I remain, yours truly,

A. G. K. BORRON.

16

TOBACCO CULTIVATION.

Veyangoda, 4th May.

DEAR SIR,—In an article on the cultivation of tobacco in the Negombo district, in your Directory of 1876-8, it is said that by means of movable cattle pens the ground intended to be planted with tobacco ought to have an inch of cattle manure. I take it that this mode of treating the ground is necessary only in poor sandy soils. I have a piece of land to be planted with tobacco, the soil of which is fairly rich and approaches a sandy loam. I have n't sufficient time before me to go over the ground with movable pens. In the absence of cattle manure, will any of your correspondents who cultivate tobacco kindly inform me what is the next best manure to be used, Will lime or ashes do? The cultivators in Dumbara or the pioneers in Trincomalee will be able to enlighten A GREENHORN.

[Try bones and poonac.—ED. C. O.]

NEW PRODUCTS IN THE COFFEE DISTRICTS.

Dikoya, May 4th, 1881.

SIR,—In view of the already many fatal reverses sustained in coffee property since leaf disease and bad seasons combined have made themselves felt, and though granted that much has been done in the right direction, is it not the case that—owing in some measure, possibly, to a loyal prejudice in favor of the 'old horse,' but largely too to restricted expenditure—the planting through the coffee of suitable new products has very generally been done in only a *half-handed* and not *thorough* manner?

It is the case, I think, that working proprietors and V. A.'s now very generally recognise the expediency of doing so, and have acted and are acting accordingly, as far as means at their disposal permit. But, as to absent proprietors and mortgagees, as a rule, realizing this as keenly as they ought, it is only necessary to look around at the large areas of *only* coffee still to be seen, to doubt it. If good crops rule again—well and good—but suppose they do! What tremendous outlay need have been, or need be incurred, in planting out other things, or what loss can arise from the doing so? If coffee is to hold its own again generally before other things, as a paying investment, it will have to be known within the next three years; and cannot anyhow, as far as cinchona is concerned, enough be realized from the latter, if dug out, to more than cover its expenses? You and all others experienced will emphatically answer Yes! to this. I feel sure; provided of course the land &c. is suitable: and where in the new districts is it not? In the case of officinalis and Calisaya varieties, anyhow, little or no damage will have been done the coffee, even though it be planted, as I consider it ought, tree for tree: and I think it will be conceded that those who took this view, and earliest and to the fullest extent acted on it, have proved themselves the knowing ones. On the other hand, in the case of coffee prospects not improving in the future, in what position stand those severally interested in an unprofitable estate with nothing but coffee on it, and other products not instituted to a sufficient extent?—Can it pay proprietor, mortgagee or agent, to continue working it? And if not, I need hardly ask what that estate has absolutely done for them all! With a fine show of cocoa coming up, or a few hundred thousand cinchonas, there is a fair prospect of its paying all parties to struggle on and wait. And is a suggestion now out of place to mortgagees and agents, and more particularly, perhaps, to the large capitalists at home, whose support, I take it, may at present be considered the mainstay of the planting enterprise generally for their own interests' sake, as to helping their clients with their approval and funds, to fully fortify their properties

with whatever new product may be judged most suitable? But a few hundred pounds, and where plants are, less will suffice on each estate. As far as private mortgagees are concerned, if the agents do not care to come forward with the extra advance, those who arrange for this somehow, will, depend on it, prove their wisdom. Where done, and claims treated with consideration and not pressed against proprietors, till good times come again, it will probably avert loss and bring good cheer to all again. In the case of cinchona, the comparatively miserable sprinkling of trees put in, in past years, more by way of experiment than otherwise, have been and are meeting much of the whole expenditure on many estates, and as soon as ever trees now planted can be profitably cut—quantity per acre as making up for size and age—depend on it, they will very generally bear. With this in view, and looking at the immense market in Africa and Asia all but untapped as yet, and where quinine ought to be a household word in many districts, I hardly think there is much fear of Ceylon and India combined prejudicing present prices appreciably for many years to come. As against these suggestions, in many cases proprietors have been forced by their backers, or by personal need to dispose of these plants to meet current extremities. Is this not a suicidal policy truly?

That owing to a partial failure in coffee crops Ceylon is on a troubled sea at present, is, I think, openly admitted now by all, but it is not owing to a want of innate capability, and is it not in the power of those most interested in the Island, by taking proper precautions at once, to render their prospects sure again, and yet reap full returns?—I am, sir, yours faithfully, BREAKERS AHEAD.

LIME—LIME—TONS TO THE ACRE WANTED.—A planter writes:—"If we could get plenty of good caustic lime cheap, a Schrottky or a Ward would be unnecessary. With a railway, we might apply 3 tons an acre in the new districts."

THE CEARA TREES (writes Dr. Trimen in a note received to-day) are yet full young to tap, but the impatience of the planters may force me to premature action in the matter. But I scarcely think this tentative experiment is likely to settle the question as to yield, as we have yet to find out the best method of procedure, time for operation, and subsequent preparation of the milk. I will consider the desirability of asking any planters to the milking.

COFFEE AND CINCHONA.—According to statistics published in the *Ceylon Observer*, there are now 35,000 acres in the island planted with cinchona, the total number of plants being nearly one hundred million, valued at two millions sterling. About 10,000 acres are planted with tea, giving an annual yield of 500,000 pounds. The relative importance of coffee in Ceylon is not what it was; but yet it is gratifying to hear that the prospects for the forthcoming crop are very good.—*Academy.*

CEYLON TEA IN AUSTRALIA.—A Ceylon Colonist lately arrived in Melbourne, writes:—"I have been busy on the Ceylon Tea question and will give you the result. Several dealers, grocers, and private persons agree in this. Large merchants *cannot* push Ceylon tea on the market, in opposition to China and Indian tea. But if an agent or person interested in Ceylon tea takes the trouble to go with samples to the large inland towns, and amongst the country people, he can dispose of large quantities of Ceylon tea *in small parcels*. The retail price of tea is from 2s. to 3s. 6d. a lb., and if an agent was to offer Ceylon tea in 2, 4, 6, 8, or 10 lb. packets at prices slightly below the quoted rates, he could sell freely; and, as soon as the tea was made known, the dealers would have to buy in large quantities."

"THE TEA AND CINCHONA PLANTATIONS CO., LIMITED."

The full prospectus of this Company referred to by our London correspondent in his last letter has reached us. It states that

Morowa, the district in which these Estates are situated, with its heat and ample rainfall is particularly well adapted for the production of Tea. There is at present a good local demand, besides large and increasing markets in the Australian Colonies as well as in Europe. Taking the average value at 1s. per lb., and the yield at 400 lb. per acre, it is estimated that Tea, when in full yield, will give a net minimum profit of £6 10s. per acre per annum. The Cinchona trees (from which Quinine is extracted) of which there are 11,400 from one to two years old, will cost very little for up-keep, being planted amongst the Tea, and when ready for barking may be reasonably expected to yield a profit of about 8s. per tree—say £4,560, being nearly one-third of the entire purchase-money of the whole property. From the Cardamoms now planted (the indigenous variety grows wild in the Forest lands of these properties) a maiden crop will be gathered this year. It is stated on good authority (see Appendix) that from one acre of the Malabar variety as much as £40 has been recently cleared, that a field of one year old plants has been valued at £60 to £70 per acre, and four year old plants, in full bearing, at £200 per acre. Tea, Cinchona, and Cardamoms are perennials. Labour is cheap and abundant in the district in which the Company propose to commence operations. There is a large reserve of land on these Estates very suitable for all the above-named products, the cultivation of which may be extended to the following, viz.:—

Tea	...	1200 acres, yielding when in full bearing, a yearly profit at £6 10s. per acre		£7,800
Cinchona	...	250 acres,	do £40 do	£10,000
Cardamoms...		250 do	do £10 do	£2,500
		1,700 acres, giving an estimated yearly revenue of ...		£20,300

It is estimated that an outlay of £40,000 on extension and up-keep will amply suffice to obtain this result being, with the purchase-money, a total of £55,000, the profits on which, when the Estates come into full yield, will give a proximate yearly dividend of 37 per cent.; but by raising money on the issue of debentures the dividends may be increased up to 50 per cent. on the aggregate of calls on Shares. There still remain a reserve of about 635 acres available for other purposes, and on the Forest Trees, which must be left to shade the Cardamom plants, there is reason to believe that Vanilla, which is a most profitable article, may be extensively and successfully grown. The permanent buildings on the property comprise Store-houses sufficient for present requirements, an excellent bungalow for the Superintendent, and the usual lines for labourers. The leading features of the scheme of this Company are:—*Firstly*, that it should not depend on any one article of produce alone. *Secondly*, that, from the present cultivation, it should pay the Shareholders a fair rate of interest from date of payments on calls, until such time as the proposed extended cultivation shall yield sufficient to pay the larger dividends anticipated.

Valuation of the Company's Estates.

The following estimate of the value of the "Anningkanda" Estate, was made by Mr. Richard A. Bosanquet, of the firm of Messrs. Courthope, Bosanquet & Co., Colombo, on the 24th December, 1879, viz.:—

"Tea 1½ year old, at £40 per acre: Tea, planted in 1879, at £20 per acre; Forest land, at "£5 per acre; Chena land, at £2 per acre."

Based on this valuation, with the addition of only £10 per acre as increased value of the Tea for the 15 months'

additional growth, the following moderate value at the present time is arrived at, viz. :—

47	Acres of 2½ year old Tea, at ...	£50 =	£2,350
123	do 1½ do do	30 ,,	3,690
12	do Cardamoms	20 ,,	240
	5,400 Cinchona Trees over 1 year old	4s ,,	1,080
	6,000 do do recently planted	1s ,,	300
	333,876 Tea Plants in Nursery, at 10s. per mile	,,	166
952	acres of Forest Land, at £5 per acre	£5 ,,	4,760
1,207	do Chena Land, at £2 per acre	£2 ,,	2,414
2,335	acres, of the aggregate value of ...	,,	£15,000

[The valuations of tea and cinchona seem to us high: above the rates recommended in our Handbook. The appendix to the prospectus consists of extracts, chiefly from the *Observer*, on the subject of tea, cinchona, cardamoms and vanilla in Ceylon.—ED.]

CULTIVATION OF THE FIG IN TURKEY.

The United States' Consul at Smyrna states that the Aidin district is the only one which produces figs for exportation. The fruit will grow anywhere in the neighbourhood of Smyrna, of a good quality for consumption, in a green state; but the Aidin plain is unique in its climate and soil as being favourable for the proper curing of the fig. The thermometer seldom falls below three or four degree under freezing point, and in the summer seldom rises above 130 degrees Fahrenheit in the sun. In Aidin, the winters are generally wet, the dry weather commencing in May and continuing till the end of October. Any rain at the end of July, or during the month of August and September, when the fruit is under the process of drying, injures the quality by causing it to burst, hardens the skin, gives the fig a dark colour, and spoils its keeping quality. Heavy dews will cause the same evils.

The fig tree will grow in almost any soil; a rich heavy soil is, however, preferable; but to produce figs that will dry well and please the merchant, the soil ought to be of a good depth, and of a rich, light, sandy nature; this, if the weather be favourable, will produce large figs, of a white thin skin, and of the finest quality. Before planting, the ground is well ploughed two or three times, to a good depth, well fertilised, and freed from all weeds and extraneous roots. The fig is propagated from slips, selected with as many fruity buds as possible. To form a tree, two slips are planted, one foot apart, and then joined at the top. The trees, if planted in rich soil, should be placed about 30 feet apart, and for poor soil, about 25 feet distant from each other. The cuttings are planted in the month of March, two in each hole, at about 9 inches or a foot apart at the root end, and during the growth of the trees, the ground is ploughed up two or three times during the winter or spring, and the space between them is used to cultivate cotton, sesame, or Indian corn.—*Indian Agriculturist.*

THE ADULTERATION OF TEA IN AUSTRALIA.

A few months ago we gave the results of a series of analyses of milk sold in Melbourne, made at the laboratory attached to the Industrial and Technological Museum by Mr. Frederic Dunn, under the supervision of Mr. J. Cosmo Newbery. From the same source we have now obtained some particulars of the analysis of many specimens of tea purchased in Melbourne. Great reliance is naturally and deservedly placed by the public on the reports on various articles of food occasionally emanating from this laboratory. Such reports usually refer to analyses spontaneously undertaken, and the particular sources whence the articles experimented upon are obtained are not divulged. Consequently, they cannot be considered as advertisements either of the merits or defects of any individual product. Moreover, they are not usually paid for by any private person. The laboratory, too, is a branch of the public service, and the gentlemen employed therein are not directly under the control of any Minister of the Crown. Very much work has been done at this laboratory in the direction of exposing food adulterations; and if this work has not resulted in as great a diminution of the sophistication of the articles we habitually eat and drink as could be wished, it is not the fault of the scientists who make the analyses, but of public authorities who neglect to utilise or pay due heed to the information contained in their reports. With regard to the experiments on teas now under consideration there is much of disquieting character in the information supplied by Mr. Dunn, as it shows that a large proportion of the tea that goes into consumption in Melbourne is shamefully debased. But it also shows that the white and yellow rogues who derive a profit from the systematic corruption of this article of food could, under a proper law efficiently administered, be punished or, at all events, checkmated. In England, grocers are frequently fined for selling adulterated tea; but here adulterations of all descriptions are allowed to go unpunished.

However opinions may vary as to the effects of tea on the animal economy, there can be no doubt that injury is done to health by using adulterated tea. At any rate, if any persons do entertain doubts on that point, they had better refer to recent proceedings in the Medical Society of Victoria, when the subject of tea-drinking was before that body. Nor is it necessary to describe the process by which analysts detect the sophistication of tea. The various methods of adulteration of tea may be defined as the addition of "leaves other than those of tea, except those used for scenting; exhausted tea leaves and damaged tea; an undue proportion of stalks or vegetable matter foreign to tea of any kind whatever; foreign mineral matter, especially sand, quartz, soapstone, China clay, magnetic oxide of iron, &c. Lastly, the substances used for artificially colouring or painting the teas, as ferrocyanide of iron, or Prussian blue, indigo, turmeric, &c."

Probably most of the sophistication to which tea consumed here is subjected, is done in China. In that direction the Celestials have acquired a degree of skill far and away beyond that to which Europeans have attained. In Melbourne, very many families buy their teas from Chinese hawkers, whose ways are "quite too winning," the lollies which Chinky Chinky Chopsticks gives to the young ones at the door being a very successful bait to induce the housewife to deal with him. Their teas are highly scented with a good "grip" on the palate; in fact they are such teas as the Cautou short-leaf mixtures, which will be referred to further on. The use of such teas is gradually depraving the public taste. Housekeepers request their grocer to supply them with a similar article, and he asks the wholesale merchant to enable him to meet the demand, and thus the evil increases.

The quality of tea is judged, not only by its aroma and by the flavour and colour of the infusion, but by the amount of soluble matter or "extract," as it is called, which it yields. But, generally speaking, tea is classified according to the proportion of extract, mineral ash, soluble salts, and theine obtained. This rule, however, is subject to modification, inasmuch as chemical analysis sometimes reveals that the leaves have been mixed with some foreign matter, evidently added to give extract. Genuine tea contains between 4 and 6 per cent of mineral matter, 3 per cent. of which consists of soluble salts, and yields in its ordinary air-dried condition extract ranging from 32 to over 50 per cent.

As a rule, the younger and better the tea, the higher the percentage of extract. The following table gives an analysis of genuine teas :—

Name.	Locality.	Percentage of Mineral Ash.	Percentage of Extract.	Percentage of Soluble Salts.	Percentage of Theine.	No. of Samples Averaged for the Analysis.
Pekoe	... China	5·90	38·40	3·75	*	1
Do	... Ceylon	4·71	45·60	3·16	1·81	26
Do	... Indian	5·19	41·41	3·19	1·77	2
Do Souchong	... China	6·00	36·40	4·14	*	1
Do do	... Ceylon	4·78	45·11	3·06	1·81	13
Do do	... Indian	5·42	39·66	3·19	2·05	7
Souchong	... China	5·80	40·80	4·24	*	1
Do	... Ceylon	4·72	43·68	3·10	1·79	13
Do	... Indian	5·26	38·85	3·04	1·62	3

* Not determined.

With regard to this table, it would not be fair to use it for the purpose of making a comparison between different tea-growing countries inasmuch as the Ceylon teas were Exhibition teas, while the Indian and Chinese were obtained from bulk samples which had been sold in Melbourne.

The next table gives the results of an analysis of Chinese teas obtained from the importers, and taken from bulk samples :—

Name.	Price per lb. in bond. s. d.	Percentage of Mineral Ash.	Percentage of Extract.	Percentage of Soluble Salts.
Congou	1 0	5·26	27·52	2·90
do	2 3	5·74	32·24	2·83

There are very few teas in this lot that would pass the standard for a low class genuine tea, and this, too, notwithstanding the high price paid for a number of them. The majority of the samples must be classed as made-up teas, and consisted principally of exhausted tea-leaves re-fired, tea dust, and withered leaves. In many of the samples an excess of stalks and foreign leaves were detected. In some, especially those mentioned in the table as being sold at 10d. to 1s. per lb. in bond, chemical analysis distinctly showed that, besides the adulterants already named, the leaves had been mixed with some foreign matter evidently added to give extract and colour. One or two samples had been very strongly faced, or artificially coloured, with plumbago. Starch paste was likewise found. Had it not been for these foreign matters, which are soluble in water, the percentage of extract would have been much lower. As it was it will be seen that in the great majority of cases the percentage of extract was below the minimum for the lowest classed genuine teas.

With regard to Canton short-leaf, it may be mentioned, in the first place, that Canton is the centre of tea adulteration. An analysis of a sample of this description of tea showed that, in 100 parts, it contained :—

Percentage of stalks	... 28·71
Percentage of green tea	... 15·74
Percentage of black tea	... 55·55
	100·00

Many stalks were found foreign to the tea plant, and were ascertained to be cut-grass stems. The percentage mentioned as black tea was, in reality, a green tea which had been faced, probably with plumbago. Foreign and withered leaves were also detected, as were likewise a large number of small nodular particles, which proved, on analysis, to be tea-sweepings or lie, tea, held together by starch paste. An analysis of the whole sample of Canton short-leaf gave the following results :—

Percentage of mineral ash ...	... 6·70
Percentage of extract ..	... 37·69
Percentage of soluble salts ...	... 3·17
Percentage of theine ..	... 0·72

This percentage of theine, which is one of the chief constituent parts of tea, is very low. At the same laboratory, about 70 samples of Foo-chow congou yielded 1·67 per cent. of theine, the lowest percentage being 1·50. In 71 samples of Ceylon (exhibition) teas, the average percentage was 1·89, and the lowest 1·82; and in about 60 samples of Indian tea, the average percentage was 1·77, and the lowest 1·44. It may be added, with regard to Canton short leaf, that it has a very large sale, and is used by grocers to give the pronounced flavour which is so appreciated by the public. Jasminum sambac, evidently used for scenting purposes, was likewise detected in the samples.

As a rule, Indian and Ceylon green teas, which have been analysed at the laboratory, have proved to be perfectly free from adulteration, and the opposite may be said, with a few exceptions, of Chinese green teas. Some 60 samples of Chinese black teas, obtained from the most respectable grocers in Melbourne and suburbs, and sold at a retail price of 2s. to 2s 6d. per lb., were a short time since analysed. The following is a summary of the analysis :—

Name.	Price per lb. s. d.	Percentage of Mineral Ash.	Percentage of Extract.	Percentage of Soluble Salts.	Remarks.
Congou ...2	6 5·40	35·20	3·50		Highest percentage obtained from 30 samples.
Congou ...2	6 5·47	26·78	2·56		Lowest do.
Congou ...2	6 5·63	31·92	3·26		Average of 30 different analyses.
Congou ...2	0 5·52	34·80	3·13		Highest percentage obtained from 28 samples.
Congou ...2	0 5·60	19·57	2·49		Lowest do.
Congou ...2	0 5·55	30·08	3·06		Average of 28 different analyses.

We will conclude with a few general remarks. The sales by public auction of China teas for the six months ending 31st December, 1880, is stated to have been 3,391,000lb. Of this 2,005,000lb. were sold at and under 1s. per lb. in bond. The remaining 1,386,000lb. were sold at 1s. 0½d. to 1s. 10d. per lb. in bond. The duty on tea is 3d. per lb. There can be no doubt that grocers make a great profit out of tea. Some articles they sell at a very low price to get custom, but they make up for that on tea. Pure tea will go much further than the ordinary teas, and consequently less need be used. It is well to bear that in mind because when pure tea is used, too much may be put into the pot, and its very goodness may create a pre-

judice against it. Many persons condemn a large leaf tea as being of little strength. Such an opinion is erroneous. Some of these teas have been proved by Mr. Dunn to be very rich in extract, soluble salts, and theine. Of course these remarks do not apply to an excessively large leaf.—*Melbourne Argus.*

TIN TEA BOXES.

The following reference to these new boxes is from the pen of Colonel Money, the well-known authority on tea:—The boxes measure $15\frac{3}{4} \times 10\frac{5}{16} \times 10\frac{5}{16}$. They are handsomely illustrated with Indian Tea Plantation subjects.* Each piece runs into a groove in the adjoining one, so that one minute will put a box together and a touch of solder here and there completes it: they are then perfectly air-tight. The boxes are very sightly. Price is now 2s. 5d. per box. Boxes sent to Calcutta up to this have been charged 2s. 7d. The price is dependent on the fluctuating price of tin, which is somewhat lower now. Of course they are sent out in pieces. Cases holding pieces for 100 boxes weigh 4 cwt. The firm tell me that Messrs. Scheene, Kilburn and Co., and Messrs. Begg, Dunlop and Co., in Calcutta have consignments of the boxes, so any of your readers can see them. In my opinion there are several advantages to be derived from their use. They will help to open up new markets. The ungainly, unwieldy packages we have used hitherto, are certainly detrimental—at least where Indian teas are not known. By the use of these tin boxes the sale of our teas, would, I am sure, be extended at home, and they would also give great facilities for successfully introducing Indian Tea into Australia Canada, the United States, the Cape, &c. It seems some Indian Tea has already been sent home in these tins, and I am told it met with a ready sale, quite to 8d. per lb. over what it would have brought in chests. This is, of course, too good to last, but less than one penny a lb. increase would pay for their use. The tares of these boxes is, and must be exact, viz., 3 lb. $15\frac{1}{2}$ oz, so only a few would be opened at the Custom House, and the great loss by the deterioration of tea being exposed (few know *how* great it is) would be avoided. There is no doubt tea will keep better in transit in these boxes than in our old packages. How are they to be packed? Chests holding four tin boxes were recommended. I think crates of strong light battens would answer perfectly, and 6 or perhaps 8 boxes might then be placed in each. The rule of the Custom House is to discard fractions of a pound both in the gross and the tare. But in the gross the number *below* is written, in the tare the number *above*. In the case of our ordinary Indian packages, if we could regulate our tares exactly, so as to make the gross weight only one ounce *above* the whole number, and the tare one ounce *below* the whole number, the loss would necessarily be much decreased. This, however, is impossible, for, as a rule, the tares are one or two pounds less when they arrive in England than when they left the garden, owing to the wood drying in transit; and thus it is quite a chance what the real tares come out here. But, with the tin boxes in question the tares, that is their weight, being fixed and equal, and not liable to change, we can so arrange the weights that the loss will be very trifling, thus:—

	lb.	oz.
The box weighs	3	$15\frac{1}{2}$
We put in tea	20	2
Gross weight	24	$1\frac{1}{2}$
In the Customs the gross is written	24	lb.
And the tare is written	4	"
The Tea paid for will be	20	lb.

* Top, is "the tea garden." Front, "weighing leaf." Back, "packing." Ends, "elephants with howdah," or, if desired, the Plantation mark.

that is a loss of only 2 ounces, or not much above half per cent., instead of 3 per cent., as shown in the old packages. Roughly, the cost of using these tin boxes would be, all told, from $1\frac{1}{2}$ to $1\frac{3}{4}$ per lb and with our lead-lined boxes it averages perhaps one penny. The difference of a half penny, or even three farthings per pound would not be much for the advantages detailed.

LIME AS A MANURE.

The very abundant and highly important substance popularly called lime, but dignified by chemists with the name of *protoxide of calcium*, has long been used by agricultural nations as a manure It has been in use for nearly 2,000 years, for, according to Pliny, the Gauls successfully raised heavy crops of corn with it; while the Romans found an application of lime very beneficial to their vines and olives. It was, however, about the middle of last century before liming was introduced into this country.

The reason why lime acts so powerfully on vegetation is that combined with decayed animal and vegetable matter, it forms into a compound soluble, which, melting by the action of rain, supplies the plants with the chief elements of vegetable life—oxygen, hydrogen, and carbon; while it at the same time attracts carbonic acid from the atmosphere and forces the plant to absorb those gases more rapidly than usual.

Lime is found to be more efficacious upon 1. Land that has been habitually lightly manured than upon land that has been habitually heavily manured. 2. Land that in its composition contains no alkali than upon land which does contain alkali. 3. Land containing lime in its composition which has been habitually ploughed deeply than upon land in a similar state habitually ploughed lightly. 4. Newly broken up old grass land than upon land which has been previously continually cropped.

Lime ought not to be applied at all to lands which, according to their nature, already contain any of it in their composition; neither ought it to be applied to soil, no matter how rich that soil may be in other manures as long as the remains of any previous applieation continue to exist therein. It is well known that lime from its nature, always seeks down into the ground; and it is also well known that some soils retain its influence longer than others. According to one authority, twenty years is supposed to be the limit of its beneficial action over a great part of the south of Scotland; while another, a farmer in one of the Border counties, after laying down and liming a field of grass, found its influence extended to nearly thirty years.

Lime greatly accelerates both the dissipation of manure and the chemical decomposition of the soil; and in the very degree in which it increases fertility by this species of action, the land on which it operates must, in order to maintain the fertility, be supplied with proportionally large doses of manure, and perhaps with occasional doses of such mineral constituents as combine chemically and nutriently with the lime. Grass lands which have been allowed to run to seed, and which have become overrun with rushes and coarse vegetation, may be greatly improved by a dose of quicklime; for, according to Dr. Hunter, 'Quick-lime is an instrument of death to the coarse herbage of meadows.' The same authority says that it is also known to change the taste of certain kinds of grasses altogether. 'If a handful of lime be thrown on a tuft of rank sour grass, which has in former years been invariably refused by cattle, they will afterwards eat it close down.' Fine pasture lands have likewise been found to be naturally benefited by a top-dressing of the mineral in a mild form.

Now, when the old days of farming are passing away, in which, according to a seventeenth century writer, 'rains and dews cold and dry winters, with stores of snow, I reckon to be the best kinds of manures, impregnated as they are with celestial nitres,' I cannot conclude better than in the words of Liebig:—'A time will come when plants growing in a field, will be supplied with their appropriate manures prepared in chemical factories, and when plants will receive only such substances as actually serve them as food.' *David Swan, in N. B. Agriculturist.*

CULTIVATION OF VANILLA.

The high price of vanilla should encourage the cultivation of this plant in many of our Colonies, which are well adapted to its growth—*e.g.* Ceylon, Queensland, New South Wales, the West Indies, British Guiana and Honduras, Fiji, and parts of New Zealand. Some portions of South Africa and many districts in India would no doubt also prove capable of yielding an abundant supply of excellent vanilla. Mauritius is at present our only Colony where the culture of this plant is systematically carried on, though small experiments have been made, with encouraging results, in Jamaica.

As it requires special treatment, a few remarks upon its cultivation may be of interest to those who may be tempted to make the experiment.

In Mexico, vanilla is planted either in a forest or in a field. In the former case the underbrush, climbers, and large trees are cut down and removed, and young saplings only preserved to serve as supports to the vanilla plant, preference being given to trees having a milky sap; near each tree two cuttings of the vanilla plant are placed side by side in a shallow trench 1½ inch deep, and sixteen inches long, three knots of the stem being laid in this trench and covered with dead leaves, brush, &c. The rest of the cutting to the extent of three or four feet is placed against the tree and tied to it. The supporting trees should not be nearer than twelve or fifteen feet apart, to give sufficient room for the development of the plant. After a month the cutting will have taken root and must be carefully kept free from weeds and briars of all kinds. In the third year the plant begins to bear fruit which it continues to yield for many years.

When the vanilla is cultivated in a field the Mexicans first plough the ground thoroughly and raise on it a crop of maize. In the protection afforded by this plant a number of young milk-bearing trees of the fig family grow, which in a out twelve or eighteen months are large enough to answer the purpose of supports to the vanilla plants which are then placed as above described. In Mexico and Guiana the plant is allowed to climb up the trees, the fertilisation of the flowers is left to nature, and a large number of flowers consequently remain unfertilised and the yield of vanilla is small. In a few days after fecundation the flower falls off and the fruit continues to grow till the end of the first month: it takes, however, another five months before it is completely ripe. Each pod must be gathered separately, and not the whole cluster at once, the time to gather them being indicated by the pod cracking when pressed with the fingers. If too ripe the pods split in drying, changing in colour from yellow to brown and black. If not ripe enough the fruit will lack fragrancy and proper colour. The ripe fruit has no odour at first, the agreeable odour of vanilla being developed by a process of curing While the fruit is drying, an unctuous dark red liquid, called balsam of vanilla, exudes.

In Mexico the pods are collected and placed in heaps in a shed to protect them from rain and sunshine, and left there for a few days; they are then, if the weather is warm and clear, spread early in the morning on a woollen blanket and exposed to the direct rays of the sun; at about midday the blanket is folded round the beans, and the bundle left in the sun for the remainder of the day. In the evening it is enclosed in tight boxes to "sweat" all the night. The next day the same treatment is adopted, and the beans, after exposure to the sun, acquire a dark coffee colour, the shade being deeper in proportion to the success of the "sweating" operation.

If the weather is cloudy, the vanilla is collected into bundles, a number of which are packed together into a small bale, which is first wrapped with a woollen cloth, then with banana leaves, and finally with a stout matting, which is firmly bound and sprinkled with water. An oven is then heated to 140° F (60° C.), and the bales containing the larger beans are placed in it. When the temperature has fallen to 113° F° (45° C.) the smaller beans are introduced and the oven closed tightly. Twenty-four hours afterwards the smaller beans are taken out, and twelve hours later the larger ones. The vanilla has then acquired a fine maroon colour.

The drying operation then commences. The beans are spread on matting and exposed to the sun every day for about two months. When the drying is nearly complete it is finished in the shade in a dry place, and the pods are then tied up in small bundles for sale.

In the Island of Reunion a different method is adopted. In the first place the vanilla plant is never allowed to grow out of human reach, the different trees on which it is supported being connected by pieces of bamboo or other wood, placed horizontally, so as to form a kind of lattice, on which the vanilla can spread freely. As the vanilla loves a moist soil, and will not bear a burning sun the trees are never cut down. If grown in a field the support chosen is usually the physic nut *Jatropha hureas*, on account of its rapid growth and abundant milky juice.*

When the trees are of sufficient size to shelter the plant, the cuttings are set between the trees in a trench, eight inches deep, and covered with dry leaves, straw and a little soil This is generally done in the rainy season, as the cutting requires frequent watering while it is taking root. The shoots are trained on the lattices when they have begun to grow freely, and in two years are in full bearing. A length of stem of twelve to twenty-six inches in a state of nature, although it may produce more than forty flowers, rarely yields more than one pod—the flowers being only capable of fertilisation by the aid of insects.

A man named Edmund Albins, a former slave in Reunion, discovered that if the pollen of one flower was made by artificial means to fertilise the stigma of another flower, it was possible to obtain more than 3,500 pods from a single plant, although this would cause the death of the plant before they could ripen. The method adopted, therefore, is to choose on each cluster the finest flowers, and only fertilise those presenting a large and fleshy peduncle. These are known to be successfully fecundated, if the flower, instead of dropping off, remains and dries on the top of the fruit. When this is observed the rest of the flowers are cut off.

When ripe the pods are sorted according to length and scalded. The long ones are dipped into water at 194° F. (90° C.) during ten seconds, the medium ones fifteen seconds, and the shorter ones, one minute, or longer. They are then exposed to the sun between woollen blankets until they acquire the characteristic maroon colour, which occurs in about six or eight days. The pods are then spread on hurdles, and placed in garrets to dry gradually. As in this Colony the roofs are flat, and covered with tin, the garrets are in reality drying closets with a stream of warm air continually circulating through them. When the drying has proceeded so far as to allow the pod to be twisted easily round the finger, the operation called "smoothing" begins; and this requires great care, as every bean must be passed through the fingers from time to time, so as to spread the oil which exudes on the whole length of the bean, as the fermentation proceeds, for the lustre and suppleness of the vanilla depend upon this treatment. The beans are also turned frequently, so as to ensure their drying equally on both sides. In a month the pods are dry, and are then sorted according to their length, and into the three following varieties: 1st. Fine vanilla, from eight to eleven inches long, glossy, dark brown, and unctuous, and soon covered with minute, frost-like crystals, technically known as *givre*. 2nd. Woody vanilla, from six to eight inches long, lighter in colour, not glossy, presenting grey spots

* How far the irritating property of vanilla, which is sometimes manifested in vanilla ices, &c., may be due to the growth of vanilla on an acid euphorbiaceous plant may be worthy of enquiry. The use of fig-trees, as in Mexico, would seem at all events to be safer and more judicious.

on their surface and having very little *give*. These generally come from pods not quite ripe. 3rd. Vanillon, consisting of two varieties, both of which are short. The best are obtained from ripe fruit and are covered with white crystalline efflorescence; the inferior are obtained from abortive or unripe fruits, and owe any odour they possess to having been in contact with those of better quality.

A slightly different method of drying is adopted in other vanilla-growing countries. In Guiana the pods are placed in ashes and left there till they begin to shrivel. They are then wiped, rubbed with olive oil, tied at their lower end, and hung up to dry in the open air. In Peru the vanilla is dipped into boiling water tied at the end, and hung in the open air; after twenty days the pods are rubbed over with castor oil, and a few days later are pressed into bunches.—*Colonies and Ind a.*

JAMAICA PUBLIC GARDENS AND PLANTATIONS.

CINCHONA—LIBERIAN COFFEE—COCOA—TOBACCO—VANILLA—RUBBER—JALAP—COCONUTS.

We have received the annual report on these gardens for the year ending 30th September 1880. With regard to the distribution of plants, Mr. Morris says:—

In the distribution of Economic Plants from the Public Gardens, in addition to several thousand Cinchona seedlings and plants distributed from the Cinchona plantations, new Sugar Canes, Fruit trees, Banana and Pine-apples from the Hope, and Coconut plants from the Palisadoes plantation, some 26,937 plants, including Trinidad Cacao, Nutmeg, Clove, Cinnamon, Liberian Coffee and Vanilla, have been distributed from the Botanic Gardens at Castleton. The total distribution during the past year is estimated at an aggregate of nearly one-hundred-thousand plants of economic value.

There have also been exchanges of plants and seeds with private persons and public gardens, the latter including ours at Peradeniya. It is stated that

In exchanges maintained with Botanical Institutions and Gardens abroad, 753 packages and 8 boxes of seed, 9 wardian cases, and 1 box of plants have been received; the latter containing 356 plants of economic value. In return, this Department has forwarded 10 Wardian cases of Plants, 6 boxes and 3 casks of Seed, and an aggregate of 874 packets of Seed weighing 376 pounds. Six Wardian cases, containing nearly 500 Plants, were forwarded to the new Botanic Gardens, Demerara. Several cases of Mahogany and Guango Seed were despatched to India and Java; and numerous packages of Cinchona Seed were forwarded to applicants in India and Ceylon.

A scientific catalogue of all the plants in the public gardens is in course of preparation, and meanwhile Mr. Morris gives in an appendix to his report a list of the most interesting trees, shrubs, fruit trees, economic and medicinal plants, with their English and botanical names. Mr. Morris says:—

The public are kept well informed, by periodical notices in the local papers, what plants are available for distribution, at any particular season, and I am glad to find that, by these means, a considerable impulse has been given to the distribution of valuable economic plants, which cannot fail to be permanently beneficial. The year was in many respects unfavorable for planting operations, the unusual rains of October 1879 being followed by a comparative drought. At the cinchona plantations the rainfall was 50 inches less than in the previous year—128·15 against 177·46. Before the country had had time to recover from the conditions brought about by these circumstances came the hurricane of August, which did great damage to coffee properties, to bananas and fruit-trees, and to agricultural produce generally. Notwithstanding this, however, Mr. Morris says,

After the lapse of only a few months there are indications of a return to the normal conditions of agricultural pursuits; the Coffee crop, now being gathered, is expected, in many districts, to be a good average; the fruit trade is rapidly recovering and with the great activity generally displayed by the peasantry in opening up and replanting their banana and provision grounds, it may, naturally, be hoped that with a few seasonable showers in the earlier months of the year there will be a renewal of favourable conditions among all agricultural interests.

He then relates how the cinchonas damaged by the hurricane were utilized, and adds:—

The successful harvesting and utilization of Cinchona Bark appears, therefore, to be in a great measure independent of times and seasons, and this experience may well commend itself to all Coffee planters in the Island; suggesting the advisability, if not the absolute need, of combining Cinchona with Coffee cultivation, wherever they can be successfully pursued; thus utilizing the stability and certainty of the one, as compensating for any unfavourable conditions that may arise in the other.

Each garden is then reported on separately, first coming the Castleton gardens, of which we read:—

It is satisfactory to learn that although the loss to the gardens in valuable Economic trees &c. destroyed by the late hurricane was very great, particularly, in Clove, Cinnamon, Nutmeg, Trinidad Cacao, &c., very few species have been entirely lost, and the damage will, it is hoped, be remedied in a few favourable seasons. The *debris* resulting from the storm, was cleared away by means of the ordinary labour of the Garden and without additional grants and Mr. Syme reports "that although the grounds present a somewhat open and ventilated appearance they probably look as well as they have ever done before." During the past year, the principle of charging certain fixed, but reasonable, prices for the valuable Economic plants distributed from these gardens, has been attended with such success, as to fully justify its adoption. Not only has a larger number of plants been actually distributed, but they have been taken up by persons thoroughly in earnest about their cultivation, and likely to give them every care and attention. The total number of plants distributed during the year from this Garden amounts to 26,937, as against, 24,141, distributed in the year 1878-79; the different kinds were represented as follows:—

Trinidad Cacao ...	7,180	Liberian Coffee ...	953
Nutmeg ..	800	Sweet Orange ...	9,074
Clove ..	436	Vanilla ...	239
Cinnamon ...	145	Palms, Orchids, &c.	8,110

Rainfall—104 inches.

Next comes a long report on the cinchona plantations, of which Mr. Nock says:—

"During the year 1879-80 about 50,000 Cinchona plants have been set out in their permanent places. Of these about 43,000 were *C. officinalis*; 6,000 of *C. Calisaya*? and 1,000 *C succirubra*.

A summary is given of the various sub-divisions of the cinchona plantations, as follows:—

1. *Lower Latimer.*—4,800 feet to 5,500 feet; about 30 acres, originally planted in 1868, with Red bark (*C. succirubra*) at distances of from 10 to 12ft. apart. The majority of these trees were uprooted for the bark crops of 1878-79 and 1879-80. A few trees only are left, and these are preserved for seed. It is proposed to replant this area, with good kinds at distances of 4ft. by 4ft.

2. *Upper Latimer*:—5,330 feet to 5,900 feet; an irregular patch of about 25 acres, very widely planted with the Crown bark (*C. officinalis*), the Red bark (*C. succirubra*), and a few of the hybrid variety. These trees are from 4 to 10 years old and number, in all, about 10,000 healthy trees.

3. *Monkey Hill*:—5,900 feet to 6,300 feet. This is

the highest of the Plantations occupying almost the crest of the main ridge of the Blue mountains: about 15 acres; planted entirely with Crown bark (*C. officinalis*), about 11 year ago. This plantaion has yielded the greater proportion of the Crown bark, shipped during the last 2 years.

4. *New Haven*:—5,500 feet to 5,700 feet. A small patch of about 6 acres planted with Crown bark, (*C. officinalis*), of nearly the same age and character as last. About 2,000 trees have already been taken and the remainder are doing well.

On both the New Haven and the Monkey Hill Plantations, the original planting has been completely masked by the abundant growth of self sown seedlings some of which are now large enough to be cropped. These plantations are, in this respect, are the most successful of any, and they will probably yield a succession of valuable crops for several years. Root bark from these trees has realized 10s. 1d. per pound, and trunk bark 7s. 11d. per pound.

5. *White's Piece*:—4,900 feet to 5,400 feet; containing about 8 acres. All the trees, consisting of Red bark and the hybrid variety, between 10 and 11 years old, were "coppiced" on this piece last year and the stumps left to throw up fresh roots. After making a start, many of them died off, and it was ultimately decided to uproot all, but about 200, which are now growing well. After being cleared, this piece is in course of being replanted by the hybrid variety at distances of 4 feet by 4 feet.

6. *Belle Vue*:—4,800 feet to 5,500 feet; containing about 30 acres, very sparsely planted about 4 to 5 years ago with *C. succirubra*. Owing, however, to "dying off" and the severe effects of the late hurricane, the number of trees on this Plantation is now reduced to about 2,000. Under these circumstances, it is proposed to re-line, and re-plant the whole area, at 4 feet by 3 feet, and establish the large leaved Crown bark, *C. officinalis, var. condaminea*.

7. *Upper Buzza*:—4,800 feet to 5,400 feet; containing about 40 acres; of which 4 acres are planted in Jalap. This plantation was opened and planted during the years 1879 and 1880 with the Crown bark (*C. officinalis*) at the top; the Red bark (*C. succirubra*) at the bottom, and some plants of the hybrid variety between. All these are placed at distances of 6 feet by 6 feet, (giving 1,210 trees to the acre) and appear to be well established.

8. *Lower Buzza*:—4,500 feet to 5 000 feet; about 30 acres in extent; planted with Red bark, (*C. succi, rubra*) from 6 to 9 years old; containing about 5,000 healthy trees.

Three nurseries were established during the year containing about a million plants, but these were so damaged by the hurricane that only about a third were saved, which have been chiefly used in planting up the plantations. The principal kinds of cinchona hitherto cultivated in Jamaica were the crown and red barks and the hybrid variety. With regard to the plant or hard Carthagena, brought by Mr. Cross to England and entrusted to Mr. Morris by Dr. Hooker in 1879, we read:

I am glad to be able to report that the plant, so kindly presented to the Government of Jamaica at the request of Sir Joseph Hooker, has been the means of thoroughly establishing this species in the Island. Early in 1880, a number of good plants were successfully raised by Mr. Nock, from cuttings, and five are already planted out in their permanent places; some at 5,000 feet, and others at 5,500 feet, and all are apparently doing well. To those probably several others will be added during the course of the present year.

Of other kinds we read:—

Yellow Bark:—As it was found that the true Yellow barks were not in the Island, efforts were made to procure seeds of the best kinds from India and Java. Through the kindness of Dr. King, a packet of the seeds *C. Calisaya vera* was obtained from the Sikkim Plantations, which has produced about eight thousand strong healthy seedlings. As Calisaya is the source of the Yellow bark of commerce and the most valuable of all the medicinal sorts, this addition to our collections will duly appreciated.

Ledgeriana Bark:—Towards the close of the year the Plantations were enriched by the arrival of three plants of the celebrated *C. calisaya var. Ledgeriana*, a variety which has, hitherto, been almost entirely in the hand of the Dutch Government at Java. These plants were raised at Kew by cuttings from a plant presented by Mr John Eliot Howard, F.R.S., the eminent Quinologist, and Sir Joseph Hooker very generously placed them at the service of the Government of Jamaica. The plants have already been planted out near the Director's residence, and are in a most satisfactory condition. They measure, (December 1880) respectively, 12, 16 and 18 inches in height. Mr. Howard remarks that "*Ledgeriana* is the prince of all Cinchonas." Quite recently bark of Ledgeriana has been sold in the London market at the high price of 14s. 8d. per pound, and bark from Ledgeriana trees grown in Java, has been sold in Amsterdam at 17s. per pound. These remarkable prices show the great importance which should be attached to the due selection and propagation of the best kinds of Cinchona; and though the successful cultivation of the Red and Crown barks, in view of the very satisfactory prices lately obtained, will continue to be remunerative in Jamaica for many years to come, it is obviously prudent to introduce the more valuable kinds, whenever, they can be obtained, for the purpose of giving the enterprise a thoroughly permanent and remunerative character.

Large leaved Crown bark:—Through the kindness of a planter in Ceylon a quantity of seed has also been received as *C. officinalis, var. Condaminea*, harvested at the Government Plantations, Dodabetta, Southern India. This is regarded as a robust large-leaved variety of the true Crown bark, and it is intended to plant about ten acres with it at the Belle-Vue Plantation, in order to test its merits in Jamaica.

Regarding the bark harvested during the year, of which the account sales are given in an appendix, Mr. Morris says:—

On reference to appendix A, attached to this report, it will noticed that four consignments were made within the year, containing in the aggregate 27.299 pounds. The gross return on this quantity was £5,380; leaving after deducting shipping-charges, insurance, brokerage and expenses in England, a nett return of £5,145-19s. The bark, above mentioned, was produced by 8,246 trees, of all kinds, from 8 to 10, and 12 years old; giving an average return of 3¼ pounds of dry bark, per tree, and an average nett value of 12s. 5½d. per tree. Of the 8,246 trees, 210 were of the hybrid variety, which according to returns contained in appendix A, yielded an average of 4½ pounds of dry bark per tree, or a value for each tree of £1 4s. 2d. Of the remainder, 3,945 trees, were the Crown bark, *C. officinalis* yielding an average of 1½ pounds of dry bark per tree, and a value of 9s. 3½d. Again, 4,091 were Red bark trees, *C. succirubra* yielding an average of 4¾ pounds of dry bark per tree, with an average value of 16s. 1d. per tree. Taking the above average values, it would appear that, tree by tree, the hybrid variety was the most valuable of all; but taking into consideration the small number of trees barked, 210, and the fact that they were exceptionally fine specimens, the comparison of these with the 3,945 trees of the Crown bark of all sizes, is not quite a fair test—also with the Red bark, the average value of these trees at 16s. 1d. compare most favourable with the Crown bark trees at 9s. 3½d. Here, again, it must be remembered that the Red bark trees cannot be planted, so closely, as the Crown Bark and they take several years longer

—probably twice as long—in arriving at maturity ; and on our highest ridges where the Crown Bark is, completely, naturalized, it attains maturity in 5 to 7 years, whereas, the Red bark, suitable only for lower elevations would require from 10 to 12 years. This comparison is made on the supposition that the Red and Crown Barks are equally in demand. But as the Red bark is not a good quinine-yielding bark, it is not bought by the quinine manufacturers but the druggists. Hence, if there should be a fall in the prices of Cinchona Bark, from its more abundant supply, and the purposes for which it is used, the Red bark would suffer first ; whereas good Crown Bark from its more abundant per centage of quinine, and larger demand, would always meet with ready sales. Taking the actual returns of the Crown Bark as mentioned above, and assuming that they were planted at elevations, 5,500 to 6,300 feet, and at distances of 6 feet by 6 feet, or at the rate of 1,210 per acre, an acre of this species would give a gross return of £563. From the working expenses of the Government Cinchona Plantations it may be safely assumed that an acre of Cinchona trees could be established, including purchase of land and all expenses up to the third year, for £30, or up to the sixth or seventh year, when the bark would probably be ripe, about £40 per acre. The cost of barking, curing, shipping and brokerage has hitherto averaged about 8d. per pound. This would make a total cost of about £100 to grow and put in the market 1,815 pounds—the produce of an acre—of dry bark realizing £563. As the yield of an exceptional tree, Mr. Nock records the following :—One of the largest trees on the plantations was uprooted and barked on the 7th of April last. It yielded 40 pounds of trunk bark, 5 pounds of twig bark, and 9 pounds of root bark, equal in all to 54 pounds of green bark. This when thoroughly dried was reduced to a total of 16 pounds. At the average price obtained for this kind—the hybrid variety—viz :—6s 1¾d. per pound, the produce of this one tree was worth £4 18s 4d. It may be added that this tree was growing in a sheltered situation in good soil, and was nearly twelve years old, It measured 40 feet in height and a circumference at the base of about 30 inches. The spontaneous growth of cinchonas, especially officinalis, by self-sown seedlings on the Blue Mountains had been already noticed. Mr. Morris adds another fact of the same tendency :—

It appears that in 1867-68, before the sites of the present Government Plantations had been fixed, Mr. Robert Thomson, the late Superintendent, planted out with the consent of the owners, several seedlings in nurseries on Hibernia, Whitfield Hall, Farm Hill, and other estates for experimental purposes. When the Latimer plantation was finally opened in 1868, most of these seedlings were removed—a few only, of the smaller and weaker plants being left behind. The patch planted at Whitfield Hall, occupied a small area at an elevation of 4,800 feet, surrounded by forests about two miles from Whitfield Hall Great House. After the removal of the plants, in course of time, the road to the nursery became overgrown ; and the locality and its associations had apparently passed out of notice. While in the neighbourhood last year, meeting with a man who had assisted in removing the plants from Whitfield Hall to Latimer in 1868, and hearing that a few Cinchonas were still left, I was led to visit the spot in order to examine the trees and their condition after the lapse of so many years. It was evident that, since 1868, nothing, whatever, had been done to the spot. The road was quite overgrown and the surrounding forest was thick and almost impenetrable. The condition of the Cinchona trees occupying an area of about 120 square yards, was, however, very remarkable. By carefully counting them, I found that there were 379 trees on this small area ; some of which were only 9 inches apart. Most of the trees consisted of the Crown bark (*C. officinalis*) ; they were about 20 feet high, with tall clean stems ; the largest measuring 15 inches in circumference at the base, and the smallest 8 inches. Being the remains of a nursery, it was, naturally, expected that some of the trees would be very close and others considerably isolated. They appear, however, to have grown up and completely shaded the ground ; for underneath, the soil was clear of weeds, and covered with a thick covering of fallen leaves. The condition of the trees and the locality in which they were found showed clearly that Cinchona trees thrive best when they are planted closely, together, and when the ground is well shaded and kept cool and moist Moreover, these trees indicated that when a Cinchona Plantation has been thoroughly established and the trees completely cover the ground, (say in the 3rd year from planting), no further attention is necessary till they have arrived at maturity and are fit for barking. As indicating the value of Cinchona planting in the Blue Mountains,—taking these 379 trees, which occupied an area of less than 120 square yards.—it was estimated that if they yielded on the average one pound of dry bark per tree, (younger trees, at the Government Plantations yielded 1½ pounds per tree), each tree would be worth at least 5s.; this would give £94 15s 0d. as the value of 379 trees on an area of 120 square yards—one-fortieth of an acre. Under ordinary conditions it would not, however, be advisable to plant the trees so closely as this, but the value of an acre of land planted with trees even at one-half the above rate would amount to more than £1,890. Large as this sum may seem, it appears that with the precious Ledgeriana Bark, grown by the Dutch in Java, (a few plants of which have just been introduced to Jamaica), the yield per acre, as quoted by Mr. John Eliot Howard, F.R.S., (*Pharmaceutical Journal*, No. 534 *p* 244) is estimated, from actual sales, at £2,000, per acre. The natural inference from these remarks will be,—If Cinchona is so productive a cultivation and these large sums are obtainable with so much ease and facility, will not such large areas be ultimately planted with Cinchona as to lower the prices and render the culture unremunerative ? Commercially, of course, cheapness means small profits, and, as with all other products, so with Cinchona, the supply should not exceed the demand. But to examine these points in detail. The demand for quinine is so extensive, and the terrible death roll amongst all nations of the world from fevers, for which quinine is the sole remedy, is so vast that, there is no prospect, whatever, at present, of the price of quinine being seriously reduced. On the other hand, the prices of good quinine-yielding barks have been steadily rising. Again, when we consider the comparatively small areas in which all the conditions necessary to the production of the best qualities of Cinchona Bark obtain, we shall find that very few tropical countries can enter, successfully, upon the cultivation; and of these, possibly, only two or three will possess in so eminent a degree all the favourable conditions enjoyed by Jamaica. What is, absolutely, necessary is to select suitable sites where the plants will enjoy the requisite climate, shelter, and soil ; to cultivate only the more valuable and quick-growing species, and to establish plantations on systematic and scientific principles, whereby, the utmost value is obtained for the outlay and the conditions of growth carefully studied

Mr. Morris evidently realizes the duty of the Government with regard to the cinchona plantations, as may be seen from the following remarks :—

The demands of the market for the best bark are so extensive that for many years to come the quantity likely to be sent from Jamaica will be very small compared with the extensive shipments from South America, and the East Indies ; but if chief attention is devoted to the kinds which

are rich in quinine and of quick growth, Cinchona cultivation in Jamaica, as already proved by the quality of the produce cannot fail to be a remunerative industry. The objects of the Government in maintaining the Cinchona plantations for so many years, were, I apprehend, not of a pecuniary character—merely for the return they were likely to yield—but, in order, to prove that Cinchona bark of good quality could be successfully grown in the Island. In addition to this, the plantations had an important work in the successful introduction and cultivation of new or richer kinds; and, in such necessary pioneering and experimental work which private enterprise could not, or would, not undertake The first of the above objects having been attained, the plantations may not unnaturally now devote special attention to the propogation and distribution of Cinchona plants for the purpose of establishing the cultivation on a large scale in private bands. Much remains to be done in this respect, and while the plantations are thus engaged, such valuable species as are the result of discoveries or improved methods of cultivation may be introduced, from time to time, and such careful and systematic experiments prosecuted, and made generally knowu, as will place the Island in a position to compete successfully with other countries.

The lands now proved to be so valuable for cinchona culture, have hitherto, been considered of little use. Being too high for coffee they have been almost given away and deemed fit, only, for negro provision grounds. They are tracts of extensive forests clothing the higher slopes of the Blue Mountains. On the Southern slopes it is estimated that, above the line suitable for coffee, there are some 120,000 acres of land on the greater portion of which cinchona may be very remuneratively grown. On the Northern slopes very little coffee has hitherto, been grown,—although that produced is of superior quality; and an extensive zone, quite unopened, about 12 miles long, and four to six miles wide rising from 2,500 feet, to 4,000 feet is still avail ble for this profitable culture. Above 4,000 feet, and up to 6,500 feet, this extensive tract would be most suitable for cinchona cultivation.* I am glad to find that, in one or two instances in which application has been made, the Government has encouraged the experimental cultivation of Cinchona by favourable concessions of portions of these lands and, I have no doubt that, if the circumstances attending cinchona cultivation in this island were more generally known, English capital and energy would soon develop on these hitherto uncleared lands, and in one of the most salubrious climates in the world, a most successful and flourishing enterprise.

With regard to cinchona febrifuge Mr. Morris says:—

It appears that by a simple and inexpensive process, a preparation known as cinchona Febrifuge, possessing the properties of true quinine, can be obtained from cinchona bark at so low a cost as 2s 6d per ounce At the request of His Excellency, the Governor, I prepared, in September last, a Memorandum on the subject, and I hope to obtain such detailed information from India as will place the matter in a practical form. Should the demand for cinchona Febrifuge, in the West Indies, justify its manufacture being undertaken here, there would be a considerable saving effected at the plantations by the utilization of "prunings and thinnings" which often, at present, do not cover the expenses of curing and shipping; while, at the same time, an effective and valuable Febrifuge would be placed within reach of the poorest. It is satisfactory to learn that the Febrifuge is now being tried, in Jamaica, under the direction of Deputy Surgeon-General C.B. Mosse, C. B., Superintending Medical Officer, with the view of carefully testing its merits.

Regarding the cultivation of jalap we read:—

As mentioned in the last Annual Report, the Jalap plants, hitherto, under cultivation here, have been planted among the cinchona trees, but as the tubers were found to exhaust the soil and the vines to injure the young plants, it was decided to remove the Jalap tubers as completely as possible and establish a separate plantation where the comparative results of the cultivation might be more carefully watched. The Jalap plantation, between 4 and 5 acres in extent, occupies the South-Eastern portion of the Upper-Buzza plantation; the ground is laid out in a succession of terraces, about 4 feet wide with drains on the inner side; the tubers are planted about 8 or 10 inches apart, and covered with soil to a depth of about 4 inches. Last year, owing to the soil being fresh and newly cleared, the growing shoots soon after making their appearance were eaten off by "grub," but after the May rains, they started again, and their subsequent growth has been most satisfactory.

It may be added, that, the Jalap bas become quite naturalized on many parts of the plantations and when once established, in a congenial soil, it is almost impossible to eradicate it. Indeed, in many places, it threatens to become a troublesome weed and like the strawberry, (*Fragaria vesca*), to cover the ground (where it caunot find anything to climb upon), with a thick matted carpet of green leaves. The chief difficulties which have been, hitherto, experienced in the utilization of the Jalap crop have been the proper drying and curing of the tubers. In the moist, cool, climate of the cinchona plantations, it was fouud impossible to dry them thoroughly, by exposure to the sun, and, it was proposed to import a fruit-drying machine from America for experimental purposes. The success which has attended the curing of the cinchona bark at the Parade Garden, Kingston, has however, suggested the possibility of a similar treatment for the Jalap tubers, and it is intended to send the coming crop to the plains to be cured.

The Palisadoes plantation is chiefly an experimental coconut plantation. We read:—

Nearly three thousand more plants have been put out, bringing up the total number of trees of all sizes to twenty-three thousand. The trees, in bearing, have been carefully counted by numbers marked upon them (as they come into bearing), in red paint. During the year, the bearing trees have increased from one thousand five hundred, to three thousand three hundred. The yield of the plantation for twelve months has been forty-nine thousand nuts, of which four thousand have been utilized in the nurseries. The remainder are being sold locally, at rates varying from 65s to 70s per thousand. Supplies of young growing plants have been distributed, free of charge, for planting on the Pedro and neighbouring Cays, at Port Royal, and other places along the coast, where they might be useful as land marks, or, as affording shade and ornament. A case containing coco-nut leaves, carefully dried, has also been forwarded to Kew, for the purpose of enabling Dr. Hugo Müller to carry on his researches on the occurrence of quercite in members of the palm family. We may expect to have Jamaica as a rival in the manufacture of coconut products, if Mr. Morris's suggestions are carried out:—

Now that the trees are coming into bearing, it has naturally been suggested whether some means might not be adopted for utilizing its resources for the manufacture of coconut oil and coir. As a first step in this direction, it is proposed to prepare a quantity of copra, (the kernel thoroughly dried in the sun), and send it to the English or American market in order to test its value. For this no machinery is required, and as it is a wellknown and lucrative article of ex-

* For the information of those contemplating taking up Cinchona cultivation in Jamaica it should be understood that these lands are, for the most part, quite unopened by roads and from 30 to 40 miles from Kingston.

port in other countries, there is no reason to doubt that it will prove, equally so, in Jamaica. In view, however, of the numerous advantages to be derived from the local manufacture of coconut oil and poonac, (the residual cake) and of the many purposes to which coconut fibre, properly prepared, may be applied, the desirability of establishing coconut mills, with suitable machinery, is a question which must yearly suggest itself in view of the increasing returns from the coconut plantations in this island. It is true, that the English and American markets are capable of utilizing, at fairly remunerative prices, all the nuts that may be sent them, but the advantages to the island in the sale of nuts are not at all comparable to those which would arise if the local manufacture of coconut oil and coconut fibre were undertaken, and carried on in an efficient manner.

At Hope plantation, we read,

The *Sappan*, an East Indian dyewood, of great value, appears to grow with great vigour, and plants have been largely propagated.

Of the Bath garden Mr. Morris writes :—

This interesting remains, of what was the only Botanic Garden, of the Colony, for more than eighty years, is still maintained for the sake of its valuable trees and palms. I regret to record that, during the late hurricane the fine Pinus in the centre of the garden was blown down and that two valuable nutmeg trees were lost. During the past year. I have endeavoured to increase the usefulness of this garden by establishing nurseries of Liberian coffee, cacao, nutmeg, cinnamon, &c., &c., in order to render it available for the distribution of these plants in the Eastern portions of the Island. As already mentioned in a report, published after my first visit to the Bath Garden, this district appears to be eminently adapted for the successful cultivation of most tropical plants requiring a rich soil, and a warm, humid climate. The plants of Liberian coffee, already, growing in this and the Plantain Garden River district, are among the most promising in the Island, and if cacao and nutmeg were added, these would constitute sources of industry particularly suitable to the wants of the people, and likely to be most productive and successful.

Mr. Morris's remarks on Liberian coffee are substantially the same as those quoted by us from his separate pamphlet on the subject, Of cacao we read :—

In the propagation and distribution of this valuable product attention has been almost entirely confined to the best kinds of Trinidad Cacao. From trees of these varieties imported in 1873-74, a large supply of pods have been gathered and about 12,000 seedlings established in bambu pots. Several cases of pods have also been obtained direct from Trinidad, which had been carefully selected and packed under Mr. Prestoe, the Government Botanist's personal supervision. As the ultimate success of cacao cultivation, in Jamaica, will depend on the nature and value of the produce, the first consideration of every planter will naturally be the selection of the best varieties as seed trees. From these, when established, he will be able to extend the cultivation, selecting again those varieties which appear to be most suitable to the particular circumstances of the soil and climate. This must naturally be a slow process, but I would at the outset of what possesses all the elements of a sound and successful enterprise, recommend that, only the best varieties of Trinidad cacao be planted at first, and that the cultivation be kept carefully free from such deteriorated and worthless varieties, as will only lead ultimately to disappointment and loss. Efforts are being made through Dr. Ernst, to introduce some of the best varieties of Caracas cacao, About fifty plants of Trinidad Cacao have been lately planted at the Hope, in the neighbourhood of the land irrigated by the water courses, and they have hitherto done, well. Owing to the effects of the hurricane no pods are expected to be produced on the trees at Castleton for some time, but the stock of plants already established, will, it is believed, be sufficient for present requirements. The collection at Castleton has been increased by planting out 54 plants during the past year, in the old canefield, where they are doing well. On the general distribution of Trinidad cacao from the Castleton Gardens, Mr. Syme makes the following report :—

"Plants of this variety are in great demand, but, strange to say, it is by the well-to-do of the community. It is to be regretted that the peasantry, settled on some of the best cacao-growing lands of the colony, do not cultivate more of this plant. One reason for this is that they are disheartened by the raids made on the pods and their contents by the rats. It would well repay them for the trouble and expense of systematically poisoning and otherwise preventing the rats from getting to the pods; or by simply training the young trees to a single stem for a height of from 4 to 5 feet, and then fixing a piece of sheet tin around each stem." Although Cacao cultivation was an important industry in Jamaica about a hundred and fifty years ago it had so declined that twenty years ago the only trees in the Island were a few inferior kinds scattered here and there in settlers' gardens. Owing, however, to the encouragement given to the industry by Government, by introducing the best varieties of Trinidad Cacao and disseminating information on the cultivation and curing of this important product, a decided improvement has, lately, taken place, both in the quantity and quality of the exports.

Tobacco and vanilla are also favourably reported on. Of indiarubber it is said :—

A Wardian case, containing a number of Landolphias or African rubber plants was lately received from Kew, and they are a valuable addition to the India rubber plants already in the Island. Mr. Syme reports that they are doing well, and are readily propagated by cuttings from twigs. Of the India rubbers, already introduced the most promising is the Ceara rubber tree, (*Manihot Glaziovii*), a native of Ceara, a coast town and district of Brazil in lat. 4° 5′, possessing "a very dry arid climate for a considerable part of the year." This plant is, evidently, of a very hardy character and adapts itself readily to the exigencies of culture. Plants at Castleton, (600 feet), and at the Farade Garden, Kingston, (50 feet), are doing well. At the former gardens young trees when about 9 to 12 feet high were beginning to flower, but the hurricane deprived us of the hope of procuring seed this year. Some four or five hundred seeds, received from Ceylon, will, however, afford good opportunities for further extending the cultivation Judging by reports received from S. America it is possible that extensive tracts of dry, and stony almost worthless lands, in the plains, may be turned to good account by means of this cultivation.

Of the Pará rubber there are only two plants in Jamaica, and of the *Castilloa elastica* none. Mangoes are doing well, the areca grows and fruits freely, and the kitul quickly attains to maturity and an immense size. Another staple of ours is reported on thus :—

A plant of the best variety of Ceylon Cinnamon was brought out from Kew early in the year. It has been planted out at Castleton and under Mr. Syme's care is growing freely. From what has come under my observation, it appears that there are two kinds of Cinnamon in the Island. One is undoubtedly a form or variety of the Ceylon Cinnamon, *C. Zeylanicum*, but, whether, owing to the nature of the soil and climate or to deterioration from other causes, it does not appear to possess the delicate aroma, taste and colour, of the true Ceylon Cinnamon. The Cinnamon tree, even, in Ceylon, varies in a peculiar manner ac-

cording to the character of the soil and rainfall. The natives of Ceylon reckon the variety known as, *Rase Corundu*, as the only genuine kind; six others, almost indistinguishable botanically, are considered spurious. As a plant of the true kind is now, in the Island, it will soon be possible to test the influences of the soil and climate of Jamaica upon it.

The demand for nutmeg plants is great, but this is not the case with cloves. The report closes with remarks on fibre-yielding plants, fodder plants, and vines.

CULTIVATION OF THE RHEEA PLANT ON TEA LANDS.

The species Urtica (*Boehmeria*) *nivea*, belongs to the genus *Urtica* [Stinging Nettles], which form the type of the Natural Order Urticaceæ—the Nettle and Fig Family. The species *Boehmeria nivea* is the Rheea of Bengal, and is also known by the name of the "China Grass" and "Grass-cloth" Plant, as the investigations of Dr. Falconer have proved it identical with the plant that yields the celebrated grass-cloth of China. It is "an erect shrub, with alternate, cordate leaves hoary beneath, and small, dioecious, greenish yellow flowers, in axillary, pedunculed, globose heads."* It bears no sting. The plant is remarkable for the tenacity of the liber of its bark, which yields a remarkably fine fibre, and from which the so-called "grass cloth," a most delicate fabric, is prepared.

Textile manufacturers are endeavouring to bring it into use as a substitute for, or at least an addition to, cotton, wool, flax, hemp, and jute. In 1803 some specimens of the *Urtica tenacissima* from the Malayan Islands and Peninsula were placed in the Botanical Gardens. This led to the cultivation of the plant in other parts of India. In 1814 a quantity of the fibre was sent to England, and favourable reports were received of its probable usefulness. But a difficulty has stood in the way of the development of regular industry in the fibre of the Rheea plant. There is no process, nor machine, that will properly and efficiently separate the bark and fibre from the stem, and the fibre from the bark. This is a problem yet to be solved. In 1870 the Government of India offered two prizes to the inventors of the best machine or process for its manufacture: the offer was renewed in 1877, but up to date no satisfactory results have been achieved. The Government therefore do not deem it advisable to renew the offer of rewards until—

"Private enterprise has shown that the cultivation of the plant can be undertaken with profit in these or other parts of the country, and that real need has arisen for an improved method of preparing the fibre in order to stimulate its production."

We are told however that:—

"Rhea is naturally an equatorial plant, and it requires a moist air, a rich soil, and plenty of water, while extremes of temperature are unfavourable to it. Such conditions may be found in parts of Burmah, in Upper Assam, and in some districts of Eastern and Northern Bengal: and if Rhea can be grown in such places, with only so much care as is required in an ordinary well-farmed field for a rather superior crop, it is possible that it may succeed commercially."

Although the Government have withdrawn their offer of rewards, they have not withdrawn their aid *in toto*. For in their report we read:—

"But in order to aid persons who are anxious to try the cultivation of the plant in localities which are *primâ facie* suitable, the Government will be willing to place roots at their disposal. A plot of about 2 or 3 acres will, therefore, continue to be kept under Rhea in the Botanical Gardens at Howrah for the supply of roots to intending growers."

Now that Tea is giving such poor returns, any thing that may pay to grow, in addition to the tea plant, will no doubt be welcomed by all Tea Proprietors and Tea Planters. Why not try the Rheea Plant? Although no efficient process nor machine has yet been discovered suitable for separating, cleaning, and dressing the fibres, if the industry is taken up on a large scale, machinists will no doubt soon invent machines that will answer the purpose. If Planters will turn their attention to its growth, and to the process of manufacture of the fibre into a suitable form for the spinning and weaving factories, we feel sure that the requisite discovery would soon be made, and the problem solved. It would then go well hand in hand with the cultivation of the tea plant, and the two industries combined would no doubt yield as handsome returns as any other in the world.

The strong fibres obtained from the plant by simple maceration, are used by the natives for many useful purposes, but the working of them up for textile goods is the difficulty which has to be overcome. The natives simply scrape the fibres to fit them for making twine, thread, fishing nets, &c. One of the necessary conditions essential to success, is that the fibre should be rendered saleable in India at a price not exceeding £15 per ton. The subject has attracted very great attention of late in England and France, and even in America to some extent. Renewed attempts are being made to introduce the fibre into European factories. The Chambers of Commerce of Liverpool, Leeds, Bradford, and Belfast, have taken up the matter, and the spinners of Yorkshire are experimenting on various mixtures of the fibre with wool and cotton, and trying the suitability of the mixtures for making fancy trimmings, ladies' dresses, and upholsterers' textiles; the fibre possessing qualities unlike those of any other material employed in textile work.—*Indian Tea Gazette.*

* Oliver's First Book of Indian Botany.

CINCHONA BARK.—Large supplies of cinchona bark continue to be sent to England by the P. and O. canal steamers. About four hundred bales of bark were put on board the steamer "Ancona" last Thursday.—*Madras Standard*, 15th April.

COFFEE LEAF DISEASE.—Mr. Schrottky is quietly but steadily going on with his treatment. He has operated on 250 acres in the Dumbara valley, and will begin on a similar extent in the Dimbula district in a few days. Mr. Schrottky has also been making experiments of great importance in reference to cinchona cultivation, but we are not at liberty for the present to refer more particularly to these.

NILGIRIS, March, 1881.—A great deal of the tea produced in the Nilgiris is sold in the Presidency I am told, and, most likely, much more would find a local market if planters would be content with a moderate price. I judge they ask exorbitant figures, from the quotations of retail merchants in the advertisements. This may not be so; but anyway the shops should be able to sell Pekoe Souchong at 0-12 instead of R1-8! Tea is generally cured here by means of a furnace and iron plate, with drawers on top. There seems to be a degree of laxity in tea-making, sorting, and packing, in this district, which requires thorough reform; but this is a subject for a letter in itself. But Tea planters must not pose as the only unfortunates. The local paper has the following:—"The coffee crop of 1880-81 has been a most unfortunate one. Estates estimated to yield 60 to 70 tons gave only 4 and 5, while others have absolutely no crop at all. It is a mystery what became of the fine show of blossom early in the year."—*Indian Tea Gazette.*

TOBACCO CULTIVATION IN INDIA AND CEYLON.

There is hardly any part of this vast country, from Peshawur to Cape Comorin (or Dondra Head), in which tobacco of some sort or another cannot be grown, and is grown for native consumption. Naturally, as with any other plant, some soils and climates suit it better than others, and at present Madras and Burma claim the reputation of producing the best leaf. There appears to us, however, no reason why, with proper care and attention in the cultivation and curing, as good tobacco should not be produced in Bengal, or elsewhere, as in the two parts of the country which have already acquired a name for it. Nay, as a fact, it is already produced, and consumers of Madras and Burma cheroots may be surprised to hear that a good deal of the tobacco of which those favorite brands are made is first exported from Bengal, and then returned here in the shape of genuine Madras or Burma cheroots. Some of it also, perhaps, re-appears in the disguise of the genuine Havannah, for there is a large quantity of tobacco exported annually from this country to Germany, and a good many of the cigars sold here as Havannahs are manufactured in the neighbourhood of Berlin. The consumption of tobacco throughout the world increases annually in a larger ratio than the population, and it has long been a matter of surprise to us that greater efforts have not been made to increase the cultivation and improve the manufacture of tobacco in this country. An experiment on a moderate scale has certainly been tried by Messrs. Begg, Dunlop & Co. at Ghazipur and Pusa, during the last few years, and the results, the report of which for the year 1879-80 is now before us, are, we consider, quite sufficient to justify not only those gentlemen in extending their manufacture, but to induce others to follow their example.

The chief operations of this firm are at Pusa, in the Durbhanga district of Behar, carried on under the supervision of European and American managers and curers, and employing about four hundred natives. In 1877-78 the quality of cured leaf exported was 29,993 lb., which sold at an average of about 3½*d.* per pound, an excellent average for the first year's curing, as it was the same average rate as that at which American tobacco was then selling in England. The French Government were also so favourably impressed with the samples they examined that they at once gave an order for forty maunds, and enquired to what extent the supply might be relied on. This seemed to promise a good opening, but the present proprietors do not appear inclined to extend their operations. In the next year they only increased the area of cultivation by 75 acres, and the season turned out very wet and therefore unfavourable to the proper curing of the leaf. Other causes also operated to prevent an extension of the export of the produce, though we should have thought that these would have conduced to a more extended cultivation. We are told that the demand for the tobacco in the Indian market developed so rapidly that it was soon found that, with the present establishment and the present extent of cultivation, the firm would have for a time to give up any idea of competing in the European field; for the enterprise has not yet become sufficiently strong to carry on the struggle in both places. The insufficient quantity of the outturn during the last two years, the initial expenditure incurred in importing machinery and training up hands in the manufacturing processes, the greater certainty of success, the immediate and higher profit expected in this branch of the industry for the capital (R 1,00,000) which the firm have sunk—all decided them in favour of confining themselves to manufacturing to meet the demand for local consumption. How long a time will elapse before the firm again finds itself in a position to export, it is difficult to say; year by year the extent of operations is increasing, but large supplies of tobacco cannot be available for export until the Indian market is thoroughly satisfied.

Here then is a fine opportunity for others to compete, for the Indian demand is not adequately satisfied, and the foreign markets may be said to be untouched. For the benefit of any one who may feel inclined to engage in the enterprise we add a few lines as to the system of cultivation adopted, which is as follows:—For tobacco some rotation of crops is practised and cultivators seldom sow it on the same land for three years together. The crop generally preferred to precede it is the root crop, *Batatas edulis* (shakarkand), extensively used as food by the poorer classes for some months in the year, which is sown in the rains and dug up in the cold weather. After this, or some other rabi crop has been taken off the field, the land is well dug with a hoe, and then ploughed twice every month. The manure used is chiefly cowdung, which is thrown on the land, or cattle are penned on the ground. Land being thus well-ploughed and well-manured, is fit for planting with tobacco on the cessation of the rains in the month of September. The seed is first sown on a seed-bed from which the young seedlings are transplanted to the field. After this, it requires very little care, except a little weeding and picking off the superfluous shoots, leaving ten or twelve leaves on the plant. No irrigation is necessary; a little water is only allowed for two days at the time of transplantation. The crop is ready for cutting in February or March. The yield of an acre is from twelve to twenty maunds, which is generally sold at R5 to R8 per maund. It must be remembered that the coarse thick leaf produced by natives on their field, by the excessive use of nitrogenous constituents, does not answer the purposes of the factory. Finer leaf, with considerably less acrid taste, is only fit for curing purposes. The outturn per acre of leaf for the factory is therefore estimated at 800 lb. instead of 1,600 lb. (20 maunds), as in the native-cultivated land. Indeed, the outturn at Pusa during the last two years did not exceed 600 lb. per acre, owing to the finer texture of leaf grown, and to the land not being so heavily manured with animal matter as the native lands. But all the leaf produced in a tobacco field does not give prime tobacco. An acre generally produces about 10,000 plants, of which one-fourth gives first class tobacco; one-fourth, second class; and the remaining half, third-class tobacco. All these classes will give a total weight of about 600 lb. of marketable article.

As to the cost we learn that the price paid for an acre of tobacco (600 lb) is about R40, or 15 lb. per rupee, or a little above one anna per lb. The cost of curing is very small, probably not exceeding more than a rupee for 100 lb. The cost of growing and curing tobacco has thus been reduced from what was estimated by Mr. Buck, in his report of the 18th October 1876, *viz.*, 5*d.* per lb. delivered in England, and it is now considered possible to deliver cured tobacco in England at 3*d.* per lb. with even a small profit.

We think that we have now said quite enough, backed up as we are by official reports, to show that tobacco manufacture in India ought to prove a most profitable investment, if properly managed.—*Asian.*

The largest sale for artificial fertilizers is in the South Atlantic States, the lands in which have become impoverished by cotton and tobacco culture.

It is estimated that the manurial products annually emptied into the river Thames by the sewage of London, if applied to a barren soil, would impart to it a productive power capable of feeding 150,000 people.

A ton of cotton-seed meal contains 38 pounds of potash, 56 pounds of phosphoric acid, and 78 pounds nitrogen. A ton of average barnyard manure contains 12 pounds of nitrogen, 6 pounds of phosphoric acid and 13 pounds of potash.

ROYAL BOTANIC GARDENS, CEYLON.

REPORT OF THE DIRECTOR FOR THE YEAR 1880.

I TOOK over the charge of the Gardens on 20th February, a few days after Dr. Thwaites's retirement. During the remainder of the year the ordinary routine duties of management and maintenance have been carried on, and require no further mention here. Since, however, some new departures have been made and changes introduced, it may be well to put on record the character and condition of the Gardens, and the directions in which I am desirous to further develop them and have already commenced to do so.

I.—PÉRÁDENIYA GARDEN.

The principles of management consistently carried out in these gardens for many years past aimed at the preservation, to as great an extent as possible, of their natural character. The result has been all that could be desired in that respect, and their luxuriant and tropical wild beauty has been a characteristic feature of the gardens. Trees were rarely felled but allowed to decay, new ones were planted without regard to their surroundings, crowded together and never pruned, and the struggle for existence permitted to go on almost unchecked.

The result of this was naturally the predominance of some plants and the more or less complete destruction of others. Few were able to exhibit their full proportions and complete development; even the flower-beds, never weeded, formed dense thickets under the shade of large trees, where it not unfrequently happened that rare and interesting species were choked and barely alive from the inordinate luxuriance of some dominant but worthless weed. The same principles forbade any arrangement or systematic classification of the plants in accordance with their affinities, or the attachment to them of any explanatory labels. In short, many portions presented more the appearance of a beautiful wild jungle, where plants from the tropics of all latitudes strove for the mastery, than of a scientific garden for the public utility.

My first duty seemed to be to ascertain the contents of the garden, but in the absence of labels, of any fairly complete or properly arranged catalogue, and of available detailed records referring to the past, this work will be one of some duration, and is only partially carried through. During the explorations necessary for this purpose, several successive portions of the garden have been opened out and greatly improved. The accumulated débris has been taken away, numerous dead, dying, and unsightly trees and shrubs have been removed, and those harmful from shade felled. The greatest care has however been taken to conserve every specimen of interest, and of course all unique specimens; some have been re-planted in more favourable positions, and thus others have had the opportunity afforded them of attaining their true development and taking their natural form. By the sacrifice of common and often-repeated sorts room has been also gained for planting additional species. Much more similar work has yet to be done.

The grand scenic character of the gardens is due largely to the magnificent trees—palms, bamboos, and figs especially—which they contain. Effective objects of this kind it has been my endeavour to isolate and enhance in value in the landscape; and I have not hesitated to take off unsightly or superfluous portions, and to clear away native wild vegetation and inferior specimens which destroyed their symmetry or hid the proper display of their beauties.

Roads.—These are numerous and remarkably well planned and constructed. By far the greater part are adapted for carriages, a point of some importance in a tropical garden. It is worth putting on record that the total length now open extends to nearly four miles of carriage drives and one and a-half mile of foot-paths. All are in excellent repair, but require constant attention, especially after heavy rain. In places a better system of drainage will have to be employed.

Buildings.—An addition to these is the house lately vacated by a clerk in the employ of the Public Works Department, which has been put into thorough repair, and is now occupied

by the draftsman of this establishment. A small grant has enabled this and other pressing repairs to be carried out. The clerk's and gardener's offices, the store, and the entrance lodge have all been put into good order, and a new and substantial carpenters' shed and a new plant-shed erected. Repairs have also been made in the houses of the head gardener (lately in occupation of the draftsman) and the plant-collector, and the more pressing wants of the "Assistant Director's" bungalow (occupied by the Cryptogamist) have been supplied. The roof of this house is however in a very unsubstantial condition, and requires thorough renewal. The roof of the herbarium building is also in a leaky state, and needs further attention.

The young plants and cuttings in the plant-sheds suffering from want of light, windows or sky-lights of glass, so far as it could be obtained, have been inserted in the roofs, and shelves and trestles erected.

Improvements at Entrance.—The approach to the gardens from the high-road was (as remarked in the Report for 1870) inconvenient and unsightly. It afforded access only from the Kandy direction, and turned into the gate at a dangerously sharp angle. In the Pérádeniya direction was a foot-path only, made four years ago. Both these have been enclosed, dug up, and grassed over, and two short carriage roads of easy gradient and symmetrical curves have been formed from the high-road to the gate. The triangular space thus enclosed has been levelled and turfed, and the hedge replaced by an iron fence sixty yards ong. In thus forming an entrance more worthy of the garden it was necessary to sacrifice ltwo of the trees of *Ficus elastica* on the right hand of the gate; the effect has been greatly to enhance the striking appearance of the grand avenue of the same species on the left hand side, so much admired and now much better seen. The fine mahogany and star-apple trees remain as before, and some fresh ornamental trees have been planted. The steep bank which here forms so good a protection and screen to the gardens has been draped with large ferns and foliage plants.

The well-known palm-grove just within the entrance (as well as the newer one in the circular road) has been carefully gone over. Its beauty had become somewhat impaired from the great height many of the trees have attained. The bare dead stem of one of the talipot palms which flowered in 1877 has been felled and its base converted into a seat; it measured sixty-eight feet in length and twelve feet in circumference. A few other specimens have been taken out, and brushwood and undergrowth removed; and two young talipots and several specimens of other and fresh species planted. The ground under the trees has been carpeted with small ferns and selaginellas.

Ornamental Lake.—A principal want here has been a piece of water suitable for the growth of aquatics and as an ornamental feature. The new water supply, completed last year, has now allowed the transformation of a small muddy pond in the southern part of the garden into some approach to an ornamental lake. It has been cleaned out and enlarged, the banks sloped and turfed, many trees and bamboos surrounding it cleared away, and an unsightly piece of jungle and a rubbish heap in the neighbourhood removed. A constant supply of water, brought by an open channel 650 ft. long, falls into this little lake which is about 30 ft. above the river, from which it is only separated by a steep wide bank probably permitting some soakage. Several of our more ornamental native water plants are now growing here, and it is hoped that some more striking exotic species will soon be added. But unless the water can be emptied out, and the bottom, which is very foul, be properly puddled to an uniform depth, little success can be hoped for.

Grass.—The fine stretches of grass which give such a park-like aspect to the garden are a source of heavy and constant expense. More than one-third of the whole expenditure on labour is absorbed by grass-cutting, which is nearly always going on. It is wholly effected by the primitive method of reaping with heavy grass-knives and never succeeds in producing anything like a turf, as it is impossible to do it with sufficient frequency. Nothing would more tend to improve the grounds than greater attention to the grass: were this once properly levelled, cleared of stones and weeds, and the coarse grasses and other plants kept short and never permitted to become rank or to seed, the wild untidy portions could be readily and quickly replaced by fine dry lawns of short tuft. I therefore urgently request to be provided with means to purchase a large mowing machine for bullocks, and I feel confident that the large first cost will be quickly repaid by the saving of labour, which

will also then become available for attending to other parts of the garden which now too often suffer from the imperative need of the grass-cutting.

New South Garden.—About sixteen acres of land at the south of the course of the old Colombo road, and extending to the satin-wood bridge have hitherto not been brought into cultivation, but have for many years lain in an unfenced and neglected condition, a tangled scrub of coarse weeds traversed only by a few cattle on their path to the river bank. A preliminary clearance of this adventive vegetation revealed the ground to be much undulated and picturesque, and the soil in parts appears to be superior to that in most portions of the garden.

I propose to lay out this area mainly as a systematically arranged scientific garden, as represented by a classified collection of trees and shrubs and of herbaceous plants. But space will also be afforded for new nurseries and for growing a larger stock of plants of commercial value for the benefit of the planters and others and for experimental purposes.

Another feature of this new portion of the garden will be a fine drive, connected (at the lake) with those already existing, and passing near the river bank almost to the satin-wood bridge, commanding pretty views. This road has been commenced and will be pushed on to completion as rapidly as possible.

I venture to urge the necessity of a sufficient protection to this addition to the garden, along the high-road. A hedge of dwarf bamboo has been planted, but this is not sufficient to keep out cattle and other marauders. The only effectual protection is an iron wire fence, and this I consider to be very necessary. The length required is 305 yards.

Labelling.—The utility of a public Botanic Garden is greatly increased by a judicious system of labelling. Indeed without it little more than a feeling of admiration can be experienced by even intelligent visitors, and this is often mixed with a sense of confused dissatisfaction. It has been customary here to accompany visitors over the grounds and attempt to supply by word what could be far better conveyed by the eye, but the objections to this as a regular practice are obvious.

A really good permanent label for a moist tropical climate is still a desideratum, nor is a single sort possible for universal adoption. I am also limited as to cost. For interesting, valuable and striking species I intend to employ printed labels cemented by resin between two plates of thick glass, and the whole enclosed in a painted zinc frame. A few of such labels have been set up and found to answer very well. The ordinary labels will be of white metal with black letters.

Each label gives, besides the scientific name, the English and Singhalese ones (where such exist), the natural family to which the plant belongs, and its native country.

The new systematic garden will also be carefully labelled, and in connection with this I hope to complete a full systematic catalogue of the contents of the garden to supersede the preliminary list printed last year. How eager the public are to acquire any help towards a knowledge of the contents of the garden is seen by the comparatively large sale of that catalogue; but a small guide pointing out the chief plants of interest would probably be of more general utility to visitors.

Propagation.—As may be seen by the amounts given below (§ vi.), the sale of plants and seeds has now reached a considerable magnitude. The sum thus accruing and returned to the Treasury has been more than double as much during the year 1880 as during the previous one, a result partly due to a system of quarterly advertisements in the principal newspapers, initiated in June. It is certainly not in my opinion an object to be aimed at by a State Botanic Garden to bring in a revenue. In the absence however of any professional florists or nurserymen in the colony, the garden must continue to do their work, however more satisfactorily the time and labour thus spent might be employed. But it may be hoped that this will gradually cease.

A great assistance and relief to the staff has been effected by the appointment of a head gardener. Mr. Clark, who was selected by the Director of Kew Gardens for the post, arrived towards the close of the year. He at once initiated changes and additions to his department. A temporary hot-bed has been erected, and a potting-house and other conveniences made; an open orchid house or shed has been commenced, and the work properly distributed. I have every reason to expect that a greater measure of success in the raising and propagation of foreign plants will result from this appointment.

The soil of the present nurseries, which have been in use for over half-a-century and are much exposed to the N.E. wind, being greatly impoverished, I propose to make fresh ones in the recently cleared south garden.

The principal want in this department is *glass*. A few glass frames are required for raising grafts and cuttings and protecting young plants from drip, draughts of wind and rapid changes of temperature, whilst yet affording light. Hitherto old Wardian cases have been generally employed.

A still more pressing need is glass roofing for the plant sheds (or one of them), and the orchid-house, which is at present thinly thatched with grass in the manner so successfully practised at Calcutta, but not suited to a purely tropical and very moist climate like Pérádeniya. This glass should be obtained from England, and its cost would not be large, though beyond the ordinary means at my disposal.

A well-shaded rockery has been formed near the office and store, and planted up with (chiefly) native ferns, ground orchids, sonerilas, balsams, acrotremas, &c.

II.—Hakgala Garden.

The Superintendent has been engaged during the year in the formation of a new Plantation of *Cinchona Ledgeriana*, in barking and preparing for the market some trees of *C. officinalis*, var. *crispa*, in digging out and barking stumps of old *C. officinalis* and *C. succirubra*, and in re-planting a portion of the ground with var. *crispa*. He has also succeeded in raising some Himalayan and other conifers from seed.

The water-course in this garden still requires some attention from the Department of Public Works, the masonry work having been left in an unfinished state.

There is room in Hakgala for very great improvement in almost every respect, and in accordance with the desire of His Excellency the Governor I have lately submitted a plan for its more efficient management. As the details of this are still under consideration, it is not at present possible to say more than that they are framed with the object of rendering Hakgala garden of greater and more varied usefulness to the Colony.

III.—Henaratgoda Garden.

Each year appears further to demonstrate the utility of this branch, the management of which is very satisfactory. The trees and plants are well cared for and in good health; a new nursery for the propagation of Para India-rubber has been formed, as well as fresh plantations of Liberian and Jamaica coffees and of cacao. The various new economic plants suitable for hot-country cultivation sent from Pérádeniya to a more congenial climate have been carefully planted out, and are well attended to and flourishing.

Several large trees of *Ficus modesta* have been felled, being found to injure the young plants beneath; the walks have been partially remade, and a bamboo fence has been erected round such parts of the boundary as were specially liable to the trespass of cattle.

The bridge at the entrance to the garden which had become dangerously insecure has been repaired.

IV.—Economic and Useful Plants.

Coffee.—In spite of the great impulse lately given to the cultivation of other plants, which is still gaining strength, coffee remains unquestionably the staple product of the Island. In view of the continued prevalence of leaf-disease, one of the earliest hopes of the planters was the introduction of new varieties, it being, not unreasonably, thought that in some of these there might be found to reside a greater power of resistance to the growth of *Hemileia*. With this view His Excellency the Governor obtained from the Jamaica Government a considerable supply of seed of the best Blue Mountain coffee there cultivated. This, as stated in last year's report, germinated well; and by desire of His Excellency, young plants to the number of over 26,000 have been distributed free of charge to such planters as cared to possess them. I regret to say that the hope expressed by my predecessor in the report just referred to has by no means been realized. The disease attacked the seedlings with remarkable intensity, and not a few actually succumbed under it. It is worth remarking that a small plantation of this variety made at Henaratgoda is in a very healthy condition, the plants, now one year old, three or four feet high, and commencing to flower. It will be interesting to watch the further development of these at so low an elevation.

By the kindness of Messrs. Leechman I have had the opportunity also of growing seed of a coffee from Nakunaad, Coorg, which had a reputation as "disease resisting." It is however now suffering from a bad attack.

Mr. S. M. Kay-Shuttleworth brought from Java seed of nine varieties of coffee there grown, all of which we have raised at Pérádeniya. One of these is a remarkable plant, with very narrow leaves, and perhaps may be distinct species. All have been attacked by *Hemileia*.

There is indeed very little reason to suppose that any variety of *C. arabica* is "disease-proof." Even other species are the hosts of the Hemileia parasite ; our native wild species, *C. travancorensis*, and the African *C. liberica*, are both susceptible ; yet it by no means follows that all suffer equally in health. It is fortunately not necessary for me to attempt to go further into this matter, as the whole subject of "leaf-disease" is undergoing an exhaustive examination by Mr. Marshall Ward, specially appointed for the purpose and attached to this Department. During the year Mr. Ward has published two able and original papers embodying the results of his investigations into the character and structure of the fungus itself, the mode of its life in the coffee leaf, and the precise nature of the damage it works. A true knowledge of the disease is thus being steadily completed, and the progress already made appears to me to be highly encouraging for the future.

Liberian coffee has now taken its position as a valuable crop in the lower districts. The beautiful naturally-grown trees in Pérádeniya continue to bear well. It is to be regretted that the efforts made to induce the natives of the low-countries to take up this culture, so eminently adapted for them, have had such slight results. A box of seeds has been sent to the Maharájah of Travancore at his Highness's request.

Tea.—Hopes are entertained that a market may be found for this product in the Australian Colonies, samples of Ceylon-grown tea sent to the Melbourne Exhibition having met with much appreciation. This has given a great impulse to the cultivation in our planting districts. A box of seeds has, at the request of the Director of the Botanic Garden at Manilla, been transmitted to that place.

Cinchona.—An impulse has been given to this cultivation during 1880 unparalleled in any previous period, and indeed it may be said to have become general, to a greater or less extent, on all estates in suitable situations. It is principally *C. officinalis* and *C. succirubra* that are being so extensively grown ; of these, many planters have now very extensive nurseries, and little or no seed has been purchased from Hakgala. Nor is it necessary for the Government to continue any further large propagation of those species.

The remarkable suitability of the climate of our higher elevations for *C. officinalis* is very evident, but at heights below 4,500 feet it appears more desirable to grow other sorts. This species shews considerable variation in the form of leaf, ranging from a narrow lanceolate up to a broad oval. A large-leafed form much in favour from its quick growth (often but incorrectly termed *C. condaminea* in Ceylon) may not improbably be the result of crossing with *C. succirubra*. The narrowest-leaved variety *(C. crispa)* has been grown at the Hakgala plantations since their establishment, and thence spread over the estates. As it appears admirably fitted for the highest situations, I submitted a sample of the bark from trees about nine years old to my friend Mr. Howard, F.R.S., who has favoured me with the following analysis and remarks :—

"This bark used to be called *crespilla*. It was the Quina fina de Loja. I am glad to say it keeps up its character for goodness, thus :—

Quinine	...	4·10
Cinchonidine	...	0·70
Cinchonine	...	0·20
Quinidine		0·20
Total alkaloids		5·20

This would give of sulph. quinine 5·45 per cent., very much better than most of the bark grown in Ceylon."

I have had some of these trees coppiced, and a small quantity of bark has been shipped for sale in London.*

* This consignment was highly appreciated in Mincing Lane. At the sale, early in February in 1881, after a brisk competition it was sold for 7*s.* 6*d.* per lb., Mr. Howard remarking on its superiority over most Ceylon bark. [Note added March, 1881.]

Of the more valuable *C. Ledgeriana*, it is a matter for regret that I am not able to report a larger stock in the Government garden at Hakgala. There are at present about 3,000 seedlings, mostly raised from the seed received from Java in 1878, but some from a little seed received this year. I was able to meet the great desire of planters to possess themselves of this important plant only to a very small extent; but a distribution of 1,250 young plants to 32 applicants was made. However I have satisfied myself that there are scattered over several estates a considerable number of *C. Ledgeriana* from seed obtained by private application from the Government gardens in Java, Darjiling or the Nilgiris, the whole being the descendants of the seed originally brought over by Mr. Ledger. I desire to press upon the attention of the owners of these trees—many of which are now commencing to flower—the extreme importance of minimizing the chances of their being crossed by the pollen of other and inferior kinds. If any of these be in the immediate neighbourhood, they should be destroyed. Selected and marked or numbered trees should be analysed by a competent chemist, and the results compared with the characters of the trees. Those with a good bark-analysis should be kept as seed-trees, those with a bad one ruthlessly destroyed. In this way alone it is possible after a few years to obtain seed which will come true. No pains should be spared in this matter. It is important that growers should realize that before long (assuming that quinine retains its commercial pre-eminence over the other alkaloids) it will be only the best barks that will secure good prices; the inferior must hang on hand and only be disposed of at reduced rates.

Though *C. Ledgeriana* (like its close ally *C. Calisaya* in all its forms, of which indeed it may be one) is difficult to propagate by cuttings, it is without difficulty grafted on *C. succirubra*. The method consists merely in cutting a straight flat flap in the stock and inserting the sloping end of the graft (also cut perfectly flat) so that the naked surface of its wood, cambium and bark shall be in accurate contact with the same portions of the stock. The flap of bark embraces the graft on the outside, and the whole is kept in position by a firm bandage of soft thread. The plants require to be kept in an equable temperature and protected from draughts till union is complete, when the upper portion of the stock may be removed.

Twelve plants of the hard Carthagena bark (believed to be *C. cordifolia*) were sent from Kew under the charge of Mr. Clark. In spite of his attention, they suffered greatly in the passage through the Red Sea, and it is much to be regretted that only two recovered sufficiently to be sent on to Hakgala. Should they ultimately not survive there, it is confidently hoped that some fresh ones may be obtained from Darjiling, where Mr. Gammie has been very successful in its propagation.

I have also received from the Government plantation at Neddiwuttum, Nilgiris, a Wardian case with some young plants of the kind called *C. officinalis* var. *pubescens* by Mr. Howard but considered a hybrid by the late Mr. McIvor. Owing to remarkably careless packing these were nearly all dead on arrival, but a few have survived and are doing well. They possess much the appearance of *C. succirubra* at present.

In September I had the pleasure of accompanying Mr. Moens, the Director of the Government Cinchona Plantations in Java, on a tour of inspection through a part of our hill-country estates, and of gaining much useful information about the methods employed by him in his successful management of the Dutch plantations.

Cacao.—The Secretary of State for the Colonies, on the representation that there are superior varieties of cacao grown in Trinidad not yet in cultivation in the East, has caused young plants of them to be sent from that colony to Ceylon. The plants were selected and packed by Mr. Prestoe, Government Botanist at Trinidad, and despatched to Kew on 8th September. Here they remained but a few days, being brought on at once by Mr. Clark in six Wardian cases and arriving here on 5th November. In spite of the long double journey and indifferent packing, they arrived in fair condition. The varieties are eleven in number. It is intended that a proportion of these shall be forwarded to the colonies of Singapore and Fiji. Mr. Prestoe, in his report accompanying the plants, points out that some variation from parental characters may be expected in these seedlings, also that the varieties are so slightly marked as to be generally ignored by growers in Trinidad. He also remarks that it is "certain that some of the best varieties of cocoa are already in Ceylon."

This valuable consignment was accompanied by fifty young plants of the shade-tree generally grown with cacao in the West, *Erythrina umbrosa* (also called "Bucare" and "Bois immortelle"), and a packet of seed of the same species had been previously received

from Mr. Prestoe, through the Royal Gardens at Kew. These have been sown in batches in August, October and December, and have germinated and grown well. As they were gathered in March, it is obvious that the belief of Mr. Prestoe, that they "do not retain their vitality for many days," is unfounded. Cuttings have been made from these seedlings and they root with the greatest facility. A large number can be raised at any time should a demand arise. In the Kandyan country however cacao does very well without protection of this kind; but in the hotter and dryer low districts it will probably be found an advantage to employ the Erythrina.

It is probable that cacao will become one of the leading products of the Colony and largely contribute to its future prosperity.

India Rubber.—Of the three species of South American trees here in cultivation, *Manihot Glaziovii* (Ceara rubber) is still the only one which has flowered. Seed of this has been supplied during the year to the Government gardens in India (Calcutta, Saharanpore, Ootacamund) and distributed as widely as possible among the planters in the Colony, 24,550 seeds having been thus disposed of as well as 1,879 rooted cuttings. We have also sent small quantities to the Botanic Gardens of Singapore, Mauritius, Jamaica, British Guiana and Kew, to the Acclimatization Society of Queensland, and to Mr. H. Low, H.B.M.'s Resident in Perak Soon after my arrival at Pérádeniya I wrote a few "Notes" upon these plants which were printed as a Government paper, and have been distributed with the seeds. I have also given a botanical description, with an acurate figure, of *Manihot Glaziovii* in the London "Journal of Botany" for November. This plant is now flourishing in Ceylon in suitable places, and proves very hardy; in the new estates in the Trincomalee district it is reported to be thriving, but to have shewn itself intolerant of wet. In the Nilgiris I am informed it is doing well at 2,400 feet, and Major Seaton reports from British Burmah that there are 500 and upwards set out and well established in the Mergui plantation.

With regard to Para rubber *(Hevea brasiliensis)* its cultivation will be probably found to be satisfactory only in rich land not much above sea-level, where the temperature is high and equable and the rainfall large. At Pérádeniya the trees are now making but slight progress and suffer from wind, especially in the dry north-east monsoon. At Henaratgoda their progress is all that could be wished; our largest trees are now at three feet from the ground, sixteen inches in circumferencc. During the year 662 cuttings were raised and distributed. *Hevea* has proved completely unsuited to the climate of Calcutta, but is doing well in Burmah and Perak. In the latter place a tree has flowered sparingly (at two and a-half years and thirty-five feet high): Mr. Low kindly promises seed if any ripen, but this must be a premature blossoming, for Mr. Jenman of British Guiana informs me that he has not observed trees to flower with a stem of less than ten inches in diameter.

Two plants of *Castilloa* have been sent to Calcutta. Those in Burmah are reported to be flourishing. Much better success now attends the propagation by cuttings of this fine species. Our largest trees at Henaratgoda have now a circumference of nearly seventeen inches at a yard from the ground, and the trees are beginning to take their true form.

I hope during the coming year to make an experimental trial of the yield of caoutchouc from these S. American species.

With regard to other rubber-yielding plants, we have a fine plant of a species of *Landolphia* flourishing at Henaratgoda. Several plants of this genus, all climbing shrubs, afford African rubber, which appears to be also yielded by a fig, *Ficus (Urostigma) Vogelii*. This latter, and one or more kinds of *Vahea* (not distinguishable as a genus apart from *Landolphia*) from which Madagascar rubber is obtained, have lately been imported into Ceylon by several gentlemen. Our plants of *Gutta Sanggarip* (probably *Willughbeia martabanica*) from the Malay Peninsula, sent in 1879 by Mr. Murton, are doing well.

Gutta Percha.—This valuable commodity is afforded by numerous large trees of the family *Sapotaceæ* growing in the Malay Peninsula and Islands. Of the best known and most valuable of these, *Dichopsis Gutta*, there are several young trees in Pérádeniya and Henaratgoda, and I have during the year, through the kind exertions of Mr. Low, our Resident at Perak, received a consignmentof germinating seeds of the second best variety of that country.

This is called "Gatah Sundek," and Mr. Low informs me that it forms a very large tree 120 feet high, but quick growing. From specimens of the foliage and fruit sent with

the seeds, it would appear (so far as can be determined without flowers) to be a species of *Payena*. This is a valuable gift, as "the Gatah trees in Perak [as everywhere else] sufficiently large to produce the gum are now very rare, and very great difficulty arises in procuring seeds or specimens." The young plants are growing vigorously in Pérádeniya and Henaratgoda. The commercial necessity for a systematic cultivation of Gutta-percha yielding trees is rapidly becoming a pressing one.

Cardamons, &c.—The cultivation of the Malabar variety of this condiment has considerably extended in Ceylon, being found to be highly profitable lately. Applications for roots and seeds have been so numerous as to be beyond our power to supply them, though a considerable increase to the space allotted to their cultivation has been made. Nutmegs, cloves, ginger, turmeric, vanilla, pepper, arrowroot, and other hot-country plants have also been distributed in considerable quantities.

Ipecacuanha.—I cannot report much progress with this culture. Though readily enough propagated, the plants remain small, and even at Henaratgoda where they seed, make exceedingly slow growth both above and below ground.

Timber trees.—Several applications have been made from India for seed of the Mahogany, from an erroneous idea that it is produced here abundantly. It may be therefore well to mention that the production of a ripe capsule is a rather rare event in Ceylon, though the tree flowers abundantly. It is to be regretted that a plan for the formation of a plantation of this valuable wood in the Southern Province has fallen through for want of funds. Our beautiful native woods, especially calamander, which is becoming very scarce, are also now calling urgently for protection, and I strongly advocate the formation without delay of Government plantations, under proper and efficient management.

The following are some of the more interesting additions to the collections during the year :—

DICOTYLEDONS.

Calodendron capense, Thunb. A handsome rutaceous tree. The wild chestnut of the Boers. Cape of Good Hope.

Rhus rhodanthema, F. M. Queensland. Remarkable in the genus for its large red flowers.

Erythrina umbrosa, H. B. K. Native of Trop. S. America where it is called Bucare. The "Bois immortelle" of the W. Indies.

E. velutina, Willd. Trop. S. America and W. Indies. Like the last, used to shade Cacao.

E. Vespertilio, Benth. Queensland. Remarkable for the shape of its leaves.

Pterocarpus santalinus, Linn. f. Red Sanders wood. South India ; a rare and local tree.

Copaifera officinalis, L. Central America. One of the trees probably yielding the drug Copaiba.

Bauhinia Vahlii, W. & A. Central India. A gigantic climber.

Holarrhena pubescens, Wall. (var. of *H. antidysenterica*, Wall.) The Kora of India. Used in native medicine for dysentery.

Euphorbia resinifera, Berg. Morocco. Affordsthe gum Euphorbium of commerce. And other species of *Euphorbia*.

Jatropha podagrica, Hook. Central America. A curious plant with bottle-shaped stem.

Croton Eluteria, J. Benn. Bahamas. The source of Cascarilla bark.

Brosimum Galactodendron, Miq. The "Palo de Vaca" or cow tree of Venezuela. A large tree with a juice closely resembling animal milk, and used as an article of food. This, of which both seeds and plants have been safely transmitted from Kew, is an interesting addition to the garden.

MONOCOTYLEDONS.

Teysmannia altifrons, Zoll. & Reich. f. I have little doubt in referring to this species the seeds sent from Perak in June last by Mr. Low, and now growing well here. He describes this palm as the handsomest and most graceful imaginable, and it appears to be very local. *Teysmannia* is only hitherto known from Sumatra, but from the description in Miquel's Flora must be almost certainly this Perak palm. Major McNair, R.A., informs me that it is called "Daun Pâyong" (leaf umbrella) by the Malays. and it would appear to be the palm mentioned recently by Mr. Murton in the "Gardeners' Chronicle" under the name of "Duan Sang."

Smilax officinalis, Kunth. New Grenada. The source of "Jamaica" sarsaparilla. The plant figured in Bentley and Trimen's Med. Plants, t. 289.

Bambusa Brandisii, Munro. Tenasserim. Described as a magnificent bamboo, the stems reaching 120 ft. in height.

I am very anxious to increase our collection of Orchids, and take this opportunity of offering our native kinds and some of the Indian and Malayan species in exchange for those of South America and the West Indies.

VI.—SALES.

The number of stocked Wardian cases, plants and seeds sold during the year 1880 principally to residents in the Colony, was as follows :—

	Péradeniya.	Henaratgoda.	Hakgala.	Total.
Wardian Cases	17	—	—	17
Economic Plants	19,890	12,857	8,542	41,289
Seeds of the same	118,556	13,987	—	132,543
Garden Plants	6,531	372	42	6,945
Ornamental Trees	1,318	—	—	1,318
Packets of Seeds :				
Forest Trees	112	—	—	—
Garden Plants	75	—	—	—
Vegetables	42	—	—	—

The number of purchasers was at Péradeniya 918, at Henaratgoda 239, at Hakgala 43 ; Total 1,180.

The receipts from the sales, paid to the Colonial Treasurer, were

	Rs.	Cts.
From Péradeniya	5,392	38
Henaratgoda	1,373	8
Hakgala	1,072	15
Total	Rs. 7,837	61

This is an increase of 4,012 rupees and 28 cents over the receipts for last year, 1879, or considerably more than double.

VII.—HERBARIUM AND LIBRARY.

Herbarium.—The collections of dried plants are mostly in fair order. The Ceylon Plants ("C.P.") containing the types described in Dr. Thwaites' "Enumeratio" and many of those of Moon and Gardner's publications, are however lying loose on half sheets of paper, and need to be fastened down to prevent further loss and displacement, and damage by breakage of fragile specimens. I intend to carry this out as time may serve.

Pressure of work in this first year of my charge has, I am sorry to say, prevented me from making any tour for collecting. A few species have however been added to the Ceylon flora during the period by the garden collectors and by the exertions of Mr. W. Ferguson of Colombo. I cannot but express a desire that other persons, especially those residing in the little known parts of the Colony, would send me fresh or dried specimens of any plants they may think rare or curious, for my examination.

The Foreign herbarium has been arranged for more easy reference, and some new trestles erected for its accommodation. The only addition has been a small but interesting packet of South Indian species from Col. Beddome.

I am desirous of bringing together a structural and economic Museum of Ceylon Botany, to comprise the large and hard or soft and pulpy fruits and seeds unsuited for preservation in the herbarium, stems, barks, roots, resins, gums, fibres, oils, medicines, &c., as well as simple manufactured articles from these. This will, I feel sure, be a valuable adjunct to the Gardens, and I shall thankfully receive any donations from native or European gentlemen who will assist me.

I felt the want of some such collection in connection with the Melbourne Exhibition. I received an unaccountably late notice, only some five or six weeks before the closure of the time for receiving articles, and had therefore no opportunity of doing more than rapidly bringing together an imperfect and fragmentary assortment of hastily prepared specimens. Such as it was, however, I am pleased to notice it has proved acceptable and interesting.

During the clearing of parts of the garden a few stems and roots of structural scientific interest were cut down and uprooted. I sent a selection of 15 of these to the new Natural History Museum (British Museum) at South Kensington, and have received the thanks of the Trustees for them, who also defrayed the cost of their transmission.

The Draftsman has added 22 finished drawings to the fine series of coloured illustrations of the plants of Ceylon, having accompanied me on a visit to the Nuwara Eliya District. A portion of his time has been occupied in making duplicate drawings of Ceylon Lepidoptera for the serial work now being issued in London on that group of insects. He has also the general care of the herbarium.

A good number of our mountain and sea-shore species still remain to be figured, as well as many common ones, and nearly the whole of the grasses and Cyperaceæ, but the series, which is entirely the work of one family (father and two sons) of artists, is now a very full one, and probably unequalled in the East for accuracy of botanical detail combined with beauty of delineation. It is to be regretted that no selection from them has ever been published, though suggested thirty-five years ago by Dr. Gardner. Such a selection could still be made—though many of our plants have since been figured in the works on Indian Botany of Beddome and others—and, with suitable text, would form a valuable and handsome contribution to science, worthy of the traditions of this establishment and spreading a knowledge of the interesting and peculiar vegetation of Ceylon.

Library.—All the books included in the printed "Return of Botanical Books" and in the MS. additions thereto, I find to be in the library; of a few there are duplicate copies, most of which (including some on Cinchona) I have sent to the Hakgala Garden.

In addition, I found on my arrival a large quantity of books and pamphlets not entered in the "Return." Of these I have made a list.

Dr. Thwaites, with great liberality, permitted me to go over the valuable books he had left behind him at Pérádeniya, and to select what I pleased for the library. This I very gratefully did, and thus have been added some important works. Others which we already possessed, or which were not botanical, I sent, with Dr. Thwaites's permission and in his name, to the library of the Colombo Museum.

Having since gone over and re-arranged the whole of these books, I am now engaged on a proper systematic catalogue to replace the quite incorrect "return" abovementioned. With this I have made considerable progress, and its compilation has revealed rather numerous imperfect books. Such gaps I am endeavouring to supply, and my thanks are due in several quarters for help in so doing. Colonel Beddome has kindly sent the parts necessary to complete our copies of his indispensable works on Southern Indian Botany, the Colonial Office has supplied the three concluding volumes of Bentham's "Flora Australiensis," and Kew has sent Baker's "Flora of Mauritius" and several smaller works. Other benefactors, besides Dr. Thwaites, have been Mr. C. B. Clarke, now of Kew, Sir Ferd. von Mueller of Melbourne, Mr. G. Wall of Colombo, and others. I must also specially mention the Council of the Linnean Society of London, who in the most liberal manner have offered me the 23rd to 30th volumes of the valuable "Transactions" (needed to complete our set) at one-half of the reduced price allowed to Fellows. This is the second occasion on which the Pérádeniya Library is indebted to this celebrated Society.

Many books being out of repair or altogether unbound, 38 volumes have been bound during the year in an inexpensive manner in Kandy.

VIII.—Expenditure.

The whole expenditure on this establishment during the year has been as follows:—

		Rs.	Cts.
Salaries	...	13,544	70
Gardeners' and Labourers' Wages—			
Pérádeniya (Revenue Service)	...	6,667	01
Henaratgoda (do.)	...	1,999	83
Hakgala (do.)	...	2,995	91
Pavilion (Miscellaneous Service)	...	2,195	23
Office Contingencies ...	...	1,948	81
Travelling (Transport) ...	...	1,462	76
Total ... Rs.		30,814	25

Pérádeniya,
1st January, 1881.

HENRY TRIMEN, M.B.,
Director.

CEYLON TEA.

We call special attention to the letter which our late Governor Sir Wm. Gregory has very kindly written in the interests of Ceylon tea planters. We feel sure that the continued interest thus manifested in the promotion of our planting industries will be generally appreciated. We do not, of course, forget that it was during Sir Wm. Gregory's term of Government that attention was first properly directed to "new products," more especially to tea and cinchona, and in respect of the quality of the former our late Governor has all along been a firm believer in the capability of Ceylon to produce the finest teas. The suggestion now made is one well deserving the attention of our planters, many of whom have individually been entering into arrangements with retailers in different parts of the old country. Why not combine and establish a West End "Ceylon Tea and Coffee Room," or simply a store for the sale of packets of such produce from a few lb. up to a cwt.? The subject is one which might well be discussed by the Planters' Association as preliminary to definite action. The custom of the large number of metropolitan residents now connected with or interested in Ceylon would, of itself, ensure a fair amount of support for a West End Store of the kind we speak of.

NEWS FROM BRAZIL.

(*From Our Own Correspondent.*)

PATENT LAWS—LABOUR LAWS—COFFEE PROSPECTS.

Fazenda Angelica, S. João do Rio Claro,
20th March 1881.

In answer to a correspondent's enquiry in your paper a few weeks ago, I would say there is every facility for getting a patent for an invention in Brazil. Give some one a power of attorney, plans and specifications, and copy of original patents given in another country (latter not practically necessary), and the attorney through himself or an agent in Rio de Janeiro will make application. The cost will be from £50 to £100, including agency.

I have not time at present to give you a report. I will merely say that coming crop (1881-82) is expected to be two-thirds the last one.

Here in S. Paulo, it will be nearly the same, as young coffee coming into bearing will make up for old coffee trees, which have very little fruit on them this year.

A blow has been struck at international or interprovincial slave trade. In the three coffee-producing provinces, a tax of £150 (1,500$000) in province Rio de Janeiro, and £200 (2,000$000) in provinces of S. Paulo and Minas Geraes, on each slave entering from any other province, has to be paid at time of registration. Coffee cultivation can now be extended only by the use of free labour. This weakens the power of the Emancipation party, as they expected that the other 17 provinces of the Empire, as soon as they got rid of their slaves, would outvote, the three coffee,-producing provinces, who had bought them, and declare for immediate emancipation.

The hands of the advocates of the "dying out" system of emancipation are thus strengthened. I am willing, however, to believe that the real intention of the law-makers in framing, and of the Government in sanctioning, the law was to enforce the coffee planter to use more energy in obtaining free labour.—Yours truly,

A. SCOTT BLACKLAW.

CEYLON TEA IN AUSTRALIA.

(*From a correspondent.*)

MELBOURNE, April 24.

I have been out of town seeking for information respecting Ceylon tea, and from all I can learn it appears that we must try up-country, if we wish to break down the hold that China tea has upon the market. I asked a storekeeper up-country the other day if I should send him some samples of Ceylon tea. His answer was: "I never buy from samples, unless the bulk is at hand to be compared with the samples. Show me a few chests, and then, if they are equal to samples, I may buy."

Three persons *in Melbourne*, are trying to sell Tea by sample. They do not, and will not succeed. I have written to two gentlemen in Colombo, asking them to send me down a few chests of Tea, and if they do, I will take it nearly 100 miles from Melbourne, and try the country. I bought a few pounds of Tea before leaving Colombo, and have given it all away. I gave a small quantity to a farmer's wife without telling her what it was, and after trying it, she said "that *is* fine Tea! where did you get it?"

COFFEE still quoted at 81s:—It strikes me that if things go on as they are doing we shall all be short of coin very soon. The German firms report a panic as prevailing in coffee at home. Short crops kill us here, it will be a funny thing if extraordinarily big crops should kill Brazilian coffee planters: prices becoming unremunerative, and at the same time the price of labor rising is not a healthy state of things!—*Cor.*

SHEVAROY PLANTING NOTES, April 26.—I understand that a company has been formed to open out the Kollymullays, a range of hills lying to the south of the Shevaroys, very accessible from the plain, and favourably situated as regards rain, soil and elevation for coffee planting. The area available for planting on the Shevaroys is becoming much circumscribed, and capitalists are forced to look for "pastures new." With heavy jungle and abundance of water, some of us might do better by migrating "bag and baggage" to the Kollymallays. There is, however, one drawback—the hills are said to be very feverish. For all that I wish the pioneers of coffee-planting on the Kollymullays every success. So mote it be. —*Madras Times.*

FOOD ADULTERATION.—Not long since the *New York Hour* referred to the discouraging report of a Committee of Experts appointed by Congres to inquire into the adulteration of articles of foods and drink in this country. A similar inquiry in Vienna, by a Society for the Protection of the Public Health, has resulted quite as unpleasantly. Almost everything examined proved to be more or less adulterated. Out of nine hundred and fifty samples of milk, nearly all, were found to be skimmed and diluted with water while some had come from diseased cows and some were given a delusive richness through the medium of borax, soda and soap. Of two hundred specimens of butter, all contained an excessive proportion of water, and many showed component parts of beef fat, lard and stearine. Lard, in its turn, was adulterated with borax and lime, but this came from Hungary and America. Ground coffee consisted mainly of roasted grain, beans and chiccory. Bread was found to contain numberless less savory and wholesome ingredients than flour. Even the wine and beer, those mainstays of the Fatherland, had not escaped adulteration. Of one thousand one hundred samples of Austrian and Hungarian wines, fifty-two were artificial concoctions outright, while many others were found to be largely watered and artificially colored. Finally Pilsner beer showed soda, Vienna beer contained glycerine, and seventy-three of the liquours examined had traces of arsenic or copper, besides other deleterious substances.—*New York Hour.*

Correspondence.

To the Editor of the Ceylon Observer.

SIR WILLIAM GREGORY ON CEYLON TEA.

Coole, Gort, Co. Galway, April 8th.

SIR,—An extremely good letter on the subject of Ceylon tea written by Mr. Mackenzie has recently appeared in the *Observer*. It ought to attract attention to induce planters to combine and obtain a better position for this product in the London market.

I cannot at all understand its being so lightly esteemed by the dealers at home, as every person of my acquaintance who has tried it praises it, and I find a pound of Ceylon tea to be a most acceptable present to all ladies of my acquaintance who have received it. We drink no other tea in my house; nor shall I do so, as long as I can get a regular supply of the same quality as heretofore. It strikes me that the planters might obtain an agency for the sale of their tea in the West End of London. I do not know whether it would be expedient to combine it with any agency for the sale of Indian tea, or whether it might not be introduced into the Co-operative Societies. Of course precaution would have to be taken that teas of an inferior quality should not prejudice the sale of those of a higher standard.

There are always difficulties in the way of newcomers, such as your tea. They are regarded as intruders and as likely to affect vested interests, but these difficulties can be, and ought to be overcome. Your uncle, Mr. A. M. Ferguson, has done right good work in Australia by introducing Ceylon tea there, and I expect that ere long many a pannikin of it will be brewed in the bush, for its excellent flavour will make it a favourite without milk.

I take so much interest in Ceylon, and especially in its tea, from personal predilections that I feel aggrieved at a product which ought to be so popular meeting with such little favour hitherto, in fact being almost unknown. The small amount as yet received in England will account in a measure for this, but as the export of it will soon be large, I may be excused for recommending that some combined action may be taken in respect to it, without loss of time. —I remain, sir, yours obediently,

W. H. GREGORY.

COFFEE:—THE YIELD OF LAWRENCE ESTATE, DIKOYA.

Lawrence, Dikoya, May 9, 1881.

DEAR SIR —With reference to the yield from this estate, quoted by you from a correspondent's letter, I beg to say that having gone into the figures a couple of months back with Mr. Hard ng, they shew an average crop of over 23 bushels of parchment (nearly 24) per acre, for the *nine* years ending 1879-80 from coffee in full bearing, nearly 5 cwt. per acre, instead of 3½ as your correspondent says.—Yours truly,

WALTER S. AGAR.

TEA AND CINCHONA.

SIR,—Talking of 'puffing': have you seen the prospectus of the "Tea and Cinchona Plantations Company, Limited"? Companies might be the medium of doing much good in developing the resources of the country. But in Ceylon the best known of the e have done much harm. Yet a man who has been deluded into investing money on a promise of 19 per cent (even 70 per cent was promised in one case) is thought a "*very rude person*," if he makes any remarks other than laudatory of all concerned, or asks awkward questions, when instead of 19 per cent., he finds considerably less than nothing is the result. (But then the directors have gained experience, and as your daily contemporary says in reference to the recent meeting of a Company, experience not paid for is not worth having! Some consolation doubtless in that.) To be successful in the end, Companies should not require much puffing. The new Company above-mentioned has got together in the shape of extracts from *Observer*, and other papers market reports, essays on tea, Mr. Ballardie and Mr. Downall's reports and letters's &c. &c. evidence to prove that this tea will give them 39 per cent profit, and their cinchona £40 per acre of annual production "being about half of the lowest result which has come o their notice." True, with reference to their Tea they appear to think they prove too much, and they *reduce their profits* to £6 10s per acre per annum. Now, the directors and promoters of this Company are doubtless all honorable men and have had the best advice from the best sources of information; and we may accordingly all look forward to the day when Ceylon will find its 200,000 acres of cinchona will be reaping an annual profit of £8,000,000 (eight millions) sterling!! A pity to break up our ground for gold digging!! Figures can be made to prove anything *on paper*. Of course, the directors make no mention of the low dividends of the Indian Tea Companies; of the fact that cinchonas die out, of the failures recently experienced in attempts to replant this product, of the total annual consumption being only a fraction of £8,000,000; nor of the report current in Ceylon that the best of the two properties in Morowak Korale, which the directors have arranged to purchase, and for which we must suppose they are to pay the larger half of £14,000 (that being about the sum for which the estates are to be bought) was recently offered for sale for £3,000, and that the only bid was £100! Why don't they publish their prospectus in the *Observer*, that they may cheer the hearts of the many disappointed men now amongst us? If this Company's property can be turned to such account, why not that of others?

W. McK.

COFFEE-MANURING ON "ALOOWIHARE" AND "VENTURE" ESTATES.

DEAR SIR,—With reference to the extract from an up-country report, which appeared in your issue of 4th instant, and insofar as it applies to Mr. Ross, his estates, and the manure used by him, I should like to make a few remarks, with a view to correct the false impression likely to be conveyed by the statements therein made.

Mr. Ross has all along been in the habit of manuring liberally, and of late has in his system of cultivation, been guided by the best scientific advice he could get and would seem to be satisfied with what he has done, and the result of his expenditure on the manures recommended to him, judging by the fact that he is about to send out a large consignment of the same again this season.

And now, in the first place with regard to Alloowihara. Until last season, this estate got none of the manure sent out for Venture, when about 20 acres were treated with it as an experiment, and the result was most satisfactory. Your correspondent makes rather a misleading statement when he says "Alloowihara has actually fallen off in crops as much as any estate in Matale, certainly more than any estate which has received similar case and outlay. This too in the last four years while manures have been made from analysis." Now until last year, the soil of Alloowihara had not been analysed and the first of the manure now in use on Venture was only applied on that estate two years ago.

That this estate has fallen off in crops cannot be denied, and Mr. Ross himself attributes the same to the effect of successive attacks of leaf disease, and the fact that manuring has not been carried out so extensively of late as formerly. But your correspondent would have you believe that it was doing no better than any other estate, in fact not so well as some which had got similar attention. Would he say what place or places he refers to, as I am not aware of any estate in that neighbourhood which has had the same amount of cultivation as Aloowihara has had, even of late?

Is your correspondent aware that this estate for years averaged from 7 to 8 cwts per acre, so that if it has fallen off, there was some room for it to do so and still leave some profit over expenditure?

He may be right in this way: that it has fallen off more cwts. per acre than any other estate about there, as it was not possible for many of them to fall off 3 cwt. per acre, and continue to give any crop at all. If it only gave 4 cwt. per acre last season, it is nothing so very extraordinary, and was still sufficiently ahead of the average of the country to justify the expenditure on manure.

And now, with regard to Venture and its crops: in the two years 1876 and 1877, the coffee in full bearing gave an average of 6½ cwt. an acre, and in the last three years it has averaged 5¼ cwt. This crop is estimated to average, at least 6 cwt. per acre, which will bring the four years average up to 5½ cwt. and the six years' to 6 cwt. per acre.

Now, will your correspondent name any unmanured estate in Dikoya district that comes within 1½ cwt. per acre of this? I doubt it, and moreover, there *is* no estate in the neighbourhood, that has been without manure for that time.

Again, the manure now in use has only been once applied over the whole estate—about August and September 1879. Last year's supply has only now been applied, and instead of its "*consisting chiefly of bones and poonac*" there is not an ounce of either in the composition of the manure as prescribed by the agricultural chemist.

Again, your correspondent says:—"Surely Venture (naturally the finest estate in Dikoya) would have given at least 4 cwt, per acre without manure during these three years 1879, 1880, 1881." Upon what does he base this supposition? What estate without manure has done so? As I said before, there *is* no place in the neighbourhood that has been without manure, and I deny that Venture is *naturally* the finest estate in Dikoya. The upper half or more may be, but the lower 100 acres was chena land that had been planted before and abandoned, and every planter knows what that means.

Again, if Lawrence, until two years ago averaged within 1½ cwt. per acre of Venture, why has it fallen off since then? I have shown that Venture for six years will show an average of nearly 6cwt. per acre.

Will Lawrence estate, which your correspondent has taken as a criterion show an average of 4 cwt. per acre for these three years 1879, 1880, 1881, as he seems to infer a good estate ought to do without manure; and has there been no cattle manure, lime, bones and poonac, applied there during these three years?

I must ask the proprietor of Lawrence estate to excuse my bringing in the name of his property so frequently in this letter, and I only do so, because your correspondent has pointed it out as an example of an unmanured estate adjoining Venture. In conclusion, I don't think Mr. Ross desires or stands in need of any advertisement of himself, his estate, or his manure. I believe he is content to take his own line and go his own way which, I think you will agree with me, seems to answer very well, judging from the figures I have given you above.—I am, dear sir, yours faithfully. PLANTER.

22

A NEW RUBBER.

155. Fenchurch Street, London, 14th April 1881.

DEAR SIR,—As I know you like to be to the front, I send you enclosed some seed out of a small "post packet" of a new rubber, *Tabernaemontana Crassa*, just received from Africa. I found this plant among some of my Landolphias. I have had three lots of seed and fruit over; all bad. I hope this may be sound. Some of the Ceylon agents here begged a few at 6d each seed. They go out to-day.

I return half of all I get to the senders of the seed to reward them for their trouble, and with the sender of this I have advances out (of) £400. Knowing he lived among those valuable plants, I hoped he would send me some carefully put up. This and other new rubbers kept No. 4 back of "Commercial Plants." Even one rubber I give the engraving of I can't name, as the base of the flower was off. I hope Dr. Trimen may flower it first. We have no similar plant in the Herbarium of this country.—Yours faithfully, THOS. CHRISTY.

You will notice that the *Tabernaemontana utilis* is the cow tree of British Guiana, famed for its milk, so this is part of the way on the road for proof that it yields well. I sent fruit, flowers and leaves to Kew early last year for their opinions, and for this name of *T. crassa*. [The four seeds received will have a fair trial given to them.—ED.]

COFFEE LEAF DISEASE:—MR. GRAHAM ANDERSON'S EXPERIMENTS:—THE JAVA GOVERNMENT OFFERING NO REWARD FOR A REMEDY FOR *HEMILEIA VASTATRIX*.

Barguni, Munzerabad, Mysore, 3rd May 1881.

DEAR SIR,—I deem it my duty to hand you an extract from an official reply which I have just received from the Government of Java with reference to my application to be registered as a competitor for the reward for a remedy for leaf disease (*Hemileia vastatrix*). Having seen frequent allusion made in the *Observer* and several other papers to the "reward offered by the Java Government" I shall await with interest any information you may obligingly offer in regard to the way in which we have all indulged in a popular hallucination.

My own attention I may observe, was first attracted by a paragraph in an English paper in which it was clearly stated that extensive experimeuts on separate estates would be conducted with all remedies which might be suggested.

Encouraged by the frequent allusions to the reward I have devoted much time, attention and money to the conduct of numerous experiments and having forwarded detailed information in regard to all my researches to the Java Government, I now find there is no chance or prospect of any remuneration whatever.

As you are aware agricultural experiments are most costly luxuries to indulge in, and my experience of voluntarily attempting to assist to the best of my ability will be scarcely of a nature to encourage others to imitate my example.—I am, dear sir, yours faithfully.

G. ANDERSON.

Extract from an official letter No. 2 925 dated Batavia, 2nd April 1881. Departement van Binnenlandsch Bestuur. "I am happy to say that the leaf disease on this island is not of such a serious nature as would warrant our Government making experiments on a large scale for combating the same.

"It is on this account that you will not be surprised on being informed that our Government has not deemed it necessary to advertise any reward for a remedy against the leaf disease (*Hemileia Vastatrix*) so that the information you seem to have had on the subject is entirely erroneous." (Signed) G. S. H. BENN,

Director for Agriculture.

COFFEE MANURES: MORE ABOUT POTASH.

Colombo, 12th May 1881.

SIR,—It may help towards a more intelligent use of artificial manures, if we examine the composition of Ceylon made cattle manure. Two samples received from Mr. Joseph Fraser of Damboolagalla estate, Matale, had the following composition. No. 1 is the analysis of cattle manure from cattle fed upon coconut poonac and guinea grass, the bedding being mana grass. No. 2 is the analysis of manure from cattle fed upon guinea grass only, the bedding mana grass.

	No. 1	No. 2
Moisture expelled at 212° F.	80·487	74·674
Organic Matter and combined Water	14·442	19·177
Ash	(5·071)	(6·149)
Insoluble Silica	1·805	1·664
Soluble Silica	·209	·193
Oxide of Iron, Alumina and Phosphates	·569	·430
Lime	·497	·717
Magnesia	·067	·171
Potash	·951	1·068
Chloride of Sodium and Soda	·575	·827
Sulphuric Acid ...	·159	·217
Carbonic Acid and loss	·239	·862
	100·000	100·000
Nitrogen	·446	·644
Phosphoric Acid ...	·250	·092

The most striking feature, in these analyses, is the fact, that of the four chief manurial ingredients viz. nitrogen. phosphoric acid, lime, and potash, by far the most abundant is potash which averages fully 18 per cent of the manure ash. The proportion of potash is much higher than in English farm yard manures, is indeed double as great. Analyses of the ashes of mana grass, guinea grass and coconut poonac, separately, would be desirable to ascertain the proportion of potash and other ingredients derived from each of these sources. The percentage of potash in the manure from cattle fed on guinea grass only is slightly higher than in the other, when calculated into the weight of the manure as it stands; but if calculated into the weight of the ash of the manure, it is slightly higher in that from cattle fed upon both poonac and guinea grass. The latter manure has a very decided advantage in respect of phosphoric acid. It was contrary to my expectation to find No. 2 richer in nitrogen than No. 1, and in the case of a substance so difficult to sample, from its want of homogeneity, as cattle manure: more analyses are desirable before accepting this as a general fact. It was, however, to some extent confirmed by analyses of dung from cattle fed on guinea grass only (analysis No. 3), and that from cattle fed on coconut poonac as well (analysis No. 4).

	No. 3.	No. 4.
Moisture expelled at 212° F... ...	73·500	75·186
Organic Matter and combined Water	20·53	21·195
Ash	(6·247)	(3·619)
Insoluble Silica	3 667	2·221
Soluble Silica	·328	·159
Oxide of Iron, Alumina and phosphates	·499	·438
Lime	1·037	·464
Magnesia	·078	086
Potash	·213	·091
Chloride of Sodium and Soda ...	·076	·043
Sulphuric Acid	·112	·078
Carbonic Acid and loss	·237	·039
	100·000	100·000
Nitrogen	·529	·392
Phosphoric Acid	·139 ...	·174

Here again we notice that in the dung from cattle fed upon both coconut poonac, and guinea grass, although the percentage of ash is much lower, yet the phosphoric acid is higher than in the guinea-grass-fed cattle dung. When guinea grass is the only feeding material, it would appear that both the dung and total manure are much richer in lime, than when coconut poonac is used as well.

From the large percentage of potash in Ceylon-made cattle manure, those holding different views regarding this substance will, most likely, drawn opposite conclusions as regards its place in artificial manures. Thus the nitrogen and phosphate manurists will argue, that the very fact of cattle manure being richest in potash shows that the soil from which it was derived is best able to supply this ingredient, and there is therefore no occasion to add it to our artificial manures. The nitrogen, potash and phosphate manurists, on the other hand, will argue, that, since potash is such a conspicuous ingredient of cattle manure (the stand-by of the planter), it is wise to introduce a considerable proportion of it in manures for coffee, of which it forms by far the most abundant mineral constituent. The balance of what little experimental data is as yet before us decidedly favours the latter view. We have the testimony of Mr. Graham Anderson and Mr. Talputt, founded on actual experiments, in its favour, the said experiments, moreover, having been carried out on soils richer in potash than those of Ceylon. In the March number of the *Journal of the Chemical Society* an extract from a leading continental scientific magazine informs us, that "experiments which were carried out at Potsdam shewed the most suitable manure for fruit trees to be a mixture of potash sulphate and superphosphate which increased the number of blossoms considerably." Mr. Fraser also, I understand, has found that on Damboolagalla estate those fields at least, the analysis of which shewed a lower percentage of potash responded very well to sombreorum, which is essentially a mixture of potash sulphate and superphosphate of lime. Of the commercial salts of potash, besides wood ashes, our choice from considerations of expense, is probably restricted to the nitrate, muriate, and sulphate. The first can be obtained from India. A very good sample for agricultural purposes submitted to me by a Colombo firm contained nearly 90 per cent salts of potassium, the nitrate constituting nearly 80 per cent. Much of the crude Indian nitre, however, is greatly inferior to this, containing much common salt; but, if cheap enough, is useful as a manure. Nitre of 80 per cent furnishes fully 11 per cent of nitrogen, so that is a highly nitrogenous as well as potassic manure.

Commercial muriate of potassium contains about 88 per cent of muriate and costs about £8 or less per tou. A crude muriate of potassium and magnesium called carnallite can be had from Stassfurt in Prussia for less than a third of the cost of the purer salt; but, as it only contains 25 per cent of muriate of potassium, the purer salt would be the cheaper as a source of potassium. Kainit is a crude potash sulphate which comes from the same mines at Stassfurt. Voelcker's analysis of it is as follows:

Moisture	3·36
Water of combiuation	10·88
Potassium Sulphate	24·43
Calcium Sulphate	2·72
Magnesium Sulphate	13·22
Maguesium Chloride	14·33
Sodium Chloride	30·35
Insoluble Silicious Matter	·71
	100·00

A cheaper source of sulphate of potash, if still to be had at its former price of about £8 per ton, is

a lye product called plate sulphate of potash, from kelp. The following are Dr. Richardson's analyses of it, made on samples taken from parcels of 100 tons.

	Irish.	Scotch.
Sulphate of Potash ..	77·43	75·28	83·06
Sulphate of Soda ..	21·31	20·89	14·89
Sulphate of Lime ..		·80	
Chloride of Sodium ...	·76	·54	·67
Insoluble Matter ...	trace	1·04	
Moisture ...	·59	1·55	1·44
	100·09	100·10	100·06

Sulphate of potash has this advantage for agricultura purposcs over the nitrate and muriate that it is less soluble in water. The muriate dissolves in 3 parts of water at 60°, the nitrate in 7, and the sulphate in 11. The sulphate, moreover, in the hands of Mr. Anderson has been found to have a certain curative or preventive effect on leaf disease. A good deal more might he done by analysis to ascertain whether or not there is a connection betweeu leaf disease and a deficient supply of potash to the coffee plant. The coffee leaf not being of direct commercial importance, little has been done as yet in determining the composition of the ash in the different stages of the leaf's growth. The tea leaf, on the other hand, has been analysed in all its stages, and it is remarkable the extent to which potash disappears from the leaf as it grows old, so much so, that Zoller affirmed "that the age of tea leaves may be determined from the analysis of the ash. Thus, young leaves of which the best teas consists contain much larger amounts of potash and phosphoric acid than the older leaves, which are comparatively deficient therein, while they become richer with age in lime and silica. The ash of a sample of young tea, grown in the Himalayas, amounted to 5.63 per cent, and it contained in 100 parts 39·22 of potash, 4·24 lime, 4·38 of oxide of iron, 4·35 of silica and 14·55 of phosphoric acid" (Hassall.) In marketable teas the amount of potash in the tea ash varies to a great extent, as the following examples from Watt's Dictionary of Chemistry, quoted by Hassall, will shew, and where potash is low, it will be observed, soda is high and *vice versa* :—

	Souchong.	Souchong.	Oolong.	Young Hyson.	Young.	Ning.
Soda	25·46	1·70	40·00	9·26	12·88	
Potash	3·70	44·96	12·38	33·95	28·38	
Lime	11·36	8·77	7·68	8·17	8·39	
Phosphoric Acid ...	12·62	11·46	8·26	16·64	17·44	
Sulphuric Acid ...	10·14	6·96	8·27	4·89	4·76	
Silicic Acid ...	16·04	8·79	7·81	10·89	5·59	

Potash being the dominaut elemeut of the ash of the coffee seed, the formation of fruit must tend to drain the leaves of their potash and if the supply is not equal to the demand, we can imagine an abnormal condition of the leaf to be induced, rendering it liable to the attack of *hemeleia* while the seeds would be reduced either in number or size. Again, if at any stage of its growtb, the coffee leaf, like the tea leaf, requires a much larger proportion of potash than at other stages, and the supply be not equal to the demand, we may in this case also have an abnormal condition of leaf and disease the result, I think, at all events, that this liue of investigation is worthy of attention. M. COCHRAN.

COFFEE AND LEAF DISEASE.

8th May 1881.

DEAR SIR,—Regarding the cure of leaf disease: the leaf disease appears to have come in a most mysterious fashion, and will, no doubt, go away as mysteriously as it came, and I do not thiuk that any earthly agency or power can do otherwise than simply assist the afflicted trees by doses of manure and proper cultivation. Beyond that, nothing can be done until the disease leaves of its own accord, and I think, from a general impression which I have somehow got, that it has begun to go off already. I have noticed that good paying coffee, which had been abandoned during a time of finaucial depression, and which has now been brought back iuto cultivation, was all the better after the abandonment, and looked most vigorous and healthy. Perhaps a good way with fields of leaf diseased coffee might be to manure them well and then abandon them for a time, letting suckers and everything grow, until the power of the tree asserts itself over the disease. When, and if, the tree has thrown off the disease, it may then be handled or pruned and the ground weeded. I do not think that weeds harbor the disease: otherwise, were they to do so, they would manifest signs of suffering from it themselves. I merely describe what has come under my practical obeservation, and I should be glad to hear the opinions of others on the subject.—Yours truly, FACTS AND FANCIES.

CACAO CULTURE.

Dickeria, 12th May 1881.

SIR,—Every *Ceylon Observer*, I eagerly look out for more information of our new products. And that "kittle" one Mr. Drummond wrote about cacao, has baffled me more than any plaut I ever tried in the clearing, either as plants in pots, stumps, seed at stake, or any other way I can try it. Stumps I have tried and been the most unsuccessful. In large, medium and small plants, all are the same, although they got every care given to them. Even a lot of strong healthy plants got eaten down by hares, leaving 2 to 7 or 8 inches of a stump above ground, which was afterwards carefully protected. But almost all have died, so I say stumps no more.

Seed at stake: with a good protection from wind, and a light shade, if the season is favourable, success must follow.

Plants in pots or baskets well hardened about a foot high, their little rootlets as little disturbed as possible and immediate protection from wind, should also do well, if planted in season. After they are planted out, a checkered sunlight does more good than dark shade; and when they make a fair start in growth, gradually get them into full light. A stirring up of the soil round about the plant 18 inches to 2 ft. also brings the plant on very fast. They are also the prey of many insects, and consequently require much attention. But when they get up, where, or what, will we get for a more handsome lucrative tree, loaded with fruit, giving recompense for our care and attention? I so far agree with Mr. Drummond that cacao does require shade, according to clearuess and power of the sun, but I do not care for jak, it being dense. But with my little experience as yet I cannot say what tree would be the best. Perhaps, a mixture of Liberian, rubber, Cloves and a few plants here and there—in fact any light shade tree that will give returns and be remunerative, and wind-protecting. Belts of nutmegs ought to keep out any amount of wind.—Yours truly, R. C.

ROOT CROPS.—It is astonishing that the cultivators of India should never have considered it a part of good farming to cultivate root and other crops purely for cattle feeding purposes. We give the results of a series of experiments at home, from which it will be seen that a crop of 30 tons (81S) maunds of turnips has been raised from an acre.—*Indian Agriculturist.*

FROM CEYLON TO FIJI.

(By an ex-Travancore Planter.)

THE VOYAGE FROM MELBOURNE TO LEVUKA; LIFE IN FIJI.

The "Suva" left Melbourne on January 12th, passed Lord Havre's Island January 17th, and on Jan. 23rd sighted Kandava, the first of the Fiji group. On the same day, we anchored in the harbour of Suva. The entry to it is by a break in the coral reef by which the island of Viti Levu, like nearly all the rest, is surrounded. Those reefs to a certain extent form a natural breakwater. The Bay of Suva was very beautiful, the water calm as an inland lake, the forest-clad hills rising up from its southern margin, wonderfully fresh and green. They rose to a height of about a thousand feet, when they bordered on a "glorious cloudland" that would form a fine subject for Mr. Skeen's *camera*. The other side of the bay is low-lying and covered with an orange-green grass intermixed with light scrub of a deep green. The forest does not appear to be so heavy as in India: it gives the impression of being soft and luxuriant. The forest scenery on the whole has a good deal of resemblance to the low-country hills nearest Colombo on the Kandy railway, if they were brought down to the sea. The grass of Fiji has the appearance of being very rich; when it is well cropped down by cattle it forms a beautiful sward. Sewa at present does not consist of more than a store or two, a hotel, and about a dozen houses, but there is a lot of building going on. Some unmistakably English cattle that I saw grazing gave a homely look to the place. I made the acquaintance of the South Sea Islanders for the first time at Suva. They are a fine muscular race, copper coloured, with broad noses, protruding lips, and hair like merino wool. The Fijian trims his hair to stand on end in a curious fashion, but the imported labourers take no trouble with theirs. The Fijians are not good workers, I am told. They were Fijians, however, who landed the cargo from the steamer. Generally, they are employed on such jobs, as, though incapable of sustained effort, they can work very heartily for a short time, and, being strong men can carry big weights. The South Sea Islanders are not at all so servile as Hindus, but the shrewd look of many a Tamil cooly and kangani is wanting. Unlike the Hindus, they are always laughing and joking. The fibre of a tree generally forms the dress of the Fijian: he wears a piece of it round his waist, and many folds in a turban on his head. This natural cloth has often a sheen not unlike that of satin. A ball dress made entirely from it is exhibited in the Fiji Court at the Melbourne Exhibition. The imported labourer, I think, nearly always wears cotton clothing.

About 2 o'clock on the 24th January, we left Suva for Levuka, and arrived there about 9 o'clock at night. The *ci-devant* capital of Fiji looks very beautiful when viewed from the sea at night. Its lights are rendered wonderfully brilliant by being set in the dark shade of the hill. The impression I formed of the place then was not displaced next morning by the test of daylight. It is really at any time a picturesque place. A town entirely of wood and iron was novel to me, and I was reminded of descriptions I had read of American townships "Out West." On the hillside above the business part of the place, there are a good many houses tastefully built and situated. The principal street naturally faces the beach. The most prominent building is the Mechanics Institute. The Bank of New Zealand is very tastefully finished. The *Fiji Times* issues from a fine new building. The houses in Levuka, as all over Fiji, are of wood, generally with iron roofs, but sometimes with shingle. The preference given to the former roofing would lead strangers to suppose that the people of Fiji, not content with the climate, endeavour to bring it up to the highest standards of tropical heat by attracting with the agency of iron as much as possible of the sunshine to their dwellings and places of business. Shingles are quite as easily obtainable as iron. Timber is imported from San Francisco and New Zealand. Native wood is not much used, sawing in pits under European supervision being very expensive, and only one saw-mill being yet erected. The inhabitants of Levuka as a rule, go about in shirt sleeves, and with hats that in Ceylon would be regarded as most inadequate protection from the sun. Children attending school go considerable distances to their homes at midday for their meals, and return to school again; apparently without any evil effect. Here, a European, however high his rank, does not think it necessary to move about in a bandy as in Ceylon and India. Riding is more in vogue. Horses are imported here at reasonable rates. They receive very little attention from their owners, and many are allowed to graze about at will. Sheep and cattle are reasonable in price. Sheep do not do so well, as they grow too fat for breeding purposes. Angora goat-farming has been instituted, but I have not ascertained if it has reached beyond the experimental stage. Pigs do very well in some places. They are found in a wild state, and they with a few kinds of fowl constitute all the sport. Fish is very plentiful—in the sea. The finny inhabitants of the Fijian waters are singularly sagacious, and, as a rule, give a clear berth to the baited hook. Some, of a small description, are caught in nets by women. It is a very curious sight to watch them on those expeditions. Some hold the net in a suitable spot, while others frighten the fish towards it, by approaching in a line, and making a peculiar sound by clapping the hands under water. Plantations are near enough to the sea, but Ceylon planters who may think of coming to Fiji need not entertain any fairy visions of fish. Fresh and very good meat is always to be got in Levuka, but such is not always the case in the outlying islands, where people are often obliged to be content with salt beef, which has the merit of being of good quality, however questionable its suitability in a salted state for the tropics.

The two principal districts in Fiji are the Rewa and Taviuni. The latter island I have seen, and it well deserves the appellation of the garden of Fiji. It rises in a very fine slope to a height of several thousand feet, and there is very little indeed of it upon which coffee would not grow. The coffee I saw was at an elevation of about 1,500 feet. It was free from leaf disease and in fine vigorous growth. The soil is a dark vegetable mould, almost peaty in appearance. It seems to suit the coffee plant admirably. It is of great depth, but, though this will give greater freedom to the tap-root, I do not see that soil for ages buried at this level can supply more vitality to the plant than any other kind of sub-soil. Owing to the volcanic origin of the soil, it absorbs the rain very rapidly, but there is certainly some wash. I think draining would be an advantage, but that is not the opinion entertained here. Coffee is found not to do at all well under shade. Belts for the wind are supposed to be a mistake too, and have been felled in some cases. I think, however, they should be as valuable here as they undoubtedly are in Travancore. I saw the effect on coffee of the very heavy gale that swept over these islands a few weeks ago. The coffee was two years old and unstaked. There were no leaves blown off, but a good many trees were shaken, which would have been prevented had they been staked. Land suitable for coffee costs about £3 per acre, but I think it can be bought cheaper inland. Eight and ten cwts the acre is not a fiction that distance fabricates, but sober fact. On well-kept coffee there is seldom any picking below the figures, and not

unrarely they are exceeded. There is a curious fact in connection with coffee leaf disease in Taviuni. A comparatively old estate, which had been neglected and allowed to grow weedy, is suffering from leaf disease. Very near, and in constant communication with it is a young estate. It has remained all along free from the disease. I have seen chinchona succirubra plants growing a few feet above sea level. The growth seemed everything to be desired, but I fancy the analyses cannot turn out well at such a low elevation. There is, however, plenty of suitable high land. I also saw a few tea plants, and they seemed all right. One considerable item of estate expenditure is buildings. Only European carpenters can be obtained, and they receive 16s. per day. Timber also is costly. The South Sea Islanders seem to have no mechanical genius whatever, and the attempts of missionaries to teach them useful arts have failed. They are quick to pick up common duties, and, on the whole, seem to be as good workers as the Tamils. The Government is accused of being morbidly anxious for their well-being. Whether this be the case, is hard to say. No doubt, when Sir Arthur Gordon unfurled the British flag, very different laws to those of the old native Government were necessary to give every one the liberty of the British subject, and the old settlers must have felt the difference, and given an exaggerated importance to the subject. The labourers, being engaged by Government and guaranteed protection, no doubt fully avail themselves of the situation: more so, certainly than if the planters dealt directly with them. Superintendents—they are but "overseer chaps" down here—are, as a rule, boarded by the employer and receive salaries ranging from £6 to £15 per mensem; a few managers of large properties are paid better. These rates chiefly refer to sugar, which is as yet a much more important industry than coffee. I think the public of Fiji might with very good taste do away with the term overseer; there are so many disagreeable associations connected with the word. Any K. C. B. objecting to sit at table with artizans should not come to Fiji. It is a very democratic colony. The missionary work is chiefly in the hands of the Wesleyans. They, and the Roman Catholic missionaries in a less degree, stopped the horrible vice of cannibalism, and prepared the islands for the advent of the British settler. This fact should be an unanswerable argument to use with those who ridicule missions. The inter-insular trade of Fiji is carried on by a large mosquito fleet. There are a few pretty large steamboats and vessels engaged in it. There is communication once a month with Sydney, Melbourne and Auckland. The Sydney boat, rejoicing in the Indian name of "Ganga," is a very fine large steamer.

SILK PRODUCING.

On Silk-producing, and other lepidopterous insects, by Alfred Wailly (Membre Lauréat de la Société d'Acclimatation de France), 110, Clapham Road, London, S. W. England.

The following paper on this subject will, we think, be found interesting to many:—

During several years, I have studied and reared many species of silk-producing Bombyces and other lepidoptera. My reports on this subject, have appeared in various numbers of the "Bulletin de la Société d'Acclimatation," Paris; the "Journal of the Society of Arts," and "the Entomologist," London; "Isis," Berlin; "The Scientific American," New-York, &c.

Of the wild silk producers reared in Europe, I may mention: Attacus Yama-Mai, from Japan; Attacus Pernyi and Attacus Cynthia, from North China; Telea Polyphemus, Samia Cecropia, S. Promethea, and others from the United States of North America; Attacus Mylitta, Attacus-Atlas, and Actias Selene from India.

The sending of living cocoons and pupæ (which I purchase every year) has always been successful from North America, but as this has not been the case with respect to live cocoons sent from India and South America, I shall make a few remarks on the sending of live cocoons and pupæ from India, and other distant countries to Europe.

The time for sending these living insects should be from about the beginning of October, till about the beginning of April, so that the cocoons should not be subjected to the heat during the whole time of the voyage to Europe. On the cases containing the cocoons and pupæ, there should be written in large letters: *Living cocoons* or *Pupæ of lepidoptera*, with request to keep them in the coolest places in the ship. The cocoons should be well packed in the straw, hay, moss, or anything that will deaden the shocks, to which the cases may be subjected in transit. Bare pupæ must be placed in bran, saw-dust, or soft moss, &c. All should be sent, as soon as possible, after their formation. Small quantities of cocoons pupæ should be sent by *sample post* in *registered boxes*, not exceeding eight ounces in weight for each box; the boxes must be strong, and it is best to tie a label to each box, and affix the stamps to the label

Persons, living too far inland to send living pupæ, may send dead specimens of the perfect insects, butterflies, and moths. These should be *in good condition*, and placed with folded wings in paper envelopes. As it is well known, butterflies are caught with a gauze net, they should be killed immediately after they are captured, which can be done by carefully pinching the thorax of the insect when its wings are folded; or, as it must be done with moths, they should be placed in a bottle, containing cyanide of potassium, or some other poison. It is also important, when the dead insects have been put in a box, to add some poison to protect them from the attacks of mites, dermestes, beetles, ants, &c., as there are great many entomologists in Europe, who make a particular study of the larvæ of lepidoptera. I shall now pass to this subject.

To rear lepidoptera from the egg, the moths should be placed in cages (having muslin sides) for the inception, and the laying of eggs. Moisture should be maintained in the cage. When the ova have been obtained, they should be placed under a glass, with a small branch, or leaves, of the proper feed plants, so that the larvæ should find their food as soon as they are hatched.

When the larvæ (caterpillars) are small, I rear them under bell glasses, having a few holes on the dome. These glasses, which are of various sizes, according to the number of size of the larvæ, rest on saucers, full of sand, covered with a piece of paper. Small branches of the food plants are plunged through the paper into the sand, and keep fresh for several days, even without water. The glasses must, of course, be kept in the shade. Some species can be reared in this manner, till they turn into pupa (chrysalid state. With respect to the larvæ of the large Bombyces, after the first or second moult, it is best to rear them, without the glass covering on branches (the longer the better) plunged in water; small twigs must be avoided.

The larvæ should be reared in the open air, but sufficiently protected from enemies, or in a well-ventilated room; also (and this is the best plan) on the living trees, protecting them from birds, &c.

Larvæ, which go into the ground to turn into the pupa state, should be reared in cages, containing a few inches of light soil; such cages must be used with larvæ, the habits of which are not known. An open box or case containing a few inches of soil is often all that is required. A branch of the food plant is plunged in a bottle containing water, and the

bottle is placed in the box. When a box has to be closed, air must be given by means of perforated zinc on the sides of it.

Larvæ can be found in almost unlimited number, on bushes, shrubs, trees, and low plants. Larvæ, which feed by night, can only be obtained in large numbers, by looking for them with a lantern at night.

Cocoons are found on the branches, on the trunks, or at the foot of trees; pupæ by digging at the roots of trees; others are found on the stems of grasses, on branches in the bushes, and on walls and fences.

To conclude, I may say, with regard to the sending of cocoons, pupæ, and also ova of lepidoptera, that, with a little care, and especially, if they were given in charge of the captain, or some other person on boardship, they could be sent to Europe from distant countries, and arrive alive in good condition.

In 1864, salmon and trout ova, were safely sent from England to Australia and Tasmania, packed in a box, which was placed in the ice-house of the S. "The Norfolk." In the same manner, silkworm ova, cocoons, and pupæ could be sent to Europe from very distant countries, and arrive in perfect condition. Alfred Wailly, 110, Clapham Road, London, S.W.—*Indian Daily News.*

CALIFORNIAN BEE CULTIVATION.

There is ground for supposing that there were no bees in the New World prior to the invasion of the European. The Indians agree that the busy little insect is never found far distant from the outskirts of civilisation, and there is a recorded tradition that the invasion of California by the backwoodsman was predicted by a warrior of the Gumas tribe, on discovering a bee-tree on the Gila River. As civilisation advanced, however, its pioneers soon learned to value the honey; and a race of hunters grew up, who made it their business to track the flight of the wild bees to their nests in old hollow trees, and then, by smoking the bees out, and cutting down the tree or its branch, with a hatchet, obtaining the combs, which were carried away in buckets and tubs. It is only in recent years, however, that anything like bee culture has been attempted; but so rapidly has the system extended, that it has now become quite an important industry, more than thirty-five millions of pounds of honey being annually produced and sold in America. The trade is principally carried on by large capitalists who have often from 2,500 to 5 000 swarms of bees, and even larger numbers, one firm having as many as 12,000. Perfect organisation is necessary for the management and care of the little workers. In the United States the bees are "farmed out," *i.e.*, apiaries of say a hundred swarms are placed in the grounds of farmers, the distance between each apiary being generally from three to four miles. The farmers receive either a fixed rent or a share of the honey for the accommodation. The bee-owner has a staff of skilled workmen who clean out the hives and remove the boxes of surplus honey as they are filled. In addition to these experienced bee-men, occupation is afforded for many other people in manufacturing the boxes in which the honey is transported to the different markets, one firm alone, we believe, finding employment for nine men and two steam saws during six weeks of the year in cutting up the timber for the 72,000 boxes which they require. The glass-makers also find some custom from the honey dealers, the slides and ends of the boxes being of glass. On an average one acre is estimated to support twenty-five swarms of bees, and the yield of a swarm is generally about 50 lb. of honey; so that the trade is evidently capable of yet further development. Much attention is paid to the improvement of the breed of bees, and, with characteristic ingenuity, the Americans have introduced many contrivances to save the time and labour, not only of the honey dealers, but of the bees themselves.—*Graphic.*

AN OLD PLANTER ON CEYLON PLANTING PROSPECTS

This mail brings us a letter from a Kadugannawa and Walaha pioneer, whose communications were well-known in our columns in "Days of Old" under the sobriquet "Saxon." We quote from his communication as follows:—

"I am at present at Bath. It is a very beautiful city and neigbbourhood, with a genial climate, but their spring, like everywhere else the cold east winds have been, is very trying. The weather is now fine and mild and spring may be said to have come at last. Farmers are having a hard time of it with such seasons. I am glad to hear a good crop is expected and that planters' prospects are looking up. It is always the way: people run from one extreme to the other. When I left Ceylon, planters were in high glee, and expecting great things. I must say they have been very extravagant and now that many have got to the end of their tether, they think it all up with them.

"I hope it will do many a great deal of good and and make them more cautious when good times return, to take advantage of their opportunites and make hay while the sun shines. How many times before have hard times come on the planters, generally at the time least expected. There is nothing new therefore in the present depression: it might have been expected, and there is no reason why good times should not again return, as they have always done before.

"Until you get two or three rattling good heavy monsoon rains, you will not get rid of leaf disease: all other remedies will prove useless and unavailing.

"The rain must come at the proper time. You should have a very heavy monsoon next May, if my observations be correct. Remember me to all old friends in Ceylon. I still read the *Observer* with great interest, and only wish I could return again to have another spell at planting and to stir up your degenerate Government."

SOUTH INDIAN TEA AWARDS.

The *South Indian Post* publishes the awards for South Indian teas at the Melbourne Exhibition and adds:—

The above must satisfy even the most sceptical that for excellence of quality, our South Indian teas stand unrivalled. The Nilgiri Tea Planter has, of recent years, been much disheartened at the low prices that have ruled in the English market for Indian teas. The depression has been variously accounted for. Indian produce was insignificant till very recently, and the overwhelming influence of the importers of China tea has been brought to bear, to drive it out of competition. The fall in price has been disastrous to many concerns within the past twelve months. Scores of tea gardens have been abandoned in the North. Quality not quantity has been the continuous cry from the brokers at home, and the reason for a demand of this nature is not far to seek. Systematically Indian teas have been used to mix with the inferior China article much to the detriment of the Indian tea industry. Fresh markets have, of course, been suggested as a remedy, and investors in Indian tea gardens have not been slow to discover and take advantage of such outlets as offered. The Melbourne Exhibition offered a capital opportunity for establishing a market in Australia, and the high awards for our tea must be most flattering to the fortunate planters who had been to the trouble of competing. Two of the Coonoor gardens—Brooklands and Glendale—have taken the first order of merit for their

Orange and Flowery Pekoes. We believe both these estates adopt the same processes of manufacture. For a sound bulky tea, the Kodanaad Estate takes a high place. This estate alone manufactures no less than four hundred thousand pounds of tea per annum. The sati-factory results above will do more to push Indian tea in Australia than a year's advertising.

CURE FOR COFFEE GRUBS.

We very seldom forget a handwriting (any more than a face) we have once seen; but we are puzzled to identify the old colonist and probably contributor, who sends us the following "pencil notes" by last mail from the Highlands of Scotland. Certainly, his contribution to the "grub" discussion could not have arrived at a more seasonable time, for the evil is at this moment under the consideration of the Committee of the Planters' Association, and will probably form a topic of remark at the general meeting to be held early next month. "Grubbing" with the aid of pigs is surely worth a trial. Here is what our correspondent says :—

"Enclose, say, a quarter of an acre of badly grubbed coffee with upright stakes with waratchies interlaced sufficiently strong to prevent a pig breaking through: into this enclosure put 2 or more healthy hungry pigs with a bucket of water and sufficient poonac daily to keep the pandies in life merely, and let them hunt with their noses for the rest of the living—make them work for *their grub* in fact, and in a fortnight I would be surprised if there is a grub left in the enclosure—the droppings from the pigs will also in a great measure pay for outlay in poonac, and if a really well fed and educated "sandy" is wanted for the bungalow there he is! Thirty years ago—alas!—I remember a fearful epidemic of typhoid fever having set in, in a large set of coolie lines—the mortality was fearful. A medical man was engaged and stationed on the estate to watch progress. He at once ordered the coolies to be removed from the lines to the store, or any other available houses, and condemned the old lines to be burned. This was done and a site for a new set was looked for. This was fixed upon a very badly grubbed bit of coffee, as useless for further cultivation. I remember the appearance of the white dried stems and branches with just a leaf here and there to shew there was still life in the plant. Well the lines were built, coolies dwelt therein and once more the sound of song and tomtom arose among the survivors of the unfortunate crew who dwelt in the old lines on the patana. The coolies were allowed small patches for gardens, as the ground was considered worthless for coffee cultivation. They also kept pigs, and with the upturning of the earth, grub hunting, the plot was in a very short time like a newly ploughed field! In less than six months, tender young leaves began to come out on the dried branches, and in the following year they came out abundantly, looking as glossy, fresh, and green as any planter would like to see. Grand healthy trees took the place of the old dried ones, and up till 1862, when I saw them last, they were perfection, and bearing, I should say, 15 cwt. per acre, at least. Some will say that this occurred only in the immediate neighbourhood of the lines, but no; the improvement stretched for acres round, and was clearly traceable to the grubbing of the pigs. The experiment cannot cost much, and I hope it will be carried out with favourable results. Pigs, it is true, help themselves to coffee berries, but a wreath of the Longden thorn, or any other substitute, would prevent them from putting their noses where they were not wanted! Should the experiment be found a success, improved hurdles, such as they keep sheep in the turnip fields here, could be made at little expense."

COFFEE LEAF DISEASE AND MR. SCHROTTKY'S REMEDY.

LINDULA, 14th May.—Although it is a dull time of the year, our district is not entirely void of work interesting to coffee planters. I refer to the operations which are going on for the expulsion of our worst enemy, *leaf disease*. But is it necessary to name it? For it is ever in our thoughts, a source of continual anxiety and biting care.

Passing through Gleneagles on Friday morning, any one would have thought that snow had fallen in the night. A portion of the estate looked quite white. The cause of this was soon apparent, for along the lines of the coffee arose great puffs of smoke, as if our artillery had been brought up to extirpate the long suffering coolie.

On getting nearer, however, I saw that the coolies themselves were casting on the winds handfuls of pinkish white powder, so fine and light that the slightest breeze carried it along in rolling clouds, enveloping completely, trees, coolies, and superintendents. The effect on the trees was as if they had been snowed upon, every leaf being as covered with the powder as the lilacs and laurels along the Clapham road are with dust on the evening of the Derby day. The coolies looked like millers but seemed as jolly as sand boys, though the powder is annoying enough at first, and results, until one gets accustomed to it, in a pretty strong fit of sneezing.

This was the scene of Mr. Schrottky's process of vaporization, and whatever the ultimate effect may be in keeping away or checking the disease, the application is most thorough. Not only the leaves, but the branches, the stems of the coffee trees, and every inch of ground is covered with the impalpable powder, and the smell of it is all-pervading. What chiefly recommends itself to me in this method is the simplicity and ease and *thoroughness* with which it performed, and I think Mr. Schrottky can be congratulated in having devised this practical form of applying carbolic acid to the trees as a cure against leaf disease. All authorities seem to agree in considering carbolic acid a specific for parasitic fungoid life, but the difficulty of applying it, seemed insurmountable, as no one ever thought of applying it but in a liquid form. It was a bright idea to incorporate it with a dry medium and use it as such an impalpable fine powder. The success of the application if success there be as I heartily hope, will be due entirely to this. I hear that 60 average coolies have yesterday gone over nearly 80 acres, and Mr. Schrottky hopes to finish the estate (about 200 acres) on this, the second day.

MR. GRAHAM ANDERSON'S revelation of the views of the Java Government in reference to coffee leaf disease certainly astonishes us. Apart from the probability that the statement about a reward (which was certainly published in Batavia journals) was never officially communicated; was in fact a planter's or merchant's idea misconstrued—the wish being father to the thought: yet how can we reconcile the *official* answer that *hemileia vastatrix* in Java has never assumed a serious form, with the actual results of the present coffee season in Netherlands India? Is it not shown on the same official authority that we must go back to 1834 to get a coffee crop so small as that anticipated for this year from Java, and to what but leaf disease can this extraordinary falling-off be attributed? The Java authorities would seem to be blinded to the fact, and yet, only last year, they proposed sending an expensive Commission to travel through Ceylon and India and report on *hemileia vastatrix*!

In the Brazilian province of Bahia the juice of a certain climber has been found to yield a wax from which excellent candles can be made and, from the resinous bark, candles are obtainable which rival spermaceti in whiteness and brilliancy of light.—*S. A. Journal.*

TEA IN CEYLON.—MR. MAGOR (partner in the well-known Calcutta House of Messrs. Williamson, Magor & Co.) has been on a short visit to Ceylon. He spent a fortnight in visiting the Yakdessa and Ambegamuwa tea districts, Dikoya, Dimbula and Hewaheta. He was much pleased and rather surprised to see our progress in tea and thought a great deal of our prospects where the tea was planted on fairly good land, but thought it was a mistake to plant on chena or old worn-out land.

SUN-STROKE AND DIET.—Dr F. T. Oswald writes as follows about sunstroke in the *Popular Science Monthly*, for April last:—"To abstain temporarily from animal; food taking refrigerating diet such as vegetables, fruits, &c, counteracts the effects of a high atmospheric temperature, but the calorific influence of meat and fat, combined with solar heat and bodily exertion overcomes the organic power of resistance; the pyretic blood changes produce congestion of the brain and sometimes instant death. I venture the assertion that in 19 out of 20 cases of comatose sunstroke it will be found that the victims were persons who had gone to work in the hot sun after a meal of greasy viands. One to two p. m. is the sunstroke hour.

TEA AND TEA.—There are frequent complaints from "the Lane" as to the quality of the China tea sent over to this country. There is a marked deterioration even as compared with the inferior quality of some of last season's shipments. China tea of a kind has been sold as low as 2¾d per lb., a price which we venture to think is sufficiently indicative of the kind of rubbish which now finds its way into the market. Indian tea, although prices are not encouraging to growers, is becoming more and more popular among consumers. Grocers are directing attention to it, and now it is the rule to see trade announcements in regard to blends of Indian and Chiua, while not a few retailers sell pure Indian tea, and think that the exigencies of the times demand that they should announce the fact in large type.—*H. & C. Mail.*

MINING INDUSTRY.—No better method of developing on a large scale the mining resources of any country has yet been discovered than by the formation of public companies. The "Benighted" Presidency has been singularly fortunate in securing a large share of the confidence of London capitalists in respect of the Wynaad and Nilgiri gold regions, no less than sixteen Companies having been formed for the purpose of gold mining in the district of Devala alone. This will bring a great deal of foreign capital into that Presidency, and if gold quartz be turned out in a fair proportion of the mines in paying quantities, a new era will have commenced there, both for capital and labour.—*Times of India.*

YIELD OF RUBBER TREES.—The twelfth volume of the *Encyclopaedia Britannica* just published contains an article on "India rubber," by Messrs. E. M. Holmes and T. Bolas. We shall give this ere long, but meanwhile we give the figures for yield of caoutchone from different varieties of trees. Pará (*Hevea Braziliensis*) yields 6 ounces in 3 days, the juice yielding generally 32 per cent of its weight as caoutchouc. For Ceará (*Manihot Glaziovii*) the yield is not given. Central American (*Castiloa elastica*): a tree 20 to 30 feet high to its first branches is expected to yield 20 gallons of milk, each gallon giving about 2 lb. rubber. Assam rubber (*Ficus elastica*): about 20 oz. milk collected in August gives 15 oz. caoutchouc, but the percentage is sometimes so low as 10 per cent. From February to April the milk is scantier but richer in caoutchouc. Borneo rubber (*Urceola elastica*) yields sap in three years. Rangoon rubber (*Chavannesia esculenta*) yields 3½ lb. at 7 years. This is certainly very encouraging

THE WAX PALM IN PERNAMBUCO.—The Camanba palm (*Copernicia chifera*) seems to be a much more important plant in some parts of Brazil than is generally supposed. In Pernambuco the plant is very abundant, and the uses to which it is put very numerous. The wood for instance, is used for roofing both as beams or rafters, and as laths upon which to support the tiles; the fruits are used for feeding cattle, and the leaves are used for making hats and mats. A valuable medicine is obtained from the roots, which has recently been brought to notice in this country. From the shoots or leaves a wax to obtained; for this purpose they are cut before they unfold, dried in the sun, powdered and boiled, the wax rising to the surface of the water. This wax, it is stated, is not produced in any thing like the quantity that it might be. It is shown, in a recent report of Her Majesty's Consul at Pernambuco, that the export of this wax during 1875-76 amounted to 18,668 kilos. valued at £778; in 1876-77 to 171,980 kilos valued at £6,957; in 1877-78 it fell to 89,482 kilos of the value of £3,168; and in 1878 79 to 1,542 kilos valued at only £61. By far the largest portion of this wax finds its way to this country. It is shown that the decrease during the last year was due to the famine and drought which so severly crippled all industry in the province. It is not a little remarkable that, at the time when roasted date stones are proposed as a substitute for coffee, we should also learn that the stones or seeds of the Camanba palm, when roasted, are used in Pernambuco as coffee.—*Journal of the Society of Arts.*

THE DEGENERACY OF INDIAN CATTLE.—The *Indian Empire* remarks on this subject:—If the inferior breed, we now find, were indigenous to the country, it might have been useless to complain. But such is not the case. So far back as nearly seven centuries ago, Marco Polo, speaking of Bengal, which he evidently never visited, but wrote about from report, says:—"The people have oxen as tall as elephants, but not so big." At any rate, the *Ayeen Akhbarry* mentions that very beautiful white oxen of great size and capable of carrying a load of 15 maunds were to be found in Sharifabad, the modern district of Burdwan. Nor is the description in the *Ayeen Akhbarry* improbable or exaggerated. To this day especially the districts of Hissar and Hurrianah in Northern India are famous for the large size of their cows, which are sometimes used for draught purposes by the Commissariat Department, and are occasionally to be met with in the streets of Calcutta. Keeping in view the extremely varying conditions of soil and climate in Burdwan and those two districts of the North-West, we are decidedly of opinion that neither the soil nor the climate is responsible for the great deterioration in the present breed of cattle in the Lower Provinces. The first step that should be taken to prepare and smooth the way for a fair chance to the improvement of the present breed of cattle must obviously be to encourage the cultivation of green crops which will yield a supply of the most nutritious fodder. When this first step has been taken and generally adopted, it will then be possible to give a fair chance to the physical revival and fuller development of the present miserable breed. It will be time enough afterwards to attempt the improvement of it by crossing it with better and more vigorous stock, imported from other parts of India, and even from other countries in the world, which excel in the size, physical strength, and milk-producing capacity of their cattle. If only the economic value of this reform were once fully realised, it is probable that some earnest effort to bring it about would be undertaken. But it is not within the province of the Government to initiate such an enterprise, nor is it within the scanty means of the agricultural classes to undertake it. It lies with the zemindars to take the matter up.

SALE OF JAVA CINCHONA BARK.

In publishing the following Sales-return, it is necessary to remind our readers, that the prices realized are given in cents of a florin, which coin is equal to about 1s 8d sterling and therefore, practically, to our rupee. It must also be noted that the "half-kilo" is 1 1-10th lb. avoirdupois. It will thus be seen that no very wonderful prices were realized at the latest sale of Java bark, the very best being 398 cents for 1st quality officinalis stem bark, the equivalent of about 6s 1d per lb. Calisaya Schuhkraft sold for a better price than Ledgeriana; but of course none of Mr. Moens' carefully selected produce can have been offered on this occasion:—

On 11th March 1881 the following lots of Java cinchona bark were sold at Amsterdam:—

86 *bales* and 29 *chests Java cinchona bark.*

COFFEE-PLANTING IN SOUTHERN INDIA AND CEYLON.

The following letter recently addressed to the editor of the *Madras Mail* is worth reproducing:—

COFFEE CULTURE IN INDIA.

SIR,—As I am about to invest in Coffee, I should be much obliged if any practical Coffee Planter would kindly give me, through the medium of your columns, the results of his experience on the following little points.

Often, in walking over estates of two hundred acres and upwards, you will observe single trees and little patches of coffee here and there, bearing at the rate of ten cwt per acre, and in the case of the single trees often as high as at the rate of four tons per acre. On enquiry you will find that the average crop of the whole estate is under thirty tons. The expenditure you will be told is about two thousand pounds per annum, and with a shrewd guess you will know that your friend is receiving some five hundred pounds a year as interest on the money sunk in his estate, and considers himself rather a lucky man and worth (by his own valuation) some ten thousand pounds—the value of his two hundred acres of coffee. He will blandly tell you that coffee property is cheap at fifty pounds per acre. I am told that this would be a good estate. On the other hand you will often see gardens, of an acre or so in extent, about bungalows in towns where manure is easily got, bearing annually at the rate of one ton per acre. Now, what I want to know is whether I should buy a large estate, or whether I should buy fifty or sixty acres of the best jungle procurable, and having opened it out, begin with heavy manuring from say the second year of its growth. By heavy manuring, I mean sufficient to force it to give at least ten cwts per acre. As single trees on a large estate, without manure, will give ten cwts. per acre, I presume that by manuring sixty acres sufficiently heavily, at least thirty tons could be produced annually, and at a much cheaper price than it could be on an estate of two hundred acres, and of course with a great deal more profit. About manure not being procurable in sufficient quantity for the above system of cultivation, I am told that any quantity of bone dust and poonac meal can always be got on the Western Coast, and furthermore that these manures, if only on account of their easiness of application, are cheaper in the end than cattle manure is. CARACTACUS.

It has, of late years, been an admitted fact that it would be far better for coffee planters to have 100 or even 60 acres of really good land under coffee than 200 or 300 acres of indifferent quality. In the same way, certainly, better to cultivate the former area highly than to divide attention over twice or four times the area without capital or labour to do it justice. Sixty acres of coffee yielding 10, or let us say 8, cwt. per acre would be equal to a gross return of about R20,000 from the plantation, against which expenditure at the rate of R150 per acre would amount to R9,000, leaving a satisfactory annual profit. We have made a liberal allowance for expenditure, provided the plantation is not very badly off for labour and means of transport. In Ceylon, in many cases, expenditure has been reduced to R50 per acre without manuring, and R120 per acre is now considered here a liberal allowance even with high cultivation. Where labour is abundant and land freely available, the temptation is, of course, to go on felling and extending, one argument being that a European planter can look after 200 acres of coffee as easily as 60 acres; and another that in only most exceptional cases (in Ceylon) are the trees and soil now-a-days equal to yielding 8 cwt. per acre: 4 cwts. being more like the return even from liberal cultivation; and, therefore, a greater area must be counted on to make the investment worth the while of European planters. We feel sure, however, that the belief is becoming increasingly prevalent, that it would have been far better for most of the Ceylon planters had their motto been *Festina iente* in the extension of their plantations. Had the average area under coffee in the young districts been 100 instead of 200 acres per plantation, while the reserve forest was gradually planted with new products (tea and cinchona more especially), the position of the planters would be much stronger and

better to-day. Grub, leaf disease and other enemies would have been less prevalent; the capital outlay would have been much lower; and time would have been given to learn whether coffee, tea, or cinchona was the most suitable product to cultivate. We remember, in visiting the Dimbula district so far back as 1872, and hearing on all sides the boast of one man planting 300, 500, 700 or even 1,000 acres with coffee in one year, recalling the fact that in the "days of old," when work was more carefully done, a fifty-acres clearing was considered enough for one planter in a season. However, we may take it for granted now, that the era is past when purchasers of blocks of forest-land in Ceylon of 200 and 300 acres used to enter forthwith into felling contracts for the whole to be cleared in one season, in order to be planted with coffee. The order of the day with our planters now is, for a would-be proprietor to plant gradually, 50 or at most 100 acres in a season and with *a variety of products*. Let our neighbours in Southern India who are not benefited or affected by the "gold fever," take a note and profit by the dearly-bought experience of their Ceylon brethren.

A LOW-COUNTRY TRIP THROUGH "TERRA INCOGNITA" :—RAKWANA TO BENTOTA.

For a good many years, we had been pressing on the Rakwana planters to explore the country westward between their mountain range and the sea, with reference to the question of Railway Extension as well as to the opening of new districts. We are much obliged to the gentlemen who at length undertook the journey, and more particularly to "H. W.", who has furnished us with the following very interesting notes. It will be seen that, while there is no great encouragement offered at present for a railway or for pioneer planters, yet that the picture is not all darkly shaded. There are resources for cattle-feeding, for developing a timber trade, for gemming, and even for Liberian coffee and cocoa planting from Kabaragala westwards, which shew how great a change might be effected by road or rail and the introduction of capital. We feel sure that the report now furnished on this line of country will not be thrown away, but that it will be the means of directing the attention both of the Government and the public to what has hitherto been an overlooked and neglected district.

FROM THE GONGALA RANGE TO THE SEA.

We had long meditated a trip from Rakwana to Bentota. A plan of the country to be crossed was obtained from the Surveyor General, but it was little more than a sketch, and, as it turned out, we found that only three Europeans were known to have crossed the dividing ridge between Kukulugama on the Kudugama, an affluent of the Kaluganga and the Bentota river. One of these was Dr. Thwaites, who botanized in that country, and one a Government Agent of Ratnapura. It was veritably a *terra incognita* we were to explore. We could take no horses, and we had to trust a good deal to our good luck for food supply.

We started towards the end of February; it was a little late and the weather was showery, but a young moon promised its assistance as our journey progressed. Our party consisted of our two selves, an appu, fourteen coolies, and two Sinhalese guides. We called for the latter at the first village, where we found a harvest festival was being kept, the men all standing *en queue* two by two with hands joined and upraised before a temporary altar at which a young man officiated, intoning a service, and at the end of each sentence the villagers joined in with a vigorous "Hoch," which, if more than usually loud, elicited smiles of approbation.

The morning was far advanced before we felt that the distance covered warranted our stopping for breakfast, which we took at the foot of some giant bamboos on the banks of the stream we had followed all the morning. The stream here was broad and shady with deliciously cool looking pools that invited to bathe, and, while breakfast was being laid out, we had a swim and a change.

Our course so far had been a descending one, but we were now well away from the hills, and crossing the river entered upon a series of flats that succeeded one another with hardly a break to *Kukulugama*. These flats are narrow and border one or both sides of the river and are laid out as paddy fields or planted with minevi, which just now was young and of a bright-green colour. Sweet-potato plots also abounded, and these and the young minevi were carefully and very neatly palisaded, A few stiles would have been very useful, as our loaded coolies had frequently great difficulty in getting over the fence.

We halted at *Pennapella* for dinner at the Vel-Vidana's house. I may as well here remark that we had good and sometimes very good house accommodation all through our journey, stretchers and sometimes jakwood bedsteads and mattresses being at our disposal. We got a few snipe before dinner, which we took by the light of a kerosene lamp. An outhouse afforded space for the coolies' cooking operations, which were continued with great gusto, the rice being *ad libitum*, and only measured by their containing powers and the absence or happy presence of each article of curry-stuff being freely commented upon.

We carried our guns next morning, getting an occasional shot at a snipe, and breakfasted at the Muhandiram's bungalow at *Wedagala*—a new house and built on a strange-looking site high above the river. He explained that it was out of the way of the floods, which are the bane of this country. After this, we noticed that all the buildings were on elevations, and the alluvial deposits forming these strangely flat lands were now accounted for. What quantity of rain falls here in the twelve months is not known, but it must be very great, and leads to floods and famines, one of which is alluded to in an Administration Report of a former Government Agent of Ratnapura, as having caused the abandonment of thirteen (13) villages in the Kukulu Korale.

At *Delgoda*, which by the foot-paths is 25 miles from Ratnapura, we stayed two days at the Ratemahatmeya's new bungalow which he gave up to our use. He was expecting the Assistant Government Agent from Ratnapura, then Mr. C. A. Murray, who came to Kukulugama partly to receive the paddy dues, but chiefly to see this part of his province.

We employed the time in ascending the Wepanagala, two miles from Delgoda, which is 2,350 ft. high, and from which we had a good view of the country. Chena everywhere, in the hollows and on the hills, nothing but chena: suggestive of a large population with an insatiable desire for burning huge areas. The population is really very small, the rainy season is a long one, and I tried, but failed, to account for the total absence of big jungle. Ten miles to the south ran the Sinha Raja forest, running from the Morawak Korale in an unbroken line westward for some fifteen miles, almost uninhabited and away from available water carriage: with this grand exception, the landscape presented to the view a rough broken country, all chenaed. It may be that the constant rainfall is prejudicial to the growth of the jungle trees. The Ratemahatmaya told us it was usually fine in January and February, and sometimes in December, but wet all the other nine months, and that the fields are frequently flooded.

The advent of the Government Agent at Kukulugama caused a general movement to that village. The

foot-path crosses a number of tributary streams to the main river: many of these are wide and deep and are crossed by edendas. To a nervous man the transit over some of these is very trying, but to loaded coolies it would almost seem an impossibility. Our Tamils declined to attempt to cross on the swinging bamboo with loads, and we had to get the villagers to carry the loads over, not without much delay. The path twice crosses the main stream, and ferry boats at both crossings were available, seemingly without charge.

Kukulugama is the largest village in that neighbourhood, and we found a goodly assemblage had congregated to receive the Agent. Mr. Murray had ridden a portion of the distance from Ratuapura, but after leaving *Karawiti* the remaining seven miles had to be done on foot owing to the want of bridges. Since then, I believe that owing to Mr. Murray's representations something has been done to improve the road from Ratnapura, but a good deal must still be wanting. The roadway itself, as I understand, from *Agalawatta* in the Pasdun Korale to Ratnapura is well laid, chiefly an embankment, but bridges are required.

The poverty of the people was rendered very prominent by the price realized by the sale of the paddy rents—a few rupees. Sweet-potatoes are largely grown, but merely for local consumption. Gourds and beans of all kinds would grow well and are growing, but "It is not the custom of the people" was the reply, when we asked why they were not more cultivated. Tamarinds and limes were growing at Kukulugama. Fowls and eggs were scarce, and we were generally told to shoot the fowls as they could not be caught, the "custom" of the fowls being to roost in the trees round the huts.

It would be well if fairs could be instituted at the principal villages, say on the occasion of the paddy rent sale, and exhibitions of produce, accompanied by prizes, held. It must first be begun by the authorities, and later on the village headman would take a pride in keeping them up. Athletic sports and games of skill, say shooting matches, could also be held to unite all ages in desiring the recurrence of the fair day.

The true wealth of this district lies in its *cattle breeding* facilities. Nowhere have I seen such pictures of healthy cattle. Pasture-fed, as they necessarily are, they appear to be in prime order for the knife. But want of roads is the great drawback and enterprise is as usual wanting. I made frequent enquiries and I only heard one man say he had sold any cattle to the butcher.

Before leaving the Kukulu Korale, I will summarize my notes. The population is small and poor. The soil is very poor; some of it is flat alluvial land and might be suitable for tea and Liberian coffee. The climate is excessively wet, and I should say a very undesirable one for Europeans. The elevation of Kukulugama is 838 feet. The river there is about 60 to 80 feet broad, but navigation is hindered by falls lower down.

From Kukulugama we took the pilgrims' path and progressed southwards. Our way ran over a hill covered with jungle, a part of the Sinha Raja forest. The path was at first pretty good, was partly cut, and is kept in order by the villagers for the benefit of the pilgrims from Galle. The lower portion of the hill was, as usual, chenaed, but the top and further side were covered with large forest. We passed a small village—*Bambarabotuwa*, and shortly after topped the ridge, at about 1,200 feet. Here, and on the south face, was heavy jungle, all one kind, bora, the large leaves of which strewed the ground. The descent on the south side was painful, the path being a mere track over loose rock on very steep land.

The jungle was said to be infested with elephants. We stopped for breakfast and lighted our fire near a newly cleared bit of land, surrounded with jungle. There was a small hut on the clearing which we approached to make some enquiries from two boys in charge. The hut was a mere shed and served as cover for cooking operations, while their true abode was a hut in a tree. I went up the ladder of about twenty feet and found a well-built room of ten feet square securely placed in the branches, out of reach of the elephants, of whom the natives appear to be much afraid.

The distance from Kukulugama to Kalugala is about (15) fifteen miles. With the exception of the hora jungle there is little to note—broken hilly lands chenaed with but few signs of present habitation. At Kalugala we entered on a new aspect: a large population, healthy and robust and enterprising; the houses were remarkably good, tile roofs, handsome verandahs with carved wood pillars and well-built whitewashed walls, presented an appearance which the interiors sustained. One bungalow contained a dining table sufficient to seat two dozen people, and there were chairs sufficient to accommodate all. The potato plots were large, one I noted as being about (3) three acres, and numerous coconut trees and fruit trees bespoke better soil and greater wealth.

The natives are chiefly engaged in timber cutting for the Colombo market. Water carriage is convenient, and some of the timber I saw was enormous. Whether much is left is a question. We saw but little, and could not learn of any as available; but it is possible we were purposely misled. To a canoeist, I cannot imagine a better country for a survey, deep streams running for miles in every direction, well supplied villages, and good lodging. From what I saw, I think it would well pay a man able to buy jungle land to make a trip up those waters in search of timber for the saw pit.

Gemming is carried on on that side, and we just missed meeting Mr. Symonds who had come up to superintend the survey of some gemming lots.

At *Hewisse*, I made a special trip to a piece of jungle, and I see my notes are:—alluvial soil, jungle trees of small size, with deep roots: top soil, sand and black loam for 12 in. deep: sub soil, yellow earth, sand and clay mixed—for 8 inches—in one hole 20 inches deep. Very suitable I thought for cocoa. I dug another hole, with similar result. There were no stones.

Apart from the water carriage, the means of transport are very defective. The edendas are better and more substantial than those in the Kukulu Korale, but the paths are worse. The ridge of the paddy fields formed the basis of the path in many places, changing with each crop, and at the best very treacherous. One well laden cooly slipped off the little ridge, and sticking manfully to his load would have disappeared, but for timely aid. In the wet season boats must be in great request, but they cannot supply the place of a road. A road from Colombo to Galle passes within a short distance of Hewisse and Hattá, and branches from that into the villages are required.

At *Hattá*, the Bentota river or Gin-ganga is 50 feet wide, very deep, and navigable for four miles further up. Very suitable for a steam launch—the river having little current and there being no obstructions. We made the distance from Hattá to Bentota twenty miles. We were told that a road also existed to Bentota from Hattá, but it would appear to be in little use. Whether there is large jungle near the river was not made clear. We saw none, but the boatmen spoke of one block as being not far away.

The journey to Bentota by boat was easily done in the day.

Looking back, the one thing noticeable was the want of means of communication. No roads, no bridges, rendered locomotion difficult and tedious.

From village to village, the direct road was merely a short cut, sometimes the rocky bed of a stream, impassable except in moderately fine weather. The constant wet produces a plentiful supply of sweet grasses, and the true wealth of the district should lie in cattle rearing. A little encouragement from the authorities by prizes being given once a year, and roads made to enable the cattle to be brought to market, would tend to develope this source of wealth so suited to the natives. The streams run in deep beds with abrupt steep banks. Fords are few and bridges are much required.

The population is small (the largest village being Hewisse with 523 inhabitants; Kukulugama may have 400); but probably enough to pay for the upkeep of the roads, after they have been made or put in order.

To sportsmen, Kukulugama in January would be a pleasant enough spot for a week's stay. There are elk, deer and peacock. If snipe and pigeons fail, the natives will allow of their fowls being shot! There must be lots of hares, and altogether I could fancy many a worse place for a visit. H. W.

CINCHONA CULTIVATION IN JAVA UNDER THE DIRECTION OF MR. MOENS.

It seems rather late in the day to publish Mr. Moens' Report on the Cinchona Gardens and experiments under his care, for the year 1879. Nevertheless it will be found that the information contained in the Annual Report for 1879 fully justifies its translation and publication in our columns at this time. There is no current source of information open to our cinchona planters of more interest than that afforded in Mr. Moens' Reports, and we need only attract attention to a few of the experiments made and discussed by him in order to shew their practical importance. For instance in reference to his favorite Ledgeriana,—the process of grafting which on Succirubra is specially referred to—we are told how difficult it is to get the tree to blossom (and consequently to seed) unless it has a long dry season. No wonder, therefore, though Mr. Moens when visiting Ceylon last year disapproved of the young and high districts between Great Western and Adam's Peak as a field for Ledgeriana. A lower and drier elevation will be required, and everything points to the Uva climate and soil as most likely to suit this richest of the quinine-yielding barks. The Madulsima Company and other proprietors who have already planted in the Principality are to be congratulated. So conscious are the former of the value of their cinchona enterprise that we learn they are to send out a trained analytical Chemist who will attend solely to their interests, reside on their properties, and no doubt carry on experiments similar to those in which Mr. Moens has led the way. To return to the Java Report, it will be observed that Mr. Moens had tackled the problem of growing a second set of cinchona trees *on the same land*. He pronounces it a very difficult task, but does not apparently despair of success if care and a little extra expense are given to the cultivation. The result will be awaited with interest in Ceylon. Again, Mr. Moens pronounces in favour of close planting, a point on which there is a considerable diversity of opinion among local planters. His careful statistics (compiled with all the accuracy of a chemist accustomed to deal with minute particles and fractions) of the actual yield of bark from both officinalis and Ledgeriana trees of different ages, and grown under different specified circumstances, will be of permanent value and are very useful for comparison with the results obtained on our hills. To enable comparisons to be made, we may remind our planters again that the kilogram is equal to 2 1-5th lb. English, and a meter is about 1 1-10th yard. The cost of harvesting the bark by the new process of scraping is given, and Mr. Moens has satisfied himself that drying the shavings in the sun does not affect their quality prejudicially. The destruction of a clearing of Ledgeriana—over ½ bouw (very nearly an acre) in extent through grub is an unusual experience. Has any one observed grub attack cinchona in Ceylon, or is it possible that some part of the mysterious dying-out of trees here may be attributable to this cause, no proper examination having taken place? It will be observed that the highest price secured for bark during the year under review was about the equivalent of 13s 9d per lb., and that this was paid for a case of shavings off Ledgeriana trees.

In the Report for the first quarter of the present year, it will be seen that Mr. Moens confirms the good opinion of the Ledgeriana-succirubra grafted trees, and this is really the special step in advance which Ceylon planters have next to practise; but how can this be done until the precious variety is made available here, our so-called "Ledgerianas" being tested analytically. Mr. Moens acknowledges that he profited in several ways by what he saw and learned during his trip through Ceylon and India, and we shall look forward with much interest to his special Report on the journey.

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA FOR THE YEAR 1879.

By J. C. Bernelot Moens.

1. STATE OF WEATHER.

During 1879 the weather was very favorable for the plantations. The proper dry monsoon failed, for the rain continued steadily and it was seldom dry for more than a few days consecutively. The plants in consequence made on the whole satisfactory progress. On two places on the establishments situated to the south of Bandoeng—Tjinjiroean and Kawah-Tjiwidei—rain-gauges were placed by the meteorological observatory at Weltevreden, and the rainfall was measured daily. On Tankoeban-Praoe this was considered to be unnecessary, as observations are already being taken there on the private cinchona garden Soekawana.

2. INCREASE.

The total number of plants standing in the open at the end of December was 1,678,670. Of these 44,100 were Ledgeriana cuttings and 310,970 Ledgeriana seedlings. In the nursery beds were 397,550 plants more, of which 7,460 were Ledgeriana cuttings. At the end of 1878 an abundance of excellent Ledgeriana seed was obtained, so that not only the nurseries of the Government enterprise but also those of private planters were fully supplied with plants of the best kinds. As was predicted in the former annual report, the first ripening of the Ledgeriana seed in 1879 was very late—in November and December. And the quantity was small, so that

the orders of private planters in Java could scarcely be executed, while to British India and Ceylon planters on this occasion no seed of this variety could be spared. The Cinchona Ledgeriana appears, more than the other kinds, to require a long dry season, in order afterwards, when the rain falls, to bring forth blossom in abundance, so that after the extremely dry year 1877 nearly every tree blossomed. After the unusually wet east monsoon of this year, there is the fear that now also again little blossom will appear,—and in that case that in 1880 also the fruit will not ripen before December. The planting of cuttings of Ledgeriana was continued steadily, but the success continues small, although attempts were made in many ways to introduce improvements into the mode of treating the cuttings. As the experiments made sometime ago—especially in 1876 - to graft Ledgeriana on other varieties of cinchona were not crowned with such success as to lead to their continuance, this year another method of grafting was practised which has succeeded excellently and promises well. The Ledgeriana grafts are now grafted on succirubra stems of about a year old, or on good rooted cuttings of this variety, in the manner employed in Europe for the grafting of rhododendrous &c. The whole operation takes place in the forcing-houses, where plants remain until they have made a good growth. A portion of these grafts, about 2,600, have already been planted out, and they are now at the commencement growing very vigorously. The question is,—and it can only be settled by the experiment,—if the graft can continue to grow on the succirubra stem and then share in the advantage of the quick strong growth of the red cinchona, or if this cannot take place in the long run. In the latter case an experiment will be made of placing the grafts very low down on the succirubra stems, and then planting the-e so deep that the graft itself will have the chance of seuding out roots and growing on its own account. The great advantage expected from this artificial propagation is, besides a quicker growth of the Ledgerianas, the possibility of obtaining a number of plants from the best of the trees experimented on. The attempt to grow cuttings of these, though often made, never succeeded, while now about a thousand thriving grafts of these trees very luxuriantly developed are ready to be planted. Among these are *inter alia* about a hundred slips of the tree No. 67 which yielded 13·3 p. c. quinine. The layering of Ledgeriauas, formerly tried now and then with good results, has been carried out this year on a larger scale, and this method of propagation also succeeds excellently. The plantations of C. officinalis were extended only on the high-lying establishment Kawah-Tjiwidei: the newly opened gardens there continue very good. C. succirubra was planted especially where the soil or the lay was less suitable for other varieties of cinchona. The number of trees of this species was increased by 42,600. The decrease in the total number of plants in the open is due to the following circumstances. 80,000 plants of C. officinalis have been written off as worthless, as will be further mentioned in sec. 3. At Lembang and at Tjibitoeng old gardens of C. Schuhkraft were rooted out, which showed little sign of further growth, so that a replacement by C. succirubra appeared desirable. The uprooting will be continued during 1880. At Tjinjiroean, where, in fields planted for the second time, great mortality was experienced, it appears from an enumeration that from this cause the figure for the existing plants was put too high, and this number has therefore been proportionately diminished. The harvesting reduced the number by about 200,000 plants, mostly of badly developed trees of inferior varieties. Of the best kinds, C. Ledgeriana and C. officinalis, this year the harvesting has been chiefly by the taking off of strips and the cutting in slivers (scraping) of the bark, and with officinalis also by the partial stripping after McIvor's method. Only on Nagrak about 2,400 officinalis plants were uprooted from a field which needed thinning out.

3. EXTENSION; UPKEEP.

At Kendeng Patoeha another piece of ground of about 10 bouws in size was opened. The want of work-people hindered the completion, so that at the end of 1879 only 4 bouws were cleared for planting. At Rioen-Goenoeng also a piece of jungle land about two bouws in size was added to the existing plantation. On the newly opened land situated on the Malawar mountains to the north of Tjinjiroean, and now as a separate establishment bearing the name Tirtasari, a wooden house was erected as a temporary residence for the superintendent. The want of labour here also prevented the speedy carrying out of the preparation of the land, but still by degrees some bouws were cleared for planting, while good progress was made with the chief roads. As this establishment has hitherto been reserved exclusively for C. Ledgeriana, obtained from the original trees by artificial reproduction (cuttings, grafts and layerings) the further operations could be put off until a supply of labour offered. In November the first two bouws there were planted, half with cuttings, the other half with grafts. On the old establishments progress was made with the rooting out of the fields of inferior kinds, chiefly to make room for Ledgeriana seedlings. It has been found that cinchonas grow much less readily on ground which has already been planted with cinchona than upon fresh jungle land. The same is the experience with the coffee estates, and in the case of the Government coffee culture the result has been a system of cultivation whereby the old gardens are being constantly written off and allowed to revert into fields of alang-alang, glagah*, and lantana, and new forest is felled for the purpose of opening new gardens. Notwithstanding the great expense attendant on a first opening, the advantage to the enterprise apparently is greater—on account of better and quicker growth of the cinchona trees—if the old fields, as soon as the first planting is cropped, are regularly abandoned, new land being opened. However, it is not for a Government enterprise to act such an example, and it will therefore be endeavoured by an increased and rational culture of the soil, and by bestowing more pains upon the plants, to bring those lands which from time to time become of a less satisfactory condition into a flourishing state. Since it is thought more advantageous to cover these lands, planted for the second time, as quickly as possible with a close grove of trees, closer planting is adopted on these places,—at scarcely four feet apart in fact. After three to four years the garaeus will need thinning out probably, and will even then yield, in the case of Ledgeriana, bark of some value. As, on account of the want of labor, there was not enough land at Kendeng Patoeha prepared for the officinalis plants, which were too big to remain longer in the nurseries, it was necessary to plant at only three feet apart. With this variety, which has a very slender stem and scarcely any side branches, there is every hope of a good result following on this plan. Here also in time thinning out will have to be considered. The chemical analyses of young Ledgeriana seedlings and officinalis plants of 3 to 4 years old also served for the collection of more data for the regulating, according to knowledge of ascertained facts, of the distance at which it is necessary to plant. A four year old Ledgeriana tree yielded on an average 0·26 kilogram of bark, so that four trees of this age are needed to give one kilogram of dry bark. The three year old officinalis

* *Saccharum spontaneum*: see Mr. W. Ferguson's Ceylon Grasses, No 139.—TR.

trees gave per tree 0·088, the four year old 0·155 kilogram dry bark, so that 12 to 7 trees respectively would be necessary to produce 1 kilogram of bark. The trees on which these experiments were made stand at distances of 6 feet for Ledgeriana and 5 for officinalis, and are growing well. According to the analyses the average value of these barks was estimated at *f* 6 and *f* 4 per kilogram, according to the present market rate. Measurements were also taken in a flourishing garden at Tjibeureum of two year old trees planted at 5½ feet. The average height was 1·45 meter, the diameter of the top 1 meter, * while the circumfereuce of the stem was 0·1 meter measnred at 0·1 meter above the ground. Among 50 trees standing together, which served for the purpose of this measurement and will also serve for the continuation of these experiments, only two could be considered hybrids. The maximum given by one of these trees was a height of 1·9 meter, a diameter of the upper part of 1·4 meter, and a thickness of the stem circumference of 0·14 meter. The *Helopeltis Antonii* continued its attacks on the plants, though not to any great degree. The catching of these insects was carried on steadily. But when they appear here and there at the very highest tops of the succirubra trees where they cannot be reached they spread once more over the plants, and the extermination of these pests is most unlikely. At Rioen-Goenoeng half a bouw of Ledgeriana plants was entirely destroyed by the koe-oek, † the larva of a chafer, which had chosen the finer rootlets in this plantation for its food. In the young succirubra gardens at Lembang many caterpillars of *Daphnis hypothous* CRAM. ‡ were found, which were feeding on the leaves of this variety of cinchona but otherwise did no harm to the plants. As the officinalis gardens at Tjinjiroean, Tjibenreum and Rioen-Goenoeng—which were apparently opened at too low an elevation for this variety—were steadily getting worse, were continually damaged by the *Helopeltis*, and were gradually dying out entirely, it was resolved at the end of the year to write off the whole of the trees, to dig out what remains, and to use the land for other varieties.

4. HARVESTING OF BARK.

The crops of 1879 amounted to about 53,000 kilos, of which 51,000 kilos were destined for dispatch to Europe and 2,000 kilos for the medical service in [Netherlands] India. At the end of the year 36,134 kilos had been exported. The continuous rainy weather greatly hindered the drying of the bark, and this process went on only very slowly, as no complete appliances for artificial drying were available. The dispatch was attended with difficulties. So few laborers were to spare on the establishments that none of them could be taken to transport the packed bales and chests to the cinchona packing houses at Tjikalong and Tjihanjoewang, and coolies were not be had for months for that purpose. Since November the needed draft cattle also, for the transport carts, were not to be had, as they were required for the ploughing of the sawahs. On this account in the beginning of January there were still 16,960 kilos left in the packing-houses. The cinchona bark of 1878 was sold at Amsterdam in two batches, on the 30th April and 2nd July. The following prices per half kilo were realized :—

C. Calisaya	Ledgeriana	...	*f* 6·31[8]	...	*f* 5·60
,, ,,	Javanica	...	,, 1·38[3]	...	,, 1·33[7]
,, ,,	Schuhkraft	...	,, 1·20[6]	...	,, 0·98[4]
,, ,,	Anglica	...	,, 1·58	...	,, ——

* Apparently the diameter of the crown of the tree across the branches is meant.—ED. C. O.

† It is to be regretted that Mr. Moens does not give the scientific name of this insect : *koe-oek* (pronounced *kúwák*) in Malay means a tiger-cat.—TR.

‡ Dr. Snellen van Vollenhoven has kindly identified insects useful or noxious to the cinchona culture only.

C. officinalis		...	*f* 2·80[5]	...	*f* ——
,, succirubra		...	,, 1·75[6]	...	,, 1·47[4]
,, Hasskarliana		...	,, 1·23	...	,, 0·83[4]
,, Pahudiana		...	,, 1·10	...	,, ——
,, lancifolia		...	,, 1·57[2]	...	,, 1·15
,, caloptera		...	,, 1·35[6]	...	,, ——

The average price of the first batch was *f* 1·77[16], that of the second *f* 2·09[8], per half kilo. The highest price, *f* 9 per half kilo, was paid for a chest of shavings of Ledgeriana bark, the produce of the experiment of cutting off only the outermost layer of bark from the living tree. The total amount realized was *f* 197,417·23 ; the expenses of sale and dispatch were *f* 17,716·30, so that the net result was *f* 179,700·93. The experiments with the mossing system of McIvor were continued, and in 1879 1,129 succirubra and 716 officinalis trees at Tjibitoeng and Kawah-Tjiwidei were again treated by this method. For covering indjoek was chiefly used this time in place of moss, as it had already been found that this stuff succeeded quite as well, was more easily procurable, and allowed of a more rapid completion of the trees. Of the hundred succirubra trees which were treated in this manner in 1877 for the first time at Tjinjiroean and Tjibeureum not one has yet died. In 1878 the second strip was not taken from 18 of these trees, as the first had not completely renewed. In 1879 it appeared that on 12 trees the second strip had not completely renewed. The renewed bark of the first strip, which was thus two years old, was now taken off. In those parts where the renewing had succeeded well the bark was quite loose and was 6 to 8 millimeters thick. In many places however it was thinner and adhered closely to the stem. Altogether 160 Amst. lb. were obtained from this experiment. These trees have thus yielded :—

In 1877	240	A. lb.	original bark,
,, 1878	280	,, ,,	mossed original bark.
,, 1879	160	,, ,,	renewed bark.

On stripping for the third time the impression was created, that it would be better, in place of taking off the renewed bark in the third year of the experiment, in this manner, when it is two years old, to wait another year, and thus to give the tree a year's rest. According to information from British India the same result has been arrived at there. In 1878 at Tjinjiroean, Tjibeureum and Tjibitoeng together 1,000 trees were stripped according to McIvor's method, which yielded 1,252 A. lb. bark. At Tjibitoeng, on the removal of the second strips of original bark, the trees were carefully examined, and it was found that of the 454 trees, which were covered half with moss and half with indjoek, in the case of 274 the first strip had renewed completely, in 178 it was not entirely renewed, and in 2 it had entirely failed to renew. Of these trees 23 had been injured by the larvæ of coleoptera, and of these 28 had been covered with moss and 4 with indjoek. At Kendeng Patoeha (Kawah Tjiwidei) in 1878 50 officinalis trees were partially stripped. They then yielded 27 A. lb. bark. In 1879 the second strip was removed, and again 27 A. lb. bark were obtained. Seven trees had died, in ten the first strip had not renewed, and many had been injured by the larva of a chafer (*Eurytrachelus eurycephalus* BURM.) which, under the moss, bored through the stems. In 1879 2,316 trees were again operated on, which yielded 826 A. lb. dry bark. At Nagrak the experiment was made on C. Calisaya Schuhkraft. From the first stripping in 1878 70 A. lb. and from the second in 1879 65 A. lb. original bark were obtained. At the end of a year four of the trees were dead, and on 20 the bark had not entirely renewed. The expenses of mossing were made up in various ways, and depended chiefly on the greater or less difficulty of procuring moss and indjoek. They averaged, in the case of succirubra,

at the first stripping: for moss covering 15—24c. per tree, for indjoek covering 10—18c. per tree. At the second stripping 51—2c. was necessary, at the third about 11c. per tree. The indjoeking of the officinalis trees at the first stripping cost 5c., the mossing 6½c. per tree. On the whole the impression conveyed by this method of harvesting in the case of succirubra is not unfavorable, so far as the experiment has gone. The succirubras which have been three years under this treatment have as healthy an appearance as trees left intact, as in the case of those where the bark did not renew the bare patches of wood, which died on the surface, were for the most part covered by the outgrowth of the interjacent strips. That many of the officinalis trees and several succirubras will be attacked by insects, was feared from the first. By covering with indjoek the evil will apparently undergo a diminution. The renewed bark is of very good quality and of a high commercial value. There are however some great drawbacks connected with the method. The material for covering, where the work is done on a large scale, is difficult to procure. The stock of moss in the immediate neighbourhood of the gardens is soon exhausted, and it has then to be sought longer and at a greater distance. Indjoek is also difficult to procure in quantity, and if it has to be brought from a distance it is expensive, has to be often fetched, and thus takes away too much labor. Private persons in British India are already making use of the straw of a species of grass, the fruit of which is eaten by the natives (coraly-grass), which is apparently *Cynosurus coracana*. On account of the scarcity of labour at present prevailing in the cinchona gardens it is with difficulty that men can be spared for the stripping and covering, which moreover requires the best men. The experiments of treating other varieties besides succirubra and officinalis according to McIvor's system gave results which cannot justify their continuation, as the renewed barks were not much better than the original. Renewed officinalis barks will for the first time be analyzed in 1880. The experiments with the method first begun in 1878, of cutting the bark in chips from the living tree, were continued in 1879. A year after the bark was cut from five experimental trees this was repeated for the second time. On the first occasion there was obtained from these trees about 0·52 kilo and on the second 0·41 kilo dry bark per tree, so that the bark had replaced itself to almost its original weight in one year's time. On these trees only half of the bark was cut from two sides of the stem, while the two other sides were left intact. Regarding the chemical investigations of these barks, which are very remarkable, information is given under sec. 8. Although the quantity was very satisfactory the quality left something to desire, and it will be advisable to give the barks somewhat longer—at least two years—rest. For this reason the larger experiment, with 60 trees, has not been continued this year but will be deferred till 1880. For the first time this method has been tried on 110 officinalis trees, which yielded 95 A. lb. bark, on 121 succirubra trees, which gave 339 A. lb. bark, and on 459 Ledgerianas, from which 590 A. lb. dry bark was obtained. These barks were dispatched with the crops of 1879, for the purpose of ascertaining their commercial value. The officinalis trees suffered apparently not in the least, the Ledgerianas somewhat more than formerly, and the succirubra trees looked very sickly for some weeks. Probably one reason of this is that whereas the former experiment with this method was made in the dry season the bark is now cut off at the beginning of the rainy season, it being supposed that the trees bear this treatment probably better in the period of rest than when the flow of sap is in full force. The injury is not permanent, for at the end of one to two months the appearance of the trees was perfectly fresh and healthy. The cost of scraping was: for succirubra 5 cents per tree or $1\frac{1}{10}$ cent per lb. bark, for Ledgeriana $2\frac{7}{10}$ cents per tree or $1\frac{7}{10}$ cent per lb. bark. The succirubra trees were scraped to a height of 3·8 meter, the Ledgerianas to 1·8 meter above the ground. The stems were not covered with moss or indjoek. The experience, that the replanting of a land where a cinchona plantation has been already cropped occasions such difficulties, makes it all the more important to find a method which permits the obtaining of a regular supply of bark without killing the trees themselves for that purpose. There was sold this year at Amsterdam on account of private parties 165 bales and 29 chests of cinchona bark, the produce of the lands Pamanoekan and Tjiasem, Tjiomas, Waspada and Lerep. The barks were analyzed for sale by Messrs. d'Ailly & Sons. The prices were in accordance with the qualities offered, and the yield of alkaloid satisfactory.

5. ESTABLISHMENT; MATERIAL; EXPENSES.

By the Government order of 15 Jan. 1879, No. 7, it was determined that the staff of the cinchona enterprise should be increased by an overseer of the second and one of the third class. In the previous order of 7 Nov. 1878, No. 4, the appointment of an assistant director was promised. These were accordingly fulfilled by the appointment of the controleur of the 1st class R. van Romunde as assistant director, by Government order of 22 June 1879, No. 2. By order of the Director of the Inland Affairs dated 26 Feb. 1879, No. 132, E. J. Veulemans was appointed to the office of overseer 2nd class, and A. A. Stauffenbeil Zijmers was appointed overseer 3rd class. There was no change in the rest of the European staff. The fixed native establishment comprised at the end of December: 1 cinchona mantri, 1 carpenter, 1 packing-house mandoer also postman, 14 mandoers, and 175 boedjangs. The obtaining of labour during the year was difficult in the extreme, and at the time of the paddy harvest most of the establishments lost a great part of even the fixed laborers, who could not only work to greater profit but found a more pleasant occupation, coupled with feasts and the association of acquaintances and friends. The establishment that suffered worst from this was Rioen-Goenoeng, which for months had to manage the upkeep of about 150 bouws with 11 fixed laborers and their wives. In November and December the people returned again, and several came to offer themselves to be taken on as boedjangs. The nursery-houses are in good condition. The great nursery-house at Tjinjiroean was specially adapted for the Ledgeriana grafts. At Nagrak a new nursery-house was completed, which gives every satisfaction. The expenses connected with the enterprise consisted of:—

	f.
Salaries of the European staff ...	25,375·00
Stationery	330·00
Travelling and halting expenses ...	2,187·69
Salaries of the fixed native staff ...	17,460·00
Pay of day laborers	10,506·04
Construction and repairs of tools ..	642·98
Transport and packing of bark ..	2,475·42
Do. of money and materials.	62·75
Materials for the upkeep of nursery-houses and sheds	1,156·87
Daily requisites for the analytical laboratory	251·50
Servants for the laboratory	180·00
	60,628·55

being *f*4,681·44 less than was estimated in the budget of 1879.

6. Distribution of Cinchona.

Ledgeriana seed was sent to a number of private persons, whilst officinalis and succirubra seed was also distributed in large quantity. From Ceylon there was also a request for lancifolia and Calisaya Javanica seed, which was supplied. But the endeavours of many Ceylon and British India planters to obtain Ledgeriana seed also could not this time be gratified, on account of the too limited supply. The native population are still as little inclined as ever to plant cinchona. Succirubra seed was applied for by the foresters of the jungle districts of Samarang, Bayelen, and Madioen. These officers wish to try and utilize this tree for the planting of portions of the woodless mountains of their districts. The applications were fully met. Twelve wardian cases were sent to Japan, containing officinalis, Ledgeriana, succirubra and Calisaya Schuhkraft (Josephiana) plants.

7. Information on the Varieties of Cinchona Cultivated in Java.

As it was important, on account of the notorious proneness to hybridization of the varieties of cinchona, to obtain a more accurate knowledge of the mode of fertilization, particular attention was paid to this subject at the proper blossoming season of the cinchonas, which lasts from January to March. The cinchonas have heterostyle flowers, which are thus brought into mutual fertilization by insects. In most cases the corolla tube is pretty long, and the style often very short, so that, as a rule, only insects possessing a long proboscis can be of help in the fertilization. At the top of the inferior ovary, and thus at the foot of the style, is found a disc, which secretes honey, and the insects cannot get at the honey unless they penetrate the corolla tube with their proboscis, and in doing this bring the pollen of the mature stamens in contact with the pistil. But they also carry off a portion of the pollen on their proboscis from one flower to another, and so the fertilization takes place easily enough. Not only in the case of the insects to be mentioned afterwards, is the pollen found on all parts of the mouth, but on the drones (*Bombus rufipes*) it is met with in clusters on the metatarses of the hindlegs, and easily recognized under the microscope as cinchona pollen. The chief agent in the fertilization is the drone already mentioned, *Bombus rufipes*, LEPEL., which is found in millions in the cinchona plantations, attracted by the very strong odour of the cinchona blossoms, an odour which can be perceived at some distance. These hymenopters are to be seen flying with eagerness from one cluster of blossoms to another and not omitting a single open flower: from each blossom they gather honey and increase their stock of pollen. If one stands in the midst of blossoming cinchona trees soon every sound is overpowered by the hum of the thousands of busy insects. Besides these drones there are several lepidopters of the largest kinds which aid in the fertilization, notably *Papilio Priamus*, BOISD., *Ornithoptera criton*, FELD., *Ornithoptera Pompejus*, CRAM., whilst some smaller ones are also met with, especially *Pieris Crithoe*, BOISD., *Terias Hecabe*, L., and *Iphthyma Stellera*, ESCHSCHOLZ. These insects also appear in thousands in the gardens during the blossoming season, and the first three named, exceptionally large butterflies, are seen from early morning till evening near sunset flying regularly from flower to flower seeking their food. Now, as these insects fly also from one plantation to the next, from one variety of cinchona to another, it is evident that frequently pollen from the one variety is transferred to the other, and so often from seed hybrids are obtained: and also that in a year like 1878, when, after the preceding drought, almost all the Ledgeriana trees blossomed, the chance of hybridization is much less,—as the insects can then keep more to the one variety of cinchona, and do not need to fly from one to the other,—than is the case when in each plantation only a few trees of the same variety come into flower at the same time. Among the plants from the seed of 1878 moreover there appeared much fewer hybrids than among those raised from seed obtained in other years. Experiments were tried purposely this year with artificial fertilization, and of these the following succeeded: micrantha × Calisaya Javanica, micrantha × Calisaya Schuhkraft (Josephiana), micrantha × officinalis, Pahudiana × Calisaya Schuhkraft, and succirubra × Calisaya Javanica. The fruits are not yet ripe: the seeds will be kept separate in order to gain further knowledge of the product of these crossings.

8. Chemical Analyses.

The state of the weather was not favourable for the blossoming of the Ledgerianas. On this account also little bark from blossoming trees was analyzed—only the numbers 22, 71 and 72 refer to such analyses. The analyses 1—21 are of various portions of bark from the same tree. The analysis showed that in the case of these (now twelve years old,) Ledgerianas the bark over a great portion of the stem is very rich in quinine, and that only that from the upper portion of the tree and from the thinner branches is of less value. Perfectly inexplicable is the variation which was observed: that, for instance, the bark at a height of 5 meters was equally rich in quinine as at 1½ meter above the ground, while the portion lying between them contained less of that alkaloid. It was in accordance with previous experience that the root bark contained much more cinchonine than the stem bark, and it is noteworthy that quinidine, which is entirely wanting in the stem bark, was found only in this root bark. In order to have a basis of comparison for the Ledgeriana seed plants it was ascertained what was the yield of alkaloid from the intermixed bark obtained by cutting a strip of bark from ten two year old strong shoots of coppiced original Ledgerianas. The analysis is given under No. 48. As a second basis of comparison, use can be made in the investigation of the young twig bark under No. 21. In the examination of the Ledgeriana seedlings several important results were obtained. In the first place it appeared that the young trees followed as a rule the composition of the mother trees, so that for example when the latter contained quinidine the seedling also contained that alkaloid. In the second place, it was seen that it was possible to pick out the very worst, mostly hybrid sorts, for when this was done the analysis showed quinine-yield corresponding with the valuation based on the external appearance. If of seedlings of one same parent tree four types were taken, of which 1 was considered the best and 4 the worst, the analysis generally confirmed this. And lastly it was found that in general the quinine-yield for such young trees is very satisfactory, and gives the best hope for the future. The analyses 29—43, 49—69, and 73—80, refer to these young three to four year seedlings. Those distinguished by letters (A, B, C, &c.,) were examined, partly as representatives of the Ledgeriana type, partly (29—53) as types of large-leaved micrantha-like descendants, which, as was supposed, appear to be of little value. Very high figures for quinine were given by No. 32, 36, 37, 38, 41, 61, and 69. Of otherwise similar descent and exterior, those trees which had developed most gave the highest figure for alkaloid-yield. As was said in sec. 4, the five test trees which a year ago were scraped now again had the renewed bark taken off. For comparison of the difference in composition between the original bark and that renewed, after

scraping, in one year, they are here placed side by side :—

It will be seen that there is a remarkable agreement in these renewed barks. No. 2 alone shows a difference, which cannot be explained. But if this tree is left out of the reckoning there is very little difference in the results of the four remaining analyses, although the yield of the original bark varied greatly, so that it appears that in this renewing, at the beginning at least, a bark of very uniform composition is formed, as regards the alkaloid yield. The formation of so much cinchonine in this young tissue is also peculiar—a peculiarity which is also noticed in renewed succirubra bark. No. 2 cannot owe its high quinine-yield to the moss-covering, else the same influence would have operated in 4 and 5. The cutting off the bark in shavings from the living tree was, as an experiment, also tried on officinalis and succirubra trees. The analyses of these barks are given under 117 and 90 and 91. The examination of renewed succirubra bark was also continued, and no diminution was observed in the yield of quinine, which rather increases steadily. The renewed bark, No. 85, which was 26 months old, is certainly of very great value. The renewed bark of some other varieties of cinchona gave no remarkably good results. In the following table are placed side by side the analyses of the original, original mossed, and two-year renewed bark of the same trees :

	C. Succirubra 1.			C. Pahudiana 2.			C. Hasskarliana 1.			C. Hasskarliana 2.			C. Micrantha 1.			C. Micrantha 2.			C. Calisaya Schuhkra t.

In succirubra there is usually some quinidine formed in the renewed bark, but specially distinct is the formation of a large quantity of quinine and the diminution of a great deal of the cinchonidine, while the

yield of cinchona sometimes remains the same; though it usually somewhat increases. In the other barks there is an evident disposition to form more quinine and less cinchonidine, but the increase is not remarkable and is not complete enough to justify the application of McIvor's method on a large scale to these sorts. The barks which were rich in quinidine—Hasskarliana 1 and Calisaya Schuhkraft—produced this alkaloid also in the renewing of the bark. The analyses of C. officinalis, C. lancifolia and Calisaya Schuhkraft will be concluded in 1880. The analyses 97 and 98 were carried out with a view to ascertain if such young officinalis trees had already an appreciable value. The result is assuring. The experiment was made by choosing ten trees of different exterior and origin in a plantation, cutting from each two strips, mixing them, and analyzing. The wounds were covered with moss, and in two months they were all covered with new bark. It was found by previous experiments that hark cut in quills was not injured by being dried in the sun. But the question was whether bark cut in shavings (scraped) could also bear the drying in sunlight without a decrease taking place in the yield of alkaloid and especially of quinine. The analyses 23—28 and 90—91 were carried out to gain data for the answering of this question. The bark, cut from one stem, was divided into two equal parts and the one half dried in the sun, the other over an oven. This experiment was tried three times with hark of different Ledgeriana trees and once with succirubra. The differences are on the whole so insignificant that there need be no fear of drying in the sun, even for these harks cut in shavings. The Cinchona cordifolia—No. 116—was analyzed in order to better determine the value of this kind. It belongs to the cinchonine producers, approaches in that respect to C. micrantha, from which, however, the variety differs greatly, and is of little value. This tree grows best in the lowest lying gardens at Lemhang.

9. PREPARATION OF FEBRIFUGE ALKALOID.

In the analytical laboratory of the medical department, Weltevreden, by de Vrij's method so-called, out of 3,000 kilograms of dry bark 56 kilograms of quinetum were prepareded—less than 50 per cent of the alkaloid that was present in the bark. With this quinetum, trials will be made in the different military hospitals. Analyses were made of differeut kinds of quinetum, the result of which is given below. Of these analyses the second was performed by Mr. J. Hekmeijer, principal of the analytical laboratory at Weltevreden.

COMPOSITION.	1	2	3	4

Coloring matter and residuum...	1·08	1·08	5·36	1·60

Quinetum No. 1 is that prepared in British India and sold by the Governmeut there at 20 rupees per English pound. It is of a fine white colour, and has a peculiar sweet smell. It is packed in tin boxes holding ½ an English pound, which are provided with directions for use in English and Hindustani. No. 2 was prepared at Weltevreden. It has the same appearance and smell as the Bengal, but is a little darker colored. No. 3 is a sample of the first quinetum prepared by Broughton in Madras and called by him amorphous quinine. It is a yellow stuff, sticky like resin, and looking like rhuharb powder,—on the whole a very impure preparation. Equally with the samples 1 and 4 I owe this also to the kindness of Dr. King, superintendent of the Bengal cinchona gardens. No. 4 is quinetum of the manufacturer Whiffen in London. This had a gray-brown tint, smell of methyl-alcohol, and left a sandy residuum on solution in dilute hydrochloric acid. Besides these samples of quinetum another preparation was analyzed, produced hy the same maker, under the name of quinetum sulphate. It has been tried in British India, and consists of

23·26 per cent sulphate of quinine,
51·40 ,, ,, cinchonidine,
24·30 ,, ,, cinchonine.

This has a very good appearance and greatly resembles the quinine sulphate of commerce, hut with the microscope the larger crystals of cinchona sulphate can be detected. This preparation is appareutly combined mechanically hy the mixture of ¼ cinchonidine sulphate with ¾ quinine sulphate and an equal quantity of cinchonine sulphate. The quinetum of different preparations was also of very different composition. As the loss is so excessively great in the preparation by extraction with dilute hydrochloric or sulphuric acid (de Vrij's method), that about half of the alkaloids are as good as lost in the process, another method of preparation is to be adopted in Bengal, and at the same time a large proportion of the quinetum will he made into sulphate compounds, with a view to remove the amorphous alkaloids, which sometimes form ¼ of the whole, and to which disagreeable results are ascribed.

The Government cinchona gardens were visited during the course of this year hy many cinchona planters from British India and Ceylon. Dr. King also, the director of the botanic gardens in Calcutta and superintendent of the cinchona gardens in British Sikkim, visited Java, chiefly with the object of inspecting the Ledgeriana gardens. By Government order of 5th Dec. 1879, No. 23, it was determined that the director of the Government cinchona enterprize in the Preanger Regencies should visit the principal cinchona gardens in British India in 1880.

[Since writing our preliminary remarks we find that Mr. Moens' Report is really dated January 1880: it was probahly kept back by the Netherlands authorities from the public for some reason, while the Quarterly Statements are at once given.—ED.]

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE FOR THE FIRST QUARTER 1881.

The weather continued very rainy during the past quarter. At the end of January the Nagrak establishment was again visited by a severe storm, hy which about 2,000 trees were destroyed. On the other establishments, at the same time, heavy gusts of wind were indeed experienced, hut the plants suffered no damage worth mentioning from this cause. The plants are on the whole flourishing. In some parts of the gardens they suffered somewhat from excess of moisture. This was the case especially on the Lemhang establishment. But now that the showers of rain are less heavy the trees are beginning to recover. The harvesting by partial stripping and hy cutting in chips (scraping) of the hark was carried out during the rainy weather, and renewed three year old bark was also gathered. For the covering of the stripped trees use is now generally made of alang-alang and other local varieties its grasses, which so far do very well. The last batch of the crop of 1880 was sent to Batavia in February. The quantity intended for sale in the Netherlands amounts altogether to 109,080 Amsterdam lh., packed in 26 chests and 825 bales. This amount will probably

be sold in Amsterdam about July. For day laborers £2,719 was paid. The supply of labor was satisfactory. The Ledgerianas grafted on succirubras are becoming exceptionally hardy. They have a different shape to plants grown from seed. The lowest branches of the grafts grow much more vigorously than those of seed plants, and the trees on this account assume a handsome pyramidal form. After they had stood for one year in the open the medium height was 0·88 meter, the diameter of the crown 0·60 meter, and the circumference of the stem 0·069 meter. They beat the cuttings planted at the same time in the same gardens, which had a mean height of 0·62 meter, a crown-diameter of 0·37 meter, and a stem-circumference of 0·04 meter. Since the catching of insects and the cutting off of branches where their eggs could be laid the *Helopeltis Antonii* has not been noticed at Tertasari. The director of the cinchona enterprise returned to Batavia on 31 December from his journey to British India. His observations on the cinchona culture there will form the subject of a separate report. Various modifications in the method of cultivating plants, followed in British India, and which appeared of practical advantage, have been introduced by way of experiment into the cinchona establishments and so far succeed very well. The method of harvesting by which the bark is taken from the living tree in portions, the tree being preserved, will also be more generally practised: it was seen that the cinchona trees on the Nilgiris had borne this operation already for a long period without great harm. The chemical analyses which are being performed will be reported on in the next quarter. An analysis of some British India cinchona barks proved that barks of the same variety but from very different places of growth have the same yield of alkaloid. Of importance is the result of an analysis of succirubra bark renewed after scraping and two years old. The same alteration which results from the practice of McIvor's method of partial stripping, viz. increase of quinine and diminution of cinchonidine, was also observed in the case of this renewed bark.

J. C. BERNELOT MOENS,
Dir. Government Cinchona Enterprise.

Bandoeng, 4th April 1881.

The number of plants in the nurseries and in the open on 31st March is as follows:—*Nurseries*: 278,390 Ledg. (including 8,240 cuttings and grafts), 248,950 suc., 83,000 of.; *open*: 535,130 Ledg. (including 60,000 cuttings and grafts, but not counting the more or less 6,700 original Ledgerianas), 601,100 Cal. and Hass., 495,990 suc. and calop., 410,520 of, 16,700 lanc., 260 micr.: total 2,670,040.

THE CEYLON HANDBOOK AND DIRECTORY FOR 1880-81:

ACREAGE UNDER OLD AND NEW PRODUCTS ON PLANTATIONS IN CEYLON.

THE LIBERIAN COFFEE ENTERPRISE IN CEYLON.

Among the references to our Handbook of a kindly complimentary nature which we have recieved (and published, from time to time) are some of more than a mere passing interest to which we have too long delayed to refer. For instance, the Chairman of the Planters' Association has favoured us with some valuable criticism of the mode we ventured to adopt in estimating the area cultivated with new products on coffee plantations, as well as on other subjects. Mr. Wall, writing soon after the volume appeared, said:—

"I turn to account a few spare moments, before leaving the office, in a *friendly* criticism of your solution of the extremely difficult problem of reducing the new products planted amongst coffee to their respective *acreages*. I venture to suggest that, however unfair it may seem to retain the original acreage of the coffee, after it has been all, or part planted with cinchona, or cacao, it is even more unfair, and quite confusing to *reduce* it. *In fact*, it is not reduced. The productive power may be, and no doubt, in most cases, is reduced, but not the *acreage*. Moreover, the breadth of land actually planted with cacao or cinchona amongst coffee, is not *reducible* to an equivalent *acreage*. The case in which 100 acres of coffee is planted up between the rows with cacao, or cinchona, is not represented statistically by *any* division of that acreage between the two! After you have assigned a proportion, say 70 acres for the coffee, and 30 for the other product, the *fact* remains that you have no such acreages at all, *but* 100 acres of *both combined*. However the tables may *seem* to be simplified by such a proportioning of the two, they are *in fact* complicated very much thereby; for it may and most probably *will* happen, that, in some cases, the 70 acres of coffee will disappear, and the 30 acres of cacao or cinchona will *become* 100 without the planting of a single additional plant. Some people are planting wide in order to retain *both* products in cultivatiou; whilst others are planting the new product *close* to take the place of and entirely supersede the coffee. Now, I foresee that future statistics of *production* will be seriously hampered by the system of *apportioning* the total acreage between the two; for it cannot be expected that the cacao or cinchona planted in the coffee, will yield precisely, or even nearly, as it would do if it occupied the ground alone. The produce returns, hereafter based on such a system, will be inconsistent and confusing.

"You will say, perhaps, that I ought not to criticise a system without being prepared to propose a better, but I think it quite fair. I hope you will think so—to point out the consequences likely to ensue upon your plan, even though no better were offered!

"I have not given sufficient attention to the subject; but, as far as I see at present, I think it would be better to have 3 columns instead of 2—one with coffee only; one coffee and cinchona or cacao; and a third with the number of growing trees of the new product. For example

	Coffee.	Coffee and cacao.	Cacao trees.	Total.
Estate ...	30 acres	70 acres	2,100	100 acres

This would give the *actual* and unmistakeable statistics. In the case of cinchona, I think that the additional figures which would be necessary to distinguish between the large and small descriptions, would be amply repaid, thus:—

	Acres coffee				
	Acres coffee.	and cinchona.	Trees succirubra, &c.	Trees officinalis.	Total acres.
Estate...	40	60	36,000	90,000	100

"I am sure that with your well-trained mind you cannot feel *satisfied* with the compromise of apportionment in the case of mixed products; nor with the "*allowances*" you have had to make for supposed failures in the case of cinchona and cacao. Against both these solutions of the difficulty your mind *must* have revolted. For, after all, the *acreages* do not really represent in the one case, nor the allowances in the other, any true statistical data. As regards the latter difficulty, I should propose to class all plants, whether of cinchona or cacao, *under 6 months old*, along with *nurseries*; and take statistical account only of plants that have been out in the field over 6 months. By this means, failures may be put out of the question, because *supplies* are never counted. As these do but fill the vacated places of plants already taken into account, they are never afterwards added as new plants.

"In this way, all 'intended' planting would, of course, be excluded; and the number of trees would be of those *fairly recognizable*. True, many of the cinchonas, and some few cacaos, would fail *after* the 6 months; but, as the failures would be supplied, the statistical value of the record would be but little affected, as the percentage of failures *after* that age may be very fairly estimated.

"You will see that I wrote the first six pages of this letter before leaving home. In the meantime, I have thought well over the subject, and am satisfied that the suggestions are worth your consideration; though at this moment they are too late for your present issue.

"This idea, viz., that it is too late, deters me from making other suggestions, especially as they are comparatively unimportant, and your preliminary review is admirably good and complete *as it is*. But I add a few notes :—

"*Mixed* cultivation will, I believe, be henceforth rather the rule than the exception. There is a strong feeling now against great breadths of land being occupied by any single product; and there is a growing belief that the qualities of the soil may be more completely utilized by mixed products than by single. Hence, a strong reason why a good and satisfactory system of statistical record should be at once established.

"I feel confident that the *apportionment* of the acreage between the various products, by an imaginary division of the area occupied by both, will not answer in the long run. So satisfied am I, that I would most willingly confer with you, and give you any help you may think proper to accept, to make the record at once reliable and intelligible.

"You set down the failure of crop in 1871, our first *general* and serious disaster, to leaf disease! But it was not till 1872 and '73 that it became *general*, nor till 1875 that it was quite *universal*.

"A Quaker firm, who were much interested in Liberia, showed me samples of Liberian coffee in 1851; and they were classed with our very highest Ceylon marks; which, at that time, and for years afterwards, realized much higher prices than the ordinary run of estates in general. I mean such marks as I M P, D L B, K & G, C H C, Gonavy, &c. These fetched 20s more than ordinary marks. I was then the owner of K & G (Pallagolla). on the Ramboda pass, and I got 80s odd when Elkadua and other good plantation was worth only 60s. My Quaker friends were great coffee roasters. The reason I did not then bring this kind of coffee to Ceylon, was that the low-country was universally regarded as extremely unhealthy, and there was *abundance* of cheap land in the fine mountain regions; and very little inducement to extend *coffee* cultivation even there Still, I well remember that these excellent judges classed Liberian (*when properly cured*) with our best Arabica kinds.

"A most important feature of Liberian coffee in *said* to be its fruiting again and again on the same eyes. The fact that Arabica fruits only *once* from the same eyes, is the reason why pruning is *imperative* and why the trees ultimately must become crippled. When I say that pruning is *imperative*, I mean that unless you *cut* off the exhausted twigs, they must die of their own accord : and when they die, it is always uncertain where the process of mortification, once begun, will stop. The fact, if it prove to be one, that Liberian will go on producing from the same eyes, will not merely be a saving of pruning to a great extent, and a preservation of the symmetrical framework of the trees, but it is a guarantee for longevity and permanence!

"The case of a tree that goes on producing fruit, must not be confounded with that of an *annual*, which has a separate *generation* every year. We are, in fact, raising our new plants from the fruit, in many cases, of the identical trees from which most of the early plantations were raised. Nearly all the estates I have planted have been from Allacolla (Maturata) seed. The introduction of Blue Mountain seed offered very little encouragement; for the plants so raised were worse punished than any others by leaf disease! A *great many* of them are said to have *succumbed* outright!

"I think it is a mistake to say that the samples of our coffee have fallen off in quality : Ceylon fine marks still maintain their high character *in all respects*, price, outturn, and proportion of triage. Mr. Dandlicker (Volkarts) remarked, spontaneously, a few weeks ago, on the high quality of the produce, especially from the old estates and old districts. A short time ago, one of the leading merchants asserted that the quality had declined, and I forthwith challenged the opinion, Put to the proof by extensive comparisons of *Mill* accounts, he was obliged to give in; but maintained that the proportion of *triage* was greater. The comparison was therefore reserved and it was proved that there has been no such falling-off. Seasons make a difference, no doubt; but, on the whole, there is no proof of decline in quality, but the contrary.

"In the matter of precarious blossoming season, it should be remarked that *Liberian* seems able to blossom at almost any time, and in spite of almost any weather! Of course, we need more experience to confirm this idea, but it *seems*, so far, probable.

"It is quite illusory to set down *any* number of trees of cinchona as representing an acre. Almost *any* number, from 1,000 to 5,000 *might*, under certain conditions of species and circumstance; but none actually *does* so statistically.

"The principal factor in the calculation of the future prospect of cinchona, in my opinion, is the relative future values of quinine and quinetum. The very best authorities (though I did not know Howard was amongst them till I read your paragraph) agree, that the alkaloids are as efficacious and as valuable as quinine! King appears to have *proved* it. Dr Trimen remarked to me one day lately that nothing but *fashion* and prestige kept quinine in the position it has hitherto held! Recent advices from home show that the value of the other quinoid alkalies is becoming rapidly recognized. Will, then if this be so, what will be the future position of the hardy succirubra with its high perceutage of alkaloids, as compared with the less robust kinds, that produce *less* alkaloid, but more quinine? The prospect of a febrifuge for the *million* is grand for humanity, but the degradation of quinine proper to the level of quinetum as an article of commerce, will seriously disturb calculations based on existing relative values!!

"When I said that I did not know Howard as an authority; I meant, of course, as one who recognized the value of the other alkaloids. Everyone knows Howard as one of the very highest authorities on this subject, but I had an impression that he held the relatively high estimate of quinine over all the other alkaloids."

On the other hand, here is Dr. Trimen in the Report just published warning planters against succirubra and other poor yielders of quinine, and advocating, above all, the cultivation of the rich Ledgeriana. So far as the market at present goes, the worthy Director is, of course right; but, the question of what grows best in our climate and soil must be considered, and, as we have said in our Handbook, and as Mr. Wall points out, we may possibly ere long see a revolution in the market, and the inferior but cheaper alkaloids more sought after than quinine.

As regards our apportionment of the area planted

with different products, the arrangement in the present Directory is confessedly an *ad interim* one, and we had fully determined another year to give fuller details and in a more convenient form or somewhat as follows:—

ACREAGE :

Total.	Cultivated.			
	Coffee.	Tea.	Cinchona or Cacao.	Other Products.

It is, of course, impossible to give separate columns for all the minor products—an ever-increasing family—with which our planters are experimenting, and it is equally impossible to expect to attain perfection in any work such as that under review ; but it is certainly satisfactory to feel that the Chairman of the Association is not alone when in a second and later letter he is good enough to say :—

"The division of the work into two volumes is an immense improvement. The Directory, in constant use for reference, is far handier in its separate form, and that immense mass of information which you have accumulated on all the most important subjects affecting the agriculture, commerce, and social condition of the Colony, is much more conveniently studied in its present form. It is, in fact, an ample volume of itself, and of incalculable value to people interested in the island and its enterprise and progress."

CHLORATE OF POTASH has become so thoroughly popular as a medicine that it is not amiss to remember that it cannot be employed recklessly, at all events for children, since the use of it has caused death. In one instance a boy of three years was given 180 grains in thirty-six hours and died at the end of ten days, with symptoms which indicated an abuse of the remedy.—*New York Hour.*

CINCHONA.—The Conservator of Forests will be desired to forward direct to Mr. Thomson, formerly of Jamaica but now of Bogota, an adequate supply of seed of the fine kind of "cinchona officinalis" which grows on the Nilgiris. On receipt of intimation by Government of its despatch, the Secretary of State will be informed accordingly, in view to Sir Joseph Hooker's services being enlisted for obtaining plants of the "China cuprea."—*Madras Standard.*

A NEW SUBSTITUTE FOR TEA OR COFFEE.—The following is an extract from the *Grocer* :—Mr. William Taylor, commission agent, York-street, Glasgow, has been appointed agent for "Teako," which is described as "a new substitute for tea or coffee." We should be glad to know of what this new substance is composed. The result of a chemical analysis of it should be published : it would no doubt prove interesting, and perhaps surprising.

A LONDON TEA AGENCY FOR CEYLON.—Mr. Turing Mackenzie's suggestion for a meeting of Ceylon tea-planters as a preliminary to united action for the establishment of a West End Tea Agency is well deserving of attention. Such a meeting would be the first step towards the establishment of a Ceylon Tea Syndicate. Perhaps, it will be well to wait now for the return of the Ceylon Commissioner to get the benefit of his experience and counsel. We have no doubt, that Sir Wm. Gregory and other home friends of Ceylon would give the movement all the support in their power.

Correspondence.

To the Editor of the Ceylon Observer.

A LONDON TEA-ROOM AND AGENCY FOR CEYLON TEA.

Maskeliya, 16th May 1881.

DEAR SIR,—I was afraid that my proposal to establish in London a tea-room and agency had quite fallen to the ground. I see, however, that Sir Wm. Gregory comments favourably on my letter ; and as you yourself have taken the matter up I begin to hope that something may yet come of it.

I feel convinced that such an establishment would be the best advertisement that our tea planters could have ; and as a considerable portion of our planting community is now interested in tea, it would only seem natural for the Planters' Association to move in the matter.

Want of funds, of course, would be the serious difficulty ; but surely the numerous gentlemen now engaged in tea planting could, if united, command sufficient influence to start a Company for the purpose of establishing a tea-room and agency in London, with a view to stimulating a demand for our teas.

It may be said by some that we have no tea, should a large demand arise, and what is the use of creating a demand before we have the supply to meet it? But if we wait to create a demand until we have a large stock of tea, the market will be glutted, and prices ruinously low. Clearly, therefore, the ooner a start is made the better.

Apart from the benefit of the tea-room as an advertisement, the agency would be most advantageous to planters, who by shipping direct could realize a decent profit themselves, while they could put their tea in the market cheaper than if they went through the brokers' hands—in fact, the planter would sell at a low retail price, and the consumer would get a good genuine article at a cheap figure.

The General Meeting of the Planters' Association is close at hand : could not the tea planters contrive to meet and discuss this question?—Yours faithfully,

W. TURING MACKENZIE.

GRUB.—I see Mr. W. Smith is tackling the grub again. Did anybody think patana had anything to do with breeding or harbouring them ? Perhaps the richest fields of young coffee I ever saw were on the flat lands in Rakwana, and they were always killed out in a few years by grub 40 miles from any patna. All flat lands on the south side of the island have been liable to it. Did ever anybody see damage done on steep lands?—*Old Planter.*

MADAGASCAR PADDY.—Mr. Robertson, of the Government farms, Madras, submitted lately to the Board of Revenue a report on the experimental cultivation of Madagascar paddy which he considers the home of the Carolina species. The product of the experimental cultivation of this variety of rice appears to the Board of Revenue to be of sperior quality, and if Mr. Robertson's present opinion, the it thrives with a quantity of water less than the indigenous varieties, should be confirmed by further experience, the result should be of great value to localities where the rainfall is scanty and water not always abundant. The samples received by the Board will be forwarded to the Chamber of Commerce, whose opinion the Government would be glad of both as to the article itself and upon the suggestion to send the grain and rice to London for valuation. 48 lb. of seed sown on the 20th September '80 yielded on 2nd February '81 1,483 lb. grain, and 2,436 lb. straw. —*Madras Standard.*

THE PROSPECTS OF INDIAN TEA.

The days are passed when tea planters hoped to make a fortune in a few years. There are mainly two reasons for this. Firstly, the prices of tea have fallen greatly, in many cases 30 and 40 per cent. This is due to the fact that supply, in the case of Indian tea, has overtaken demand. Still, there is some comfort to all interested in the industry to be derived from the low prices which have ruled during the last two years. So cheap have Indian teas been that the attention of the trade has thereby been directed to them, and consequently the deliveries of the last few months have exceeded any known previously. It is calculated by those best able to judge, that if the present rate of deliveries in London continues, the stock in June next will not exceed 12 million pounds, and the truth is, strange as it may appear, that below this point it is not well that the stock in hand should fall, because, if it does, dealers will not be able to meet their requirements, and will then perforce buy more China. There is another point which should give comfort and hope to the Indian planter, in spite of the fact that we are heavily bandicapped in our race with China inasmuch as owing to more expensive labour our cost of production *must* exceed theirs. This source of hope is the great point now generally admitted, that Indian tea is better and goes further than China Tea. The experience of each of us can quote instances of individuals dropping China tea and taking to India; who knows of any one doing the reverse? We admit the taste for Indian tea is more or less an acquired one. Still, the public at home have already been educated to the taste by the yearly increasing proportion of Indian mixed with China tea. Speaking generally (though the exceptions are many and increase yearly), it is true that Indian tea is not obtainable pure, but no more is China. The bulk of the tea now sold to the public in the United Kingdom is a mixture, three parts China and one Indian, and all points to the fact that in a few more years the general mixture will be half-and-half.

We are thus surely paving the way, in other words, teaching the English public, to like Indian tea, and the broad fact that, once used, it is never abandoned for its rival, is surely a very hopeful feature. The truth is that were it possible to *make* the population of England, Australia and America drink Indian tea for one week only, the demand after that week would be enormous, and we should hear no more of "supply exceeding demand;" nay more, many thousands of acres would at once be added to the present cultivation in India.

But we have somewhat wandered from the question we set out with, *viz.*, *why* tea does not pay now as it once did. The first reason we have given; the second is that there is now no market for tea seeds. This last reason is little dwelt on, but it is a very important factor. The days were when R300 per month, and even more, was paid for tea-seed, and though this did not last long the price for many years up to 1878, was about R100. Now it is simply unsaleable. The receipts for tea-seed, during all these years, formed a large part of mature garden earnings, and, to quote one instance, thereto in a great measure were due the big dividends paid by the Assam Company.

But though tea prices may, and we think will, improve, it is not likely we shall ever again see the rates obtainable formerly. This being so, it is probable that only those plantations in the future will pay that produce tea cheaply. How is this to be done? Those gardens that are heavily weighted by unsuitable climates, by a bad class of plant, by slopes which are too steep, by inordinately expensive labour, or other causes, will have a hard time of it, but plantations with natural advantages need in no way despair; though, as we said above, we cannot, in the matter of cheap labour, vie with China, we have a great advantage over the Flowery land as regards economy of production in another respect. We allude to the use of machinery, which does much now, and will do more and more as each year passes, to reduce the cost of production. Machinery in the manufacture of tea is, we believe, almost unknown in China. There each and every operation is performed by hand; here in India, many now do, and eventually all will, wither, roll, fire and sort by the help of machines. It says not a little for the enterprise and the inventive genius of the Anglo-Saxon race that, while in China the manufacture of tea dates back many centuries, and yet all the tea is still made by hand, we in India, who have only planted tea some 40 years, have invented machines and use them to-day for each and every operation in manufacture. It is but as yesterday that we imported Chinamen to teach us the *modus operandi*. We now know far more than they do on the subject, and, verily the pupil has beaten his master.

Though machinery reduces the cost of production, and in more than one case improves the quality of tea, and planters know it, the difficulty before them to-day is to know which is the best machine for each operation. Unanimity on this point is not to be expected yet. One swears by Jackson, another by Kinmond, others by Ansell, Barry, Lyle, the inventor of the Sirrocco, and so on. The machines and names of inventors are many, and each has its disciples. Perhaps the most favourite rolling machines are Jackson's and Kinmond's. But we see the latter has just produced what he calls a "Centrifugal Rolling Machine" which he thinks will supersede all others. We have not seen it, though it is at work on several gardens, and so can give no opinion about it; but another of Kinmond's machines, his Dryer, we know well. It was long a moot point if tea could be efficiently fired by any other agent than charcoal. Many affirmed that the fumes of charcoal were necessary, and when, years ago, Colonel Money, so well known by his writings in tea matters, affirmed from experiments that charcoal was not necessary, but thay any fuel would do the work, few believed him, for people said it was impossible to credit that the Chinese would have gone on using charcoal (so much more expensive than other fuel) for centuries, were it not a necessity. What Colonel Money then predicted has already come to pass. Much of the tea now produced in India never sees charcoal at all, and it is very certain that in two or three years all Indian tea will be fired by machinery. We say this is certain, simply, because, apart from the saving effected by using other fuel, the value of teas fired by machinery is increased. It is natural it should be so, because by the use of the best machines invented for that purpose, the heat can be regulated to a nicety, an impossibility by the old mode of charcoal firing.

Kinmond's Dryer is, in our opinion, the best tea-dryer machine yet invented. Space forbids our describing it minutely (besides only those, and they are few, who understand tea machinery would appreciate our description), but its general features we will shortly touch on. In the comparatively small space it occupies in a factory, and in the large quantity of work it does in a given time, we think it unrivalled. This last feature does away with the necessity of night-work, which, apart from other drawbacks, is prejudicial to the excellence of tea, because, among other reasons, its color cannot then be appreciated in its several stages. Tea made at night is never very good. With sufficient motive power, sufficient rolling machinery, and Kinmond's dryers, the factory, let the leaf gathered be what it may, can be shut

up at dark. Kinmond's dryer may yet be improved upon by himself or by others, but as it now stands, it possesses a feature peculiar to itself, and all-important. The hot air, driven by a fan (the speed of which, under control, regulates the temperature), does not pass successively through the different trays, for the hot air, drying the tea in each tray, has a separate inlet and outlet. By this means is avoided the objection of carrying the moisture absorbed by the hot air from one tray to the other. Another peculiarity in the machine is, that the same air is used again and again, being re-dried and re-heated each time. By this two advantages are obtained: 1, fuel is saved; it is easier to heat air which still retains caloric, than fresh air: 2, the aroma of tea is very volatile, and when hot air, which dries it, passes away, some of the essence and strength of the tea goes with it. But here the same air being used again and again, the volatile essence (how much who can say,) is returned to the tea. It is reasonable to suppose that this will increase the value of the tea; indeed, we know it did so materially in one garden last season.

We do not doubt that the unanimity wanting at present amongst planters as regards machinery, will more or less come with time, but only long experience can settle the merits of rival machinery. One thing, however, is very certain, if the exports of Indian tea ever vie in quantity with China, it will be due to the use of machinery in manufacture.—*Friend of India.*

JAMAICA.

The Governors of the Jamaica Institute have offered a prize of £20 for the best Essay on the fibre produced from either the Penguin, Banana, Rhea or China-grass, Aloe or other Island plants susceptible of cultivation in sufficient quantities to form the basis of a sustained industry. Also a prize of £15 for best samples, not less than 112 lb. (avoir.) of clean marketable fibre produced in the island from either of the aforementioned plants.

Mr. W. Bancroft Espent lectured in the City Hall on Tuesday evening last. His subject was "The Timbers of the Island." The audience was a very respectable one, and the attendance was good. The chair was occupied by His Lordship the Bishop. The Lecturer spoke in terms of praise of the qualities of native lumber, preferring it to foreign. He described the saw mills at Chepstowe, and showed specimens of Jamaica shingles, barrel staves and coconut plank out of which he got beautiful panels made for his house. He spoke in refercuce to pimento trees showing that pimento walks did not as is generally supposed, owe their formation to accident alone. He also produced two specimens of pimento trees grown at the Botanical Gardens by Mr. Morris.—*Gall's News Letter.*

NEW PRODUCTS: LOW-COUNTRY REPORT.

Weather and Drainage—Liberian Coffee and Crickets—Cacao—Bambu Fence.

Western Province, 12th May 1881.

April has been a wet month here. Indeed, from 17th March, when the dry season may be said to have closed, we have had no lack of moisture, and would very willingly have spared a moiety of our portion had we been the disposing parties, for we have had more than a pleasant dispensation of all the elements of storm,' except frost, snow, and hail.

I have been chiefly employed in trying to perfect a drainage system to save in some measure the awful wash that comes of awful rains, but I am sorry to say my success has only been partial. I can only look on in despair when I see a drain four feet deep and five feet wide silted up and running over when ten minutes' rain fills an escaped drain four feet wide to the depth of eighteen inches.

Of the Liberian coffee seed I have put down since the beginning of the year, less than ten per cent failed to germinate, but I have lost perhaps as much as five per cent, by the crickets. I am therefore hastening to transplant them into baskets, where alone they are safe, for several months at this stage. Of course they are again exposed to this enemy when put out in the field. Last season, it was towards the end of November when they disappeared absolutely, during three months, the very first plant cut being discovered on the 1st of March. During March and April, their ravages continued to increase, and only during the last fortnight: have they fallen off, from the havoc they were previously carrying on. I was however warned a week ago not to congratulate myself too soon. One part of the field had not been touched when this month began, but now it is brought up to nearly the same percentage of cutting as the other fields; fine healthy plants, six to nine inches high, cut clean off; the greater part of them so close to the surface, that there is small chance of fresh shoots. After a careful examination, I estimate the losses up to date at one-fourth of all the plants put out last planting season. It is very annoying, after all the trouble and anxiety of carrying the plants through the dry season with little or no loss, to have them destroyed, just as the season became favourable to quick growth, and I am obliged to own myself at the end of my resources. The means of protection, that seemed effectual last season have signally failed now, and my only hope is that they have nearly run their course for the time, to appear again in August, if we have as in the last two years a dry June and July. So far as I have been able to ascertain their habits, they breed twice a year, the old race dying out during the heavy rains of the two monsoons in May and November, after having deposited their eggs in the soil, where they are hatched by sun heat, during the dry season, and the dryer the season, the more abundant will the brood be: they only infest soils of a loose, dry, warm, nature, and especially those rich in organic matter, avoiding clays and coarse gravels. On the present occasion, they first appeared on steep stony grounds, facing the morning sun, and on several such faces they have hardly left a plant uncut. For the rest, there seems no rule. Sometimes on one side of a road one half of the plants are cut, on the other side none; round one boulder all are cut, round the next one none. As I already stated, the south-west face of this place, remained untouched till some time after the destruction had slackened on the eastern side, and on the former it still goes on, though it has almost ceased on the latter. Nothing could be more satisfactory than the growth of the plants that have escaped, and I hope they will be out of danger before the next brood appears. Many of those, however, that were too strong of stem to be dealt with have had every leaf cut off, and have their growths much checked thereby. All the stems that have been cut above lowest buds are making an effort, but my former experience is that the next brood of crickets attack by preference those that have been injured by their parents, but I have found the preseut brood so much more acute and enterprising than the last, that the race may possibly be intellectually progressive.

I had made up my mind that I would not meddle with cacao any more here, unless I were under orders from superior authority, but such a change has come over every surviving plant, since the middle of March, that hope has revived, and I now propose, on one part of the plantation, to carry out the original design of

alternating in the lines Liberian coffee and cacao plants, by filling in the vacancies of the latter at once. I now know that all the losses of plants, on land not exposed to the S. W. wind, has been due to too much dry weather, either immediately or remotely before the young plants got a firm hold of the ground. Now I see plants that two months ago ago looked all but dead, expanded into brilliant and abundant foliage, and running up like Jonah's pumpkin; and though I may still have many failures, I now entertain no doubt of ultimate success, even in such seasons as we have had during the last two years, which, from all I can learn, were considered by my native neighbours unusually dry.

Those who carry on planting operations in the midst of native villages ought to be thankful for a wrinkle, with regard to the material of an impenetrable fence. The Calcutta bambu, *Bambusa arundinacea*, planted three feet apart, becomes a perfect fence in twelve months on tolerable soil, and needs no more labour to keep it in order than any other living fence. I sowed the seed twenty-three months ago, and have it now in good spots thirty feet high. I find it grow well on all soils, except hard gravel or wet swampy ground, and it can be freely propagated to any extent, by dividing the roots. Nothing could be better as a belt to break the wind in exposed situations, and, when a few years old, it will supply nearly all the material for light temporary buildings. I planted it ten feet apart with a teak plant midway, but even at that distance it has filled up the spaces in the best soils in twelve months.

DATE COFFEE IN AMERICA.

It is satisfactory to learn that the coffee merchants, retailers and consumers of North America are inclined to give no quarter to the attempt to foist on them "date" or any other abominable coffee mixtures. The following is from the *New York Daily Tribune* of March 17th :—

MAKING COFFEE OF DATES.

A VAST SCHEME PROPOSED IN LONDON,

THE AMERICAN PEOPLE SOON TO BE GIVEN AN OPPORTUNITY TO INVEST IN THE DATE COFFEE COMPANY —$25 SHARES SOLD IN LONDON FOR $160— SELLING PATENTS IN OTHER COUNTRIES—WHAT IS THOUGHT OF THE SCHEME HERE.

The people of the United States are soon to have an opportunity of investing large sums of money in a wild speculation now occupying the attention of the English public. This is a project for making coffee out of dates. A company has been formed in London, called the Date Coffee Company, which proposes to revolutionize the coffee trade of the world. It has issued flaming prospectuses, has expended large sums of money in advertising and has actually succeeded in selling its shares in the English market at $160 each, their par value being only $25; and all this before the company has made a dollar of legitimate profit or fairly begun operations. The originators of this bold scheme have succeeded so well in England that they have already turned their attention to America, and they are publishing in London glowing accounts of their prospects here. They estimate their profits in this country to begin with at $2,500,000. They have already opened correspondence with some brokers in this city, and an agent is soon expected here to begin operations. The first movement will be, it is said, to close a contract with an advertising firm by which $50,000 will if necessary, be spent in advertising the project, after which the projectors anticipate no difficulty in relieving the American public of a few millions of dollars. The whole scheme from its inception to its present wonderful success in London reads so much like a chapter of the "South Sea Bubble," or John Law's exploits in Paris, that persons on this side of the water almost doubt, the truth of what they read in the London press in regard to it. There is no doubt, however, that even in this age of enlightenment such a project can be successfully carried out in London when it would fail here.

The Date Coffee Company (Limited) was formed over a year ago to manufacture a partial substitute for coffee out of dates according to a patent obtained by T. F. Henley. The patent consists in drying the date fruit by a process which separates the seeds from the pulp. The seeds are then placed in a revolving vessel, and subjected to heat, under the influence of which they become in color like roasted coffee. When cool they are crushed and mixed with real coffee and a little chicory, and the whole is claimed to produce a mixture "superior to the best Mocha coffee." The company was started in London early in 1880, with a proposed capital of $250,000, divided into 10,000 shares of $25 each. A few months afterward application was made to the London Stock Exchange for an official settlement and a quotation. The settlement, which gave the company an official standing, was granted, but the quotation was refused on the ground that there were too many shares in the hands of the directors, it appearing that only 265 shares had been really purchased. The company then found that the English Government would not allow this adulterated coffee to be manufactured in England, but would allow it to be imported at a duty of 4 cents a pound.

The works were then started in Kurrachee, India, where dates are said to be plentiful. As the sale of the article as coffee is accompanied by a statement of how it is adulterated, it does not come within the prohibition of the adulteration act.

At the end of the first year the Company showed no profits. It then occurred to Mr. Haymen, the chairman, according to the Company's reports, that as the Company only owned the patent for England, the patentee, Mr. Henley, might establish companies elsewhere and thus open undesirable competition. Negotiations were therefore opened with Mr. Henley to get the whole of his patents without further payment. He saw the force of this brilliant idea at once. It would virtually pay him by "the enormously increased value" of the large number of shares he already held, or by "the enormously increased value of the dividends he would get from organizing in different countries companies to work the patents." From that time forth the projectors saw fortunes within easy grasp. It became their business to sell patents rather than manufacture adulterated coffee. They claimed to manufacture coffee at less than half the cost of the genuine article. The samples they exhibited from the manufactory at Kurrachee were slightly adulterated with "date coffee," and, of course, were principally composed of real coffee. How the managers revelled in figures may be understood from the following letter, written by the chairman to an inquirer:

"Herewith statements showing the profits the Date Company expect to make. The original prospectus showed a profit of $250,000 a year on a make of forty tons of coffee a week, or 100 per cent per annum on the entire capital, but our capital is, even when the debentures are converted into shares, only $200,000. The estimates upon which this profit was worked out have been proved by actual working to be correct. Since these estimates were made we have obtained the whole of Henley's patents, and our capital account is the same.

"We estimate that we shall sell these patents for $250,000 each, which would amount to $2,500,000, or $250 a share; but we shall, in addition, have Founder's shares in each of the different companies entitling the Date Coffee Company to one-half of all profits after 50 per cent has been paid to the shareholders of these different companies.

"Now, as our figures show that each Company's profit will be $500,000 a year, the Date Coffee Company will have a yearly profit of $125,000, or $1,250,000 in all, to which add $250,000, the profit you will make, and you have the following results:

"Each $25 Date Coffee share will receive a bonus of $250 per share, and annual dividends of $3,000 per share.

"Assuming, therefore, that shares are bought to pay 10 per cent, the Date Coffee shares, after receiving $250 bonus for each $25 share, ought to be worth $1,500 per share.

"The figures are large and look extravagant, but they are, I think, beyond dispute. Yours faithfully,

HENRY HAYMEN."

The first effort was to start a French Company. This was done by the same men who organized the English Company and they sold the patent to themselves for $250,000. This gave them the start required. The $25 shares of the English company immediately rose in value from almost nothing to $160. A German company was then organized without trouble. The chairman said: "I have had twenty-five years' experience in the city of London, and I have never in my life had money pressed upon me so fast as I have had in connection with the French and German companies." All the shares of the German Company were applied for two or three times over. A proposal was received to pay $100,000 for the Russian patent, and the speculation in the shares of the companies seems to be general in London.

At this stage the managers have turned their attention to the United States. At a recent meeting of the stockholders Chairman Haymen said:

"In the United States and Canada during the years 1877 and 1878 about 140,000 tons of coffee were used; during the same time the quantity used in the United Kingdom was only 15,000 tons, while on the Continent of Europe it was 300,000 tons. You will see, therefore, there is a much larger field in the United States than there is upon the Continent, comparatively speaking. I except France, which we consider finished. Therefore we have thought it better that we should take up the United States after the German is finished; so it will be the third company. [Cheers.] Now the United States is equal to five patents. We can put up our works at five different seaports at such a price as will enable each one in those divisions to more than equal the United Kingdom. The terms upon which we have negotiated I cannot say are concluded. I calculate we shall realize from the United States a minimum of $2,500,000, and it may be even more than that."

A well-known American, who has been interested in the coffee trade in London for some years, in speaking of the Date Coffee Company and its product, said:

As actually sold in the English market this 'dates coffe' is declared in the printed label on the tin box in which it is sold to be 'a mixture of dates with one of the finest coffee and a little chicory,' which being translated means—this compound is caramel coffee and chicory. Now caramel is roasted sugar, well-known all over France, employed to color brandies, in universal use among cooks for soups, etc., and largely in use combined with coffee. 'Café Cercella' is an article of wide consumption in Paris and has enjoyed great repute for years. This 'date coffee' is infinitely inferior to it. If the Company does actually roast the dates—which I very much doubt—it obtains only caramel, not a whit better than roasted cane sugar and much more expensive. It they do actually roast some dates, my opinion is that it is only enough 'to swear by.' It would be an interesting question to know why they put chicory in the article they sell. We had all sorts of coffee substitutes during the war, but as soon as genuine coffee could be had again the substitutes disappeared. This humbug will have its day and the promoters of the scheme will line their pockets, and no doubt some of the first purchasers of shares will make money; but it is lamentable to think of the fate of the last comers."

F. B. Thurber, of H. K. & F. B. Thurber, was asked if he knew anything of this new scheme. "I do not," he replied, "but it can be safely set down as a sham. Surely things can be more easily got on up in England by means of joint stock Companies than in this country."

"Do you know of dates ever having been used to adulterate coffee?"

"I have heard of their use abroad. In this country, especially during the war, peas, rye, chicory and various other things were used to adulterate coffee. There are essences sold now, composed of caromel, chicory, etc., which are used in coloring coffee and giving it a fictitious appearance of strength. Since the retail grocers have taken to grinding coffee for customers, the use of adulterated coffee has been largely decreased. The only safe way to buy coffee is in the bean. We impress that upon all our customers. Coffee in the bean is not adulterated. The fact that this Date Company is so particular to refer to Mocha coffee is but another evidence of its being a fraud. Now, Mocha coffee is not the best. Coffee was originally obtained in Arabia and exported from Mocha, hence the name Mocha coffee. Since then, better coffee has been found elsewhere. But Mocha coffee is comparatively scarce, hence it is higher in price."

"You do not think, then, that there is a chance for 'date coffee' in this country?"

"No. There is no necessity now for adulterating coffee. The price has been tending downward for years, and the use of adulterated goods of any kind is reprehensible, and becoming justly a subject of legislation. There is a better chance for adulterated coffee to sell in England than here. Any one who has been there knows how difficult it is to get a good cup of coffee there. Americans use about three times as much coffee as Englishmen, perhaps because they know how to make good coffee. The largest consumption of coffee per capita is in Holland. Germany comes next, and then France and the United States, in which two countries the per capita consumption is about the same. As for the use of dates for coffee, on the scale proposed by this Company, it is absurd. There would not be dates enough to supply such a use, and of course the demand for them would increase their cost above that of pure coffee."

Other large coffee dealers were consulted in regard to the date coffee scheme, and they all considered it a plan for defrauding the public, and predicted that it would find no favor in this country. One of them said: "There has been over $7,000,000 lost in coffee in this country in a year owing to the increased production and declining prices, and it is absurd to talk about introducing adulterated coffee under such circumstances."

THE DEVELOPMENT OF NEW BRANCHES OF INDUSTRY IN INDIA.

A paper sent to us by the Madras Government contains a communication from the Under Secretary to the Government of India, Home, Revenue, and Agricultural Department (Public), to the Chief Secretary to the Government of Madras, forwarding an extract from Section I, Chapter VI, Part II, of the

Report of the Indian Famine Commission, and inviting attention to the views expressed by the Commission as to the desirability of encouraging a diversity of occupations and the development of new branches of industry in India. The extract is headed "Encouragement of Diversity of Occupation," and states that "at the root of much of the poverty of the people of India and of the risks to which they are exposed in seasons of scarcity lies the unfortunate circumstance that agriculture forms almost the sole occupation of the mass of the population, and that no remedy for present evils can be complete which does not include the introduction of a diversity of occupation through which the surplus population may be drawn from agricultural pursuits and led to find the means of subsistence in manufactures or some such employments. It will be almost self-evident that such a change in the condition of the people could not be brought about by any direct action of the State, and that there would be much risk of interference of this description, discouraging the spread of sound principles of trade and retarding the operation of private enterprize. So far as we are able to form an opinion on a question so difficult of solution, the desired result can only follow upon an increased desire to apply capital to industrial pursuits in India, which again will be a consequence of a growing conviction that adequate profits may be secured on investments, under a condition of continued peace and good government. The State should certainly use its utmost endeavours to assist in the preparation of the country for reaching such an advanced condition, but it will, we believe, be by indirect means, such as the extension of railways and the development of local trade and foreign commerce, that the end will be attained rather than by any attempts to give adventitious aid to particular branches of industry. Capital will accumulate in the country or will flow into it for investment in proportion as security is maintained and facilities for obtaining profitable markets for all sorts of produce are enlarged."

The obstacles that stand in the way of the investment of English capital in India, such as the climate, the distance, and the want of exact knowledge of the country, are then referred to, the writers pointing out that direct State aid could not be given to any undertaking without some corresponding power of control or interference, and the exercise of any such power would be almost certainly incompatible with the successful management of industrial occupations, and they add :—"It is probable, moreover, that the whole available means of the State will yet be required for many years, either for railway extension, with or without the co-operation of private enterprise, or for the extension of irrigation works which are no less necessary, and which experience has shown to be unsuited for management by private Companies. There are, however, directions in which we have no doubt the Government might usefully aid in fostering the inception of new industries. The introduction of tea cultivation and manufacture is an instance of the successful action of the Government, which should encourage further measures of a like character. In this case, the Government started plantations, imported Chinese workmen, distributed seed, and brought the industry into a condition in which its commercial success was no longer doubtful. It then retired from any share in it, sold its plantations, and left the field to private capitalists. The cultivation of cinchona is a measure of a somewhat similar description, though it has not yet passed entirely into the hands of private persons. In treating of the improvement of agriculture, we have indicated how we think the more scientific methods of Europe may be brought into practical operation in India by help of specially-trained experts, and the same general system may, we believe, be applied with success both to the actual operations of agriculture and to the preparation for the market of the raw agricultural staples of the country. Nor does there appear any reason why action of this sort should stop at agricultural produce and should not be extended to the manufactures which India now produces on a small scale or in a rude form, and which, with some improvement, might be expected to find enlarged sales, or could take the place of similar articles now imported from foreign countries. Among the articles and processes to which these remarks would apply may be named the manufacture and refining of sugar; the tanning of hides; the manufacture of fabrics of cotton, wool, and silk; the preparation of fibres of other sorts, and of tobacco; the manufacture of paper, pottery, glass, soap, oils, and candles." Some of these arts are already practised with success at Government establishments, and these institutions afford practical evidence of the success of the arts practised and are schools for training the people of the country in improved methods; and so long as any such institutions fairly supply a Government want which cannot be properly met otherwise or carry on an art in an improved form, and therefore guide and educate private trade, their influence can hardly fail to be beneficial. The same may be said of the workshops of the Government and the railway companies which are essential for the special purposes for which they are kept up and gradually train and disseminate a more skilled class of artizans. The writers continue :—"The Government might further often afford valuable and legitimate assistance to private persons desiring to embark in a new local industry or to develop and improve one already existing by obtaining needful information from other countries or skilled workmen or supervision, and at the outset supplying such aid at the public cost. So far as the products of any industries established in India can be economically used by the Government, they might properly be preferred to articles imported from Europe, and generally the local markets should be resorted to for all requisite supplies that they can afford. We are aware that steps have been taken within the last few years to enforce these principles, but more can certainly be done and greater attention may properly be paid to the subject. Otherwise than as above indicated, we do not think it desirable that the Government should directly embark in any manufacture or industry in an experimental way. Such experiments to be really successful or valuable must be carried out on a commercial basis. The conditions of any Government undertaking are rarely such as to give it this character, and the fear of incurring an undue expenditure on what is regarded as only an experiment will often lead to failure, which will be none the less mischievous because it was thus caused."

The writers conclude as follows :—"There is no reason to doubt that the action of Governments may be of great value in forwarding technical artistic and scientific education; in holding out rewards for efforts in these directions, and in forming at convenient centres museums or collections by which the public taste is formed and information is diffused. The great industrial development of Europe in recent years has doubtless received no small stimulus from such agencies; and the duty of the Government in encouraging technical education is one to which the people of England are yearly becoming more alive, and which it is certain will be more adequately performed in the future. All the causes which rendered such action on the part of Governments desirable in Europe apply with greater force to India. Experience, however, is still wanting, even in England, as to how such instruction should be given, and for India it will be hardly possible at present to go beyond the training of ordinary workmen in the practice of mechanical or engineering manipulation. To whatever extent it

is possible, however, the Government should give assistance to the development of industry in a legitimate manner and without interfering with the free action of the general trading community, it being recognised that every new opening thus created attracts labor which would otherwise be employed to comparatively little purpose on the land, and thus sets up a new bulwark against the total prostration of the labor market, which in the present condition of the population, follows on every severe drought."

This paper was communicated by the Madras Government for remarks to the Board of Revenue, the Director of Public Instruction, the Chief Engineer, Public Works Department, the Commissary-General (through the Military Department), and the Superintendent of the School of Arts.

KALUTARA AS A LIBERIAN COFFEE DISTRICT.

(*Contributed.*)

A few years ago, Kalutara was not even thought of by European capitalists as a place affording a fair field for investment in lands for coffee cultivation. But no sooner had 'leaf disease' laid low the once flourishing estates in the Central Province, than attention was turned to the cultivation of new products. Thus, the hitherto hidden resources of unimportant districts were developed, contributing to the material wealth of the country. The construction of the Kalutara Railway offered no small inducement to local capitalists to open out lands in the Kalutara district, the soil as well as climate having been previously ascertained to be eminently suited for Liberian coffee. Messrs. Leechman and Aitken, Spence & Co. seem to have been the pioneers of this coffee in Kalutara, Culloden and Puttupaula estates are reputed to be two of the most flourishing and lucrative Liberian coffee estates in the island. Almost every year finds two or more estates opened up. This is due, in the main, to the encouragement offered to enterprising men by the unqualified success which has attended the cultivation of Liberian coffee in the district. But what has the Government done to render the burden and risk of the planters light? Where are the roads?—without which, the most obtuse official must perceive, the hazard attending the opening of an estate is considerable. Even the existing roads are so badly kept that they would shame a barbarous country; but strange to say, with the except on of the effort only *now* put forward by the Planters' Association at Kalutara, no voice was hitherto raised by the planters there to have new roads opened up. If Mr. Wace, the Assistant Government Agent at Kalutara, has the true interest of his district at heart, he should not rest until the roads and bridges in Pasdun Korale are put in thorough repair, and new roads, rendered necessary by the clearing of new crown lands, are opened up. The minor road which runs along the Kalu ganga, leading to Uda Piti ya Koda, is in a most disreputable state; and the bridges along the road are rotting. Nobody seems to take the slightest notice of this road. Want of funds, it was said, was the reason why the work of repairing could not be taken in hand by the road officer. Of course he is not to blame. But *somebody* will be haul over the coals in case of a carriage or horse accident, if it happen on that road. I sincerely hope Mr. Leechman will make out a strong case in favour of the Kalutara Planters' Association, who, I see, have moved in the matter, and shame Government into opening out more roads leading to the coffee estates in the district.

There can be no gainsaying that Kalutara will, in a short time more, draw a considerable number of capitalists who will lay bare the rich resources of the lands surrounding it. The soil in some of the new clearings has been pronounced by competent authorities to be very rich and capable of comparison with any in the island. The surface soil, about two feet in depth, is a sort of loose loam, and the atmosphere surrounding the lands is so humid that there is no chance of a season of drought telling severely on the plants during their early stage. Planting in baskets is a capital idea, and the only safe way in which a large proportion of the plants could be grown successfully. The system of shading the plants with the ordinary fern to be found in marshy grounds is very judicious indeed. But in continual wet weather the covering should be removed, as I found in the plants which had the shading on (while the rain continued for a few days) that some of the leaves rotted off, owing to the incessant dripping of water from the fern.

The only enemy that seems to attack the young plants is the bloodsucker, which appears to take a malicious delight in gnawing away the plant about the middle of the stem.

The tea plants in the Kalutara district are, I learn, doing remarkably well. The easy distance from Colombo to Kalutara ought very soon to bring more enterprising men there.

NETHERLANDS INDIAN NEWS.

COFFEE—SILK—TRAMWAYS.

(*Straits Times.*)

Tigers it is said, have caused a falling off in coffee cultivation and silk culture in the Southern districts of Acheen Proper judging from the following statements in a report on a tour of inspection recently made there by Mr. Van Wyck, a controller:—

"On the 19th February, I went with the headmen to the coffee plantations which the *Kejuruan* [a local chief] had laid out with the aid of 10,000 guilders advanced to him by Government. The state of these plantations left very much to be desired. The recently planted portion, especially, looked miserable and badly cared for. In many places the young plants had been choked by lalang and weeds and had died off, so that traces of cultivation could only be found with difficulty. The headmen told me that the little care taken of the plantations was attributable to the great number of tigers appearing in them of late. Fifteen men had already been killed by tigers, and many of the persons who lived on the plantations had abandoned them from dread of sharing the same fate. Within the last few months, however, less had been heard of tigers, so that there was a prospect of the cultivation of the plantations being resumed.

"Silk culture is falling off. I was assured this was in consequence of the difficulty of finding the necessary food for the worms. These insects feed on the leaves of a plant named *Daun kerta*, which grows in the jungle on the neighbouring mountains. Owing to the great number of tigers which have appeared of late in these districts, the inhabitants no longer dare to go out looking for the said leaves, so that this industry is retrogressing. Some cocoons were shown me at my request. They have wholly the appearance of the silk-worms grown in Europe. These cocoons were boiled in water, the silk being afterwards spun off or reeled."

During his tour through these districts—Lohong, Lepoug and Kluang—which had suffered least from the war, Mr Van Wyck was hospitably and cordially received by both headmen and people, and met with everyA attention and regard from them. He states the cochineal there are far advanced in agriculture, their fields being irrigated by well constructed canals, and kept free from weeds. Besides coffee and paddy, pepper, sugar cane and tobacco are grown. The cultivation of pepper had, however, decreased owing to the blockade. Cattle rearing was unimpor-

tant, from disease. Among the exports were guano to Penang and birds nests similar to those of Java. Gold is found at many places, and petroleum is known to exist. Mr. Van Wyck was favourably impressed by the Achinese of the districts, whom he describes as not fanatical but susceptible of instruction, eager for information, and industrious, his firm conviction being that much may be made of them by the spread of knowledge, and that, when they once understand the good intentions of the N. I. Government, they will prove good subjects. He examined the land applied for by Messrs. De la Croix and Brau de St. Pol Lias, and assembled the headmen concerned, who expressed their approval of the application for the land, and their desire that the Government would give the permission asked for. During his whole tour, the only articles stolen from him were potatoes—one or two at a time, with the object of planting them. He hence soon distributed them among te people and gave directions how to grow them. Achinese seemed to be partial to cultivating potatoes, from their profitable nature and tastiness.

The firm of Dummler and Co. has obtained a Government concession for laying a double line of steam tramway from Batavia to Meester Cornelis. The cars are to run on sunken rails at the rate of 15 kilometres per hour as the extreme limit, and the line is to be completed in two years. At Surabaya, an application has been made for a concession to lay a steam tramway there also.

"Surabaya, 21st April.—To those who consider more frequent communication with the Moluccas desirable, it is glad tidings that a Singapore firm which owns the steamers "Thamcs," "Penang," "Celestial," and "Bivouac," intends from the 15th May, to run a vessel (the "Thames") from Surabaya to Macassar, Menado, Gorontalo, Amboyna, Banda, Timor, Deli, and Bima, and back. Should the experiment succeed, the "Penang" will also be put on this line.—Batavia Dagblad, 26th April.

To develop the resources of Java, another association with a paid up capital of 500.000 guilders has been established in Holland, styled the East Java Culture Company, to manage Coffee and Cinchona plantations.

The Java coffee crop for 1881 was officially estimated at 815,300 piculs on the 31st March.

It is officially reported that the tin yield in Banka, last year, was 72,684.92 piculs, against 77,615.44 piculs in 1879.

THE MANUFACTURE OF COTTON OIL from the cotton seed, according to the *London Times*. is becoming of importance in the United States, there being at the present time upwards of 41 oil mills, of which nine are in in Mississippi, nine in Louisiana, eight in Tennessee, six in Texas, four in Arkansas, two in Missouri, two in Alabama, and one in Georgia. The annual quantity of seed converted into oil now amounts to about 410,000 tons, the yield being at the rate of some 35 gallons of oil to the ton of cotton material. Moreover, each ton leaves 750 lb. of oil cake of admirable fattening qualities. A great deal of the cotton oil is imported to Italy and other countries where the olive oil is a staple; and, in point of fact, cotton oil is there superseding the olive oil, not only for utilitarian purposes, but also as an article of food. It is said, too, that the use cotton oil in this way is gaining ground in some parts of the States. The following are the statistics of consumption :—

	Export.	Home consumption
	gallons.	gallons.
1876-7 ..	1,316,000	2,000,000
1877-8 ..	1,457,000	1,800,000
1878-9 ..	5,750,000	2,425,000

Indian Agriculturist.

COFFEE.—We learn from Yercaud that the coffee crops this year are not likely to turn out well as the want of rain is greatly felt. Up to the 1st instant, the rainfall in the coffee-growing tracts of the Shevaroys was next to nothing and the trees which gave promise of a bumper crop this season, do not look so well as they would under other circumstances. It appears that, in the past year, rain fell in Yercaud during the whole of April, and that about this time last year the trees looked at their best. It was expected that this year would be a good one, but the hopes and expectations of the planters have, to some extent, been blasted. If rain does not fall during this month, the coffee crops of the Shevaroys will be very small. Some fine estates belonging to a firm at Madras that lately went into liquidation were placed by the trustees in the hands of an experienced planter, and we hear that under him they are doing well. The proprietors of coffee estates in the Shevaroys are giving increased attention to their condition, and it is hoped that their anticipations in respect to cops will, later in the year, be realised.—*Madras Standard.*

THE FERTILITY OF NEW ZEALAND is very great, and for agricultural purposes the percentage recorded below would, were there no financial drawbacks, point irresistibly in favour of that country :—

	Average yield per acre.			Mean of six years		
	Wheat.	Oats.		Potatoes.	Hay.	
	bush.	bush.		tons	tons.	
Victoria	13 ..	18⅜	...	3¾ ..	1¼	
New South Wales	14¼ ...	19	...	2½ ...	1⅜	
New Zealand	27¾ ...	33	...	5 ...	1¼	
South Australia	8¾ ...	12⅜	...	3¼ ..	1¼	
Queensland	12 ..	10	...	2¼ ...	1.3	
Tasmania	17½ ...	24	...	3½ ...	1¼	
Western Australia	11½ ...	16¼	..	2⅝ ...	1¾	

The average of these is 15 bushels, and we are surprised to find it so low, in a new country like Australia, in India the average is 14 bushels, but this must be remembered is only the *rabi* crop. The land is beside, frequently called on to produce a *kharif* crop as well, so that compared with Australia, which only produces one crop a year, our yield must be considered better than theirs.—*Economist.*

THE STRAITS SETTLEMENTS AT THE MELBOURNE EXHIBITION.—We (*Straits Times*) have been favoured with the following list of awards for Exhibits from the Straits Settlements in the Melbourne Exhibition :—

Order of Merit.	Exhibitor.	Exhibit.
First	Paterson, Simons & Co.,	Gum, Copal [& Gutta Percha.
do	Guthrie & Co., Gums,	Gutta Percha &c.
do	Too Tye Sin, (Penang)	Indian rubber and [Gutta Percha.
Hon. mention	D. D. Daly.	Pewter & Blocktin Ware.
Hon. mention	T. B. Rowland,	Ornithological specimens.
First...	N. P. Trevenen,	Models of Malay implements.
do	Borneo Company,	Collection of Ores.
do	Government of Straits Settlements,	Collection of Tin Ores.
Second	Captain China	Tin Ores.
First	Guthrie & Co..	Gambier.
do	W. H. Read.	Gambier.
do	C. Favre.	Crystallised Fruits.

List of Awards.
Class 43.

Order of Merit.	Exhibitor.	Exhibit.
Fourth.	Penang Sugar Estates,	Rum in Bulk Dark.
do	J. Lamb, Penang	Rum in Bulk, White
do	Penang Sugar Estates	do
Fifth.	Onderming, Sumatra*	Cigars.

* This appears to be a mistake, as the Onderming Co. only exhibited tobacco.

LIBERIAN COFFEE IN DEMAND IN AMERICA.

Our readers will remember our report of a conference called, at the instance of Mr. Wm. Walker in London, to consider the merits of Liberian Coffee and to meet Mr. Edward Morris of Philadelphia, an enthusiastic member of the Society of Friends who believes in the regeneration of Western Africa through education provided for by Liberian Coffee. "Plant Coffee" was to be the burden of his cry to the negroes of the West Coast, and in return for the resulting produce, America would send all that was required to ensure the education and christianization of the tribes. This mail has brought us the following letter from our philanthropic friend :—

Philadelphia, April 13, 1881, Office 609, Walnut St.

MR. FERGUSON, MY DEAR SIR.—You will remember giving me a copy of a book with yellow cover, full of information about Liberia Coffee, and its introduction into your promising Island of Ceylon. I value it very much. I lately loaned it to some one, cannot tell who, I consider it lost, never expect to see that copy again. I beg of you to send me another copy regardless of cost—and I will make returns for it—if it is out of print please advertise for a copy, and I will pay you.

Ever since I had the pleasure of meeting you in good old England, I have been intending to write to you, to encourage some, no matter how many, of your planters to ship me a hundred or a thousand bags of "Liberia-Ceylon coffee." In view of my well-known connection with Liberia *here*, I am quite certain I could create a *high price* trade for Liberia-Ceylon coffee. Do make the effort, to this end. Forward the book, and let me hear from you. I will sell your coffee and make returns in a draft on London or in American merchandise—as per order,—Respectfully,

EDWARD G. MORRIS.

We publish this letter as the best means of making Mr. Morris's request known. It must be remembered that his firm in Liberia send coffee to the United States, and at the Philadelphia Exhibition Mr. Morris carried off the first prize for the finest coffee, since which time he has not been able to meet the demand for the quality of produce they are able to send from Liberia. The price he mentioned to us, at which he was selling, was a very high one, and we have not the slightest doubt that if any Ceylon merchant or planter consign some of their produce to Mr. Morris, he will do his best to find a good market for it and to promote a profitable sale.

PLANTING AND SCIENTIFIC EXPERIMENTS.

Notwithstanding the high position already attained by the typical "Ceylon Planter" in the estimation of the tropical agricultural world, there is no doubt that by accurate observation and logical reasoning, he has still to arrive at many important truths bearing on his profession. The routine of working an estate is a small matter, which any one with a moderate allowance of brains should readily pick up. Indeed the existing system of planting has grown out of a very limited number of minds, and many of the practices now held to be demonstrated truths were very slow in making way against adverse prejudices, supported in many cases by men in whom their fellows put confidence. If, however, the planter has still a wide field for his individual investigations, this age of specialities has opened up fields of scientific enquiry that can only be properly cultivated by co-operation. There can be no better means of applying science to a planter's practical work than in the way we have so often advocated of establishing Experimental Stations, to test the practical value of the various manures and fertilizing substances within his reach on the plantation or offered to him in the local market. It will be generally admitted that costly manures have been applied to cultivated land in Ceylon, without yielding the reasonably anticipated results. Henceforward, no doubt, the custom is likely to grow among our planters, of obtaining an analysis of the soil to be operated on, so as to know with some degree of certainty in what elements of fertility it is deficient with reference to the cultivated plant. The planter who takes this course is on the true scientific path, but he has to provide all the cost himself and is not called on to publish his results for the public benefit, whether these be success or failure. Few people like to publish their failures, and if they publish their successes, the chances are they will not be believed.

Ceylon with its Central Planters' Association, and with branches in every important planting district, already possesses the principal element for carrying out a series of public experiments that would settle once for all a number of pressing questions affecting the interests of every estate proprietor in the Colony. As such experiments would have value only when conducted on the soundest scientific principles, a special Agricultural Chemist would have to be appointed to carry them out. The salary paid should be a liberal one, so as to secure a first-rate man, and contributions towards it should be made by the District Associations according to their strength and numbers. Surely when so many "Visiting Agents" make handsome incomes out of the planting interest, one Scientist could be maintained by the whole body for the general benefit without the individual contribution being considered a hardship. When individual planters are found to incur the whole expense of analysis and experiment, in the firm belief that it will pay them, it is only those who have already given an *a priori* decision that all manuring is "*bosh*," and that the soil and climate of Ceylon have ceased to suit the plant that has for above forty years yielded its principal staple, that are likely to oppose the general adoption of such a scheme. There are some amongst us, judging by the correspondence which reaches us, who believe that recent critics absolutely delight in the picture of ruin (so far as coffee is concerned) they have drawn; but this is a mistake, for "W. McK." himself has confessed to us personally that notwithstanding his remarks in reference to the "Aluwihara" and "Venture" experiments,—criticism altogether premature—he believes Mr. A. Ross, senior, is on the right track in the course he has adopted. Mr. Ross's example is, we are aware, to some extent being followed in other places : various experiments are being made with new and old manurial substances—kainit and gypsum have, for instance, been imported,—but unless stations systematically conducted are established for the benefit of all, it is quite certain that the majority of isolated individual experiments will simply result in money being thrown away without even the proprietor concerned reaping benefit, much less the general public. The application no less than the selection of experimental manures as well as the inspection of the results, require more scientific guidance than the planter usually has, or can afford to give. District Experimental Stations are therefore imperatively called for.

COFFEE OIL.

We give the following translation from the *Indische Mercuur* for March :—Although we make daily use of coffee as a drink we are not yet fully acquainted with the chemical nature and the composition of the products which result from the roasting or burning of it, nor with the oil, which constitutes one of the most interesting and characteristic elements of the bean. The presence of coffee oil is completely manifested by roasting, when the oil, driven out of the bean by the power of the heat, is thereby partially liquefied, and diffuses, together with other products of the combustion, the peculiar aroma of burnt coffee, an odour not possessed by any other substance. In very strongly made coffee the oil can also be seen floating in little drops of fat on the liquid. The amount of oil present in coffee beans varies from 8 to 13 per cent, and at least half of this is lost in the roasting. It should be a not unprofitable experiment to try to collect this oil, especially in large establishments, where large quantities of coffee are roasted, and thus also large quantities of oil are lost. In the year 1871 not less than five hundred thousand tons of coffee were consumed, the amount of oil lost from which may now be easily calculated. Dr. Cech of St. Petersburg tried the experiment of collecting the oil in one of the coffee-roasting establishments in Berlin; he connected the machine in which the coffee beans were roasted with a sort of condensor and a receiver, so that he first cooled the ethereal oil and then collected it as a liquid. At the commencement there was scarcely any vapor to be collected any-where in the machine, but when the beans became brown and the whole mass was well heated such a large quantity of ethereal oil was produced that it could be collected after condensationin the form of successive drops. If this operation is performed in a chamber, without making use of such a condensor, the oil runs in little streams along the cold walls. The requirements of roasting have hitherto been of such a nature that the roasting and stirring take place in the open atmosphere, which makes the condensing and collecting impossible. Experiment has taught however that the coffee which is being roasted must, as soon as thebeans are brown, be brought away from the heat to be stirred, as it is feared the mass would be burnt if this were not done. Andthat is just the moment when the oil is being most largely produced. If any one could think of a method of uniting the spit with an exhauster, which would collect the gases and convey them to the condensor, and which wouldon the other hand admit sufficient air to cool the beans completely, he would be on the road to success. Dr. Cech is of opinion that the oil extracted is admirably adapted for the manufacture of liqueurs. In order to study the properties of coffee oil Dr. Cech pounded 50 lb. of different kinds of coffee to powder in a mortar, than made a decoction of it with alcohol and ether, and so obtained two and a half lb. of extract. The beans used were not all of the same good quality : some sorts had 8 others 13 per cent of oil, indeed there were some that had less than 8 per cent oil. The coffee oil is green, thick, and transparent, and after it has stood for some time fine long needle-shaped crystals are deposited. These appear to be caffeine. This oil becomes turbid in the space of half a year, though it may have been kept in opaque stoppered flasks. In the course of time more and more crystals are deposited, and after about a year the flask is half filled with a dirty colored mass of crystals; the liquid floating above however appears transparent, clear, and of a fine green color, from which it is to be inferred that a portion of the coffee oil consists of a fluid oleaginous acid. The percentage of composition of the coffee oil is however so far not yet ascertained. This still needs the attention of practical chemistry. Time must teach what can yet be made with the oil.

CINCHONA CULTIVATION.

DR. TRIMEN ON RED BARK.

MR. ELIOT HOWARD EXTINGUISHING "C. PUBESCENS HOW."

We draw special attention to Dr. Trimen's letter giving a full explanation of his views in reference to the cultivation of red bark. It seems that the Director in deprecating the extension of cultivation with the inferior sorts, referred to the Calisaya species only and not as we supposed to Succirubra. In addition to the reasons now given for regarding the red bark with favour, we may mention the fact that it is used in the manufacture of beer in Germany, and the probability that through the shaving process, the renewed produce may prove to be a manufacturer's bark of no mean value. Crown bark in all its degrees requires no advocacy, and of course the fortunate possessors of Ledgerianas and the finer Calisayas are to be envied rather than treated to words of encouragement; but we would fain put in a good word even for the "inferior" Calisayas in so far as to deprecate discouragement after the very satisfactory analytical and market results obtained by Mr. J. A. Roberts of Pussellawa and the proprietors of Emelina. It seems probable that in the Ceylon climate and soil *C. Hasskarliana*, *Josephiana*, &c., will, for some reason or other, give better results than in Java. At any rate, the trial ought to be persevered in by those who have already planted these kinds, while in all future clearings, planters should as far as possible aim at putting out the best, taking elevation, climate and soil into account as well as the plants available. Where C. officinalis succeeds well in Ceylon, it may be a question if a more profitable kind can be planted taking everything into account. We suppose the finest and most promising cinchona clearings of this kind to be seen at the present time in the island are between Udapussellawa and Nuwara Eliya in the Kandapola division, at elevations of from 5,500 to fully 6,000 feet. Nothing can exceed the regularity and vigour with which crown bark trees flourish in this region, and it will be interesting by-and-bye to compare the yield of bark and prices obtained for the same, with those realized for the Ledgeriana trees grown in Ceylon.

Our correspondents "T. N. C.," "W. F. L.," "T. C. O.," and other cultivators of cinchona will be interested in the letter which has just reached us from Mr. J. Eliot Howard. Our readers will remember the discussion which took place in our columns over the different varieties of Officinalis and on the value and position of certain hybrids. "C. pubescens, Howard" was freely referred to as one of the best recognized hybrids between C. Officinalis and Succirubra, and Mr. Clements Markham's mistake in putting it as a hybrid of Calisaya and Officinalis was commented on. We think "T. N. C." stood alone on that occasion in his wish to drop the name "C. Pubescens" as misleading for the hybrid, but here we have Mr. Howard himself asking that the *coup-de-grace* may be given to the variety associated with his name, the term "*C. pubescens*" being used for a species long ago established and having quite different characters. Mr. Clements Markham will have to correct his book. Mr. Howard writes as follows :—

Lord's Meade, April 29th, 1881.

DEAR MR. FERGUSON.—I have to thank you much for a copy of your Hand-Book for Ceylon just received.

I find that I am credited with having created a new species of Cinchona, the "*C. pubescens How.*" I do not say that I find this in your book; for I have not had time to examine it; but my correspondents in Ceylon are writing to me about it. I think I have pointed out before that this is all an error, arising from my suggesting to Mr. McIvor the word *pubescens* as applicable to one out of two *hybrids*, found by him

at the same time, and similar except in the above characteristic.

The bark of this sent me by Mr. McIvor was very rich, but then what he subsequently sent was quite different.

The rich form of this hybrid is, I find, now cultivated by certain planters, but it will not, I think, come true from seed, being only *a hybrid* as Mr. McIvor thought, I believe.

The "*C. pubescens*" is a *species* long ago established and having quite different characters.

There is no end to the confusion of botanical nomenclature unless the *original* designation of species are adhered to.

If you will favour me by giving the *coup de grace* to "C. pubescens How." you will much oblige me.—Believe me, yours very truly,

JOHN ELIOT HOWARD.

We have no doubt that Mr. Howard's wish will henceforward be complied with in Ceylon.

PRICES FOR CEYLON AND INDIAN CINCHONA BARK IN 1880.

We have received a copy of the usual set of tables showing the prices realized by the different marks of Ceylon and East India cinchona bark sold at public sale during 1880, compiled by Messrs. C. M. & C. Woodhouse, and printed for private circulation. Prefixed to the tables is an epitome of the quantities received from the different districts, and the prices realized compared with 1879. We see from this that Prospect estate on the Nilgiris again topped the market with 12s 6d for renewed crown against 12s 8d in 1879. Mungpoo in Sikhim came next with 10s 10d for yellow quill. The Government Gardens at Ootacamund did not do so well as in 1879: 10s 2d for renewed crown and 8s for mossed crown were the maximum prices in 1880, against 11s 7d and 9s 3d in the previous year. Jamaica's highest figure was 8s 10d, against 10s 1d in 1879. The highest figure for Ceylon was 10s for root bark. We will now give a summary of the highest prices realized. Table I gives the "Government cinchona grown at Ootacamund," the highest price 10s 2d being obtained for renewed crown of 1866 and also of 1869 planting. Table II gives the "Government cinchona grown in the Royal Botanical Garden, Mungpoo, Calcutta.' (This description is somewhat equivalent to "bark grown in Hakgala, Colombo," Mungpoo being in British Sikhim.) We have already mentioned the highest price obtained by this garden. Table III refers to Jamaica, and Table IV to Darjeeling, the bark being supplied almost entirely by one estate (the Darjeeling Tea and Cinchona Association), the highest price being given for a case of quill at 6s 6d. Table V gives "other East India," a somewhat indefinite description: most if not all of the estates are South Indian. Besides the 12s 6d for Prospect bark, 9s 10d to 9s 11d was paid for renewed crown Doveton, and 8s 1d for NSH quill. Table VI gives the Ceylon barks. The following are the prices over 6s:—AHT quill 6s 10d; Ardallie quill 6s 4d to 6s 6d, root 8s 6d to 8s 7d; Bambrakelle quill 6s 7d to 8s 4d, chips 6s 8d, root 7s 6d to 7s 10d; BBWD quill 6s 2d, root 10s; CBLM root 8s 10d; Calsay quill 6s 1d to 6s 7d, root 6s 2d; Chrystler's Farm quill 6s 6d to 8s 1d; Cabragalla quill 6s 1d, root 9s 6d; Cranley quill 6s 1d to 6s 3d, root 8s 1d; S & Co. root 6s 7d; Dessford quill 6s; Elbedde quill 6s; Glentilt root 7s 11d; Great Western quill 6s 3d, root 6s 4d; Loolcondura quill 6s 2d to 8s 1d, root 7s 1d to 7s 3d; MK quill 6s to 7s 4d; Maria quill 6s 1d; Maha Ellia quill 7s 2d, root 7s 10d; Manickwatte quill 6s 7d to 8s 2d; Norwood quill 6s 1d to 6s 4d; Queenwood quill 6s 2d to 6s 10d, root 7s 3d; Rookwood quill 7s 3d to 7s 4d, root 6s 5d; Sutton quill 6s 5d to 7s; St. George root 6s 4d; Tronp root 7s 8d; Wannerajah quill 6s 6d to 7s 1d; Wavendon quill 6s 6d to 6s 9d, root 6s 1d.

A TEA OR "GENERAL PRODUCE" SYNDICATE FOR CEYLON.

We can see no good reason why the tea-planters of Ceylon and the mercantile agents interested in their product should not combine for the establishment of a Syndicate after the fashion already set before them in Calcutta. If there is not sufficient unanimity to secure adequate support for a local Syndicate, then we would advise an application to Calcutta for permission to establish an affiliated branch of the institution now working so successfully in India. For innately this very idea has been promulgated already by a gentleman closely connected with the Calcutta Syndicate, Mr. Magor, who recently visited Ceylon, and who was reported to be well pleased with all he saw of our tea industry, dropped the suggestion while here that inasmuch as the interests of Indian and Ceylon tea planters were practically identical in regard to opening new markets, they might well work through one and the same Syndicate. Mr. Magor, we find, is Secretary to the Committee (which is composed of Messrs. Jardine, Skinner & Co.; Begg, Dunlop & Co.; William Moran & Co.; Macknight, Anderson & Co. and Williamson, Magor & Co.) of the Calcutta Syndicate, and he has been good enough to send some papers with its proceedings to a friend in Colombo, from which we gather particulars of special value with reference to the project now before the public. The Calcutta Syndicate was formed at a meeting held on 9th February 1880 of merchants interested in opening up a trade in Indian Teas with Australia. Certain sums were subscribed by the Firms who agreed to join, for the purposes of the Syndicate, and a managing Committee was appointed consisting of three Tea Agency Firms, one a firm of Tea Brokers and one of Shippers of Tea, in order to collect subscriptions, to solicit the aid of Government and deal with the shipment and sale of the teas. Three months later it was found that many public Companies and plantation proprietors were anxious to co-operate with the Syndicate by forwarding consignments of tea for disposal on their account at the best price obtainable in the Melbourne market. The great point was to secure uniformity in the quality and appearance of the tea shipped, so that the same description could be easily and at any time repeated if orders were sent by dealers and others. The Syndicate therefore determined to bulk all teas received from each district, classifying them simply as Assam, Darjeeling, Cachar tea and so on, and retaining standard samples for reference. All such bulked teas are shipped under the Syndicate mark. At the same time the following detailed instructions have been issued for tea plantation managers as to Quality, Classification and Packing:—

The requirements of the Australian Market, as far as can be ascertained are principally for the lower grades, and the Committee therefore recommended that the bulk of tea forwarded should consist of—

1. *Broken Souchong, or Broken Pekoe Souchong.*—Black *leafy* with strong, dark, full-flavored liquors.

N.B.—Dusty Broken to be particularly avoided.

2. *Souchong and Pekoe Souchong.*—Small even-made leaf of good appearance, with clean, dark liquor.

The above two classes should form the bulk of the Consignment but a small quantity of the following probably find a ready sale, *viz*:—

3. *Pekoe.*—A Good medium Pekoe leaf with some tip.

Fair strength and brisk flavor Darjeeling Pekoes and Pekoe Souchongs, and also Souchongs, if not too bold, with good quality and flavor would probably sell well,

but no *extra fine* Teas should be sent. Nothing worth over about 14 As., and this should only form about a quarter of the Consignment.

Packing.—The packages should be as uniform as possible in size, strongly nailed, *but not iron-hooped.* The size of the box should be 25″ × 17″ × 12″, inside measurement, 45lb. to be packed in each package.

The Boxes should be neatly made, and Tares as even as possible.

Marking.—The only mark required is the garden mark, to distinguish the boxes on arrival in Calcutta, and "Tea Syndicate" on the opposite side.

Invoice.—To accompany each parcel.

It is the province of the Calcutta brokers carefully to inspect and value every parcel and to set aside for bulking only those parcels which they consider suitable. The proceeds of sales are returned to the various contributors of tea in proportion to the value fixed on each parcel before bulking. The Syndicate was started with a contribution of R20,000, subscribed by merchants and agents, and a grant from the Indian Government of R10,000 towards the expenses of the undertaking. We believe the Government grant was made on condition that the operations of the Syndicate should be gradually extended to "general produce" and not simply confined to tea.

Now here we have information of great value in helping us in Ceylon to decide on the best course for promoting the interests of our young and promising Tea industry. The advantages of the course of action adopted in Calcutta are not confined to the better opportunity afforded of establishing a large trade in the class of tea required for the Colonies, but the system also ensures that unity and identity of interests so essential to success where it is attempted to create a market for a new and comparatively unknown description of product. It seems to us in the first instance that the Ceylon tea planters and their agents could not do better than unite to form themselves into a branch of the Calcutta Syndicate. All approved teas supplied to the local Committee would then be inspected, and if approved, valued, bulked and classed as Ceylon Tea and forwarded to the Syndicate's Agents in Melbourne, Sydney, New York, or to whatever other destination it may be intended, in which operations have been begun. The great advantage of working along with India would be that we should at once share in a system and concern already well-known, and profit by the wide-spread advertisements of its teas already circulated by the Syndicate. Under the same head of "Indian Teas," the produce of Assam, Cachar, Ceylon, Darjeeling, would thus, hereafter be offered for sale by the Syndicate's Agents. Whatever new efforts might be deemed needful in Great Britain or Europe generally, would be for the benefit of Ceylon equally with that of each of the Indian Districts. Already the Syndicate have determined to operate in America, and they have sent Mr. D. A. Sibthorp (who is a professional Tea-taster) thither in charge of considerable consignments. This gentleman has become acquainted with the nature and quality of Ceylon teas at the Melbourne Exhibition, and we feel sure he would do justice to bulked consignments sent from this Colony. It only remains, therefore, for the planters and their agents to consider whether the hint dropped by Mr. Magor when passing through Ceylon, should not be taken up and acted on, enquiry being made in the meantime as to the terms of affiliation and the conditions under which Ceylon tea would be taken charge of by the Syndicate's Agents.

CALISAYA LEDGERIANA FLOURISHING IN MASKELIYA.

Nothing will give us greater pleasure than to be placed in a position to assure Mr. Moens (and the cinchona planting world generally) that, whatever may be the case in Java, "a long dry season" is not required in Ceylon to enable the precious Ledgerianas to blossom and seed, any more than to grow luxuriantly. And a few more facts added to those furnished in the interesting statement made by Mr. Christie of Maskeliya, ought to convince even Mr. Moens of the fitness of certain portions of our younger districts between Adam's Peak and Great Western for the cultivation of this valuable species. After all, although blossom is an important matter, it is not *the most* important in respect of cinchona. If the Ledgeriana trees grow vigorously and put on bark after the fashion of the "succirubra" species (as stated by Mr. Christie) certainly the cultivation should be pronounced a decided success. His comparisons speak for themselves, and we trust these will be followed by others made by the possessors of Ledgeriana calisayas of an appreciable age in Boltumbe or West Haputale, in Madulsima, Maturata, and other districts. The piece of bark sent to us by Mr. Christie requires no microscope to discover its quality; to break it and taste it is almost sufficient! The analysis shews that Ceylon "Ledgerianas" of the true type are not likely to be a bit behind those of Java in their value to the manufacturers of quinine. Mr. Howard will be greatly interested in the experience of Mr. Christie (whom we heartily congratulate), and we shall forward to the veteran Quinologist the piece of bark sent to us, to enable him to judge of the result even at this early stage.

THE PRODUCE MARKET: THE FALLING-OFF IN PRICES.—This time last year prices were higher than now, as follows:—

Middling Plantation Ceylon ...	...	14 per cent.
Good Ordinary Native Ceylon	...	19 ,,
Mysore Coffee	...	22 ,,
New York Fair Rio ...	...	35 ,,
Coconut Oil	...	12½ ,,
Cochin	...	10 ,,
Mid. Uplands Cotton *in London*	...	15 ,,
Tinnevelly ,, ,,	...	13 ,,
Fair Dhollerah ,,	...	26 ,,
Good Fair Westerns ,,	...	26 ,,

"GOLD IN CEYLON."—We are indebted to a correspondent signing "Granite" for the following:—"A quick and inexpensive method of testing quartz is much needed at the present time. Here is one: take a candle and a blowpipe and apply the flame to the face of a promising lump of quartz, concentrating the heat on one particular spot for three minutes more or less. If there is gold, it will very shortly become coated with the precious metal. 'Contrary, no.' This test I have seen applied to good specimens of silver ore, with the result, as may be supposed, of completely plating the heated surface. Having fancied that the ardour of the gold-seekers was abating somewhat, I have sent this note, and am in hopes it may give a fillip to their flagging zeal."

CITY ANALYST'S REPORT.—Mr. Thomas Jamieson, F.C.S., public analyst for the city, has examined in the course of the past three months examples of milk, confections, tea, oil, and butter. In the milk there was no excess of water and no deficiency of cream. In two cases the confections contained no injurious ingredients, two varieties were "harmless," one was injurious, and one "suspicious." The oil was free from injurious ingredient, and the butter was found to contain 51 per cent. of butter fat and 49 per cent. of other fat. Mr. Jamieson examined four samples each of teas of 1st, 2nd, 3rd and 4th qualities. Of the 1st and 2nd qualities the samples were unadulterated, in the 3rd quality one contained 8 per cent of other than tea leaves and in the 4th quality there were two such samples one of which contained 21 and the other 3 per cent. The amount which the analyst earned in fees was £1.—*Aberdeen Journal.*

Correspondence.

To the Editor of the Ceylon Observer.

TEA, CINCHONA, AND COFFEE CULTIVATION :—IN EXPLANATION.

The Tea and Cinchona Plantations Co., Limited.

DEAR SIR,—In the prospectus of this Company is printed the following from Mr. H. J. Seymour, dated Jany. 25th, 1881 :—

"I am glad to be able to give you some information respecting tea in Rakwana and Morawa Korale district (the district in which the whole of the Company's properties are situated). I was in charge of 'Barra' estate (about five miles from the Company's land) for a year or so, and we did very well with our tea which was planted on abandoned coffee land. I am not sure as to the yield of leaf, but think we got between 500 to 600 lbs. per acre, &c."

You will note Rakwana and Morawak Korale are made out to be *one district*, and Panilkande and Anningkande are said to be only *five miles* from Barra. Now the real distance is quite fifteen miles, and although, no doubt, tea grows exceedingly well in Morawak Korale, the Rakwana and Morawak Korale districts are very different in most respects. On "Barra" there is still fine coffee which was old when Morawak Korale district was opened, whereas the Morawak Korale coffee is already almost entirely abandoned.

Again, Mr. Seymour had really nothing to do with tea on "Barra." Mr. Ryves was in charge of it, and I have the very best authority for saying that the yield per acre was then just about half of the quantity above stated. In fact, there were only about twelve acres in partial bearing, and none in full bearing at the time Mr. Seymour was on "Barra."

I adhere to the "facts" mentioned in your correspondent's letter, as to "Venture" and its crops and manures. Up to quite recently the bulk of the manure was *bones and poonac*. The quantity and composition of the mixture are in my possession, having been given to me by the proprietor and superintendent of the estate.

But, as you have pointed out to me, you did not say Mr. Ross had already got 3 to 4 cwts. extra per acre from his manure, but merely that if he did get that quantity at an expenditure in manuring of R70 per acre it would repay him, I quite agree with you. Many others besides me understood you to imply that he had already increased his crop by 3 to 4 cwts per acre.

That Mr. Ross does not now use bones and poonac proves that he is still experimenting; and, as his experiments are under the guidance of one of the best practical chemists in Britain, we may depend upon everything being done in accordance with the best principles. That he may succeed must be the fervent wish of all who are interested in coffee; that he deserves success all who know him will admit. He has long been recognized as one of our most plucky, intelligent, and enterprising planters. W. M. K.

Mr. Ross's manure of 1878-79.

Herewith copy of prescription for manure handed to me 2½ years ago :—

		£	s.
5 tons dissolved phosphates	@	8	10
7 ,, sifted guano (Peruvian)		13	0
8 ,, muriate of potash		8	10
4 ,, sulphate of magnesia		4	15
4 ,, nitrate of soda		16	15

To above add 30 tons bones and 60 tons castor or other cake.

30

C. SUCCIRUBRA AND THE CINCHONA ALKALOIDS.

Royal Botanical Garden, Peradeniya, 23rd May, 1881.

DEAR SIR,—I fear from a remark in your columns on Saturday that the observations I made in my annual report for last year on the cultivation of cinchonas have been misunderstood in one point by you, and I am anxious to put myself right. It was very far indeed from my intention in those recommendations to "warn planters against succirubra." On the contrary, as many planters are well aware, I have been strongly recommending them to keep up a good back-bone of that species so as to be prepared for possible changes. The advice in the report was addressed to those who are so fortunate as to possess plants of Ledgeriana, the inferior sorts alluded to being specially the various Calisayas, so liable to be mistaken for it. I also expressly guarded my observations by the remark "assuming that quinine retains its commercial pre-eminence over the other alkaloids," for, of course, a change in this respect materially alters the whole conditions of the enterprise.

He would be a rash man who ventured to predict the future course of events; but though the *ultimate* issue may not improbably be that a pure mixture of the four alkaloids without any other substance mixed with them will be generally used, there are no signs of any speedy change in the present state of things, and therefore I feel justified in the advice I have given.

Fashion and custom have extraordinary power in Pharmacy (extending even to the constant prescription of drugs which are known to be almost inert, though possessing a high popular prestige), and the great quinine-manufacturers, whose power is undoubted, may be expected to resist with all their strength any change in the present estimation of quinine.

There is another matter in which *C. succirubra* plays an important part; that is "bark" itself as a drug. It must be remembered that cinchona bark is still largely prescribed for many complaints. In connection with this, I send you a copy of the *Pharmaceutical Journal* just received, in which attention is drawn to an important article by Professor Flückiger of Strassburg, the leading pharmaceutist in Europe. I have been lately in correspondence with him on the subject of this article, and was able to assure him that we in Ceylon grew extensively the true *C. succirubra* as understood by Howard. You will see that he gives his reasons for fixing upon the bark of Indian grown *C. succirubra* as *the* official bark of the new German Pharmacopeia to the almost complete exclusion of other kinds.

This decision is of especial importance when it is remembered that the necessity of an internatioual Pharmacopeia is now generally recognized and likely to be actually undertaken, in which case the action of Germany in this matter of bark might not improbably be generally adopted.—I am, sir, yours faithfully, HENRY TRIMEN.

The article referred to is as follows :—

CINCHONA BARK AS AN ARTICLE OF THE OFFICIAL MATERIA MEDICA.

In a recent number of the *Pharmaceutische Zeitung* Professor Flückiger has drawn attention to the uncertainty now prevailing as to the kind of cinchona bark that would be best to use for pharmaceutical purposes. He considers that from the importance of that drug as a medicine this circumstance alone is sufficient to justify the existing desire for a revision of the German Pharmacopœia, and the same view may be applied to the Pharmacopœias of most other countries.

One of Professor Flückiger's objections to the three kinds of cinchona bark now officially prescribed is

that they are referred to only as of South American origin, and he points to the development of the supply of bark from British India since 1867 as having now reached a stage when India-grown bark requires to be considered in a very different manner from what was possible when the last German Pharmacopœia was published in 1871.

The question to be considered is how the cultivated cinchona bark imported from India should be dealt with in a new Pharmacopœia, and Professor Flückiger is of opinion that its consideration must not be confined merely within the limits of a pharmacopœia commission, or undertaken exclusively from a medical or pharmaceutical point of view, but that it must be conducted also with suitable regard to the present position of cinchona bark as an article of commerce as well as the probable form that it may take in the future.

From an examination of the various circumstances obtaining in regard to those varieties of South American cinchona bark which are now official, Professor Flückiger arrives at the following conclusions, which, we think, will be of interest to our readers.

The flat calisaya or yellow bark of the Pharmacopœia, he finds to be more scantily and less regularly exported than formerly and at the same time it has become inferior in quality, the amount of alkaloid in the Peruvian and Bolivian calisaya bark being very much less than we were formerly accustomed to. Whatever may be the cause of this deterioration it is unquestionable that the official calisaya bark does not meet the requirements which the Pharmacopœia should demand of cinchona bark to which preference is to be given; such bark ought to be obtainable abundantly and uniformly at a comparatively moderate price, and it should contain an adequate as well as a constant amount of alkaloid. In addition to these points it is to be remembered that the therapeutic action of cinchona bark must be in part ascribed to other constituents besides the alkaloids. The quinotaunic acid, quinovin and quinovic acid, as well perhaps as quinic acid, are present in smaller proportion in the stem bark of calisaya than in most kinds of branch bark. All these facts are regarded by Professor Flückiger as being so unfavourable to calisaya bark that, he would recommend its being abandoned as an article of the official materia medica. As a further reason for taking such a step, he refers to the geographical as well as the political situation of the frontier lands of Bolivia and Peru where the cinchona calisaya is indigenous. The high table-land surrounding the Titicaca Lake is very difficult of access, very insufficiently connected with the rather defective ports of the Pacific Coast Islay, Arica, or, if the territory in question be somewhat further extended, even Iquique and Cobija. Occasional violent floods and earthquakes also combine to render the development of these localities very questionable, and the present unsettled state of the country is a further reason why the pharmacist should not rely upon such an uncertain source for the supply of such an important drug as cinchona bark.

The same remarks are applied to the bark known as Loxa or Huanuco bark, and even somewhat more forcibly. Though perhaps it may be hoped that at some future time the Chilians may improve the condition of the southernmost cinchona district adjoining the ports of Cobija and Iquique, there is now little propect of rapid economical advance in the central district of Peru surrounding Huanuco. If the Peruvians have not hitherto seen the desirability of making a sensible use of their cinchona wealth, it is not likely they will now be able to undertake the cultivation and planting of trees as a business, and it may be feared that impending revolutions will scarcely leave the Government of that unfortunate country time or means of opening up the interior for trade.

As to red bark, it is urged that the district where the *Cinchona succirubra* is indigenous in South America is so limited as to account for the very scanty supply of this bark and also for the high price it commands. Whether bark of the same character may not eventually be obtained at a cheaper rate from India is a question that must be left for the future to solve, but for the present there can be no hope of obtaining thick stem bark, such as is ordered by the German Pharmacopœia. Such bark is not often to be had at all, and its intrinsic value seldom corresponds to its price.

In Bolivia and that part of Peru within the valley of the Amazon cinchonas are probably abundant, as indicated by Ledger's discovery of the very valuable tree named after him; but those sources of supply will become accessible only when the numerous rivers of that immense region shall have been opened up for regular traffic. The possibility of exporting cinchona bark of excellent quality from that locality has already been practically demonstrated, but it will probably be a long time before there be any trustworthy means of communication.

Beyond these sources of South American cinchona bark there is the northern part of the cinchona region in Columbia and Venezuela, to which belong the *C. lancifolia* and *C. pitayensis*. The south western section of this district is partially connected with the Atlantic Ocean by the rivers Cauca and Magdalena and this part of South America undoubtedly still yields the greater portion of the cinchona bark of commerce. At the ports of Carthagena and Savanilla especially, as well as those of Maracaibo, Puerto Cabello and La Guaira, are very considerable harbours, which are connected with the Atlantic Ocean by the Carribean Sea, and for the shipment of bark they have an obvious advantage over those situated on the Pacific. The objection raised by Professor Flückiger to taking the bark supplied from this district for pharmacopœia purposes is based upon the difficulty he thinks there would be in making a selection from among the various kinds differing very considerably in their appearance and in the amounts of alkaloids, etc. For the preparation of quinine, mere differences of character are of less importance, provided that the amount of alkaloid be sufficient; but in selecting a variety of cinchona bark for the Pharmacopœa, it is, in Professor Flückiger's opinion, at least necessary to put prominently forward a specific kind of bark, even if it be not exclusively ordered. If the bark thus adopted, is to be moderately uniform in outward appearance he thinks it is scarcely possible to look for it from Columbia or Venezuela, while at the same time he thinks there is much reason for giving preference to a branch bark rather than a stem bark. The latter is always proportionally more costly, since it is better to work in the quinine factory.

After thus surveying the native habitat of the cinchonas from the Central Cordilleras to the northernmost extremities of the mountain range without finding any part of it whence cinchona bark is to be obtained to suit the requirements of the Pharmacopœia, Professor Fluckiger points to the cinchonas cultivated in India as presenting the most advantageous opportunity for the selection of an official bark for the Pharmacopœia.

As regards the amount of alkaloid in Indian grown bark, experience has shown that it is increased by cultivation and though all Indian grown cinchona bark may not be equally rich, that is also the case with the bark growing wild in South America. As time progresses it may be expected that the systematic culture of cinchona trees in India and Java will have led to a knowledge of the most favourable conditions for securing the largest and most uniform produce. It is now beyond question that India furnishes excellent cinchona bark and it only remains to inquire

whether that country can be relied upon for yielding enough of it. At present the supply from India may be taken as amounting to about one-tenth part of the entire production from all countries, although it was only in 1867 that the first India cinchona bark made its appearance in the Loudon market. Professor Flückiger thinks, therefore, that it is only a question of time when South America shall be equalled in this respect by India and other colonies and that the latter may even become the chief source of supply.

Following up the question as to the kind of bark to be selected from among those grown in India, Professor Flückiger does not approve of deciding altogether from the amount of alkaloid. He holds that if the physician desires to have recourse to the curative action of the alkaloids it is best to employ them in a pure state, and to employ cinchona bark or some one of its pharmaceutical preparations, chiefly in cases where the accessory influence of other of its constituents is desired. From this point of view it is admissible to dispense altogether with bark, which like good flat calisaya, is of value chiefly on account of the quinine it contains.

In selecting from among the branch bark of various kinds of cinchona there is some difficulty, but taking all things into account Professor Flückiger inclines to that of *C. succirubra* as being most suitable to adopt as official for pharmacentical purposes; but in order to provide against any possible future experience contrary to that we now possess, he would not entirely exclude other kinds of bark provided they contain a sufficient amount of alkaloid.

INDIA-RUBBER PLANTS.

London, 6th May 1881.

DEAR SIR,—I have received another lot by post of *Tabernaemontana* seed, and it was eagerly purchased here by Ceylon men, who see that it is a great advantage to get the seed of new trees rather than have to pay 10s for plants and wardian case and the freight and expenses.

As I found that after Brazil, the west coast of Africa sent the next largest quantity of rubber to this market, you will admit I was warranted in searching out for these trees that yielded this supply. I have still about four unnamed. Professor Oliver of Kew worked out the details of this? *Tabernaemontana crassa* from the specimens I sent him.—Yours faithfully, THOS. CHRISTY.

A LONDON AGENCY FOR CEYLON TEA.

Strathellie, Nawalapitiya, 25th May 1881.

DEAR SIR,—Mr. W. Turing Mackenzie's suggestion of a London tea agency for Ceylon should not be allowed to fall to the ground. I should propose that a meeting of those interested in tea should be held in Colombo to discuss the matter. If any gentlemen in the mercantile community could find out for us the best way of proceeding, or the probable cost of establishing an agency, I will undertake to do what I can towards getting the promise of a lot of tea, and I think I am safe in saying that if there is a prospect of getting a good sale for it I could get contributions of from 10,000 lb. to 20,000 lb. of tea to help to start the thing. Money would be required too, and I dare say many who have only a little tea at present and expect to have a good deal more would give a money subscription. Of course, no one supposes this tea will be given away, but those who contribute it must take their chance of a good or indifferent sale, and I for one, from experience gained by sending tea home, am certain we shall have no difficulty in selling our tea, if it is only properly advertised.

The pruning season is now at hand, and I suppose much tea will not be made for some little time, but in the meantime let those interested think the matter over, and let us have a meeting in Colombo, say in August. Race week is generally a good time for getting men together there. If I can be of any use in collecting promises of chests of tea or promises of money I shall be glad to hear from those inclined to contribute either.—Yours faithfully, P. R. SHAND.

"LEDGERIANA" CULTIVATION UNDER THE SHADOW OF ADAM'S PEAK

MASKELIYA BEATING JAVA!

St. Andrews, Maskeliya, 23rd May 1881.

DEAR SIR,—In your preface to Mr. Moens' Report on the Java Government Cinchona Gardens, you add the weight of editorial opinion in corroboration of Mr. Moens' disapproval of the young districts as a field for C. Ledgeriana cultivation. Now, bad enough things are said of the young districts without this, and I must ask you to beg the young districts' pardon and heal the wounded feelings of my Ledgeriana trees by retracting this statement. I did not think Mr. Moens had sufficient experience of our climate to form a fair opinion about it; and even granted that our climate is too damp to induce profuse blossoming, that is no reason why the quantity or quality of our *bark* should be condemned. However, I do not think that our climate is too wet to produce a proper amount of blossom, but as the blossom is very slow in coming out, it does get too much rain on the top of it, and in Java such would also seem to be the case. Most of my old trees are covered with bud and blossom, and Mr. Agar tells me that the trees at Mahaniilu, which he obtained from me in 1876, are also in blossom.

My oldest Ledgerianas will be five years old next month, and are well-grown, robust-looking trees, and many of them would give almost as much bark as a succirubra tree of the same age; for, though the stem may be smaller, the bark is far thicker. I measured four of the best to-day, growing side by side. They averaged 16 feet in height, and stem $13\frac{3}{4}$ inches, in circumference a foot from the ground. Now to compare Ceylon with Java, Mr. Moens says that it takes four of his four year old Ledgerianas to give one kilogram of dry bark, *i.e.*, *each tree gives just nine ounces*. This statement is not very clear, and I can hardly believe it to mean that if a tree were cut down *all* the bark would only weigh nine ounces. Perhaps it means that nine ounces can be taken from a living tree without killing it. I unfortunately have no four year old trees, but I am perfectly certain that at four years my trees would have averaged more than twice nine ounces, and one tree (one of the best) broken across by the wind last year (when it was four years) gave almost three lb. of dry bark, exclusive of the stump and root.

Mr. Moens' interesting figures about his fifty Ledgerianas, two years old, led me to compare mine.

To-day I most carefully measured 52 trees beginning at the first tree of the first line, passing over only two, one with a double stem, and one that had been broken across; the other 50 were a fair average and included two small supplies. If my calculations of the Java metre* is correct the Java and Ceylon figures are:—

	Fifty Java 2 years old Ledgerianas.	Fifty St. Andrews $22\frac{1}{2}$ months old Ledgerianas.
Average height ...	... 57	65 inches.
,, stem circumference 4 inches from ground ...	3·937	3·965 ,,
,, across branches ..	39·37	38· ,,
Maximum height ...	.. 74·80	84· ,,
,, stem circumference ..	5·51	5·5 ,,
,, cross branches ..	55·12	48· ,,

* Mr. Moens' metre is, of course, the French one of 1·093638 yard.—ED.

Mr. Moens describes his measurements as being from two year old trees in a "flourishing garden at Tjibeureum"; mine are from trees planted out on 5th July 1879 amongst coffee. So, taking all these circumstances into consideration, the Ceylon figures are so much better than the Java ones that I cannot help thinking that Mr. Moens dates his four or two years from the day the seedlings are pricked out, and not as we do in Ceylon from the day the plant is put out in the open. If Mr. Moens continues to record the growth of his 50 trees, I will be much interested to continue the comparison.

My old trees are planted at an elevation of about 4,000 feet. The 50 recorded above are growing on steep land, with deep gritty soil at an elevation of about 4,250 feet. I believe that the non-clayey slopes of the hills in the centre valleys of Dimbula, Dikoya and Maskeliya will grow Ledgeriana perfectly, and that with a sheltered eastern aspect, it will do well up to 5,000 feet, although I would prefer 3,500 or so.

I send you a small bit of bark from one of my old trees; in similar bark I have *seen* the alkaloids and it gave an analysis of 4·79 sulphate quinine at four years of age—probably the richest Ceylon bark, of its age, upon record. If you break the piece of bark, examine the fracture under a microscope, I dare say you will see the particles.

I see that Mr. Moens, as well as Dr. Trimen, remarks upon the difficulty of getting "cuttings" to strike. I hardly know what the technical meaning of a "cutting" is. Does it include *suckers* from the stem of the tree? I have no difficulty whatever in getting suckers to strike, but with the ends of branches it is very different, and only two or three per cent root.—Yours truly,

THOS. NORTH CHRISTIE.

TEA.—Letters from Darjeeling say that they are having an exceptionally hot and dry season, though it opened very promisingly, indeed, with fine soft weather. The latest estimates from this district do not place the crop of 1881 as larger than that of 1880; but labor is reported to be very plentiful, and this, coupled with the rising prices at home, many make a better season than was anticipated.—*Indian paper.*

JAMAICA planters have been reoiced to learn that something is at last to be done towards the improvement of railway communication in the island. The Crown Agents for the Colonies are now advertising for tenders for the construction of works described as follows: 1. a railway beginning at the Old Harbour Terminus of the Jamaica Government Railway and terminating at Porus, the total length being 24 miles, 1 furlong, 7 chains, or thereabouts; 2. a railway beginning at the Angel's Branch Terminus of the Jamaica Government Railway and terminating at Ewarton, the total length being 14 miles, 2 furlongs, 3 chains or thereabouts.—*Colonial Register.*

PRESERVATION OF EGGS.—I give a few recipes, and will feel thankful for satisfactory results. The former I have tried from the months of June to February; the eggs kept fresh for ahout three weeks:—

1.—Place the eggs on their smallest end on a perforated wooden rack.

2.—Oil of linseed or poppies, it is said, will keep the eggs fresh for two years (?)

3.—Solution of gum arabic applied to the shells. *Result*:—One year fresh (?)

4.—Unslaked lime, 14 lb.; table salt, 4oz.; cream of tartar, bitartrate of potash, 1oz. each; and water sufficient to form a solution to float an egg. This is Jayne's liquid reduced, I believe. Have any of these recipes been tried? The last, it is said, will keep a year.—*Asiatic.*

CEYLON AT THE MELBOURNE EXHIBITION.

FRUIT AS AN ARTICLE OF FOOD.

Mr. Buck, before his departure for India with Mr. Inglis, came to the conclusion that amongst the millions of India, especially Northern India, Australian fruit would be acceptable and in demand as an article of food. Hence the article which you will see in the *Argus* of 28th April. Mr. Moody told me of the intended trial shipment for India of apples, and asked me about a similar shipment to Ceylon. I could not honestly hold out the prospect of any very large demand in our colony, but I am not sorry to learn that a shipment of Tasmanian apples was made by last steamer. Had I known the fruit was positively going, I should have written about it. Knowing that apples from Australia are pretty frequently in our markets, I did not care to send any on my own account, but I asked Messrs. Law, Somner & Co. of this city to forward 20 to 30lb. of grapes through their agents at Adelaide, Mr. Withers of the P. & O. Company having kindly consented to allow the box go in the ice-room. I fear there has been some hitch, as Messrs. Law, Somner & Co.'s agents have never responded to their request. Non-resinous sawdust is the substance usually employed for packing grapes, but I saw an account of a very successful shipment to England in cork-dust. If this could be obtained, it would, no doubt, be preferable, but with special arrangements for carriage, quick voyages and cheap freight (which are all close at hand), I quite feel that India and Ceylon could take and would be immensely benefited in taking large quantities of the delicious grapes grown so profusely in these lands. Apart from "the grape cure," what nicer or more nutritious lunch could any man partake of than a couple of Swallow & Ariell's Australian biscuits and a bunch of Australian grapes? What renders a trade in fruit precarious and fruit consequently expensive is the liability of fruit to spoil. But by attention to mode and period of plucking, careful packing and quick transit in cool chambers, fruit could certainly be carried to India and Ceylon as well as to England in good condition. Mr. Inglis, who long resided in India, has made certain calculations of cost, profit, &c., which Australians do not regard as very encouraging, considering the rather high cost of fruit in Melbourne itself,—this as regards apples. But from Tasmania, South Australia and Queensland any quantity of fruit could be sent to a farely profitable market. The Curator of the Horticaltural Gardens here, having called at the Ceylon Court and offered to supply fruit or seeds, I visited the gardens a few days ago, and was much interested in what Mr. Neillson shewed me and told about apples, pears, peaches, cherries, "persimmons" (a Japan fruit) &c. The many hundreds of varieties represented surprised me, and I was specially intercsted in trees dwarfed by a species of double grafting. The stock is the "paradise" apple, and on the first graft a second graft is put. The result is that trees about the size of coffee bushes grow 4 dozens each per annum of very fine apples. It strikes me that some of these dwarf planted in tubs might bear good fruit even in Ceylon I remember Sir John Cheap bringing to the *Observer* office some fine apples produced in Deltota, on small three year old trees grown in tubs. Mr. Neillson will make up boxes of choice apples for Ceylon when I advise him, and is ready to give plants of vines, figs, persimmons, &c., I hope to arrange about this. Of peaches a good many remain in these garden, although a species of "blight" (aphis, I believe) has within the past few years, threatened to annihilate this fine fruit in Victoria. The American blight has also affected apples, and a moth has been very bad with 'black spot" on the leaves and fruits of pear trees.

While there are portions of Australia where wheat cannot be grown in consequence of rust, it is reassuring to learn that a grub, which some years back threatened to put an end to cabbage culture, has entirely disappeared. Mr. Neillson finds that the best remedies for the insect blight are superphosphates applied to the roots of the trees, and the form of carbolic acid called phenyle* syringed on the foliage. The acid, if applied so strong as to be likely to injure the foliage, is washed off after a few minutes by the application of water. But I must reserve for notice on a future occasion a series of the Garden Reports from 1872 to 1880, courteously furnished to me by Mr. Neillson. Insect pests are occasionally as common and as mischievous in Australia a are the cockchafer beetles and their grubs in Ceylon. Mr. Wallis of the Agricultural Department has kindly complied with a request from me by presenting me with two sets of lithographed and coloured sheets (one for the Ceylon Government, the other for myself) of the poisonous snakes and of the insectivorous birds of Victoria. Before I had seen the sheet of 36 birds, I had been struck with the habits of a tame "Australian magpie" at the abode of Mr. Ferguson, of the Mount Macedon State nurseries. A large horsefly on my clothes was instantly snapped up by the bird, as were all insects within his purview. The so-called "magpie" would, I believe, be a great acquisition in Ceylon, not only as a preyer on chafers and grubs but for the sake of his sweet, pathetic notes, a combination of the dove and thrush. Less remarkable but far more prevalent than the "laughing jackass" with his cacchinatory shouts—*theirs* rather, for male and female kingfishers respond—are the "magpies" and their notes. If we laugh with the "laughing jackass' we listen with surprise and delight to music from magpies. I am contemplating taking or sending a few pairs to Ceylon. The "magpie" is the largest considerably of the birds figured as insectivorous and is thus described :—

"WHITE-BACKED CROW-SHRIKE, OR MAGPIE (*Gymnorhina leuconota*). LOCALITY : Generally distributed over Victoria. FOOD : locusts, grubs and larvæ of various kinds."

Next in value appears to be "HARMONIOUS SHRIKE-THRUSH (*Colluricincla harmonia*). LOCALITY : all over Victoria. FOOD : beetles, caterpillars and insects." This second shrike seems to be also a song-bird as well as a devourer of insects (as all the shrikes are), but the superior size of the "magpie" renders him the more desirable bird for a trial. He is nearly as large as a crow, and in captivity whistles tunes beautifully. The magpies ought to feel at home on the gum trees now so common on estates in Ceylon and which I have seen loaded with cockchafers on warm evenings.

INDIA-RUBBER FROM INDIGENOUS TREES.—A merchant brought us a branch and a box of seed the other day, taken from a tree which had yielded an abundant supply of milky juice likely to be of value when prepared as India-rubber. "W. F." writes :—"The branch you sent me is well known to me by its Sinhalese name Kiripælla, and is the Ficus infectoria. See what I say about it in Mendis' list No. 45:—'Kiripælla, Ficus infectoria, Willd. Urostigma do. Miq. Thw. En. p. 265. C. P. 3.083. The bark of this tree is used by the natives for chewing with betel, but the timber of this tree and of most of the other species of Ficus are scarcely ever used for any valuable purpose. They are all nearly worthless.' All the figs and we have about 23 species in Ceylon, are natives, but is the rubber from them worth the expense of collection?" That is just the point which only a practical test can settle : our mercantile friend is right in trying the experiment.

* Little's soluble phenyle.

CEYLON COCOA IN GREAT REQUEST.

COCOA.—The market at public sale this week was strong, Trinidad selling at full rates, Grenada at 2s to 3s advance. Since the auctions there has been business of some importance transacted privately, the market being reported firmer. A little lot of Ceylon cocoa 12 bags Palli, sold at the enormous price of 115s 6d. As regards the sample, it was much the same as those to hand previously, if anything we think the beans were rather smaller. Ceylon cocoa is very much liked, and appears to be very well cured, and remarkably free from moisture, so that the loss in weight is almost *nil*. As we have, however, pointed out before, these sales of little lots at high prices must not be taken as absolute proof of the real value of Ceylon cocoa in quantity. In this particular instance we happen to know that two brokers had orders for it without limits, so that the price was driven up considerably. When the supply of any article is large, such orders are rarely, if ever, given :—

THE TEA SEASON IN CHINA.

HOW THE BIG TEA COUNTRY REGARDS ITS YOUNG RIVALS.

The mail steamers are bringing out the usual flock of tea-buyers, who will soon be off to Hankow to inaugurate the 1881-82 campaign, and before it opens we may be pardoned a few remarks on the season now departing. It was not a profitable one; in fact, it is only about once in ten years that tea merchants own to having had a successful season, and still outsiders wonder how it is that the same number of buyers can come out each year, the same rush to ship take place in Hankow, if every year except the tenth comes with disaster in its train. There is a well-spring of hope in the teaman's breast that never fails. However despondent he may pretend to be to his fellows and the general public, in the sanctity of his own tea-room his cares fall off, and he makes a victim of himself once more as if every tea-master concealed a trust-worthy guarantee of profit.

It is not so many years, in fact the time is within the memory of many of those who will be in Hankow next month, when China was the only tea-producing country. It was sufficient then for the buyer to watch the deliveries at Home and the export from China, to be guided, with little chance of error, in his operations. But the fatal energy of our race has reared up in British India a frightful rival to the Flowery Land, and India not only demoralises China by sending opium here, but demoralises our tea markets by sending tea in increasingly enormous quantities to London. There are no squeezing mandarins in India; there is European supervision in the packing and firing of the leaf, and the plantations are connected with civilisation by the railway and the telegraph. Everything is done to give India an unfair advantage over China. Consequently Indian tea of the same quality is far cheaper in London than the ill-regulated produce of Hankow and Foochow, and it is only the conservatism of the consumer, who is not yet entirely habituated to the Indian flavour, that prevents our losses being much heavier than they are. Every year this preference for the leaf that has been longer known is wearing away, and our buyers will soon have to reckon with its disappearance. As yet, Indian tea is hardly taken on the Continent of Europe at all: but here too it will penetrate sooner

or later, as it is doing into America and Australia: and then there will be no corner of the earth where the sway of China tea will be undisputed. Java is competing too, and Ceylon is threatening: even the much-vaunted Johore is supposed to be seriously considering the policy of exchanging for tea its rising plantations of coffee.

To believe the warning voices heard from Home, the new season is not opening auspiciously. England has not yet recovered from the recent depression, and cheapness is the watch-word of the dealer and the consumer. Notwithstanding a general lowness of prices, consumption at Home last year did not show the normal rate of increase in tea generally, but rather a fair increase in Indian and a heavy deficiency in China tea. The consumption in England in 1880, as we gather from the London annual tea circulars, was two-and-a-half million pounds less than in 1879; and as the consumption of Indian tea was eight millions larger in 1880 than in the previous year, the actual consumption of China tea showed an unexpected falling off of ten millions and a half. This deficiency was largely remedied by an increase in the export from London to the continent of eight millions, an increase as welcome as it was unhoped-for; but if it had not occurred, the collapse in China tea would have been frightful. This should give a serious warning to the sanguine buyers who are calculating the credits they are about to exhaust in Hankow; whether its lesson is appreciated, the next two months will show. There is little chance of the curtailment of the supply of Indian tea. Even at the low prices at which it was sold in London this last season, it gave profits to all but the oldest and most expensive gardens, and until foreigners can supervise the packing of the leaf in China as they do in India, the produce of the latter country will continue to have an unfair advantage. The time no doubt will come when we shall be able to go up and buy the raw leaf on its native hills, pack it by our own methods, and bring it down by railway to Shanghai for shipment; but for years yet we labour under the disadvantage of having to buy it just as the Chinamen choose to prepare it, without any real knowledge of the total crop at any time, or any immediate power to manipulate the teas to suit the tastes of consumers.

The most remarkable feature of the season now closing is the enormous increase in the export from all China and Japan to foreign countries. In 1868-69 the total export from all China and Japan to all foreign countries was about 205,000,000 pounds; eleven years afterwards, in 1879-80, it was nearly 245,000,000 pounds, the increase in eleven years being forty millions, half of this increase being in Japan tea. This shows a wonderful expansion, considering that in those same eleven years, Indian tea assumed enormous proportions. But this last year has seen an increase as large as in the whole previous eleven years. The total export last year was 285,000,000 pounds, or forty millions above that of the previous season. Japan is only responsible for five millions of this increase, the export of China tea alone being 35,000,000 pounds above that of the season ending in 1880. Half of this increase went to London: America, Australia, and the Continent divided among them the other half. It is easy to understand the present depression of the London market, and to appreciate with what caution buyers should approach the campaign now opening.—*North China Herald.*

FIJI.

(*From a Correspondent.*)

The planters are chiefly interested in growing sugarcane, coffee, and cotton. The spontaneous product of the cocoanut-tree is also turned to lucrative account. There are some other industries of minor importance. The sugarcane (Vico, if it is the true cane) is an indigenous plant and attains to a height of from 20 to 30 feet. But the best kinds of foreign cane have been introduced, and are seen on the plantations, which are not a tangled mass of cane, as in India, but are carefully and systematically-planted-fields. The plan adopted is on this wise: pieces with five eyes or points are laid (two inches under ground) end on in parallel rows, about five feet being left between the ends and the rows so that a cart can be taken down in any direction: thus during the growing process, the canes get light and ventilation, and can be readily watched and tended. The average yield is 35 tons the acre. Crushing power is at present very limited, but the advantage to be gained by the erection of modern machinery on a large scale has been seen by the wealthy and important Australian Sugar Refining Company, which is now putting up extensive works on one of the most promising cane-growing islands, Viti Levu. But there is plenty of room elsewhere for similar enterprise, with equally good prospects. The crushing now takes place all the year round; it is a bad system, but the want of mills with adequate crushing power necessitates the commencement of cutting before maturity, and the leaving a large part of the crop to over-ripen for months. The result is that the density of the juice from one crop is very uneven, and is seldom taken at its highest. Still, with all its drawbacks, the industry is a paying one, and will in time be highly remunerative to both planters and mill-owners. The exportation of sugar rose from £3,417 in 1875 to £26,687 in 1879; the land under cane cultivation being now about 2,000 acres. Coffee is being successfully cultivated, but it is only within the last three or four years that it has attracted the serious attention of the planters, and already they have had to contend with disease, necessitating the destruction of at least one plantation. The crop, picked in 1880, yielded from 300 to 450 lb the acre, and the berry was of good quality and flavour. The beautiful island of Taviuni takes the lead in coffee, but there are flourishing plantations on other islands, and there seems to be no reason why coffee should not be as successfully cultivated in the Pacific as in Ceylon and in India, and find as good markets. Cotton—Sea-island cotton—has world-wide celebrity; it is easily cultivated in the Fijis, but the production has latterly fallen away, the quotations being too low to tempt the planter. At present there are about 3,000 acres under cotton, but the exports have dwindled from £28,706 in 1875 to £15,690 in 1877. The prices quoted last year were from 2s. to 2s. 6d. per lb., and if those prices could be maintained no doubt a fresh impetus would be given to the industry. The great industry is copra-making, a very simple one, affording a maximum of profit with a minimum of risk, outlay, and trouble. One tree is held to yield 100 nuts a year; 50 trees are planted to the acre, giving about one ton of copra, worth on the plantation £12 10s. But, as a rule, the trees are far too closely planted, especially on the old plantations, and are covered with creepers; so that for want of light and air, they are not nearly so fruitful as they otherwise would be. It is calculated that there are about 10,000 acres under cocoanut, and the value of the copra exported rose in 1878 to £122,194. Besides the copra, the fibre and oil are valuable products; and it is very clear, therefore, that cocoanut-tree planting is a profitable industry in the Fijis. It may be remarked, in passing, that the smell from copra is so disgusting as to make the propinquity of a copra store house, or life on board ship with a freight of it, very trying. Among the minor agricultural or forest products it pays to cultivate or collect for exportation, are ground nuts, of which the annual export is at present about £3,000; arrowroot, some of which is of excellent

quality and fetches in the London market 10*d.* a pound, and the root of the yangóna or kava (*piper methysticum*) so much esteemed by the natives. This plant, the yangóna, is indigenous to the islands; but will only grow under certain conditions, and is used on all ceremonious and festive occasions. It is prepared for use in the presence of the assembly by servants who chew up the root to pulp, which is then mixed up with water in a kava bowl and the liquor after being strained is drunk off. The taste is something like an aromatic, but not very pleasant compound known as Gregory's mixture: the effect is slightly exhilarating if much is drunk; but it affects the legs and not the senses, and the effect soon goes off. It is said to have considerable recuperative powers on the system after any over-exertion. The natives are very fond of it, and many Europeans make a practice of drinking it. The root has found its way into the London market, and is used medicinally. At Levuka, it fetches 2*s.* 6*d.* a pound. Mr. Horne, F.L.S., who visited the islands in 1878, is of opinion that cocoa (*Theobroma cocoa*) would do well there, and that, roughly estimated, there are a hundred square miles on which tea and cinchona could be successfully cultivated. Tobacco certainly answers, and some good leaf and fairly well manufactured and flavoured cigars (quite as good as anything from India) were sent over to the Melbourne Exhibition. Tapioca, ginger, pepper, and spices of all sorts, camphor and vanilla would also be a success in the hands of persons acquainted with the cultivation and manufacture of tropical produce. It will be seen that in the Fijis there, is ample scope for fortune-making but there as elsewhere, money is necessary.—*Pioneer.*

"DATE COFFEE," CUSTOMS DUTY, AND THE ACTION OF THE BRITISH GOVERNMENT.

A Ceylon merchant, now at home, writes to us by this mail:—"Kent, 4th May.—With reference to the compound called Date Coffee, which is now being forced into notice by dint of hard advertising, and the description printed on the labels that it is a mixture of 'Date Coffee' mixed with a portion of best coffee, much has been said about the iniquity of calling burnt date powder Date Coffee, but it does not seem to be generally known that the fraud is in a manner countenanced by the English Government, in admitting the importation of date powder, before it is mixed with coffee, on payment of 2d a lb., the duty to which genuine coffee is liable.

"I gather that this is the case from what was stated at one of the meetings of the Company, on which occasion the exremely plausible chairman said, that an eminent firm of Mincing Lane had undertaken to buy all the powder landed by the Company, at 5d per lb., and that the firm would have to pay 2d per lb. import duty, which would make the cost 7d per lb. Be it remembered that this is the pure date powder before it is mixed with the fourth part of coffee. The Government, for some reason of its own, would not allow the mixture to be effected out of the United Kingdom.

"Now, it may be asked what on earth is the meaning of paying 2d per lb. on dates when the customs tariff does not exact such a duty on that fruit? Simply, I imagine, to make the public believe that the powder is a kind of coffee. Does the Government impose a duty of 2d to protect growers of coffee, or to help in swelling the revenue? Of course, such a tax would not amount to much, but 'every little helps,' and Mr. Gladstone's great aim seems to be to have a surplus revenue. It does seem extraordinary that an article is allowed to be imported into England under a fictitious name, and that a duty is collected upon it, as if it was the genuine article.

"The imposition of the duty is, perhaps, some protection to coffee planters, but it seems nevertheless a singular proceeding on the part of the English Government.

"Any other vile imitations of other articles of commerce might be introduced in the same way, under the high sanction of the crown, for the delectation of a gullible public."

[Not a day should be lost in protesting against this official scandal and we are glad to think that our planters and merchants are preparing to memorialize.—ED.]

COFFEE AND SILK.

(*Straits Times*, May 19.)

The authorities in Acheen have taken in hand the encouragement of Silk culture and coffee cultivation, with results thus officially set forth in the *Daily Times*.

"The controller stationed in the XXII Mukims reports that silk worms recently procured from Japan through the Consul General for the Netherlands in the Straits Settlements, had been received with great satisfaction, and that in all respects they had proved a success in the Mukims styled Sibrew, Baid and Indrapuri, and Lamgarung. Two parcels of cocoons had been sent by this official to the Assistant Resident of Acheen Proper. With these, experiments were being made in the IV. Mukims. The interest taken by the people in silk culture is very great. Persons from elsewhere are continually coming to the campongs where the experimental culture is carried on, to ask for cocoons. Probably, ere long, these will be supplied to applicants on a larger scale. These Japanese silk worms have thriven wherever tried in almost every instance. The number of white ones was relatively the smallest. At Campong Riki in Indrapuri where, after distribution of cocoons to neighbouring campongs for the extension of the culture, a quantity of them remained, silk was reeled off from these cocoons which proved far superior in fineness to the Achibese product. The Government intends to pay unremittiug attention to silk culture in order to enable to flourish anew this branch of productive native industry which of late years had been falling off in Acheen Proper."

"The reports received concerning the Liberian coffee planted here and there in Acheen Proper, are generally speaking very satisfactory. In this culture too great interest from the first has been taken by the people. As the soil and climate of Acheen Proper seem to be eminently suitable for the cultivation of Liberia coffee, it may be expected that it will succeed very well here. and as hedge and village coffee, become a source of wealth to the people. The necessary measures have been taken to forward one thousand Liberian coffee beans of good quality to Acheen."

"The method of drying coffee invented by Mr. Van Mannen has of late undergone considerable improvements, so that, at a temperature of only 60° C. and in 20 hours' time, coffee can be wholly dried by this process. Shortly, we understand a commission of experts will repair to the Kredjo estate to inquire thoroughly into the value of the process. One official will be one of the commission."

A FREE TRADE UNION BETWEEN ENGLAND AND THE COLONIES.

The Conference of Delegates, convened by the Dominion Board of Trade of Canada from the various Colonies and Chambers of Commerce, to consider the subject of Inter-Colonial Trade Tariffs, has held several meetings, at which the following Resolutions were unanimously passed:—

"That in the opinion of this Conference it is a matter of the utmost importance for the promotion of the Commercial interests of the British Empire,

and preservation of its unity and integrity, to draw closer the trade relations between its various component territories."

"That, considering the increasing importance of the Colonial Trade of Great Britain, and that her colonies are without direct representation in the Imperial Parliament, and, considering, also, that Commercial Treaties with Foreign Countries, whereby Colonial interests are deeply affected are entered upon by the Mother Country without adequate consultation with the Colonies, this Conference is of opinion that in all matters of Imperial or International Treaties, where Colonial interests are directly or indirectly involved, an endeavour should be made to ascertain the views of the Colonies, and that proper weight be attached to their opinions."

"That it is desirable to form an Association, whose Head Office shall be in London, to be called the Britain and Colonial Union for the consideration and furtherance of Inter-Colonial Trade and Trade between the Colonies and Great Britain."

"That it is desirable that the powers and numbers of the present Royal Commission for the Defence of British Possessions and Commerce abroad should be enlarged or that another Royal Commission should be appointed with the view to taking evidence on the subject of the Trade and Commercial Tariffs existing and in force between Great Britain and Her Colonies and Dependencies; and that this Conference do appoint a Deputation to wait upon the Right Honourable the Earl of Kimberley, Her Majesty's Principal Secretary of State for the Colonies, and the Right Honourable the Marquis of Hartington, Her Majesty's Principal Secretary of State for India, to urge the consideration of this matter upon Her Majesty's Government."

"That, considering the vast and increasing importance of the trade between Great Britain and her Colonies and Dependencies, and that no department of the Executive Government exists, which is specially charged with the consideration of the relations under which such trade is carried on, this Committee would record its opinion that it is highly desirable that those functions of the Executive Government of Great Britain which especially relate to Commerce and Agriculture should be administered by a distinct department, under a Principal Secretary of State, who should be a member of the Cabinet."

The association, under the title of the British and Inter-Colonial Trade Tariff Union, has consequently been founded. the members of the conference itself enrolling themselves as members.—*Colonies and India.*

TEA FROM AN EX-DEALER'S POINT OF VIEW.

(*Home and Colonial Mail.*)

The following letter has much that is worth the consideration of both planter and retailer. We think that our friends in India would do well to study the criticism of a not unfriendly outsider as to their work. Looking at the valuable admission the writer makes to teas of Indian growth "possessing everything necessary for the production of a perfect mixture," our planter friends cannot question the *bona fides* of advice coming from such a quarter. We trust the retail grocer will also take the lesson to heart and use Indian teas more fearlessly in future:—

"Sir,—As the output of our Indian tea gardens increases, so the quality seems to decrease in the same ratio. Managers who aim at a 'big crop' seem to lose sight of the fact that hasty or imperfect manipulation reduces the price, and consequently the profit, very considerably. A few 'gardens' yet remain whose managers or proprietors seem to possess sufficient forethought to counteract this evil, and these are amply repaid for their extra trouble. If quantity rather than quality is to be the leading feature of our planters, it will be equally a serious matter for them and for our own trade. As it is, a very large proportion of Indian tea sold on the London market by dealers is 'undesirable,' chiefly on account of the 'washy' and insipid character of the liquor. At present it is left to the few to know how to select and blend Indian tea—if not to sell alone—to aid the necessary strength and quality to the China growths.

"Then again as to 'brokens.' It is an indisputable fact that better value can be obtained in these than in leafy teas, and yet the average grocer, either from a lack of knowledge of their intrinsic value in a mixture or from prejudice, is slow to appreciate them. Of course, it can be urged on the other side that the 'British public' have been trained for many years to use leafy teas, and that it would be unwise to go off at a tangent and use brokens entirely.

"To the Irish, and particularly to the Belfast dealers, must be assigned the post of honour in educating their customers to use blended, broken Indian tea, and we must admit that nowhere can such value be obtained (not even in London) by the public as in Belfast, for this sole reason.

"By far too many English grocers adhere to the old and worn-out method of 'overdosing' with scented, sometimes combining two or three kinds, which accounts for the oft-repeated complaints of 'herbiness.' Everything necessary for the production of a 'perfect mixture' can be obtained in Indian growths, but it requires very careful handling, and only by constant tasting and 'experimental blending' can this result be obtained.

"If grocers as a body would devote more time to this important branch of their business they would be able to get better profits, and at the same time give the public a much better article than at present, for no one who knows tea can travel through many towns in England—whether staying at hotels or with friends—without coming to the conclusion that the decoction usually obtained as tea is scarcely worthy the name.—I am, &c.,

"EX-DEALER.

"London, April 20th."

FARMING.—I see the editor of the *North British Agriculturist*, discoursing last week on farming failures and changes of tenants in the Lothians, gives some startling particulars. He says:—"When we go beyond seven or eight miles of Edinburgh we find failures and changes of tenantry to an almost incredible extent." In a stretch of Lothian country to the west of Edinburgh, not quite twenty miles in extent where twenty-seven holdings are let to tenents, he is informed, "no fewer than twenty-three farmer out of the twenty-seven have become bankrupt during the past nineteen year, sixteen of them having been left penniless. Of those still in possession, nine have lost most of their capital, while the rest are new tenants." What a lamentable record and loss of tenants' capital. If we care to consider for a minute where go these played-out farmers, we cannot but realize that the rotten systems of land tenure are ruining the best blood of the nation. If we reflect on the intense love of country Scotchmen in general possess, and the effects of the association of a life-time with a particular part, we cannot but be moved at the thought of the future of these old farmers. Love of country! Recal Walter Scott's return to Abbotsford from his visit to Italy. It was his love of country that kept his body together and survived the wreck of his grand intellect. The played-out farmer is unfitted for an active town life, nevertheless to a town he drifts, and there buries himself from old acquaintances and mopes life away, subsisting on the scanty income of those members of his family who are able to work, and have not yet been drafted from his side by marriage.—*Aberdeen Cor.*

COFFEE LEAF DISEASE.

We have more than once pointed out the close affinity which subsists between the fungus which is known as "the potato disease" and *Hemileia vastatrix*, the great enemy of coffee in these modern days. The history of the one fungus is precisely that of the other, only that the one has existed for forty years, and the other twelve, and that more minds have been directed to the investigation of the older pest than to the later arrival. The scientists, however, agree in the circumstance that up to date no remedy has been found for either, nor—if we take European experience as our guide—can we be sanguine of one being likely to be found in the direction of local applications. The result of Mr. Ward's and Mr. Schrottky's experiments has yet to be seen, and we most certainly wish them all success; but it is uphill work trying to accomplish for a perennial fruit-bearing shrub in the tropics, afflicted with fungus what all the science of the West has been unable to accomplish in reference to so important a vegetable, and annual, as the potato. One fact stands forth in the history of all blights, so that those who run may read. The oïdium, the phylloxera, the potato fungus, the coffee bug, the *Hemileia*, and we suppose the grub, too, have all appeared, spread and multiplied, where large tracks were under one species of plant. If this can be proved to be connected with blight, as an ever-associated fact, it may be fairly assumed to be one of the causes, till it is proved an error. But, at the same time, we cannot forget that blights have appeared, spread far and wide, done immense damage, and then disappeared, as mysteriously as they came. We must therefore conclude, that great breadths of one cultivated plant do not complete the sole cause of blights, some passing condition of the soil, the atmosphere, or the electric currents, may operate to the rapid multiplication of an insect or parasitic fungus; which, combined with the great quantity of food provided for them, may give the whole of the conditions necessary to make a destructive blight. If such conditions do exist, they probably lie too deep for science with its present powers to reach, and if they were discovered, they might finally be found beyond human control. The one warning that the cultivator can in the present avail of with certainty is to mix his species, and, instead of one product, have twenty, if he can find so many that will pay for the ground they occupy. This has indeed of late years been the course our Ceylon planters have taken, and it is to be hoped none of them in the future will plant large unbroken breadths of any one plant; for, let it be remembered by cinchona, tea, Liberian coffee, and cocoa planters that what are known as "new products" are just as liable to blight as coffee, if the conditions are created. The spread of canker in cinchona seems to be a case in point, although we are aware that the most diverse opinions exist on the subject:—some, like Mr. Forbes Laurie, for instance, believing that close continuous planting over a considerable area is a direct inducement to the disease; others, again, that it is all a matter of soil and drainage, the disease being neither infectious nor contagious; while Mr. Morris of Jamaica in his last Report writes in direct support of close planting as producing the healthiest and most thriving plants. Returning however to coffee leaf disease, we have to lay several contributions on the subject before our readers to-day, including (in order to gratify, and, we trust, finally dispose of our correspondent) one from Mr. Oliver Jones, of Dindigul Medical School, who is so determined to hold all the scientific and planting world wrong in regarding the evil wrought on the coffee leaves as the work of a fungus instead of, as he has found to his own satisfaction, an insect. Mr. Jones' letter will be found to afford amusing, if not very instructive reading!

Since writing the foregoing, two letters from planters in Fiji have come to hand, and it will be observed that Mr. Storck adopts a tone of the utmost confidence in reference to his discovery of "a cure" for leaf disease. We shall certainly await with interest this gentleman's further experiments in Fiji, and when he has cleared the group of coffee-bearing islands in the South Pacific of the fungus-pest, Mr. Storck will be most welcome to try his hand in Ceylon, although the rate of £4 per acre even for "a perfect cure" is rather high.

LEAF DISEASE AGAIN: MR. OLIVER JONES' MOTH THEORY.

(*Communicated.*)

It used to be a favourite simile in the good old times, the likening of truth to a rock. Our worthy forefathers meant thereby to indicate that there was something substantial and abiding about it, something that could be handled and held on by, and if you came again and again, it would be found still there immovable and unchangeable.

It would appear, however, that in this rapidly progressive age scientists have come upon new forms of truth, which are as Protean in shape, and unsubstantial in essence, as cloud or gaseous matter.

Witness the history of coffee leaf disease. It seems a long time now since the scientist pronounced the red dust a fungus, and described all its paraphernalia of sporidia mycelia, and all the rest of it, and prescribed sulphur in fumes or otherwise as a poison that would be the death of it. By-and-bye, lime was added to sulphur, to kill it twice dead as it were, so that, turn as it might, the disease found sure death on the one hand and no mercy on the other. It is as unnecessary as it is painful to relate that the disease escaped death notwithstanding.

Then came more scientists and found that there had been some dodging on the part of the mycelia, or something or other, and one of the said learned men began seuding carbolic acid solution or dilution up the bark of the trees to catch and choke every sporidical mycelia dodger of the lot in their "howfs"—in the cells of the leafs and slay them all outright. Next came the vaporizatiou to smother them as they emerged from their hiding-places.

Then science, under the guidance of the learned, detected new phases, and sulphur and lime were again in demand.

Now comes an embodiment of multifarious science from Dindigul, and after following truth with watchful eye as it went through its various evolutions, he has detected that the whole thing is a moth and its belongings, and the sporidia are no fungus at all but mere dirt, and the mycelia only the threads of silk spun by the said creature. And the medicine that is to do for that moth is ready; yclept in apothecary lingo "cocculus indicus and camphor."

This might be all very well, but there are others again who affirm that the sporidia are real fungi, and find their way into the mouth of the moth, instead of "tother way."

Now all this, of course, is very interesting to those who are engaged in the pursuit of science, but what can non-scientific folks like us make of it all? They may all be right, but one is tempted to think that some one of them has got hold of the wrong end of the thing. Yet when they get so little out of the modes of truth (it used to be modes of error in olden times), how can plain unscientific men "make head or tail of it"?

The Dindigul scientist dwells on the advantages of a theory, and a theory has just occurred to me. In

the hope of its being advantageous I give it. Every one in Ceylon must have been struck with those odd imitations of vegetation in animated life shown in the stick insects, the leaf insects, and the flower insects.

There 's no mistaking these, for they show clearly enough to be the work of some mischievous fun-loving imp, playing his fantastic tricks to puzzle Darwinians and Evolutionists generally.

Now have we not got here the same imp of mischief, or there may be more than one of them, practising on our scientists, say on the Dindigul scientist in particular, producing in flesh and blood and its etceteras exact imitations of the fungi sporidia-mycelia, *et hoc genus omne*, down even to their destructiveness on the coffee tree; and all merely to get a "rise" out of a few eager scientists. I do not offer the theory at all to the scientists however. From experience, I know the stores of scorn they have stowed away in their cranial receptacles to be emitted on any one who ventures to promulgate a theory not emanating from their own fermenting noddles.

I lay it with all humility before the unscientific public, glad, if they find it suit them, that they *make what use of it they like*, so that, one way or another, the happy result may be arrived of leaf disease NEVER AGAIN.

MANURE AND THE SETTING OF BLOSSOM.

We learn that, in the case of a very carefully conducted series of observations on an estate in Dikoya, it was found that 60 per cent of the blossoms on manured land had set; while on the unmanured portion of similar land no more than 14 per cent could be reckoned as safe!

INDIA-RUBBER.

The Director of the Botanic Garden, we now hear, has experimented on some of his Ceara rubber trees with satisfactory results both as to quality and quantity of milk. From one tree, it is said, the yield of milk was equal to three ounces of prepared caoutchouc of very superior quality, and this quantity of milk was taken without at all exhausting the available supply. No douht, the Director will he publishing the results of his work very shortly.

LEAF GATHERING AND DESTROYING will never do. At great expense with a large force of lahour you might clear the ground of an estate one day, and the next day find it just as much littered over with diseased leaves. One planter said he saw apparently a regular cloud of spores or dust arise when the coolies were gathering. The fall of leaf lasts for weeks sometimes, so the gathering would have to he almost daily work, or else hy postponing it as some suggest, the greater part of the spores would be left behind. In one place where I saw the hurning going on, I noticed that a great many trees had heen burnt, and that was in their poor coffee too. If science can't he practical let it cease to teach.—*Old Planter*.

PHYLLOXERA AND HEMILEIA.—The Melbourne *Leader* says:—"The best plan for suhjecting vines infected with the phylloxera to the action of sulphide of carhon is that devised hy M. Bourdon. He lays down a system of drains in which an air current is set up. The sulphide is in this way disseminated so thoroughly that the whole suhterranean atmosphere of the vineyard is thoroughly impregnated with the poison, and none of it is wasted. The expense of the drains is considerable, hut the sulphide is economised, and the work is really done. It is certainly cheaper to go to a considerable expense in the thorough accomplishment of a result than to waste half the amount in an abortive attempt." Although the hemileia is a fungus and not an insect like the phylloxera, this treatment might prove efficacious as a remedy for the coffee leaf disease.

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE LEAF DISEASE.

SIR,—I, for one, do not expect that a cure for this pest will he found through any local application. We have heen bidden by our scientific advisers to burn, bury, or disinfect, all matters to which germs are or may be attached, but we should now he aware of the fact that if a coffee plant is constitutionally predisposed to an attack, it will he attacked if there were not an affected leaf within fifty miles. Six years ago, I raised only one Liherian coffee plant from a handful of imported seed, in a part of the island where no coffee was grown; yet, before it was six months old, it got leaf disease, which never left till about six months ago. It has flowered frequently during the last four years, hut not one blossom set till last January, when it threw off the disease altogether, and now promises to give a moderate crop. I have since grown thousands on the same ground, and that was the only one that ever had a spot of disease. I helieve that the germs are in the air, and will inevitably reach the plant that is constitutionally suited to their growth, and that the only way in which a plant can he protected is through improving its tone, by some process to he yet discovered.—Yours truly,

PLANTER.

CURE FOR LEAF DISEASE IN FIJI.

Belmont Plantation, Upper Rewa, Fiji, April 8th, 1881.

SIR,—In your issue of January 20th I just notice, under the heading "Still They Come," a reprint from the *Fiji Times*, in which my name is mentioned as having discovered a "remedy" for coffee leaf disease. Now, although this heading does not contain a positive slight, it implies a doubt, either of my assertion or of the veracity of your contemporary. Luckily, it will not alter the fact of my having succeeded in thoroughly and lastingly curing a considerahle number of coffee trees, both Arahian and Liberian, of Hemileia vastatrix. The treatment was discontinued as long ago as July last, and the trees of hoth species have since grown three times the size, are in full spike (the Liberian) and splendid condition; and though exposed to accidental re-infection from without (this district is full of disease) have up to this day remained entirely free of the pest. The nursery, made on old, infected ground, is entirely free of disease, as are also some self-sown seedlings, which have sprung up in various parts of the area once covered with coffee (some 15 acres) and destroyed hy the Commissioner for Coffee Leaf Disease early in March 1880. Although I am fully aware of the importance of my discovery to many coffee-growing countries, it was and is my amhition to operate in Fiji first, not for the purpose of making further experiments so much, as, firstly, because Fiji is the land of my adoption, and I have some personal interest in it, and, secondly, to gain an insight into certain administrative details connected with the treatment, on a smaller scale, before offering my services to the planters of Ceylon and neighbouring countries for so stupendous a task as those countries would present in the application of my own treatment or any other.

What I have done I have accomplished through the outward application of a well-known factor, which material, so far from being dangerous to the health of the coffee tree, will, after doing duty against the disease, remain on the ground as manure. In my correspondence with the Government of Fiji, I have presented a rather high estimate of cost approaching £4 per acre. This may seem a large figure, but in reality is not so, the actual cost heing represented

by the difference of labor entailed in dusting the trees with what will afterwards remain as manure on the soil, and that of the mere spreading of the substance over the ground. Three months of sharp work will effect the cure for good and for ever, if such a thing is possible in Ceylon.

If I for sometime sbared the mistake as to a filamentous phase of existence of the fungus, why, better men had accepted Mr. Morris' theory; and really there was nothing so very strange in it. The main point remains, which is, that it does not make one iota of difference in my treatment nor the results of it, of which I challenge inspection.

And please be informed that I hereby claim priority before the whole world in what I have accomplished and am ready to do again.—I beg to remain, sir, yours very faithfully, JAMES C. P. STORCK.

Levuka, 9th April 1881.

SIR,—Understanding from Mr. Storck that he has written to you concerning the treatment claimed to have been discovered by him for curing coffee leaf disease, I write to offer my testimony to the fact that in December 1879 I observed the coffee trees on Mr. Storck's estate to be covered with disease. They were all destroyed, except a few, which Mr. Storck informed me he operated upon, and these I saw last December when they were apparently free from disease. I saw them again last Sunday, when they appeared to be in the same state as on my previous visit and particularly vigorous. It is only fair to Mr. Storck that I should say this much.—Your obedient servant,

WM. FILLINGHAM PARR.

P. S.—I think Mr. Storck's estimate of the expense (£4 an acre) to be very greatly in excess of what the actual cost will be for adopting this treatment.

THE COFFEE LEAF FUNGUS (? INSECT).

Dindigul, 12th February 1881.

SIR,—Believing with Hartley that any hypothesis which has so much plausibility as to explain a considerable number of facts helps us to disgest these facts in proper order, to bring new ones to light and make experimenta crucis for future enquiries, I am therefore constrained to follow up my report on coffee leaf disease with a few further remarks, in which it is to be hoped that greater light may be cast on the truth that leaf disease has no connection whatever with the fungus theory as advocated by Mr. D. Morris, late of Ceylon, particularly as the facts now put forth contain personal observations over a period of some 14 months. The conclusions arrived at are not deduced from mere speculative analysis, but from careful observation and tedious manipulations with the microscope. But since none of the great scientific advancements have been established without encountering much opposition, the views promulgated by me, concerning the true cause of coffee leaf disease, have as a natural concomitant provoked adverse criticism.

The following notes, however, will doubtless serve to help the readers of the *Observer* to judge whether my investigations in leaf-disease are based on a mere hypothesis or on some basis of sterling reality.

I note that in the beginning of December 1879 a diseased primary branch of Coffea Arabica was submitted for my examination by a coffee planter in the district. The branch was a beautiful specimen, the different phases of the disease being well developed. The diseased leaves were at once submitted by me to the following examination:—

a. A quantity of rust was carefully scraped off, mixed with water and its reaction taken, while a small quantity was sipped from the vessel containing the solution: it was insipid and leafy.

b. Macerated three of the diseased leaves in a basin of cold spring water for 18 hours and found on examination that the dark brown spots were isolated patches of dead tissue. In pathological language one would be inclined to call them islands of ulceration, in as much as they had no connection with the surrounding healthy tissue. The dark brown spots were quite destitute of cuticle and parenchyma. They were simply the remains of reticulate portions of the leaf.

c. A diseased leaf was placed under the microscope and examined: quantities of flocculent matter and bright masses of granular stuff were seen in abundance. This was done with a lens of low power.

d. Placed a minute quantity of rust on a slide and viewed it with a lens of high power. A magnificent cluster of oval shaped orange cells, forming distinct groups, were made visible. These cells however were quite destitute of nuclei. If we admit that the cells are non-nucleated, but filled with a protoplasmic yolk, still one fails even with high magnifying media to detect fission of the mass or segmentation or cleavage of the protoplasm. In truth I am of opinion that the fibrils of silk and the digested cell-tissue (that constitute the main mass of rust) lie entirely external and have no relation with the internal structure of the leaf. Some of the fibrils may be seen in very close proximity to the tissue surrounding the margin of the brown spots, dipping as it were into their interspaces), so that the entire morbid process has its origin and development from without and not from the intercellular tissue of the coffee leaf.

e. A piece of diseased leaf on which the rust and floss were thickly set was cut out and carefully examined with the microscope. The floss was found to be made up of fibrils of fine silk: can trace no hyphæ or conidia.

f. Placed on glass a small quantity of the floss and moistened with water, and when submitted to an examination shewed no signs of germinating, seemed a little elongated, doubtless due to the fact that the fibres were sollen from the moisture in them: not soluble in acetic acid.

g. Having after repeated examinations failed to discover organs of sexual generation, I had no other alternative left but to believe that the orange oval-shaped cells were not *reproductive sporidia*. Because, unless sexual organs of some kind existed, the vital act of reproduction, either by gamogenesis such as takes place in the potato blight or congregation could not be produced. It is a well established law in physiology, that propagation of spicies, either in the vegetable or animal kingdoms, can only be effected by the union of cell with cell, the elements of the male uniting with those of the female, from which the germ cell is produced, and since it is ordained by a higher power that every *living organism* must be derived from a germ it was but natural for me to conclude that coffee leaf-disease was not due to the growth and development of the fungus *Hemileia vastatrix*, at the expense of the soft cellular tissue of the coffee leaf, but to some other cause, the details of which have already been published in the columns of the *Observer* of the 19th January 1881.

That the larvæ discovered by me do not suck out the spores as advanced by the editor I am confident, for I have frequently, with a low magnifying lens, been able to see that it was the cellular tissue they were feeding on, the movement of the mandibles being lateral, *i. e.* from right to left and *vice versa*. I have also on several occasions been made cognizant of the fact that the excreta cast from the larva was done with a wriggle and dilation of the anal segment; this excreta is identical in color and character to the orange sporanges of Mr. Morris.

In conclusion I can only add, would that the larvæ decrease in number, for with it there shall be a corresponding diminution in the development of coffee leaf disease.—Yours faithfully, OLIVER W. JONES,

Asst. Supt. Med. School, Dindigul.

P. S.—April 21st.—The moths referred to by your planting correspondent from the interior are in my opinion quite distinct from the moth made mention of by me, for I find that the living caterpillars in my possession continue still to exist in their pupal state and shall do so until the end of March, or at a period corresponding with the first blow of the coffee flowering season, when the moths shall escape further confinement, to enjoy their short life among the sweet smelling flowers of the coffee trees. If the planters would carry out my instructions as regards the destruction of all fallen and diseased leaves by burying them, there would be a corresponding diminution in coffee leaf disease next season—but please note that this must be done before the end of the month.

CEYLON AND JAVA LEDGERIANAS.

A Dimbula planter writes:—"Many thanks for the loan of Mr. Moens' report, which I now return. I was most anxious to compare the analysis of his two year old shoots of original Ledgeriana with an analysis Mr. David Howard had kindly made for me of six thirteen month old Ledgerianas from Conon estate. I cut these six trees down and sent home the whole of the stem bark. The best analysis was No VI, viz. 2·1 % sulphate quinine. The average of the whole six was 1·3 %. As Mr. Moens' analysis No 48 is of two year old shoots, of old trees and is only 2·86 % sulphate quinine, I think there is no doubt that Ceylon will be able to grow as good Ledgeriana bark as Java, by analysis, and Mr. Christie has shewn that we can also compete with them in growth."

COFFEE LEAF DISEASE.

Reports received from a number of districts both north and south of Kandy agree in the opinion that a general outburst of leaf disease is once more imminent. As yet the symptoms are not very apparent to the eye of an inexperienced observer, and very probably the coming attack will not be a serious one; but our older planters have now got to know the indications so well that they can tell its approach some time before the disease becomes apparent. As typical illustrations an estate in Matale East and one in Dimbula are brought under our notice: on both the coffee still looks dark green and vigorous, but scarce a leaf can be plucked from the former and held up to the light that does not shew the fungus at work, while of the latter a Visiting Agent relates how, when approaching it some days ago, his eyes caught a peculiar tinge which he has always regarded as indicative of the early appearance of *Hemileia vastatrix*. In these cases the attack seems to be coming on simultaneously all over the plantations. This is contrary to the experience of others who hold that an attack usually commences from a centre, in a single tree or group of trees, and that it is possible, if observed and dealt with properly in time, to confine and even overcome and extirpate such an attack. One old planter declares that, with a limited area in cultivation, he is able to watch over his coffee as a doctor would over a convalescent patient liable to a recurrence of illness, and that he believes he has more than once been successful in fighting leaf disease by dealing forthwith with the trees about to be attacked, covering over the manure applied (whether cattle-manure or bones-and-poonac) with lime and simultaneously coating the trees with wood-ashes. In this way an incipient attack has apparently been circumscribed and dissipated, and fair average crops have been maintained. But this experience has been gained on a limited area, and with comparatively young coffee. In the majority of cases it is impossible to say in what part of the estate an attack commences, and the manuring, liming and covering with wood-ashes would be rather too difficult and costly a process to apply simultaneously over 200 or 300 acres. Much more feasible, if it can be shewn to be equally effective, is Mr. Schrottky's vapourization with carbolic acid and lime. This gentleman has now completed his operations over the several areas in different districts placed under his charge, and he is as full of confidence in the practical value of his process as he was after his first series of experiments. It is too soon probably to judge of the fields recently operated on, but it will be remembered that around Kandy, and more especially in Dumbara, certain coffee was treated in January, and we have been shewn reports from the Managers concerned which testify to the unmistakable benefit derived by the coffee,—in fact, to an almost entire immunity from disease which has been running through the adjacent coffee. The principal condition of success is to fix on the right time for application, just when an attack is coming on, and in mist weather when the application at once takes effect. Mr. Schrottky says he has found in practice that three applications to conquer or ward off an attack are not required:—two being sufficient at an interval of a fortnight and *costing not more than four rupees per acre* for each application. Mr. Schrottky has, in an official letter, called the attention of the Planters' Association to his "Seven Months' Campaign against Leaf Disease" and its results, and as he is shortly leaving the island, we think these results deserve a formal investigation at the hands of this representative body in the interests of all concerned. There will be the more reason for this course, if it be true that the experimenis spoken of favourably by the Government Cryptogamist, at the planters' annual meeting, have since fallen through, proving failures, and that Mr. Marshall Ward is wellnigh hopeless of any practical remedy if it be impossible, as the planters say, to burn or destroy the diseased fallen leaves. If therefore, for the present, there is nothing encouraging in the official outlook, the Committee of the Planters' Association owes it to themselves and their constituents, not to allow Mr. Schrottky to take his departure without putting some, at least, of his experiments to the test of observation and report. The day for the general meeting is close at hand, but Dumbara being so easily reached, it surely would not be impossible for the energetic Chairman to arrange for a visit to the treated coffee in that valley. Mr. Gibbon is closely connected with Dumbara, and if he and Messrs. W. Mackenzie and C. Young accompanied the Chairman and Secretary, their report, embodied by Mr. Philip, could not fail to be received with attention and interest at the meeting to be held next week. Mr. Schrottky would, no doubt, be ready to attend and give explanations (if asked to do so) while the Managers in any case would be available on the spot to answer questions. As the inspection would be an unofficial one, Mr. Wall might be able to induce Dr. Thwaites, as an Honorary Member of the Association, to accompany the party to Pallakelle and Gangapitiya, and to render valuable aid in testing the value of the vaporizing process with carbolic acid and lime.

COCONUT ESTATES IN JAFFNA.—Leaving out of account the small account gardens owned by natives, there are thirty cocanut estates, covering in round figures 10,000 acres. This number does not include "new clearings" which are now on the increase. All the 30 estates were opened up by Europeans. There ate 650 men employed on them in various capacities. The copperah derived from them at each season is reckoned at 3,000 candies bringing R75,000. We hear that two estates owned by Sir J. D. Elphinstone have recently been purchased by Mr. F. Mortimer for R60,000.—*Morning Star*.

GUMS AND RESINS.—Dr. G. Bidie, Superintendent, Government Central Museum, has forwarded to Government a descriptive catalogue of gums and resins, and Colonel Beddome has forwarded a report through the Board of Revenue. The samples collected are to be carefully packed and despatched to the Master Attendant for transmission to England, addressed to the Secretary of State. The thanks of Government have been communicated to Dr. Bidie and Colonel Beddome for the valuable information they have furnished.—*Madras Mail*.

FIBRE-YIELDING PLANTS.

A modest announcement made by the Institute of Jamaica, that it will give two prizes of 20*l.* and 15*l.* respectively, for any essay on the fibre-yielding plants of that island, accompanied by samples of fibre collected there, derives additional importance from a report which reaches us from Mauritius that a gentleman in the latter island has discovered an effectual and simple means—which he anticipates will also solve the difficult problem of extracting the fibre of the rheea or China-grass—of treating the aloe fibre, for which the Colony is famous. In the single industry of paper-making there is a vast field for the consumption of largely-increased quantities of fibre. Attempts have been made from time to time to supplement the existing supplies of paper-making materials, and utilising banana fibre, young bamboo shoots, ramie or China-grass, and other tropical produce; but there is great room for improvement in all that has hitherto been attempted, and in the introduction of new varieties of fibre. And it is not only for paper-making purposes that new fibres are wanted, but for the manufacture of various textile fabrics. As has been pointed out over and over again in these columns, the happy discovery of the value of the fibre produced by a particular species of aloe growing in Mauritius has helped to supply our shipping and our fishermen with ropes and lines almost indestructible in salt water. Carefully conducted experiments, carried on in the countries in which the fibres are grown, are far more likely to be successful than those made in England with material necessarily dry, probably injured, possibly ruined, by the conditions of transit. The Mauritius aloe fibre, prepared in the island from the green plant, is a different product altogether from that manufactured in England from shrivelled specimens; and by encouraging research in this respect our Colonies will be laying the foundation, not merely of new agricultural pursuits, but of new and thriving industries.—*Colonies and India.*

COCONUT CULTIVATION.

More important than any industry we have noticed is coconut cultivation. This occupies a very prominent place and its history is both interesting and instructive. More than half a century has gone by since the opening of the first estate in Jaffna. Of that hardy, enterprising race of planters who cleared jungles and opened up estates in parts infested with wild beasts and seldom frequented by man, there is not one left to tell the story of their trials and reverses or to enjoy the fruits of their toils and labors. Those who bore the heat and toil of the day have disappeared from the scene and already two generations have been numbered with the past. The pioneers of coconut cultivation in the North have been succeeded by men vastly different from them. The most painful circumstance connected with this industry and which has often forced itself on our minds is that under an unwise system of agency leaving the management of estates solely in the hands of indifferent men on the spot, the original proprietors had been induced to part with their properties for a mere song, dissatisfied with the poor returns derived. The scheme, such in truth it was, was cleverly worked and the result was that coconut property was under-valued or fell into disfavor and men who as agents or superintendents condemned the estates ultimately became the owners upon very easy terms. We will not say anything more than that without a single exception all of them have amassed a large fortune and continue to prosper. One gentleman, however, escaped the effects of his policy and retained his property against good and bad report, sometimes leasing it out and sometimes managing it at his own expense. He is Sir J. D. Elphinstone, the Proprietor of Tattovankotty and Waverly estates. Not long ago both were offered only R30,000 but Mr. G. H. Elphinstone in charge, convinced that coconut property was not such a drug in the market in Jaffna sent out an experienced and trustworthy manager in the person of Mr. S. Ramanather to inspect, report upon, and work them. Well has he shewn himself deserving of his noble master's confidence! With a long and varied planting experience, acquired under such Planters as Messrs. Elphinstone, Tytler, Bosanquet, and Leake, with a reputation unsullied even by the breath of scandal and remarkably industrious, he worked them for the last three years, shewing a large profit and fixed their value at R60,000. Under his careful and intelligent management, such improvements were effected that higher offers were sent up. But it was resolved not to sell them for less than R60,000. We have just heard that they have been purchased for this figure by Mr. F. Mortimer. This circumstance redounds not a little to the credit of Mr. Ramanather who has effectually disproved the report set agoing by interested persons that Coconut plantation does not pay in Jaffna. From a study of the facts bearing on the subject, we have arrived at the conclusion that Coconut culture is most profitable.

Our Coconut estates are situated in the District of Pachchellapallai. Leaving out of account the small Coconut gardens owned by natives, there are thirty Coconut estates covering in round figures 10,000 acres. This number does not include "new clearings" which are now on the increase. All the 30 estates were opened up by Europeans. There are 650 men employed on them in various capacities. The copperah derived from them at each season is reckoned by an experienced Planter at 3,000 candies, bringing R75,000 at R25 per candy. Very often, however, as in last year, the price per candy goes so high as R38 or 40. Since January, a decline in the price of copperah has taken place, driving many out of the business. There is not the shadow of a doubt that this business carefully conducted is a very remunerative one.—*Jaffna Patriot.*

TEA TASTING.

It is necessary for a tea-taster to have the three senses—sight, taste, and smell *jointly* exercised, to form a correct judgment; or, can he dispense with any one of them, as for instance sight, add yet arrive at a correct conclusion?

We are of opinion that tea-taster cannot do justice to his profession, unless he possess the three senses above mentioned unimpaired.

In valuing tea for the market, the chief characteristics which a tea-taster looks to, are—

(1) its liquor.
(2) ,, infusion.
(3) ,, leaf.
(4) any distinctive characteristics it may possess.

In deciding as to its intrinsic value, he has to consider the following qualities with regard to—

(*i*) its liquor: whether strong, rasping, pungent, brisk, flavoury, full, thick, malty, dark. or, wanting in strength, dull, insipid, thin, burnt, soft, etc.

(*ii*) its infusion: whether of bright or dull colour; or mixed with green, or any dark or burnt leaves; over or under-fermented, etc.

(*iii*) its leaf: its make and appearance; whether black, wiry, even, regular, good, well twisted, flaky, bold, tippy; or grey, brown, dusty, little or badly open twisted, irregular; wanting in tips, etc.

(*iv*) any distinctive characteristics it may possess: as *e. g.*, its "nose," *i. e.*, the character of its aroma; whether of a strong, rich scent, or musty, burnt, highly fired, dull, etc.

In testing the qualities of a tea, therefore, the mind exercises the following faculties:—

(i) the taste, (ii) the sight, (iii) the sight, (iv) the smell.

Thus the faculty of sight bears an important part in the process of tea-tasting when valuing for the market.

Our correspondent perhaps thinks that by the sense of sight being used, the mind exercises a certain amount of prejudice, either in favour of, or against the tea—according to its make and appearance, before the sense of taste comes into play: in other words, before it is tasted. But this is an erroneous notion, as is well known by any planter of experience. Teas which would be condemned were they to be judged of and valued by their appearance, often fetch the best prices. If the liquor and infusion of a tea are good, its appearance and make will in very few instances tell against it, or lower it in value; if, however, in addition to the above good qualities it possesses a good appearance and make, the fact may increase its intrinsic value considerably. Thus the faculty of sight, though in itself important when placed in comparison with that of taste, holds a subordinate position.

To judge, therefore, of the real merits of a tea, and to enable one to arrive at its intrinsic value, it is essential that the three senses should be used *conjointly* But, in addition, the senses of touch and hearing are also brought into play. A tea-taster as a rule whenever the sample permits, takes up a portion of the tea he is tasting, to *feel* whether it is crisp; and moreover generally puts his hand to his ear, to *hear* whether it crackles when pressure is exerted. By so doing he is enabled to report whether the tea has been efficiently fired or not. A tea-taster, therefore, in order to be an adept at his work, requires the full and unimpaired uses of all his *five* senses. None of the senses can be rightly used by themselves without the aid of the others; each requires the help of the other in action, to enable one to form a true and correct judgment of the merits and value of a tea.—*Indian Tea Gazette.*

USEFUL GARDEN AND PLANTATION RECEIPTS.

(*From the Gardener's Year-Book.*)

ASPHALT WALKS.—1. Take two parts of very dry lime rubbish and one part coal ashes, also very dry, and both sifted fine. In a dry place on a dry day mix them, and leave a hole in the middle of the heap, as bricklayers do when making mortar. Into this pour boiling hot coal tar; mix, and when as stiff as mortar, put it down 3 in thick to form the walk. The ground should be dry and beaten smooth. Sprinkle over it coarse sand; when cold, pass a light roller over it, and in a few days the walk will be solid and waterproof. 2. An old gravel path will only require to be swept clean; a new-made one to be well beaten and rolled. Choose a warm day (the warmer the better); let the tar be boiling hot; use the common, long-handled, iron-bound tar-brush and iron kettle, holding about a gallon, for the purpose of taking only so much tar from the boiler at one time as can be used in about a quarter of an hour, and paint over with a good coat. Let a lad follow with dry sifted sand, throwing over enough to prevent the tar sticking to his feet, and then go over with the roller. Two men tarring will employ a lad to follow with the sand, and another to attend the fire and supply the tar as fast as used. This repeated every three years the surface will become quite hard, and the paths will always be perfectly dry and pleasant to walk upon even in the worst of weather.

TO PREVENT IRON GARDEN TOOLS FROM RUSTING.—If iron garden tools are laid for a few minutes in a solution of soda they will be protected from rusting for a long time, even if exposed continuously to a moist atmosphere.

TO DISSOLVE BONES.—Take a large watertight hogshead, and cover the bottom with about 6in. deep of dry soil; on this put a layer of bones of the same depth, and cover them entirely with wood ashes; on these another layer of bones, then ashes, and so on till the hogshead is full. Leave it exposed to the rains all summer and winter till spring. Then on removing the contents of the hogshead, the bones will crumble to powder under a slight pressure, and form one of the most valuable manures ready for immediate use.

TO REMOVE COARSE WEEDS FROM LAWNS.—Coarse weeds such as plantain, docks, thistles, and dandelion, may be removed from lawns by the application of oil of vitriol. Take an old blacking-bottle with a wire round it to carry it by, and a stick to dip with. The stick should not be pointed, but notched round for an inch or two at the end, the better to hold the liquid. Just one drop quite in the heart of the weed is sufficient to cause death, and the notched stick will contain at one dip enough to destroy three or four plants. If the acid is good (it varies in strength), the work of death can be both seen and heard, for the vitriol hisses, and it burns up the weeds in a moment.

GRAFTING WAX.—Grafting wax is very much used on the Continent for protecting newly-made grafts instead of the clay and horsedroppings formed into a plaster, such as is used in this country. It is also of great service in covering fresh wounds in trees, made either by accident or design, and is a much more cleanly substance, as well as a more neat application, than the ordinary grafting clay. I have here furnished various formulæ for making the grafting wax or mastic, and as I have used them all at various times they may be relied upon to answer the purpose for which they are intended. The first five require to be melted in an earthen pot over a fire, and to be applied warm, but not so hot as to injure the tissue of the bark with which it may come to contact. 1. Rosin, 1 part; yellow wax 1 part. 2. Black pitch, 5 parts; rosin, 1 part; yellow wax, 2 parts. 3. Burgundy pitch, 1 lb.; black pitch, 4 oz.; yellow wax, 2 oz.; rosin, 2 oz.; mutton suet, 2 drachms. 4. Yellow wax, 2 parts; suet. 1 part. 5. Black pitch, 1 part; yellow wax, 1 part; suet, 1 part; pounded brick, 3 parts. The following has not the inconvenience of requiring to be applied warm, and may be prepared and used without being heated. 6. Yellow wax, 1 lb.; turpentine, 1 lb.; Burgundy pitch, 8 oz.; mutton suet, 4 oz. Melt all together and mix thoroughly, and leave them to cool. Form the mass into small balls, as it will not stick to the fingers, and use them when opportunity offers.

LIQUID GRAFTING WAX.—This is a very useful application and is, perhaps, the most convenient for the purpose of all the mastics used for covering wounds and grafting. It is of the consistency of varnish, and is applied very thinly with a brush. Care must be taken not to lay it on thickly, for the surface hardens so rapidly that the alcohol is prevented from evaporating. Rosin, 1 lb; beef tallow, 1 oz. spirits of turpentine, 1 tablespoonful; alcohol (95 per cent) 6 oz. Melt the rosin over a slow fire; when melted take it off and add the beef tallow, stirring it constantly; let it cool down somewhat, mix the spirits of turpentine little by little with it, and at last the alcohol in the same way. Should the alcohol be added while the mass is too hot, much will be lost by rapid evaporation; if, on the contrary, it is too cool, it will form a viscid lump, and must be slightly heated again. Stirring briskly is indispensable to mix the ingredients thoroughly. In well-corked bottles it keeps for years. If in course of time it becomes too thick, the addition of some alcohol

will make it liquid again. For this purpose it must always be warmed. It is a good plan to put the bottle containing it in boiling water or hot water to accomplish this.

THE MADRAS GOVERNMENT AND CINCHONA.

THE Secretary of State hardly gave a satisfactory reply on the 8th ultimo in the House of Captain Price's question, whether the Indian Government undertook the planting of Cinchona in this country, to encourage private enterprise in that direction, or to compete in the open market with private trade. The Marquis of Hartington is too shrewd a statesman not to see that the question interests a large and influential body of men, who will not re-t satisfied with evasive replies or half measures. He added that the Madras Government found some difficulty in following the example of the Government of India, and manufacturing its febrifuge on the spot. What the difficulty is, and by whom created, were points left untouched, and it is these which other authorities have taken up hotly, and exposed to the detriment of the Madras Government. It may not be generally known that a committee sat to report upon the financial results of Mr. Bronghton's factory at Ootacamund for the manufacture of amorphous quinine a little before that gentleman quitted the Hills, disgusted with the treatment he had received, and sat upon by tyros, who grew more positive in assertion, the less they understood of the subject they had been called upon to investigate. Mr Markham in his recent work on chinchona, exposes the fallacies of the report.

The Madras Government submitted a calculation by which it was made to appear that the 'amorphous quinine' was produced at a loss. In the years 1872 and 1873, the quantity produced was 445 pounds. By arbitrarily charging the factory with £2,500 for the bark, and £583 for the cost of working and interest on plant and buildings they made out that the 415 lb. After Mr. McIvor's death, the Commissioner of the Nilgiris was in charge, and as a Colleetor of revenue, succeeded in obtaining a large income, to which his attention was exclusively directed. The latest blunder has scarcely yet become public in England, namely, the transfer of this Government property to the Forest Department, a Department that has hardly yet done anything for the country, or justified the enormous cost at which it is maintained. A strong movement is now on foot in Ceylon, which has, within the last few years, commenced to send cinchona bark to the English market. Corresponding action among the planters of Southern India is needed to avert the disastrous effects of this competition with private trade, which the Indian Government seem not disposed to abandon without a struggle.—*South of India Observer.*

JAPAN TEA.—With the exception of one million, pounds to Canada and half a million to England, all the Japan tea exported was sent to the New York market during the last year.—*Home and Colonial Mail.*

"INDJOER."—This substance, so favourably spoken of by Mr. Muens as a substitute for moss in covering cinchonas, is thus referred to by Crawford in his Malay dictionary:—"*Ijuk* (Jav. *duk*). The black horse hair-like substance at the insertion of the fronds of the gomuti plant. *Borassus gomuti*, and from which cordage is made." Marsden's dictionary describes it thus:—"*Ijo* or *hejo*, a vegetable substance resembling horse hair which envelopes the stem of the *anau*, or borassus gomutus. It is also known by the names of *gamuto* and *cabo negro*." *Injuk* (or in Dutch spelling *indjoek*) is the Sundanese form of the word. The tree has a great many native names, and is known to botanists as the *Arenga saccharifera*. The only one in Colombo flowered and died some years ago at Mr. Justice Dias's house.

Correspondence.

To the Editor of the Ceylon Observer.

LEAF DISEASE AND THE DIFFERENT VARIETIES OF COFFEE.

June 1st, 1881.

SIR—In the last *Weekly Observer* you remark about the Peradeniya Gardens' report:—"The new kinds of coffee seed introduced from the Blue Mountains, Jamaica, and from Coorg, with a view to overcoming leaf disease, have by no means been a success, the fungus attacking the plants freely and in some cases very severely"—omitting to mention Dr. Trimen's important qualification: "There is indeed very little reason to suppose that any variety of C. Arabica is 'disease proof.'" Even other species are the hosts of the Hemileia parasite; our native wild species, C. Travancorensis, and the African C. liberica, are both susceptible; yet it by no means follows that all suffer equally in health.

I remember it was said the first imported plants of Liberian coffee were badly attacked by leaf disease, but after a time they threw it off. That this is likely to be so with the other new varieties would seem to be indicated by Dr. Trimen's further observation:—"It is worth remarking that a small plantation of this (Blue Mountain) variety made at Henaratgoda is in a very healthy condition, the plants, now one year old, three or four feet high, and commencing to flower."—Yours truly, NUBLUD.

COFFEE LEAF DISEASE AND ITS TREATMENT.

2nd June 1881.

DEAR SIR,—I am glad to see Mr Oliver W. Jones' letter in your paper giving an account of his further investigation to prove that the first cause of leaf disease is an insect (moth). This was my opinion as written in a letter to you some time ago and now referred to by Mr. Jones, but you differed from me and expressed yourself to the contrary. You, no doubt, believed that Messrs. Thwaites and Morris ought to know best. I do not pretend to dispute the ability of these gentlemen nor to make out that I can hold even a candle to them as far as learning goes; but, with all due respect for those authorities and Mr. Ward, it has often been the case that when doctors cannot agree or cure a person in humble position and without much learning is called in or drops in by accident, and with a simple or plain treatment, which would be scoffed at by the doctors, cures the patient. I differ from Mr. Jones as regards gathering up diseased leaves. I have found by scattering wood-ashes and lime over diseased leaves where there are lots of leaves from shade trees also on the ground, there was no spreading of the disease, but the coffee got more vigorous.

Leaf disease, as a rule, first appears on ridges and in patches. As soon as discovered, fork in lightly some manure around the trees and scatter coral or country lime over the forked ground; also throw wood-ash and *country* lime over the trees. The latter may have to be repeated but the lime and wood-ashes is a manure, and no doubt Mr. Storck's treatment in Fiji will be nearly the same, as no outward vapour or application which does not help to strengthen the trees will ever do. I have driven leaf disease away with the above treatment (it appeared at different times in patches), kept my trees in good heart, and got good crops.—Yours faithfully, J. H. W.

[There is nothing in J. H. W.'s experience incompatible with the disease being a fungus, while there are a thousand proofs that the attack has nothing to do with an insect!—ED.]

BOHEMIAN TEA.—For some years past spurious black and green teas have been manufactured from the leaves of the *Lithospermum officinale* (Gromwell) in Bohemia. These have in some instances been palmed off in the market as "Chinese," but have mostly been used not only in Bohemia but in other countries in Europe as an adulterant for fine teas. The chemist, A. Vogel, has subjected the plant to a careful botanic chemical analysis, and found that :—Theine or any other alkaloid is not found in the plant, but only cellulose, gluten, gum, glucosides, fat, ethereal oil, resin, tannin, chlorophyl, albumen, acid salts, water, &c. Dextrine also appears to be present in it. The composition of the teas made from the plant we are told "differs greatly and notably from that of Chinese tea." The genus of plants *Lithospermum* belong to the natural order *Boraginaceae*. There are several species of the plant, but the most important is the *Lithospermum officinale!—Indian Tea Gazette.*

GOLD PROSPECTING IN SOUTH INDIA.—A paper published by the Madras Government refers to the question of *prospecting*. In previous orders the Government resolved to omit this subject from consideration in framing leases for mining for gold and metals other than gold, but it has since occurred to them that some kind of temporary exclusive privilege might properly be given to prospectors who desire to test specific localities closely. They think that ordinary prospecting does not require any special protection, but where prospectors have obtained promising indications it may be reasonable to grant what may be termed "*proving*" leases for a limited time over a limited area to test results more closely, say for six months or a year, over half a square mile, though the area might be extended if the block was compact. This arrangement would afford reasonable facilities for testing before applying for a mining lease, and would protect intelligent and scientific research. It is necessary that the area should not be excessive to avoid risk of excluding others who may have more *bona fide* intentions than the concessionaires.

CULTIVATION OF KAPOK IN JAVA.—A planter in Bantam writes :—"In your issue of 19th March, I notice a remark about planting 'kapok' trees. I am doing that on a small estate of my own. The cotton trees are planted between the rows of Liberian coffee and give just enough shade for the coffee, and at the foot of the cotton trees I am planting pepper. You of course already know that pepper thrives the best on kapok trees. At least, it is thought so by all people of experience in this country. I am using *two* of Fowler's steam ploughs on this estate, and I am happy to say we are gradually overcoming all the difficulties which attend the introduction of *such things* in India and *especially* in *Java*. Others have already followed my example, and I trust the use of steam cultivating will soon become general here. For cane steam ploughs are *the* thing. *I also* prepare the ground for tea, and Liberian coffee with them."

CULTIVATION OF THE ALOE.—A discovery which promises to have important results has lately been made by a scientific gentleman in the island of Réunion, situated near the Mauritius. He claims to have succeeded in solving the problem of extracting vegetable fibre from the aloe or other leaves in an economical manner, and one which can be generally adopted. The principal features of the invention are as follows: —The leaf is first placed for 10 minutes in a bath heated to 95 Fah. and then removed to a second bath of water at its normal temperature, in which some inexpensive chemical substance (not yet made public) has previously been mixed. The leaves are allowed to remain some little time in the second bath, after which it is said that the fibre can be washed out by women or children without any trouble. A patent has been taken out for this process by its inventor. As the aloe is known to grow as freely as weeds in this colony this discovery would appear to present the means of establishing a new and profitable industry for a very large proportion of our population. —*The Inquirer.*

CINCHONA SEED.—Sir Joseph Hooker has received an important communication from Mr. Robert Thomson, formerly Superintendent of the Chinchona Plantations, Jamaica, but now resident at Bogota, in which an account is given of a new kind of Chinchona, the cultivation of which in British possessions may prove to be very desirable. The bark which is now a considerable article of commerce, only contains two to three per cent of quinine. Mr. Howard, however, says that "the quinine, though not abundant, is pure." Its botanical origin is at present unknown, but according to Mr. Howard, the bark is known as *China Cuprea*. The important feature about this species from the point of view of cultivation is the low elevation above the sea at which it will grow, its native range being from 2,000 to 3,000 feet. Sir Joseph Hooker is extremely anxious to obtain seeds and plants of the new species with the aid of Mr. Thomson. In the mean time Mr. Thomson is anxious to procure in some quantity seed "of the fine kind of *Chinchona officinalis* spoken of by Mr. Howard that grows in the Nilgiris." The Conservator of Forests, Madras has been desired by Government to forward direct to Mr. Thomson an adequate supply of seed of the fine kind of 'Chinchona officinalis' which grows on the Nilgiris. On receipt of intimation by Government of its despatch, the Secretary of State will be informed accordingly, in view to Sir Joseph Hooker's services being enlisted for obtaining plants of the *China Cuprea*.—*Madras Mail.*

PLANTING IN SOUTH COORG.—A planter writes from South Coorg to a Ceylon friend :—"In this, the 'Bamboo district' of Coorg, the best coffee is to found. The soil is very rich and jungle good. Nearly all the estates are under shade and on any new land opened the timber or jungle shade, is kept, as it is the best. Where the trees are of a bad kind, they are cut down and artificial shade planted. Last year on some estates here the crops were a failure, but although rather shorter than the year previous we had very good crops, and this year better prospects all over are anticipated. Cinchonas are being tried here and are doing well on high elevations. Round about my bungalow here they are doing well: 'succirubra' plants, at an elevation of 3,300 feet or so. We have just got up a supply of cocoa plants for a trial. You of course grow them successfully in Ceylon. I wish you would give me the 'straight tip' as we are novices as yet in cocoa cultivation. We can put them in at an elevation of from 2,500 feet up to 3 500 feet, under shade or in open in loamy soil or friable. Our rainfall last year was 52 inches, but it ranges between 45 and 75 inches in this locality, but within fifteen miles or even less 250 inches can be got. I would like you to give me some information also about the indiarubber tree, the varieties for cultivation, &c., and if seed can be procured. A little Liberian coffee has been tried on a neighbouring estate here, and after it had been in for eight years it is not at all a fruitful tree. It grows there at an elevation of 2,500 feet or so. A few plants are to be tried between this and Tellicherry at an elevation of about 1,000 feet, but doubts are entertained of its ever being successful here. Coffee is such an uncertain thing that people are beginning now to see that something else must be tried to keep the 'pot boiling' when bad crops of coffee are got. There was a great gold mania here and everywhere else, about two months ago, but it is dying out. That there is gold is certain, but the quantity is not large enough for profit, as far as assays have yet gone."

COFFEE LEAF DISEASE.

The absence of sufficient time is likely to prevent the Chairman of the Planters' Association and his fellow-Committee members from visiting the scene of Mr. Schrottky's experiments in the Dumbara Valley before Thursday's meeting. But the work done should not be overlooked on that account, and the members generally cannot but feel obliged to Mr. Schrottky for the paper he has drawn up for them with a resumè of his experiments and their results so far as he and the planters associated with him have been able to judge. We have no doubt his statement will be carefully considered, and at the very least it calls for acknowledgment at the hands of the Committee with an expression of thanks to the gentleman who has devoted so much of his time to the service of the planters without any prospect of direct remuneration. We do not know how far Mr. Schrottky's confidence in his vaporization process will be shared among members of the Association, but certainly so far as the estate reports go, the results up to date are favourable. Most people however, we suspect, will reserve their judgment until the period for another attack on the large areas recently treated has passed over; but that reserve should not prevent due notice being taken of the good work done and the satisfactory results already obtained.

COFFEE LEAF DISEASE.

MR. SCHROTTKY'S SEVEN MONTHS' CAMPAIGN.

TO THE CHAIRMAN AND MEMBERS OF THE PLANTERS' ASSOCIATION OF CEYLON.

SIRS,—When in November last, while on a touristical visit to Ceylon, I decided to make use of a month's leisure, to institute with the help of some practical planters a series of experiments with the view to determine, whether it was really beyond the reach of Chemistry to give Coffee Planters a remedy or palliative of coffee leaf disease (this most dire infection) I had no idea that the work would occupy seven months.

I came very early to the conclusion that science in this case would not be so helpless, as she is generally represented to be, and that the disease (being fairly accessible) could not only be topically destroyed by a number of chemicals, but that the conditions of the sap of the tree could be artificially so altered as to make it less favourable to the development of the disease in the leaf cells. But to reduce this conclusion into a practical form, to devise a practical and cheap method of using any of these chemicals as topical applications or otherwise, and after having found a method, to obtain such proof of the results of the same as would be readily understood and acknowledged by practical men :—this I have found an arduous task which I more than once despaired of bringing to a satisfactory conclusion, and which has occupied a time that I have only been able to give to it by greatly neglecting and sacrificing my interests elsewhere.

With some professional repute engaged, I was naturally reluctant to leave such an important work half done, and with its practical issues involved in doubt. It is therefore with more than ordinary pleasure, that I proceed now to sum up the results these experiments have yielded up to date, and which I think warrant some very satisfactory conclusions regarding the method I recommended for the mitigation, if not prevention of leaf disease, viz. vaporization with Carbolic Acid.

Having a practical object in view, I have investigated the whole subject (as far as I was able, having only a general and not a special knowledge of Mycology) mainly from a pratical point of view, and desiring to make this paper as short and concise as possible, it will, I hope, be understood that my main conclusions though stated in a few words have not been arrived at, without full consideration of every fact that I have been able to observe myself, or been able to collect from such of the planters whom it has been my privilege to meet in my seven months' study of the subject.

THE FUNGUS.

As described generally by mycologists, and more specially by Mr. Marshall Ward, what is known as coffee leaf disease is a parasitic fungus (Hemileia vastatrix) propagated by spores, whose germinal tubes when in contact with the lower surface of a living coffee leaf, enter into its stomata, establish themselves in the intercellular tissue, develop at the expense of the cell sap into mycelium which finally forms a receptacle (the Uredo) from which arise and break through the epidermis of the leaf, kidney-shaped orange-coloured Uredo-spores, forming clusters of what constitutes the well-known rust. The same mycelium also produces a secondary spore, the Teleuto-spore.

Before fruiting the presence of the fungus or rather of its mycelium in the leaf tissue, is evidenced by pale-yellow circular spots (called pinspots) transparent or opaque. The healthier the disease, the more opaque the spot.

The fungus has been classified (by Berkeley and Broom I think) as belonging to the Uredineæ. Any doubt as to whether this classification is correct has been removed by Mr. Ward finding the Teleuto-spore.

It is, therefore, perfectly reasonable to look forward to Mr. Ward (the mycologist specially engaged in Ceylon in the investigation of the different forms of this fungus) describing to us, before he closes his work, the three different cycles of generations of this fungus, and the other hostplant on which the transition takes place, this being a distinguishing feature of the Uredineæ.

But what makes this disease so formidable an enemy is the peculiar capability of the Uredo-spores (or rust) to reproduce themselves indefinitely by their constant germination and reproduction without the necessity of passing throug the cycle of generations. These orange-spores, of a heavy oily character, germinate in contact with moisture (dew, rain, etc.) and their contents pass into a germinal tube. The spore becomes an almost empty cell, and the whole fabric is then extremely light and capable of wide diffusion.

Wind is, in my opinion, the chief cause of the dissemination of the spores before, but far more so (on account of their lightness) after germination, from one disease spot to another, from one leaf to another, from one tree to another, from one field to another.

As far as I have observed, and from information I have collected, the leaf disease fungus spreads, during the periods favourable to the germination of its spores and to their establishment in the leaf, from chronically diseased centres and travels in the direction of wind currents

The idea that an estate is absolutely free from disease for, say, three months, and that then it appears simultaneously all over the estate, has, I think, its origin in untrained and defective observation and is greatly due to the extraordinary rapidity with which the disease spreads when all circumstances are favourable.

The germinated uredo-spore will not establish itself in an incongenial nidus. Where congenial conditions do not exist, it will, even when over a stoma, simply dry up.

We may take it for granted that, considering, comparatively, force and direction of wind and neighbourhood to diseased parts of an estate, each square inch of lower leaf surface of a coffee estate will receive an almost equal number of spores that maintain adher-

ence. But on different trees the disease establishes itself in a different (but for the same tree rarely varying) force. There exists, therefore, a condition of the coffee tree, or more properly speaking, a condition of the sap of the leaf cells which is peculiarly favourable to the development of the disease. In some trees this condition is continually present, and on these the disease can nearly always be found; it is there in a constant and chronic form. In the generality of trees, however, this condition occurs only twice a year, and it is during those two periods that the disease spreads itself from a few confined disease patches more or less all over the estate.

In the majority of districts these two general attacks of the disease can be distinguished into a south-west and north-east monsoon attack, and they coincide closely, but generally precede by a little the natural, so to speak autumnal fall of the coffee leaf which takes place to a more than usually appreciable extent twice a year. In many cases only one such fall will be acknowledged.

These are periods, comparatively speaking, of a minimum of activity, of a minimum of alkalinity of the sap of the tree—periods when the trees are preparing their gathered stores of nutritious material for a new flush of leaves, when the cellular starch deposits are either changing or on the point of changing into glucose, in order to enable its passage from one cell to the other for the formation of cellulose at the apical or axillary buds.

It is the period just before a maximum activity of the tree, during which the condition of the sap of the leaf cells appears to be most favourable to the penetration of the germinated uredo-spore into the stomata of the coffee leaf and to its establishment in the intercellular tissue. The germinal tubes of this fungus share, no doubt, the apparent property of other absorptive vegetable forms, viz. that of an instinctive knowledge of the presence of congenial food. The condition of the sap of the coffee tree most congenial to the establishment of the fungus is, I take it, when the cellular starch deposits of the leaf are in a state of transition into glucose or sugar, which substance, I am greatly of opinion, furnishes the chief food of the fungus. And this transition, be it well borne in mind, can only take place in the presence of a free acid. The sap of weakly trees seems to be always in that condition.

It remains only to be said that while I agree with others in considering the chief damage done by the disease due to the premature fall of leaf I would add to this, that I feel assured that the disease has a reactionary influence; that it leaves behind in the tree, after a severe attack, a subtle poison, causing a subtle disposition in the tree to recreate the conditions favourable to its re-development, which interferes with and is antagonistic to the natural disposition of the tree to form stores of insoluble starch deposits. From these starch deposits fruit, in first the instance is formed. The fungus requires its food in a soluble form and after a series of attacks the trees appear to readily furnish it. Combine this with the premature fall of leaf, and short crops and the non-setting of blossom can be easily accounted for.

EXPERIMENTS:

WITH PROBABLE REMEDIES FOR THE DISEASE.

My experiments were directed, 1st to ascertain whether the condition of the tree by assimilation of any chemical could be rendered less susceptible to the disease, and 2nd whether a practical method of topical application of some chemical or other, could not be devised that would act better than the sulphur and lime treatment and which would not result, as the latter seems to have done in the majority of cases, in leaving the trees, for some considerable time afterwards, in a more susceptible state as regards the disease than if they had never been treated.

1st SET OF EXPERIMENTS.

To eliminate all chance of error and of mistaking cause and effect in these experiments, I decided to introduce the chemicals direct into the cambium of the stem by a system of lateral absorption, which I called Inoculation. Doubt was expressed at the time as to whether absorption through the cambium could take place. This matter has finally been set at rest; for experiments made by me at Holbrook-estate with cinchona trees, showed that trees of about 150 lb. weight each, exclusive of roots, were capable of absorbing through the cambium in 7½ days up to 60 lbs. of different chemical liquids, the non assimilated portion of the chemicals accumulating in the leaf cells until (only however in some cases) total collapse of the same ensued.

These inoculation experiments have been detailed by me in a paper written at Doteloya and published in January and need not be republished. My general conclusions are:—chlorides, nitrates, bisulphates, superphosphates and all acids and sour organic manures are apt to increase the susceptibility of the tree to the disease. Sulphates, phosphates, or generally speaking neutral salts that can combine with another atomic weight of acid, all alkalies and antiseptic chemicals (other than chlorides and such as do not owe their anti-septic character exclusively to their oxidising or deoxidising power) decrease the susceptibility of the tree to fall a victim to the disease. Pre-eminently successful among the latter, I found carbonate of potash and carbolic acid. When absorbed into the system of the tree while the fungus was healthily established in the leaf tissue, either of these chemicals prevented the fructification of the pinspots, in some cases entirely; in no case more than 22 per cent of them fruited, while on adjoining untreated coffee, under exactly similar conditions and during the same period, from 76 to 100 per cent of the observed pinspots had fruited.

Carbolic acid was the chemical I experimented with almost conclusively, after the preliminary experiments were over, as it had given me even more satisfactory results than the carbonate of potash.

It was applied to the stem of the tree, mixed into a paste with fine soil and water in about 5 per cent strength, a slip of stout paper being tied round the tree in the shape of a cup to hold the paste.

The chemical penetrated in sufficient strength into the cambium cells to cause their collapse for some distance inwards, but the strength and causticity of the chemical decreased of course until weakened enough to effect entrance into the living cell without causing collapse. Traces thereof (in a combined form of course) were bound to exert their influence on the leaf cells.

One of the chief properties of carbolic acid is its capability of arresting organic change or decay, this power being appreciably asserted in its most dilute form. The fungus, according to my conclusions, luxuriates in cellular tissue, contents of which are in a transient stage. The faintest trace of carbolic acid will arrest this, will stop for some time the conversion of the starch deposits into sugar; that is to say, will prevent the formation of what constitutes, in my opinion, the chief food of the fungus—the result will, of course, be that the mycelium, if still young, will die without fructification for want of suitable food. And this has virtually been the practical result of the above treatment. But the effect of the carbolic acid thus used is of an evanescent character, and I came, somewhat reluctantly, to the conclusion that for this method to be of any practical value, considering the wide and universal prevalence of the different forms of the fungus, it would have to be supplemented by topical application calculated to destroy these forms.

This led to reconsideration of the results of the second set of experiments, ending in my being able to combine the essential features of both.

The inoculation process involved some danger to

the trees, for in some cases the carbolic acid penetrated in sufficient strength to collapse *all* the cambium cells; but this danger could have been easily eliminated by weakening the strength of the application.

2ND SET OF EXPERIMENTS:

Instituted to determine with what success the fungus, in its more or less developed state, could be destroyed by external applications, choosing such substances and chemicals as were known to be inimical to fungoid life.

Out of the many substances tried (sulphate of iron and copper, arsenical solutions, acids, potash, etc. etc.) two chemicals were found, in our preliminary experiments at Doteloya, to have an eminently decided effect both on the fully developed orange spores of the hemileia and on the yet unfruited mycelium, which both it killed *without* injuring the healthy tissue of the leaf. These two were sulphate of soda (10 per cent solution) and carbolic acid (1½ per cent solution).

Either chemical in these solutions changed the orange-coloured spores into whitish looking bodies considerably shrunk, appearing under the microscope as white empty shells, the unfruited mycelium dried up and left a brown spot as far as its ramifications extended.

The observations were made under the microscope. Both these chemicals were tried on a practical scale by syringing their solutions through the foliage. The sulphate of soda application was practically a failure, not more than ten per cent of the spots and spores being destroyed by it. The fungus seems to possess a power of refusing contact with it when applied as a spray, and this practical difficulty will probably occur with most saline solutions.

The application of carbolic acid gave more satisfactory results. Mr. James Blackett and Mr. Drummond, on close examination of the area a few days after the application, decided that from 40 to 50 per cent of the diseased patches and spores of the fungus on the trees had been destroyed, without injuring the young shoots or leaves. But the practical difficulties of syringing a whole estate seemed insurmountable, and to quote from Mr. Blackett's appendix to my report on the results of these preliminary experiments: "*the external application of the solution of sulphate of soda or the diluted carbolic acid have too many drawbacks in my* [*Mr. Blackett's*] *opinion to make them at all practicable.*"

Mr. Blackett laid more weight on the results of the 1st set of experiments, and I put aside therefore all consideration of topical applications, until I came to the conclusion that the results of the inoculation process with carbolic acid were not sufficiently good to enable us to battle with the disease with any chance of success.

I then once more considered carefully the subject of external applications, the practical difficulties of applying liquids etc., and finally decided to try carbolic acid absorbed into and used as dry powder in the same manner as sulphur and lime, as an external application. I used this powder, consisting mainly of finely slaked and sifted coral lime, in a strength of about 3¾ per cent acid.

Though the carbolic acid is essentially an alcohol, it enters into a feeble combination with caustic lime, and forms what may, though somewhat incorrectly, be called a carbolate of lime.

On exposure to the atmosphere the carbonic acid thereof combines with the lime, sets the carbolic acid free, which thus escapes as vapour into the atmosphere.

Used in this way, the carbolic acid powder has given me such satisfactory results that I have had no reason yet to change either its strength or the mode of application. The treatment of a diseased area with this powder cast broadly through the foliage of the trees results in stems, branches, leaves, and every square inch of ground being covered with an appreciable layer of the powder. The ground, stems and branches are covered most thoroughly, but a portion of the lower surface of the leaves seems to the naked eye always to have escaped somewhat the application, though under a magnifying glass, the fine, impalpable particles of the powder can even there be seen in multitudes.

The effect of the treatment on the disease is: 1st the destruction of spores and other forms of the fungus on the ground, 2nd destruction of spores on fallen leaves, on the stem and branches 3rd destruction of spore patches on the foliage of the lower branches and the drying up and prevention of fructification of the pinspots on the same; and 4th the *partial* destruction of spores and drying up of pinspots on the diseased foliage of the higher branches.

Bearing in mind the great importance that has been laid by Messrs Abbay, Ward, and others, on the gathering and burning of the diseased leaves which only represent a small fraction of the spores that have been shed in any one area, the benefit derivable from a wholesale destruction of not only the spores on the fallen leaves but also of those that have fallen on the ground and the majority of others distributed elsewhere in the treated area will, no doubt, be fully appreciated.

The treatment will have a maximum destructive effect on the different forms of this fungus on the ground, on the foliage of the lower branches, in the absence of high winds and in coffee which covers the ground well and when there are heavy dews or a slight shower *after* the application to supply the moisture necessary for contact. I have not yet finally decided whether heavy rain *immediately* after the application neutralizes the benefit. Heavy rain a day or two afterwards does not. Under favourable circumstances, pinspots and spores, even on the highest branches, will be affected by the vapour being retained within the area. It will, on the contrary, have a minimum destructive effect during high winds, on badly covered ground, open patchy places, on trees bordering the upper side of road etc.

The vapour of the carbolic acid in an area thus treated under average favourable circumstances is distinctly noticeable by its penetrating smell for about eight to ten days after application; and in addition to the destruction of countless numbers of spores on the ground and on the fallen leaves by the 3¾ per cent carbolic acid powder, there has been unmistakable evidence collected that so long as the atmospheric air is tainted with the vapour of this most powerfully antiseptic chemical, the disease can make no progress. The carbolic acid vapour is, of course, during this period breathed and absorbed into the system of the tree by the stomata of the leaf, and its effect of reducing the susceptibility of the tree to the disease is very much the same, and rests on the same basis as the effect of the inoculation process with the same chemical, and which already has been fully explained.

It will now be easily understood that if an estate is dosed in a proper manner, and at a proper time, with this carbolic acid powder, it may be carried through the period of an attack with little appreciable damage.

I have since March last now treated over 800 acres of coffee with this method of vaporization; have also carefully, from time to time, examined what had been done in January last, as well as what of the large area had been done first, and have now finally come to the conclusion that by two applications costing R4 to R5 each per acre, used at a proper time and under average favourable circumstances, an estate can be carried through an attack of the disease with little damage, and that the diminishment of spores (when operations are carried on over a considerable area) and the general improvement in the tone of the trees

which seems to follow the treatment will make the area less liable to suffer from the disease during the next favourable period for its development.

But still I would advise that four applications costing a total of R16 to R20 per acre, including everything, should be given during the first year. An expenditure of R8 to R10 or even less the second year should suffice. The preparation and application of the powder is extremely simple. The cooly understands it readily, and, though disagreeable work does not object to it; so that under average intelligent management I believe it perfectly feasible to battle successfully with leaf disease with the above reasonable expenditure.

The degree of success obtainable will depend on how and when the applications are given. Detailed instructions as to how and when this treatment should be applied will form the subject of another paper which I have under consideration, and which I hope to finish after another visit to the estates that I have treated, before my departure to India.

The fungus will best be regarded in the light of a weed which has been allowed to over-run and firmly establish itself on an estate. It will involve some trouble and a good deal of expense in the first instance to try and keep it under, but in the natural course of things the damage done by it ought to be sensibly reduced at each periodical attack following the treatment I have recommended; and the cost of keeping it out of a certain area, when operations are carried on over an appreciable extent, will be after a year or eighteen months very trifling. For though the danger of infection from neighbouring untreated estates is considerable, the spores thus re-introduced into a treated area will amount only to a very small fraction of the countless millions of spores that are accumulated by unhindered growth and fruition of the fungus *within* a given area. It is almost needless, I think, for me to add that disappointment will result if any planter thinks he has only to scatter a handful of powder over one part of the estate, to see the disease disappear out of the other part. But once the battle is earnestly begun, there are two qualities that will ensure success—PATIENCE and PERSEVERANCE.

The following records and reports of the observation of the different planters with whose assistance I carried on my experiments and who tried and tested the treatment as finally recommended will, I trust, be accepted as independent testimony that my conclusions are based on data and results, that were apparent not only to the trained eyes of an experimentalist, but which were also apparent to the careful and intelligent observation of practical planters.

The cause and effect of the vaporization treatment with carbolic acid on the incipient forms of the fungus when established in the tissue of the coffee leaf cells, and of reducing the susceptibility of the tree to the disease, I find exactly the same as in case of the inoculation process. The observation and results of the experiments made with the latter process may therefore be fairly accepted as proof of the merits of the former in that respect, when operations are made under circumstances that admit of the vapor breathed and absorbed into the system of the tree.

INOCULATION PROCESS WITH CARBOLIC ACID.

DOTELOYA ESTATE.

Operations on a Few trees only.

Observations on the fruiting of healthy pinspots: On treated coffee trees, none fruited; most dried up and turned brown. Untreated coffee trees—83 per cent fruited.

Results examined by Messrs. James Blackett and John Drummond and testified by James Blackett.

12th December 1880.

Bellongalla Estate.

Operations on one acre. Observations on the fruiting of healthy pinspots specially marked for observation: On treated area—87 per cent did not fruit, most dried up, 13 per cent had thrown out a few isolated spores. On the adjoining untreated area—all the pinspots had fruited, additional pinspots and already developed spore patches had formed.

General Observations:—Progress of disease on treated area decidedly checked; progress of disease on untreated area at the end of ten days about 300 per cent.

Results examined and testified by ALEX. THOM.

28th December 1880.

Extract from letter to myself:—"I certainly think the trees which have been inoculated are freer of leaf disease, either in the pinspot or red rust stage, than the adjoining untreated area, but so far I cannot say that the inoculation of carbolic acid has *eradicated* the disease." W. D. GIBBON.

5th January 1881.

Moragalla Estate.

Observations on the fruiting of pinspots:—no effect of treatment observed on old shuck trees, nearly all pinspots fruiting. On the main area treated, not one of the pinspots fruited, spots turning brown.

Results examined and testified by Mr. GEO. SLOAN PAXTON.

29th December 1880.

Fairieland Estate.

Observations on healthy, specially marked pinspots. Treated area—In *no single* instance had any of the pinspots thrown out any spores. The pinspots themselves had turned brown and were pronounced (and in this all were guided by Dr. Thwaites' decision) to have been injuriously acted upon.

Untreated adjoining area—In *nearly every* instance had the pinspots on this area thrown out spores, a few only had not done so.

Results examined by Dr. Thwaites (late Superintendent, Botanical Gardens), Messrs. Anderson, Dewar, and Pyper and testified by

J. LEWTHWAITE DEWAR
13th January 1881. and GORDON PYPER.

Roseneath Estate.

Observations on pinspots: Treated area—22 per cent of pinspots fruited, the rest did not.

Untreated area—76 per cent fruited.

Result examined by Messrs. Anderson, Dewar and Pyper, and testified by

J. LEWTHWAITE DEWAR
13th January 1881. and GORDON PYPER.

Sufficient evidence being now collected to establish that the checking of the progress of the disease, as evidenced by the non-fruiting and the dying off of the pinspots, in the treated area, was due to the treatment and not to accidental natural causes, comparative minute observation on adjoining untreated area, except broad comparison as to the prevalence and state of disease and general appearance of the coffee, was considered by me not further necessary.

Pallekelly Estate.

Observations on healthy, specially marked pin spots: Out of 183 pin spots, only 11 had thrown out a few isolated spores which looked pale and unhealthy. Nearly the whole of the pinspots had been affected and had turned brown.

Results examined by Messrs. Vollar, von Kriegsheim and Gibbs and testified by Mr. H. J. VOLLAR.

14th January 1881.

Peradenia Estate.

Inoculation followed upon the 4th day by vaporization. Observation on healthy pinspots and bright orange coloured rust patches: "No single pinspot" on the marked leaves had thrown out spores, large majority showed a brown patch in centre, and were to all appearance dead. Bright spore patches had

turned brown and most spores grey, a few only retained orange tinge.

Results examined and testified by MR. G. ROSS.
15th January 1881.

Following I give now in the first instance the history, almost up to date, of the area that had been treated early in January last, on Pallekelly and Peradeniya estates, by the process I have finally recommended, viz :

THE VAPORIZATION PROCESS.

With carbolic acid temporarily absorbed and bound by a dry powder.

Pallekelly Estate.

As it was here for the first time, that I tried the above process, I selected for the operation as heavily a diseased field as I could find, paying particular attention to obtain for the experiment healthy and vigorous fungus, so as to eliminate all danger of wrong conclusions The field was heavily diseased. The disease was at its height and in the centre were about 20 shuck trees in a bare patch, the foliage of which was at the time simply one mass of fruiting fungus, and which would come under the classification of chronically diseased trees.

I.

Observations made on the 8th day after treatment : Out of 104 marked pinspots that presented every appearance of health and vigour before treatment, only one spot had thrown out an unhealthy looking isolated spore. The rest in nearly every instance had turned brownish and appear to be dying off. Bright orange spores and spore patches ; 30 per cent of these have been injuriously affected, the spores having lost all colour and patches have blackened. 21 per cent are fading ; the rest of the spores still maintain a bright tinge but patches by blackening in most cases. From the general appearance of the field, a decided check of the progress of the disease is discernible. Results examined by Messrs. Vollar, von Kriegsheim, and Gibbs and testified by Mr. H. J. Vollar.
14th January 1881.

II.

" At Mr. Schrottky's request, I have gone carefully over the field of coffee treated under his direction, a month ago, by vaporization and which had two applications. The last was three weeks ago.

" To what I reported at the time about the result of the treatment, I can now add that I see no bad results. The coffee is throwing out new wood, which looks perfectly healthy, not even the tenderest bud having been injured by the vaporisation. The field was heavily diseased at the time of application, and certainly looks much better now ; though I cannot say that the disease has been eradicated.

" I can see no unusual fall of leaf, and comparing it now with the adjoining coffee untreated, its general appearance is decidedly better."

H. J. VOLLAR.
5th February 1881.

III.

" From what I have seen of the experiments, I fully agree with what has been said (the above) by Mr. Vollar." This addition authorized by Mr. R. B. Tytler.

IV.

" I have much pleasure in stating that on close examination of the field that was treated by your process of 'vaporization,' some three months ago, I find that it compares very favourably with the adjoining untreated coffee. On the latter, leaf disease is again showing up, while on the treated area it was difficult to find a leaf diseased."

H. J. VOLLAR.
9th April 1881.

35

N. B.—This part of the estate was suffering to some extent from a fresh attack in March, while I was in India. There is no indication of the treated field having suffered to any appreciable extent.

E. C. S.

V.—" The field treated in January and with a couple of subsequent applications has kept remarkably free from disease. With the exception of one tree, now badly diseased, the field is almost entirely free of disease. The shuck trees that were in January full of disease have been keeping and are still without disease."

H. J. VOLLAR.
31st May 1881.

Peradeniya Estate.

Here as well I selected fields that suffered from the disease in a pronounced and vigorous form, and I rejected several fields proposed by Mr. G. Ross, as I did not consider them sufficiently diseased to enable us to judge correctly of the results. In fact, we had some difficulty here in finding a field sufficiently diseased for the purpose.

I.

A four acre field first inoculated, then vaporized, in the usual way.

Observations made on healthy pin-spots and brig h orange-coloured spore-patches :—Not a single pin-spot fruited. The spore-patches had almost al died. The patch had turned brown and the orange spores grey A few only still showed a faint orange tint.

A one acre field ; only vaporized but with three applications within ten days, one of unusual strength.

Results much the same as above. No pin-spots ha fruited, and spore-patches nearly all died. " I [Mr. G. Ross] am of opinion that the disease has been checked on the treated area, and this opinion is strengthened by comparing it with untreated coffee elsewhere on the estate "

Results examined and testified by
15th January 1881. G. Ross.

II.

II.—" I have carefully watched the *four acres* of coffee on this estate which were treated by both inoculation and vaporization according to Mr. Schrottky's system, and under his direction. In addition to what I reported at the time the results were examined, I now state that as far as I can see no injury whatever has been done to the coffee on this area. Nor is leaf disease present to any appreciable extent. The attack, however, is apparently passing away all over the estate.

" The *one acre* referred to by Mr. Mackenzie situated some distance from the field referred above, received an overdose. This was done at Mr. Schrottky's request with a view of gaining experience of how far the chemical could be used with safety to the trees. A very heavy dose (applied through Week's patent sulphurator) and two doses of usual strength (a handful to a tree) applied all within ten days were followed by a fall of leaf greater in the so-treated area than in the surrounding untreated coffee. I think the damage is confined to this, as the trees are now making new wood.

" On the margin of this patch, there were at the time of treatment, some trees very heavily laden with Rust, and Mr. Schrottky remarked that he did not expect much impression could be made on these. It was from one of them that Mr. Mackenzie carried away the branch which he sent to Colombo "

7th February 1881. G. Ross.

III.

The management of this estate changed and the next manager writes :—" In reply to your request to report on the coffee, on which you experimented, I can only state, that it is certainly looking very well and does not appear to have suffered at all from the ap-

plication of your treatment. There is apparently very little leaf disease on any portion of this estate."

6th June 1881. T. C. HUXLEY.

Results of my own inspection is very much to the same effect. There is however palpable evidence that of what little disease there is generally, there is appreciably less on the treated than on the untreated area. The one acre field look well but the four acre field looks, I think, remarkably well.—E .C. S.

OPERATIONS ON A LARGE SCALE.

A few observations made of the immediate result of the application will perhaps be acceptable. But here we are looking now for a broad, general benefit, which I think, there can be no further doubt, will ultimately result, if my instructions are carried out and the treatment persevered in.

Gangapitiya Estate, 150 *Acres*.

I.

About ten days after application: "I examined some of the leaves that had a bad attack on them (before treatment) and it appeared, as if the lime and carbolic was killing or eating up the fungus, and left the diseased patch with the same appearance, as if the leaf disease insect had been feeding and sucking out the spores. But some seem still to have escaped." Extract from estate reports to Messrs. Whittall & Co. by.

30th April 1881. L. B. VON DONOP.

II.

"I met Mr. Schrottky this morning at Gungapitiya and we examined together the results of the treatment here. He considers them most satisfactory, and *so far* as the experiment has gone, I most certainly agree with him.

"In exposed places such as along roads and ridges trees were found very badly effected, but this it appears is caused by the powder [or rather its vapour.— E. C. S.] being blown away from there, as inside for every twelve leaves affected, only on one could a living fungus be found. The rest of the leaves had a black spot, where the fungus had been established. On those where the disease had only commenced, a dried-up pale yellow mark was observable but in both cases (which I consider most important), the leaves appeared healthy and performing their functions." Extract from a letter to Messrs. Whittall & Co., by L. B. VON DONOP.

31st May 1881.

From my observations, I came to the conclusion that this estate has passed through a pretty severe (as evidenced by the large number of dead pinspots throughout the estate) attack of leaf-disease during this month, but which had failed to develop itself, except in places where the treatment could reasonably be said to be able to exert little or no influence. Two applications were given. E. C. S.

Pallekelly Estate, 100 *Acres*.

"Undernoted is what I have to say on the 100 acres treated with the carbolic lime. The field had its first application on 18th April (2nd on 19th May.) Then leaf-disease was not very noticeable; only on a few patches was it bad.

"Looking at it to-day, these patches have decidedly improved and comparing the field with untreated coffee, the comparison is most satisfactory as regards the effects of the treatment.

"The leaf disease found on the treated portion was only a few isolated spores on a tree here and there, whereas on the untreated portion the diseased leaves are covered with spore patches (16 leaves with isolated spores were picked from the treated area in six minutes, whereas in the same time 76 leaves—badly diseased—were got from the untreated coffee.

"P. S.—The calculation worked out is about one and one-third spore-patches on the treated, to 40 spore-patches on the untreated." H. J. VOLLAR.

31st May 1881.

Colombo, 7th June 1881.

COFFEE MIXTURES.—In answer to the opinion that coffee adulteration is not so common in England as is supposed, a well-informed correspondent writes:—"I suppose some people go by analyses of *coffee*, sold *as such*, and probably purchased by parties whose appearance would put the vendors on their guard. The evil exists in the great manufacturing centres, *and in the lower class of shops*, where the million are served. *There* the stuff handed across the counter in answer to applications for coffee, is what needs scrutiny. It is all very well for certain gentlemen to say that the buyers have their remedy, and know what they buy. But, in fact, the Courts of law are no remedy for *them*. Their remedy is in buying *tea* and letting coffee (so-called) alone. They would have coffee, if they could get it in decent form; but they are not born with either coffee mills to grind for themselves, nor with education to understand the bearing of the subject."

THE PROSPECTS OF CINCHONA PLANTATIONS.—Although the profit on cinchona plantations is said to be from 70 to 80 per cent., cinchona growers in Ceylon and the East Indies will need to look closely into the cost and possible profit of their plantations, since they may soon have to compete, not only with the Government plantations, but with enterprise in Bolivia. In 1878, a few private individuals tried the experiment in that country of cultivating the cinchona tree, and now, according to the report of the Dutch Consul, there are on the banks of the Mapiri, at La Paz, four or five hundred thousand young trees of two years' growth. In other places also new plantations are springing up, chiefly on the mountain slopes, which are cultivated for three-fourths of their height. The cultivation of the cinchona in its original home is, of course, easy, the chief danger being from drought or ants during the first two years, and the only labour necessary is to keep the young plants free from weeds during the same time. To give shade to the seedling plants bananas are planted between them. Already excellent yellow bark from Bolivia has been sold in this country, and cultivated South American red bark, yielding 3 per cent. of sulphate of quinine, has lately appeared in the London market. At the drug sales this month large quantities of the bark known as "cinchona cuprea" have again been offered, and with it some bark closely resembling it in external appearance, but not containing quinine. Several other parcels of bark have also been offered which do not appear to contain quinine, and probably do not belong to the cinchona genus at all. The variety of gum which gives a ropy mucilage, in appearance like white of egg, is still to be met with in commerce. It may interest those who have it in stock to know that it may be restored from its allotropic to its natural condition by dissolving it in hot water, and allowing it to stand for twelve hours or so in a warm place. In appearance the gum is hardly to be distinguished from the best "Turkey" sort, but is of a greyish, rather than a yellowish-white tint.—*Pharmaceutical Journal*.

Correspondence.

To the Editor of the Ceylon Observer.

LEAF DISEASE AND A POSSIBLE REMEDY.

DEAR SIR,—If Mr. Marshall Ward is correct, and the very air of a coffee estate is laden with the sporse of Hemileia vastatrix, would not the forming smouldering heaps, upon which carbolic acid or other powerful disinfectants should be placed, to windward of fields of coffee have a beneficial effect? It would be a cheap way of applying the vapour.

The smoke from the heaps without the disinfectants might possibly do some good, particularly if several adjoining estates would set fire to the heaps on the same day, and the heaps be large enough to go on smouldering for many hours.

The present season of strong winds would be a favourable time to try the experiment. E. F. T.

P.S.—If the fields be large, parallel heaps at requisite distances might be formed,

[Great care would have to be takeu to prevent the coffee catching fire.—ED.]

CINCHONA CALISAYA THE BEST VARIETY FOR LOW ELEVATIONS:—NEARLY 24 LB. DRY BARK PER TREE OBTAINED AT 2,500 FEET.

Pooprassie, 6th June 1881.

DEAR SIR,—Perhaps you may consider the following figures of interest as bearing on the mooted point, which is the best variety of cinchona to grow at certain elevations.

With the object of making my Lemagastenue calisaya trees as pure and select as possible, I rooted out forty out of my original eighty trees, keeping only those trees true to the type that gave the best analysis. From these forty trees, I got 955 lb. dry bark, which Mr. Symons sold for nine in Colombo for R912·65. This is equal to 23·87 lb. bark per tree, or R22·81. The price realized per lb is not very good, and I might have done better if I had sold at home. But when you consider that these trees were growing on poor patana soil, at an elevation of 2,500 ft., and that they were selected as being inferior, I think it will be allowed that calisayas are the best varieties for low elevations.—Yours truly, J. A. ROBERTS.

CINCHONA CULTIVATION:—WEEDS AND DYING OUT OF TREES,

WHY NOT TREAT CINCHONA LIKE LARCH PLANTATIONS?

Hamilton, Lanarkshire, 11th May 1881.

DEAR SIR,—I am obliged to you for inserting my two letters of the 23rd February and 2nd March in your paper, and I have now further evidence to bring forward in favour of my theory of not weeding. In Mr. Morris' Report on Jamaica Gardens and Plantations, he gives an instance where a cinchona nursery had been made in the forest adjoining a coffee estate in 1868, from which most of the seedlings were removed the same year, and only a few of the smaller and weaker plants left behind. Mr. Morris writes;

"Hearing that a few cinchonas were still left, I was led to visit the spot in order to examine the trees and their condition after the lapse of so many years. It was evident that since 1868 nothing whatever had been done to the spot. The road was quite overgrown and the surrounding forest was thick and almost impenetrable. The condition of the cinchona trees occupying an area of about 120 square yards, was, however, very remarkable. By carefully counting them, I found there were 379 trees on this small area, some of which were only nine inches apart. Most of the trees consisted of the crown bark (c. officinalis); they were about 29 feet high with tall clean stems: the largest measuring 15 inches in circumference at the base, and the smallest 8 inches. Being the remains of a nursery, it was naturally expected that some of the trees would be very close and others considerably isolated. They appear, however, to have grown up and completely shaded the ground, for underneath the soil was clear of weeds and covered with a thick covering of fallen leaves.

"The condition of the trees and the locality in which they were found shewed clearly that cinchona trees thrive best where they are planted closely together, and when the ground is well shaded and kept cool and moist.

"Moreover, these trees indicated that when a cinchona plantation has been thoroughly established, and the trees completely cover the ground (say in the third year from planting), no further attention is necessary till they have arrived at maturity and be fit for barking."

I am glad to see that Mr. Wickham's experience is favourable to non-weeding. Mr. Forbes Laurie, in his reply to my former letters, makes the most of the bad effects of weeds in robbing the soil of its productive qualities, but takes no note of the gain in soil from rotten leaves, branches, cut weeds, etc., etc., of the bad effects of the sun to the exposed soil and to the cinchona rootlets How does Mr. Forbes Laurie account for chena land or abandoned coffee estates gaining in soil by lapse of years, if weeds are such exhausting crops as, he makes them out to be?

Mr. Morris is clearly of the opinion that cinchona roots should be kept cool and moist, and the simplest and least expensive way to do this is to let weeds grow, cutting them down periodically when they grow too high. The weeds cut down would act as a mould-ing and would eventually decay and form soil. After the cinchonas cover the ground, the weeds do not grow, as experience shows.

I do not see any reason why cinchona plantations in Ceylon should be treated differently to larch or other plantations in this country, where clean garden-like weeding is never thought of.—Yours truly,

H. J. McCALL.

INDIA-RUBBER AND GUTTA PERCHA.

London, 13th May 1881.

DEAR SIR,—I send you by this mail proof of No. IV. of my Commercial Plants. One of the points to bring out is that the demand for rubber and gutta is increasing every day. Telegraphs and telephone, cables, and many other uses demand constant supplies, which will increase. The old Indian plan can't be depended upon.

I have sought for the trees and seeds for our colonies where the supply of rubber came from. It is most difficult testing the milk to see if it has a large enough deposit of cream—if you like to call it to make the rubber worth while collecting.

But if a poor rubber is well collected and clean, it will fetch a good price. Little is known yet of the best plan for taking out the elastic gum from the juice of the tree.—Yours faithfully,

THOS. CHRISTY.

FORMATION OF A TEA ASSOCIATION.—A meeting of representative members of a large number of Colombo firms interested in the cultivation of tea was held at the Chamber of Commerce on the 18th instant to consider the question of forming a Tea Association, with a view to consultation and united action in matters of common interest, such as notably, the regulation of the hours system; extension of use of Indian Tea in India; dealing with bridle-paths and improvement of communications; questions affecting the tenure of land; Inland Emigration and the like. Mr. Charles Mar-

TASAR SILK IN INDIA.

We have received from the Madras Government a paper containing Major Coussmaker's account of his experiments in Tasar Sericulture during the past year. He writes from Camp Rajur, Taluka Akola, and reports that though he has not succeeded in gathering a crop of cocoons of his own rearing, he has yet gained so much more experience of the knowledge of the difficulties in the way that he believes that he will eventually be able to overcome them without increasing the expense of the cultivation. His failures last monsoon were owing to the imperfect construction of the cages in which he tried to rear the worms. These were at first entirely made of tarred screens of split bamboo, and served the purpose of keeping out rats, mice, birds, squirrels and lizards, but being dark the plants did not thrive well, and the worms were always striving to escape. He then altered the construction, made them longer, and put netting at the top instead of pieces of screen, and here everything throve well for a time, until some wasps and other insects managed to get in and puncture the silkworms, from the effects of which the majority died and very few lived to spin their cocoons. He is to try to counteract this next monsoon with coarse open cotton cloth which will, probably, turn out to be cheaper then netting. He also states that the small plantation which he laid out is thriving and will eventually be able to support a considerable number of worms. His collection of cleaned perforated cocoons ready for the manufacture now amounts to about 30,000, weighing about 60 lb. and sown up in bags, in which state they will remain without deterioration for an indefinite period. Eggs were distributed in Ceylon amongst other places, but the names of the persons are not mentioned. We hope the experiment will be a success.

AUSTRALIAN FRUIT FOR CEYLON AND INDIA.

The Melbourne *Leader* of 7th May says :—

"We have frequently suggested to fruit growers the advisability of seeking a market for their produce in in Ceylon, India, and other neighbouring countries, in preference to England, and among the benefits which the Great Exhibition is likely to confer on the community we may now look forward with hope to the accomplishment of the means of a profitable disposal of surplus fruit. The Commissioners for India having interested themselves in the matter, and communicated with the committee of the Horticultural Society on the subject, that body at once instructed Mr. Neilson, curator of the gardens, to prepare cases of apples of different varieties, by way of experiment, and these were despatched to Calcutta a few days ago by the steamer 'Hydaspes,' consigned to the hon. Mr. Inglis, brother to the Executive Commissioner for India. Nine cases in all were sent :—one for the Governor-General, one for the Lieutenant-Governor of Bengal, a third for other officials, and the remainder to be sold by auction ; so that a fair estimate of their value is likely to be obtained."

The cases contained upward of 400 varieties, English and American, besides eight seedlings and some pears. The fruit was packed in ordinary bushel cases, each sender packing as he thought best, those from the Horticultural Society further being wrapped separately in different kinds of paper, the sides of the case being also lined with double sheets of paper. The *Leader* regrets that the experiment was not on a larger scale, a case of each variety being sent ; and also that the ordinary fruit cases were used, these being not strong enough for a long sea voyage. Deal cases would not do, on account of their imparting a flavor of turpentine to the fruit, Kauri pine being however an exception. The *Leader* suggests eucalyptus or other woods, and points out that the Americans have shown that close barrels cannot be excelled for the conveyance of fruit, but it is added :—

"These are in some respects more convenient than any other form, yet rectangular cases could be better stowed on boardship, and would probably be equally good for the purpose."

As to the profits to be made, it is said :—

"Little can be surmised as to the profits likely to be obtained, though Mr. Inglis has made a calculation, in which he states that apples sell in India for 1s 6d to 1s 8d per score, which would amount to 10s to 12s the bushel ; and he estimates the expenses of transit, &c., at 2s 6d, which would leave 7s 6d to 9s 6d for fruit and case."

On this, another Melbourne paper says :—

"Fruit in bad condition invariably lands exporters in loss, as those know who have been unlucky enough to have fruit spoilt *en route*. At last week's market apples ranged from 2s to 8s a case, and as the season advances the value of best apples will be higher, the glut of non-keepers having gone by. It would appear, then, that the 5s or 6s per case, the estimate of Mr. Inglis, will be likely to prove too low to attract the right sort of fruit. The few cases just sent experimentally to India and England will hardly afford reliable grounds for estimating the probable results of shipments made on an ordinary commercial scale. Growers will have to wait results of larger consignments, and it will not be until after several trials that the best methods of packing, the best varieties, and the best seasons of year for the business, will be ascertained."

A GOOD TIME COMING FOR TEA.

(*Friend of India.*)

A good time seems to be dawning for the Indian tea industry. The cause of the painfully low prices, which for two years have weighted down the hopes of all engaged therein, has been simply that supply has outrun demand. But the low prices that have ruled stimulated consumption, and at last a change seems to have set in. The London deliveries for April were 4,300,000 pounds. If such last (and there is every reason to think they will, for Indian tea grows in favor at home daily), it equals a yearly delivery of nearly 52 million pounds, and we can at the outside, this year, only give them 50 millions ! This must send up prices, in fact the prospect of it has done so already. Fine teas have quite lately been quoted 2 or 3 per pounds higher.

Good news also comes to us from Australia. Thanks to the efforts of the Calcutta tea Syndicate, our teas are now appreciated and enquired for there. One year more (and we believe the Syndicate has no idea of abandoning that field for at least so long) and the trade with Australia may safely be left to private enterprise. America also looms in the distance for the Syndicate intend exploring that field too. Luck attend them, for with a considerable portion of our teas diverted from the London market, we might almost see again the prices that ruled three and four years ago.

We look for help also in another way. A new method has lately been introduced for packing Indian teas in slightly decorated tin-boxes holding 20 pounds. These are manufactured by Messrs. Harvey Brothers and Tyler, of Mincing-lane, and are used already on many gardens. They have several advantages, which I have no space to set out now, but in my opinion their greatest claim to favor is the good they will work for the tea industry generally, by introducing Indian teas into places where they are unknown, and by fostering the habit of drinking our teas pure. For sold in this shape they will go much into consumption,

and will not be used, to the same extent, to bolster up inferior Chinese kinds.

There is yet another point. It is generally admitted now that India cannot vie with China in the production of coarse cheap teas. In short, that, if success is sought, quantity must give way to quality. As regards fine teas, none can beat us, in fact none *can* make as good as we can. Speaking generally, planters this year are picking finer than they have done hitherto. This of course will lower the produce; indeed, so much so, I doubt if the fifty millions allnded to above will reach the United Kingdom this season.

Brighter days are therefore dawning, and I think the dividend columns of Tea Companies in the spring of 1882 will not show so many ominous "nils" as they present now. E. M.

NOTE.—We trust our correspondent, who is an authority on the subject of tea, is right in his expectation that the prices will rise, but our own hopes in that respect are not quite so sanguine.—ED. *T. of I.*

NETHERLANDS INDIAN NEWS: CINCHONA AND DATE COFFEE.

(From the *Straits Times*, 28th May.)

CINCHONA CULTURE.—From a description of the cinchona barks intended for sale in the Netherlands from the crop of 1880 amounting to 109·080 half kilogrammes, it appears that the proportion of quinine in the many varieties differ greatly. As an example, we subjoin the product, first quality, of the Malawar estate. The proportion of quinine amounted in the Succirubra to 1.0, in the Colisaya 1.5, in the Schuhkraft 0.9 in the Haskarliana 1.8, in the Officinalis 2.6, in the Pahudiana 0.4, and in the Ledgeriana 7.9 per cent.—Samarang *Vaderland*, 7th April.

Java Cinchona planters will hear with great interest that Mr. A. H. J. Diemont intends to establish at Amsterdam, a steam manufactory for the preparation of sulphate of quinine, land for the purpose having been bought. So far as we are aware, there are in America three, Germany three also, and in France, England, and Italy, only one each of the manufactories of this description. The manufactory to be built will, therefore, be the first in the Netherlands and the seventh in Europe.—Batavia *Dagblad*, 2nd May.

The Surabaya *Handelsblad* gives the following further particulars regarding date coffee:—'A Frenchman noticed that the poorer classes in Persia, in default of coffee, roasted dates and used them as substitute for the same. He followed the example, and with an Englishman manufactured the so called date coffee. A speculator bought the so-called secret, and succeeding in getting out a patent for it in England. This patent was made over to a Company, and which secured rights in other countries. In France and Germany, these patent rights were sold to other Companies for sums that forthwith recouped the original English Company its capital. This naturally caused a great rise and a brisk speculation in shares; with an eye, above all, to the sale of the patent rights in other lands, especially America, where five minor Companies had undertaken to find a market for the shares. The rising of the shares passes for proof that the product is in demand. As soon as this gambling abates, the affair will again sink to nothing, and the profits made will consist of the losses which silly people will have suffered from who buy shares 300 per cent above par. From date coffee itself no profit can be made, for the article is nothing more or less than an adulteration of genuine coffee—namely 75% burned dates and 25% coffee. It is said that the French-English Company has a manufactory at Kurrachee, but no dates appear to be there."—*Ibid*, 3rd May.

To coffee planters, it is certainly important news that the experiments with the drying system of Mr. Van Maanen, made in the presence of a commission of experts, have led to the most satisfactory results. In 22 hours, the drying of a quantity amounting to 50 piculs of coffee was accomplished, and the cost of the same was not more than 6 cents per picul. Should it turn out that coffee dried in this way continues of good quality on arrival in Europe, Van Maanen's mode will soon be adopted everywhere, for the expense of putting up the apparatus is comparatively small.—Samarang *Zondagsblad*, 8th May.

CEYLON AT THE MELBOURNE EXHIBITION.

COMPLETE LIST OF AWARDS TO CEYLON.

JURY I.—FINE ARTS.

II.—A. M. and J. Ferguson, Colombo, engraved and lithographic maps.

JURY 3.—EDUCATION.

III.—A. M. and J. Ferguson, Colombo, maps, &c.

IV.—School of the Church Mission, Cotta, technical and special schools; A. C. Dixon, maps, &c.

JURY 4.—BOOKS AND STATIONERY.

Commended.—Government Agent, Kandy, styles and books: A. M. and J. Ferguson, printed books; Rev. C. de Alwis, printed books.

IV.—Ceylon Government, printing.

JURY 5.—PHOTOGRAPHY.

I.—W. L. H. Skeen & Co., Colombo, landscape and building photographs, bronze.

II.—L. E. Douffet, landscape and building photographs.

JURY 9.—FURNITURE.

II.—D. F. De Silva, carved ebony stand and pair of ebony couches.

III.—Don Andris, Galle, two carved ebony lounging chairs.

IV.—A. C. Sumps, lounging chair and teapoy.

JURY 11.—GOLDSMITHS' WORK.

I.—Ceylon Government, Colombo, goldsmiths' and silversmiths' work, service; Government Agent, Kandy, goldsmitbs' and silversmiths' work, silver.

II.—J. B. Gomes, Mudaliyar, goldsmiths' and silversmiths' work.

III.—D. F. De Silva, goldsmiths' and silversmiths' work; P. B. Halipane, Ratemahatmeya, goldsmiths' and silversmiths' work; D. J. Werasiri, goldsmiths' and silversmiths' work, ornaments; J. B. Gomes, gems and precious stones; Don Gabriel Dewapura Jayesinghe, gold hairpin and earrings.

IV.—Halpe, Ratemahatmeya, goldsmiths' and silversmiths' work; Don Suwaris, gold and silver jewellery; Don Carolis Ratnawibusane, gold and silver jewellery; Bentara Yahatugoda Tepanihami, ivory charms for chains.

JURY 12.—BUILDING MATERIALS.

Hon. Mention.—John Kyle, Colombo, concrete.

JURY 13, 22.—MEDICINAL BARKS.

II.—E. H. Cameron, cinchona bark; Lee, Hedges, & Co, cinchona bark; Mackwood & Co., cinchona bark; T. C. Owen, Oonoongal a Estate, cinchona bark; Delmege, Reid & Co., essential oils; Dr. Trimen, Director of Royal Botanic gardens, Kandy, collection of medicinal herbs, roots, bark, &c.

III.—D. A. T Dessanaika Mudaliyar, medicinal oils.

Hon. Mention.—Ceylon Government, Colombo, Hal resin; Dissaraika, Mudaliyar, tanning barks.

JURY 14.—FANCY GOODS.

I.—D. F. D. Silva, Colombo, dressing cases, work-boxes &c., bronze.

II.—Don Adrian Wijenarayane, Galle, dressing cases, work-boxes, &c.; D. J. Werasiri, Galle, fancy articles, carving, &c.

III.—A. W Subehami, Galle, dressing cases, work-boxes,

&c. ; H V Carolis de Costa, Galle, dressing cases, work-boxes, cigar cases, &c ; B. Y. B. Banban Hami, Galle, dressing cases, work-boxes, cigar cases, &c; Don Nicholade Silva Weerajayasundra Goonoowardene, Galle, dressing case , work-boxes. cigar cases, &c; K Hormusjee, basket and straw work.

V. G. Y. B. Tepanis Hami, Galle. fancy goods; Don Andris Dewapuratne Jayasinghe, Galle, fancy goods; Don C. W. Abeynarayane, basket and straw work.

JURY 15.—WALKING-STICKS.

II.—Don Adrian Wijenaryane, Galle, walking-sticks.

JURY 18.—CORAL AND SHELLS.

HON. MENTION.—Government of Ceylon, Colombo, shells A. De Dominico, Colomb , black coral.

JURY 19.—TIMBER.

II.—Ceylon Government, Colombo specimens of Ceylon woods; H. B. Peiries, Morotuwa, specimens of Ceylon woods.

III.—Don B. G. Andris, Kumbalwella, specimens of Ceylon woods.

IV.—D. J . Dissanaika, Hapitigam Korale, specimens of Ceylon woods; D. A. Wijenarayane, Point de Galle, specimens of Ceylon woods.

V.—Gabriel Fernando, Alutkuru Korale North, specimens of Ceylon woods; R. H. Martos, Kumbalwella, specimens of Ceylon woods.

JURY 20.—FIBRES, TOBACCO, &c.,

I.— Delmege, Reid, and Co., flax, hemp, fibers, silver; Armitage Bros., oils silver.

II.—Delmege, Reid, and Co., oils; Government of Ceylon Colombo, oils; Dessanaika, Mudaliyar, oils.

III.—Dessanaika, Mudaliyar, flax, hemp, fibres; Government Agent, Kandy, candle nuts, oils. nuts, &c ; Dessanaika, Mudaliyar, gum, resins, and wax; Delmege, Reid, and Co., Colombo, leaf tobaccoes, Ceylon Government, Colombo, leaf tobaccoes; T. L. William, Heneratgoda, leaf tobaccoes.

IV.—A. C. Sumps, Colombo, flax, hemp, fibre; J. F. Drieberg, Ekelle, oils; J. P. Williams, Heneratgoda, gum, resins, and wax; J. R. Ingleton, Dumbara, cigars; Mackwood and Co., Colombo, flax, hemp, &c.

JURIES 24-25. AGRICULTURAL IMPLEMENTS.

V.—Ceylon Government, Colombo, models of various implements.

JURY 28.—MINING, METALLURGY.

II.—W. A. Fernando, Colombo, plumbago

III.—Delmege, Reid, and Co., plumbago; Armitage Bros., pumbago; A. C. Dixon, B.Sc , F.C.S., collection of rocks, minerals, ge s, &c.

IV.—A. M. and J. Ferguson, Colomb , plumbago, enclosing quartz, showing what care must be taken to s parate foreign matter.

JURY 30. NAVIGATION AND LIFE-SAVING.

II.—Government of Ceylon, Colombo, models native boats nd vessels.

III.—Delmege, Reid, and Co., Colombo coir rope; Messrs Leechman, Colombo, coir rope.

JURY 31. ALIMENTARY PRODUCTS

COFFEES.

I.—Mackwood and Co., Goonambil Estate, coffee, silver; S. Rajapakse, Mudaliyar, cinnamon, bronze; J. F. Driebers; Ekelle Estate, cinnamon, bronze; J. F. Baker. (Polwatte Mills,) Yakkabendakelle Estate, coffee, silver; Whittal and Co., coffee, silver: Lee, Hedges, and Co., coffee, silver; Colombo Commercial Company, Colombo, coffee, silver; Keir, Dundas, and Co., Loolecondera Estate. coffee, silver; Courtchope, Bosanquet and Co., coffee, silver.

II.—H. De Silva, cinnamon; Lee, Hedges, and Co., cinnamon.

III.—Thotulagalla Estate, coffee; Delmege, Reid. and Co., coffee; Delmege, Reid, and Co., Kintyre Estate. coffee; Delmege. Reid, and Co., Tillicoultry Estate, coffee; Armitage Bros., coffee.

HON. MENTION:—Commissioners for Ceylon, Colombo, paddy and rice.

SUBDIVISION JURY 31.—TEAS.

ORANGE AND FLOWERY PEKOES.

I.—All Silver—Keir. Dundas and Co., Loolecondera Estate, Upper Hewahetta; Keir, Dundas and Co., Loolecondera Estate, Upper Hewahetta; Keir, Dundas and Co., Loolecondera Estate (two awards); The Ceylon Company (Limited), Koladenia Estate, Ceylon. &c.

III.—Keir, Dundas, and Co., Loolecondera Estate; C. A. Hay, Windsor Forest Estate; Macwood and Co., Galbodde Estate; Keir, Dundas, and Co., Loolecondera Estate.

PEKOES.

I.—Haldane and Anton. Dimbula, silver; A. J. Stork, Blackstone Estate, silver.

III.—A. J. Stork, Blackstone Estate; P. R. Shand Dunedin Estate, ; Mackwood and Co., Galbodde.

PEKOE SOUCHONG.

I.—Keir, Dundas, and Co., Loolecondera Estate, silver.

II.—P. R. Shand, Dunedin Estate.

III.—Mackwood and Co.; G. and W Leechman, Agra watte Estate; Ceylon Company, Hope Estate; Ceylon Company, Sogama Estate; C. A. Hay, Windsor Forest Estate, Ceylon.

SOUCHONG.

II. - Keir, Dundas, and Co., Loolecondera Estate.

III.—Mackwood and Co., Colombo; G. and W. Leechman and Co.; Windsor Forest Tea Estate ; Ceylon Company (Limited), Koladenia Estate.

BROKEN PEKOE.

I.—Keir, Dundas, and Co., Loolecondera, silver; Ceylon Company (Limited), Sogama Estate, silver.

III.—C. S. Armstrong, Rookwood Estate, Deltota; Mackwood and Co., Galbodde (two awards).

CONGOUE.

III.—J. A. Smith, Lonmay Estate; Keir, Dundas, and Co., Loolecondera Estate.

MIXED TEAS.

III.—T. C. Owen, Oonoonagala.

COLLECTIVE EXHIBITS.

I.—Keir, Dundas, and Co., Loolecondera. Upper Hewahetta, silver.

II.—Mackwood and Co.. Galleboda Estate.

JURY 36.—SEEDS.

II.—Government Agent, Kandy, kekuna and gingelli oils, mandal seeds.

Commended.—G. & W. Leechman, Colombo, produce of coconut palm.

JURY 37.—MISCELLANEOUS MACHINERY.

V.—Government Ceylon, Colombo, Kandyan spindle and comb.

LADIES JURY.

I.—E. P. Tenishami, lace; Rev. T. R. Dowbiggin, exhibit of lace supplied by Mission School.

II.—Don Adrian Wijenarayane, lace.

INDO-AUSTRALIAN FRUIT TRADE.

I was glad to hear by last mail of the perfect success of an experiment of mine to send fresh Australian grapes to Ceylon, and by the "Khedive" free by kindess of Mr. Withers, the P. & O. Agent will go,) two boxes of choice apples from the gardens of the Horticultural Society of Victoria: one box for His Excellency the Governor; the other for the Editor of the *Observer*, in order that he may open at the office and distribute the fruit, noting the result in the paper. In fruit as well as meat, cheese, butter, &c., I have no doubt a considerable trade will yet spring up with India and Ceylon. I enclose a copy of the Memorandum on the subject drawn up by Mr. Jas. Inglis, the Commissioner for India, who has the benefit of Indian and Australian experience:—

INDO-AUSTRALIAN TRADE.

MEMORANDUM ON EXPORT OF FRUIT FROM AUSTRALIA TO INDIA.

Indian Court M. I. E. 19th April 1881.

In previous papers issued from this Court by Mr. Buck on the subject of the export of Australian produce to India, it has been noted, that in any dealings on a large scale, it is of little use to study the requirements of the European Residents. The wants of the natives must be ascertained, and if these can be met, the trade is worth consideration.

Fruit of all procurable kinds is greatly in demand by the natives of India, especially in the northern

parts, where fruit is scarcest; and where there is a numerous middle class who can afford to buy it.

Large quantities of apples need to be brought to Calcutta by the Ice ships from America. The multiplication of ice machines of late years has somewhat checked this supply: but there is still the same demand as formerly.

Apples dried and fresh, dried apricots, figs, raisins, pistachios, almonds, walnuts, pomegranates, and grapes, &c., are imported from Afghanistan. Dried fruits and nuts in the largest quantity. The cost of carriage is great, as hundreds of miles have to be traversed by the camels who carry the fruit.

The statistics for importation from Kabul and Kandahar, taken from the Inland trade Returns, are about £120,000 worth, yearly.

The price of apples, of smallish size, at Cawnpore, in the centre of Northern India and in Calcutta is about a rupee, or from 1/6 to 1/8 a seore. The grapes are of a long whitish kind, with thickish skins, very sweet, and they are packed in round chip boxes, three rows to each box. Each grape is cut from the bunch, and laid separately on layers of cotton wool. In this way, they bear long journeys, a large per centage keep good for months and they sell in Calcutta at an average of about a rupee per box. I estimate each box to contain, say about 100 grapes.

It is proposed by Mr. Buck, Director of the Department of Agriculture and Commerce N. W. P. & Oudh, and President of the Indian Committee for the M. I. E. to send from India to the Horticultural Society of Victoria, samples, prices and other information of all the fruits imported, and the information thus obtained will doubtless appear in the Society's annual report.

The Cabulee fruit, after the stones have been taken-out, is dried in the sun. Fruit drying seems to be but little practised in Australia, though large quantities are annually wasted from want of a ready sale. Orchard cultivation is rapidly extending and the supply of fruit year by year, more and more outpaces the demand.

There are two issues now to be tried:—

I. Whether Australian fruits can be succesfully sent to India.

II. Whether, if sent, they will command a sufficiently profitable market.

As to the first point, I will briefly state what is being done.

Mr. Buck addressed a series of questions to the Horticultural Society of Victoria, and at a recent meeting of their Committee, it was arranged at my suggestion to send up a, small trial consignment, and this, under Mr. Neilson's careful supervision is now being prepared. By the kindness of Mr. Withers, the courteous representative of the P. & O. Co. in Melbourne, the cases will be carried at a reduced freight, and will be specially taken care of during the voyage. Mr. Cole of Richmond—for presentation to the Governor-General contributes a special case of choice varieties, so also does Mr. Lang of Harcourt and Mr. H. U. Cole of Upper Hawthorn, and indeed every grower who has been applied to, has liberally and promptly responded. It is desirable to have as many fruit-growing districts represented as possible, and all particulars will be accurately noted and reported on, as to which varieties, and from what districts arrive in finest condition, and offer best prospects of being successfully exported.

The apples are being packed in different ways, and the present shipment is, in fact, purely an experimental one, with a view to gather useful hints from the result, whatever it may be. Every method and every season should be tried, and by following this up with small shipments monthly, until the right plan and right season are definitely ascertained. Dried fruits especially should be tried, and the best mode of drying should be ascertained by experiment.

Calcutta is probably the best market, but there is a transhipment at Galle which militates somewhat against the export of whole fruit. Bombay and Ceylon are likely to prove good markets, and should be tried, and I am sure Mr. A. M. Ferguson, Executive Commissioner of Ceylon, would be happy to take charge of a trial consignment for Ceylon, and report thereon. Mr. Buck has also agreed to obtain fuller information from Colonel St. John, the Resident at Kandahar, about the methods pursued in drying fruit in Afghanistan, of what sort are the apricots, &c.

As to the second point "whether, if sent, our fruit will command a profitable market." it should be borne in mind, that the present price of fruit in India is not to be taken as that which would be obtainable for large quantities and regular supplies. A poorer stratum of purchasers would have to be reached, who would not take the fruit at the price given by the richer classes, for the present limited supply. At the same time, it must be remembered, what a vast population there is, and how, even a small profit, multiplied by a great consumption, would make a trade worthy to be grasped.

It is computed that there are by weight about 40 lb. of apples in a case, or about 56 cases to the ton. Let 1/—per case represent freight, and cartage &c. Price of case 6d. average price per case in local market say 5/—to 6/—Sundry charges 1/6. Total cost 9/—(and I think that is a liberal estimate.) It would not be difficult to calculate the profit in India, if the apples sold at 1/6 per score.

Ir is not improbable that the wood of the cases would fetch a good price, for the manufacture of tea boxes or for other purposes.

Whole fruits have been sent from Melbourne to Vienna, grapes and oranges from Adelaide to London. so that there seems to be a fair promise of success, in inaugurating a fruit trade between Australia and India.

The foregoing notes might equally apply to the oranges and lemons of N. S. W., the grapes of South Australia, and the delicious fruits of Tasmania, as to the rich ripe harvests of the orchards of Victoria.

JAS. INGLIS,
Executive Commissioner for India.

There can be no doubt that bunches of fresh grapes from Australia would be far preferable to the single fruits which come from Cabul. A pretty fair trade in apples already exists, but a great and useful trade in grapes has to be developed.

With reference to Mr. Inglis' Memorandum, he and I have received letters from a Mr. F. A. Palleine of Hobarton, Tasmania, about fruit "de-hydrated" by a patent of his. I encouraged his proposal to send a trial shipment at the reduced rate, to Ceylon, and if I am able to take a run to Tasmania I'll see his process and report the result. I feel that in all matters of this kind I can be of some use to Ceylon, apart from my special functions as Exibition Commissioner.—Yours faithfully,

A. M. FERGUSON.

LIBERIAN COFFEE.—It will be good news to all interested in "New Products" to know that Messrs. Robinson & Dunlop have made a sale, the first, we believe, locally of Liberian Coffee at R40 f.o.b. This coffee was from Mr. Forbes Laurie's Liberia estate.

SALE OF CEYLON TEA IN MELBOURNE.—Mr. Henry Poett reports sale of 12 chests of "Sambawatte" tea at 1s 6d per lb. in bond. The tea was pronounced of excellent quality. Advices from Queensland give very encouraging accounts of the opinion of experts on samples of Ceylon teas distributed there. It is much more liked than Indian. There is a good prospect for our teas in Queensland, if care is taken to send nothing but a good article.

CEYLON TEA IN MELBOURNE.

The following results for Ceylon tea sold in Melbourne by Messrs. Greig & Murray on the 10th May have been received by this mail :—

1. 31 half-chests Loolecondera pekoe 40 lb. small black very even leaf few ends, strong malty rich very brisk pekoe flavour ... 1s 4½d
2. 24 half-chests do pekoe souchong 40 lb. well twisted greyish black leaf, rich and full ripe malty pekoe flavour 1s 5d
3. 48 half-chests Loolecondera pekoe souchong 40 lb. blackish brown well curled leaf, strong full ripe pekoe flavour 1s 2d
4. 11 half-chests Calsay broken pekoe 38 lb. small black very even leaf full of tips, pungent thick heavy and very flavory ... 1s 0½d
5. 10 half-chests Calsay pekoe 38 lb brownish black rather loosely twisted leaf, extra fine very oavory brisk pekoe kind 1s 1½d
6. 11 half-chests Calsay souchong 38 lb. bold black fairly curled asd even leaf, strong and pungent ripe full flavory 10½d
7. 18 half-chests Calsay pekoe souchong 38 lb. blackish brown well curled leaf, pungent and strong full ripe flavor 1s 1½d
8. 38 half-chests Boos pekoe souchong 38 lb very handsome small wiry leaf full orange pekoe tips, rich full ripe malty pekoe flavor 1s 1d
9. 20 half-chests Rookwood broken pekoe 43 lb. small black very even leaf, orange tips brisk burnt very flavory malty pekoe 1s 2d
10. 45 half-chests Kandal Oya pekoe souchong 38 lb. boldish black fairly curled evenish leaf strong and rather pungent rich flavory 11½d
11. 18 half-chests Kandal Oya souchong 38 lb bold greyish brown curled and twisted leaf, full ripe brisk flavory 10½d

Analysis of Coffee Pulp.—The *Indische Mercuur* says :—A French chemist named Poussingault has subjected this fruit to a careful chemical analysis, and has found as the result that it contains 2·37 per cent cane sugar, 8·73 per cent grape sugar (glucose), and 2·21 per cent sugar of milk. This chemist is still doubtful whether alcohol can be extracted from this fruit to any useful purpose, so that further experiments in that direction are very desirable.

Coffee in the Shevaroys.—We learn from the Shevaroys that coffee prospects are as unfavorable as they were in the beginning of the month, and that the slight showers of rain experienced there in the past few days have not done anything towards improving the prospects of the coming crop. In the early part of the year the best anticipations were entertained about the prospects of coffee and many of the planters were pretty sure of making up, during the present year, the losses they experienced in the past. Leaf disease has not quite disappeared from the estates and the planters are doing their best to get rid of it. The use of bone manure has something to do with the appearance of this enemy of the planter, but it is believed that with perseverance and industry, the difficulty will be overcome, and that leaf disease will disappear. That the Shevaroys are still attractive to those who are determined to do a fair business in coffee, is evidenced by the fact that, only a few weeks ago, a European planter from the Wynaad applied for and obtained land at the Shevaroys and has already begun operations. The coffee estates belonging to the late firm of Messrs. Lecot and Co. are said to be steadily progressing, and if the next season turns out to be better than present appearances warrant, the liabilities of the estates will be paid up much sooner than anticipated. The good luck that has attended the planters in Wynaad, is not likely to attend those on the Shevaroys as regards gold. But what is there to dissuade planters from prospecting? In every part of the Neilgherries and Mysore, gold has been discovered, and it may even be found on the Shevaroys if diligent search is made.—*Madras Standard.*

Correspondence.

To the Editor of the Ceylon Observer.

CINCHONA C. LEDGERIANA IN CEYLON AND JAVA.

Lynford, Bogawantalawa, June 8.

Dear Sir,—I send you measurements of 12 Ledgerianas growing on North Cove. They are grown at an elevation of at least 5,300 feet, and are not yet one year old.—Yours faithfully,

A. R. LEWIS.

	Java 2 years old Ledgerianas. inches.	St. Andrew's 22½ mos. Ledgerianas. inches.	North Cove 11½ months Ledgerianas. inches.
Average height.....	57	65	58
,, stem 4 inches from ground.....	3·9	3·9	3·1

COFFEE ADULTERATION ; CHICORY MIXTURES AND DATE COFFEE.

Kent, 19th May 1881.

Sir,—"A bonus dividend of 8s per share, making, with the payment on March 3rd last, 100 per cent. this year, has been declared by the Date Coffee Company (Limited)." I see by an *Overland Observer* lately received, that the Planters' Association was about to memorialize the home Government against the legalized adulteration of coffee with inferior and cheaper substances, and permitting its sale to the public under the simple condition that its mixture is stated on the label. I do not think there is the slightest chance of such memorial meeting with any success at the hands of the present ministry, in whose minds the idea of protection in any shape seems to be utterly abhorrent and opposed to the spirit of the age. I think, however, that the planters are quite right in protesting against the permissive adulteration of their produce, not only as an injustice to themselves, but as having a demoralizing effect upon the English trading community. As some check upon the extent to which this practice might be carried on, I think your suggestion that the exact proportion of the substances used should be stated on the label affixed to the package is a good one and I would further suggest that this information should be given in much larger type than at present used, and not as it were squeezed into a corner, in small type, in the hope that it will not be perceived, as in nine cases out of ten it is not. I was told the other day that the German Date Company has advertized its intention of prosecuting for libel any detractors of the Company—rather a significant proceeding and the meaning of which I leave to the understanding of your readers. The Chairman of the Planters' Association will, no doubt, with his well-known ability, put the grievance in as strong a light as it can be placed, and I do not see the great necessity of the Chamber of Commerce joining in the movement. The planters after all are the parties most injured, and they are numerous and important enough to command attention.

Leaf disease, I see, continues to be a subject of anxiety, but I think I perceive a lessening fear prevailing among planters generally, and a more hopeful feeling setting in. The better prospects in regard to crop may partly account for this : and with reason, for it is a proof that, destructive as the disease is, the coffee plant is still capable of yielding fruit, provided it has fair play in the way of good weather at the blossoming season, and other critical periods of the year.

I am very sanguine that, with the general practice of destroying fallen leaves, and invigorating the trees,

when it can be afforded, with manure, the disease will be stamped out finally, and that prosperity will reign again among the hard-working and much-enduring planters of Ceylon. The farmers of my neighbourhood are beginning to grumble at the want of rain. The ground is fearfully dry, and cattle and sheep are starving for want of grass. There has been a good lambing season, but the poor mothers can scarcely afford the little things sufficient nourishment owing to their emaciated condition. Hay will be at any price I expect, unless we have 24 hours of a good down-pour almost immediately. There is a grand promise of fruit, but rain is wanted to fill it out. Should the farmers have another bad year, it will be a terrible thing for the country. I am a landed proprietor to a small extent, and am beginning to have dismal forebodings as to Michaelmas rent. One of my tenants, whose lease of 21 years will expire next Michaelmas and who has hitherto paid £240 a year, has given notice that he cannot continue the tenancy, unless I reduce the rent to £150, and then he will only continue as a yearly tenant. The land he occupies is in one of the most fertile parts of Kent. This will give you some idea of the state of agriculture in England at the present moment.—Yours truly, AN OLD COLOMBO MERCHANT.

TIN TEA BOXES.—We have received from Messrs. John Walker & Co. a sample of the tin tea box so strongly recommended by Col. Money, and which we have no doubt will be largely adopted by Ceylon tea planters.

KALUTARA TEA.—We have been agreeably surprised at the quality of three samples of tea, supplied to us by the Manager of Culloden Estate, Kalutara district, from the first considerable quantity manufactured by him. Mr. Davidson deserves great credit for the preparation which, so far as we can judge, is very satisfactory. But our surprise arises from the very agreeable flavour of tea grown in a district comparatively only a few feet above sea-level. We should judge that the liquor of the Kalutara tea will not be as strong as that of leaf grown higher up, more especially in Ambagamuwa. But it is evident now that Ceylon can produce a tea of a superior marketable quality from sea-level up to 6,000 feet elevation.

PUBLIC SALE OF CINCHONA BARK.—Messrs. Robinson & Dunlop put up for public sale to-day at their offices, Baillie Street, the undermentioned lots of succirubra cinchona bark. The bark was from trees, 7 and 8 years old, grown on the Deyenellekelle Estate, Walaha Valley, Lindula, average elevation 4,200 feet. Average of five analyses by Messrs. Cochran, Dixon, Powell Jones and Symons of the stem quills shewed 2·52 yield sulphate of quinine. Analysis by Mr. M. Cochran of the mossed bark shewed 2·91 yield sulphate of quinine:

	Sold for.
Lot 1.—1,074 lb. stem quills	R1·75
Lot 2.—2,514 lb. stem pieces	R1·10
Lot 3.—570 lb. branch bark	·75½
Lot 4.—300 lb. root pieces and dust	R1·50
Lot 5.—.05 lb. large root piece s	R1·05
Lot 6.—200 lb. mossed stem quills	R1·85

Next came bark from trees, 4 and 5 years old, grown on the Erroll Estate, Dikoya. Average elevation 4,200 feet. Average of two analyses by Messrs. Dixon and Symons, of the shavings from 5 years old trees shewed 2·77 yield sulphate of quinine. Analysis by Mr. Symons of the shavings from 4 years trees shewed 2·32 yield sulphate of quinine.

Lot 1.—1,174 lb. shavings from 5 years old trees ..	R1·61
Lot 2.—234 lb. shavings from 4 years old trees.	R1·45
Lot 3. 41 lb. stem bark.	

There was an attendance of over 20 mercantile gentlemen, and the bidding was fairly spirited, the German firms buying most of the bark

ARTIFICIAL DRYING OF COFFEE.

The following is a translation of the report on the Van Maanen process by the Commission appointed by the Commercial Association at Samarang:—

"We the undersigned, having assembled as a commission at the request of Mr. P. J. van Maanen and of the Commercial Association of Samarang, to be present at a trial of the process discovered by the aforementioned gentleman for the artificial drying of coffee, and to give an opinion on it, have much pleasure in reporting as follows The drying apparatus on the estate belonging to Messrs. J. and A. M. Engelken situated in the Soeracarta residency on account of its great simplicity costs exceedingly little to set up. The experiment was made with a quantity of coffee of the same quality as about 36 picols dry and prepared which had previously lain for a day on the drying grounds; the process in the apparatus lasted 22 hours, after which the coffee appeared to be completely dry and ready to be stored away. The operation requires little oversight, is exceedingly simple, and cheap, only about 5½ cubic ells (more or less) of fuel (jungle wood of different sorts) being required for the drying of the above amount Although we readily state that the drying takes place very uniformly, and that the coffee was exposed neither to exceptional heat nor to prejudicial damp, we must reserve our judgment especially on the question of the influence which the artificial drying may exercise on the taste and colour of the coffee, as it can only be ascertained on arrival in Europe fi the quality has suffered or not. In order to settle this point Messrs. Engelken intend to send a batch of coffee to the Netherlands, treated in the following manner:—

25 picols dried in the ordinary way on built grounds.

25 picols dried first artificially and then further in the usual way.

25 picols dried first on the grounds and then thoroughly by the artificial process.

25 picols dried entirely artificially.

This batch, shipped to the Netherlands and brought into the market simultaneously, will enable brokers to pronounce a decided opinion on the influence of the process of Mr. van Maanen on the colour and flavour of the coffee, and the final judgment on the utility of this method must depend upon this. If the result of this experiment should appear to be successful we do not hesitate to recommend strongly this process for all coffee estates and especially for those which on account of their elevation experience constant difficulties with the ordinary manner of drying Although all the advantages enumerated by Mr. van Maanen in his pamphlet should not be realized (for instance the expense in some cases will probably be higher than fixed by him though even then far below that of the present system of drying or what a Guardiola apparatus costs) there can be no doubt that the van Maanen process has great advantages, which will very speedily recoup the cost of setting up as well as of purchase. In conclusion we may mention that the experiment was seen by Mr. D. Pies, Chief Inspector of the Government Coffee Culture, who showed himself greatly impressed with the drying apparatus of Mr. van Maanen.—Samarang, May 1881. F. J. Knoops, K. van Gessel, A. Bauer, J. H. Dezentje."

INDIAN WHEAT.—We have received from the Indian Government a "Supplemental Report on Indian Wheat," by Dr. M. C. Cooke. It appears that in his report of 1879 Dr. Forbes Watson remarked on the weevilly condition of the samples of Punjab wheat received by him, and consequently a second series of samples was sent, and this report gives a very satisfactory statements of the quality of the wheat, the best being valued at 50/6 to 51/ and said to be "very finest, like Oregon."

NETHERLANDS NEWS.

Tramways—Coffee Companies—Mangosteen Shells.

(From the *Straits Times*.)

Batavia 20th May.—"In Java there is at present a rage for steam tramways. It is expected that the Batavia one will soon get its materials for construction. In Japara three gentlemen have obtained the concession for laying a probably very remunerative line. It is also intended to apply for a steam tram concession for a line between Surabaya and Grissee, and for another between Batavia and Tangerang."

"At Surabaya, three coffee growing companies are in course of formation. There is good news from Samarang to the effect that along the north coast of Java, opium smugglers are vainly looking for the contraband opium receiving vessels which have been obliged to keep away owing to better surveillance."—*Batavia Dagblad*.

"*Mangosteen shells.*—Mr. G. Naeff, at Lochem, has made a comparative examination of mangosteen shells and oak bark, to determine the value of the former as tanning material in leather making. It appeared therefrom that the mangosteen shells contain one sixth more tannin than oak bark, and that the value of the former may therefore be set at about 7.50 guilders per 100 kilogrammes."

AUSTRALIAN GRAPES FOR INDIA AND CEYLON.

To the Editor of the "Melbourne Daily Telegraph."

Sir,—With reference to the efforts made, in connection with the grand Exhibition which has just closed, to promote a trade in fruit from the Australasian colonies to India and the East generally, you may perhaps allow me to state the result of a small experiment with grapes made at my instance. My order was given to Messrs. Law, Somner, and Co., of this city, and they confided its execution to Mr. Charles Pitt, of Adelaide, Mr. Withers, the obliging agent of the P. and O. Company, having consented that the box should not only be placed in the ice-room of one of the company's steamers, but that it should be carried free of cost. In this liberality regarding small trial consignments, Mr. Withers is emulating the example set by Captain F. Bayley, the P. and O. Company's agent at Galle. By last mail I heard of the arrival of the box containing about 40lb. of grapes, and superlatives are resorted to in order to describe the perfect condition in which the fruit had arrived, and its deliciousness. The time of transit was about twenty-five days from Adelaide to Colombo, but as not a single berry showed the slightest sign of injury or decay, there can be little doubt the fruit would have have retained its good condition for double the period. Of course, the fact that the box was carried in the ice-chamber of the steamer may have contributed largely to the favourable result, but probably fruit well-selected and well-packed, as in this case, would carry well if merely placed in a cool part of the ship. In an account of a recent experiment where grapes were sent from Adelaide to London, I observe that corkdust was the packing substance used; but in the case of the package to Ceylon, nice clean sawdust seems to have answered admirably. Such experiments as these show that, provided moderate freight can be arrauged, a large trade in grapes from Australasia can be carried on. The fruit packed in bunches, and not subjected to much land carriage (railways being generally available, both in India and Ceylon to render land transit as rapid and as little injurious as possible), must be greatly superior in freshness and good condition generally to the Kabul fruits, packed one by one in small boxes, to which Mr. James Inglis, Commissioner for India, referred in his valuable paper. The value of a plentiful and fairly cheap supply of so refreshing and and nutritious a fruit as grapes to Europeans residing in the hotter parts of India and East can scarcely be exaggerated. One of the most trying, and, if not checked in time, one of the most fatal affections to which Europeans are subject in the tropics, is what is popularly known as "sore mouth," from its prominent symptom. The tongue and mouth assume a pink colour, as the evidence of inflammation of the whole mucous membrane. This inflammation is periodically relieved by natural means, but continues to recur, and if the disease does not end in acute dysentery, but becomes chronic, it wastes away the patient, much as phthisis does. One of the great remedies prescribed for this disease is "the grape cure." Patients are ordered to a vine region, and directed to make grapes their chief article of diet. The late Chief Justice of Ceylon (Sir Edward Creasy, anthor of "The Decisive Battles of the World") came to Australia on such an errand. Without undervaluing the benefits derived from a sea voyage, and the change of scene and air, there can be no doubt that good ripe grapes possess large curative propertiet and probably their use as a common article of diet in the tropics would act as a preventive of the painful and depressing affection I have noticed. A full supply of grapes, therefore, would be a great boon to Europeans in India, Ceylon and the East generally; while, if supplied at a fairly moderate price the millions of natives would also be large consumers. Let us hope that a large trade in this and other fruits which flourish, and can be grown to any extent in these favourd lands of the south, may speedily spring up, to the mutual benefit of suppliers and receivers. If the experiments I have detailed, or any further efforts I can make, tend to such an end, I shall feel—and I am sure I can speak for the Indian Commissioners also—only too glad to believe that a part from the direct duties of my position, my visit to Melbourne has resulted in some good. I may add that, thanks to the liberality of the P. and O. Company, trial specimens of Messrs. Swallow and Ariell's flour and meat biscuits (supplied without charge) went by last steamer to Ceylon, and that choice apples from the Melbourne Horticultural Society's Gardens are to go forward on Tuesday next, one box for the Governor of the colony, and one for the Editor of the *Observer* to distribute and notice.—I am, etc.,

A. M. Ferguson,
Commissoner for Ceylon.

LOW-COUNTRY PRODUCTS: GENERAL REPORT.

Weather—Cacao and Crickets—Liberian Coffee and Blossom—Cinchona—Fiji Cotton—Garden Stuff, &c.

Western Province, 7th June 1881.

The weather during May has been very satisfactory our longest spell without rain being only eight days. On the last day of the month the monsoon opened very mildly, and up to date very little rain has fallen, but some has fallen every day. The weather, at present, is rapid alternation of sunshine and cloud, with an occasional short sharp shower—nothing could be better for growth. All the cultivated plants are thriving, but the weeds best of all.

The crickets have disappeared for the season, and I have been able to estimate the loss of plants, which I find much less than I expected. I think now the supplies will not need, to be much more than 15%. The cut plants amounted to about 34%, but with the fine growing weather a good deal more than one half of them are growing anew. We may expect that the weaker ones will be attacked again, as some of those put out two years ago have been cut four

times, and are now behind the seedlings put out last November, of which all that escaped the enemy during March and April may now be considered out of danger.

During last month I have transplanted all the seedlings I had in the germinating sheds into baskets, where they are thriving; but unfortunately they are not safe for the field, else I could have got the whole place planted up in this glorious weather.

The old plants promise a great blossom towards the end of this month, but it would have been greater, if we had been treated to less rain, since the middle of March; the trees having gone more to leaf and wood, than to the formation of flower; and so we have a pair of secondaries, instead of from twenty to thirty flowers, at points of the primaries. I suppose, however, that there will be the more blossom on a future occasion, from the greater quantity of wood. To bear well, the Liberian coffee wants much sun. I have plants, *not under shade*, but so situate, that they get only a few hours of sun daily. They run up rapidly, with large spaces between the leaves, the leaves are of an immense size, and have a very brilliant gloss, but with a height of six feet, and with the lower primaries thirty inches long, they never have had a blossom, and show no signs of it now; while more exposed plants of half their size have scores of half-grown fruit, and much promise of flower. It is only, however, where the plants have advanced to the dignity of two or three pair of leaves, that they begin to appreciate sunshine; and even then, they must have sufficient moisture in the soil. I have seen trees droop, after a month of drought, that were six feet high.

I said in my last report that I would once more lift in the failures of the cacao on that side of the estate, where the least failure of the former plantings took place. I thought to get seed from the Government Garden, and accordingly sent for a sample, with the usual luck of those who have trade dealings with Government: that is paying 20% higher than the current price, while the goods are of inferior quality, to the extent of 50% seeds not much larger than Liberian coffee, and only 60% germinated, producing plants too weak to carry the seeds erect. I returned to my old vendor, a wiser man; and from the seed now in nursery I hope to fill all vacancies on the eastern side of the rocks, where the survivors are now coming on with a rush. It is less than two years since the first plants were put in, and several of them are in flower. One especial pet has been in flower for above six months, but has not yet formed fruit. The white-ants still continue to settle some of the weaker plants, but they have now nearly finished all that suit them.

I have not great expectations from the cinchonas, but so far they have made no complaint. In a few weeks, we may expect them to declare their intentions fully.

The other things that have been planted are generally thriving. Fiji cotton is becoming a weed. The most advanced teak tree is 25 feet high, and as upright as the monument. The Calcutta bamboo threatens to give some trouble to keep within bounds, where the soil suits it, but much is to be forgiven to a plant that promisses before long to become a fence that no bullock can storm. Young jak plants grow at the rate of a quarter of an inch daily, and the *Holcus Sorghum* grows ten feet in two months. I have grown some thousands of orange plants, but they are attacked by insects, as soon as they come above ground, and the work goes on day by day, whenever a bud appears, till the plant perishes, battling long and hard for its life. Out of all my plants, I have only one that I can say is out of danger. As for native garden stuffs, were we to turn our attention in that direction, they could be grown in cart loads. Two years ago, a couple of chilly plants were put in a recess about three feet wide, between two large boulders. The crop gathered twice a year is half a bushel. Of arrowroot, I made a cwt., from a patch less than a square chain in extent, while beans, brinjals, bandakaiy, betel give great crops. Such European vegetables as have been tried, however, have been conspicuous failures. About twelve months ago, I stuck in some hundreds of pineapple plants among the rocks. They are now fruiting abundantly, but they are never allowed to ripen. The crows and the coolies have all the benefit, but I do not care for them myself, and the transport to a market would swallow up all the proceeds. If the new process we hear of comes to anything, something may ultimately be done with the fiber.

There is a story of an Australian colonist who sowed shelled rice, and was deeply disappointed, when it did not grow. We, in Ceylon, have no right to laugh at this wise Willie, for in the year of grace 1880, an eminent planting agency, of long standing, imported the husked seed of the African oil palm, and sold it to experimentalists, for the purpose of propagation. It was no doubt all done in good faith, but a good deal of disappointment resulted. "Ignorance, sheer ignorance, madam," as Dr. Johnson said, when taken to task for a blunder in his dictionary. A thousand of those seeds were sent to me, but I was not disappointed, having had some experience in the cultivation of palms. Your Aberdeen correspondent some time ago suggested, opening a trade in cocoanut poonac with England. I expect we can advantageously use all the poonac we produce for our own purposes, and English stock-keepers have in African palm meal a very superior feeding substance, relatively much cheaper than poonac. I believe the trade in palm oils is a great and a growing one, and in the habitat of the plant they can be got for little more than the labour of collecting them. Some of your correspondents can perhaps tell us the result of their experiments with this palm. If it can be successfully cultivated, it will be come an important element in the industry of the island. I have no faith in imported seed, but every seed produced in the colony should be used for propagation, as soon as it is ripe.

On my next visit to the Henaratgoda Garden, I will get seeds or slips of all the new products to be found there. Anything that succeeds there can hardly fail here. I think that, as a rule, there is too much shade maintained on that garden, and that many of the plants cultivated would thrive better with more sun. So far as Liberian coffee is concerned, I have no doubt whatever, and for cacao, however much it may enjoy shelter, I greatly doubt the utility of over-head shade.

SCIENTIFIC MANURING:—INSOLUBLE VS. SOLUBLE PHOSPHATES.

(Communicated by an Old Planter.)

Mr. Hughes, in his last letter to the *Observer*, alludes to the Aberdeen experiments, in support of his advice to the Ceylon planters, to administer powdered coral to their land. The advice is no doubt a good one, but the use of powdered coprolite in the "A. A. A." experiments had no reference to the use of lime in any form as a manure. It appeared to Mr. Jamieson, and the Association he serves, that the dicta of the "Voelcker" school of chemists, which decided that insoluble phosphates, and especially insoluble mineral phosphates, were of no manurial value, should not be accepted, without further tests than the dogma had been founded on. For this purpose, the A. A. A. experiments were instituted, and carried out, during a series of years, with great care, and scientific skill. The almost utter failure of the phosphates of alumina and iron to increase the crops tended

to comfirm the former belief, as regarded those substances, but the results were very different with the insoluble phosphates of lime, which on an average of several hundreds of tests were found only 7 per cent less effective than the soluble phosphates. It was then objected that the Aberdeen lands being deficient in lime, it was probably the lime, and not the phosphate, that effected the increase of crop. Mr. Jamieson at once admitted that the objection was tenable, till the results were confirmed by further experiments on land that had already sufficient lime in its composition to render the tests of phosphate more independent. To this end, two fresh experimental stations were established in different parts of England. The same experiments were repeated in the Lothians, under the auspices of the Highland Society, with results even more favourable to the use of insoluble phosphates, than those obtained by Mr. Jamieson. The question is one of nearly as much importance, to the Ceylon planter, as to the British farmer, and its settlement will be impatiently waited for by the students of scientific cultivation. If Mr. Jamieson succeeds in fully proving his case, it will enable the cultivator to supply his crop-bearing plants, of all kinds, with the necessary amount of phosphatic manure, at a very much lower price than the substances hitherto in use bears. It would be presumptuous in one who is ignorant of the A. B. C. of Agricultural Chemistry to offer an opinion, where authorities disagree, but my sympathy is with the man who questions nature, for the advantage of the public, and I wish Mr. Jamieson well through it.

INDIAN TEA IN AUSTRALIA.

A correspondent writes:—"Indian tea growers and shippers must not be discouraged by the negative results of the shipment of Indian tea to Sydney. It is the old story of the Pearls and the members of the Porcine tribe. I am myself an old Australian, and remember the time—before my palate became educated—when nothing but the "Post and Rail Variety of Tea" was enjoyable to me. "Post and Rail Tea," thus called, because of the quantity of timber that would be floating in the quart pot in which the camp brew had been made. We really did enjoy it, for we knew no better. It must have left the importers an immense margin of profit, such a margin as they certainly would not make on really good tea. The Australian storekeeper who retails tea buys on credit from the importers. Long credit, too. Mostly Post and Rail Tea is good enough for him. Why should he look out for better? Why, at much loss of profit, educate the palate of his customers? If that cargo of Indian tea had been sold and parcelled out to tea-drinking New South Wales, not another stick of Post and Rail would have been sold again. But the time is near when soon the Australians will drink better tea. A little organisation, a few samples judiciously distributed, and the days of Post and Rail are numbered: Why not present a chest or two of sound Indian tea to one or another of the temperance leaders in the colony?—*Home and Colonial Mail*, May 13th.

QUEBRACHO WOOD.

(*Journal of the Society of Arts.*)

Mons. F. Rhein has lately communicated a paper on the "Quebracho Wood" to the *Société Industrielle du Rouen*, from which the following particulars are extracted:—This wood belongs to the family of the Asclepiades, and comes from America. Being very hard, and composed of a great quantity of interlaced fibres, the tannin it contains is different from that of chestnut or of oak. Gelatine precipitates this tannin out of a water solution with a flesh colour, while salts of protoxide of iron give an ash-grey precipitate, and the peroxyde salts a dirty greenish colouration. When boiled with weak sulphuric acid, the tannin is not converted into gallic acid. According to a German chemist, quebracho wood contains 18 per cent. of tannic acid. The back of this wood contains an alkaloid analogous to quinine. Extract of quebracho, now much used in wool dyeing, giving a yellow shade with a tin solution. It gives even shades, resembling those of cutch, if used with bichromate of potash, but its principal use is for obtaining blacks, for which the wool is given first a bottom of the extract, then passed through iron, and dyed with the quebracho; this, in these conditions, can replace cutch. Solutions of quebracho wood, or extract, will only keep limpid if heated to a certain temperature, but get turbid on cooling. Dyeing experiments, with the dry quebracho extract, as manufactured by a French firm, in comparison with cutch, have proved the former of more value, since, with a lower price, it possesses a greater richness of colouring matter. There series of trials were made: one, by passing the cotton prepared in a quebracho or cachou bath through bichromate of potash; the second, through iron; and, in the third, the patterns were passed through iron and then chromed. In all cases the same results were obtained, showing the advantage of the quebracho over cutch, in spite of a slightly more greyish shade of the colours obtained with the former. The same results have been got by printing mordants on calico, ageing, dunging, and dyeing with quebracho extract or cutch; in all cases the quebracho shades being identical with those of cutch, not only for the tone of colour, but also in regard to fastness.

EXPERIMENTAL STATIONS AND MANURING.

From the *Aberdeen Journal* received by last mail we extract the following from the report of the Annual General Meeting of the Aberdeenshire Agricultural Association. The committee report for last year:—"The experiments for last season, which comprised oats, turnips, and grass, have on the whole been very successful, and yield new and valuable information, for which reference must be made to Mr. Jamieson's elaborate and valuable report.

"The conclusions indicated in Mr. Jamieson's first reports regarding the action of manures on turnips have been now so fully confirmed by repeated experiments that they may be accepted by farmers as a guide to the economical and effective application of manures.

"The conclusions suggested by the experiments on oats and grass during the last two years remain to be verified or modified by further experiments in coming seasons.

"The two stations in England have not entailed serious expense on the Association, and will probably be continued by the localities. The information yielded by these stations confirms the conclusions arrived at from our experiments in this county. It must be highly satisfactory to the members to learn that the example set by this Association has been followed on a more extensive scale by a similar association in the county of Sussex. It is hardly necessary to point out that the more numerous the stations conducted systematically, the wider and more reliable the information gained for the benefit of all. The committee again desire to express their sense of the great value of Mr. Jamieson's labours, and of the devotion he applies to this most important and valuable branch of scientific investigation."

The Marquis of Huntly said: "I hear that on all sides there is but one opinion that our able chemist has held his own, not only in the opinions he has expressed, but in the newspaper warfare to which he has been subjected." The first conclusion we ar-

rived at—viz., "that phosphates of lime decidedly increased the turnip crop, but that the farmers need not trouble themselves to know whether the phosphates are of animal or of mineral origin," was met by a storm of criticism. A great many experiments have been made, and in every case where properly conducted, have supported our conclusions. The second conclusion which we first published, and have continually repeated, is "that soluble phosphate is not superior to insoluble phosphate to the extent that is generally supposed." We are obliged to keep these conclusions in the foreground, and to show by our experiments year by year the evidence in support of them, because it is felt that great difficulty arises (attendant on their acceptance) for more than one reason. We have to contend against the teachings implanted during a generation; a tendency of the masses to be carried away by floods of plausible words; the custom of farmers to imbibe their notions of manures from manure dealers, and the opposition of manure dealers or manufacturers, although I am bound to say that, regarding the last, no difficulty has been felt in this neighbourhood, as all the manure manufacturers in this town and district have been most eager to assist in every way the work of the association. (Applause.) I am pleased to see that they are an eminent exception to the trade in other places. When we consider the enormous amount of money which has been taken from the farmer by the erroneous doctrine that insoluble mineral phosphate has little or no effect on plants, the necessity is seen for repeating yearly the important words in the second conclusion we originally arrived at. The additional drain upon the farmers by reason of the other error of ascribing to soluble phosphate twice the manurial value of bone phosphate enforces us to publish and republish the fact that we find yearly the superiority is on the average only about 10 per cent. I hope that on some early day a general acceptance of these facts will be adopted, and until such time we must continue to repeat our conclusions, and to add our proofs.

"On the 29th of November last we carried out the following experiments:—First of all 600 turnips were left in the land as they grew without any protection. I need not say that when these were taken up on the 26th of March this spring they were all rotten. Secondly, a row of 600 turnips was furrowed up with the plough in the usual Aberdeenshire fashion, and when taken up about 83 per cent were rotten, or about five rotten to one whole turnip. Thirdly, we tried what I might call the Forfarshire system, by opening a furrow with a single-boarded plough; two drills of turnips pulled, without anything cut from them, were laid against the perpendicular side of the furrow, and the soil turned back over them with the plough. Of these, about 28 per cent. were destroyed or rotten, but of the good turnips many were wet and dirty. Fourthly, we opened a deep furrow with a double-boarded plough; the turnips were shorn of leaves with the scythe, harrowed out, and eight drills put into the furrow. They were partly covered by one round of the single-boarded plough, and the remaining uncovered portion covered with earth by spade. Out of these 600 turnips about 16 per cent. were destroyed, but they did not come up quite so clean as they should have done, or as those in the next experiments we tried, and which I may call the English way, which was putting the turnips into pits. I had three different pits, about six feet square. Into No. 1, 600 turnips, as they were pulled, without anything cut off, were thrown. This is the ordinary way I have seen it done in Huntingdonshire since I was a boy. In the next the 600 turnips had the leaves cut off; and in the third pit, they had the leaves and the roots cut off. The pits were 3 to 4 feet high, and each contained about 1½ cart loads of turnips, and were covered with 4 inches of earth. In No. 1, there were 552 healthy turnips, out of the 600, and 48 destroyed, or 8 per cent.; in No. 2, there were 550, and 50 destroyed or 8 per cent.; and in No. 3, there were 570, and 35 destroyed, or 6 per cent.; and the great advantage was that the bulbs were healthy, clean, and dry. Now, I cannot say how deeply important I think these facts are to the Aberdeenshire people. At a very slight cost, by throwing these turnips together and covering them with 4 inches of earth, you can get them comparatively healthy after four months' time. After paying a high compliment to the ability of the Association's chemist, Mr. Jamieson, the noble Marquis concluded by moving the adoption of the report.

Mr. J. W. Barclay, M.P., in seconding the report, said the experiments carried out in Aberdeenshire had been watched with the greatest interest in England, and he was sure that in one form at least agricultural depression would be met by the increased information which that and such like Associations were collecting. The more of these stations throughout the country with the view of eliciting information on certain definite points the greater advantage would it be to them and to the whole community. It must be gratifying to the subscribers to the Association to see that they had entered upon a very good work, and that the work they had done so far had been so appreciated that their example was to be followed in other parts of the country. He should hope that the Government might be able to see its way to do something for this branch of scientific investigation. No doubt there were great difficulties connected with it; but if the Government was going to aid agriculture in any way, he did not see how it could do it more effectually than by some system of scientific investigation akin to what had been carried on by that Association. He had much pleasure in moving the adoption of the report. (Applause.)

PLANTING IN SINGAPORE.

The planting interest in Singapore is reviving, and we are glad to find that the growth of tapioca has rewarded the enterprise of those who embarked in it. The extraordinary failure of the nutmeg trees some twenty years since discouraged Europeans from planting them. Such was put down as worthless. It is due to Mr. Chassariau that he has demonstrated the capability of the land. Some ten years since he purchased from Government about a thousand acres of land at $1·75, and subsequently Sir Andrew Clarke made him a grant of two thousand acres in order to show his appreciation of the efforts and success of his planting. There has unfortunately been some difficulty in giving possession, and up to the present time only eight hundred acres had been made over. We believe that the Government allege that they have no more land in the locality, and offer some in a different part of the island at terms differing from the original grant. This is an undignified proceeding, and hardly accords with the service rendered by M. Chasseriau, which was duly appreciated by Sir Andrew Clarke. The extent of the estate is about 2,200 acres, with about twenty-six miles of road. The yield is about 15,000 piculs for the year, the market value being about $5 per picul. Next year will probably yield 20,000. It is chiefly exported to London and Marseilles. The retail prices are enormously out of proportion, being about 300 to 400 per cent. in advance of the import prices. This naturally checks consumption, and does an injury to the planter. The improved machinery made by Messrs. Dalbonze, Paris, which has lately been laid down, can produce 100 piculs

per day. The Brazilian plant has lately been introduced and its yield is some 20 per cent. more than Straits, or Java. The coolies are Chinese and Javanese who are free, and are engaged on daily wages. The position of the estate as extremely pretty, and the barometer ranges four to five degrees less than the town. Messrs. Putfarcken, Reiner and Co., Singapore, are the financial general agents for the estate.

Another enterprise is that of the Trafalgar Estate, under the management of Mr. Knaggs, who is a part owner with Messrs. Maclaine, Fraser and Co. This estate has been opened a little over two years. The present area under cultivation is about 1,000 acres, out of a total of 2,000, and the yield at present is about twenty piculs per acre. The machinery is capable of turning out about sixty piculs per day. Great attention is paid to the forming and manipulation, and the highest prices are thus obtainable. The number of men employed is about 300 to 400 Chinese, and Javanese, at 17 to 20 cents per day wages. Mr. Knaggs is an old planter in the West Indies, and has been some years in Province Wellesley.—*London and China Express.*

CEYLON PLANTERS, when they are inclined to grumble, ought to think of the extremely hard times experienced by farmers and *proprietors* in the old country. We refer to a woeful account of farming prospects in England given in the *Pall Mall.*

AUSTRALIAN MEAT AND FLOUR BISCUITS.—We have now circulated in the Fort and among the Planters at their General Meeting some of Messrs. Swallow & Ariell's "Beef Biscuits" and we shall be glad to have opinions of their value.—A merchant writes :—"I consider the Australian Beef Biscuits a palatable and wholesome food. They would, I think, be found a useful and agreeable addition to the provisions of the jungle traveller. A few crumbs taken from one of these biscuits and moistened with water, will, when placed under a microscope, exhibit small bundles and shreds of muscular fibre."

MANURES AND MANURING.—In another place will be found an interesting letter from a gentleman whose relative in South America shews the way in which fertilizing substances can best be procured direct from the source of supply in Chili and Peru. We fear the Ceylon planting industry cannot at present face the commencement of an enterprise of this kind, but we trust the day is not far distant when we shall see vessels carrying cargoes from Valparaiso to Colombo. There will also be opportunities then for procuring plants and seeds of cinchona as well of other new and valuable products. The paper from the *Field* on the various substances commonly classed under "Lime" by the cultivator, their nature and uses, is full of interest and instruction.

COFFEE.—A few weeks ago, we alluded to the prospects of coffee in the Shevaroys and stated that the present season was not likely to turn out favorable, owing to the scanty fall of rain at the proper time. We hear that a slight change for the better has taken place in the condition and prospects of coffee in the Shevaroys, but further advices are awaited. From South Coorg we learn that coffee propects there are favorable, and that owing to seasonable showers of rain the estates in many parts of South Coorg look promising, and planters expect a good crop, which, if they secure, will make up, to some extent, the loss they suffered last year, when the season, though it looked very favorable at the outset, turned out a very disappointing one. The weather at the date of our advices, 3rd June, portended rain : the south-westerley winds had set in, but the rains had not made their appearance. The fall of rain in South Coorg from 1st January to 2nd June was 10·96 inches against 9·81 inches in the corresponding months last year.—*Madras Standard.*

TEA AND COFFEE.—The *Rangoon Gazette* says :—"Tea is not the only article which will succeed in India and Burmah ; we have Coffee thriving well in many a gentleman's garden here, one party having to our knowledge kept himself supplied for about a fortnight with the produce of a few coffee shrubs in his compound. As all varieties seem to thrive even in the heart of Rangoon, they should yield large crops on the Karen and Arakan Hills ; in fact in any place where there is high ground. We are glad, therefore, to hear that a gentleman of Akyab has undertaken the cultivation of Mocha Coffee, and we hope every encouragement may be afforded to him. In the latest published official report (September) from the Amboyna residency, it is stated that coffee cultivation is extending there, more than 200,000 coffee plants having been set in the ground in one month in a single district. The Rajahs of Lesser Ceram have also given permission to introduce this cultivation there. In the islands of Ceram Nusa, and Haruku, the coffee trees looked well and were bearing heavily."

ADEN CATTLE.—A paper published by the Madras Government contains a report from Mr. W. R. Robertson, Superintendent of Government Farms on the experiment begun at the Saidapet Farm, in 1874 in breeding and rearing cattle of the Aden breed. In the Annual Report of the Farm for the year ending 31st of March 1874 Mr. Robertson stated that with the view of effecting some improvement in the cattle of the district around Madras it was intended to import a few animals of the Aden breed. He added:—"The Adens have a high reputation as dairy animals; the name Aden by which they are distinguished has probably originated from Aden being the port from which cattle of this breed are generally shipped, they are not found in the neighbourhood of Aden, but are brought from districts situated at considerable distances from the coast. They are small animals, and the bulls of the breed are therefore better suited for use in the early stages of experiments, in improving the breeds of small cattle generally found in Southern India, than are bulls of the Nellore and Mysore breeds, which in some instances have been used for this purpose." In June 1874 the cattle arrived at Madras. One of the cows died during the voyage ; the remaining animals, consisting of one bull, one cow, and two calves, reached Madras in safety, but were all much out of condition when landed. The cost of the stock in Aden was R208·14-0, and for their conveyance, &c., to Madras the charge was R630 12-0, making the total outlay on account of this importation R839-10-0. Mr. Robertson was disappointed with their appearence, but subsequent events proved that they were more valuable then they looked. In the four years 1877-80 the cow gave birth to four calves, and during all that period careful statistics were kept of the quantity of milk yielded in addition to that consumed by the calves, the average monthly yield being about 75 Madras measures. The milk was excellent in quality, 16 to 17 pints yielding one pound of butter. From May 1877 up to nearly the end of December last the total yield of milk was 2,910 measures, or 1,091 gallons, and during this period the cow reared four calves. The food of the cow was daily 4 lb. of groundnut oil cake, 2 lb. of wheat bran, 30 lb. of green fodder, ½ oz. salt. These are now at the farm of the Aden breed five bulls, one cow, and three heifers. The bulls are in considerable request for use with the small cows of the neighbourhood. They are regularly employed in farm-work carting, ploughing, &c., and are remarkably docile and steady at work. The result of the experiment has been so encouraging that Mr. Robertson asks sanction for the expenditure of a sum not exceeding R1,200 in importing a fresh supply of the cattle from Aden, say two bulls and four cows with calves.

Correspondence.

To the Editor of the Ceylon Observer.

"CINCHONA *VERSUS* LARCH OR ANY OTHER PLANTATION?"

DEAR SIR,—In reference to that letter of Mr. McCall's from Hamilton, concerning the cultivation of cinchona in Ceylon, I may be allowed to make a few remarks on the treatment of forests in Scotland, as compared with cinchona plantations in Ceylon.

I have advocated for the last three years that cinchona will grow as well, if not better, more closely planted than what we are doing at present.

We are endeavouring to grow trees, "and not bushes;" by so running them up good clean stems will produce a greater amount of bark.

Trees that are grown for timber in Scotland are generally planted 2½ by 2½ feet and 3 by 3 feet; often a mixed plantation of Larch, Beech, Ash, Elm, Oak, Scotch Spruce, and Silver Firs. But a great deal depends on the locality and condition of the soil in planting a mixed forest. All the inferior trees are partly thinned out after the tenth year, and again when necessary. In a well cultivated plantation the grass and natural plants are always kept down, until the trees are strong enough to choke them out. As the trees grow up, all herbage gradually disappears.

Who has not roamed through the forests, under shade of fine trees, and found the ground covered with nothing but vegetable mould, decomposed leaves and twigs. Why mention a larch plantation? Since the disease has been so bad among the larches, foresters have found out that in planting a forest of mixed trees the larch trees grow better and are not so subject to that fatal disease. I would advice, all those planting cinchonas "to plant close," and as the plantation comes on, thin out all the straggling and weak trees: little pruning would then be wanted, in removing strips of bark, no shading or moss is required, and very few weeds will grow after a time. In fields where the cinchonas begin to die out in patches, "as if from dampness," a few more drains should be cut, and the plants stuck in thick, about a foot apart.

I do not advocate leaving the weeds and only cutting them down occasionally. Keep your plantation clean, if possible. In planting timber trees in abandoned coffee land or for wind belts, "plant close," the one tree will protect the other. Go wherever you may, you will find that close planting is always carried out in growing timber trees, and the same will hold good for cinchona. We grow timber which gives us bark. Planters feel the want of advice on arboriculture, not having a practical forest department in the Island. If Mr. McCall will pay a visit to Perthshire, he will find a great deal to interest him, in the fine forests of Dunkeld, Scone, Dupplin and Taymouth,—I am yours,

AN OLD MEMBER OF THE SCOTTISH ARBORICULTURAL SOCIETY.

CEYLON TEA AND THE AUSTRALIAN MARKET.

c/o Messrs. R. Scott Johnson & Co.
15 Government Place, East, Calcutta.
May 23rd, 1881.

SIR,—I am tempted to drop you these few lines on a subject of great importance to the Ceylon planting community, and Ceylon trade in connection with Australia. I am well-known in the Bengal presidency and also partially in Madras, as having been of old days connected with the Indian Press; and for many years past I have made Australia (New South Wales) my home, and been also in several of the other colonies. As I feel and know that I have something essential to say on the *Tea trade* which you wish Ceylon to open up with Australia, you will excuse my addressing this letter to you, and the Ceylon public through you.

Being a late arrival from Australia, I was aware while there, of the efforts made (by you) to give the budding trade a fair start; and my attention was again drawn to the subject by a planter, as I passed through Galle.

I have tasted Ceylon tea, and am familiar with Indian teas, having been on the seats of their production in Assam, Cachar, Kangra, and other parts; and I have no hesitation in saying that your Ceylon tea carries off the palm in flavour and body from nineteen-twentieths of Indian teas; and in fact, for its price, ranks as the best of the teas we have anywhere.

Such being my deliberate judgment, and I have no mean knowledge of the subject—even of China teas from the variety made for the palates of Emperors and Shahs, to the beastly rejections so largely exported to Australia—I should heartily, as a great tea-drinker, wish to see good tea make its way in the world; and as an Australian, wish to see Ceylon tea supplying the half-a-crown and even three and six pence *stuff* so common in the great southern continent.

But permit me to say that however praiseworthy valuable your *introduction* of Ceylon tea to the notice of Australia was, during the late Melbourne Exhibition, as an Australian who knows Australia well, and how things are managed there, that a great deal and indeed every thing is now needed really to *establish the trade.*

If nothing now be followed up as I indicate below, Ceylon tea will be forgotten in a few months in Australia, even if there be kept up a small shop for its sale in Melbourne, or Sydney, and there appear an occasional advertisement.

You must be a young and inexperienced man indeed if you think that where old interests are concerned (in this case of the China tea merchants) and the field fully occupied, a new article can be made to make its way into popular favour by the mere force of its being the best. I know all the obstacles in the way of Ceylon tea supplanting Chinese teas in Australia, and it is because I know them, and the way to go about in the matter, and am convinced that if my plan is adopted that Ceylon tea will be the favourite with high and low in New South Wales and Victoria, that I take the trouble to write this, and even offer to carry it out.

First and foremost, then, you can do nothing in Australia—at least you will do nothing in this matter, without an active, energetic, practical travelling agent, or as we call it there, commercial traveller. He must have some standing among and knowledge of the merchants, as well as know Australian ways and manners, especially among the tea-grocers and suppliers, well.

Then, with this knowledge, and those abilities, with earnestness, if he is "worth his salt," he will in at most a couple years be able so to start the trade that, with ordinary attention thereafter, it will continue to grow and expand.

There ought to be one agent for New South Wales, and one for Victoria; for the field of country is very large, and probably as much change will be brought about through the medium of the large numbers of store keepers (tea-sellers) in the interior (and there are numerous towns in the interior) as through the merchants and tea-importers in Sydney and Melbourne. Of course, a small shop in a very prominent place, will have to be kept in both localities. This would, however, for two agents entail a

double expense, which will probably come heavy on your tea-planters. Or the plan of *one* energetic agent may be adopted for both Sydney and Melbourne, only the two capital cities, with an occasional run into the interior. *Or*, one agent may be appointed for only New South Wales, the Colony best adapted for the purpose, and should the trade take root there, then Victoria be afterwards taken in hand. These last two plans would entail only, with *one* agent, a *single cost*.

I think I have detailed enough, without being too prolix; and I am ready with both my knowledge of tea, and practical knowledge of Australia and the subject, to place all my services heartily at your disposal to ground and establish the trade in tea of Ceylon with Australia. I am sure of success.

But of course for such an end the tea-planters of Ceylon must unite and form a Syndicate as in India, and I must enter into a regular engagement with their recognized managing agents in Colombo, who ought to be one of the leading and most respectable firms there.

In my case personally, for I cannot answer for the cost of the services of others, the expense would amount to about £600 per annum for a period of two or three years, as salary £300, as travelling expenses and room rent £300. I am convinced the thing could not be done for less with any agent worth entertaining. After the above period, the trade being better known and grounded, the travelling expense may be reduced. A small commission over sales above a certain quantity may be added as an additional incentive to effort.

My plan is now before you and your planting readers. They may be sure that no other will succeed, and that if the trade be not now established at the beginning it never will. They require to be united, and contribute only a very small fraction individually for a short period of say 3 years to see what may be done. Of course everything will depend on the ability, energy, and thorough Australian knowledge of the agent.

I have done, and you are at liberty to communicate my address to those who may wish to bring the subject to a practical issue.—Yours truly,

ALEX. MACKENZIE CAMERON.

[It is not likely that Mr. Cameron's proposal will receive attention for the present at least: one reason being that Ceylon has already half-a-dozen agents at work in the Southern Colonies: Messrs. Jas. Henty & Co. promise to do all they can for Ceylon teas; Messrs. Poett and Heury have advertised themselves as Melbourne agents, and Mr. Rowbotham is doing something in tea in the same place. Mr. Hector Mackenzie is working hard and successfully to bring Ceylon tea into notice in New Zealand. Another planter is likely to start for Adelaide, there to establish himself as a Ceylon agent, and an enterprising Colombo merchant has just started for Brisbane and Sydney to see what can be done in the Colonies, of which they are the capitals. All these gentlemen look to their commission for remuneration, and there is therefore no chance of the Ceylon tea planters pay-£600 a year for a special "commercial traveller" of their own. Far better would it be to join the Calcutta Syndicate and get Ceylon teas introduced into America and other new countries under its auspices.—ED.]

SALT has been used most successfully in the cultivation of onions. It is said to expedite the growth of the onion while it destroys or weakens that of weeds, and does a great deal to ward off the attacks of insects. Grubs and wire worms cannot be destroyed by this agency without using it in such quantities as also to destroy vegetable life.—*South of India Observer.*

AGRI-HORTICULTURAL SOCIETY OF INDIA.

At a meeting held on the 26th May last, the following from Clements R. Markham, Esq., C. B., dated London, 27th March, in reply to an application for seed of Cuzco Maize and Quinua seed for trial in the Himalaya, as suggested by Captain Pogson was read:—"A good supply of quinua seed," writes Mr. Markham," "was sent out to the Government of India in 1874, which I obtained through Messrs. Antony Gibbs & Sons of Lima. Mr. Hume said it was *bathu*, but this is a mistake, *bathu* is the "Chenopodium album" of the Punjab, which grows on the plains, and is not a hill product. Quinua is the "Chenopodium quinua," which is cultivated at very great elevations. I suppose the Government gave a portion of the quinua seeds sent out, in 1874, to the Agri-Horticultural Society of India. [The Society did not receive any.] I trust this was so for I fear that, in the present state of affairs in Peru, it will be difficult to get fresh supplies for some time to come. All the chief ports are occupied by hostile Chilian forces, there is no communication with the interior, and many of the merchants have left. It is quite uncertain how long this will last, but I will bear in mind your wishes both as regards Cuzco Maize and Quinua. Meanwhile I will consult Messrs. Gibbs as to the prospect of renewing communication with the interior of Peru."—*Pioneer.*

AUSTRAL-INDIAN FRUIT TRADE.

The experiment that is about to be tried in Australia, of endeavouring to establish a trade with this country in fruit, is one that will have a direct interest for a large number of Anglo-Indians. Few stations, indeed, are so well off in this respect, that the prospect of a good and varied foreign supply—if it could be obtained at a reasonable cost—would not be most acceptable. Excepting for the brief season when the mango and lichi are obtainable, and the few places where, when obtainable, they are good, it must be confessed that the Mofussil has not much to boast of in the way of fruit. The tasteless water-melon, the sickly guava, pachydermatous oranges thick of flake and innocent of juice, dry pomegranates and woolly custard-apples, to omit the commoner abominations of the country, are not these the total resources of an ordinary Indian garden? In Australia on the other hand, thanks to the admirable climate, English fruits have thriven as well almost as English rabbits; so much so, that the excellence of the display in this branch of horticulture is said to have been a feature of the Melbourne Exhibition. It is not singular, therefore, that Mr. Buck, the zealous pioneer of Indo-Australian trade, should have suggested that out of their superfluity, the Australians might turn their attention to supplying India. It is stated that Mr. Buck has been in communication with the Horticultural Society of Victoria as to the quantity of fruit available for export, and as to the prices at which it could be supplied. The Society seem to have entered into the idea very heartily; and some of the leading growers have already inaugurated the trade by sending presentation cases to the Viceroy and to the Lieutenant-Governor of Bengal. It would, of course, be premature to offer a conjecture on the prospects of success, until something is known of the prices at which it will be possible to offer the Australian produce in this country. The market, we should fear, would at first be very limited; and unless it is carefully managed at starting, there will be little chance of any great extension. Were it not for the example of America, there would be a difficulty in believing that fruit conveyed from such a distance could ever be anything but an expensive luxury. As it is, however, there seems to be no reason why Melbourne pears and Tasmanian grapes should not enrich Indian dinner tables, within a month of their being gathered from the parent tree.—*Pioneer.*

CINCHONA CULTIVATION :
QUININE AND CINCHONIDINE.

We give special prominence to the extract from the letter of a Java planter which Mr. E. H. Cameron is good enough to send us. His correspondent is in constant communication with Mr. Moens, and writes therefore with all that gentleman's authority. The fact that there is an age beyond which the cinchona tree seems to cease to add to its bark, or at any rate to the secretion of the more valuable alkaloids, has been already pretty well understood. No doubt we have a great deal to learn in reference to the age at which this stage is reached in different countries, and, indeed, at different elevations with varying soils and climates. The further fact that at a certain period trees containing cinchonidine begin to increase the secretion of this alkaloid at the expense of the quinine is a discovery closely affecting the possessors of Ledgeriana and other valuable types. It is evident that trees containing no cinchonidine never lose their richness in quinine. But Ceylon must do a great deal more in analysis as a guide to the planter before the latter is able to discriminate between his trees in the same way that Mr. Moens does in Java. Nevertheless, it is of importance to follow, step by step, the very valuable discoveries of him who certainly stands first in the scientific cultivation of cinchona; and not his least contribution to our knowledge will be this discovery respecting the reason why quinine is diminished in trees after a certain age. The letters are as follows :—

To the Editor "Ceylon Observer."

SIR,—I have just received a letter from Java containing information important enough to be of great interest to those of your readers who are interested in Cinchona. The writer speaks with authority, being the largest private grower of Cinchona in Java, and also having the advantage of exchanging ideas with Mr. Moens almost daily.—I am, &c.,

Agra Patana, June 18th. E. H. C.

(*Original, verbatim et literatim.*)

Mainteuant encore quelque chose pour la connaissance de kina, specialement de Ledger. On sait déjà depuis quelque temps qu'il y a dans les barques quelque rapport entre le chinine et le cinchonidine; par exemple renewed bark de succirubra ou officinalis *perd* en cinchonidine et *gagne* en chinine, monte donc en valeur. La plupart des Ledgeriana n' a pas de cinchonidine, cependant il y a aussi, qui en ont, même de très riches. Mr. Moens a trouvé ça toujours un mauvais signe; il préferait *p. e.* une barque de 8 % sans cinchouidine, toujours à une barque de 10 % de chinine avec 1 % de cinchonidine;—et ça surtout pour la semence, il le croit un signeque l'arbre est un peu bâtard. Son opinion est maintenant bien constaté. Mr. M. a analysé pour la deuxième fois quelques arbres primitifs (maintenant 14 ans), qui étaient analysés à l'âge de 8 ans. *Tous* les arbres sans cinchonidine ont maintenant encore juste le même contenu de chinine; les autres ont *perdu* de chinine, et gagné de cinchonidine, donc perdu en valeur. Un arbre, qui avait dans le temps 10·7 % de chinine avec un *peu* de cinchouidine a maintenant seulement 7·5 % de chinine et 3·4 % de cinchouidine.

Fiez vous donc un peu de toût, qui a de cinchonidine; c'est au moment peut être bon mais ça devient mauvais. Des autres alcaloides, *quinidine* est *bon*, a même une assez grande valeur; *cinchonine* ne vaut rien, mais ne nuit pas.

(*Translation.*)

Now some more facts on the subject of cinchona, especially Ledgeriana. It has been known for some time that there is in the "barques" some connection between the quinine and the cinchonidine: *e.g.* "renewed bark" of succirubra or officinalis *loses* in cinchonidine and gains in quinine, the value therefore increasing. Most of the Ledgerianas have no cinchonidine: there are, however, some which contain a little, even very rich ones. Mr. Moens always looks upon that as a bad sign, and would always prefer *e g.* a "barque" of 8 % without cinchonidine to a "barque" of 10 % of quinine with 1 % of cinchonidine: and this especially for seed,—as he thinks it a sign that the tree is a little hybridized. His opinion has now been confirmed. Mr. Moens has analyzed for the second time some original trees (now 14 years old) which were analyzed at the age of 8 years. *All* the trees without cinchonidine have now exactly the same amount of quinine; the others have *lost* in quinine and gained in cinchonidine, and therefore lost in value. One tree which had at that time 10·7 % of quinine with a *little* cinchonidine has now only 7·5 % quinine and 3·4 % cinchonidine. Therefore, do not reckon too much on any that have cinchonidine: it may be good at the time, but it will become bad. As to the other alkaloids, *quinidine* is *good*, is even of some value; *cinchonidine* is worth nothing, but does no harm.

CINCHONA LEDGERIANA SEED AT £236 PER OZ.—Some people in Java think Ledgeriana seed worth not a little—£236 an ounce! Such is the tenor of a mercantile advice which states that for a small quantity of Calisaya Ledgeriana Cinchona seed of a superior kind from trees of a good age, the bark of which has been chemically tested, as much as 100l. (£8·6·8) per gramme of 3,000 seeds is asked As the ounce contains 28·34 grammes, this is at the rate of £236 per ounce!

VICTORIAN APPLES.—The two small cases of Victorian apples sent forward by the P. & O. steamer by the Ceylon Commissioner as a trial shipment arrived here to-day. One case was for His Excellency the Governor. The other contained, packed with tissue paper in two compartments, about 130 apples of different varieties. Out of this number 30 (or 25 per cent) were quite bad; and half as many more nearly so. Out of the remainder we are making a distribution in the Fort as well as we are able, so as to give business men some idea of Victorian apples. What are good—say 60 per cent—are very good: palatable and of fine flavour.

THE SALES OF CINCHONA BARK reported by this mail are chiefly noteworthy on account of the 9s per lb. paid for one case of fine crown renewed from the Nilgiris with the well known mark "W. R. A. Prospect." For good medium quill 5s 7d was bid, but not taken. For red bark, bold mossed quill, 3s 9d paid. Some of the "Price Currents" wrongly put the Prospect bark down as Ceylon. The highest price got for Ceylon bark at these sales was 4s to 4s 3d for bold chipped quill crown, 4s 3d being bid for the root bark but not taken. Messrs. James Cook & Co. have the following remarks on our bark:—The 264 packages offered, went off slowly without change in prices, the principal mark sold was a good shipment of Hamilton, which, being bark of a nice character, met with competition at full prices, good and fair quill, although mixed with some weak branch and a little coarse growth stem, fetching 3s 9d to 3s 10d; the more broken quill sold at 2s 6d, weak and papery branch 1s 9d, and good twigs 6d. 17 bales root, however, of the same mark realized but 2s 1d, and 3 cases 2s 2d. Of 94 bales Frotoft, chiefly crown, weighing 24,000 lb., about two-thirds sold at 3s 6d to 4s 3d. GA Ouvah red very bold trunk and stem 3s 3d per lb.

Correspondence.

To the Editor of the Ceylon Observer.

CARDAMOM PLANTING.

DEAR SIR,—It has hitherto been the custom to plant single cardamom bulbs taken from old bushes. It struck me sometime ago that, as the object was to grow a good bush, a simpler plan would be to put several plants to a hole. I found that it has succeeded admirably. Even seedling plants three to four inches high can be safely put out during the heavy rains. Three to four plants to a hole, and each plant nine inches apart from the others. The young plants throw out several shoots in a few months, and the result is a magnificent bush in a year. The old method is a slow, tedious and far from a profitable one. The present prices for cardamoms, *properly gathered and cured*, are really very handsome, and should they even go down to a third, the return from an acre of cardamoms is more profitable than coffee yielding two and a half cwt. the acre. The planting out of this product should be vigorously carried on. It requires a very small outlay comparatively, if the method of planting as above suggested is followed.

R. S.

MANURING; WHY NOT IMPORT RAW MATERIALS FOR SPECIAL MANURES (AND ALSO CINCHONA SEED) DIRECT FROM SOUTH AMERICA?—MANURING WITH LIME AND GYPSUM;—ENEMIES OF COCOA.

SIR,—The enclosed extracts are taken from a letter recently received from South America. The writer is professionally acquainted with analytical and agricultural chemistry, and I send them, as they may possibly interest some of your readers.

I notice that nitrate of soda and guano form two of the chief ingredients in Mr. Ross's Venture manure. Judiciously used, they are doubtless valuable fertilizers, and I should say it would be advantageous to import them direct, both as regards purity and cost, judging by figures supplied me.

As regards potash, the remarks thereon are in reply to a query as to whether there is no simple and cheap means of extracting some from rock? Given this, and the island need not look elsewhere for a cheap and abundant supply of a substance of more manurial importance here probably than any other, judging by the analysis of tea and coffee. And it is a curious fact that cinchona bark from trees growing in a soil naturally impregnated with it, though very young, has shewn an unusually high proportion of quinine. Much of Ceylon soil is, I fancy, rather deficient in potash, but in many places large quantities of felspar exist, containing as high a proportion as 13 to 15 per cent., and much of it will be found in an already partially decomposed state from the action of the atmosphere. When the rock does exist, it might possibly be turned to good account, by crushing, as indicated. But the cost of transport on so large a proportion of useless matter would, I fear, render its removal to a distance prohibitive. Pure potash realizes £40 to £70 per ton, and were a feasible process discovered for extracting it manufacturers here would not be dependenit on a local market only. That it has not yet been hit on seems rather contrary to the spirit of the 19th century; and that *practically* science must so far confess itself unable to assist nature in the matter. At present, the whole supply, or nearly so, of purified potash is obtained by the somewhat barbarous and certainly wasteful process of reducing immense quantities of pine wood to ashes in Canada.

Whilst on the subject of manure, a very interesting article appeared in the *Field* of April 23rd on lime and its effect under its different conditions and combinations; and the different conditions of substance treated. There is an equally interesting letter in a previous number (April 16th) on gypsum.

Quick and slacked lime too, it would appear, if applied to undecomposed vegetable matter, will fix the ammonia, or at any rate will not force it; but where the slightest decomposition has set in, it does so at once and wastes it!

This being so, has not the chief virtue of many a fine heap of manure, possibly representing a large outlay in cattle establishments, been unwittingly destroyed by its admixture? And has not the effect to a more limited extent been the same where applied broadcast as a check to leaf disease or as manure, a proportion of the leaves which it may have reached, being at the time of contact with the lime in a partially decomposed state? Where manure heaps have been at once covered with earth, or the leaves and lime buried together, the earth covering will doubtless have prevented loss by absorption. Gypsum on the other hand, without a single drawback, seems to possess all the merits of lime, and more, as a manure, and at the same time the power, not only of fixing all the ammonia in substances it is applied to, but of absorbing and holding it from the air. The best results, it is said, may be secured by mixing it with other manures, natural or artificial—a mixture of gypsum with crude phosphatic and nitrogeneous manures being probably preferable to superphosphate of lime. Its effect on foliage when applied to the leaves after a slight shower of rain or dew, so that it can cling to them, is said to be very marked; and eventually, as the sulphur becomes liberated, it acts beneficially in destroying fungoid growth of all kinds. Surely such a valuable material as it would appear to be deserves more attention than it has hitherto received in Ceylon if price permits. The English price is quoted at 10s to 15s per ton only!

The cinchona referred to in the letter from South America is in the same part of the country that Ledger procured his seed from, and I fancy are varieties of calisaya. Whether the 6 to 7 per cent mentioned means total alkaloids or quinine only, I cannot at present say, but should seed be procured, it will be from analyzed trees. Now that the war has terminated so entirely in favor of the Chilians—always well spoken of, and as a comparatively energetic, progressive people—rapid development of the resources of the country may be anticipated. But I gather this at first will more be as regards the unearthing of its mineral wealth, which from accounts that have reached me from time to time must be immense, more particularly in silver, equalling Mexico and Colorado! The conclusion of peace will, however, I suppose, give a fresh impetus to bark collecting.

C. R.

P.S.—As a protection to young cocoa, &c., against white-ants, has chloride of lime been tried here? In a north country paper, a gardener states that a prior application to a seed bed will keep all insects off, and if a rag steeped in it be tied round a tree it will free it from attack. But whether injurious or not, if not properly used, I am unable to say.

Extracts from South American letter.

I have talked over the matter of nitrate with a friend, whose note I enclose. To re-ship nitrate from Liverpool or England would hardly answer. There is nothing to prevent a ship being freighted direct from this coast. The doubtful point on that score is the freight, if any, a ship might expect from Ceylon elsewhere.

It would be necessary on both sides that a business

of this kind be worked through a commercial house, of course, of good standing. I could make some arrangement with the enclosed or any other house, and get them to ship a small cargo of suitable nitrate, but the enterprise must come from your side, as many have been the disappointments here in shipping to markets where the article has lingered unappreciated.

The plan would be: along with a good house for your friends the planters, &c., to get a small cargo of say 600 tons taken up between them. I believe that from a proper application of the material they would reap nothing but benefit. It must be administered in the main only as a stimulant. But in a so-called unrefined nitrate, which I would prefer to send, there would be the advantage of the traces of iodine, &c., &c., which must long have been washed out of your upper regions, and which nature might find some subtle use for.

Rather than send a whole cargo of nitrate of soda, I should advise, say, half, in some phosphatic guano. This, mixed with a proportion of nitrate, would make an ideal manure, and especially with you, where your product draws heavily on the phosphorus in the soil. There is no better form in which to apply phosphoric acid than in these guanos. From the fine state of subdivision, the plant can assimilate as much as it requires and the rest remains. As regards the sale of guano, there should be no doubt, if the price can be kept at all within the mark, as no doubt your owners of land are well aware that money so spent is so much on the value of the land, for some years to come.

Have you any traffic in phosphoric manures in the island, by which I can reckon what you are in the habit of paying for phosphoric acid? You ought to have some sources of phosphoric acid of your own, in the shape of mineral phosphates, or antediluvia bones. Are they looked after?

You mentioned felspar as abundant. If it is *orthoclase* it might have a value for the potash it contains (a much as 10 or 12 per cent in a pure specimen. That would be supposing you had a cheap water power, by which to reduce it to impalpable powder. In that state, with the help of the carbonic acid of the air and rain, the plant could extract what potash it wanted. Mixed with a little nitrate, it would become, still more soluble, and it would be a great addition to the value, if ground up with natural phosphates. From what I reckon, quartz crushing here, the cost of grinding &c, might be 10s. per ton.

Now-a days, I observe that fine grinding is being recognized as better than solution in acids for mineral manures.

How are you off for water power? There should, I imagine, be many mountain streams with falls, if not abundance of water. With 50 ft. fall and upwards, a very little water goes a long way.

Cinchona.—If I get any seed at all, I should think it would be of the best kind, but it would be more satisfactory if luck had taken me, or still takes me, that way myself.

The principal cultivator began about six years since to re-plant in the same ravines in which the trees had erst flourished naturally, and I hear with great success. He seems to cut down the fifth year's growth, replacing accordingly, and the bark gives six to seven per cent.

The property now is supposed to be worth some $800,000, but he was mixed up with Daza (ex-president,) and now I should fancy his pecuniary prospects are clouded.

There appear to be two varieties cultivated, but my impression is that more value there is thought to be in and part of bark selected than in variety.

I have had to report a good deal lately on gold mines, which are becoming the rage again. They have never as yet done well in Chili as they have been taken up with too small a capital. I am glad to see that in Southern India they are pitched at a higher scale, and with honesty in management ought to pay.

As soon as things are settled, I suppose I shall be in Bolivia again to look at some silver mines. My last trip north was interesting, as I saw a new class of nitrate deposit not before understood.

You will have been glad to read of the success of the Chilians in Lima. The army behaved admirably after the fight, and reports you may have seen as to Chilian excesses are simply untrue.

Chili is not perfect, but its people are industrious and justice is pure, which cannot be said of Peru or Bolivia.

Extracts from the "Field" referred to.

LIME AND ITS COMPOUNDS.

THE CHIEF FORMS in which lime is used in agriculture are quicklime, carbonate, phosphate, superphosphate, and sulphate of lime. I propose to offer some suggestions on the considerations which should guide our choice of the particular form of lime to apply according to the circumstances of various cases. The carbonate, phosphate, and sulphate are natural productions, but quicklime and superphosphate are manufactured commodities.

As quicklime is the simplest form, I will deal with it first. Beside the name quicklime, it is called hot lime, burned lime, caustic lime, &c.; but the single word "lime" exactly represents its composition, and and is the best term that can be used for it. This lime is manufactured from its carbonate, which exists in the form either of limestone or of chalk, and is composed of 56 parts of lime and 44 parts of carbonic acid, making 100 parts by weight of carbonate. By heating in kilns the whole of the carbonic acid is driven off, and lime is left. By this treatment, the lime having lost its neutralising acid, has become a highly active substance, exhibiting great caustic properties, and energetically endeavouring to unite with some other body capable of satisfying and neutralising its peculiarly active character. This craving is usually satisfied in the following manner. Water may be added, or if not, the lime will get it from the atmosphere, when combination takes place. In the former case it is quickly accomplished, and great heat is consequently developed; whilst in the latter a slow union goes on, proportionately as the lime can obtain the moisture from the surrounding air. When the reaction is complete, hydrate of lime has been formed, and its composition is by weight as follows: Lime, 56 parts; water, 18 parts. This hydrate is a dry whitish powder, and is soluble in water, which fact is highly important, as it will be seen that the next change renders it a body perfectly insoluble in that medium when pure. Now the carbonic acid in the air begins to act on the hydrate, and gradually but completely turns out the water, and in course of time regains its original position of union with the lime, so that now we have the same compound that we started with, viz., carbonate of lime; and the only difference is that now it is in a minutely divided state, and so can the better be acted upon by disintegrating agencies, but otherwise it is quite as insoluble as the chalk was in the first place. Therefore, to furnish plant food for *present* use, the lime should be applied before it has taken back its carbonic acid from the atmosphere.

Now, these various changes must be clearly understood if we are to know when and how to apply lime to the soil to the greatest advantage to the land and ourselves. When the lime is in the soil—suppose, for instance, in its form of hydrate—instead of getting supplied with carbonic acid from the air, it gets it from decomposing matter in the soil, and by so carrying off the products of decomposition, aids and hastens the

decay of further portions. and thus assists in bringing them into a form available for plant food. But if the lime has been long exposed to the air before spreading upon the land, this valuable property is entirely lost.

On the other hand, it is not wise to spread the lime before it has become hydrated, as, supposing there are compounds of ammonia in the soil, the lime seizes upon the acids of these compounds and sets free the ammonia, which rapidly escapes into the air; besides, instead of causing the decomposition of organic matter in a favourable manner, it would take away its water, dry it up, and tend to carbonise it and render it useless. The lime should really be shot in heaps in convenient places, and slacked in the same way as the bricklayer slacks his lime for making mortar; and as soon as it has been mixed up with sufficient water it should be covered up with earth, to keep the carbonic acid of the atmosphere away from it. After allowing it time to slack, it should be quickly spread upon the land, and harrowed in immediately. It should not be ploughed in, as it is well known that lime rapidly sinks into the soil, so that it only requires a superficial covering of earth, just sufficient to keep the air form readily reaching it. Lime applied in this way also assists in decomposing the rocky materials existing in soils, thereby liberating the alkalies and aiding the formation of nitre, which is of such well-known value as manure. In this form also, it neutralises free acids, and also renders land light and porous—sometimes, in fact, too porous for wheat and other crops requiring compact soils for their perfect development. In cases of this kind, the roller will generally be a sufficient remedy, as it is only the mechanical action of the lime, and not its chemical composition, that has caused the difficulty. Indeed, it is impossible to injure heavy land by the application of lime in any quantity, provided it is properly slacked and applied in its hydrated form. With lighter soils it is different, and if too much lime in its caustic form be applied to these, it quickly decomposes the small available quantity of organic matter which such soils contain, and uses it up in one short season. No doubt it whips up the immediate crop, but it does so at the expense of the future. To soils of this kind, sulphate may be applied as a source of lime in large quantities, without the slightest fear of injury, and, indeed, with the most beneficial results; but of this I will speak later on. With regard to the limes manufactured from chalk, it is believed by farmers that those made from the lower grey chalk give better results than the purer and whiter limes from the upper beds, and many who have had long agricultural experience willingly give a much higher price for the grey than the white. It might seem strange at first sight that a lime containing alumina and other impurities should be more esteemed for agricultural purposes than the purer article but it is no doubt these that really enhance its value. Professor Way discovered that the fertility of soils largely depended upon the presence of certain forms of double silicates of lime and alumina, potash and alumina, and ammonia and aluminа; and it is more than probable that these clay-containing grey limes hold their silica in the form of a double silicate of lime and alumina, and possibly that very form of double silicate Professor Way found to be so valuable. The value of this double silicate of lime depends upon its property of passing into the double silicates of potash and ammonia in presence of these bases respectively, and so forming compounds easily soluble in the carbonic acid contained in rain water, and in the weak organic acids with which they come in contact.

Before leaving the consideration of this simple form of lime, it may be well to mention that if it is mixed with *perfectly fresh dung* no harm will happen; but if decomposition has commenced ammonia has been formed, and, no matter what from it may have taken—whether carbonate, humate, ulmate, &c.—the lime will inevitably seize upon the acid, and set the ammonia free to escape into the atmosphere.

Phosphate of lime, such as is found in bones, coprolites, and other natural substances, is composed of lime 168 parts and dry phosphoric acid 142 parts, by weight. In this form it is a perfectly insoluble substance, the bone production being, however, more readily changed to a soluble form than the mineral. When the dairy pastures, especially of Cheshire, became exhausted through furnishing for a length of time the phosphates to build up the bones of the young stock raised on them, and also those carried away by the milk which was sold for human consumption, it was discovered that an application of bones, either fermented or ground more or less finely, produced excellent results, often entirely renovating land which had become almost useless. These effects, however, were produced slowly, as bones in their *natural* form cannot act as plant food. Whether they are heaped with earthy matter, or whether as bone dust they are applied to the soil, the subsequent action in either case is similar. The organic portion is fermented and decomposed, and the phosphate of lime is acted upon in the following manner. Carbonic acid is perhaps the most obliging acid known. It is turned out of its combination with all basic substances by the direct application of any other acid under the sun; but in the case under consideration it has a slow but effective revenge. It has such an affinity for lime that, under such conditions as it finds in the soil or compost heap, it gradually takes away one-third of the lime from the insoluble phosphate, forming with it chalk, and leaving the remaining two-thirds behind. These two-thirds are now in combination with the original quantity of phosphoric acid together with some water which has also been admitted, and the substance now formed is bi-calcic phosphate of lime, its composition by weight being as follows: Lime, 112; phosphoric acid, 142; and water, 18 Here, it will be seen, the carbonic acid has taken away 56 parts of the lime to form chalk, whilst 18 parts of water have replaced the 56 parts of lime taken away. The new body is fairly soluble, and is probably the very best form of phosphate of lime to add to the land. It is able to furnish plant food slowly but surely; it is sufficiently soluble, but it is not rapidly used up, and it feeds the plant through all stages of its growth. Agriculturists were perfectly satisfied with fermented and ground bones, until it was discovered and made known by Liebig that, if bones were subjected to treatment with sulphuric acid, a much more soluble, and, it was supposed, better manure, was obtained.

This discovery was immediately utilised by a well-known manure manufacturer, and so great was his success that other large makers sprung into existence one after another, until the industry has now become of enormous dimensions. Now many hundreds of thousands of tons of pyrites are imported annually, for the manufacture of the sulphuric acid required to make this manure. These are shipped to the Thames or the Tyne, &c., where the manure maker burns out the sulphur and oxidises it to sulphuric acid, after which the copper is extracted, and the residue then passed on into other hands for the manufacture of iron. The principle involved in the production of superphosphate is as follows. After the gelatine has been extracted from the bones, they are treated with sulphuric acid, in proportion of 196lb. of pure acid to 310lb. of bone phosphate. As before stated, this bone phosphate is composed by weight of 168 parts of lime, and 142 parts of dry phosphoric acid.

The sulphuric acid now acts in precisely the same way that the carbonic acid in the soil acted under the older system, but it does exactly twice the work of the latter, and does it rapidly, instead of by a tedious process. Instead of taking away 56 parts of

lime as the carbonic acid did, it appropriates 112 parts, forming gypsum in this case, instead of chalk, as in the former, and leaving the new compound—namely, superphosphate of lime,—to possess the following composition; lime by weight, 56 parts, phosphoric acid, 142 parts; and water, 36 parts. So now we have less lime by 56 parts, and more water by 18 parts.

The gypsum formed artificially in the manufacture of this 234 parts of superphosphate amounts to 272 parts, and the two bodies are in a state of intimate mixture, and so remain to be sold as is well understood as superphosphate of lime and some manufacturers further add large quantities of ground gypsum as a "drier." Therefore commercial superphosphate is very largely made up of gypsum. It was found that mineral phosphates, such as coprolites, might be mixed with the bones without seriously interfering with the quality of the manure, and it is now often the practice to mix equal quantities, and afterwards treat the mixture with the sulphuric acid. This has the effect of keeping the price within reasonable limits. The action of superphosphate depends greatly upon the composition of the soil to which it is applied. Leaving the gypsum for the present out of consideration, it is found that, if there are no free basic substances or carbonates present in the soil, the superphosphate is quickly dissolved, and causes rapid and rank growth; but its effects are quickly exhausted, and the plant then fails to acquire that nourishment it needs to fill its cells in the later stages of its growth.

But it almost always happens that there is more or less lime, or carbonate of lime, in the soil, and this immediately seizes upon a portion of the phosphoric acid of the superphosphate, and leaves precisely the same compound as that obtained by the fermentation of bones which compound is the mean between the natural insoluble tricalcic phosphate and the extremely soluble superphosphate of lime. This medium compound is also the form of the so-called "reduced superphosphates," which from age and contact with basic substances have lost some of their phosphoric acid; and though thereby they have become commercially depreciated in value, their practical utility has for many purposes increased. So, as a rule, after superphosphate has been applied to land, it becomes exactly similar to fermented bones, with one great difference, however, viz., that the former contains at least half its weight of gypsum; and some of the good results usually ascribed to superphosphate are due to the presence in its composition of this large proportion of sulphate of lime. Superphosphate should be applied in small quantities to turnips, swedes, &c., and to all soils that are short of phosphoric acid; but it would often be found that a dressing of gypsum mixed with bone dust and soot, &c., would be equally efficacious at a less cost.

Carbonate of lime, in the form of chalk, marl, shell-sand, &c., is sometimes used for applying to land, and in some cases it has its advantages over hot lime; for though it does not decompose the silicates, it does not use up the organic matter, and therefore is better adapted for light soils, which have not any organic matter to spare. It can also sometimes be obtained at a very cheap rate, and, where lime is dear, economical reasons may dictate its use. It is useful for neutralising free acids in soils, and so sweetening the herbage; but it is lumpy and insoluble, and difficult to deal with, and, with manufactured lime and ground gypsum at reasonable prices, chalk is not likely to be used to any extent by practical people.

Sulphate of lime is found naturally in the form of gypsum, which is composed of lime, 56 parts, dry sulphuric acid, 80 parts, and water, 36 parts, by weight. This requires grinding before is available for use, and it can now be obtained in the form of powder at a very moderate cost. The sulphate of lime is useful as plant food, whenever a soil requires lime or sulphuric acid. Lime is present in most soils, but many districts are very deficient in sulphuric acid, and ground gypsum is the most convenient and the cheapest form of sulphuric acid to apply. Where a sandy soil requires *lime*, in which case *quick* lime is objectionable, gypsum answers the purpose admirably. It is portable, easily spread, and slowly soluble, and it assists such light soils, both mechanically and chemically, in retaining ammoniacal and other manures that are applied to them. This form of lime is an excellent top dressing for clover, which requires both the lime and the sulphuric acid that it furnishes. Dry clover contains five parts in a thousand of sulphur, and only two parts in a thousand of phosphorus, so that in this case it is absolutely necessary to add a sulphate to the soil as a manure. Sulphate of lime is a capital manure for mangolds, the long red variety in particular taking away more sulphuric than phosphoric acids. It should be applied largely upon all lands where sheep and other stock are kept, as all animals require sulphur. With regard to this, Johnstone states that wool contains 5 per cent. of its weight of sulphur, and he says the wool grown in Great Britain and Ireland carries off four million pounds of sulphur annually, and calculates that to make up for this loss alone 300,000 tons of gypsum should be applied to the land every year. He goes on to say that the hair grown by the population adds fifty per cent. to these figures: and, if we consider the quantity of hair grown by cattle, horses, domestic animals, and vermin, it must be seen that if this were added to Johnstone's calculation the latter would be enormously increased. Sulphate of lime is also an excellent manure for all leguminous crops as beans, peas, &c. It should always be applied, with farmyard and other ammoniacal manures, to all crops, as it reacts with ammonia, and forms sulphate of ammonia, instead of the carbonate, and so saves a most valuable plant food, viz., nitrogen, which would otherwise, from its volatility as ammonia, be entirely lost.

By scattering gypsum daily over manure heaps, stable floors, and in closets, etc., an immense quantity of nitrogen is saved, the value of which, could it be calculated, would reach a surprising amount.

The best results may be obtained by using gypsum with guano, bone dust, shoddy, rags, soot, and other nitrogenous and phosphatic manures, and it would probably be found that a mixture of bone dust and gypsum would produce a more lasting effect at a a cheaper rate than would the application of superphosphate of lime.

Those who use gypsum as a top-dressing prefer to sow in dewy mornings or evenings, or during a slight shower of rain, so that it clings to the leaves of the plant, and they say that its effects, when it continues for some time on the leaves, are very remarkable. Morton's "Cyclopædia of Agriculture" holds with this view, and gives some striking instances of the action of gypsum in this way. To account for this, it has been suggested that the well-known reaction of gypsum with ammonia (the latter obtained from the air) takes place on the leaves, and that ammonium sulphate (and chalk) is formed; but the explanation generally goes no further. From all the evidence on the subject, we cannot doubt the truth of the general statement, but the explanation offered is not so clear. If the formation of sulphate of ammonia on the leaf produces such striking results, the inference would be that the plant takes in liquid food by its leaves, which is quite contrary to the accepted idea that gaseous food only can enter in that way. Or it might be that the sulphate of ammonia formed on the leaves would be washed down to the ground near to the stem of the plant, and so in close proximity

to its roots, and in a convenient position to be drawn in by them; or the gypsum may simply absorb ammonia, and give it out to the leaves gradually. Perhaps some of your readers who are also botanical students could throw some light upon this part of the subject. Sometimes it is useful to apply both lime and gypsum to soils at one and the same time. Where a soil is deficient in sulphates, and yet contains an excess of organic acids which renders it sour, an application of 80 per cent. of gypsum mixed with 10 per cent. of lime or 20 per cent. of chalk would be an efficient remedy. There are, however, some samples of gypsum, particularly that from Sussex, which contain 10 to 15 per cent. of carbonate of lime in their composition; and in such a case as the one under consideration, a dressing of this kind of gypsum would effectually cure the disease without any admixture of lime or chalk, and it would certainly be the most convenient and best kind to apply.

These samples of gypsum, which contain some carbonate of lime, also usually have a little magnesia and a proportion of the alkalies in combination, and these substances add in no small degree to the value of the manure. Liebig discovered that gypsum as well as lime, had the property of decomposing the alkaline silicates, thereby releasing the soda and potash required for plant growth; and Cossa found, by careful experiments, that a saturated solution of gypsum dissolved these silicates, and particularly acted upon the felspar, which yields large quantities of potash. Gypsum also mechanically absorbs ammonia from the air, and holds it until required by adjacent plants. My attention has lately been called by Mr. Gossage, of the well-known alkali works, Widness, to another compound of lime, which he has induced the farmers of that neighbourhood to utilise. It is the waste sulphide of lime from the local manufactories, and the way in which they use it is to apply as much as fifty tons to the acre in the early autumn. This crude sulphide kills all vegetable as well as insect life. It eradicates all noxious weeds and grubs, and, of course, nothing will grow for a certain period after its application. But by the action of the air, the sulphate of lime is gradually but completely converted into gypsum, in which form it furnishes lime and sulphuric acid in a mild and efficient manner for the use of future crops, and it is said that such an application as above described permanently alters and improves the whole character of the land, rendering it fertile where before it was comparatively worthless. Mr. Gossage states that at first the farmers were very reluctant to put this waste on their land at any price; but after the bolder spirits amongst them met with success in their trials with it, others came, and were pleased to pay for what they had previously considered a useless and cumbrous waste product. This also points to the conclusion that lime under certain conditions, and gypsum invariably, may be applied to soils with great success in much larger quantities than is usually the case.

Copyhold Farm, Red Hill, Surrey. W. J. KEMP.

The weather in Colombo is still hot and dry, and up-country also a break seems to have taken place—unfortunately for those who have planted out hundreds of thousands of cinchona seedlings. The rainfall in Colombo for this month has been from 1st June to date only ·43 inch.—June 24.

TEA.—*In re* joining the Indian Tea Syndicate—I think it would be a mistake, because Ceylon teas classed with Indian teas and sold for mixing purposes, for which most of the Indians teas are bought, would fetch poor prices in comparison. Where Ceylon tea has the pull is that it is a very nice drinking tea by itself.—*Cor.*

CINCHONA CULTURE: GOVERNMENT INTERFERENCE WITH PRIVATE ENTERPRISE.

We have received the following for publication from the Secretary to the Government of Bengal:—

No. 42c, dated Howrah, the 30th May, 1881.

From G. King, Esq., M.B., Superintendent, Royal Botanic Garden, Calcutta, and in charge of Cinchona Cultivation in Bengal, to the Secretary to the Government of Bengal, Financial Department.

Some unfavourable remarks having lately been made in Indian newspapers as to the competition of the Government of India in the London markets with private growers of cinchona bark, I was induced to go into the matter, and it may not be out of place if I lay the results of my enquiry before Government.

2. The tone of the remarks referred to would lead the public to believe that the quantity of bark sold by the Government of India during 1880 formed so large a proportion of the total of Indian-grown bark as, in a perceptible degree, to influence the market to the detriment of private growers. This view is hardly borne out by statistics. From the circulars of two London firms of bark brokers, I find that the total importations of cinchona bark into England during 1880 consisted of 76,074 packages. Of these, 57,560 were from South America, 483 were from Jamaica, and 18 031 were from India and Ceylon. The 18,031 packages from India and Ceylon consisted for the most part of red and crown bark, there being only 207 packages of yellow, and of these 207, all but one came from the Sikkim Plantation, while the odd *one* came from the Government Plantation on the Nilghiris. The yellow bark sent by the Government of India came into competition, therefore, with no yellow bark grown in India or Ceylon, the fact being that in no plantation in India or Ceylon, except in the Government one in Sikkim, do more than a few yellow bark trees exist. Of 17,824 packages of India and Ceylon-grown red and crown barks sold in London, 1,174 were offered by the Government of Madras. The rest belonged to private growers. Madras Government bark, therefore, came into competition with privately grown Indian bark to the extent of 6·6 per cent.; and of the total bark imported into England, Madras and Sikkim bark together (1,380 packages) formed a portion of about 1·82 per cent. These calculations are of packages, as I do not know the exact weights in pounds; but bark packages are always pretty much about the same weight, and the results may be taken as substantially reliable. I hardly think these figures bear out the charge, so lightly brought against the Government, of having damaged the interests of private growers by flooding the market with bark grown with public money.

3. For many years prior to 1880, no bark had been sold from the Sikkim Plantation, the policy of that plantation having from the beginning been to grow bark for manufacture into a cheap febrifuge for the people of the country—a policy which has been consistently and successfully carried out. The 206 packages sent to London last year consisted of a kind of bark which could not be manufactured into febrifuge, and of which, except by sale, there was no means of disposing. If further exportation of similar bark has been made during the present year for a similar reason: but changes about to be introduced in the factory make it unlikely that it will be necessary to send any more bark to London for sale. As regards the produce of the Nilghiri Plantation, the policy of the Madras Government has all along been to sell it in the best market.

4. The figures I have just quoted show that it would be hopeless, even if it were good policy, for Government to try to lower the price of quinine for the people of India by lowering it in the home market, because that really means lowering it for the whole world by flooding the European markets with bark

of its own growing. The direct and simple way of carrying out its avowed object in maintaining cinchona plantations is, as it appears to me, for Government to manufacture the produce of these plantations for use exclusively in India. In its plantations, Government has the means of supplying itself with bark, and with the manufactured products of bark, at a greatly cheaper rate than it could buy them in the open market. In proof of this, I need only say that, on the Sikkim Plantation, bark is produced at a cost price of about 2¾ annas per pound, and cinchona febrifuge at 9¼ rupees per pound; while bark of similar quality fetches in London prices varying from two pence (for shavings) to eight shillings and four pence for good quill, and quinetum (which is cinchona febrituge under another name) cannot at present be bought under forty shillings per pound.—*Times of India.*

LIBERIAN COFFEE AND TEA IN JAVA.

STEAM-PLOUGHS IN COFFEE FIELDS.

(From the *Straits Times*, 9th June)

NETHERLANDS INDIAN NEWS.

A correspondent of a Samarang paper, the *Indisch Vaderland*, furnishes that journal with the following particulars of a visit he paid last month to an estate in Java where steam ploughs have proved a success:—

"*Chikandie Udik*, 2nd May.—The first day of my arrival in Bautam was a very pleasant one, from my visit to the private estate styled Chikandie Udik, which lies on the boundary of the Batavia residency. Sad as generally speaking may be the situation in Bantam [owing to fever and cattle disease], it is particularly favourable and hopeful on this estate, which, everywhere bears witness to the fitness and energy of its manager. Probably throughout the whole of Java there is no second plantation where so many apparatus and machinery for modern agriculture are met with together as here. It may almost be termed a model farm. Of these agricultural improvements, the introduction of the steam plough deserves to be first mentioned. Chikandie Udik, it is true, is not the first estate in Java where that ingeniously devised implement has been in use. Years ago, it might have been seen on estates in the residencies of Samarang, Surakarta, and Surabaya, but to the manager of Chikandie Udik belongs the honour of being the first who so succeeded in practically utilising the steam plough, that the latter renders the same important services in Java as it does in Europe, America, Egypt, &c. After the failures alluded to above, it required much courage and energy to determine to risk once more the sum of 25,000 guilders in procuring such a machine, although the pressure of necessity was keenly felt when the murrain swept away thousands of buffaloes. Mr. Kimball, the manager of Chikandie Udik, has shown, however, that he does not view the matter as a mere experiment as his predecessors did. He who bought steam ploughs not as toys but from deeply felt requirements ensured the success of their introduction by procuring along with the machines, a person who knew how to manage them and could give the necessary instruction to the helping personnel. Thereby it became possible to brilliantly overcome the various obstacles on which previous experimenters had stumbled. The mistrust with which this product of modern ingenuity was at first greeted has now given place to a general acknowledgment that the enterprising land administrator, by purchasing the same, has gained a great advantage for himself, and has done a service to his country. Hence his example has found imitation elsewhere, and now there are several steam ploughs either in Java, or on the way to it. At Chikandie Udik there are two steam ploughs, a large and a small one, the first with two engines of 16 and the second with two of 8 horse power. I had the privilege of seeing the larger one at work. The two engines were 150 metres apart from one another, and the five-fold plough, which was drawn hither and thither by means of wire ropes, turned up with the greatest ease the clayish soil, then very stiff from rain. The greatest length which can be ploughed at one course amounts to 150 metres. On the plough several natives sat. One of them managed the machine in a very simple manner, while the others continually took care to keep the ploughing irons clear of weeds and adhering earth. The smaller plough works more accurately than the larger one, but naturally cannot turn over, within the same time, such a large area as that does. That ploughing with steam works favourably upon the productiveness of the soil was apparent to me from the state of the sugar canes. I must acknowledge seldom to have seen such vigorous and more regularly planted growing canes as those presenting such a splendid appearance on the ground prepared by the steam plough.

"Not only for ploughing sugarcane and paddy fields, but also in preparing land for the planting of Liberian coffee, and for turning over the earth between the rows of the young plants, the steam plough has done excellent service. The planting of Liberian coffee is also one of the remarkable things on Chikandie Udik. Against this variety of coffee, as had been the case with steam ploughs, great mistrust was felt by many. The figures giving its yield, coming to us from Africa, were very generally looked upon as humbug. Even when it appeared that the tree throve well in Java and gave promise of a great yield, it was said that the quality of the Coffee was of such a nature that it could not bear up against the competition of the common sort. Notwithstanding all this talk, the planting of it was actively pushed on at Chikandie Udik—and, now, people there have obtained results from it which go far beyond the boldest anticipations. I had an opportunity of inspecting narrowly the Liberian coffee gardens there, and can declare that it is very difficult to give a clear idea of the luxuriant growth of the trees, and the masses of berries with which they were laden. I saw thousands of trees, on whose branches whole clusters of colossal berries made a splendid show. The trees were so full of them that there was scarcely room left for young berries that were continually making their appearance. On many trees the fruit can be counted by thousands. As is well known, Liberian coffee has the peculiarity of growing by preference in low lying land, where the Arabian coffee always gives uncertain crops. Judging from the experience hitherto gained, it suffers not at all from the notorious leaf disease, and it has less need of shade than the common sort. This shade is here obtained by planting *kapok* trees and pepper vines between the high growing coffee trees, so that the same land yields three kinds of produce—coffee, *kapok*, and pepper. In the second year, the Liberian variety bears fruit. In the third year the latter can be counted by thousands. I saw trees 1½ year old which had a height of 4½ to 5 metres (a metre is 3·2809 ft.) Owing to this inclination to grow higher than the common coffee, the Liberian can be planted relatively close without diminishing production. As to the quality of the Liberian coffee, it is to my opinion more fragrant than the common variety, but when it is tried for the first time there may be something peculiarly unpleasant about it. After a couple of days this difference is no longer perceptible. To judge from what I saw at Chikandie Udik, Liberian coffee has a grand future before it in Java, chiefly because it is at home in districts where labour is more readily available than high upon the mountainous land."

"In a previous letter, I had neglected to say anything about tea cultivation on the Chikandie Udik estate. I have spent almost a whole day in the tea

gardens and the premises where the leaf is prepared, and was astonished at the simplicity of all I saw. Tea growing is here an experiment, which has, however, succeeded very well. It has been proved here that it was not at all necessary, as so many had hitherto believed, to proceed to mountains 3,000 or 4,000 feet high for the sake of this plant."

The same journal, in its number of the 24th May, comments as follows on the report by a commission on Van Maanen's artificial coffee drying method :—

"The caution exercised by the Commissioners in their final judgment, we do not disapprove of. The results obtained in Ceylon from artificial drying of coffee by another method makes such a course a duty—but we cannot leave unnoticed that the advantages of Van Maanen's invention are so great, that the adoption of the mode of drying will, in many cases, become advisable, even if it should turn out that the color or the quality generally suffer a little from it. It ought not to be forgotten that the colour of coffee, though certainly of some value, is not so greatly so that a saving of 3 or 4 guilders per pical should not counterbalance this damage. The very considerable expense of constructing and keeping the drying receptacles in repair, the wages paid to labourers charged with the drying of coffee, and, above all, the risk attending drying in the open air, are wholly avoided by Van Maanen's method. This also furnishes further the advantage, that people become wholly independent of the height and dampness of the atmosphere, and can also send their produce 2 or 3 months earlier to market."

In the official report on the Western Division of Borneo for April, it is stated that the Liberian coffee plants in the Sintang district looked flourishing and had already attained the height of half a metre. Their distribution among the people will be proceeded with.

"*Padang*, 19th May.—A correspondent writes as follows from Baudar, an out post in Palembang :—The Dempo or Holy Mountain, which has a height of it is said 10,000 feet above sea level, and is inhabited by elephants, rhinoceroses, and goats, but which according to the natives is the abiding place of hundreds of protecting spirits, *dewas* and other divinities, is now visited by an Englishman who intends to ascend the three summits—Dempo, Lumut and Berapa. He has undertaken the journey at a favourable time, if he wishes to see something, for the volcano has been very active of late. There have been gold diggings at the foot of this mountain but they are now of little consequence."—*Sumatra Courant.*

TASSAR SERICULTURE IN INDIA.

The Secretary of State for India has just communicated to the Society of Arts a despatch from Major G. Coussmaker, dated Camp Rajur, Taluka Akola, March 8, and reporting on the progress made in tassar sericulture during the preceding year. He considers that his failures last monsoon were due to the imperfect construction of cages in which he tried to rear the worms. They were at first made entirely of tarred screens of split bamboos, in which, however, the plants did not thrive. He then made the cages longer, and covered the tops with netting; but, unfortunately, wasps, &c., managed to get in and puncture the silkworms, so that most of them died. Next monsoon he proposes to substitute for netting coarse open cotton cloth. The small plantation which has been laid out is thriving, and will eventually be able to support a considerable number of worms. Major Coussmaker had not been able to get all his accounts in, but he believes that not more than 220 out of the 500 rupees granted him by Government were expended on his interesting experiment.—*Pall Mall Budget.*

ARTIFICIAL INDIGO.

A recent discourse was given at the Royal Institution by Professor Roscoe, F. R. S., on "Indigo and its Artificial Production." The professor reminded the members of the institution that eleven years ago he had laid before them an account of a discovery in synthetic chemistry of high importance, that of the artificial production of alizarine—the colouring substance of madder. That was the first time the colouring substance of a plant had been artificially obtained from mineral products. He had now, he said, to give an account of a second striking case of synthetic chemistry in a similar direction—the artificial production of indigo. It was another proof of the fact that the study of the most intricate problems of organic chemistry, and those which appear to many to be furthest removed from any practical application, are in reality capable of yielding results having an absolute value measured by hundreds of thousands of pounds. The value of indigo imported into this country during 1879 amounted to close on 2,000,000*l* sterling, so that if artificial indigo can be produced at a price to compete with natural indigo, there is a wide field open to its manufacturers. Indigo has been known as a colouring matter from very early times. Cloth dyed with indigo has been found in the Egyptian tombs. Pliny and Dioscorides describe the method of dying, which is the same as that followed in Bengal at the present day. The early inhabitants of this island obtained it from the European indigo plant *isatis tinctoria*, the wood plant or pastel. After the discovery of the passage to India by the Cape of Good Hope, the Eastern indigo, derived from a species of indigofera, gradually displaced woad as containing more colouring matter. This, however, was not done without strong opposition from the European Powers and their Sovereigns, some of whom issued edicts prohibitory to its importation. The identity of the colouring matter of woad and of the Bengal plant was not established till the end of the last century. Concerning the origin of indigo in leaves, various conflicting opinions have been held. Schunck has, however, proved beyond all doubt that neither in the woad plant, the Indian, nor the Chinese and Japanese indigo plant does indigo blue exist as such. The leaves contain a colourless principle, which has been named indican, but this readily decomposes into (1) a sugar-like body, and (2) indigo-blue. It was shown by experiment that even bruising a leaf will produce this decomposition; but to secure the result for commercial purposes is a long, though not very complicated process. Before the synthetic production of indigo could be attempted an exact analysis of the natural indigo had to be known, not only as to its molecules, but as to the arrangement of the molecules among themselves. The synthetic production of indigo had proved a far greater puzzle than that of alizarine. The first step as to the constitution of indigo was made as far back as 1840, when Fritsche showed that analine could be obtained from indigo. After some intermediate steps, it was found a crystalline body, to which the name of isatin was given, was obtainable from indigo, and then, in 1878, it was found conversely indigo could be obtained from isatin. There are three processes now known for obtaining indigo from isatin, but two of these are too costly to be of commercial value. Baeyer's process seems, however, to be even more than promising—to have established itself. He started with cinnamic acid from oil of bitter almonds, but this was too costly. Dr. Caro and Mr. Perkins have discovered how to obtain the cinnamic acid from tolvine—a coal-tar product. From cinnamic acid, however obtained, can be produced an acid complex in character, and to which a name descriptive of its composition is given—ortho-nitro-phenyl-propiolic acid. The artificial production of indigo may even now be said to be within measurable distance for commercial success, for the ortho-nitro-phenyl-propiolic acid (called for short

propiolic acid), the courless substance which on treatment with a reducing agent yields indigo-blue, is already in the hands of the Manchester calico printers, and is furnished by the Baden Company for alkali and analine colours at the price of 6s. per pound for a paste containing 25 per cent. of dry acid. With regard to the nature of the competition between the artificial and the natural colouring matters, in the first place, the present price at which the manufacturers are to sell their propiolic acid is 50s. per kilo. But 100 parts of the can only yield, according to theory, 68.58 parts of indigo-blue, so that the price of the artificial (being 73s. per kilo.) is more than twice that of the pure natural colour. Hence competition with the natural dye-stuff is not to be thought of until the makers can reduce the price of dry propiolic acid to 20s per kilo, and also obtain a theoretical yield from their acid. This may, or it may not, be some day accomplished, but at present it will not pay to produce indigo from nitro-phenyl-propiolic acid. Nevertheless a large field lies open in the immediate future for turning Baeyer's discovery to practical account. It is well-known that a great loss of colouring matter occurs in all the processes now in use for either dyeing or printing with indigo. A large percentage of indigo is lost in the "cold vats" in the sediment. Another portion is washed off and wasted after the numerous dippings, while, in order to produce a pattern, much indigo must be destroyed before it has entered into the fibre of the cloth. Moreover, the back of the piece is usclessly loaded with colour. The proper way of looking at this question at present is to consider ortho-nitro-phenyl-propiolic acid and natural indigo as two distinct products not comparable with each other, inasmuch as the one can be put to uses for which the other is unfitted, and there is surely scope enough for both. Still, looking at the improvement which will every day be made in the manufacturing details, he must be a bold man who would assert the impossibity of competition with indigo in all its applications, for we must remember that we are only at the beginning of these researches in the indigo field.—*Overland Mail.*

LIBERIAN COFFEE IN AUSTRALIA.

By degrees the advantages of Northern Queensland as a field for tropical agriculture are being realised, and sugar, spices, coffee, and other tropical produce are being gradually introduced into the Colony, to be grown almost alongside of wheat, and within a comparatively short distance of farms devoted to sheep and cattle rearing. An experimental growth of Liberian coffee, made by Mr. H. A. Wickham at his plantation at Maragen, on the Lower Herbert River, has proved very successful. The young plants, from seed supplied from Kew by Sir J. D. Hooker, have just ripened their maiden crop, and are described by the fortunate and enterprising planter as looking very promising for the future. The vast resources of Northern Australia for such an industry as coffee-planting or sugar-growing ought to be much better known in England than they are. The soil is fertile, and the climate better adapted to the European constitution than that of many other tropical countries whose resources have been hitherto more fully recognised. Land equal to any in the tropical world can be taken up for 5s an acre, and the payment can be spread over a period of ten years. Here is a chance for young Englishmen with a little capital, and leisure to study the requirements of the country and the best methods of tropical agriculture before rushing into expenditure. Some of the surplus population of India should find congenial occupation and climate in Northern Australia, where they would find a heartier welcome than the "heathen Chinee"; but while Coolie labour would probably be found best suited for the heavier labour of a plantation, there is ample scope for English labour, and still more for English capital, in tropical Australia.—*Colonies and India.*

"NEW COMMERCIAL PLANTS AND DRUGS."—We have received from Mr. Thos. Christy No. 4 of this series of pamphlets. This number deals with Ceará Rubber, Maugabeira rubber, Urostigma Vogelii, apocynaceous rubber, Landolphias, &c., and a number of drugs some new to Europe. Regarding the Urostigma Vogelii Mr. Christy says:—"As Dr. Trimen has some of these plants growing in Ceylon, I look forward with interest to his accounts of the india rubber which they yield, and hope in a future number to be able to give some account of their value from an agricultural point of view." Apocynaceous rubber is thus described:—"A plant yielding rubber which grows in East Africa, and the seeds of which one of my correspondents sent me home among a collection of plants, together with a piece of very fine india-rubber obtained from it, appears to belong to a hitherto undescribed species. I planted the seeds corresponding to the rubber, and find it to be a *creeper*,* but on account of the flower not being perfect, and there being no plant that exactly corresponds to it in the Herbarium at Kew or at the British Museum, it is impossible to give it a name until it has flowered. Some of these plants have been sent to Ceylon, to the Botanical Gardens and to merchants." Of the papaw we read:—"Dr. Bouchut (*Archives Gén. de Med.*, July 1880) has found that both the diluted juice and Papaine, have the property of digesting living, tissues, normal or pathological, such as enomata and cancers, and converting them into peptones in exactly the same way as dead ones. It seems probable that this knowledge may be turned to account in the treatment of cancer and other abnormal growths. The false membranes of croup and diptheria removed by tracheotomy, and also worms, such as tape worm, and round worms, are attacked and digested in a few hours by the Papaw juice." In the preface Mr. Christy says:—"The Ceará rubber has been so highly spoken of as to cause a great demand for the seed. The supply is short for the time being, owing to the trees being killed by the drought over a large radius of country in Brazil. According to Hecht, Levis and Kahn's report for 1879, 25 tons of Ceará Rubber and 900 tons of African Landolphia Rubber were imported some 350 tons of Assam (*Ficus Elastica*), 250 tons of Borneo (*Willughbeia*), 500 tons of Mozambique (*Landolphia*) Rubber. By this it will be seen that next to the Pará Rubber, of which 6,651 tons were imported, the Landolphia Rubber occupies the first place, while the Ceará, owing, no doubt, to the severe drought which has been prevailing in that district, only returns about 25 tons as imported into England; but I have no doubt that if this variety is well cultivated in Ceylon and other rubber growing countries, that its returns will rival with those of others. The Maugabeira will be another favorite variety of rubber tree, and it has not suffered by the drought. The fruit carries well, even to Europe, so it will be an acquisition in Ceylon. The small-leaved rubber plant I received from East Africa, and which is growing in Ceylon, is easily propagated by seed and cuttings; it has not been named, but the rubber was so much admired for its transparent appearance, that I prefered to allow the plants to go out nameless than keep them for the name. I have published the drawing as a guide to others to search to plants of a similar kinds. From the samples of stems and pieces of trees in my possession, I am convinced that there are many other rubber plants that will repay the trouble of cultivation."

* When pruned it forms a bush or tree.

Correspondence.

To the Editor of the Ceylon Observer.

THE CINCHONA BARK TRADE IN SOUTH AMERICA; VINES, COAL, GOLD, &c.

Edinburgh, 30th May 1881.

DEAR SIR,—Some time ago, you asked me to procure some information from my brother in South America, on cinchona, but, in reply to my letter on the subject, it seems that he knows little about it. I annex quotations of what he writes on this, and some other matters.—Yours truly, P. D. MILLIE.

Concepsion, Southern Chili, 13th April 1881.

Cinchona—alas! I never saw a ciuchona tree in my life! and all I know about it, is the fact, that *bark* is brought down from the interior of Peru and Bolivia; that the tree grows on the mountains there, at a considerable elevation; that the climate where it grows is a wet one, during at least half the year, and is a rather cool although semi-tropical one; that there is no cultivation of the tree, and no care taken, that it will not, ere long, be exterminated, as the natives simply cut down, and strip the bark off every tree which they can find; that in view of this wholesale destruction, leading to a scarcity of bark, the British Government has done a good deal towards introducing the tree into India. The rest *you* know better than I do, as all which I have learned has been gathered from the Ceylon papers, which you send me.

It has struck me, the tree *might* grow very well in Chili: perhaps the climate is rather too cold, too like the south of England, where I suppose it would not grow. This is just all I know about it. This is a land of corn and wine, beef, and cyder: all over the south apple trees grow wild, and the cyder orchards are the woods and meadows: nobody does more than *shake the trees* year after year. This year, they are lamenting a bad crop of apples. What wonder?

The viues are a little more attended to, and the wines are good or bad, just according to the care bestowed upon its growth, and preparation. They are dirt cheap, and moderately used, being far more wholesome than any *doctored* European stuff—too often palmed off as port, sherry, and claret, on folks at home.

I have been wandering about the coal mines, south, in Lota and Lebu. There is coal all over the south—coal, for centuries, *in sight*, besides what is *out of sight*; for the half dozen mines at present worked fully cover the demand, and those who own coal land don't touch it Posterity will, perhaps, export coal to Europe, as Europe is now doing to us, to our loss and detriment.

England sends us out coal, as *ballast* for ships, which come for guano, nitrate, wheat &c, and, as it has to be sold, the competitiou with our own mines sadly limits their output.

There is also iron, in abundance, here; but it is useless to think of working it in competition with England, short of labour as Chili is, at present. Gold is a queer subject at Lebu. I found everybody going about with nuggets, large and small, and everybody who had money buying gold from the explorers. Nuggets of all sizes, up to 40 ounces, had been bought, and one man brought in 12 lb. of gold, chopped up with a chisel and pronounced to be one nugget, which he did not wish to sell entire. It is found in the ravines, over an extent of six square leagues, and is believed to be in abundance everywhere, throughout the district.

The district is so densely wooded, that it is awful work to grope about the ravines, and grub up the jungle, at the bottom. Many of the nuggets have been so found, and the gold formation of slate and quartz is everywhere overgrown. The ravines are singularly steep and deep. No one has as yet troubled himself about *dust*: it is all rough gold, or nuggets, which they bring in for sale.

The country near the diggings is the very finest of land, and, should a *rush* take place, many will remain to farm, as was the case in California—a fine thing for Chili, which wants something to stimulate immigration.

Gold has had its mission in this way, both in California and Australia &c. The lust after gold may also be said to have been the origin of the colonization of Mexico, and South America, by Spain.

I have read all the Ceylon papers about "New Products." There is probably some truth in the remark about "high cultivation"* having a good deal to do with leaf disease. You can't keep man, beast, or plant, long up to the mark by substituting stimulants for rest or for good substantial food, as in bulk manure,—P. D. M.) T. J. M. MILLIE.

* Artificial manures?—P. D. M.

[Unfortunately for this argument the leaf fungus first began in a district where no artificial manure had been used. We have, however, to thank Mr. T. J. M. Millie for a very interesting letter.—ED.]

CARDAMOMS.—Cardamoms are largely grown in some parts of the west coast and Mercara, and both the Governments of Cochin and Travancore enjoy a monopoly of the produce in their respective provinces. In the Cochin state the forest department pays special attention to the growth of cardamoms and 1,915 parahs of land are set spart for its growth. The collection of produce in the official year 1879-80 was 1,400 lb., valued at R2,800 against 1,070½ lb. valued at R1,551 in the previous year. The Dewan says that the financial results of cardamom cultivation are as yet far from commensurate with the outlay incurred by the Sirkar, but it is hoped that in time and with careful management a substantial improvement will accrue.—*Madras Standard.*

A NEW CEYLON INDUSTRY.—Mr. C Powell Jones has been spirited enough to import from China a considerable quantity of silkworm eggs and he means to give the cultivatiou of mulberries and the production of silk a fair trial at Oliphant, Nuwara Eliya, and in Udapussellawa. The first importation of eggs was a failure; but this second has been so successful that there are more eggs than can be utilized in one or two experiments, and so a surplus is offered to the public at what seems a very moderate rate. At least any one who wants to try silkworms and mulberry cultivation cannot be deterred by a five-rupee note. It is well-kuown that the growth of the mulberry in Nuwara Eliya is most astonishingly rapid, so much so that Sir Samuel Baker recommended it to be used as a fodder for cattle. The shrub also grows freely in nearly all the coffee districts. One idea is that where ciuchona dies out—and unfortunately such areas are only too common—the mulberry might be substituted in the form of hedges and the leaves made available for feeding the silkworms. We trust the experiment will be widely tried. In the dry climate of Uva especially, the silkworm ought to flourish; but why not also in Rakwana, Matale, around Kandy, and, if in Nuwara Eliya, possibly between Great Westeru and Adam's Peak? Mr. Bury of Golconda, Haputale, some years ago sent us some samples of the silk produced under his care, which was much appreciated by Coventry manufacturers. Kept in houses even in the wet districts, silkworms may be found to flourish well. New Products and New Industries being the order of the day, we wish this youngest Industry all success.

HOW TO START A GARDEN AND MAKE IT PAY—(*Continued from page* 20).

(From the *Indian Tea Gazette.*)

SECOND YEAR.

	R.
Tea seed for planting at stake, and for nurseries, 30 maunds, at R70 per maund ...	2,100
Importation of 60 coolies, at R100 per head landed on the garden	6,000
Engagement of 10 local labourers under a two years' agreement, at say R25 per head ...	250
Wages of 125 labourers at an average of say R4 each per mensem	6,000
Establishment (The same as in the former year)	3,072
Loss on 1,200 maunds Rice, say	1,000
Garden stores, implements &c, say	800
Government fees, Law Expenses and 2nd instalment on account of Timber ...	650
Station or Steamer Agent's salary	180
Calcutta Agents' charges, say	600
Discount, Feed of live Stock, Stationery, Postage, and other Contingencies, say ...	1,348
Total...	R22,000

RESULTS AT END OF SECOND YEAR.

Receipts	Nil.
Debit Balance ...	R42,000

NOTES ON THE SECOND YEAR'S ESTIMATE.

Tea Seed.—Twenty-five maunds of seed would be required for the new extension of 50 acres, but in addition we have estimated for 5 maunds extra for the forming of a nursery or nurseries. It is advisable for many reasons that such should be made the second season. Five maunds of seed planted in nurseries would yield, the third season, sufficient seedlings to plant out 10 acres 4′ × 4′, and fill up, moreover, all vacancies that might occur during the second season in the 100 acres under plant. The third season we could thus plant out 10 acres with one year old seedlings, leaving 40 acres for planting seed at stake. The advantage of having a nursery to fall back on at the commencement of the third season is evident, for should an unusual number of plants die off in the 100 acres during the second season, the number of seedlings in the germinating beds would probably not suffice to fill up the vacancies the third season. There would in all probability, as we have stated before, be a sufficient supply of seedlings (raised from the first year's seed) in the germinating beds to meet all demands during the second season, but the requirements of the third season could not be met without the assistance of a nursery.

General observations.—All timber from the new clearance of 50 acres that is of any use for charcoal should be cut up, stacked in bhattas, made into charcoal, and then carefully stored in the charcoal godown. As much of the timber as will not answer for charcoal, should, instead of being allowed to lie about, be stacked under cover for firewood. The value of these suggestions will be felt in the fourth year, when, for the purpose of making charcoal, instead of having to take off a large number of hands from some other important work, much to its detriment, there will be a goodly store in the godown—more than sufficient most probably for the demands of the season. To succeed, everything should be done decently and in order. If from the very commencement a regular system of work is adopted and carried out, everything will go on smoothly, and nothing will be found undone that should have been done. In some gardens work always seems to be behind-hand, and everything seems to be done in a hurry. The reason is not difficult to find. Unless there is a regular system drawn out, adopted, and rigidly adhered to, the work cannot be carried out properly. We would advise all Managers to draw out a regular routine of work for the season, and to stick to it most tenaciously. What a difference it would make in some gardens. Instead of everything being behind-hand, the work would always be in an advanced state; there would be no hurry, and consequently everything would be done thoroughly and well. Successful results are achieved by orderly working,—doing things by degrees, and not all of a heap at the last moment. It is advantageous in many other ways besides that noted above, to remove all timber instead of allowing it to lie about and rot. It gives the garden a much neater appearance, and by not being in the way of the coolies when hoeing, the ground is better cultivated. We have heard it stated, also, that rotting timber lying about tends to bring on blight, and it may be it is the cause indirectly of some of the blights by which the tea bush is attacked.

The 1 year old bushes towards the close of the season will require a *slight* "tipping." If they are vigorous healthy bushes, the amount of leaf obtained off the 50 acres would most probably be about 800 lb. green leaf = 2 mds. 20 seers manufactured tea. On no account should more than this quantity of leaf be allowed to be taken off.

We consider it most essential that the Factory should be completely furnished and fitted in every respect before the commencing of manufacture in the fourth season. The Tea Machinery also should therefore be ordered now, as a long time must needs elapse before it can be landed on the garden. The cost of the machinery, fittings, &c., we include in the estimate for the third year.

THIRD YEAR.

	R.
Tea seed, for planting at stake and for nurseries, 30 maunds, at R70 per maund ...	2,100
Importation of 60 coolies, at R100 per head landed on the garden	6,000
Engagement of 10 local labourers under a two years' agreement, at say R25 per head ...	250
Wages of 176 labourers at an average of say R4 each per mensem	8,448
Establishment	3,672
Loss on 1,800 maunds Rice, say	1,500
Tea Machinery, landed on the Estate, say ...	12,500
Corrugated Iron Roofing, Fittings for Tea-house and Bungalow, Garden and Tea-house Stores and Implements, Furniture for Bungalow	4,000
Government revenue at 3 annas per acre, Government fees, Law expenses, and last instalment of Timber	1,000
Station or Steamer Agent's salary ...	180
Calcutta charges, say	750
Discount, Feed of live stock, Stationery, Postage, and other Contingencies, say ...	1,600
Total	R42 000

RESULTS AT END OF THIRD YEAR.

Receipts	Nil.
Debit Balance	R84,000

NOTES ON THE THIRD YEAR'S ESTIMATE.

Yield.—During this the third season we have one hundred acres under plant, from which we can obtain a small quantity of leaf.

Two (rising three) year old bushes .. 50 acres.
One (rising two) ,, ,, ,, ... 50 ,,

We estimate that from the former we should be able to take off without any the least injury to the bushes 1,760 lb. of leaf, and off the one year old bushes 800 lb., giving thus a total of 2,560 lb of green leaf = 8 maunds of pucca tea. But we wish it to be distinctly understood that this plucking of leaf is simply done for the benefit of the bushes, and not for the sake of obtaining a "return." Two year old and one year old bushes demand that they should be lightly

"tipped," to enable them to thrive and form into good bushes; they must therefore be plucked,—but, remember, *very lightly*, simply *tipped*, that the bushes may be *spared* as much as possible.

FOURTH YEAR.

	R.
Tea seed, for planting at stake and for nurseries, 30 maunds, at R70 per maund	2,100
Importation of 70 coolies, at R100 per head landed on the garden	7,000
Bonuses to 35 coolies for a two years' re agreement, say	800
Engagement of 10 local labourers under a two years' agreement, at say R25 per head ...	250
Wages of 224 labourers at an average of say R4 each per mensem	10,752
Establishment	3,672
Loss on 2,000 maunds Rice, say	1,650
Government revenue, fees, law expenses, &c. ...	500
Station or Steamer Agent's salary	180
Calcutta charges, say	750
Discount, Feed of live stock, Stationery, Postage, and other Contingencies, say	1,346
Total	R29,000

RESULTS AT END OF FOURTH YEAR.

Receipts	R5,000
Debit Balance ... ... ,,	1,13,000

Yield.—This season we have 200 acres under plant, but we can only obtain leaf from 150 acres, and of this area 100 acres must only be "tipped." We have—

Three (rising four) year old bushes ... 50 acres.
Two (rising three) ,, ,, ,, ... 50 ,,
One (rising two) ,, ,, ,, ... 50 ,,

We have assumed that hitherto the bushes have only been "tipped;" that they have been spared as much as possible; and that the garden has been kept throughout in the highest state of cultivation: consequently we may assume that the three year old bushes, have proved themselves fine, strong, healthy, well-formed bushes, giving abundance of leaf. We may therefore safely calculate we have made from the leaf gathered off them, 1½ maunds of pucca tea per acre. Accepting of the same figures as we showed the last year for the other bushes, we obtain a total of 83 maunds, or say in round numbers 85 maunds pucca tea, as our outturn for this the fourth year. Taking into consideration that a tea-house complete in every respect is on the garden, a *net* average of at least 12 annas per lb. should be obtained for the same, without any difficulty. We should therefore have a clear return of at least R5,000 this year, and we note down this amount in the estimate under the heading of "receipts."

SUGAR AND CACAO.—The quantity of sugar shipped to end of April, is = 23,863 hhds.; and of cacao 5,747,900 lb.—*Trinidad Chronicle.*

PUBLIC SALE OF CINCHONA BARK.—Messrs. Robinson & Dunlop will put up for public sale on Saturday, 25th instant, at noon, 14 lots of cinchona bark. The first 5 lots are Stonycliff bark, 3 succirubra and 2 officinalis. The analysis by Mr. M. Cochran, of the stem and the root succirubra, lots 1 and 2, shews 1·78 average yield of sulphate of quinine. Total alkaloids 4·86. Lots 6 to 9 are Rickarton succirubra, and lots 10 to 13 are mixed succirubra and officinalis from Agrawatte, Carolina (Ambagamuwa), Wigton (Dimbula), Heenwelle and Hunucotuwa (Kotmale), the analysis by Mr. A. C. Dixon of the mixed stem pieces shewing 1·15 yield of sulphate of quinine in total alkaloids 3·97. Lot 14 is succirubra from Gavatenne. Nothing extraordinary in quality, but good serviceable lots.

COCOA IN GUIANA.—We hear encouraging accounts of the Cocoa industry which has been put on foot, the young trees testifying that the soil of this colony is admirably adapted for this cultivation, the late continuous drought having had no bad effect upon them.—*Georgetown Gazette, May 5th.*

MR AGOSTINI'S Coffee-piece at Coblentz is throwing out a most abundant show of blossom (Saturday 30th), and will look still better to-morrow and Monday. The St. Ann's hybrid in particular, is magnificent in its vigour and promise of a great crop. The little plantation—so near at hand—is well worthy of a visit just now. The hon. proprietor, delighted at his success, freely invites an inspection of his experiment by the gentlemen of the town.—*Trinidad Chronicle.*

TRINIDAD.—The shipment of cacao to date is 5,367,270 lb. Cacao expectations from most quarters are only moderate or small; but from Maracas Valley we have a very good account. Five coolie ships have come in from Calcutta this season, *i.e.*, since September 30th last, and two more are due. The five arrived are the

	arrived.	Imm. l'nded	pd. pssge.	d'ring bths.	pss'ge dths.	returners.

—*Trinidad Chronicle.*

THE south-west monsoon threatens to be a failure in Ceylon and Southern India: at the present moment it is dry and hot with no prospect of rain. We fear for the grain crops in India. As regards coffee, leaf disease is beginning again to appear in certain districts, and crops in many cases are not to fulfil the promise which the fine blossoms led planters to hope for. Still the trees look well even without what planters used to think should be the annual dose of manure. This is the report from Dimbula. As an evidence of the success of Mr. Schrottky's vapourizing with carbolic acid and lime against leaf disease, we learn that the fall of leaf on Gleneagles estate on the operated coffee compared with that on adjoining coffee not treated is as to 11 to 81! Mr. Schrotty leaves the island to-morrow to return possibly in September.—24th June.

COFFEE IN NATAL.—We had hardly anticipated having again to use this heading, but the meetings and journeys of the Coffee Commission have caused some little interest to be taken in this defunct enterprise. The Commission seem to be having rather a jolly time of it, "borer and bark disease" do not interfere with many a pleasant luncheon. All the Commissioners have sunk money in coffee planting, and have taken to other pursuits they should therefore have little difficulty in determining the reason why everyone failed to make the enterprise pay. We hope the climate of this country will be compared by them with that of other successful coffee growing countries. Reliable data can now be secured for the past 15 or 16 years, a period covering the birth and death of the enterprise. Reit Valley estate is constantly quoted as a successful coffee estate; but before accepting the statement it would be interesting to learn what the capital account now amounts to, and whether a pound of coffee costs more to grow than it is worth. If enough money were forthcoming, it would be possible to grow coffee in England—under glass. Or perhaps the climate of Reit Valley, which is very different to that of the other localities in which coffee was grown, may compare favourably with that of successful growing countries.—*Natal Mercury*, May 2nd.

CULTIVATION OF THE FIG IN TURKEY.

(From the *Journal of the Society of Arts.*)

The United States Consul at Smyrna states that the Aidin district is the only one which produces figs for exportation. The fruit will grow anywhere in the neighbourhood of Smyrna, of a good quality for consumption, in a green state; but the Aidin plain is unique in its climate and soil as being favourable for the proper curing of the fig. The thermometer seldom falls below three or four degrees under freezing point, and in the summer seldom rises above 130 degrees Fahrenheit in the sun. In Aidin, the winters are generally wet, the dry weather commencing in May and continuing till the end of October. Any rain at the end of July, or during the months of August and September, when the fruit is under the process of drying, injures the quality, by causing it to burst, hardens the skin, gives the fig a dark colour, and spoils its keeping quality. Heavy dews will cause the same evils.

The fig tree will grow in almost any soil; a rich heavy soil is, however, preferable; but to produce figs that will dry well and please the merchant, the soil ought to be of a good depth, and of a rich, light, sandy nature; this, if the weather be favourable, will produce large figs, of a white thin skin, and of the finest quality. Before planting, the ground is well ploughed two or three times to a good depth, well fertilised, and freed from all weeds and extraneous roots. The fig is propagated from slips, selected with as many fruity buds as possible. To from a tree, two slips are planted, one foot apart, and then joined at the top. The trees, if planted in rich soil, should be placed about 30 feet apart, and for poor soil about 25 feet distant from each other. The cuttings are planted in the month of March, two in each hole, at about 9 inches or a foot apart at the root end, and during the growth of the trees, the ground is ploughed up two or three times during the winter or spring, and the space between them is used to cultivate cotton, sesame, or Indian corn.

The fig harvest generally lasts about six weeks, and when the fig is ripe, it falls of its own accord from the tree. Women and children are employed to pick up the fruit into small baskets, to be conveyed to a place in the garden well exposed to the sun, where they are spread on a bed of dry grass, or mattiug, singly, and not one on the top of the other, and are turned over every day, in order to get every part of the fig exposed to the sun. After a few days of this exposure, those figs which are sufficiently dry are selected from the mass, and divided into first, second, and third qualities, care being taken not to dry them too much. They are then sent to Smyrna, where they are assorted and packed for shipment.

On arrival at Smyrna, they are conveyed to the fig bazaar, or market place, where the merchants attend early next morning to effect purchases. The parcels belonging to each individual owner are separately examined, each purchaser giving his own price; a broker is nearly always employed as an intermediary by the merchant, on payment to him of 2 per cent of the value, the amount being ultimately refunded by the seller. A seller is but seldom the owner himself, this latter being generally represented by a Jew or Armenian merchant, at an exorbitant charge of 7 per cent as a commisson. The figs are then, after purchase, conveyed to the packing establishment, to undergo manipulation and putting into boxes; the sacks are emptied out on the floor in a square heap, and on all sides squatted rows of women and girls, employed in merely twisting round each fig two or three times between the forefinger and thumb, to render it soft, and give it the required oblong form. On the heap are a row of low baskets, into which are thrown separately the first and second qualities to be used for packing; at least 10 per cent. of the whole number is worthless for putting up in cases, and, during the first process, the inferior fruit is picked up and thrown in a separate heap. Undersized, tough, or spotted figs, and such as are burst, come under this category, and are packed, or rather preserved, promiscuously in small boxes, and labelled "Figs for family use." Sometimes, when the parcel is unusually good, three qualities are selected instead of two. The figs are then laid on long benches, at which are seated the practiced packers. Each man has a box before him, and swiftly and dexterously the figs are placed alongside each other in rows, the rows varying in number according to the depth of the box, the flat ones, which are in more general use, requiring but two. This mode of packing is called "pulled." Above all, a row of "layers" is then placed, to show the figs to advantage. The "layers" are stretched out by means of both hands, and laid flat side by side in parallel rows. Of late years, "layers" throughout the boxes have come into great demand, and nearly all the best qualities are packed in this way. In packing, the fingers are now and then dipped into a bucket of sea-water, to ease their working; the figs become thus moistened with salt water, which it is said, has the effect of hastening their sugaring. The boxes are again passed on to the women, who complete the process by placing laurel leaves between the upper rows, before the final nailing down and polishing off by the carpenter. The packages used are of various dimensions and forms; at one time all figs exported to the United States were placed in drums or paper boxes, but of late years flat wooden boxes are being extensively shipped. Very few drums, if any, find their way to the English market, to which the best qualities are usually sent. America consumes but little of the superior qualities, though the demand for such has now increased. Small canvas bags are now being used with much success, and in fact, every season some novelty in the style of packing may be noticed. The refuse, or "naturals," are put into large boxes or barrels, and shipped to England, Egypt, Europe, and Turkey, the high rate of duty in America entirely excluding those inferior figs from the market.

TOMATOES.

(From *Hogg's Gardeners' Year-Book.*)

The Tomatoe or Love-Apple.—The love-apple or tomatoe (Lycopersicum esculentum), is a native of Mexico and South America, but it is also found in the East Indies, where it is supposed to have been introduced by the Spaniards. The Malay name is Tamatte, and in Mexico it is called Tamalt. The whole plant has a disagreeable, acrid, and nauseous odour; and its juice inspissated over the fire emits a vapour so powerful as to cause vertigo and vomiting. The fruit, which are the only part used as an esculent, are extensively used in Spain, Italy, and France in soups, sauces, and pickles; and even in their natural state they have an agreeable acid flavour. In our own country the cultivation of love-apples is becoming much greater than formerly, and the more the community becomes acquainted with the many agreeable forms in which the fruit can be prepared, the wider will the cultivatoa be extended. For soups, sauces, ketchup, preserves, and confectiouery they are equally applicable, and the unripe fruit makes one of the best of pickles. By analysis the fruit of the love-apple has been found to contain a particular acid; a volatile oil; a brown very fragrant, extracto-resinous matter; a vegeto-mineral matter; muco-saccharine, some salts, and in all probability an alkaloid. According to the analysis of Foderé and Hecht the tomato was found to contain:-1. A peculiar acid which is destroyed by a distilling heat, and which is combined by a bitter

principle, probably solanin. 2. A volatile oil difficult to separate, and which evaporates with great rapidity. 3. An extracto-resinous brown matter, of a pitchy consistency, having a strong smell and a bitter-sweet taste, soluble in water and partly soluble in alcohol and either. 4 An albuminous matter which readily putrifies. 5. A little mucous sugar detected by the smell of caramel at the commencement of combustion. 6. Sulphate of potash, a little chloride of potassium and calcium, pure potash, and probably a vegetable alkaloid, which resides much more abundantly in the leaves than in the fruit. Professor Church gives the following quantitative analysis of the tomato:—Ripe tomatoes contain in 100 parts:—Water, 89·8; albumen, 1·4; sugar, 6·0; malic acid, 0·7; cellulose and pectose, 1·3; mineral matter, 0·8. In 1 lb.:—Water, 14oz. 161 gr.; albumen. 9Sgr.; sugar, 420gr.; malic acid, 49gr.; cellulose and pactose, 91gr.; mineral matter, 56gr. For one part of flesh-formers in tomatoes there are about four parts of heat-givers, reckoned as starch. Few products of the gardeu have increased so rapidly in popularity as the fruit of the tomato. A few years ago the demaud for tomatoes was extremely limited. Iu many private gardens a few plants trained against walls afforded all the fruit that was required, but now plants are largely grown under glass, and a supply of fruit if expected all the ycar round. In markets, too, the demand for tomatoes was of the slightest, and where a hundredweight was sold a few years ago a ton is sold now; indeed, it is not unusual for a London fruit salesman to dispose of a ton of tomatoes in a day. Since the tomato has become so popular, and as it is unquestionably wholesome, it would not be inopportune to refer to the various modes of using the fruit.

The following are the chief uses to which the fruit is applied:—

Tomato Sauce.—Bake six tomatoes in an oven till they are quite soft; with a spoon take out the pulp, which strain through a coarse cloth or strainer to take out the seeds, then add salt, cayenne pepper, and as much vinegar as will give it the consistency of cream.

Tomato Sauce (French).—Cut ten or a dozen tomatoes into quarters, and put them into a saucepan with four onions sliced, a little parsley, thyme, one clove, and a quarter of a pound of butter. Set the saucepan on the fire, stirring occasionally for three-quarters of an hour. Strain the sauce through a horsehair sieve, and it is then ready for use.

Tomato Sauce (Italian).—Take twelve or fifteen tomatoes, a bit of butter, a little salt, half a dozen allspice, a little India saffron, and a glass of stock. Slice five or six onions, and put the whole into a saucepan. Set it on the fire and stir frequently, as the mixture is apt to stick. When the sauce is observed to be tolerably thick strain it like a *puree*.

Tomato Soup (1).—Wash, scrape, and cut small the red part of three large carrots, three heads of celery, four large onions, and two large turnips. Put them into a saucepan with a tablespoonful of butter and half a pound of lean ham. Let them stew very gently for an hour, then add three quarts of brown gravy soup and some whole black pepper, with eight or ten ripe tomatoes. Let it all boil an hour and a half, and pulp it through a sieve. Serve it with fried bread cut into dice.

Tomato Soup (2).—Take a shin of veal and put it into a pot with three quarts of water, two carrots and two onions and three turnips sliced, some peppcr and salt, and one or two dozen tomatoes. Boil it for three hours, and strain through a sieve. Toast some bread very brown, cut it into small dice, put it into a tureen, and when the soup is ready put it over the bread.

Tomato Soup (3).—Wash the tomatoes and slice them without peeling. Measure and put them to cook in a porcelain kettle. For every three quarts of sliced tomatoes add two onions, one carrot, and one turnip, all cut or chopped into small pieces; also two bay leaves, six cloves, a stick of cinnamon, a blade of mace, ten peppercorns and as many grains of allspice, a teaspoonful of sugar, and a head of celery or some bruised celery seed. Boil steadily for two hours, then strain through a sieve, pressing so as to obtain all the pulp without the seed. Wash out the kettle and return the liquid to it. Boil slowly for two hours longer. Season to taste with salt and cayenne pepper. It should be, when done, like thick ketchup. Stir frequently to prevent scorching, and be sure to use only a wooden spoon. Tin or iron utensils used in cooking tomatoes impart an unpleasant taste. The soup may be bottled, corked and sealed the same as ketchup. In serving, dilute it with strong meat broth (veal is best) until of the desired consistency. Flavour to taste with salt, pepper, and tomato ketchup, and serve with *croutons*. Cut these little diamonds of stale bread very small and even, fry them to a light brown in boiling dripping, drain well, then put them in the tureen and pour the soup, which should be hot but not boiling, over them.

TEA CULTIVATION IN FIJI.

TO THE EDITOR OF THE FIJI TIMES.

Sir,—As the introduction of any new industry must of necessity tend to increase the material prosperity of the colony, I think a few remarks on the capability of Fiji for the cultivation of tea may not be without interest to the public, and I venture to indulge a hope that the opinions of a practical man, who has had fifteen years' experience of tea growing in India, may be entitled to some weight with those who are likely to take an interest in this matter.

During my residence in Fiji I have met with soil and situation suitable for the cultivation of tea, both in Taviuni and Vanua Levu. The limited extent of my observations elsewhere precludes my being in a position to speak as confidently of other localities, but I am sure, from what I have heard gentlemen maintain as to land and soil, that there are many other portions of the group equally suitable.

Tea requires a light black loam soil, 60 per cent sand, balance clay, but of course other soils will grow it, but not to that perfection. The elevatiou required differs greatly. I have seen tea growing within 20 feet of the sea, and that splendidly, and the quality of tea made from it really good; but most planters are of opinion that a certain altitude is required, and that is my opinion as well. If we can get say an altitude of 900 feet it will be quite sufficient. These requisites are fully met with in the islands I have named, and success I am certain of. I am enabled to judge from a practical example, which is better than any theory of soil and situation. On the Alpha coffee estate, the property of the Hon. J. E. Mason, is a small patch of Assam hybrid tea plants, now about two years old. The demands of coffee cultivatiou, perhaps, has not permitted Mr. Mason's manager to bestow any great care on these, yet spite of this want of attention, they will compare most favourably with plants of similar age in India. When on the spot, I, of curiosity, manufactured a small quantity of tea from some of the old leaves, but of course, not having the necessary sieves on hand, could not produce the different qualities, and the quality of leaf I had to manufacture was anything but good; yet the sample produced after infusion was fair, and I say with confidence that tea made in Fiji will equal, if not surpass, that of India, for the growth here is more luxuriant than that of the latter place. It must be understood that all qualities of tea come from one and the same plant, and, as I have said before, the qualities are separated by means of sieves.

Tea begins to yield a small return the second year, but the yield is very small, as you are then bringing your plants into form for future operations. The third year the returns will probably be sufficient, not only to meet the year's expenses, but also to leave a small sum over and above.

The realization of crop during the fourth year should, with good management and no disaster occurring, leave a considerable margin over expenses.

The fifth and sixth year's crops steadily increase until the seventh year, when the plant is considered to be in full bearing.

Say the tea garden under cultivation is 200 acres in extent, I consider the fifth year's crop should reach at least 64,000 lb. of made tea; this is a low average from a hybrid planted garden, for I have known the same area to turn out 96,000 lb. of made tea.

Tea, it must be remembered, is a perennial plant, and plantations once formed will go on bearing for an indefinite period. I do not know to what age the plant will continue to bear, but in one instance I have seen the age of bearing plants is probably beyond 100 years. A small patch was planted out in Chittagong, and is owned now, I believe, by a Mr. Fowler; these plants have been picked for upwards of 40 years, and their yield when I was there some time since, was splendid. Once in bearing, the tea planter looks for a crop of 500 lb. to 1,000 lb. made tea per acre, but I have put the return of made tea at 480 lb. per acre that I may be within the mark.

Every planter makes his teas that they will fetch all round 2s per lb., and this a great many people will be deceived in, by looking at paper sales, for on every plantation there are high and low class teas made; for instance, our congous fetch say 10d to 1s per lb., but the others, such as flowery and orange pekoe realize 4s to 5s per lb., and the middle tea, which is pekoe souchong, gives from 2s to 3s per lb. Another thing is that in dry seasons teas are always inferior to those made during rains. Within a very short time machinery has been introduced for preparing the leaf or rather rolling, and the plant suitable for a 200 acre factory would cost, with tables complete, £300 to £350.

I would propose in the first place to follow the original plan of hand rolling, and the only expenses therefore attendant to the preparation of the leaves outside plantation work would be boxes, nails, clamp and tea-lead.

This is a small item when the good returns are considered.

Another subject which should be brought to notice is, that although some may think to the dividends being given on many plantations are low, the reason is because they are continually extending, and the surplus over goes for that extension.

The Companies that have stopped extensions are paying from 20 per cent to 37 per cent dividends, and any one has only to look over the Tea Company's accounts when such figures will be found.

I have not the least doubt that tea cultivation is destined to become one of the mainstays of this colony.

In starting such a company as I would propose, a capital of £4,000 should be raised. This amount need not be called up all at once, but let a first payment provide for the expenses of first year, and some margin over, say £1,500, in good time to meet operations of second year, and since third year's crop would not be required until currency of fourth year, a final call would be necessary to meet current factory account, after which the factory always pays expenses and leaves a handsome yearly profit to investor.

This sum there should be no difficulty in raising among the merchants and planters of Fiji.

The following is my estimate of the cost of opening out and cultivating a tea garden of 200 acres with returns that may be expected from it to seventh year:—

Outlay.		£	s.	d.
1st year,	Land, 400 acres ...	800	0	0
1st ,,	Expenses	900	0	0
2nd ,,	do.	1,000	0	0
3rd ,,	do.	1,200	0	0
4th ,,	do.	1,600	0	0
5th ,,	do.	1,750	0	0
6th ,,	do.	2,000	0	0
7th ,,	do.	2,400	0	0
Incidentals ...	... ...	3,500	0	0
	Total...	£15,150	0	0

Income.						
1st year,	nil					
2nd ,,	2,000 lb.	made tea	1/9	175	0	0
3rd ,,	32,000 ,,	tea @	1/9 ...	2,800	0	0
4th ,,	48,000 ,,	,, @	1/9 ...	4,200	0	0
5th ,,	64,000 ,,	,, @	1/9 ...	5,600	0	0
6th ,,	80,000 ,,	,, @	1/9 ...	7,000	0	0
7th ,,	80,000 ,,	,, @	1/9 ...	7,000	0	0
Total				£26,775	0	0
Outlay				£15,150	0	0
Balance at end of 7th year				£11,525	0	0

It will be acknowledged that this is a very splendid prospect; altogether too splendid many will say, but my estimates have been carefully considered.

I have calculated expenses as I think at a maximum, while the returns are below what I should consider a minimum. Tea, it must be remembered, is a very hardy plant, much more so than most tropical plants, and there is not much fear of a hurricane doing it any damage for more than a month or so, for its limbs are flexible as cane.

I am confident of success in this industry, and it only requires people to come forward and subscribe the necessary capital to start the industry at once and secure orders from India of this season's growth seed. The capital required for such profits shown is so small that many will say such cannot be accomplished, but whatever is stated is thoroughly correct, and if profits are not even larger I shall be greatly disappointed.—I am, &c.,

C. S. PEARCE.

TEA.

A correspondent of the *Indo-European Correspondence* writes:—

Tea planting in India must be a prosperous speculation, since the exportation is increasing yearly. In 1861 we could only send home 1,250,000 pounds; in 1864, the double; in 1867, 6,000,000; in 1870, 13,500,000; in 1878-79, 33,000,000, worth 30,000,000 of rupees. Though the whole of this fair exportation is nearly concentrated on the London market alone, it does not as yet supply more than 24 per cent of the wants of the United Kingdom for tea. 79 per cent, *i.e.*, more than 124,000,000 of pounds are still to be brought and exported from China. Therefore a very large field is opened to competition, and if the Indian tea-planters wish to satisfy the wants as well as the taste of the mother-country only, they must go ahead by improving and enlarging their tea plantations. But should Australia, Canada, the other English Colonies, and the world at large take a liking to Indian tea, what would our tea market become? It would be enlarged a hundredfold. It is far from being improbable? Not at all if we judge from what we have seen of late in the United Kingdom. How

many a *gourmet* who, from infancy, had been accustomed to the taste of Chiuese tea only, now relishes a fine cup of Indian tea? It is not owing to a mere fancy, but to our Indian tea being perhaps more savoury and certainly more cleanly and more carefully prepared than the Chinese article. Why, then, could not we hope that in a few years more Indian tea will find a way open to it in the markets of the five parts of the world?

This prospect, pleasant as it may be, is too high for me. Why look so far away beyond the seas? I will now take a much more nearer view of the matter and look only at the very threshold of India.

There, at our own door, is to be found a good export tea market; so much the better for us that it would not lessen the existing London market by a single pound of tea. This seems to be rather paradoxical, though very true, and calls for some explanation.

The tea bushes must be pruned every year, or at least every third year; every year, too, a large amount of leaves escape the plucking of the buds and small leaves; once too old and too coarse they are allowed to dry, to fall down on the ground, they are lost as tea, and they can be used for nothing but manuring the plantation. From what I heard, Chinamen of the western part of the Se-tchuen Province are not so foolish. They know well how to fill their purse with over 10 lakhs of rupees, quietly coming to them, from the sale of this rubbish which is despised by us great gentlemen! Some of them, I am told, even let their tea gardens grow almost wild in order to increase the heap of prunings, small branches, coarse leaves, and other rubbish to be prepared for tea. They are contented with a small quantity of fine rolled tea to be used in the district itself, not to be exported, because the best profit of their tea gardens comes from this coarse unrolled tea, which we think not worth the sweepings of our godowns. Besides this, the space between rows of scattered plants of tea are used as fields of Indian corn, of beans and other vegetables; so much so, that a Chinese tea garden on the western hills of the Se-tchuen Province when seen from some distance, looks very much like a field or a common garden newly opened amongst the jungles.

Far from me, of course, the thought of commending to our tea planters such careless a method of cultivation. Though Chinamen were tea-planters of old and our teachers, we are more enlightened, more civilized, and, thanks be to God, less greedy of money than they are. We know very well that the more weeds and even useful plants we allow to grow into our fields, the less nourishing substance will remain for the intended cultivation. Even for the sake of our superior civilization our shadows must be spread over our tea gardens which we must always keep well tilled, well manured, perfectly clean and elegant, as it becomes gentlemen. But when it is a fact that many Chinamen, greedy of money as the whole of them are, prefer making coarse tea to preparing fine tea, there must be a reason for it. This reason is no other than because it is more profitable to them; and it is profitable only because the coarse tea market is near at hand, whilst the fine tea market is very far off. This coarse tea market is Thibet, the emporium of which is Ta-tsient-loo, distant only a few days' journey from the tea-producing country, whilst Canton and Shanghai are so far away and of so difficult of access.

For us, I know, it is quite different in India. From Upper Assam, Darjeeling, Tirhoot, &c., to Calcutta or to any of the seaports, it is nothing but a short and easy promenade, thanks be to our railways, our beautiful inland steam navigation, our roads, our conveyances. Therefore, we must not on any account drop the bone and the meat to grasp at the shadow. But as this shadow can pour down into our pockets at least as many lakhs of rupees as it does yearly into the pockets of the Western Chinese tea-planters, and as the very same market is nearer to our own doors than the doors of Western China, why should we not avail ourselves of this good opportunity by preparing the same kind of tea, better adapted to the taste and means of the Thibetans, when it is sufficient for it to employ only the rubbish and leavings of our plantations?

Has the experiment been made. I do not say with the Thibetan people who sometimes come down to our market places, but even with the Sikimies and Bouthias who are living with us at Darjeeling, who are either under the protection of the English Government or at least under its powerful influence. To my knowledge, only one planter tried once and he failed. Why? Very likely only because he did not know how to prepare his Thibetan tea according to the taste of his intended customers. What has he done? I do not know exactly, but I fancy he merely swept away the prunings of his plantation after they had become dried by the sun's rays, when scattered all over his garden; then at some other time collecting the naturally dried and yellow leaves and mixing the whole together he got a kind of green yellow stuff without any juice or taste; this gentleman's intention was very good and in the right direction indeed, but if he acted so, no wonder that he failed in his laudable attempt to open up the Thibetan tea market. Had he asked for advice from some Chinaman of the Tsen-ky-hien, of the Yueu-ken-hein or Ya-chow districts in Western Se-tchuen, (there are perhaps some of them in Calcutta) he would have learned to his great advantage that the prunings before becoming dried, and the coarse green leaves before becoming nationally yellow, must be collected in October or thereabouts and subjected to some kind of fermentation which by destroying the green chlorophylle of the leaves gives them a brown colour without destroying the tasty juice which is rather increased thereby.

As fermentation is a capital point it is good to dwell a little upon it. According to my informant, the Chinamen dig two holes in some sheltered place of their compound. Into one of these holes they pile up the prunings, *i.e.*, the fresh little branches cut off with their leaves in small pieces about two or three inches long. Into the other hole they pile up the coarse green leaves plucked up from the bushes. If these materials are not moist enough they sprinkle a little water on the successive layers, which they press down with their feet in order to make the heaps compact and prevent by so doing as much air as possible remaining between the leaves inside of the holes. When they are full they cover them with mats, cloth, or blankets to prevent any contact with the atmosphere. Soon after, the natural fermentation begins, and heats the whole mass which becomes of a brown colour in the centre and at the bottom, whilst the upper part remains of a rather light yellow colour. To judge of the proper degree of fermentation, we must not therefore be contented with having a glance at the surface, but we must dig to the centre and see whether the leaves have become properly heated and tinged with a brown colour, without being however burnt by the heat or rotted by over humidity. After a few experiments it will be easy to judge from the time only.

As soon as the fermentation has come to a proper point, the yellow leaves of the surface are put aside to be packed up as an inferior quality of tea, or are piled up anew in another hollow place to be submitted to a better fermentation. The brown leaves and the brown prunings are then separately dug over by small quantities of four, five, or six pounds, sprinkled with a little rice water, *i.e.*, the water which has been used for the first ebullition of rice, which being impregnated with a certain amount of gluten is apt to

aggregate the leaves together. These leaves are then forced down into many wooden forms by means of a crow-bar and press attached to each form, or to which each full form is submitted. After a little while the brick is taken out of the form and allowed to dry under some shelter. The same process continues as long as there are leaves or prunings to be dug from the holes.

When perfectly dried, each brick of tea is entirely wrapped into double or treble sheets of oiled paper. At last these bricks are packed four by four, into mats of split bamboos. They are ready for exportation to the market of Ta-tsien-loo. * * *

RHEA FIBRE:

PRIZES FOR THE BEST MACHINE OR PROCESS FOR THE PREPARATION OF THE RHEA FIBRE.

(From the *Indian Daily News.*)

Extract from the Proceedings of the Government of India, Fort William, the 19th March, 1881:—

Read papers on the subject of the renewal of the offer of a prize for the best machine or process for the preparation of the fibre of the Bhomeria nivea, popularly known under the names of Rhea, Ramie, and China grass.

OBSERVATIONS.—With a view to the development of regular industry in the fibre of the rhea plant, the Government of India offered in 1870-71 a prize of £5,000 to the inventor of the best machine or process for its preparation. It was believed, from the information before the Government of India at the time, that the only real obstacle to the utilization of this staple was the want of suitable machinery for the preparation of the fibre. Only one machine was, however, presented for trial; and as it was found to be imperfect in some important respects after having been carefully tested in the autumn of 1872, the Government decided that the inventor should not be adjudged the full reward.

2. As the need for a good machine appeared still to exist, and no inventor had in the meantime come forward, the Government of India decided in 1877 to renew the offer of a prize. Accordingly, Notification No. 45 of the 31st August of that year was issued and widely published in India, Europe, and America. Briefly, its terms were that a reward of R50,000 would be given to the inventor of the best machine or process which would separate the bark and fibre from the stem, and the fibre from the bark of the Bohmeria nivea, and a reward of R10,000 to the inventor of the next best machine or process, provided it was adjudged to possess merit, and to be capable of adaptation to practical uses without difficulty. The machine or process required was to be "capable of producing, by animal water, or steam power, a ton of dressed fibre of a quality which shall average in value not less than £45 per ton in the English market, at a total cost, including all processes of preparation and all needful allowance for wear and tear, of not more that £15 per ton laid down at any port of shipment in India, and £30 in England after payment of all the charges usual in trade before goods reach the hands of the manufacturer." The machinery was to be simple, strong, durable, and inexpensive, and suited for erection in plantations where rhea was grown. The competition was to take place at Saharanpur, and the Government was to provide shelter and accommodation for the competing machines, as well as the motive power required. The Government was also to pay for the transport of all machines from the sea coast to Saharanpur up to a limit of one ton for each machine, and to allow a free second class ticket by rail to that station to any person in charge of a machine.

3. The trials were fixed to commence on the 15th September, 1879, and the following Committee of Judges was eventually appointed to conduct them:—

President.—E. C. Buck, Esq., C. S., Director, Department of Agriculture and Commerce, North Western Provinces, and Oudh.

Members.—W. Duff Bruce, Esq., C. E., Vice-Chairman of the Port Commissioners, Calcutta; Angus Campbell, Esq., Superintendent of the Canal Foundry and Workship, Roorkee; and Dr. Murray Thomson, Chemical Examiner to Government, North-Western Provinces.

4. Twenty-four applications for permission to compete were received; but only ten competitors ultimately arrived at Saharanpur, and of these three withdrew from the competition. The trials were held in September and October, 1879. The following is a list of competitors and a brief account of their machines:—

I.—Mr. J. P. Vander Ploeg.—His appliances consisted of a crushing machine and scutching machine. He cleaned the fibre finally by boiling it in a prepared liquor.

II.—Mons. J. Nagoua.—His appliances consisted of a combined crushing and scutching machine, the same machine being adaptable for both operations.

III.—Dr. R. H. Collyer.—He departed much from his original specification. He ended by boiling the stems first in water with a very little soda He then passed the stems through a machine which broke them up, and again through the same machine to clean them. He produced and used also another machine worked by hand. The smaller or hand machine cost only £60, but it would not be suitable for a regular factory.

IV.—The Paris machine belongs to a French Ramie Fibre Company, Messrs. Laberie and Berthet, who have exhibited in Paris. The machine crushed the stems which were kept constantly wetted. Then the fibre was steeped in a bleaching liquor, and an alkaline liquor.

V.—Mr. J. Cameron.—He abandoned the machines described in his specification, and brought a hand implement.

VI.—Mr. C. F. Amery.—He altered his specification. He broke the stems in a crushing machine, boiled them in an alkaline solution, and then passed them through the breaking machine again.

VII.—Mr. C. E. Blechynden.—He abandoned his original specification. He steamed the stems, then peeled them by hand, and then beat them by hand with mallets.

5. Then fibre turned out by each of the competing machines was carefully packed and despached to the Secretary of State, with a view to its being tested and reported upon by experts in the trade at home. The reports received from the Secretary of State with his despatch of August 12th, 1880, concur in stating that the samples are far inferior to the fibre imported into England from China, the value of which at that period was £50 a ton. The samples of which the reports speak most favourably were—

No. 28, (M. Nagoua) described by Messrs. Mark Dawson and Company, of Bradford, as containing "some good fibre, and fairly marketable." This was valued at £26 by the brokers (Messrs. Noble and Company)

Nos. 33, 34, and 35 (Mr. Cameron) valued by the brokers at £15, £18, and £18, respectively.

Messrs. Mark Dawson and Son approved of No. 33 as being "the best sample as far as freedom from bark was concerned: but the fibre was broken and tangled, would never give so large a yield in silver as No. 28, nor would the silver be so long; on the whole, it is the most valuable sample."

No. 34 is a "nice clean sample, similar but not equal to No. 33."

The Brokers (Messrs. Noble and Company) remark of the whole series submitted to them—"no one of

these samples are nearly up to the requirements. The only one is No. 28, which could be used for China grass purposes, and this would only sell freely when the market is bare of the regular fibre.

6. The reports of the experts were sent to the Committee, and they have now furnished their final report and recommendations. As no competitor has produced a fibre of a value even approaching the amount fixed in the Resolution of August, 1877, the Committee do not recommend the grant of either of the prizes to any of the competitors. They are however, of opinion that some of the machines possess sufficient merit to warrant the grant of a reward to the owners; and the gentlemen mentioned by them, as deserving of remuneration, are Messrs. Nagoua, Vander Ploeg, and Cameron. The fibre turned out by Mr. Vander Ploeg was valued less highly than that produced by Messrs. Nagoua and Cameron, but the Committee attribute this to the fact that he aimed at producing the fibre in a finished state fit for the spinner (a condition in which it is understood that the English dealer does not require it), and not to the inability of his machines to yield as good fibre as those of Massrs. Nagoua and Cameron. They remark also that there is little novelty in Mr. Cameron's process, and that it is only an improvement on a method by which fibre is actually extracted from various plants by the natives of India. The same method is also applied in many of the Indian jails for the extraction of aloe fibre. The process is simple enough to be employed by the natives with hardly any instruction, and any kind of stems, green or dry, short or long, could be treated by it: but it would be difficult of application in a rhea plantation where the stems of many acres of land would have to be worked off quickly. Having regard to these circumstances, the committee recommend that a grant of R5,000 each be made to Messrs. Nagoua and Vander Ploeg, and another of R1,000 to Mr. Cameron.

7. As none of the fibre produced came up to the conditions prescribed, the Governor-General in Council agrees that the prizes offered by the Government of India in 1877 cannot be awarded. At the same time, he concurs in the Committee's opinion that some recognition of their efforts is due to the three gentlemen, whose machines yielded the best results or appeared to possess superior merit, and he sanctions the grant to them of the sums recommended by the Committee.

8. From the low valuation put by the English firms on the samples of fibre produced at the late competition, it does not seem probable that Indian rhea fibre will be able, for the present at least, to compete successfully with the Chinese product, while the experience which has been so far gained also points to the conclusion that in most parts of India the cultivation of rhea cannot be undertaken with profit. Rhea is naturally an equatorial plant, and it requires a moist air, a rich soil, and plenty of water, while extremes of temperature are unfavourable to it. Such conditions may be found in parts of Burma, Uppar Assam, and in some districts of Eastern and Northern Bengal: and if rhea can be grown in such places with only so much care as is required in an ordinary well-farmed field for a rather superior crop, it is possible that it may succeed commercially. An experiment on a somewhat large scale has been undertaken in the Dinajpur district—one of those in which rhea has for many years past been cultivated on a small scale by the peasantry for their own use—and the results will be watched with interest. Until, however, private enterprise has shown that the cultivation of the plant can be undertaken with profit in these or other parts of the country, and that real need has arisen for an improved method of preparing the fibre in order to stimulate its production, the Government of India thinks it inadvisable to renew the offer, which it has now made for the second time without result, of rewards for suitable machines. But in order to aid persons who are anxious to try the cultivation of the plant in localities which are *prima facie* suitable, the Government will be willing to place roots at their disposal. A plot of about two or three acres will, therefore, continue to be kept under rhea in the Botanical Gardens at Howrah for the supply of roots to intending growers.

9. A sample of China grass valued at £50 a ton in the English market has been deposited in the Economic Museum at Calcutta, and in accordance with the recommendation of the Committee, an endeavour will be made to obtain specimens of the fibre produced by the several competitors at the trials at Saharanpur from the Secretary of State, to whom all the samples were sent. These samples, with the valuations of the experts noted on them, will also be deposited in the Economic Museum for inspection by the public.

ORDER.—Ordered that a copy of this resolution be forwarded to the President and Members of the Rhea Committee; to the competitors; and to the Government of Bengal, with reference to para. 8; and with a request that the necessary instructions may be communicated to the Superintendent of the Royal Botanical Gardens at Howrah.

Ordered also that a copy of the Resolution be forwarded to the Department of Finance for information and further orders, and that the Resolution be published in the Supplement to the *Gazette of India*.

(True Extract.)

C. W. BOLTON,

Offg. Under Secretary to the Government of India.

THE TIMBER-TREES OF THE STRAITS.

(From the *Straits Times*.)

As a great deal of uncertainty exists in connection with the botanical nomenclature of our best timber trees, I have been induced to offer for publication in your columns a short résumé of the information I have been able to collect upon the subject during my five years' residence in the colony, principally with the view of calling more direct attention to them than they have as yet received; and inviting discussion, and the opinions of others who have had practical experience with them, as by this means a large amount of original information is often drawn out, as instanced by the amount of information collected in the Straits on the origin of Malayan Guttas and Caoutchoucs since my first contributions to their history in 1877.

With the exception of Col. Low's Dissertation, as given in Cameron's *Malayan India*, and Major McNair's Report to the Secretary of State for the Colonies, which was published in the *Government Gazette* last year, very little, so far as I know, has ever been published on the subject.

The botanical names which I contributed to Major McNair's report were professedly provisional, and a more intimate acquaintance with the writings of Miquel, Horsfield, Maingay, and others, has disclosed several errors of nomenclature in it which I propose to correct in the following notes.

It is to be regretted that the large stock of samples of our indigenous timber trees in the offices of the Public Works Department in the Colony was not made use of for Major McNair's report instead of using Col. Low's descriptions *verbatim*.

India, owing to its perfectly organized system of forest conservancy, now deservedly stands at the head of all the British dependencies—if not of the whole world—for the way in which its forest wealth has been developed, and the amount of accurate and valuable information that has been collected and published on the subject.

In the remainder of the British Colonies, as shown by the official reports that have been sent to the different Secretaries of State for the Colonies during the past five years in response to a Colonial Office circular, the information collected, or available to the public, is meagre and unreliable. One or two facts are painfully evident—t at in the early days of colonization, the original forests were recklessly destroyed wherever it occupied land that could be adapted to any other purpose, however small; while the largest and finest trees were used for fuel or charcoal, no attempts were made to rectify the mistake by subsequent planting; and even now the same state of things exists, where in other respect a new regime has been inaugurated.

That the Straits are sadly behind the times in this respect it is unnecessary to say here. On this subject Mr. Van Volxem, writing in the *Gardener's Chronicle* for June 22nd, 1878, says:—

"When I visited the Straits Settlements I wondered at the enormous amount of clearings made by the Chinese emigrants for their Gambier gardens, which, after a period of seven to ten years, are abandoned for virgin plots and allowed to return to jungle, not the majestic primitive forest fuel of beautiful and useful trees, but a secondary growth of ugly and worthless shrubs, a perfect eyesore to the lover of Nature, and to the prosaic matter-of-fact man also—a curse to neighbouring plantations, as nests of weeds.

The questions and answers appended to Major McNair's report may not be uninteresting, and are worth a wider publicity than they are likely to get through the *Government Gazette*, aue they are consequently reproduced here in full. About the Return "A," I have more to say further on:—

Q.—I. What are the kinds of timber trees produced in the country, and to what uses are they generally applied? (State the botanical name where known.)

A.—*Vide* Return A.

Q.—II. Are forests or lands producing the trees owned by the Government or by private persons?

A.—By the Government chiefly, excepting a few estates in Selangor and several thousand acres of forest land in Sungei Ujong, which have been given for coffee, cocoa, and tapioca planting.

Q.—III. What is the approximate extent of timber-producing forests or lands at the present time?

A.—In Singapore, 22,000 acres; in Penang and Province Wellesley, 130,000 acres; in Malacca, 45,000 acres; in Perak, about 6,000 square miles; in Selangor, 1,720 square miles; and in Sungei Ujong 300 to 400 square miles.

Q.—IV. Is this area increasing or diminishing?

A.—Diminishing.

Q.—V. If diminishing, from what cause?

A.—In the Straits Settlements, from the sale of land and extension of cultivation, and too often from illicit felling and charcoal burning. In the Native States, coffee planters and other agriculturists are making enquiries about the lands, and, as these are suitable for various cultivations, it may be expected that much forest will be destroyed in succeeding years.

Q.—VI. Are any steps taken for the prevention of waste or for replanting any area which has been cleared?

A.—The Government has one Forest Ranger at Singapore and two at Penang, and frequently men are brought before the Police and punished for felling trees on Government land, but no steps are taken to replant any area, which has been cleared, with fresh trees. In Perak, no such steps can possibly be efficiently taken in the present state of the country. Charcoal burners for the tin miners destroy large quantities of the most valuable timber; an attempt has been made to prevent this, but it created much dissatisfaction and was very ineffective. Abundance of young trees of all kinds spring up where shelter from the rays of the sun is secured, so that felling for charcoal or timber does not altogether destroy the forests as coffee planting and rice cultivation do. There are forest reserves declared at Kuala Lumpur, the mining and populous centre of Selangor. Persons clearing and felling jungle in Sungei Ujong without a permit are liable to be severely punished. No steps have yet been taken to replant.

Q.—VII. What is the quantity of timber which might fairly be cut every year without permanent injury to the forests?

A.—The Government can spare no more in either of the Settlements. At Singapore a reserve is kept round the principal hills for climatic purposes, and at Penang, Province Wellesley and Malacca there are also belts reserved for the same purpose, but it is feared that trees are often felled by Chinese, for want of a large staff for supervision. It is not known what quantity might be cut in the protected Native States.

Q.—VIII. What is the quantity actually cut every year?

A.—It is impossible to say. The estimated export of Maugrove from Perak for firewood for the supply of the island of Penang, where it is used in large quantities for the sugar mannfactories, is ten junks per diem carrying 7,000 billets each, of the value of $5 per 1,000. Timber for house building in Penang is also supplied chiefly from Perak and the Dindings. The Krian river sends a large but unknown quantity. Planks of Seraya are exported from Lukut in Selangor.

Q.—IX. What is the proportion for home consumption and for export?

A.—In the Straits Settlements mangrove is used for firewood; there is an abundant supply, and the bark is exported to a limited extent. But all timbers for building purposes are imported into the Settlements. In the Native States very little is used for home consumption, and then only for building purposes, charcoal burning for tin smelting and firewood.

Q.—X. What have been the annual exports of each kind of timber during the last ten years; stating the proportions to each country, and the value of such exports?

A.—No exports during the last ten years have been made from the Straits Settlements, and none from Sungei Ujong. In Perak and Selangor there are no statistics from which accurate information could be supplied.

Q.—XI. What are the reasons for, or causes of, the increase or diminution of quantity or value in the exports?

A.—The exports from Perak are certainly increasing on account of the greater demand from Penang, and the peaceful state of the country, which permits Chinese sawyers and others to reside in security and work in it.

Q.—XII. (If it be so), what are the causes of the small exportation in comparison with the capability of production?

A.—In Perak, want of capital, and the so recent pacification of the country. A very valuable and remunerative trade might be established, as the numerous rivers present facilities for exporting the timber, and the prices at which it could be worked, or contracted for, are very moderate indeed.

In Selangor the population is small and coolie labour is dear, in comparison with neighbouring countries, such as Java, India and China.

Q.—XIII. Have any observations been made, or conclusions arrived at, as to the climatic influence of forests, or the effect of their clearance on the rainfall, floods, &c.?

A.—It is found at Singapore that although the Crown lands have been greatly denuded of trees, there has been no marked diminution in the rainfall. No observations have been made as yet in the Native

States, but rain gauges and meteorological instruments have lately been brought into use at five stations in the States. Government has declined to permit the settlement of agriculturists on the western slopes of the Hijau range of mountains, fearing that the steady supply of water necessary for the miners' pumping-wheels would be interfered with.

Q.—XIV. Forward any reports made by departments or societies, or any Acts of Legislature bearing on the subject?

A.—There are no Acts of the Legislature of the Straits Settlements bearing on this subject, but there can be no doubt that it would be desirable that there should be attached to the Land Department a small Forestry Department, for the purpose of preserving our reserves and restoring our forests by the establishment of nurseries for young trees.

The answers given above speak for themselves, and I shall content myself with a remark or two on the influence the denudation of forest lands have on the climate. Our neighbours in Ceylon and Mauritius have proved this, to their cost in some instances, and although Singapore from its size and position is not likely to be materially affected by anything that may be done on the island itself, the reckless clearing of the Johore hills would materially alter the condition of things here, and it becomes evident that on the proper management or otherwise of the mountain forests on the mainland, the future climate of the island of Singapore will in a great measure depend. I have no hesitation in asserting that Mr. Chasseriau owes many a shower to his proximity to Bukit Timah, and if Bukit Timah were cleared like Mount Faber, the Municipality would be compelled to search for fresh sources for their water supply. From calculations made from observing the two hills almost daily for five years, I should say that at least five times as much water falls on Bukit Timah as on Mount Faber in the course of the year. This could easily be determined by the P. C. M. O.

The following extract from the *Gardener's Chronicle* of March 8th, 1879, renders anything that I could possibly write on this subject superfluous:—

Indian Forests, their Relation to Climate.—The October number of the *Indian Forester* contains an article by Surgeon-General Balfour on the influence of trees on the climate and productiveness of the peninsula of India. It contains an abstract of the conclusions arrived at by various officials in India, almost all of whom agree in the necessity of protecting what forests remain, and of planting the hills of Southern India with trees wherever a tree will grow. "Fine districts were not destined by Nature to be the prey and sport of famine and scarcity, but have been rendered subject to these calamities by the thoughtless action of man." Some valuable tables are given showing that the total amount of actual rainfall has not diminished of late years, but that man, by denuding the land of forests, is allowing the rain-water to rush off the surface, sweeping away with it the mould, breaking down the tank-dams, starving the springs, and draining off the waters of the springs, rivulets and wells. Replanting is strenuously advocated, the growing plants being protected from fire, grazing animals, and other destructive agencies. Pasturages should be secured for the animals, which should be prevented from browsing on the plantations. Even the roots of the valuable grass, Cynodon Dactylon, are, we are told, dug up in the hot weather for fodder for the horses. Moving sand should be restrained by suitable planting and a proper system of forest-conservancy introduced not only in British territory, but in the allied and feudal States likewise. The rainfall, repeats Mr. Balfour, has not diminished, but "man, partly ignorant and wholly reckless, has denuded the soil of its trees and shrubs, and bared the surface to the sun's rays, thus depriving the country of its conservative agents, and making the extremes of floods and droughts of more frequent occurrence and more severe."

As a remedy for this state of things, Mr. Van Volxem's suggestions, which refer exclusively to the Straits Settlements, are worth the attention of the Government. He says:—

Would there be any difficulty in making it obligatory to the Gambier planters, and others, to plant in the last year but one of their occupation a certain quantity per acre of useful trees, and to remit them the ground rent of their estate for these years by way of compensation, so that at the time they cease to occupy their gardens, they would, by showing so many trees per acre of a fixed kind two years planted, obtain from the Inspector of Forests a cheque for a certain sum, which would be accepted in discharge of ground rent, transferable of course? Defaulters might even be fined. Such an enactment would, at a very small cost to the Government, give an impulse to clearing the superabundant forest, and in a few years, at the smallest possible outlay, the State would become the undisputed owner of valuable patches of the most useful trees. It would be at least a remedy for the indiscriminate and wholesale extermination of the gutta-percha trees. If grown in dense masses they might be usefully managed by moderate tapping, instead of being felled all at one time as now, without any provision for their replacement. I speak chiefly of the gutta-percha, because, being indigenous there, it would certainly thrive in its native soil and climate, and besides it might perhaps be procured cheaper than any of the newly imported trees. But the same process might be useful for these last, like the various rubbers, the Mahogany, or the Cedrela odorata.

To complete the process, nurseries ought to be made where quantities of the young saplings could be had at a fixed and low price. They ought to be grown in large Bamboo joints, for easy transplantation, upon the principle so usefully employed for the last few years by my good friend Dr. Thwaites, the able director of the Peradeniya Gardens, Ceylon. He is, I believe, the originator of it. Such nurseries could be erected by contract near to the clearings. The Chinese, heaven-born gardeners, would certainly take up such jobs very effectually, and be cheaper than any other means.

Refering to planting to the tropics generally the same writer says:—

"In hot climates, however healthy, no emigrant settles with the idea of making the place his home. He comes to make his fortune as soon as possible, the sooner the better, when he can return to his native land. A little gambling excitement, resulting from the uncertainty of the crops, and the fluctuations of the produce market, keeps up his spirits. But abroad no man can afford to embark his small capital in a venture that cannot possibly bring him a return before thirty or for tyyears—quite a lifetime! So Government must step in for the benefit of the community. Government alone can afford to plant trees, either for timber, or for rubber, gutta-percha, gum, and what not else, and, after having made the planting outlay, pay for the supervision during the unproductive period of growth. Unluckily forest clearing, to make room for the new trees, is always a very costly affair, and in the nature of things Government would certainly have to pay more for it than private enterprise, however well the work might be conducted. Besides, for two years at least, there would be a necessity to employ expensive labour to check the natural growth of the forest, or the newly planted trees would soon be choked to death."

Where the replanting of waste lands is decided on, the first and most important thing to attend to, is to select species of good timber-producing trees adapted

to the climate, the different soils, and situations, and to do this a knowledge of the indigenous tree of the country is imparatively necessary; as they can mostly be depended on, while experiments with exotics have always a certain amount of speculation attached to them, and failures are by no means rare. That the Straits possess some excellent timber trees it is unnecessary to say here, as some sorts are well known in other markets, as for instance Daru, Baloo, Tampenis, Merbau, Tembusu, and others, some of which for durability are scarcely rivalled by English Oak or Indian Teak; and too much cannot be known about the requirements and habitats most conducive to their healthy and rapid development. Of some of these there are several varieties, (by a *variety* I here mean the *variation in the same kind of timber*, which may possibly be produced by *distinct species of trees*,) as for instance the Merbau and the Seraya; of the latter so many, that hardly any two samples of the timber selected at random will be found to correspond in the degree of porosity and density. Hence it becomes a matter of the utmost importance that those species which yield the best kinds of timber should receive the most attention in their native habitats; and instead of sowing seeds that have been collected at random, attention should be paid to securing only good varieties as a tree producing worthless timber absorbs the same amount (and in the majority of instances more) of nourishment, space, and attention, as its more valuable compeer.

The only plan to follow to ensure this is to acquire first some knowledge of the general appearance of various timber trees together with their distinguishing characteristics; as little dependence can be placed on native names that have not become common every-day words, otherwise they are extremely local, and the same word may be used to distinguish two very different trees,—let us say for instance, in Johore and Sungie Ujong. Then, again, the great similarity of native names often leads to confusion, as for instance Kladang, Kledong, and Kladong, which are given to widely different trees in the Straits.

The reluctance of Malays, or in fact all oriental nations, to confess their ignorance on subjects like native names is too well known, and they will often give a wrong or an impromptu name rather than confess their ignorance.

In the following notes I shall endeavour, while avoiding all technicalities as fair as possible, to give a general description of the various timber-producing trees known in the Straits under the native or commercial names most generally used, adding any less known synonyms, together with the soil and situations in which they mostly obtain; premising that the descriptions under this head are the results in most instances of actual observations; but as the same species often affects widely different habitats which have their influence on the mode and manner of growth, I trust that where my experience differs from that of your other correspondents who have paid attention to the subject, they will come forward with their quota.

I do not intend to enter very fully into their uses, as these are almost as widely known as their native or commercial names, and when once their botanical nomenclature is settled, further information can usually be found in books devoted to the subject. For their breaking weight, weight per cubic foot, and value, Major McNair's Report and Kurz's *Forest Flora, British Burma*, have been consulted. With these preliminary remarks I will close my present contribution, and in my next take up the sorts of timbers given in Major McNair's Report first.

H. J. MURTON.

Singapore, 9th April, 1881.

THE WAX PALM IN PERNAMBUCO.

(From the *Journal of the Society of Arts*,)

Mr. Francis T. Eaton sends some further particulars respecting this palm, described in the last number of the *Journal*:—

Carnauba, or vegetable wax (not Carnauba) is the produce of the leaves of the Carnauba Palm (*Corypha cerifera*; natural order, *Palmaceæ*), one of the finest palms of the Brazilian forests. Its fan-like leaves are placed in a tuft at the top of a hard solid stem, growing from 30 to 40 feet in height, the stalks of the leaves themselves being 6 or 8 feet in length. When the leaves have attained perfection, they are found to be varnished with a thin coating of vegetable wax; they are then gathered and laid in a cold dry place on cloths, where they naturally wither and shrink. In consequence of the shrinking, the coat of wax cracks, and peels off in small flakes; these are from time to time collected, and it is turned out when melted into small earthen pans, and then cooled. The lumps (as imported), are about 3 and 4 lb. each, and ad best the shape of the pan in which they have been melted; it is of light sulphur colour, with a lustre between that of wax and rosin, and rather brittle. There were imported into Liverpool, in 1878, 80 tons; in 1879, 13 tons; and in 1880, 40 tons, and the value has ranged between 35s and 85s per cwt.

Tea in Darjeeling and Julpigorie.—We learn from the "Financial Reformer," that eight new tea gardens have been opened out during the past year in each of the above districts. At present there are 152 tea gardens in the Darjeeling district, and 37 in the Julpigorie; the number of acres under tea in the former district being 37,327, and in the latter 11,079. The total yield of the season for the two districts is estimated at 5,538,040 lb.—*Indian Tea Gazette*.

Land Reclamation in Florida.—It is reported in the *Engineer* that the Philadelphia capitalists who are about to reclaim the immense tracts of land in the State of Florida known as the Everglades, have completed their contract with that State, one of the main features of the scheme being the building of a ship canal across Florida. This project almost equals in importance that of reclaiming 12,000,000 acres of rich land. It would not only shorten the distance between the American ports on the Atlantic coast and all European ports to New Orleans, Mobile, and all shipping points on the Gulf of Mexico, but it would avoid the dangers to navigation which are experienced on the countless keys and coral reefs off the southern and south-western coast of Florida.

Tea in New South Wales.—The *Colonial Review* of May 28th says:—"It is rather strange that, while in Melbourne Indian tea has been introduced with so much success, as yet in Sydney but little business has been done in it. Probably the importers in the latter city are so satisfied with their present relations with China, and the profits earned in that way, that they do not think it advisable to offer a change to the consumer. But we imagine that the distinct preference for Indian tea, which has so manifested itself in Victoria, must before long extend to New South Wales, and that the local trade is will then have to give way. In Victoria, during the seven months from August to March last, nearly half a million pounds of Indian tea were sold; and an idea of the steady growth of the trade may be gathered from the fact that about two-fifths of this quantity were sold in March alone. The Calcutta Syndicate who have had this undertaking in hand have every reason to be satisfied with the unqualified success they have attained." We have reason to believe that Ceylon tea will shortly have a special agency in Sydney.

Correspondence.

To the Editor of the Ceylon Observer.

CINCHONA CULTIVATION:—MANURING:

Dikoya, June 23.

DEAR SIR,—I should be very much obliged if any of your readers can inform me from actual experience:—(1) Does application of cattle manure to cinchona succirubra materially increase the growth; (2) does it increase the value of the bark; (3) is there anything to prevent the application to young plants say six months old.—I am, sir, yours faithfully,

---

ALOE FIBRE.

Kirimittia Estate, Kadugannawa, June 24th, 1881.

DEAR SIR,—As you are the person to whom people always have recourse for any information, I should be glad to know if aloe fibre, prepared in the same manner as the sample I send to you by post, and about five times that quantity, at the cost of one cent, would pay; and also how long the aloe takes to attain full maturity.

This being my first attempt to extract fibre from aloe, I have no doubt that it could be improved in every way.—Yours faithfully, J. HAWKE.

[Five times the quantity would be about half-a-pound, or 2 cents per lb.: that is certainly not dear, 45 rupees per ton; but we suspect a very few tons would exhaust all the available aloes. Under favourable circumstances, we have no doubt, however, that the aloe plant would come very rapidly to maturity. Mr. Hawke has possibly not observed the extract we gave very recently with reference to the cultivation of the American aloe. We quote as follows:—

"It grows in almost any soil, and requires very little care. It is supposed not to arrive at full maturity under one hundred years; but this opinion is an error, as the age at which it arrives at maturity varies, according to circumstances, from 10 to 50 or even 70 years. When it has acquired its full growth, it produces its gigantic flower stem and then perishes. The plant is useful in many ways. By making incisions in its stem a fermented liquor and favourite beverage called by the Mexicans 'Pulque' is obtained, from which again an agreeable ardent spirit called "Vino Mercal" is distilled. 'Pulque' is said to be a most wholesome drink, and remarkably agreeable when one has overcome the first shock of its rancid odour; it is said, moreover, to be an excellent application for gout and rheumatism. The dried flowering stems are an almost impenetrable thatch; an extract of the leaves is made into balls which will lather water like soap; the fresh leaves themselves, cut into slices, are occasionally given to cattle; the centre of the flowering stem, split longitudinally, is by no means a bad substitute for a razor-strop, owing to minute particles of silica forming one of its constituents; but the most useful part of the plant is the leaf, the fibres of which form a coarse kind of thread, which are called in England "Pita Flax." The natives make very good common cordage or rope with these fibres. Some samples of the fibre were sent to the Agricultural and Horticultural Society for "an opinion as to whether it could obtain any value as an article of commerce in the Indian or Home markets." Messrs. Cogswell and Robinson report on the samples as follows:—"With reference to the samples herewith alluded to in the foregoing memorandum, I beg to observe that the washed and heckled fibre prepared from the 'Agave Americana' or common aloe, is about the best I have seen, being beautifully clean and well freed from the bark or outer skin of the plant, of good colour, there being but a very slight tinge of greenish, which it is impossible to thoroughly eradicate without extra steeping, or the addition of chemicals, to the injury of the fibre; it is of very great length and strength, and a really good commercial commodity, its value to-day (November. 1880) being about eight rupees a bazar maund R220 per ton. The sample unheckled I would value at about one rupee a maund less. The sample of combings, generally known as tow, could be used in this country for paper-making only, its value as such being about three rupees a maund; but in England, where spinning machinery can be applied to it, a good yarn might be produced. As a product of shipment thereto it is of greater value than being consumed locally for paper making; for the latter, I am of opinion, it is too good and costly as jute tow, and such like fibres, are so cheap and plentiful in this market."—ED.]

NEW PRODUCTS FOR THE HILLS: "NEW ZEALAND FLAX."

Maturata, June 22nd, 1881.

DEAR SIR,—I feel assured anything pertaining to a new product or industry will not lose any ground for the want of advocacy in the columns of the *Observer*.

It is with this assurance that I submit to my brother planters the suggestions contained in the following article on New Zealand Flax or Phormium Tenax.

When we speak of "New Products," the low-country is generally understood. Any elevation above 2,000 feet is totally without a new product, if we except our cinchona, whereas below this elevation their names are legion. I am sure, if we look about us, we shall find many new products that can be grown successfully and profitably among the hills, where the climate is European, and fevers conspicuous by their absence.

My attention was first directed to the practicability of cultivating New Zealand flax in the upper country by seeing as fine a bunch of it near the O. B. C. Bank in Nuwara Eliya as I ever saw in New Zealand; also, in the Dimbula district, in the garden of a well-known planter, there is another good specimen. These individual instances almost establish the fact that it will grow, and grow well. Therefore, it only rests with me to show how the fibre is extracted and the margin of profit over expenditure. I think I can speak with a degree of authority in this matter, as my father was among the first to begin the industry in New Zealand. About 1870, the settlers were taken with the flax fever quite as much as the present gold fever in Ceylon; with this difference, they had plenty of raw material at hand, while the gold fever finds an outlet only in barren quartz hitherto. But *nil desperandum*. "Quartz is the mother of gold" is an old diggers proverb and a true one. I have seen nearly every diggings in New Zealand and many in Australia, and in all my experience I never saw such a quantity of likely quartz as I have seen in Ceylon.

But to return to my subject. Our first method of separating the pulp from the fibre was a very primitive one. We had two large wooden tanks made about 15 to 20 feet long and from 6 to 8 wide. Inside these the flax was put soon after cutting and the lids closed down tightly; then steam was injected into the flax which softened in about six hours.

The steaming was always done in the night time, so that the flax might be ready for the mill in the morning. The only other process was to pass the softened leaf through between two malleable iron rollers which were heavily weighted by compound leverage. The fibre came out clean behind the rollers, and the pulp passed down a drain prepared for it. The fibre was then washed, dried, pressed, and sent home for sale.

This process I have described was soon succeeded by a very ingenious machine which stript the fibre of the green outside matter without the trouble of steaming or rollers of any kind. When we could erect our

mill in the centre of a large field of natural flax. the calling used to pay very well. To cultivate did not do so well. This, however, can be easily explained. We had to pay eight shillings a day for ordinary labor. Our steam engine used to consume over a ton of coal per day, which cost 30s per ton. The engine driver used to receive 15s per day salary. This outlay, which is very considerable, could be altogether saved in Ceylon, for every coffee estate has its water wheel, and a command of water power. The only expense therefore which the planter would be put to would be to buy one of the small machines I speak of, and attach it to his water-wheel.

Phormium tenax always finds a ready market, and within the last few years has been applied to many uses which were not known when the industry first began in New Zealand. This illustrates the saying that supply always creates its own demand, and shews the folly of the conclusions of many wiseacres who pretend to figure out exactly what the world will want, and everything over and above is a ridiculous waste. With regard to cinchona bark of all descriptions, I have been told that the consumption of the whole world cannot exceed certain figures, and critics base their calculations on the ground that last year showed an increase over the produce of the year before, this year must be a proportionate increase, next year a further, and so on, making no allowances what ever for new uses, which extra supply always creates.

There is nothing I know of which illustrates the folly of this argument so well as our experiences in wools In the year 1845 to 1850 before the Cape, Australian Colonies, and New Zealand sent wools to the London market, the price per pound was about one sixpence. Now there is almost thirty times the quantity and the price is nearly double. Rope made from New Zealand flax was tested along with pure Manilla of equal strand and size: the result showed most favorably for flax. The Manilla broke at a strain of about 13 cwt., while the flax did not break till it reached 17 cwt. I remember seeing an account in one of the home papers some time ago, where it spoke of a fine table-cloth having been made from New Zealand flax which was presented to H. R. H. the Prince of Wales. I remember the comments on the article at the time were most flattering, and gave every encouragement to prosecute the manufacture of that class of goods from New Zealand flax. The value of a ton of flax is about 50 to 60 pounds sterling. It may have fluctuated a little lately; but not that I know of. In conclusion, I shall be glad to answer any questions that may be asked of me. Apologizing for trespassing so much on your space, I am, yours truly, PHORMIUM TENAX.

CRICKETS.—"For the last five years or so (says the *Hamilton* [Victoria] *Spectator*) the black crickets have been a source of trouble to gardeners, and the Chinese vegetable-growers particularly complain of having 'too muchee cricket.' The insects are very voracious and make a clean sweep of everything green that comes in their way. They are to be found in myriads in the neighbourhood of creeks and watercourses, and they mostly affect black clayey soils where the crevices in the surface afford them shelter. Latterly we are told that the crickets have increased to the dimensions of a regular plague, marching forth in vast armies and destroying every blade of grass in their way as completely as do the locusts. Some parts of Monivae are overrun with them, and the invaders are now advancing upon Buckley's Swamp. The only effectual means of checking or destroying the crickets is to turn out flocks of young turkeys in the neighbourhood of their haunts. The turkeys are very persevering in hunting the insects, and they gobble them up by the thousand."

THE MYSTERY OF THE TEA TRADE.

(*North-China Herald*)

We do not think it necessary to make any apology to our readers for directing their attention to the letter which appears below under the signature of "Chaa Szee." Most of the residents here have such a direct interest in the matter he treats on that we thiuk it well to make a few remarks on what appears to us a very important subject. Our correspondent states, and apparently it would be difficult to deny it, that shippers of tea are paying in Hankow from 6d. to 7d. per pound over rates current recently in London. The question then to be solved is,—are there any reasons sufficiently good to warrant such an advance? One answer to this would be—and there is probably some reason in it—that the sale he refers to was not a fair indication of the value of the tea; that the tea was, in fact, sacrificed. We have taken some little trouble to find out whether such might not have been the case, and the conclusion we have arrived at is that the tea in question would probably have fetched from 1s. 3d. to 1s. 4d. instead of 1s. 1d., had it been more carefully handled on arrival in London. This then will apparently do away at once with half the discrepancy which he asserts to exist, but it must not be forgotten that this is a risk which a large proportion of shipments must always run. It also appears that his sale is a fairly recent one, for he states that he purchased the tea in December; it could not, therefore, be on the London market before the latter end of February, when we are informed that teas of good quality were scarce and wanted, a state of things which will not exist when present purchases arrive. It is, therefore, a fair argument that the value of such tea will be less when the deficiency ceases. For the sake of argument, however, we will assume that the present value of such tea in London is 1s. 3d. per lb. Is there any just reason why 1s. 8d. should be paid for similar, or, according to our correspondent, for inferior quality? To our minds one fact only would justify such an advance, and that is the certainty of a marked deficiency in supplies. Reports from Hankow refer to a deficiency the first crop of from 10 to 15 per cent. Without going so far as to deny that this may be possible, we must confess to being somewhat sceptical on this point, nor do we think that a short first crop necessarily means a short total export. The season 1878 and 1879 is, we doubt not, still within the recollection of many of our readers, and if we are not mistaken there was a very large actual decrease in the first crop. Still the total supply of the season was ample, or, judging from the disastrous results, more than ample, that season being acknowledged as one of the worst the trade ever experienced. We are therefore unable to see that a problematical deficiency is a sufficiently good reason for paying in China 5d. per lb. more than teas are worth in London.

But are buyers in London, at the time present shipments arrive, likely to act upon the supposition that there is a short supply, or will they treat the statement as nothing more than a report? The cry of "Wolf" has been so often raised and so often proved to be devoid of truth that we have no hesitation in stating that not the slightest heed will be paid to this report until an actual deficiency will be apparent. Judging from the fact that they will carry over from last season a large surplus stock; that the supply from the south of China promises to be large; that, as our correspondent observes, there is the certainty of a large increase from India we can see no chance of any deficiency being felt in London for many months to come. Granted that the whole Chiucse crop is inferior in quality, we should—it may be in our ignorance—have supposed that this was a strong reason for paying less than usual whereas that the contrary is the case seems a tolerably well authenticated fact. That there will most certainly be a dearth of fine teas of China

growth seems inevitable, and those shippers who, taking this into consideration, have only paid enhanced prices for fine teas may probably find that they were justified in doing so, but because the whole crop proves to be inferior appears to us to be a very poor reason for raising the price all round, or at least for qualities such as our correspondent mentions. Taking a calm unbiassed view of the whole matter, we can form no other conclusion than that shippers are running enormous risks, which circumstauces, at any rate at present, do not justify. As soon as the inferiority of the China crop will be known in London, the inevitable result, to our mind, will be to considerably enhance the value of Indian teas and to the same extent depreciate the value of China teas. The public at Home is by this time so accustomed to obtain tea of really good quality for 1s 8d per lb., that they will not be easily satisfied with anything inferior. This tea is made up of a judicious mixture of Indian and China, and to make up for the deficiencies of the latter more Indian will be used and less money paid for the China.

THE MYSTERY OF THE TEA-TRADE.

To the Editor of the North-China Herald.

DEAR SIR,—If you will allow me through the medium of your columns to call the attention of tea-buyers in Hankow to the following facts, it may perhaps be productive of some good.

A week ago a gentleman from Kiukiang forwarded to me here a sample of a purchase of tea, he had just made at Tls. 28, or say, equal here to Tls. 32. I may mention incidentally that his purchase shows relatively such good value that it is worth in Hankow Tls. 32, Tls, 2 more than he paid for it.

Being anxious to see whether present purchases showed any reasonable, chance of resulting favourably, I compared it with teas bought last season at the opening of the market, but I found the difference in quality so enormous that no fair comparison could be made. I therefore took a similar district tea that I had purchased here in Shanghai last December at Tls. 21, and great was my astonishment when I found this to be fully Tls. 3 superior to the muster sent me. To be quite sure that I was not unduly favouring my own purchase I sent a muster of it to Kiukiang, asking my friend to compare it with his. I yesterday received his answer to the effect that my tea was fully equal to his.

My tea has been recently sold in London at 1s 1d per lb. I am therefore confronted with this difficulty. Leaving on one side my own opinion as to the superiority of my purchase and taking the present buyer's own statement, teas no better than recent sales in London at 1s 1d are now being hurried forward costing 1s 7d at 1s 8d and that with a *present* prospect of heavy supplies from China, the certainty of a large increase from India, diminished demand for China teas at Home, and an increased stock carried over from last season. I have, Sir, been intimately acquainted with the tea-trade for the last eighteen years, but I have yet to learn how shipping under such conditions can result otherwise than in a terrible loss.—I am, dear sir, faithfully yours, CHAA SZEE.

28th May.

A NEW TWO-LEGGED ENEMY OF CINCHONA!—Have you been told of the new enemy of the cinchona tree that we have found out? The coolies taking off the bark about a foot up from the ground, and selling it in the villages. The wily native finds a decoction of it good for fever. I came across (this morning) one of my finest trees that had been robbed. You should give cinchona planters the hint to keep watch. It is not merely the loss of the bark, but the tree is liable to be injured if not destroyed, should they ring the trees.

COFFEE AND CHICORY.—We commend an article on another page from a London trade organ to the attention of the planters, or rather the Visiting Agents who opposed the Memorial on Coffee Adulteration at last general meeting. The *Produce Market Review* says that there are "large classes of the British public who may be said to be practically acquainted with the taste of coffee, although they are very familiar with that of chicory." It turns out that some Colombo merchants who could not have signed Mr. Wall's draft, praying that the sale of all admixtures should be stopped, are quite ready to support the Memorial as amended and brought forward at the planters' meeting.

MILK A SOLVENT OF QUININE.—It is not generally known that milk is not only a good solvent of quinine, but that it also disguises its bitterness. A writer in a medical journal states that if one grain of the sulphate be dissolved in an ounce of milk the solution is scarcely perceptibly bitter. A dose of five grains may be taken in two ounces of milk without rendering it unpleasant, and if taken in a tumblerful of milk the bitterness disappears. Another surgeon recommends the use of a solution of quinine in glycerine, in the proportion of one grain to one dram, the dose to be taken in a wineglassful of milk.—*Home Paper.*

GUM LEAVES.—A correspondent of the *Bendigo Independent* thus testifies to the curative properties of gum leaves:—"I will relate something respecting the curative properties of the gum leaves. I am acquainted with three persons who have been thoroughly cured of rheumatism by sleeping on beds made entirely of those leaves. Those used were of a round shape, and of a sticky nature, growing on young plants, and the nearest to the ground. It is also well known that a dozen of these leaves made into a decoction of tea are good for a cold or for inflamed eyes. Further, if a few of the leaves are rubbed smartly between the palms of the hands and immediately held to the nostrils, taking a lengthy hard sniff, a most refreshing sensation will be the result."

NATURE is, as Mr. Squeers remarked, "a rum 'un" and it is possible enough that in her arcana there are more secrets than the scientific philosophy of Liebig, or Lawes, or Gilbert have penetrated. M. Georges Ville, a French chemist of high standing after lengthened experience of the nature as that of Mr. Lawes, has come to a different conclusion, and does not leave us in such a slough of despond as our English teacher. M. Ville is of opinion that by returning to the soil one-half of the nitrogen extracted by the crops, (the other half being supplied from the atmosphere), calcic phosphate, potash, and lime, all these subtantives being plentiful, we shall not only be able to prevent the exhaustion of the soil, no matter how heavy the crops may be which are grown upon it, but that we shall endow it with the maximum of fertility consistent with the climate and general local condition.—*Madras Mail.*

THE USE OF THE CACTUS.—The following is from *St. James's Gazette*:—"If what a San Francisco paper says is true," the *New York Graphic* remarks, "a really great discovery has been made, which may convert the far western deserts, where nought but the cactus now grows, into the chief wine-growing districts of the American continent. A man inserted cuttings from some vines into the trunks of the cactus-plants, and, the result was that the vines grew forth as luxuriantly as on the most fruitful land, and *this without cultivation or watering.* Not only did he succeed in raising fine grapes, but he also found that melons, tomatoes, and cucumbers could be grown on the cactus. That hitherto much-abused plant may now prove one of the greatest blessings of man, and the arid and sandy desert may yet become more productive than the rich, well watered prairie."

EASTWARD HO!

Planting in Johore and Borneo.

"It is an ill wind that blows nobody any good," and there can be no doubt that the wind of adversity which has blown for some years so persistently across the planting enterprise of Ceylon has been fraught with some good to our neighbours and possible rivals as plantation colonies. Were it not for the local depression of the past few years and the miserable delay over Railway Extension, it is not likely that so many of the capitalists and some of the best "planting blood" of Ceylon would have turned their attention to the Straits Settlements and the Eastern Archipelago. Men, whose capital and experience would have found a satisfactory and a very beneficial outlet in opening up reserves—high and low—throughout the extensive Uva principality, had a railway been carried into its heart four years ago, have been forced to transfer that same experience and pioneering capacity to Penang, Perak, and Johore, to Borneo and to farther Fiji. And the same retrograde, dead-and-alive policy, if persisted in, will inevitably induce further desertions of Ceylon in favour of States, more advantageously situated or better administered.

The eagerness and liberality displayed by the Straits authorities towards their infant planting enterprise reminds one of what was experienced in Ceylon in the days of Sir Henry Ward. Sir Fredsrick Weld—the beau-ideal of an active Governor—sees in the development of the forest resources and the opening of plantations the best guarantee for moral and material progress. He and his councillors seem all alive to the great opportunity before them. But they too to some extent are thwarted from home. The Governor has had a second time to return to the attack in his endeavour to obtain the consent of the Home authorities to the importation of Indian labour into the adjacent native States. But there is so far no scarcity of labour. The progress already made in some parts is well shewn in a map, which we have received by the present mail from Mr. E. A. Watson, of the Pulai range of Johore. Mr. Watson is the indefatigable pioneer of this district, and the block plan of the estates shews that all the land except certain Government reserves is taken up. Of the clearings 600 acres are planted, and lining, holing, roading are going on rapidly over the rest of the clearings. Further, Mr. Watson writes:—

"I hope soon to be able to send you plans of the 'Pantie' and 'Batu Pahat' ranges on which all the land is also taken. On the former range there is a clearing of 100 acres, and on the latter range there are 1,100 acres of clearings, of which 250 acres are now planted. The coffee is coming on very well, and promises to be a great success, and the Liberian coffee and tea on the low grounds are something wonderful to see. Chinese labour is very plentiful now; so we are all right on that point, though it is more costly than Indian labor."

Turning to Mr. Garland's splendid block plan of estates on the Gunong Pulai range, Johore, on a scale of 16 chains to the inch, and comprising 14,144 acres in all, we have apart from two or three small lots of Government reserve, a long list of responsible names in the proprietors owning handsome blocks. The list is as follows:—

Estate.	*Proprietor.*	*Area.* Acres.	*Cleared.* Acres.
——	G. A. Dick	254	——
——	G. H. H. Austen	204	——
——	T. S. Thomson	997	——
——	Late C. L. C. Falconar	513	——
Whitney	A. T. Dew	292⅝	50

Scudai Planting Coy.	S. Mohamed	404½	212
Pulai Coy. Lt.	—	1,503	——

Johore has gained at the expense of Ceylon in having among its plantation owners such men as Messrs. G. A. Dick, T. H. Moorhouse, Capt. Bayley, James Weir, F. Newman, E. A. Watson, L. C. Glenny, A. H. Murray-Menzies, and others, and undoubtedly this process of a transfer of interests will go on unless the Ceylon Government are able to relieve Uva and to open young low-country districts. On the plan before us we have one prominent spot noted as "site for Railway Station on proposed line to the town of Johore Bahru, twenty miles distant," and Mr. Garland is just the man to carry this project to a successful issue. While Johore and Perak are thus getting rapidly occupied, there is Borneo with its most extensive and varied resources being entered upon under the auspices of Messrs. Dent's powerful Agricultural Company, for which Ceylon once more provides the training and experience needful for the planting of tropical products. We shall, of course, occupy a proud position as a colony in being the mother of so many flourishing off-shoots; but we should rejoice the more in the good prospects and good management of the latter, did we feel that justice was being done to the wealth and resources of the parent.

COFFEE AND CHICORY.

(From the *Produce Markets Review.*)

The Planters' Association in Ceylon are much exercised in their minds, owing to the admixtures allowed with Coffee in this country, and are about to memorialise the Home Government on the subject. The *Weekly Ceylon Observer* says that whether the home authorities put a stop or not to the mixtures which are so injurious to the interests of the Colony, "there is one reform which, if put as an alternative in the Ceylon memorial, it seems to us cannot possibly be refused at this time of day. We refer to the declaration on the label required on such mixtures of the proportions of each substance which they purport to contain. If this is done, it will open the eyes of the consumers to the small quantity of Coffee they are really receiving in their mixtures, and moreover, it will enable a check to be put on Coffee, as on other adulterations; for, should the proportion of Coffee be found less on analysis than is declared, the retailer can, of course, be punished. Most heartily do we commend this movement to the support of Planters and Merchants. We have always thought it a reproach that the agitation commenced by Mr. Leake was not continued by his successors in the Association. Surely public men in Ceylon do not require to be told that here, as in the old country, if a grievance of long-standing is to be redressed, the efficacious mode of action is that which has been made memorable in Anti-Slavery, Reform, Free Trade, and so many more legislative victories, namely, agitate, agitate, agitate."

The following statistics, showing the use of Coffee and Chicory, separately and together, in the United Kingdom, are of considerable interest. It will be noticed that though sometimes more Coffee, and sometimes more Chicory, is used to make up that beverage which is too often unjustly called Coffee, still the consumption of the berry and the root mixed with it, taken together, is almost stationary per head of the population. Last year the high price of Coffee probably led to the falling-off per head in the Coffee consumption, and to the increase in the Chicory consumption. Large classes of the British public may indeed be said to be partially unacquainted with the taste of Coffee, though they are very familiar with that of Chicory. Doubtless the latter commodity forms a useful part of the national dietary, especially as it comes more unscathed out of the rough ordeal knowu in this country as Coffee-making than the delicate Coffee berry itself. At the present relatively low price of Coffee, however, the use of substitutes for it seems likely to decrease, except from that large portion of the public which insists on a certain admixture of Chicory. Sound roasted Coffee can be had at 9d. or 10d. per lb. and good Plantation at 1s. per lb. The Public, if once educated to pure Coffee, would, perhaps, not be so likely to return to their former preferences for admixtures, and there is no doubt a capital opening in large towns for Grocers who will make the Coffee trade a speciality. Not only is the selling of Coffee neglected, but it is too often bought without any care in the selection, and in a great number of cases actually without comparison between the samples of various wholesale houses. Further, it is kept roasted for a considerable period before it is used, instead of being freshly roasted and ground, if possible, on the very day of sale.

PLANTING IN NATAL.

We have much pleasure in publishing the following extracts from a letter written by an experienced *ex* Ceylon planter now in Natal. They are interesting and have their value, in at least showing there are worse places than Ceylon, and that every country has its own peculiar draw-backs:—"Talk about Ceylon being slow. I will bet this place to lick creation. Natal altogether is in a bad way: the roads, railways, and surveys out here are simply disgraceful. They want an *Observer* badly. I have a kaffir hut 20 feet diameter, in which I live and am pretty comfortable, although an S. D.'s bungalow in Ceylon is a palace in comparison. We have just, thank goodness, had some heavy rain, the first since my hut has been built, and did n't it just leak, although there is a regular haystack on the roof. When you come out here, mind and bring a boy and a cook. Boys out here are unheard-of luxuries, and a cooly cook can be had if you like to pay £4 or £5 a month. This is a fearful part of Natal to get grub in: nothing but fowls. I have had boiled fowl, bread and butter and tea for the last month, and as far as I can see it will be all I will be able to get for the next six months. People who have been here a long time have bacon, but none for sale. The planting season commences from about the middle of September and lasts to about the end of the year. The cinchona seed I brought from Ceylon is coming up. Labour out here is a difficulty, there is no doubt. I applied for coolies some time ago, and have just heard I may expect them in a year's time."

THE NORTHERN TERRITORY OF SOUTH AUSTRALIA.

We have received a copy of a short sketch of the Northern Territory of South Australia, being the result of personal observations during a residence of six years, by Edward William Price, Government Resident, &c. With regard to the climate, Mr. Price says that its unhealthiness has been greatly exaggerated. He says:—"Having had a fair experience of tropical climates during my service in the Royal Navy, and having visited every part of the world except India, China, and Japan, I ought to be, in some slight way, a judge of unhealthy climates; and I assert that with, perhaps, the exception of the town of Para, at the mouth of the Amazon, and its vicinity, there is no place within the tropics where a European can remain so long, or work so hard, without injury to his health, than the Northern Territory. I now speak of an average healthy person, who leads a temperature and active life." He then gives the reasons why persons have broken down in health there, viz. because of constitutional disease, intemperate habits, bad or unsuitable food &c. Fever, which is the principal disease, is comparatively mild, and the reason why so many Chinese have died of it was their own carelessness in sleeping on the damp ground after journeys of about 20 miles a day. Ague is also common, but colds, coughs, dysentery, diphtheria, and many other diseases, are almost unknown. Mr. Price concludes his remarks under this head as follows:—"I therefore say to any person thinking of settling here, don't be afraid of the climate Taking it altogether, it is a pleasanter climate than Southern Australia; and don't believe stories about mosquitoes and other tropical pests. I have used a mosquito curtain only five nights in six years, so they can't be very bad; and alligators don't walk about the streets of Palmerston seeking to devour people." Under the head of "soil," we read:—"Of course in a country containing 335,116,800 acres of land, or over half a million of square miles, there must be great diversity of soil. The question is:—can the Territory show sufficient rich soils to tempt the

capitalist to invest? and have tropical products been tried with success? and are the laws relating to the purchase of land liberal? and are there means of getting produce to the seaboard? and is cheap and suitable labor available? and, finally, where are the markets for the produce? To the first question, I reply that, as the result of my own observation, and that of far more competent judges than I could pretend to be, there are immense tracts of rich soil on the banks of the Adelaide and Daly—far more than could possibly be used for many years. There are other great tracts of rich soil also, but I only refer to that to which water carriage is available now. The price of that land is *seven shillings and six pence* per acre; but the Government are now showing their liberality to *bonâ fide* planters by giving a free gift of 20,000 acres to three Melbourne gentlemen on easy conditions of cultivation. Should other capitalists mean work, they have only to apply to the South Australian Government, give fair proof of their *bonâ fides*, and they will have no cause to complain of want of liberality on the part of the Government. To those who would try planting on a smaller scale, I may state that the most liberal inducements are held out to people of small capital, and who are not afraid to work. Any person applying for land for the purpose of cultivating any merchantable tropical or semi-tropical production will be allowed to select a block of country lands of not less than 320, nor more than 1,280 acres, at an annual rental of *sixpence* per acre; and should such selector prove, to the satisfaction of the Government Resident, within thirty days after the expiration of five years from the date of his application, that he had, at the expiration of two years from the date of his application, cultivated in a husbandlike manner one-fifth of the entire area of land selected by him with any production as aforesaid, and that after such second year he has annually cultivated an additional one tenth of the entire area, and that at the expiration of the five years he had one-half under cultivation as aforesaid, and that the whole of such land is enclosed with a fence, he shall then receive a grant of such land *free* of all charge. In fact, by paying a rent of sixpence per acre for five years he receives a free grant of the land, and he has full power to select his own block. Land may also be purchased on credit to the extent of 1,280 acres, ten years being given to pay the purchase-money of seven shillings and sixpence per acre, during which ten years a rent of sixpence per acre per annum will be charged, but the purchase-money can be paid at any time during the ten years. A new Act was passed in 1879 in reference to renting small areas of land at the reefs for the purpose of cultivating garden produce. Every holder of a miner's right, the cost of which is only ten shillings a year, shall be entitled to occupy, for the purpose of cultivation, an area not exceeding ten acres, at an annual rent of one pound, such land not being auriferous. For pastoral purposes the rent is sixpence per square mile per annum for seven years, after that a rental of ten shillings; but I believe that will be reduced to about one-fourth."

The land appears from trials made to be valuable for pastoral purposes, and as to tropical agriculture, an experimental garden was begun in 1879, 20 acres being cleared, and wells for irrigation being sunk. Eighteen Chinese were engaged as gardeners at 15s a week. "During November and December the planting went on, consisting of cotton, sugarcane of twelve kinds, arrowroot, tobacco, tea, coffee, peanut, indigo, Chinese oil plant, broom corn, rice, Chinese grass cloth, sorghum, maize, and a number of spice trees, and others that are not yet sufficiently advanced to judge of their success. Of those I have enumerated, only one has not been a success, and that is tea; but owing to the want of high land that was to be expected. It may succeed up country, but I don't think it can on the plain near Palmerston. The thirty acres contained in the nursery vary—all the soil is rich, but some shallow land. On a portion of that, the cotton was planted, and is now bursting out into bloom, but it will do better on deeper soil; but it is clearly proved that cotton will be a great success, as the sample which took a first prize at the New South Wales Exhibition was grown on much poorer soil than any in the experimental nursery. The sample of which will be exhibited at the Melbourne Exhibition, and is that to which I referred above as having been grown on fairly rich but shallow soil. Samples of cotton growing will have been sent to Manchester, and there obtained great praise from experts; but such samples will be very inferior to that properly cultivated now in the nursery. The coffee plants having been only a year planted, are not sufficiently advanced to judge of their success. The plants are growing well, and look healthy; but I don't think the land in the Territory is sufficiently elevated to grow any species of coffee, except the Liberian, of which I have not yet been able to obtain any plants. The twelve different species of sugareane, planted between the middle of November and the end of December last year, are all doing very well, especially the early planted, which, in six months, has grown an average of ten feet, and where a sufficient space was left between, have as many as forty canes in one plant. These plants were reared under great disadvantage, as the canes, through having been sent from Brisbane to Sydney, to wait the mail steamer, arrived here nearly dead. They then had to be immediately planted in mattresses, and when the ground at the nursery was ready, had to be again removed. In spite of that, and the unusually late wet season, they are now in splendid condition, and will probably be matured and fit for cutting in November; and already the saccharine matter is rising in the cane. As yet the cane has not been irrigated." As to the carriage of produce to the seaboard, there are the Adelaide, Daly, Victoria, and Roper rivers, all more or less navigable. As to cheap labor the Government is doing its best to introduce Indian coolies, and the Chinese are sure to come there in large number.

As to payable markets, Mr. Price says:—"Can North Australia produce as cheaply as the other countries from whence Southern Australia draws her supplies of tropical produce? The latter is already answered by Queensland producing sugar at a payable price. If North Australia can grow tropical produce as cheaply as other countries, it must command the market, as the carriage would be so much less. Taking Victoria as the centre of the Southern Colonies, the passage from Port Darwin by steam would be fourteen days. At the rate which manufactures are progressing in the south, it is evident that ere long cotton goods will be manufactured as well as woollen; that is, provided that the raw material can be obtained cheaply and speedily." Mr. Price sums up the question of the soil of the Territory as follows:—"I think that, while nearly every tropical produce will grow, cotton, sugar, arrowroot, tobacco, and rice will be in the future the staple commodities exported. They are certainties, and can be cheaply produced. I hope to see the nursery carry off the first prize for arrowroot at the Melbourne Exhibition, as the small sample produced last year was far superior to the imported article. In concluding this account of the soil of the Territory, I wish to mention that samples of of the various soils sent to Adelaide have met the entire approval of Dr. Schomburgk. To that gentleman is also due the first movement in reference to the experimental nursery—he always warmly advocated such an institution." He also adds:—"In looking forward, as I have always done, to a great agricultural future for the Northern Territory, I must not omit to speak of the chances of supplementing that

by the success of the pastoral and mining interest. The former has been fairly started, and now the question is to make it pay; and in considering that, it would be well to look for markets. First, there is the success of the latest system of sending beef to Europe. Should the Orient Company carry out their present intention of loading their vessels with frozen meat, and find it a success, Port Darwin will then find its geographical position of service, as the passage home will be eight days less than from Melbourne. Without the English market, I see difficulty in the way of the squatters getting rid of any large quantity of beef here for many years, and the Java and Japan markets would be very limited. But horse breeding for India would most probably be a success, as horses thrive exceedingly well here, and would have the great advantage of arriving in India perfectly acclimatised; and there would be much less risk of loss by sea voyage during the short smooth passage from Port Darwin as compared with the long and often very rough one from Melbourne. We have now some young stock born here, which seem of quite as strong and useful a build as their mothers: and their sires are unknown. With careful breeding they would, of course, be superior.

Under the head of "gold mining," we read:—"This has been the only interest that has hitherto supported the Territory. People who, perhaps, are hardly aware of the existence of the Territory as a settlement will be surprised to hear that the export of gold in proportion to the population actually engaged in mining or alluvial diggings is much greater than any other country; but such is a fact. There are now only about 150 Europeans and 2,500 Chinese on the reefs engaged in mining and the export of gold, as far as can be ascertained, is fully 20,000 ounces per year. Nearly half of this finds its way to Hong Kong in private hands, the Chinese being very fond of remitting small parcels by their friends for the support of their families." The yields have been very satisfactory both to Europeans and Chinese. "The regulations, both as to alluvial and reefing, are very liberal, the charge for a miner's right being only ten shillings a year, and one man can take up a block twenty-five yards by twenty-five yards; two men, fifty by thirty yards. The annual rental for a quartz claim lease is only ten shillings per acre per annum, the leases running twenty-one years. The other known mineral ores in the Territory are copper, silver, lead, iron, and tin, all of fairly rich quality, and all of which will be duly developed in due time with cheap labor and carriage." Mr. Price adds:—"In reference to the question as to whether I would advise any particular class to try their fortunes on the Northern Territory gold fields, I would certainly not advise married men to break up their homes, nor would I recommend unmarried men in good situations to come; but to young, strong, healthy, and above all, strictly temperate young men, in parties of two or more, I think they might give it a trial. Of course at gold digging all cannot succeed, but to men of the above class I truly believe they would have as good a chance of realising a small capital to give them a start in the south as on any goldfields in Australia. Living is cheap and plentiful now at the reefs, and a party of men could live comfortably on about twenty-five shillings a week each, this not including liquors, which are both bad and dear on the reefs." Mr. Price gives his reason for believing in the future success of the Territory, as follows:—"Australia is bound, sooner or later, to make good and profitable use of her tropical portions, as she has done of her semi-tropical; besides, it is simply impossible, in these days of rapid travelling, that the advantages of Port Darwin can be overlooked. A saving of seven or eight days' sea voyage, and that of the roughest part, is no slight advantage; and in spite of any vested interest, it is only a matter of a few years until the whole of the mails, and most of the passengers, will arrive at and leave Australia from some port on the north coast, and there is no port to equal Darwin—a safe and extensive harbour, large enough to hold hundreds of vessels, where in a gale of wind a dingy could safely pass between the ship and the shore. A town not, like so many tropical places, built in a swamp, but on a high cliff, where there is every advantage for cheaply building wharfs and jetties. In fact, at a glance one feels bound to exclaim, 'Nature has intended Port Darwin to be a great place,' and so most certainly the northern door of Australia must be." Mr. Price concludes with a statement of what the Government of South Australia have done to induce settlement in the Northern Territory, bonuses having been offered of £5,000 for the production of 500 tons of sugar; and a bonus of £500 for the discovery of a new alluvial goldfield; prospecting parties who meant *bona fide* work have been liberally assisted; roads with substantial bridges, have been made; the port is free, and the residents of the Territory are in the unique and happy position of being untaxed, either directly or indirectly, though, as a natural consequence, the revenue (chiefly derived from rent of pastoral lands) does not cover the expenditure; the administration of justice is cared for, and there are hospitals and a public library; the facilities for landing cargo at present are two causeways, but it is proposed to build, at a considerable cost, a jetty on iron piles, at which vessels can unload alongside at all times of wind and tide. "All these institutions cost a heavy annual sum, which is every year voted by the Legislature, and each year the Government pass any necessary Acts for the introduction of labor or other purposes, to induce settlement." Mr. Price adds:—"I have not touched on the subject of a railway in this article, chiefly because I have sent a long report upon that and other subjects which, in my opinion, will tend to develop the Territory, to the Minister. There can be no question of the great advantage of such communication; but while the people clamour for such a heavy expenditure, they should remember that everything is not to be left to the public purse. If the Government once see any *bona fide* intention to invest money in the Territory, in gold mining or agriculture, or planting something from which a reasonable return may be expected, then it will be fairer to ask for better inland communication." Finally Mr. Price warns the public against statements which have been published abusing the Territory which, he says, in most cases are written by men who, through their own fault, failed there, and naturally wish to throw the blame on the place.

COFFEE ADULTERATION.—A good deal has been written lately about the excessive adulteration of coffee for the home consumer, and I would call your attention to the enclosed reports of five cases brought against Lancashire and Yorkshire Grocers for selling a mixture as pure coffee. You will notice that analysis showed the several samples sold to contain respectively 25, 30, 60, 63 and 70 per cent of chicory! It would be as well if the police had a hint to bestir themselves a little more actively in protecting the public against this class of frauds.—*Ceylon Times' London Cor.*

THE LANKA PLANTATIONS COMPANY are once more to the front in securing valuable property—paying a good price for a good article. Their latest purchase is the Thotullagalla estate, Haputale, from Mr. S. Agar for £34,000. The plantation consists of 534 acres, of which 348 are cultivated, including (according to our Directory) 40 acres of cinchona. We believe, however, that 80 acres have been planted with cinchona. The Lanka Company has now a large interest in Haputale, and the influence of its Directors and shareholders ought to be felt at home in reference to Railway Extension.

Correspondence.

To the Editor of the Ceylon Observer.

NEW PRODUCTS: NEW ZEALAND FLAX.

Dikoya, 3rd July 1881.

Dear Sir,—I should feel grateful to your correspondent "Phormium Tenax," if he would kindly supplement his interesting letter of the 22nd ult.; with information on the following points:—

(1) Whence to obtain an adequate supply of reliable seed? How soon could it be got?

(2) Conditions of soil and climate essential to its successful cultivation?

(3) Mode of cultivation and cost of same per acre?

(4) Yield per acre that may be reasonably looked for, leaving margin of profit, how much?—Yours truly,

R. R.

THE CROTON OIL TREE.

June 22nd, 1881.

Dear Sir,—With reference to the letter of "C. D." to the editor of the *Indian Agriculturist*, published in your issue of 13th April, I now have the pleasure to send you Mr. Whyte's reply.

As regards the croton now growing on this estate, I am able to state positively that it is not a shrub and injurious to coffee or cocoa. On the contrary, the coffee thrives well under and close up to the tree, both the croton and coffee giving good crops. Other statements have been so well answered by Mr. Whyte that it is unnecessary for me to reply further to "C. D." 's letter.—Yours truly, J. HOLLOWAY.

Kandy, 20th June 1881.

Dear Mr. Holloway,—I have to thank you for sending me the *Observer*, containing "C. D." 's letter, copied from the *Indian Agriculturist*, in which he alludes to my notes on the Croton Oil tree (*Croton Tiglium*). I ought to have replied to your letter sooner, but have been otherwise much engaged.

"C. D" seems to look on the cultivation of this *noxious weed* (his term for the croton oil tree) as a moustrous piece of folly, and "seizes a spare moment to express a hope that no such steps may be taken," ignoring the fact that we in Ceylon should only be following in the footsteps of India, whence the chief supply of crotou seed is imported into England.

You will observe that "C. D." in his letter also describes *his* croton oil plant—which by the way "*he knows well*"—as an ugly sprawling evergreen shrub, frequently used as a "*hedge*" stick, but which is not stiff enough for the purpose.

Now from this, and the remainder of the description given of the plant he refers to, I feel confident "C. D." is confounding the croton oil tree with another plant—possibly an Indian species of the genus croton. I think, however, the plant in question is much more likely to be the physic nut, *Cureas* (formerly *Jatropha*) *pergans*, the *Wal Endaru*, or wild castor oil of the Sinhalese, a soft-wooded smooth-barked shrub bearing cymose clusters of three-seeded fruit, or seed capsules of the size of a pigeon's egg.

If I am right in my surmises as to the plant referred to by "C. D.," you will no doubt recognise it at once. It agrees almost exactly with part of the description given by "C. D." It is to be found as an ingredient, I may say, in almost every native *fence*, for in our rural districts we have not yet got the length of *hedges*; and even the term *fence* is a misnomer for the wretched stray sticks that are stuck carelessly in the ground, on the faith that nature will be kind. We teach Ramasamy a good deal in Ceylon, and we send him back to India with his pockets well lined, but I fear we have not yet taught him the method of making a thoroughly good HEDGE round his compound. We are, in fact, deplorably behind in hedge culture and the natives in this, as in most other things, are quite satisfied to do as their forefathers did, and will not advance a step.

But to return to the physic-nut plant: it is held in much repute by the natives, both for its purgative and healing qualities. From one to four of the seeds is a dose for an adult, and the milky juice of the plant is applied to wounds and cuts with the best effect. In the West Indies, the leavespounded up were invariably used as a sort of poultice, and were very efficacious in cleansing and healing foul and obstinate ulcers. It is a native of tropical America, but has been introduced into nearly all tropical countries.

With regard to the croton oil tree, you can speak with more confidence than I can as to its suitableness for shade, as also in reference to its value in a commercial point of view; and should you think it worth your while to put "C. D." right, you are welcome to make what use you think proper of these notes.—Yours truly,

A. Whyte.

The Coffee Plant Disease.—We learn that Mr. J. Macdouald Cameron, F.I.C., the agricultural chemist, has returned to this country from India, where he has been investigating the cause of the coffee disease. His report, which deals principally with the province of Travancore, will not be issued for some weeks, but we hear that he has discovered the cause of the disease to be the premature exhaustion of the phosphates and alkalies in the soil, and that he will recommend a more complete and thorough cultivation of the soil, and the liberal use of phosphates and lime as manures.—*Home and Colonial Mail.*

Land Sale and Transfer.—Why should not real estate be transferred from seller to buyer with as much safety and certainty as are stocks, bonds, and other negotiable securities? Mr. Dwight H. Olmstead has been wrestling with this conundrum and has given it up. Of course there is no reason why the transfer of one kind of property should be more difficult than that of any other. But the ownership of land is mixed up with legal fictions and historical considerations, which put it in a different category from personal property. In fact, the original title-deed to all land is wanting. Land is the gift of nature to the race, and its possession can only be justified by its use in affording food or shelter to mankind. Hence the right of eminent domain and the forcible seizure of the soil by the State whenever the good of the community demands it. Throughout Europe proposals are rife to dispossess the Church of its landed property, and in Ireland to-day it is proposed substantially to deprive landlords of a portion of their rights in the soil which they have bought or inherited. The great multiplication of conveyances in our Registry Offices is getting to be a serious matter, as searches are becoming more and more difficult and costly. There is no hope of reform. The present system is profitable to lawyers and politicians, and the only persons interested in amending the laws are those who buy and sell real estate, too small a class to be influential at Albany. It seems that the most perfect system for transferring real estate is in New Zealand. In that happy land it is as easy to buy a corner lot as a loaf of bread, and your deed is guaranteed by the Government. It would add a hundred millions of dollars to the value of New York realty if the New Zealand system could be introduced here; but the lawyers and politicians will never permit it.—*New York Hour.*

CEYLON PRODUCING THE MOST VALUABLE CINCHONA BARK IN THE WORLD.

THREE YEARS OLD LEDGERIANA BARK GROWN AT 3,000 FEET ABOVE SEA-LEVEL VALUED AT 17S. PER LB.

We are no less surprised than gratified at the very important intelligence conveyed to us by Mr. T. N. Christie in the following communications. Nothing in Mr. Moens's experience can equal this valuation (on Mr. Howard's analysis, of 17s. per lb. for bark from trees *only* 37 *months old*! Quinine is rather cheaper now than when Mr. Moens realized his famous maximum prices, and his 13 per cent of quinine was from bark taken from trees which had reached their maturity. Certainly they were not under six years of age. We heartily congratulate the gentlemen more immediately concerned in Yarrow estate and all owners of Ledgeriana plants growing at a medium elevation; and yet why should we doubt that almost equal good fortune will attend the planters in the young and high districts, Mr. Christie having demonstrated how well and profitably Ledgeriana grows under the shadow of Adam's Peak. Dr. Trimen has just pronounced flowers gathered from some of the Emeliana trees to indicate the true Ledgeriana. When it is remembered that the Uva climate is also very favourable to Ledgeriana, we have no doubt the present news will cause enquiry to be made after some of the blocks of crown forest land for which no bid could be got the other day at Kandy. Our readers must remember that Mr. Christie's correspondent is Mr. W. Fred. Laurie of Pussellawa (not Mr. Forbes Laurie of Rangala).

To the Editor of the "Ceylon Observer."

Maskeliya, 5th July 1881.

DEAR SIR,—I have been favored with the enclosed copies of letters from Messrs. Lewis & Peat and analyses of Yarrow estate (Nilambe) Ledgeriana bark.

The figures, but for the name of Howard, would be perfectly incredible, and they will be most interesting and encouraging to those whose estates are at a comparatively low elevation: they need be no longer totally dependent on red bark with its uncertain future. The trees are growing, robust, and of good size, at an elevation of about 3,000 feet, were planted by me (out of the same stock as my trees here) in December 1877, and were exactly 37 months old when the samples were taken, and they are now yielding a little seed. When 37 *month s old Ledger bark is valued at* 17*s per lb.* one can believe the story of the Java seed selling at the rate of £236 per ounce.

"Java" must draw in its horns now and take second place to Ceylon, if I am right in my belief that this Yarrow bark is, for its age, by far the richest that has ever been grown.—Yours faithfully,

THOS. NORTH CHRISTIE.

---

6 Mincing Lane, London E. C., June 22nd, 1881.

W. Fred. Laurie, Esq.

DEAR SIR,—We enclose you our report on your bark which we hope will be satisfactory. Mr. David Howard (Messrs. Howards) has taken considerable interest in these samples and analysed them for us, and we are requested to urge the cultivation of this variety by all possible means, the more especially as we understand that your trees have flourished at an elevation of below 3,000 feet. It is pleasing to find that last year we strongly advocated the planting of this variety and it must be gratifying for you to know that you are possessed of the true variety, for at the present time it is a very important matter that rich varieties, likely to realize high prices for quinine manufacture, should be grown. We shall always be pleased to give you any further information you may require and remain, dear sir, yours faithfully,

(Sd.) LEWIS & PEAT,
per T. W. Buchanan.

6 Mincing Lane, London, E. C., 2nd June 1881.

W. Fred. Laurie, Esq.

DEAR SIR,—We have now the pleasure to hand you report and valuation of your sundry samples of calisaya bark. Messrs. Howards have kindly tested them for us and we are pleased to be able to pronounce them all of the true "Ledgeriana" variety. They consist of well grown bark, somewhat young, but their respective yields from them, the best we have yet seen; though we fear in bulk the result will not be so high. We annex the analysis:—

	Per cent	Sulphate of Quinine worth about s. d.
No. 1	7	10 6 per lb.
,, 1*	9·7	14 3 ,,
,, 2	7·5	11 3 ,,
,, 3	11·2	17 0 ,,
,, 3 × 11·1	... ...	
,, 4	4·5	6 9 ,,

and they contained only traces of the other alkaloids. As 4 per cent bark is worth more than twice a 2 per cent bark yielding one, it is difficult to give an exact valuation.—We are, dear sir, yours faithfully,

(Sd.) LEWIS & PEAT.

In forwarding the letters, Mr. Laurie writes:—

"The samples were not taken from trees selected especially for their typical appearance, but from those exhibiting the greatest variety in their foliage and the result is to me perfectly amazing. Even No. IV. which in appearance closely resembles a succirubra is proved to be a most valuable bark. I was introduced to Mr. Howard, who analysed the bark, and he said that he was quite surprised himself at finding the samples so rich. He said that he thought it quite possible that the production of red bark (*C. succirubra*) might prove in a few years time to be excessive, but that so long as we could grow such bark as the samples he had analysed, there was no doubt of its giving us a most handsome return. Manufacturers, he said, would always prefer to pay a good price for a rich bark to buying an inferior one cheap, as the cost of extracting the quinine is of course less and the operation, from having a much smaller quantity to work upon, so greatly quicker. Thus he says he considers a bark containing 6 per cent of quinine worth more than twice the same quantity of a bark which contained only 3 per cent."

NEW PRODUCTS FOR CEYLON: "JUTE."

We call attention to the clever review of our Handbook and Directory from the *Dundee Advertiser* given on another page. It will be interesting, as the production of an old Ceylon colonist, for the notice taken of the past and present position of our planting industry; but its chief practical value lies in the pressing recommendation made to give a trial to "Jute" as a new product suited for cultivation in Ceylon. Such a recommendation, coming from the Jute capital *par excellence*, backed by the authority of a Dundee manufacturer who has frequently passed through Ceylon, we suppose *en route* to Calcutta, and supported by an old planter intimately acquainted with the nature of our soil and climate, deserves special attention. Clearly we have arrived at a point where an extended trade in the finer and more valuable fibres ought to be attempted. Some amongst us have been experimenting with aloe fibre in a hopeful way; by other planters the successful cultivation of New Zealand flax is almost placed beyond doubt in certain districts, and now planters of new products in low-country districts are strongly recommended to try the Jute plant. We trust the attempt will at once be made. The first step will be to get seed from

Calcutta, and seeing that the south-west side of the island is specially recommended, we would suggest that the "New Products Company" and their enterprising manager, Mr. Dobree, should be first in the field in giving the new product a fair trial. As some help to intending cultivators, we take over what is said of the genus to which the Jute plant belongs in the "Treasury of Botany":—

"CORCHORUS.—This genus of *Tiliaceæ* contains between forty and fifty species of herbaceous plants or small shrubs, with simple leaves, inhabitants of both hemispheres, but seldom found far beyond the tropics. Their flowers are produced either singly or in clusters opposite the leaves. They have a calyx of five deciduous sepals, and a corolla of five petals, with numerous stamens, a very short tubular style, and from two to five stigmas. Their fruit is long and pod-like or roundish, and splits when ripe into five divisions, each of which has numerous seeds arranged in rows on either side of a longitudinal partition.

"*C. Capsularis* is an annual Asiatic plant, growing about ten or twelve feet high, and having a straight cylindrical stem as thick as the little finger, and seldom branching till near the top. Its leaves are about six inches long by one and a half or two broad towards the base, but tapering upwards into a long sharp point, and having their edges cut into saw-like teeth, the two teeth next the stalk being prolonged into bristle-like points. The flowers are yellow, and produced in clusters of two or three together: they are succeeded by a small almost globular but flat-topped fruit. This species, as well as *C. olitorius*, yields the exceedingly valuable fibre known under the name of Jute. Only twenty years ago, Jute was hardly heard of out of India, where it had long been in use amongst the natives for making cordage and cloth, but it now forms a very important article of commerce; no less than 738,085 cwt., valued at 619,668*l.*, having been imported to this country alone in 1858. The plant is largely cultivated in India; als oby the Malays and Chinese. The fibre is separated by the ordiuary process of steeping in water. It is frequently as much as twelve feet in length, very soft, silky, and separable into fine filaments, which are easily spun. Jute is much used in the manufacture of carpets, and some kinds of cloth; but is not suitable for cordage, as it will not bear exposure to wet. Its most important use, however, is for the manufaeture of the gunny bags, so extensively used for packing cottou, rice, and other dry goods, enormous quantities of them being exported from India to the United States for that purpose. Very good paper is made from the refuse fibre, and also from worn-out gunny bags; and a kind of whisky, resembling corn-spirit, has been distilled from the waste ends of the stems.

"*C. olitorius*, is a native of India, but is now naturalised in all parts of the tropics, and extends as far north as the shores of the Mediterranean. It is an annual plant much resembling *C. capsularis*, the principal difference existing in the fruit, which in this species is two inches long, almost cylindrical, and about the thickness of a quill. The young shoots of this species are commonly used as a pot-herb in tropical countries, as are those of *C. capsularis*; it is much grown for this purpose in Egypt and Syria and being used by the Jews, it has obtained the name of Jews' Mallow. It yields part of the Jute of commerce.

"*C. siliquosus*, a common species in the West Indies and tropical America, is an herbaceous plant about two or three feet high; its leaves differ from those of the two last in not having bristles on the two bottom teeth, and there is usually a line of minute hairs along the stem. The negroes in the West Indies use it for making besoms, and the inhabitants of Panama drink an infusion of the leaves as a substitute for tea: hence they call it *te*. [A. S.]"

It will be observed that the Dundee reviewer says four months is sufficient to prove whether the cultivation of jute is likely to be a success or not. "Quick returns" would be the rule, and the prospect of from £10 to £20 an acre of gross value ought to be an incentive to coconut and cinnamon planters as well as to planters of new products to give the plant a fair trial.

THE CEYLON DIRECTORY AND HANDBOOK.

THE PLANTING DEPRESSION IN CEYLON—"NEW PRODUCTS": JUTE.

(From the *Dundee Advertiser*)

Of all Colonial Directories commend us to the Handbook published periodically by the Messrs. A. M. & J. Ferguson, of Colombo. Two years ago we had pleasure in noticing an interesting and highly useful volume from their hands relating to Ceylon, and now we have before us a still more ambitious and successful effort, entitled *The Planting Directory for India and Ceylon* (1), containing 1,500 pages, treating fully on all the chief agricultural industries of our great Eastern possessions, and we have little hesitation in stating that all who wish information on tropical matters can scarcely do better than consult this very reliable source. The Messrs. Ferguson are practical planters, as well as the successful editors of one of the oldest and best conducted newspapers in Asia. The various "new products" treated of, such as cinchona, cocoa, tea, Liberian coffee, cardamons, &c., now being successfully cultivated in Ceylon have all been introduced and fostered under their own immediate observation. It is true, agriculturists in the land "where every prospect pleases" have not of late been enjoying uninterrupted prosperity any more than their brethren in the "Land of Cakes," and it may not be uninteresting nor unprofitable to glance for a moment at the chief cause of the present troubles of our friends in the East, who, situated though they be far beyond the reach of North American competition, are yet as depressed as agriculturists in England or Scotland, and landed property has declined equally as much in value as it undoubtedly has with us. Amongst the immediate causes which have led to this decline must be mentioned the "leaf fungus" on coffee, a calamity similar to what overtook our potato in 1846, but this is by no means the chief cause, which we regret to trace to financial parasites, who are ever ready to follow in the wake of a promising enterprise and to encourage unhealthy speculation. In place of legitimate planting, "bogus Companies" have arisen like mushrooms, while bastard brokers have profusely bled the unsuspecting sons of the soil. A few years ago few countries stood in a better position financially than this model colony. Every planter was looked upon as on the highway to fortune, while to have a share in a "coffee wattie" was untold wealth! Now all is changed; to be a planter is to be pitied; to be a proprietor a misfortune. A few years ago, when the price of coffee rapidly rose from 60s to 100s per cwt. planters, flushed with success, as rapidly extended their acreage; and, as the fame of their fortune reached their native land, eager adventurers were ready to join their ranks. First sons of well-to-do fathers and feed-sciors of aristocratic families impetuously rushed into coffee, not by the old-fashioned method of first serving an apprenticeship, but arriving with money, at once became full-blown proprietors. That advantage was taken of brainless young capitalists must not occasion much surprise. For a time the demand for young estates knew no bounds, and young "estates" were, alas! rapidly manufactured to meet the demand. Indeed, it is no

exaggeration to say that thousands of acres were opened and planted with coffee no more suited to produce the fragrant berry than the Sidlaw Hills are to grow grapes. The selling price, moreover, rose from £30 to £120 per acre, and more fortunes were made by selling mock estates in two years than had been made by *bona fide* planting during the previous ten. Disappointment and ruin has followed as a matter of course. Still Ceylon stands where it stood, and must remain the key to and "garden of India," with its splendid climate and glorious scenery. The soil, perhaps, might be richer, but in good hands this is always susceptible of improvement, and, depressed as it is at present, "Taprobane" will doubtless again revive, when the lessons taught by a few years' recklessness will not be lost. One result will evidently be the introduction of several new products—cinchona—already fully established—and tea, pronounced at the Melbourne Exhibition as in some important respects the "best in the world," while cocoa topped the market the other day in Mincing Lane. But yet there is room, and perhaps we may be permitted to suggest another addition to the new products suitable for Ceylon—viz., *Jute*. Dundee alone imports yearly from Calcutta and Chittagong, Jute equal in value to that of Ceylon's chief staple, coffee; arrangements are now being made for extending the cultivation of the plant in Egypt, which has already forwarded good samples. Why Ceylon should be passed by and not participate in the benefit of producing our staple fibre we are at a loss to conceive. There must be many thousands of acres in the south-west of the island eminently suited for its cultivation now lying unproductive. Indeed, one of our largest manufacturers who has frequently visited the island believes that in many respects Ceylon would have the advantage of Egypt, if not the present source of supply, particularly in the abundance of clear water, so essential in the proper preparation of the fibre. Unlike cinchona or cocoa, which requires years of patient waiting for a result, four months would decide this matter. Will no enterprising planter scratch a few seeds into the corner of a field, or energetic native crop a portion of his paddy field with what may bring him from £12 to £20 per acre, instead of the meagre crops of grain with which he has so long been content? We are aware that cotton was not a success, and that sugar cane was all but a failure in Ceylon, owing to the humid nature of the climate, but here is a plant that rejoices in moisture as well as heat. Why should we allow an enterprise so beneficial to all concerned to be drawn away into a foreign country? Messrs Ferguson deserve great credit for the completeness and comprehensiveness of their work, and we fully hope that next issue will draw us into closer acquaintance by showing a considerable export of our staple fibre. We are glad to note that the ancient source of revenue, the pearl-fishery, still yields a bountiful harvest, the amount realised for this year being £60,000. Gold is also talked of, but we trust our friends may escape the gold fever now raging in Southern India, for, although there has doubtless been a considerable quantity of gold buried in Ceylon during the past five years, we doubt if it can be recovered by any ordinary process of mining.

THE INDIAN JUTE plant has, it seems, been successfully cultivated in Virginia, and, according to the Commissioner of Agriculture, "it is a declaration of American independence from India in the matter of jute." The yield of fibre is about 3,500 lbs. to the acre, and the United States industrial press is hoping that England will find American jute so much better than the Indian article that they will be inclined to give it the preference, as they do American cotton. It really should not be in such a hurry. No samples of Virginian jute have, we believe, yet arrived in this country.—*British Trade Journal.*

COFFEE PRODUCTION AND CONSUMPTION.

We call attention to the monthly report of Messrs. Robert von Glehn & Sons. The estimates of Production and Consumption drawn up by the principal Havre coffee brokers are of special interest, and it will be seen that the probability still is of a large reduction in the stocks of our staple by the end of the present year.

ROBERT VON GLEHN & SONS' MONTHLY COFFEE CIRCULAR.

London, June 3rd, 1881.

In our last circular we gave a table shewing that working out the total receipts for 10 months on the basis of the *daily average receipts* telegraphed weekly by Reuter, the total for the 10 months amounted to 3,929,750 bags, but the above is no doubt the more correct way, and shews that the daily average receipts are generally given too high.

A circular has been published by the principal Havre coffee brokers giving the following interesting comparison of the probable crops of coffee in the chief producing countries of the world for the seasons.

	1880-81.	1881-82.
	Tons.	Tons.
Rio	255,000	210,000
Santos	72,000	90,000
Bahia	5,000	5,000
Ceylon	20,000	35,000
Java	43,000	70,000
Padang and Macassar ...	12,000	15,000
Manila	5,000	5,000
Moka	5,000	5,000
Malabar	16,000	15,000
Haiti	33,000	35,000
Porto Rico	14,000	15,000
Jamaica	5,000	5,000
Laguayra and Maracaibo ...	30,000	30,000
C. America and Costa Rica	30,000	30,000
Mexico	4,000	10,000
Africa	5,000	
Total...	554,000	575,000

We consider these estimates as nearly as possible correct except, perhaps, the estimate of the Moka crop, which is certainly put too high at 5,000 tons, while the estimate of the Malabar crop of 1881-82 is too low at 15,000 tons. But the chief feature in the Havre circular is the following calculation showing that the stocks of coffee in Europe and America will have decreased 72,000 tons by the 31st December.

Estimate of the import of coffee in America and Europe between 1st May and 31st December, 1881:—

Rio	144,000	tons
Santos	54,000	,,
Ceylon	15,000	,,
Bahia	3,000	,,
Java	36,000	,,
Padang Macassar	8,000	,,
Manila	4,000	,,
Moka	4,000	,,
Malabar	7,000	,,
Haiti...	9,000	,,
Porto Rico	6,000	,,
Jamaica	3,000	,,
Laguayra and Maracaibo ...	6,000	,,
Central America, Costa Rica ...	12,000	,,
Mexico and Africa	6,000	,,
Total...	317,000	,,
Stocks in Europe and America, 1st May	185,000	,,
	502,000	,,
Consumption 8 months at 48,600 tons per month	388,800	,,
Probable stock 31st December, 1881	113,200	,,

And it is confidently urged by the writers of this circular that this reduction in the stock will cause prices to rise at least to the level of last year.

Looking broadly at the question it seems a contradiction to say that the production of coffee in 1881-82 will be 21,000 tons larger than in 1880-81 and yet that stocks will decrease during the next 8 months 72,000 tons. Yet this is what in fact the Havre brokers say. They estimate the production of the year 1881-82 at 575,000 tons or 47,916 tons per month, but for the first 8 months of this year they say the supply will be only 317,000 tons or at the rate of 39,625 tons per month. We know of course that the 8 months, from the 1st May to 31st December, are the months of small supply, but if the whole year is to be 575,000 tons it would follow that the supply for the last four months would be at the rate of 64,500 tons per mouth, and the prospect of such a supply would certainly counteract the effect of any reduction in the stocks on the 31st December.

Looking now at the estimates of the Havre brokers for the consumption of Europe and America we find the following figures given :—

	1879. Tons.	1880. Tons.	1881. Tons.
Consumption Europe and America	575,000	569,000	584,000
Average per mouth ...	47,916	47,416	48 666

It will be remembered that their estimate of the production of the world was :—

1880-81.	1881-82.
554,000 tons ...	575,000 tons
Average per month ... 46,166 ,, ...	47,916 ,,

But it would seem as if on the face of it these estimates could not be right, for if the production of 1880-81 was only at the rate of 46,166 tons per mouth, while the consumption of 1880 was at the rate of 47,416 tons per month, how is it that the stocks in Europe and America have increased to the unprecedented figure at which they now stand? The explanation may be that stocks in second-hands are exceptionally small now as compared with previous years.

However, we think it right to remind our readers that [as we pointed out in our last circular] in a calculation like the one referred to above, if the production be under estimated and the consumption over estimated, ever so little, the result differs very largely from a calculation with a contrary bias, and hence the danger of such calculations.

It is very remarkable that in the Havre brokers' circular, hardly any reference is made to the present low range of prices.

The fact that prices of coffee are now considerably lower than they have been for a number of years, is by far the most favorable thing that can be said of the present position of the article; elaborate calculations of the probable consumption and production of coffee made upon the basis of estimates, for which it must be admitted the information as regards actual figures for past years is somewhat uncertain, whilst the present low prices and the many direct and indirect effects which they produce are overlooked, and among the latter, we may instance the long delay that always takes place before a planter or native grower of coffee can be induced to sell at even a slightly lower price.

The production of coffee for 1881-82 is estimated at 575,000 tons, or at the rate of more than 11,000 tons a week. If the producers therefore hold back their coffee but one month longer than usual, it will reduce stocks in Europe and America 48,000 tons! And we know instances of coffee now being returned in the countries of production owing to the present unremunerative prices, which in former years would have been shipped a month or two ago.

The effect of low prices on consumers by stimulating their purchases for stocks have been too often pointed out to need repetition here, and we therefore conclude by repeating the opinion expressed in our previous circular, that at present low prices coffee is a safe investment.

Inoxydised Iron.—The problem of protecting the surface of iron from rust by chemical means has recently received another solution. The methods by which this object has been previously effected, other than by that of painting, are two—namely, by the application of superheated steam, as in the Barff process—and of heated air, as in the Bower process. The new process, which has been devised by Mr. Ward, consists in the combined application of silicates and heat, and is termed the "inoxydising" process. This is the basis of several subsequent processes for ornamenting the surface of the metal. The inoxydising process consists in coating the cast or wrought iron objects with a silicate composition, which is applied either by means of a brush or by dipping the iron in a bath of the solution. The coating quickly dries upon the objects, which are then passed through a furnace heated according to the nature of the articles under treatment. The silicate composition is thus fused and absorbed into the pores of the metal, becoming homogeneous with it. Upon cooling the articles treated are found to be covered with a dull black coating, which, it is stated, is found not to suffer change from long exposure to the atmosphere, nor to disintegrate or separate from the surfaces to which it has become applied. The ornamentation is effected by coating and furnacing the articles by the combination of the silicate composition with vitrifiable colours. By this means smooth polished surfaces are produced upon the iron, which present superior and more durable results than those obtainable by ordinary painting and varnishing.—*Glasgow Paper.*

The Colombo Public Sale of Cinchona Bark to-day, (25th June) by Messrs. Robinsou & Dunlop, was attended by the usual buyers and went off quietly. There was less competition than at the previous one, but on the whole prices obtained were satisfactory. The following were the lots offered :—

			sold at
Lot 1.—360 lb.	Succirubra	Root Bark	R0·87½
Lot 2.—680 lb.	do	Stem pieces	
Lot 3.—422 lb.	do	Twigs ...	... 0·18
Lot 4.—342 lb.	Officinalis	Stem pieces	
Lot 5.— 40 lb.	do	Root	... 0·55

The above bark is grown from trees of about four year old, at an average elevation of 4,200 feet. Analysis by Mr. M. Cochran, of the Stem and Root Succirubra, lots 1 and 2, shews 1·78 average yield of Sulphate of Quiuine. Total Alkaloids 4·86. Driage 11·55.

Lot 6.—	176 lb.	Succirubra Quills, bought in at	R0·72½
Lot 7.—	112 lb.	do do sold at	R0·50
Lot 8.—	108 lb.	do Stem Chips, bought in at	R0·62½
Lot 9.—1,034 lb.		do Twigs, sold at	R0·28

From trees grown on Riekarton Estate, Maskeliya. Elevation 4,300 ft.

Lot 10.—2,646 lb.	Mixed Succirubra and Officinalis Stem Pieces, bought in at		R0·62½
Lot 11.—513 lb.	Mixed Succirubra and Officinalis Stem Twigs sold at		R0·19
Lot 12.—153 lb.	do	and Officinalis stem sold at	R0·62½
Lot 13.—148 lb.	do	do Branch and Stem, sold at	R0·50
Lot 14— 52 lb.	Gavatenne Succirubra Stem, sold at		R0·42

The above lots (14 excepted) are from trees 4 years old, grown on Agrawatte, Carolina (Ambagamuwa) Wigton (Dimbula), Hennewelle and Hooneecotua (Kotmale) Average elevation 4000 ft. Analysis by Mr. A. C. Dixon of the mixed stem pieces shews 1·15 yield of Sulphate of Quiuine. Total Alkaloids 3·07. Driage 4·15.

CINCHONA CULTIVATION.

Mr. Cross's Report on the Nilgiri Plantations will be read with interest by Ceylon planters. Mr. Cross is a trained horticulturist, and he has now, perhaps, seen more of the different species of cinchona in their native habitat than any other authority connected with the great experiment of Eastern cultivation initiated by Mr. Markham. It is an interesting coincidence that just as the merits of Yarrow Ledgeriana bark grown at 3,000 feet above sea-level are published, we should receive Mr. Cross's emphatic condemnation of the attempt to grow Calisaya on the Nilgiris at from 5,000 to 6,000 feet, or in Northern India at all. Mr. Cross thinks the Wynaad more suitable at elevations under 4,000 feet, and no doubt in Ceylon this most valuable species will do best under that limit. Mr. Cross's condemnation of grafts, save for seed-bearing purposes, is both new and startling to those who expected so much from Mr. Moens' system of grafting Calisaya on Succirubra stocks; but there is much in the reasons adduced in the present Report, and we commend its careful consideration to our planters. No very high opinion is entertained of the stripping process, while shaving receives only a passing notice. We should be glad to learn from those who have had three to six months', or more, experience of the shaving process in Ceylon, how the trees operated on have borne the infliction, and whether the growth of bark is satisfactory.

MR. CROSS'S REPORT ON THE MADRAS GOVERNMENT CINCHONA PLANTATIONS.

(From the *South of India Observer*.)

Mr. Cross's report on the appearance and condition of the Cinchona Plantations on the Nilgiris, prepared and submitted by desire of the Madras Government, is one of the most important papers which has of late been placed at the disposal of the Press. Major Campbell Walker had previously entered exhaustively upon the subject but for some reason which has not transpired, his report in its original form was suppressed and an authorised version was issued, which that officer declined to have his name associated with. It must be from the latter that Mr. Cross occasionally quotes, but beyond an acquaintance which such a mutilated report afforded him, Mr. Cross's knowledge of the past history of the plantations is somewhat defective, and vitiates the conclusions at which he arrives. From time to time, attention had been called to the mismanagement of these valuable properties. Those who possessed a professional acquaintance with the subject were fettered with non-professional control, which destroyed all sense of responsibility, and hence arose that condition of things to which Mr. Cross calls attention, namely, that whatever the urgency or necessity, a single tree could not be cut down without the express orders of Government. The time and procedure which every such reference involved was too much for a man, who had quite enough to do with an overgrown and increasing charge, and hence neglect developed into injury till matters had arrived at the stage which Mr. Cross has so unreservedly condemned. Those responsible to Government for the condition of the plantations are of course anxious to exonerate themselves, and we expect the report will form the subject of numerous rejoinders, calculated to shew that Mr Cross has mis-judged appearances or drawn erroneous inferences. His report, however, has one salient feature which must commend it to the public and that is, its thorough disinterestedness. It is now abundantly demonstrated than the main and almost the only object which the Madras Government and its local representative, the Commission, had in view in working the plantations since 1876, was to show a satisfactory balance sheet. How successfully this object has been achieved, the bark sales of the past few years prove, at what sacrifice and permanent injury the result has been obtained Mr. Cross's report is the best evidence.

The drift of Mr. Cross's remarks in reference to harvesting is manifestly to establish the superiority of natural to renewed bark, but he states this conclusion too widely when he says, "But of the renewing system, one thing appears to me certain, which is that when once a tree has been operated on, it is placed for the future on crutches and must always remain so; and will require to be wrought after the same manner as long as it lives." We must ask Mr. Cross to compare these remarks with those recorded by him in the opening paragraph on the Dodabetta plantation, in which he says "at the bottom of the ravine there were some very fine well developed trees, presenting the most perfect form and appearance of the best specimens of this bark tree I saw in the Loxa Forest" The portion of the plantation to which the quotation applies has, to our knowledge, been barked for the past six or seven years, and if its condition compares favorably with that of the natural Cinchona forest trees of South America, we are hardly prepared to accept the crutch theory. Soil and cultivation have every thing to do with the condition of a plantation, and these given, the system of renewal is not so injurious to the tree as would at first sight appear. The present condition of the Dodabetta Plantation is evidently that which will be benefitted by a complete uprootal, and we hope this process will commend itself to Government. We quite approve of what Mr. Cross says regarding undergrowth of Cinchona in a plantation. That condition of soil which the exotic loves can most efficiently, and profitably be supplied by the method advocated. Our planting friends will read Mr. Cross's remarks upon Calisaya with particular interest. This variety is not suited to high elevations where it remains a sickly bush. Wyuaad is adapted to the species, and there it will thrive and prove profitable. There is another part of Mr. Cross's report about which we feel diffident. We refer to the assurance held out that Indian Bark is not likely to glut the market. On this subject Mr. Cross says that the present bark supplies from India average 2 per cent of the entire supply. That a partial glut has already been experienced we gather from the fact that at the late Mincing Lane sales, some of the lots had to be held over for want of bidders. If this occurs in the case of a bark, which has established a reputation such as Government Bark, the private capitalist may well entertain doubts of the future. Millions of Cinchonas have been put down within the past few years both in India and in Ceylon which in a short time will supply the English Market with bark, sufficient for the consumption of the whole world. A prospective increase of consumption will in a measure, restore the equilibrium, but beyond this we have no well grounded hope in the brightness of the prospects of cinchona planting.

REPORT ON THE NILGIRIS PLANTATIONS.

Letter from Robert Cross, Esq, to N. A. Roupell, Esq., Commissioner of the Nilgiris, dated Government Gardens, 13th January 1881.

In accordance with the desire expressed in the Government Order, with the date of 25th October 1880, I beg to state that I have examiued the cinchona plantations and now take the liberty to submit a few remarks on the general appearance and condition of the principal sorts cultivated therein.

The Dodabetta Plantation.—The first plantation visited by me was Dodabetta This, according to Capt. Walker, contains 226,936 trees, being mostly of the Crown Condaminea or Loxa bark. There is in addition

48 plants of an important species known as Pitayo bark which has not been cultivated.

On ascending from the Government Gardens the road, after a short distance, leads up the bank of the Dodabetta ravine, on both sides of which Condaminea trees are planted. The oldest portion of the plantation is that which fringes each side of the road, having been planted in 1863. These trees, it appears, have been subjected to the renewing process by moss and have been barked several times. On examining the trunks of several, some portions of decayed heartwood which had not been covered over by renewed bark was noticed though this circumstance may not be a feature in the barked trees generally throughout the plantation. I observed that any little pieces of old bark left on the trunks of these trees were very thin, so that, manifestly, when any injury results to the wood the tree lives chiefly on the bark. At the bottom of the ravine there were some very fine well-developed trees presenting the most perfect form and appearance of the best specimens of this bark tree I saw in the Loxa forests. On ascending the opposite bank the soil is often shallow with bare rocky places and stony debris and over a great portion of this slope the plantation presents a painfully thin, arid aspect, and where the trees have been wrought, I fear over ten per cent., are not in the best condition. But those trees which have not been barked, although stunted, owing to the conditions just noticed, are sound and healthy, though from the nature of the situation many have been induced to a profuse state of seeding. This circumstance has had a further effect in retarding the growth of the trees. The fact is that in this locality especially the plants at the beginning have been placed far too wide apart; indeed, as a general rule, twice as many plants should have been planted all over the plantation. On some of the more prominent brows and heights it would have been better had Blue gums been put down, but now that the bark trees are there established a more prosperous state of growth would be produced by additional plantings. In any case I would not advocate the rooting up of any portion. On crossing the Dodabetta ridge, I found the trees on the opposite slope generally very healthy, and this feature was conspicuous all the way down to the jail. The deposit in this part of the plantation would compare well with that of any of the forests in South America yielding the Condaminea, Pitayo or Soft Columbian barks. The surface is usually composed of a deep layer of rich old vegetable loam readily absorbing the rain as it falls and slowly parting with its moisture, which even in the steepest places very gradually oozes or trickles downwards, any appearance of the rills or torrents producing the 'wash' incident to deposits of a different character.

Coppicing.—A piece of land above the jail to the extent of ten acres has recently been coppiced as an experiment. Possibly one acre might have proved sufficient for illustrating the object in view. The young growths from the stools have all been removed with the exception of two, and had all these been allowed to grow up together for some time, mutual protection during high winds would have been afforded, and subsequently, by judicious thinning, a more fair estimate of the value of the coppice system might have been obtained. I may remark that the trunks have been cut too low indeed down to where the primary roots divide, whereas in all cases of coppicing from 5 to 5 inches of the trunk or collar should be left, as from this portion the strongest and most vigorous shoots push and develope sooner. The crowns of the stools have been properly smoothed, but these instead of being cut flat as has been done in this case, should in large trees, be left in the form of a very short wedge, or in the case of saplings one single short sloping cut is sufficient.

Formation of Terraces.—Respecting the terracing of cinchona land I may take the liberty to express my opinion that if the trees have been planted previous to the formation of terraces, a very modified form of terracing similar to that of a potato drill running exactly in the line of each row of trees across the slope to prevent the formation of rills or streamlets would be all that would be necessary. This course, however, might be adopted only on the steepest slopes and where there is an absence of spongy vegetable mould to absorb the rain as it falls. Moderately sloping land or undulations possessing a tufty surface soil are in my opinion better without terraces.

The Pitayo Bark.—The Pitayo trees, 49 in number, growing near the jail have not been multiplied. It appears this sort was considered to be of slow growth or that it yielded an inferior bark, though I find no actual proof on the latter head. The tree may not be so prolific as the Crown bark, but when it is considered to attain a height of 80 feet with a trunk from 3 to 4 feet in diameter it appears to me worthy of a fair trial should the bark prove of good quality. I can assert with the greatest confidence that the 48 trees growing beside the jail at Dodabetta are in the most robust state of health, indeed several of these are pushing stronger and more luxuriant shoots than any I have seen of similar size at Pitayo. By selecting sheltered sites with good fertile soil and by devoting a little more care and attention to its early cultivation, I see no reason to doubt of this tree being successfully cultivated. Captain Walker in his enumeration of the stock plants of this sort in the propagating houses at the Government Gardens gives the number as 7,000, but he has been totally misinformed.

There are not six plants fit for planting out and only a few pots of weak cuttings.

Decaying Trees in the Plantation.—I beg to call attention to the occurrence of trees in various parts of the plantation in a more or less advanced state of decay. When trees are thus allowed to die the bark afterwards becomes worthless. It appears the person in charge cannot cut down or uproot one of these trees without the express order or permission of Government. I would suggest that when a tree is seen to exhibit signs of decay it should be carefully examined and treated accordingly. If the decay is limited to the branches, these should be cut back or pruned as may be necessary. But if the trunk was seen to be affected—and this would often be found to be the case—then the roots should be closely examined, and if the unsound roots were found, it would be best to uproot the tree at once. If, however, the roots were fresh and healthy by far the best course would be to cut the tree down, or in other words to coppice it.

Injury caused by Cattle.—I observed at the head the Dodabetta ravine that cattle had been treading about a good deal in various parts. It ought to be known that any description of cattle, goats, &c., frequenting land devoted to the cultivation of trees, plants or crops do far more injury than is generally perceived. I used to calculate when travelling in South America that the rearing of pigs by the natives cost them at least eighty times more than their marketable value owing to the way these animals are allowed to run about.

Hybrid varieties of Crown and other Barks.—As regards the varieties of Crown bark, of which notices from time to time have appeared, I have not been able to see one single authentic instance. It might indeed be said that no two trees in the Dodabetta plantation are alike. The Condaminea, although a hardy prolific species, is extremely sensitive to the variable conditions of soil, moisture and exposure, and on this account the tree presents a more or less luxuriant habit of growth and foliage accordingly. The 'Angustifolia,' 'Lanceolata,' 'Crispa,' &c., &c., are simply the pure Condaminea. But that known as Pubescens and specially claimed as a hybrid, is a narrow-leaved variety of Red bark from South America. Not unfrequently it may be seen at Neddiwatam among the first

planted trees there. It was called *Pata de Gallinaoz* by the South American bark collectors, while to the broad-leaved variety of Red bark they gave the name of *teja* or 'tile' bark. Both of these varieties appear to be sold and cultivated under the name of Pubescens; but whatever may be the commercial value of the bark obtained from either, it is certain that the climate of the Nilgiri sholas is not adapted for their full development as they naturally require a lower elevation. There is not a particle of the character of the Condaminea in the sorts sold as Pubescens.

Additional Plantings and the formation of Underwood.—In order to maintain the full growth and vigour of the plantation it seems to me the best method would be to go over it annually and fill up the thinly-planted or vacant spaces with good strong plants. In this way an abundant supply of young trees to take the place of occasional failures is insured. Their annual plantings should after a time accumulate and become so thick as to form a sort of underwood which beside shading and preserving a moist surface would supply young saplings to run up where wanted and in addition yield a good deal of quilled bark of fair quality from occasional thinnings. A planter, in order to have his plantation in thorough good condition for producing, should, on going through it, be literally wading amongst growth of underwood.

If the different classes of bark obtainable from a plantation managed in this way were wrought to the greatest advantage, the yield, I am convinced, would be astonishing. Such a system of bark cultivation would be more applicable to the Condaminea than to the red bark. It could not of course be developed in one season but with diligence might in good sholas be in operation in a very few years. I make the remarks simply in this light that, whether by renewing or coppicing, whatever be the system of bark-producing followed, it will always be of the greatest advantage to have an abundant supply of young sapping growth coming up in plantations.

Collecting of Seed of Condaminea.—In order to possess a supply of good seeds either at the Government or private plantations, a small clump of trees should be set apart for this purpose and rather widely planted in a favourable situation where the plants would have the benefit of full sunshine and plenty of air. For the Nilgiris the elevation should not be less than 7,000 feet. When the capsules of seed-fruit are about half grown each bunch or panicle should be gone over and all the small fruit thinned out. By this method, seed of the very best description will be procured. Throughout the plantation generally, I think it would be well to cut off the panicles of seed with which many of the young trees are loaded as these undoubtedly tend to retard the growth. The effectual remedy, however, for diminishing too free seeding is close planting.

On the whole, I am glad to be able to testify to the generally healthy state and good condition of the Dodabetta plantation so zealously and industriously attended to by Narrainasawmy, the head Overseer.

The propagating houses attached to the Botanic Garden and partly used for raising young stock for the plantation as well as garden are chiefly "lean to" tile roofed structures with sky-light windows here and there, and for the purposes of propagation are little better suited than a shoemaker's garret. Down below in the Botanic, only a short distance away, there is a large three-ridged conservatory enveloped outside with hardy climbers, whilst the majority of the plants inside would, in my opinion, do equally well without any covering whatever. Possibly the glass of this conservatory might be utilized in roofing over the propagating houses or erecting others in convenient localities.

Examination of Neddiwuttum Plantation.—On the 7th, 8th and 9th of December, I examined the Government Red bark plantation at Neddiwuttum, which occupies the debouch of a ravine towards the plains of Wynaad. The number of trees in this plantation, according to the report of Captain Walker, amounts to 208,780, the majority being of the Red bark species, although there are also a good sprinkling of Condamineas. The soil is an excellent deep yellow friable loam quite equal I would say in fertility to the lower slopes of Chimborazo, the native habitat of the Red bark. The tree here, in the general appearance of vigour, growth and development, equals and in fact excels those I have seen growing in South America. It is true the success of Red bark plantations everywhere in the East has become proverbial. Planters from different parts of India assured me 'it rushes up like a weed,' 'it grows up and gives us no trouble.' The renewing process for obtaining bark here is the same as that followed at Dodabetta, only straw is mostly employed for covering the trunks instead of moss. The most disappointing feature about Red bark is its inferiority for the purposes of quiuine manufacture. The Condaminea, scattered throughout the plantation, appear to grow up quickly and tolerably robust, though not so much so as in some of the Nilgiris sholas. One thing I noticed, and that is that the trees do not possess the vitality of those of Dodabetta. On endeavouring to procure a sample of old bark from the base of the trunks I had to go from one tree to another, as every tree examined had more or less decay, a fact to which Mr. Hillier, who came over to Neddiwuttum, was a witness. At the same time if Neddiwuttum was thickly planted over with Condaminea and carefully managed it would, I am convinced, yield annually a prodigious quantity of bark of good quality. For such an enterprise the employment of seed from the higher sholas would be preferable.

The Calisaya Bark.—The Calisaya bark of which there appears to be several varieties at Neddiwuttum, has been the victim of a sad mistake. I knew what was wrong with these calisaya plants the moment I saw them. They have been planted at an elevation of 1,200 or 2,000 feet too high. Down somewhere in the Wynaad, the proper climate would have been found. The plants are mere broom bushes and no method has been taken to ascertain the merits of the different varieties. Lately we have been told of a planter who has "imported a man to graft Calisayas," but neither will this at too high elevations prove successful but rather the contrary. The fact is no one who knows anything about the principle of grafting would graft Cinchona trees even at the proper elevation, that is, if such trees are intended for producing a large crop of good bark. Grafted trees would grow into a spreading bushy head of branches, for the tendency of the operation is to diminish or prevent the development of the trunk. Then branch bark is to a positive certainty always inferior in quantity and quality to bark derived from the trunk. In addition to this, grafted trees are short-lived. The only thing that could be urged in defence of grafting is that the trees would come into flower sooner and produce seed more abundantly. At the same time all Cinchonas when fairly treated and planted at the proper elevation seed perfectly in India. For successful cultivation of Calisaya, it is only necessary to go down to a warmer locality. I think it not improbable that the Calisaya has been planted at too great elevations both on the Himalayas and in Java. Apart from this subject the value of the different varieties is doubtful and ought to be determined. With the assistance of Mr. Rowson, the Superintendent, I was enabled to obtain a sample of one sort. Of the others, it was impossible to obtain fair samples, by which means a just estimate might have been formed of their value on analysis

Pykara Hooker Plantation.—I made a brief examination of this estate reported by Captain Walker to contain 87,557 trees.

Both Condaminea and Red bark have been planted, but the elevation is decidedly too high for the latter. There are one or two good pieces of Condaminea, but generally speaking the plantation is in a wrecked, ruinous state and overgrown with grass and portions of it are quite vacant. It is impossible to say it is exemplary in any way. The soil is invariably good, but the plantation is out of the way and isolated, and I think it is a pity that any plants were put down at this place. The "Wood" plantation is situated on the opposite side of the Pykara river, and is chiefly planted with Red bark. Everybody said it was worse than the Hooker Estate, so I did not go to see it.

Concluding Remarks.—I will now make a few general remarks respecting the plantations and the sorts cultivated therein.

The Red bark, as also the Condaminea, seems to be sufficiently well known and widely planted, and so does not call for any special remark.

But the Calisaya bark, although introduced at the same time as these sorts, has not as yet become an established plant commercially. As there appears to be several varieties of this tree, some reported inferior while others are considered valuable, I would beg to suggest that the various varieties of this species at Neddiwuttum be noted, cleared of grass and brushwood, and properly and thoroughly cultivated, so that ample growth may be induced to afford samples of each. When these can be had, a sufficient quantity of bark of each sort could be collected and sent to a quinine manufacturer, who would no doubt be able to indicate the comparative value of each variety. If it was then thought necessary, a site for a plantation might be sought for at a lower elevation for the cultivation of the best variety of Calisaya. There still remains two sorts of known value, the Pitayo bark, ten years here but never to any extent propagated or cultivated, and the Soft Columbian or Santa Fé lately introduced. It might be well to put down a number of these two kinds among the Condamineas in the most sheltered fertile places of the Dodabetta site, and in addition one or two of the best neighbouring sholas could be added to the plantation and planted entirely with Soft Columbian in order to fully develope the cultivation of this valuable bark. It is probable that either of the species would also do well at Neddiwuttum, for the assertions that have been made that the Pitayo will not succeed there have made no impression upon me. At the same time I wish it to be clearly and emphatically understood that for permanent sites for such sorts as the Crown Pitayo or Soft Columbian I would always prefer the higher sholas of the Nilgiris.

Looking to the inferior position that Red bark occupies in the market, it may be a matter of consideration whether Government would propose to retain permanently the Neddiwuttum and Pykara Estates. This too, owing to the expressions of opinion which have been given that the Government is competing with private planters. Regarding this point, I may assure planters and others that I consider they are mistaken. It may be so to some extent respecting Druggist's bark. But for bark suited for the extraction of quinine the South American market is the source that planters really have to compete with as yet. A gentleman well acquainted with the bark trade lately assured me that the East supplies only about 2 per cent, for the manufacturers, so that there is a wide field for the private planter. But in order that every one be thoroughly successful the very best species—and these are now in India—must be cultivated. And not only this alone, but to produce the best description of bark which these sorts can yield is the supreme aim that every one must steadfastly have in view. Following in this course those who cultivate bark on the Nilgiris need fear no competition from South America, Ceylon, Java, or anywhere else.

No region of country in the East possesses, in my opinion, such a magnificent and perfect field for the cultivation of the various commercial products of tropical America as does Southern India. The Nilgiri plateau, 50 miles in length with its deep sholas on the crown, and running down both sides, affords numerous excellent sites for the cultivation of bark trees, while the densely wooded humid tracts spread along the base of the Western Ghats present a choice field for the growth of the Cocoa tree and India Rubber.

In making those statements I do not do so on mere book information. Brought up in a rural district we were early acquainted with the principles of agriculture and afterwards went through the whole course of forest planting, seed raising, and propagation of all classes of plants and trees. On commencing to travel in the Spanish Republics we were able to acquire amidst other occupations and duties a knowledge of the various modes pursued in the cultivation of the different kinds of Cocoa, likewise the picking, classifying, and curing of tobacco as practised by the best Spanish planters. In addition to these our experience extends to the forest life of bark-collecting in nearly every bark region of South America, and also the tapping or bleeding of India Rubber trees. I make these remarks to show that the assurance given as regards the adaptability of these trees to Southern India is based on a practical acquaintance with their habits and other circumstances in the distant regions in which they grow.

I have given no opinion on the various methods adopted of taking the bark from the trees, thinking it best to await the analysis of the samples, 30 in number, collected with the permission of Government and already forwarded to your office.

Whilst awaiting the results of the analysis I may at the same time remark that no one need be greatly surprised if notwithstanding all that has been said, that Renewed bark is *not* the richest in quinine. As far as I can judge the ingenious "scraping" or paring process of the Dutch is manifestly not so injurious to the tree as the renewing plan, though it seems to me that less bark would be obtained by the "scraping' method. But of the renewing system one thing appears to me certain which is that when once a tree has been operated on it is placed for the future on crutches and must always remain so, and will require to be wrought after the same manner as long as it lives.

The three Soft Columbian plants originally brought out and formerly briefly reported on, have considering all things, progressed fairly well and four young cutting plants obtained from them are in process of rooting. All these are likely to do well. Two of the largest plants have been recently placed in a position to enjoy some artificial heat so as to accelerate the growth of shoots suited for propagation in order to increase the stock as quickly as possible. Cuttings will now drop in.

I must, however, remark that the propagation of the Soft Columbian in an extensive way will be found to be by no means an easy task to any one, owing to the bad state of the hot-houses and flues and to the filthy state of the inside of these houses from slugs, beetles, spiders, insects and mould. Nor even after the plants are rooted and planted out in the beds will their preservation be an easy matter on account of the cattle and goats which feed around and find their way into the cultivated plots. These things demand remedial measures.

Now that the product of these plantations has become a regularly established article of the export trade of India, I think it would be well in all communications when making mention of the commodity to employ the word 'bark' a term which a child

can understand and which has been in use since its introduction from America. It appeared to me ludicrous to see the Auctioneer at Mincing Lane—an Englishman in the Capital of his native country—selling off the South American product as "bark" and then afterwards on turning over the leaf saying "Chinchona, yes, East Indian Chinchona," thus disposing of the same article under two names.

In conclusion I trust that these observations may meet with the approval of the Government.

AUSTRALIAN FRUIT FOR ENGLAND.

The fact that ripe strawberries grown in Australia can be easily brought home in a steamer's ice-chamber appears to have drawn the attention of Colonial fruit-growers to English market. It is generally admitted that "soft fruits" cannot satisfactorily stand the length of the passage and the heat of the tropics; but apples, pears, oranges, and walnuts, and even grapes, may fairly be expected to do so. A recent consignment of apples failed to realise a sufficient price to pay the freight; but the freight was unduly high and the fruit arrived at a time when the market was glutted with Canadian produce. Several cases of grapes have been landed in excellent condition; and there would appear to be no reason why, if care is given to the gathering and proper packing of the fruit, grapes of the best quality should not be placed in Covent Garden towards the close of winter, and compete favourably with our hothouse produce, whilst the best Tasmanian pears would not fail to lower the price of a guinea the half-dozen commonly asked for Jersey fruit in spring. Both grapes and pears would pay better than oranges, but the latter fruit will unquestiouably stand the passage best. The packing of the fruit is the main point, but it must be carefully gathered when free from dew, and packed when not heated by the sun. The air should not be entirely excluded from the fruit, and the use of dry sea-weed is recommended for lining the cases; while if each pear, apple, or orange is separately wrapped in tissue paper its condition will be materially improved. These fruits should be packed ripe; but grapes should be left to mature on the passage. Tasmanian jams are now to be bought in London shops; with the fast steamers now running, many of them provided with ice chambers, we see no reason why a little care and experience should not result in Australian fruit being placed in the English market in sufficiently good condition to ensure a remunerative return to the exporter. —*Colonies and India.*

THE POSITION OF COFFEE PLANTING IN CEYLON.

Ceylon has of late been passing through a severe commercial crisis, the end of which has not yet been reached. The signs of depression are more or less apparent throughout the island. Even the Moormen at Galle, by way of laying emphasis on the wealth of Ceylon in pearls and sapphires, speak of the coffee enterprise as quite played out. In the principal towns, more particularly in those situated in the coffee districts, and dependent on the planting interest, the complaint is the same. Shop-keepers can do little more than subsist, and that too in some cases only by shutting up half their premises. On all plantations retrenchment is the order of the day. Expenditure on manure, buildings, machinery, and labour is conducted with the strictest regard to economy. Salaries have been reduced to the lowest limit, and, wherever possible, Eurasian and Native conductors have been substituted for European superintendents. The public revenues also suffer, for not only do economy in manuring and small crops mean diminished railway receipts, but the keen competition, which a few years ago raised the price of Government land, and brought such handsome sums to the coffers of the State no longer existing there is a sensible falling off in the public receipts for land sales. In this connexion it should not be forgotten, however that even had the prospects of coffee continued as bright as they were some years ago, the amount annually realized by Government on account of the sale of land could not have gone on undiminished, the best land in the most suitable situations having already been exhausted. Altogether, the outlook whether from the point of view of private enterprise or from that of public prosperity, has for the last two years been far from satisfactory. This gloomy state of things was the other day brought home in a very disagreeable manner to the planting community by the Earl of Kimberley, who declined to accede to a memorial on the subject of railway extension on the grounds of a falling off in revenue, general depression in trade, leaf disease in coffee, and the uncertain prospects of tea, cinchona, cacao, and other new products.

While it would be useless to attempt to ignore the severe strain which the Colony has experienced during the past year or two, it would, as we shall try to show in a future issue, be a grave error to assume that the extreme pessimist view of the situation is the truth, the whole truth and nothing but the truth. The real state of the case will be found to lie somewhere between this and the extreme optimist view of the colonists themselves, who are pardonably inclined to paint every enterprise in the island in *couleur de rose*. For the present it will be sufficient to survey the principal causes that have led to the present unsatisfactory condition of things. Foremost among these must be mentioned the commercial depression which has been experienced throughout the world during the past few years, and which has affected Ceylon in common with other centres of commerce and industry. Nor must the relatively low price of coffee in the London market be left out of account in trying to explain the existing depression. For, though the prices that have ranged since coffee fell would be in ordinary circumstances fairly remunerative, they are not so in the case of estates purchased almost at double their normal value. Now it is only too true that, when the coffee mania was at its height and the competition brisk, estates were bought and worked at a cost which would never have been incurred except on the supposition of a continuance of good crops and high prices. A mistake like this at starting must have proved the ruin of not a few promising ventures, even had leaf disease and other causes not intervened to reduce the number of cwts. per acre. To make good the actual fall of about one-fifth in the price of coffee in the London market would require an increase of more than one-fifth in the out-turn of crop: a compensation with which unfortunately the coffee planter has not as a rule been blessed. The reckless speculation in coffee estates which marked the years immediately preceding the present period of depression, is the almost invariable fore-runner of commercial disaster. And as is usually the case in such circumstances, not the speculators themselves, but those with whose money they have been operating, are the principal sufferers. The proprietor who has heavily mortgaged his estate, can sometimes look with comparative equanimity on leaf disease, short crops, and low prices; not so the mortgagee, who foresees that he will soon have a worthless estate upon his hands.

The rise which has taken place in the price of forest land in consequence of competition has proved a valuable addition to the revenues of the Colony, without in any material degree endangering the safety of the coffee enterprise as a profitable investment. In 1848 the average price realized per acre was about Rs. 3, As. 12; in 1863, Rs. 26; in 1877. Rs. 30, As. 12;

in 1877 the average reached its maximum, being Rs. 43, As. 6. It was only a little lower in 1878, being Rs. 43; but sank to Rs. 27 in 1879. The above are merely the average prices realized for Crown lands of all kinds throughout the country, and give little idea of the prices which good forest land suitable for coffee could command. Prices ranging from Rs. 80 to Rs. 150 were not uncommon. In 1873 a lot was sold at Rs. 180. The highest known prices were Rs. 248, Rs. 245, and Rs. 242 paid in 1875, 1876 and 1879 respectively. Planters of experience say that land purchased even at this high figure can be made to pay; but it leaves a very small margin for the possible contingencies of short crops and low prices. Exclusive of the purchase price of the land, it costs from Rs. 250 to Rs. 300, or even Rs. 400, to bring an estate into bearing. For the first year or two after this, the utmost to be expected is that it shall pay the interest on the capital, and provide a surplus which year after year will bear a larger proportion to the expenses of working. Estates brought into bearing at a total expenditure (including the original cost of the land) of from R300 to R400 per acre, have in ordinary circumstances been able to clear themselves in a few years, and afterwards to yield a handsome profit. But it has yet to be proved that, except in exceptionally favourable situations, these estates which have cost from R450 to R600 per acre before they have yielded crop, will in the long run turn out a financial success. It is not, however, the high price paid for forest land that has imperilled the coffee industry, but the reckless way in which estates in full bearing changed hands. The average value of such estates may be set down at from R500 to R600 an acre. Yet it was no uncommon thing for sales to be affected at prices ranging as high as R1,000. To make an estate pay at this figure two things are absolutely necessary:—a succession of good crops, and the maintenance of high prices. Were it asked how shrewd men, like the Ceylon planters, could have made such miscalculations, the answer is, that the genuine planting community was invaded by a host of outsiders, chiefly sons of wealthy men at home, who, looking upon the coffee enterprise as a veritable "Eldorado" embarked in speculations with a recklessness inspired by full pockets and an empty experience. To this may be added, the almost unlimited means of borrowing which, as the Oriental Bank shares testify, has been freely made use of both by private individuals and Companies.

The same reckless spirit showed itself in the extravagant manner in which estates were managed. According as it is economically or uneconomically conducted, the expense of clearing an estate and bringing it into bearing will vary from R250 to 400 per acre. In the matter of buildings, machinery, and labour, the expenditure has seldom very far exceeded the boundaries of a wise economy. But no inconsiderable saving might have been effected in the matter of supervising agency. The institution known as the visiting agency is a costly one: much too costly for the good that results from it. There are occasions when the report of an independent eye-witness is extremely valuable. But on estates under managers of tried probity and experience, it does seem "a wasteful and ridiculous excess" to have a visiting agent on a large salary, whose function it is to forward bi-monthly reports to the proprietors. If the manager is trustworthy and competent, the visiting agent is not needed; if untrustworthy and incompetent, the hurried survey once in two months, which the visiting agent can make, will not suffice to keep things straight. The visiting agent has in fact grown up out of the system of working on borrowed capital. Banks and private individuals who advance money for the purchase and working of estates, like to have an independent agent who shall keep them informed as to the state of matters, and exercise, it may be, direct control over the working of the property. In whatever way he has originated, the visiting agent has now become a recognized institution in the planting industry, whose influence is enormous. Money being advanced or withheld at his discretion, a good report is the next best thing to a good crop. Another item of expenditure on which a prudent economy has not been always exercised is that for manuring. The mistake of allowing the cattle to graze on the patena, or grass land during the day, thus losing a large portion of valuable manure, is now carefully guarded against. But much money has been, and is being wasted in the application of artificial manures, which can be profitably applied only when preceded by an analysis of the different soils. Thousands of rupees are frequently spent in manuring without producing any result whatever.—*Madras Mail.*

FOSSIL GUM MINES.

In his report on his recent journey into the Dar-es-Salaam district, in East Africa, Dr. Kirk records the existence of what may almost be called mines of fossil gum copal, which are largely worked by the natives, who extract therefrom large quantities of this valuable material. These deposits of semi-fossil gum exist in small patches, as if they had been produced by isolated trees, and the natives often sink a number of test holes before they "bottom" on a deposit worth working. These buried stores of gum, or rather resin, are similar to the deposits of fossil kauri gum, which are found in New Zealand, the curious fact in both cases being that trees now existing yield the same kind of resinous substance. Dr. Kirk says the gum is found in red sandy soil, but he does not tell us how deep the deposits are found, nor whether they have been covered by alluvial deposit, by volcanic agency, or by any other means; but he makes the interesting observation that the underground gum is undoubtedly the produce of the same species of tree as still exists in these jungles, which now yields an inferior sort of resin; the difference between the two being in consequence of age and a chemical or molecular change effected by time. The copal tree grows throughout the Uzaramo country, and is by no means confined to the sea-coast, but is even more abundant inland beyond the first coast-ridge. It was not seen, however, at Kidunda, where the geological formation changes, and the old limestone rocks of the interior first appear.—*Colonies and India.*

LANTANA, A NEW VEGETABLE PEST IN AUSTRALIA.

In an article which appeared in our columns towards the close of last autumn, we drew attention to the fact that, favoured as the Australian Colonies are in the matter of climate, the growth of weeds is promoted by those conditions which are so favourable for the growth of saleable produce. Farmers have cause for grumbling in Australia as well as in England. In England the main causes are successive wet seasons, and the fact that other countries can place their produce on the English market at a lower figure than the English producer can accept, and yet have a profit. In Australia farmers complain that droughts are too common, and the means of conveyance are not sufficient to take their produce to market. In addition to these drawbacks, they are plagued with beasts, marsupials, and rabbits, and with Bathurst burr, thistle, prickly pear, and sweetbriar. To this list the *lantana* appears likely to have to be added. The *lantana* is a shrub resembling a gigantic raspberry bush, bearing seeds which are much relished by birds, which

scatter them far and wide, and already the neighbourhood of Sydney possesses a considerable growth of the unwelcome stranger. It appears to have been imported from France as a garden flower, and, if it could be confined to the garden, it would be an ornament instead of a nuisance. But in New Caledonia it has already covered valleys and mountain slopes with a luxuriant growth of almost impenetrable scrub, rendering a large extent of country utterly valueless until it has been rooted up and burnt. So many runs have been seriously prejudiced in value by neglect in coping with burr and thistle, and latterly with prickly pear, that it is to be hoped that this new vegetable pest will not be allowed to make head-way. The *lantana* might with advantage be included amougst the noxious plants to provide for the destruction of which Mr. Davenport's Bill was brought into the Legislative Assembly of Queensland last autumn.—*Colonies and India.*

PLANTING IN SUMATRA.

Now that affairs are beginning to settle down a little in Achecn, attention is being directed to the other parts of Sumatra under Dutch rule, and especially to that portion which is the site of the tobacco plantations. As our readers are aware, the progress in tobacco cultivation has been very rapid, and the list of estates which we published a short time back gives a good idea of the extent to which the enterprise has been brought. Thousands of acres are under cultivation, and the returns have already reached a very large figure. The advantage to the Netherlands India Government from such a large influx of capital as is expended on the estates is very great, and Deli, Langkat, Serdang, and all such places ought to receive something more than a mere passing thought by the officials. According to all accounts, however, little else falls to the lot of the planters, who are making complaints as to the way they are treated. First and foremost it is said that not a single road has ever been made by the Government, notwithstanding the fact that the planters have to pay considerable taxes on income, imports, exports, and coolies. This is a peculiar state of things, because, if there is one thing more important than another with regard to the successful opening up of a new country it is a systematic means of communication. So far as the estates themselves are concerned, of course all the roads are made by the planters, but outside the limits of the estates they have a right to expect that the Government will open up communication with the sea coast for the purpose of conveying the produce, and also to the centres where the officials reside, for the purpose of protection. As to the conveyance of produce, most of the estates have water carriage, and as to that the authorities would not have much to do; but the intersecting the country itself with, at any rate decent roads, is a matter which ought to be performed by the Government. It must always be remembered that an estate is like a little world in itself, and the management of it involves a serious amount of trouble on those who have to perform that duty. In Sumatra the planters have no authority to act in the capacity of justices of the peace, and in the event of a disturbance with their coolies (a thing which does occasionally occur), the planter can take no steps to arrest the ringleaders until the officials arrive. Owing to the few police stations, the distances beetween each, and the difficulty of communication, their arrival is, as a rule, not for a long time after the trouble, and in the meantime the rioters can do almost what they like. Under such circumstances it is no wonder that the planters are loud in their complaints. They are, of course, obliged to take steps for their own protection; but with no powers of arrest they can do nothing in the absence of the police to enforce order. It is always desirable, when there is a Government force within easy reach, to limit the powers of those not holding office, and in all cases the manager alone ought to be able to act as a justice of the peace, but it is also very necessary for the planter to be able to call in Government aid with as short a delay as possible. If he cannot do so, his powers ought to be more extended, and he should be recognised by the Government by means of a commission of the peace. It is not likely that any one who was so recognised would abuse his authority, because every act would be done with the ulterior object of maintaining peace, and thereby securing success. The authority granted would not confer immunity in cases of wrong doing, but it would materially assist the officials in the performance of their duties. The necessity for protection is well known in Sumatra, for the Battaks and Gayoos are far from well disposed towards the Dutch, and take every opportunity to create disturbances. The system of coolie work is also one which always lays the employer open to severe losses from the evil disposed, and the sums of money lost in the way of advances would cause surprise if they were made known. The fact is, the planters in Sumatra have little to thank the Netherlands-India Government for, except easy grants of land. This was certainly a great inducement, and one which the officials in the Malay States might well follow. But at the same time, as the planters have so energetically entered into the opening up of the country they have a right to expect that the Government will do all they can to secure protection to life and property. This can only be attained by a well constituted police force, a just though strong administration, and easy means of communication. Two at any rate of these the districts of Sumatra lack, and they should be at once conferred.—*L. & C. Express.*

COFFEE IN AUSTRALIA.—An experimental growth of Liberian coffee, made by a Mr. Wickham, at his plantation at Maragen, on the Lower Herbert River, has proved successful. The young plants, from seed supplied from Kew by Sir J. D. Hooker, have just ripened their maiden crop, and are described as looking very promising for the future. It is probable that coffee planting on a large scale may take place in Northern Australia. The soil is fertile, and the climate well adapted to the European constitution. Land can be taken up for 5s an acre, and the payment can be spread over a period of ten years. —*Home and Colonial Mail.*

LINNEAN SOCIETY.—*June* 2nd.—Sir J. Lubbock, Bart., in the chair. Mr. Elwes exhibited samples of quinine made by a new process, without expensive chemical apparatus, by Mr. Gammie, superintendent of the Government chinchona plantations of Sikkim.—Mr T. Christy drew attention to living rubber plants from West frica, viz., *Urostigma Vogelli Tabernaemontana crassa*, and he showed products of *Pistacia terebinthus*, viz., the nuts, the resin, and the so-called butter separated from the resin, and used for sweetmeats in the East, also Chian turpentine from the same tree.—Sir J. Lubbock read a paper 'On the Habits of Ants.'—Mr. S. O. Ridley read a paper 'On the Genus Plocamia of Schmidt,' and some other echinonematous sponges. With reference to the genus mentioned, for which he accepted Prof. Duncan's name of Dirrhopalum, he enumerated three species already described, but assigned to otber genera, which must be added to it; the distribution is thus exteuded from the tropical Atlantic to the British, Portuguese, and Ceylon seas. He described a New Zealand species, which proves to be new to science, and appears to decide a point which has been disputed, viz., the existence of ceratinous material in the skelton. Geological facts were brought forward showing the existence of the genus in the Eocene, upper chalk, and greensand formations. A new genus of the same order was described, based on a species of Lamarck and two other species; it is closely allied to Dictyocylindus.—*Athenaeum.*

Correspondence.

To the Editor of the Ceylon Observer.

COFFEE LEAF DISEASE AND THE GOVERNMENT MYCOLOGIST.

4th July 1881.

Sir,—The planters have at present gained but little benefit from Mr. Marshall Ward's presence in the island. Was he brought out to trace the life history of the fungus, and thereby make a name for himself as a microscopist and mycologist, or was he brought out to combine this with practical experiments and thus help us to find a remedy for the disease. As yet we have not heard of one single suggestion in his part as to a cure—it is better to speak plainly while he is with us than to abuse him after he leaves us—and it seems to me that, unless he soon commences to think of the practical as well as of the scientific part of his work the money would have been better spent in bringing out an agricultural chemist, placing his services at the disposal of planters.—I am, dear sir, yours faithfully, W.

[We think our correspondent is rather hard on Mr. Ward. His past reports shew that he has by no means confined himself to scientific investigation although that has been fruitful in most important results, such as the discovery that the filaments had nothing to do with *Hemileia vastatrix*; but he also engaged in a series of practical experiments, and we have no doubt these are still going on, as will be seen when his next report appears.—Ed.]

A CHALLENGE TO ALL DISBELIEVERS IN ARABIAN COFFEE.

Maria Estate, Wattegama.

Dear Sir,—Will you please allow me space in your paper to invite Mr. W. McKenzie and all other persons who have been crying down Arabic coffee to visit this and neighbouring estates and satisfy themselves. Maria estate has been giving a crop of 6 cwt. per acre for the last three years and is doing even better this year, although there have been several attacks of leaf disease. Even now there is more or less about, though for a short time only as my simple remedy never allows it to stay long or do much damage. The soil is not over rich. This year there was a fear of the blossoms being burnt off first and when rain did come and the blossoms opened, (we had heavy rain) and many people thought all the blossoms were lost. Yet, in spite of all, there is a good crop. Arabic coffee will and does pay, but it wants careful attention, nourishment, and a disinfectant on account of bad atmosphere. Come and see: seeing is believing. No Messrs. Ward or Schrottky required.—Yours faithfully,

J. HOLLOWAY.

P. S.—You know, Mr. Editor, how anxious I was to get you to come last year (see my letter of 16-7-80). This year I am even better than last. Talk about a model farm—here you will find a model estate. It may not be as clean or buildings as elaborate as some people would like, but it answers the question does it pay? Yes, and improving more and more.

HOW TO PROMOTE THE SALE OF CEYLON TEA.

Maskeliya, 4th July 1881.

Dear Sir,—Your extract from the *Home and Colonial Mail*, in your issue of 28th ultimo, shows that what the Ceylon tea planters ought to do in London—viz. establish an agency for the sale of their teas—has already been done in Dublin by an energetic Indian Tea Company, with respect to its own produce; and that the venture has been attended with success. If nothing better can be done, by all means form a Tea Syndicate to be affiliated with the Indian Syndicate; but I maintain that, by the establishment of such an agency as I advocate, a great deal better can be done than affiliation with a Syndicate whose power is necessarily handicapped by having to find markets for and dispose of such large quantities. Another point in our favor is that Ceylon tea is more readily appreciated than Indian, which, though as *good*, takes longer than ours to accustom itself to the palates of people who have been in the habit of drinking China tea.

Thanks to the untiring energy of the Ceylon Commissioner at Melbourne, and to Mr. Moody's cordial co-operation with him, a good market has been opened in Australia, but this will not take all our teas. The experience of Ceylon tea in Mincing Lane has not been encouraging, and, owing to the wretched prices ruling, the *London* market is virtually closed to us. It is not so, however, with the *English* market. I know of many people at home who would drink Ceylon tea if they knew where to get it; and out of our 2,800 European residents in Ceylon how many fond mothers and sisters are there in England who would not gladly drink Ceylon tea for the sake of the dear boys out here, if they only knew where to get it? And how many do know?

As an instance of the difficulty experienced in procuring it at home I may tell you the following:—A planter who was at home some six months ago wished to make some friends a present of Ceylon tea: after a most laborious hunt, having tried nearly all London, he at last found a grocer, who said he had the real article, *but*—the price was 5s per lb., and when he came to drink it it proved to be a very inferior stuff!

Many men approve of the idea of a Ceylon Tea Agency at home, but no one seems inclined to make a practical move towards starting it; and I am not aware of any response having been made by Mr. P. R. Shand's suggestion of a meeting in Colombo to discuss the matter.

Of course, the whole secret of success would be in advertising: and this should be done not only at home, but in the local papers here, with, at the foot of each advertisement, a "*Note*: To European residents in Ceylon: *Please cut this out and enclose it in your next home letter!*' Say 100 only responded to this, and each house used 2 lb. of tea a week—there are 10,000 lb. per annum disposed of at once!

Should anyone be still unconvinced, let him read the extract I have referred to in your issue of 28th ultimo, and he will come to the same conclusion as myself; viz.: that the "Ceylon Tea Retail Agency," once started, is bound to succeed.—Yours faithfully,

W. TURING MACKENZIE.

THE CALISAYA LEDGERIANA TREE ON EMELINA ESTATE, MASKELIYA.

Royal Botanic Gardens, Peradeniya, 8th July.

Sir,—It may, perhaps, prevent some future misconceptions, if I state definitely what has recently occured with reference to the Emelina cinchona so far as I am concerned.

I have already mentioned in your columns that when Mr. Moens and I visited the estate last September he noticed a single tree to be different to the rest of those he saw, and thought it probably *C. Ledgeriana*. But without the flowers he could not be certain in his determination, and he asked Mr. Wilkinson, when the tree blossomed, to send me some flowers for examination. This Mr. Wilkinson has now done, and I have had the satisfaction of verifying Mr. Moens' supposition. The specimen differed a little from the pure type in having the flowers rather

larger and the inflorescence more lax, but I was pleased to be able to assure Mr. Wilkinson that the tree was *C. Ledgeriana*.

In my letter to him I pointed out the drooping character of the flowers, their white colour and the shape of the buds, and in his reply he thanks me for helping him to "see the difference between the real Ledger blossom and the ordinary Calisaya."

I have seen Ledgeriana flowers from this one tree only, so far as Emelina is concerned; and I am anxious to check promptly—so far as I can—that facile exaggeration and loose deduction to which it seems not unlikely my determination of this cinchona may give rise.—I am, sir, yours faithfully,

HENRY TRIMEN.

THE SAPU TREE AS A BREAKWIND.

Lindula, 8th July 1881.

DEAR SIR,—I notice, in your paper of 5th inst., a Dikoya correspondent advocates planting sapu trees as breakwinds.

I think, if your correspondent would study the natural habits of that tree, he would observe that it is seldom or never found on blown land, and appears to flourish only in sheltered situations.

Several attempts to grow it here on ridges &c. have only resulted, after much trouble and expense, in total failure.

In addition to the natural tenderness of the tree, it possesses long delicate roots, which make it an exceedingly difficult matter to transplant it successfully.

The black wattle will, I should suppose, be found a much superior tree for wind belts in the younger districts. It has the merits of being easily planted, growing fast, and standing wind splendidly. Whether its timber is valuable or not I am unable to say.—Yours faithfully,

TIP.

DIKOYA RED BARK FETCHING 5s. 5d. PER lb.—? THE HIGHEST YET REACHED.

No. 1.

Kandy, 11th July 1881.

DEAR SIR,—I see that at a recent sale some Kirkoswald estate red bark was sold at the high rate of 5s 5d per lb. !

Is not that the highest price yet realized for Ceylon bark of this description ?

It would be interesting to know how it was prepared etc., as there must have been something decidedly superior in the curing, as well as in the bark itself, for it to have sold at such a high figure, when there is so much cinchona in the market.—Yours truly,

PERUVIAN.

No. 2.

Dimbula, 11th July 1881.

DEAR SIR,—In a recent issue of your valuable paper, I observe that Kirkoswald estate *red bark* fetched 5s 5d per lb. in London. This strikes me as an unusually high figure for *succirubra bark*, and I know the Kirkoswald trees, lately cut down, cannot be over eight years old. The bark is said to have been of "an exceptionally fine character." Are we to understand from this, that the analysis was good, or simply the appearance ? It would be interesting to know how the bark was prepared and shipped.—Yours truly,

CATEADOR.

A CEYLON TEA AGENCY IN GREAT BRITAIN.

Agra Patana, July 11th, 1881.

DEAR SIR,—In reply to a letter from Mr. W. T. Mackenzie, in your issue of 8th instant, I beg to state that the matter of a Ceylon Tea Agency is now in course of arrangement, and is in fact only waiting for a final decision from some influential gentlemen connected with the cultivation of tea in the island. A gentleman with some commercial experience is now on the point of starting for England to arrange preliminaries, and I hope that advertisements will soon appear in the home papers, and also through the medium of your journal in Ceylon.—Enclosing card,

I am, sir, yours faithfully, A LOVER OF TEA.

[As we understand the matter, several Ceylon Tea Agencies are at work in the old country: in Aberdeen there is a gentleman giving most of his time to the sale of Ceylon tea. Some of our planters have contracted, we believe, with large houses in Edinburgh and Glasgow to supply Ceylon tea. Others have arranged with London houses to despatch packets of Ceylon tea to any English address. Our advertisement columns shew how this is done. But of course there is plenty of room for a special Ceylon Tea Agency in England. Since writing the above, we have received the following from a well-known tea planter :—"I notice Mr. Mackenzie's further remarks in your paper of the 8th on the subject of a London Tea Agency. I think it a great pity that those who could help in this work do not combine to do something. In the case of this estate, my partner at home has arranged for a retail business in Glasgow and the tea is sent from here in 20 lb. boxes, and sold there for 2s. 6d. per lb. duty paid. This amounts to our tea being worth to us R1 per lb. in Colombo, or perhaps a little more. I believe that in six months 10,000 lbs. have been sold in this way, and there is no reason why the thing should not increase, as all I hear of the tea is in its favour. What Ceylon wants is just such an agency in London and other large towns. I should be glad if you could call attention to the importance of a meeting being held to discuss this question." [Our idea is that tea planters should await the arrival of the Ceylon Commissioner next month to have his advice at the meeting.—ED]

THE "SIROCCO" TEA DRYING APPARATUS.—This is an invention of Mr. S. C. Davidson for drying tea by hot air. It is in the form of a stove with drawers, and is capable of drying 20 maunds of green leaf *per diem*, with from 5 to 6 maunds of dry wood. The teas cried by this apparatus are spoken of very highly by Messrs. W. J. & H. Thompson, the well-known tea tasters, who state that the value was enhanced by the process. The price of the apparatus is £85 f.o.b., the Colombo agents being a well-known mercantile house who will doubtless bring the apparatus into use.

TEA-BUG.—Mr. J. Wood-Mason, of the Calcutta Museum, who was especially deputed by the Government of Bengal, at the request of the planters of Assam, to investigate the nature of the insect tea pests, has succeeded in ascertaining some facts about the tea bug which are disseminated through the medium of the Assam *Gazette*. Mr. Wood-Mason finds that the tea bug is armed with a serrated ovipositor, in appearance, as in sharpness, resembling a sword; with this the insect pierces the leaves of the plant, and deposits therein the eggs that eventually cause such villainous mischief. But the most important discovery is that the pest appears invariably to choose the blighted portions of bushes for these operations, and thus there is good hope that by vigorous and unremitting plucking of these parts the evil may be mitigated. While on the subject of insect pests, it may be remarked that vigorous attempts are still being carried on in Ceylon to discover a means of putting down the *Hemileia vastatrix*, which has been so destructive of late years to the coffee; Mr. Schrottky, in particular, is very sanguine that he has discovered a method of extirpating the disease, though we are not aware that its success has yet been fully established. —*Pioneer*.

COCONUT CULTIVATION.

Of late years very little attention is given to coconut cultivation in this city and its suburbs, though at one time—and this was not many years ago—owners of land, natives especially, emulated each other in forming large and well-stocked coconut plantations. Coconut cultivation is by no means an unremunerative business. In the northern and southern parts of Madras, from Royapooram to the village of Trivattoor and between St. Thome and Adyar and further south, coconut trees may be seen planted in admired confusion. It was once considered a grand thing for a moderately well-to-do Hindu, official or non-official, to possess a well-stocked garden of coconut trees either at Washermanpettah, on the Trivattoor High Road and other places and those who had no desire to enter into trade or public employ were content to be owners of small gardens on the produce of which they subsisted. But these things have now changed. To own a small plantation is considered somewhat *infra dig.*: to pass the matriculation examination, to enter the Government service, to be a subordinate in a public office, to be a prominent member of a reading or debating society are considered worthy the ambition of the members of the rising Hindu generation, while a very lucrative business is being gradually neglected. The effect of this indifference will not be felt now. Ten or twenty years hence when the plantations now in full working shall be no more, the want of the coconut tree will be felt and then we may look forward to the revival of a branch of industry that is just now neglected.

Many years ago, when people were anxious to do something whereby their names may be perpetuated, or when they wished to endow a public institution—be it educational, ecclesiastical or charitable—they generally made over lands for the support of the institutions and such lands were invariably planted with coconut trees, the revenues from which went to the support of the institution or charity. We see this especially in connection with Roman Catholic and Hindu endowments. The revenue from these plantations during certain seasons is fairly good and well able to support small charities. Some years ago when Lord Napier was Governor of Madras, he hit upon the idea of planting the grounds attached to the Gordon Refuge in St. Thome with coconut trees in the hope that revenue will in time be derived from this source for the support of the institution. A fine coconut tope has been formed alongside that useful institution but, strange to say, that although ten or more years have passed since the trees were planted, they have neither produced coconuts nor toddy. Few products of the vegetable world are adapted for so many useful and divers purposes for the convenience of man as the coconut tree. It may be mentioned that the Laccadive islands produce a very large supply of coconuts and that the islanders barter the valuable produce of their trees for blue cloth, old guns, knives, &c., which they very much prize. The revenues of the Government are, to a certain extent, dependent on the extension of coconut planting. Every coconut tree that produces toddy for the time is the property of the Government. The abkarry department takes charge of and marks the tree and the abkarry contractor of the district or village is bound to draw toddy from the tree and pay the owner a stipulated rate for the juice he extracts. The toddy contract of a large city like Madras brings in some thousands of rupees a year and in some of the mofussil districts the revenue is much larger. The contractor undertakes to draw and sell toddy in so many shops in a village or taluq of the district which he has purchased and he has to carry out the terms of his contract very rigidly, failing which he lays himself upon to severe penalties.

We have alluded to some of the advantages to be derived from the cultivation of the coconut and of the condition of some of the plantations in the northern and southern parts of the town. It is evident that interest in this valuable branch of agricultural industry is on the wane. While the Government are giving attention to other matters connected with the agriculture, it may not be undesirable to give some little consideration to coconut plantations from which the public revenues derive a not insignificant portion of their income. The abkarry department will not, ten or fifteen years hence, be able in Madras to show such a large income from the toddy contract as is now done owing to the fact that coconut plantations do not receive the same attention from private persons as they used to do. The Government of Ceylon, we observe, is giving some attention to this matter, and European planters have entered a field which was hitherto left altogether to Hindu enterprise. In Jaffna coconut cultivation a few years ago was considered very unremunerative and few European planters cared to venture in a speculation which they all along thought would not turn out well. But they have found out their mistake. One or two experiments lately tried have proved so successful that they have been encouraged to further efforts, and plantations which two or three years ago would have been willingly sold for the value of the land are at present held for much higher prices. What has been achieved in Ceylon may be easily attained in Madras and it is left to those who have the will and the means to make an effort and with the countenance of the Government, a valuable agricultural industry may be successfully worked.—*Madras Standard.*

THE VALUE OF SAWDUST MANURE.

I am glad to see that Mr. Westland has put the question as to the value of sawdust manure. The same thought had occurred to me more than 12 months ago in regard to its usefulness or otherwise for horticultural purposes. My experience here, amidst so much market-garden farming, had previously fully established its reputation as a highly-fertilising medium for fields and field-grown crops. As, however, from some cause not yet explained this material did not appear to be so popular as it should be, and knowing its value from personal observations made during my frequent visits to farmers around, I determined upon having a wagon load, and to test it for myself, as I am so frequently asked questions in regard to a manure readily obtainable for the use of amateurs. The load which I got came direct from the London General Omnibus Company's yard. It was quite fresh, and was very hot from fermentation. I had it shot in a convenient place for a day or two, and then began to test it. It would take up too much of your space for me to give in detail what I consider to be the complete success of my trial of this material with all kinds of crop, not excepting grass sward, vegetables, fruits, &c., especially raspberries, the canes upon which are now half as large again as they were previous to its use. I will give but one fact in regard to it, which I think speaks loudly in its praise. At the time I commenced to test it I had living in the greenhouse two dozen each of hyacinths, narcissi, and tulips, which had not yet been planted, though it was getting late in the season for so doing. To test this material I had a large box filled entirely with the material, and without even the addition of soil of any kind. The bulbs were then pressed firmly into it. First a row of dwarf tulips, then a row of tournesols, another of hyacinths, and at the back two of Polyanthus narcissi. These made a wonderful start. The roots seemed to run rapidly into the sawdust, and fine breaks were made. When the leaves with flower spikes were some 4 in. long, I had an intention

to pot them off into very small pots for our Whitsuntide church decorations. Imagine my surprise when I found the roots so matted together that I could not separate the bulbs in any other way than by cutting them out in squares about the size of the bulbs. I tried to pull some up, but the stalks, flowers, and all parted from the bulbs rather than lose their hold on this free, open material. The half which I left to bloom undisturbed in the box garden gave exceptionally fine spikes, &c. No greater proof is wanting that this manure is perfectly innocuous, and most valuable. I think it has received a most undeserved bad name from the fact that "sawdust manure" was at one time only to be had at the Zoological Gardens. Doubtless this mixture was too powerful for direct application to any vegetable growth. Those who now use it say little for or against it, because, as it is got very cheaply, it is to their interest to do so. It is in great demand in the neighbourhood of Manchester.—William Earley.—*Gardeners' Chronicle.*

Liberian Coffee Seed: a Serious "Sell."—A low-country planter writes:—"W. got 18 months ago 'Liberian coffee' seed, and it all came to be ordinary coffee, or did not germinate at all, and for the latter he was supplied with about 60,000 more about a year ago. In consequence of it all coming like this, he has lost a clearing for a year, and ——— who bought plants has also lost about 30 acres. And this seed got from those supposed to be noted planters and fine men. I suspected for a long time, but for months I was not looking after the place, and I have only now resumed management, and in doing so I told all I thought, and wrote to all the people who had bought plants, and my answer is the same: 'Plants no use, undoubtedly common coffee.'' This is certainly a very hard case; but if the seed was imported, it may turn out not to be ordinary Coffea Arabica, even though no larger. One Ceylon planter who visited Liberia told us he saw coffee from the size of a pea (St. Thomé coffee) up to the largest Liberian. Our correspondent's may turn out after all to be a new West African variety. Wait a little longer.

A New Industry.—A correspondent calls our attention to the following paragraph:—Sponge Culture: From the recently-issued report of Professor Baird, the Commissioner to the United States, we glean some very interesting facts regarding the recent development of this industry. Among the more recent enterprises in the way of the artificial propagation of aquatic animals is that relating to the artificial propagation of the sponge of commerce. Professor Oscar Schmidt, of the University of Grätz, has been so successful in his preliminary efforts in this direction that the Austrian Government have authorized him to attempt the development of the industry on the coast of Dalmatia. The process is very simple, consisting in selecting the proper season in the spring, dividing a living marketable sponge into numerous small pieces, and then fastening them to stakes driven into the sea bottom. These fragments at once begin to grow out, and at the end of a given time each one becomes an entire sponge. According to Dr. Schmidt, three years is a sufficient length of time to obtain from very small pieces fair-sized sponges. In one experiment, the cost of raising 4,000 sponges amounted only to £9, and this included the interest for three years on the capital employed.—*London Times.*

Demand for Indian Tea.—The *Civil and Military Gazette.*—The last issue of the *Indian Tea Gazette* contains a letter headed, "A proposed relief for overstocked markets," which contains it seems to us some valuable suggestions on the tea question. Peoples as well as individuals may look for a field while what they seek is really beneath their feet,—and this is what the writer of the letter we are referring to would have us believe is the case with the tea planters seeking a market for their produce. The cry now-a days is—develope the Australian market; educate the people of England up to a taste for Indian teas; and so forth. But why do this when we have around us a tea-loving population of over 200,000,000 souls? If the natives do not drink tea, what is the reason of their abstention?—we know there is hardly anything which they prize more highly. The answer is easy enough. They cannot afford it, at the prices ruling, and they cannot, as a rule, get it in smaller quantities than 1 lb. packets. The plan proposed is briefly this. To start a Company having for its object the "bulking" and packing of teas in small packets say 2 oz., 4 oz., and 8 oz.,—selling this tea at a fixed price to retail dealers, who could sell the teas, it is calculated, allowing a fair profit to themselves, the middleman and the Company, at 1 anna 9 pie for a 2 oz. packet, and 3 annas for a 4 oz. packet, supposing the tea to be bought, as we believe it might be, at six annas per lb. all round. If such a Company were once started, we feel pretty confident that an enormous demand for Indian tea would spring up among the natives. A man on a low salary will hesitate a long time before he commits such an extravagance as investing a rupee and a quarter, say in a pound of tea, but that same man would probably gladly give his three annas for a four oz. packet. The Company would also find a market for small lots of certain classes of tea, which when 'bulked' would command a far better price than when sold separately in small lots.—*Madras Mail.*

Indian Wheat.—With reference to the report of Dr. Forbes Watson on Indian wheat which we mentioned a short time ago we may give the following extracts from a letter of Mr. Alex. Smith, published by the Indian Government, on the same subject:—"I may remark that many of these wheats are much superior to the bulk ordinarily received from India on this market both in point of 1° cleanness (*i.e.*, freedom from earth, earthy dust, weevil cutting and admixture of other grain; 2° quality, and 3° size of berry, and this is particularly the case with 1° the long-berried hard wheats, and 2° the wheats classified as resembling Australian, Oregon, Spanish and Californian. Care and cleaning machinery seem to be greatly wanted both by the agriculturists and wheat dealers in India. If the growers would prepare a clean seed bed, and sow clean seed of the proper kind, such as any of those samples marked 'Extra' as may be most suitable to the land in question, then it appears from the quality of these samples that much of the Indian soil is suitable for growing the most valuable descriptions of wheat, and that India could always command the top prices of the day for its wheat shipments. During the last few months some shipments of very fine wheats have arrived here from Bombay showing a marked improvement in quality on those usually received from Calcutta." The Secretary of State for India, in forwarding this letter to the Indian Government remarked:—"It would be interesting if a report could be furnished by your Government giving some description of the nature of the soils in which the better classes of wheats indicated in these reports are grown, as well as of the system of cultivation followed. Thus it would be desirable to know whether the best wheats are raised on irrigated or on manured land, also whether the land has been long cultivated with wheat crops, and what is the average weight of crop per acre. It has been alleged that the productive power of the soil in some parts of India has begun to fail, and it should be ascertained whether there is any evidence of this in respect to the quality and quantity of the wheat crops raised."

CEYLON TEA AND OTHER PRODUCTS AT THE MELBOURNE EXHIBITION:

Being Extracts from the Letters of the Ceylon Commissioner with Remarks thereon.

4th November 1880.

I send you a catalogue of yesterday's tea sale with the prices, per lb., filled in at which the various lots sold. I said to Mr. Sibthorp and Messrs. Henty & Co., that all the adjectives of the English language having been exhausted in describing the Indian tea, nothing remained but to resort to the highest Latin terms where Ceylon came to be sold, and to call it "Gloriosa superba." There was a large attendance of actual dealers as well as wholesale buyers, and you will observe that the lots were judiciously made large and small to suit both classes, an example which one of the principal dealers advised should be followed in consignments of Ceylon tea. 50 lb. per chest was recommended as a good average quantity, and the hope was expressed that the packages would be better and more secure than those from India. Champagne and speeches being over, the auction commenced: the competition was keen, and a large quantity of property changed hands in an incredibly short time. Those who grew the tea would not agree in the opinion of my Mentor that the prices paid were 2d. too dear,—"for this market," he added. But if, as described, they were all 'Pekoe," it does not seem to me that even 2s. 7½d. per lb., the top price of the sale, is very good except in comparison with the wretched prices recently obtained in England. You will see that the highest price was paid for Darjeeling Pekoe. This seems to promise well for our high-grown Ceylon teas. But, it was impressed on me at the sale, that we *must* pass our big leaves through "tea cutters"* to reduce them to the size the trade and the consumers desiderate. I was assured that this process would not endanger the teas being classed as broken. I fancy there will soon be another sale of Ceylon tea, and I trust the prices obtained may compare well with those realized yesterday. I may, perhaps, obtain and send to Ceylon specimens of the tea which fetched the highest prices.

19th November 1880.

The Indian teas are evidently making way in this market, and I hope that our Ceylon product will rank even better than a good second. Many persons have said that they enjoyed the Ceylon tea at once, while some of the Indian seemed harsh. The Australian tea drinkers, however, are prejudiced against big leaves and big prices. Mr. Moody of J. Henty & Co. told me that his firm realized a large profit on some large-leaved tea which they secured at a low price and passed through a tea-cutter. Mr. Moody says that the cutting of the tea has no effect in classing it as broken.

(From the *Ceylon Observer*, 1st December 1880.)

At length the Australian press have found the opportunity of noticing the Ceylon Court and Exhibits, and from the reports we append it will be seen that a fair amount of justice is done to the enterprise of this Colony. There are many other ways, however, besides notices in the press of subserving the interests of our planters and exporters in a large commercial city like Melbourne, and the Commissioner's official report when it appears will shew that he has not been idle. His special telegram giving the result of further sales of Ceylon tea affords increased encouragement to the cultivators of this important new product. The statement, that if the Rookwood produce had been put up in chests of half the size, twopence per pound more would have been realized, is borne out by the fact that the shipments of Galbodde and Kandaloya tea made by Messrs. Mackwood & Co. in 40 lb. chests fetched 2s 0¾d to 2s 0¾d per pound. Through the courtesy of Mr. Bruce we have received a copy of the catalogue with the prices realized for Indian tea, season 1880-81, sold on 1st November, and we notice that the highest price obtained was 2s 5d per lb. for four half chests Assam Pekoe, but this fancy price we cannot help thinking must have been due more to the smallness of the lot, and to it being sold near the end of the sale, than to the quality. At any rate lots No. 6 and 7 described as follows:—

15 half-chests Assam Pekoe very handsome wiry greyish leaf, full Flowery Pekoe leaf, splendid liquor thick heavy malty flavor with immense strength

7 half-chests Assam broken Pekoe, small very even handsome Golden Pekoe leaf, pungent rasping and strong fine rich flavor

realized only 2s 1¾d and 2s 0d respectively. Of other Pekoes we have:—

4 half-chests Dooars broken Pekoe handsome small very even black leaf full Golden tips, strong thick heavy richly fired malty flavor.

51 half-chests Cachar Pekoe, very handsome wiry blackish leaf full Flowery Pekoe tips, immense strength and briskness with rich fine malty Pekoe flavor

both of which were bought for 2s per lb. The Souchong and Pekoe-souchong qualities realized from 1s 1¾d to 1s 9¾d. We shall give the full sales-list for this consignment of Indian tea in our next issue. Since writing this, we have been favoured by Messrs. Leechman & Co. with the following memorandum, shewing that Agrawatte tea has topped the market so far as Ceylon produce is concerned. This sale took place before the present mail left:—

Memo of sale of Agrawatte Estate Ceylon tea in Melbourne.

Pekoe	2s 2¼d	per lb in bond
Pekoe Souchong	1s 9¾d	,, ,,
	2s 2¼d	
Souchong	1s 1¾d	,, ,,
	1s 4½d	
Congou	1s 1¾d	,, ,,

Sold at public sale.

(From the *Ceylon Observer*, 21st December 1880.)

The following communication from the Ceylon Commissioner to the Melbourne Exhibition, kindly placed at our service, with the accompanying reports, will be read with much interest by all in the island interested in "tea." Every effort should now be made to meet the requirements of Australian merchants and consumers, so as to maintain the high reputation they already concede to Ceylon teas. Australia can take all the tea this Colony is likely to produce for a good many years to come, and our merchants ought in return to develop an import duty of considerable importance. Meantime, for the promotion of tea interests in Ceylon, capital, such as apparently only a Limited Company can readily command, is required. Suitable buildings and machinery cost money which ordinary planters in these times of depression, can ill secure. It has been demonstrated satisfactorily that we can produce tea more cheaply than our neighbours in Northern and Southern India, and yet capital still continues to flow into new "tea concerns" in the Assam and Nilgiri districts. May we not hope that, with two Indian Banks represented in Colombo, attention will be drawn to the advantages Ceylon presents for the application of capital to the cultivation and preparation of tea. A Company to start central factories and buy the leaf would do good, but there is plenty of room for the purchase of cultivated land, or forest

* Machines made for the purpose.

reserve.—Meantime, we append the Reports handed to us by Mr. Bruce:—

MELBOURNE, 25th Nov. 1880.

DEAR MR. BRUCE,—I have now the satisfaction of sending you elaborate reports on the Ceylon Tea Exhibits, the importance of which to the interests of the colony, I think it will be admitted, cannot be exaggerated; and I trust information such as I am obtaining with reference to this new industry will justify a larger expenditure on the Ceylon Commission than was anticipated. The Australians are, even more than the English, a tea-drinking people, and with the advance of population and wealth there will be an increased demand for tea, and for really good tea such as it is now certain Ceylon can supply. You will see that Messrs. Henty & Co. report that some of the samples examined by Messrs. Moody and Sibthorp "cannot be surpassed," while others are reported to be "worth any money." It may be true that some of the samples are fancy teas, but it will be observed that ordinary teas which have preserved their condition are pronounced very good and, when properly prepared, well fitted for this market Already the Australian Colonies consume a quantity of tea fast advancing from 15 millions to 20 millions of pounds, and it seems clear from the information I have sent and am now sending that, if the planters and merchants of Ceylon do themselves and the article justice, our tea should enter largely into the Australian market. Not only will this be a gain in itself, but I would repeat the remark that a demand here will be sure to react favourably on the London market. But the tea must be prepared and packed to suit this market. It is no use saying, as I have told people here, that largeness of leaf is a sign of superiority of the hybrid Assam tea over China. The large-leaved tea must be cut, and this can easily be done with Savage's machines, costing quite moderate prices (under £7 for a 2-roller machine), in Eastcheap, London. A few days ago I made one of a party to visit the extensive and very interesting works of the Oriental Tea Company here, in order to see all the processes of cutting and mixing. Much large-leaved Indian tea is cut, in order to be mixed with small-leaved China. I feared that our teas, if cut before being packed, might be classed as broken, but Mr. Moody assured me that of this there is no fear. The large leaves are usually cured straight; it is only when they are curled that there is danger of their being crushed. Mr. Sibthorp said, however, that much might be done in the direction of gathering quite young "flushes." In India, he told me, it is quite common at certain periods of the year to go over the bushes every eight days. You will see the importance which attaches to opinions offered by Mr. Sibthorp from the fact that he is the chosen Agent of the Government of India and the Tea Syndicate. He was originally a tea-taster in London and then in Calcutta. From the latter place he was sent to Assam to teach the planters how to make tea such as would command the London market. Mr. Moody has had long experience, in connection with Messrs James Henty & Co.'s firm, of the Melbourne tea market. You will observe that while Mr. Moody, with his knowledge of the local market, attaches considerable importance to appearance of leaf, Mr. Sibthorp dwells specially on "liquor" as the test for the London market. But there seems no reason why the two qualities of good-looking leaf and strong fine liquor should not be combined. To help to the attainment of this end, I hope you will move the Chamber of Commerce and the Planters' Association to take the best possible measures to enable all interested in the young but rapidly advancing tea industry of Ceylon to see the typical packets made up by Messrs. James Henty & Co. and which I have addressed to you, to go by to-morrow's mail. I much regret that a few samples of the tea sent from Ceylon to the Exhibition should be found out of condition, but I am sure that Messrs. Lee, Hedges & Co., Mr. C. Shand, and also Mr. Nelson of the Botanical Gardens, will approve of the discretion I exercise in withdrawing from the Court, before the visit of the jurors, the teas which, good enough, no doubt, originally, have got spoiled, probably from damp. No good would accrue to the exhibitors from submitting the spoiled teas to examination, while the very high character of the Ceylon teas generally would be, without good reason, lowered. "Better luck next time," for I can but repeat that it is now certain Ceylon can produce teas unsurpassed in quality, *provided they are properly prepared and packed for export.* In this connection it is curious that the sample of under-fermented tea prepared as an experiment by Mr. James Taylor, and regarding which he wrote a letter expressing the fear that the experiment would result in failure, is pronounced by Messrs. Moody and Sibthorp to be as near perfection as is possible. Such a judgment and indeed the rank generally assigned to the teas prepared by Mr. Taylor are very creditable to him, considering that, with the exception of a visit to Darjeeling, his experience has been all gained in Ceylon. The importance of training in Assam is shewn by the character of the teas prepared by Mr. Hay, either on the properties on which he is regularly employed or on those which have received the benefit of occasional visits from him. Men like Mr. Hay are the best judges, but certainly this experiment of Mr. Taylor's and the result seem to justify an opinion which has been forcing itself on me from what I have seen and read,—that our Ceylon teas are often weakened by over-fermentation and burnt by over-roasting. That the tea should be thoroughly dried over charcoal fires is, of course, essential; but it seems to me that, too often, the coolies are allowed to follow their natural desire to hurry the work, by means of fierce fires with the roasting sieves too close to the coals. I commend this matter to the most serious attention of *all* engaged in tea making. It is clear that on the quality of the teas we send to the Australian market within the next couple of years will depend the retention or otherwise of the high character our teas have already acquired. We must also try and redeem the character of our teas in the London market, to which, I fear we have been sending an article as much over-roasted as it is over-fermented. The information I now send, I am sanguine enough to believe, will largely aid in bringing about the desired results. As regards packing, I suppose it holds good that for the London market large packages as well as large breaks are desirable; but tea planters of Ceylon who send their produce to the Australian market will do well carefully to note what Messrs. Henty & Co. say about packages not larger than 38 lb. or 40. lb. net, with a fair proportion of packages half and quarter this size. I naturally asked what the local reasons were for packages not much exceeding 40 lb. in weight, and Mr. Moody told me that in the early days of the colony, before railways existed, and even now in so much of the country remote from railways or good roads, packages were and are desiderated which could be slung on packhorses, "tavalam" fashion. And not only so, but country purchasers do not understand and are not ready to give the higher sums charged for packages double the weight of their normal one. Even to prejudices at which we may feel inclined to smile, trade must adjust itself. I need scarcely add that we in Ceylon must do our best not only to produce good teas but to produce them economically. The vast majority of Australian tea drinkers have been accustomed to cheap Foochowfoo teas, and the strong high-priced Indian and Ceylon teas will, for a long time, be mainly used for mixing, and their consumption will be restricted in proportion, unless we can afford to

sell at prices within the reach of the masses. I met Mr. Goldstone of the Oriental Tea Company this morning, and I jocularly remarked: "To keep up the quality of your teas you must go on adding a larger and larger proportion of Ceylon tea." He replied that nothing but mere samples were yet available. I ventured to assure him, as I have done all others, that in a very short period Ceylon tea in ample quantity as well as of good quality will be available. While I attach the utmost importance to the reports of Messrs. Moody and Sibthorp, followed up as these will be by regular scientific analyses of samples (average) of the different classes of tea made, it will, of course, be remembered, that it by no means follows that the awards of the jurors may be in accordance with those reports. It will be seen that Messrs. Moody and Sibthorp diverge on the test of leaf and liquor, and amongst the jurors similar divergence may obtain. I know that one of those who will deliver judgment on tea objected to a gentleman nominated as juror, that at Sydney he had shewn undue preference to Indian tea. It seemed to me clear that my interlocutor was equally prejudiced in favour of the China leaf.

(*Reports referred to.*)

Melbourne, 24th November 1880.

Dear Sir,—Herewith we hand you two tins containing following samples of tea, say:—

No. 87. Pekoe value to-day 2s per lb. in bond.

No. 88. Pekoe souchong value to-day 1s 6d to 1s 9d. Both are mixed teas but fairly represent standards of a large proportion of the consumption of tea in Australasia, and we regard them as safe teas to send to the Colonies, for they will always be saleable at a price. No. 88 would command to-day 1s 9d, but think 1s 6d a safer standard value. They should be packed in 38 lb. nett weight half chests, a few at 20 lb. quarter chests and 11 lb. boxes are very saleable at about 2d per lb. over same tea in half chests, but only No. 88 should be so put up. Original packages even if weighing up to 60 lb. will meet with ready sale in a bare market, but nearly the whole of the trade is done in packages of 38 lb. nett (or not over 40 lb.) and we therefore consider it safest to work on this weight which all the Colonies are used to.

The packages can be the usual lead lined wooden ones shipped to this. Tea should be bulked so as to insure uniformity of sample throughout the break. Brand is of some importance, this would be a good specimen:—

Sinhalese pure Ceylon tea [Kandy];
Break 1
Nett weight ... 38 lb.

'New season's' to be printed or stencilled on end of package. If over 30 halfchests of one kind of tea, then divide the line say if 120 halfchests 38 lb. each, into say Break 1 30 hfchts.
,, 2 30 ,,
,, 3 30 ,,
,, 4 30 ,,
and so on. This is is to facilitate sale: our buyers are always anxious to have the whole of a line or number and yet object to too many.

Mr. D. A. Sibthorp, the representative of the Calcutta Tea Syndicate, at present in Melbourne, has in conjunction with ourselves carefully examined and liquored all the teas exhibited in the Ceylon Court, and values affixed in the accompanying Report are based on the result of some 3,000 hfchts. of Indian teas sold on the Melbourne market within the last two months. Mr. Sibthorp, who has large British and Calcutta experience, taking our standpoint, in concurring with the values affixed.

We regret that the souchong and unassorted teas of Messrs. Lee, Hedges & Co., the tea from Mr. James Nelson, and the three samples from Mr. C. Shand, are all out of condition, having probably gone wrong on the voyage through being damp. With these few exceptions the rest of the teas turn out very well packed and many samples must be unsurpassed by any thing produced in any other part of the world.

In accordance with your instructions we have made average samples of the exhibits of tea and forwarded same to Mr. J. Cosmo Newbery (the Government analyst) for analysis, say—
Orange pekoe
Pekoe
Pekoe souchong
Souchong
Congou
Green tea.

Six samples, and when we receive report will forward it to you, but as we have asked Mr. Newbery to include the Theine extract it will take some time to do.

The sample of Ceylon tea not exhibited in the Court, but handed to us a few days back, is far too large in the leaf: and liquors with thin burnt flavor, it would not be saleable in Melbourne in its present state. —We remain, your obedient servants

Jas. Henty & Co.
Pr. J. O. Moody.

P. S.—The prices realised at Greig & Murray's auction-sale early in the month for Rookwood teas were low, owing to the heavy weights of the packages, say 80 to 90 lb. The 10 cases pekoe sold at 1s 10d worth 2s in lighter weight; 16 chests pekoe souchong 1s 4½d worth 1s 6d to 1s 7d; 42 chests souchong 1s 1d to 1s 1½d, its value was too large in the leaf.

J. H. per J. O. M.

Reports by Messrs. Moody and Sibthorp, alluded to in letter from Messrs. James Henty & Co. to the Ceylon Commissioner.

No on catalogue 726—Exhibitor: Messrs. Lee, Hedges & Co., Estate Kandaloya, District Yakdessa.

1. Broken pekoe, small broken rather even blackish leaf few, tips, fair strong burnt, value per lb. in bond 1s 9d.

2. Flowery pekoe, small even wiry yellowish blackish leaf, little mixed, full of tips, thin little pungent, 2s 3d.

3. Pekoe, small rather wiry blackish leaf, little broken tips, full pekoe flavour 2s.

4. Pekoe souchong, rather large, little broken blackish leaf souchong, fruity, little peculiar, useful mixer, 1s 6d.

5. Souchong, large greyish blacish leaf } Out of
6. Unassorted, large rather blackish leaf } condi-
souchong } tion.

For the Australian trade Nos. 1 and 2 should be kept together and packed in 40 lb. and 20 lb. packages: Nos. 3 and 4 also together and packed in 38 lb. packages. The leaf of Nos. 5 and 6 unsaleable in any quantity.

Jas Henty & Co., pr. J. O. Moody,
Melbourne, 20th Nov. 1880.

The above valuations are considerably higher than the teas would be likely to obtain in London, where *liquor* is looked for more than *leaf*.

D. A. Sibthorp.

No. on catalogue 727—Exhibitor: T. C. Owen, Esq., Estate Oonoonagalla, District Kelebokka.

1. Mixed tea, rather large mixed irregular leafy tea, greenish flavour, value per lb. in bond 1s 4.

Leaf rather large for Australian trade, should be smaller packed in 38 lb. packages and a better liquor.

Jas. Henty & Co., Pr. J. O. Moody.

Melbourne, 20th Nov. 1880,

The above valuation is considerably higher than the tea would be likely to obtain on the London market, where *liquor* is more looked for than *leaf*.

D. A. Sibthorp.

No. on catalogue 728—Exhibitor: C. A. Hay, Esq., on behalf of G. H. D. Elphinstone, Esq., Estate Windsor Forest, District Dolosbage,

1 Pekoe dust, very small broken pekoe with tips. strong dull flavor, value per lb. in bond 1s 10d to 2s.

2. Broken pekoe, small rather even rather blackish leaf tips, strong brisk 2s.

3. Orange pekoe, handsome fine small even gold tipped ordinary pekoe, fine full rich liquid, extra superior, fancy price.

4. Pekoe, handsome even wiry rather blackish leaf tips, rather soft pekoe flavor 2s to 2s 3d.

5. Pekoe souchong, well-made rather bold even, rather blackish leaf tips' full thick pekoe souchoug liquid 1s 10d to 2s.

6. Souchong, rather even broken greyish blackish leaf, strong dull flavour, 1s 6d to 1s 7d.

For the Australian trade Nos. 1, 2, and 3, should be kept together; the rest of the teas are saleable. The whole should be packed in half-chests 38 lb. nett, a few boxes of 11 lb. and some of the pekoe in quarter-chests of 20 lb. nett.

Teas of above character would soon take well in the colonies.

JAS. HENTY & Co., pr. J. O. MOODY.

Melbourne, 20th Nov. 1880.

I concur—D. A. SIBTHORP.

No. on Catalogue 729—Exhibitor: C. S. Armstrong, Esq., Estate Rookwood, District Deltota.

1. Broken Tea handsome small blackish leaf with tips strong brisk flavour, value per lb. in bond 2s 1d.

2. Broken Pekoe good blackish broken Pekoe souchong with tips, strong fine pungent, 1s 9d at 2s.

3. Pekoe, handsome, fairly even blackish leaf, fine Pekoe flavor 2s 6d.

4, Pekoe Souchong large even wiry blackish leaf fine pungent flavoury liq. 1s 5d leaf 2s 6d liquor.

5. Souchong very large rather blackish leaf thin, 1/2.

6. Congou large clean greyish blackish leaf little brisk, 1s.

For the Australian trade Nos. 4, 5. aud 6 are altogether too large in the leaf, but if these teas were passed through a cutting machine aud mixed with some of Nos. 1 and 3 we think it would make a suitable tea for the Colonies packed in 38 lb. nett half-chests.

JAMES HENTY & Co., pr. J. O. MOODY.

I concur—D. A. SIBTHORP.

No. on catalogue 730—Exhibitors: Messrs. Keir, Dundas & Co. Estate Loolecondera, Upper Hewahette.

A. Flowery Pekoe } handsome flowery Pekoe
B. Flowery Pekoe tips } namuanna, value per lb. in bond fancy price.
C. Orange Pekoe } handsome gold leaf O. P. very fine liq. } worthauy price.
D. Orange Pekoe tips } very fine full liq.
E. Orange Pekoe } very fine liq.

F. Pekoe with orange tips handsome fine small even gold tip O. P. fine liq. fancy.

G. Broken Pekoe with tips small even showy golden blackish leaf tips strong fine liq. fancy.

H. Ordinary Pekoe small even blackish leaf little broken with tips, fine Pekoe flavour Darjeeling flavour 2s 6d.

I. Souchoug rather even rich blackish choppy souchong strong full pungent 2s.

K. Pekoe Souchong rather even blackish leaf Pekoe kind with tips strong rich pungent flavour, 2s 3d to 2s 6d.

L. Congou large even blackish leaf strong brisk full 1s 9d.

M. Underfermented tea, pretty small even blackish leaf, rather broken pekoe, strong, rich, very pungent flavour, fermentation correct, value per lb. in bond 2s 6d.

The teas are too good for Australian trade, the quality of the whole of them being very superior. L Congou is rather too large in the leaf to sell with us, but H I K and M would take well if packed in 38 lb. nett packages, perhaps a few quarter 20 lb and boxes 10 lb.

JAS. HENTY & Co., pr. J. O. MOODY.

Melbourne, 20th Nov. 1880.

The above teas would fetch very high prices on the London market, the quality all round being unusually good, leaf and liquor leave really nothing to be desired. The rates obtainable here at present would be unremunerative, I fear. Sample marked M underfermented is exceptionally good, the liquor and colour of outturn are as near perfection as possible.

D. A. SIBTHORP.

No. on catalogue 731—Exhibitors: Messrs. Haldane and Anton. Estate Calsay, District Dimbula.

1. Pekoe handsome even wiry gold tipped orange pekoe, and rich flavoury, value per lb in bond, fancy.

2. Pekoe souchong, rather even rather blackish leaf, high burnt 1s 6d liq. 1s 9d leaf.

3. Souchong, rather large blackish leaf their flavours 1s 4d.

4. Unassorted, large rather leafy blackish coarse burnt 1s 2d.

For the Australian trade we require a tea like No. 2, with a better liquor, packed in 38 lb. nett half chests, leaf rather too large of No. 3, and altogether so in No. 4, moderate quantities of No. 1 would sell if quality brought dowu a little to sell it at 2s to 2s 3d.

JAS. HENTY & Co., pr. J. O. MOODY.

I concur—D. A. SIBTHORP.

Melbourne, 20th Nov. 1880.

(From the *Ceylon Observer*, 5th January 1881.)

Analysis of Average Samples of Ceylon Teas Shews Their Superiority to Indian, as well as to China, Teas.

We feel sure that the following Report and Analyses, placed at our disposal by the local Secretary to the Exhibition Commission, will be read with much satisfaction not only by our tea planters but by all interested in the prosperity of the Colony. In the midst of short crops and miserably low quotations for our staple, it is some relief to learn on unquestionable authority of the good prospects before another great branch of our planting industry, and we have no doubt the result will be to give a special impulse to the extension of tea cultivation in the island. We append the Report of the Ceylon Commissioner:—

Melbourne, Dec. 9th, 1880.

Dear Mr. Bruce,—The juries are in full work now, and I suppose that before the month and year expire the awards will be proclaimed. Meantime I have received the analyses of Ceylon teas exhibited, made by Mr. Dunn of the Technological Department, under the supervision of Mr. Cosmo Newbery. As I wrote before, the analyses represent averages, pekoes, souchongs and so forth, the exceptions being those in which only one specimen was shewn. I got a copy of Mr. Dunn's report at Messrs. Jas. Henty & Co.'s office last evening, with a promise from Mr. Moody that his remarks would reach me early this morning. The paper is not yet to hand, but I know what its general purport will be, in consequence of a long conversation I had with Mr. Dunn and Mr. Moody respecting the results obtained, some of which are extraordinary, and in the case of the proportion of mineral ash anomalous. As noticed previously, the British analysts' standard for mineral ash in tea ranges from 5 to 8 per cent. So it is recorded in Mr. Newbery's office; but, as I told you previously, the result of my own rather extensive reading on the subject led me to believe that the standard for genuine tea was 5 to 6 per cent, and that any excess over 6 per cent must be due to the mixture of foreign substances, from careless preparation and packing, or from designed adulteration. On the other hand, a percentage of ash much lower than 5 per cent would at once raise the suspicion in an analyst's mind that he was dealing with washed-out leaves. Mr. Dunn's analyses of our Ceylon teas present the contrasts of the lowest proportions of mineral ash and the largest of that extract for which tea leaves are valued, ever obtained. Mr Dunn, as a chemist, felt bound to offer such explanation of the anomaly as seemed to his mind most satisfactory, and you will observe that he adduces as a probable cause the rapid growth of the tea plant in Ceylon. That he correctly judged (apart from clean and careful preparation) I have strong proof in the independent judgment of my esteemed friend Mr. Josiah Mitchell, one of the best authorities on the science of agriculture in Australia. He came here (to his brother's house, where I now reside) last evening, and I stated to him the curious results obtained by Mr. Dunn, without mentioning that gentleman's solution of the apparent anomaly of minimum mineral ash and maximum extract. Mr. Mitchell at once said:—"I congratulate you on results which ought to be deemed satisfactory to all interested in tea planting in Ceylon. The proportions of extract, soluble salts and theine to mineral ash prove that the influence of your climate is such that of the mineral matter taken by the plant from the soil all but a very small quantity is elaborated into the properties which make tea leaves valuable for consumption and commerce. The result of the analyses proves that in Ceylon the best quality of tea can be produced with the minimum exhaustion of the fertilizing matters in the soil." If, as I believe, this is the true solution of the results of Mr. Dunn's analyses, I think that you and the Committee, the Government, the planters and the merchants of Ceylon, will feel that here alone is compensation for the expense involved in being specially represented at this important Exhibition. Both Messrs. Dunn and Mitchell (especially the former) were deeply interested in information I gave them of the different conditions under which tea was grown in Ceylon and in most of the tea districts of India and China. In Ceylon, I pointed out, tea is grown within 7° of the equator, while the vast majority of the gardens of India are situated 20° farther north. In the case of Darjeeling, leaving the Terai and Dooars out of view, the factor of altitude has to be added to latitude. Some tea is grown on the Nilgiris and in a few other districts in Southern India, and about 11° north, but the vast bulk of the teas which India (and I may add China) sends into the markets of the world are grown between 20° or 30°, some even as far as 34° north latitude. The result is that the plant gets a "winter ing"—there is a stoppage of growth from November (in which month, in India, pruning, generally severe, is performed) to March. At the commencement of the tea-planting enterprise in Ceylon, Indian tea planters predicted failure from the absence of winter in our island—from the constantly forcing nature of the climate. As to quantity per acre, a comparison with Assam cannot yet be instituted on a large scale, but I submit that these Melbourne analyses, added to the tests as tea-tasters applied by Messrs. Moody and Sibthorp, and the judgments delivered by them, conclusively prove that, in the hot, moist climate of Ceylon, tea can be produced which, if carefully prepared, will rank with or even above the finest quality sent into the markets of the world. We may take it for granted that the Indian teas submitted by Mr. Sibthorp, the Agent of the Government and Tea Syndicate, to Mr. Newbery for analysis were the very best which India can produce. Well, the very highest percentage of extract obtained was in the case of Cachar pekoe, 43·85. Our Ceylon orange pekoe gave very nearly 1 per cent more, viz. 44·80. The soluble salts in the case of the Ceylon tea, it is true, shewed only 3·06 against 3·22 in that from Cachar; but then, against only 1·58 of theine in the Cachar leaf, the Ceylon tea gave 2·15. There can be little doubt, therefore, as to the first position which the Ceylon orange pekoe holds. I fancy that, though the term is not used, there was what is called orange pekoe amongst the Indian teas analysed, but let us compare our simple "pekoe" with the best from Darjeeling:—

	Extract.	Soluble Salts.	Theine.
Darjeeling pekoe	38·97	3·16	1·96
Ceylon ,,	43·80	3·32	1·82

In total extract the Ceylon leaf is superior by very nearly 4 per cent; it is also superior by ·16 per cent in soluble salts, while only in theine (the constituent in which the Ceylon *orange* pekoe specially excelled) is our pekoe ·14 per cent below the Darjeeling tea. In the case of pekoe souchong, which will be the description of the great bulk of the teas which Ceylon

will send into the markets of Australia and other parts of the world, a comparison can be instituted with similar teas from the hot Dooars, from lofty Darjeeling, from the fat alluvials of Assam, and from Cachar, foremost of Indian districts for high quality tea—(if the claims of the high-grown leaf from Darjeeling, Kumaon, the Kangra valley and the Nilgiris are reserved). Here are the figures:—

	Extract.	Soluble Salts.	Theine.
Dooars pekoe souchong	40·97	3·08	2·86
Darjeeling ,,	41·80	3·20	1·96
Assam ,,	40·12	3·04	1·66
Cachar ,,	40·66	3·24	1 44
Ceylon ,,	42·80	3·12	1 86

In this case, as in both the others, Ceylon takes the lead in the important item of total extract; shews fair figures for soluble salts, and but for the extraordinary figures for theine in the case of the Dooars tea would compare well in respect to the property which, specially present in tea, is also a principle in coffee. There is little doubt in my mind, that of all the properties of the tea leaf, theine is the most variable in proportion to care or the reverse in preparation. Let us now compare the Indian and Ceylon souchongs:—

	Extract.	Soluble Salt.	Theine.
Darjeeling souchong	36·99	3 02	1·66
Assam ,,	39 27	3·00	1·46
Cachar ,,	40·29	3·12	1·76
Ceylon ,,	40·40	3·20	1·84

In the case of this, the lowest class of tea which Ceylon is likely to make and send in quantity into the markets of the world, our produce ranks highest, not only in total extracts but in soluble salts and theine: *in all which makes tea valuable in fact.*

Had no other descriptions of teas been sent for exhibition from Ceylon, its teas would rank as without exception of "first class quality." The high average would be somewhat lowered, if the congou and green teas were to be taken into account. But I fancy Ceylon planters will, like their Indian brethern, leave to the Chinese the monopoly of manufacturing "congous," while for green tea there is at present no demand out of Central Asia. The more's the pity, for *pure* green tea (which is really of a coppery colour) is easily made and has merits of its own. But the vile "facings" and adulterations of the "Celestials" extinguished the trade in green. It is no more in demand and is less likely to succeed in this market than in that of London. The specimen analysed, it will be observed, gave a very good result in total extract, higher even than the highest yielded by Cachar pekoe, in the case of Indian teas, but 2·66 for soluble salts and 0·94 for theine were in the first case ·22 per cent lower than Foo-chow congou gave and ·90 per cent in the theine. If there were only a demand for green tea there can be little doubt it could be so prepared in Ceylon, so that soluble salt and theine would be present in better comparison to the large amount of total extract. Mr. Dunn was anxious to explain that he did not mean to condemn this and the Ceylon congou as positively bad—but only *comparatively* inferior. For mixing purposes it cannot be doubted that a tea yielding 44 per cent or extract would be most valuable. But until the taste for "green" tea revives, our wisdom will be to make black. Our quality of this description (congou) compares unfavorably with the others in extract and is somewhat below the mark in soluble salts. In theine, however, it ranks with Ceylon pekoe, and if we compare our Ceylon congou with the average results obtained by Mr. Nowbory from 15 samples of Foo-chow congous, the Ceylon tea is largely superior except in the one item of theine. The figures are:—

	Extract.	Soluble Salts.	Theine.
China congou	29·26	2·88	1·84
Ceylon ,,	37·40	2·96	1·82

Except, therefore, in a very trifling deficiency of theine, the Ceylon congou is immensely superior to the China tea which is chiefly used in Australia, the congou of Foo-chow. But, useless circumstances exist with which I am unacquainted, the Ceylon tea planters need not descend, any more than their neighbours in India do, to a competition with China in the production of *congou*. Compared with China congou, no doubt the Ceylon article is superior, but if Ceylon congou is compared with Ceylon souchong, it will be seen that the latter is better by 5 per cent of extract; by ·24 of soluble salts; and by ·2 of theine. Our aim, it appears to me, should be to send into this and other markets, teas, which on analysis, would give not less than 40 per cent of extract; 3·15 per cent of soluble salts; and 2, or, at least, 1·80, per cent of theine. The British analysts' standard for *lowest* class tea is stated by Mr. Newbery to be 30 per cent for extract and 3 per cent for soluble salts. The first test is very largely exceeded by all our Ceylon teas, while the second is also considerably exceeded in the case of all save the congou and the green tea. As they stand, the results obtained by Mr. Dunn seem most satisfactory. The average of mineral ash in our teas is only 4·82 per cent as against 5·34 in the case of Indian teas, but, as explained, this deficiency of ash is entirely in our favour as proving that so much less of the constituents taken from the soil by the plant remain inert. In total extract, which I take to be the real test of tea, the Indian average is 39·42, which is more than 10 per cent above the China congous, Our Ceylon average, even when lowered by including the congou, is 42·20, or nearly 3 per cent higher than the Indian and 13 per cent over the China. But as no congou was included in the Indian teas, the fair course is to exclude it and also the green and to take the average of the teas common to both lists. We then get for Ceylon teas 42·95 or 3·53 higher than the Indian average (39·42), and 13·69 per cent above the China congou. These are the great points in Mr. Dunn's analyses of Ceylon teas, resulting in an average of extract of nearly 4 per cent, a result never exceeded, so far as my knowledge extends. Excluding again the two exceptional teas, our average for soluble salts is a little over 3·12 per cent, against 3·16 in the case of Indian teas. The slight excess in favour of India here is as nothing when compared with our superiority in extract. We may say the same in regard to an excess of ·02 per cent in favour of India in theine, the figures being for India 1·94 against Ceylon 1·92 per cent. The superiority of India in theine is mainly due to the enormous figures, 2·86 and 2·42, against the two specimens of tea from the Dooars included in the list. But for those two exceptional teas Ceylon would shew higher than India in theine. In soluble salts the difference in favour of India is scarcely appreciable, while the superiority of our teas in total extract is real and large. And be it noted that, while the best Indian teas were chosen for analysis to the number of 15, our Ceylon teas of each description were mixed, so as to give an average. If Mr. Moody had only picked out the very best tea of each class the result of Mr. Dunn's analyses might have been still more favourable to Ceylon; but the object of this experiment was to bring out the general character of Ceylon teas, and not that of shewing individual superiority. For the latter purpose I could not use the public money, although I was very glad to send the opinions of Messrs. Moody and Sibthorp. Those opinions, so far as they relate to the superiority of Ceylon tea, have been fully confirmed by Mr. Brown, a London tea taster. He wishes his brother, who was formerly in Ceylon, to return thither to take part in the tea enterprise. As regards Java tea Mr. Brown told me that as an imitation of the best, smallest, and most curly China leaf, it could not be excelled. But the

tea is sadly wanting in lipuor. For that reason I believe it has gone out of favour in the Australian market. For the opposite reasou Ceylon tea ought, if justice is done to it in making, to come iuto high favour and extensive usc. Mr. Brown quite coincides with the recommendation to cut onr big-leaved teas. Indeed I have heard of such teas bought here for about 10d per lb. and selling for 2s. when cut. Mr. Brown even advises making a good deal of broken tea.

Of course I must repeat the remark that all the satisfactory information embodied in my letters to you may not secure favourable verdicts for Ceylon tea from the Exhibition jurors, a good many of whom are interested in the China tea trade. But no jury verdict can alter the facts brought out by the extra scientific analyses of Messrs. Moody and Sibthorp, and the strictly scientific analyses of Mr. Dnun. In answer to my questions the latter assured me, that there was no disturbing element in the Ceylon tea analyses to account for results differing from those obtained in the case of Indian teas. The large proportion of extract and the small proportion of ash in our teas are equally facts: and important facts.

Up to 2 p.m. Mr. Moody's report has not come to hand, and I fear it will not reach me to-day. I shall, however, take my letter at an early hour to-morrow morning to the office of Messrs. Henty so as to be able to include the report. Meantime I enclose a letter which has reached me from New Zealand. The writer, formerly a planter in Ceylon, thus notices the market for Ceylon tea in "the Britain of the South":—

"Moray Place, Dunedin, New Zealand,
"18th November 1880.

"I am doing a small business here as an Indian Produce and Commission Agent. I have already done a little in Ceylon tea, coffee, spices and cigars. Only a very limited market for our Ceylon tea here as yet: prices I have got for them in Dunedin are

Pekoe 2s to 2s 4d	... ...	in bond
Pekoe souchong 1s 5d to 1s 8d		,,
Souchong no offers over 3d per lb		,,
Dust and fannings	,,	,,

The markets are very quiet here at present, almost nothing doing. Our Ceylon teas are only used to work up a cheap China at present: they don't care for it alone, but rather like it in a mixture. They want as fine a looking leaf as possible on this market, and I have great bother to make them take a sample and liquor anythiug that looks coarse. They think our pekoe souchong rather coarse looking, and souchong and dust; they don't believe in at any price. I got 2s 4d per lb. in bond for a small parcel of Ceylon pekoe last week. I shall not recommend placing much of our tea on the New Zealand markets at present. Trade in everything is very quiet. Dealers are only buying from hand to mouth; money is scarce and very hard to get in. I hold a stock of over 100 half chests (40 to 47 lb. each) 'Ceylon Pekoe Souchong' just now, and I am only able to place 2 to 3 half-chests at a time these days, that is if I want to keep up prices. I notice Ceylon people always quote the duty on tea at 6d per lb. here: they are wrong in this, as the duty on tea in New Zealand is only 4d per lb. I have sent samples to Ceylon of New Zealand tweeds, flaunel, biscuits, flour, &c. The tweeds and flannels are first class: they are of the best wool; it would not pay them to mix, and are beautifully soft. I have arranged with the manufacturers to accept payment in produce, so this should be an inducement for some, as it saves exchange."

Messrs. Jas. Henty & Co. of Melbourne will no doubt be ready to do for Ceylon teas what they are doing for India: not only push them in this market, but, through their agencies, in all the Australian colonies. You will see that the prejudice against large-leaved teas is universal. The feeling against dust is even less reasonable. But we cannot at once remove traditionary prejudices. We of Ceylon must see to it that not only in quality but in appearance our teas are attractive. With such results as Mr. Dunn has obtained there is reason to suspect the genuineness of the complaint of weakness so often received from London regarding Ceylon teas.

Having received Messrs. Jas Henry & Co.'s letter, I now enclose it. You will see that no fewer than 78 samples of tea went to make up the averages which gave such satisfactory results, and that my argument is repeated, that, if averages came out so well, the best samples if picked out might have done much better. You will note what is said of the goodness of the congou, and of the deficiency of theine where it ought to abound in the green tea. I hope all in the colony will feel that Messrs. James Henty & Co. were justified in congratulating Ceylon, through its Commissioner at the Melbourne Exhibition, on the character of its teas established by repeated and careful tests. There can be now no question that for the Tea Enterprise in Ceylon there is a great future. This is specially gratifying to me, because, in my capacity of journalist, I advocated attention to tea as well as cinchona, when the majority of planters were either prejudiced against or careless about both. Every effort should now be made, I submit, to secure this important Australian market for our teas. The article is in demand, although advices from Foo-chow report 20,000,000 lb. shipped for Australia.

I was present and took part in a discussion at a private meeting convened by Mr. Buck to ascertain the tendency of feeling here as to a proposition that an agent should be employed for two years to collect and diffuse informatiou and form collections of samples of goods likely to enter into commerce between India and the eastern world generally, on the one hand, and the Australian colonies on the other. Mr. Buck's idea was to expend £5,000, of which India should bear half and the Australian colonies the other half. If the thing is done, it seems clear to me India alone must do it. I pointed out at the meeting the important effect which was sure to be produced by the regular running of the British India S. N. steamers to Queensland in addition to the P. & O. vessels to the other colonies. And now I see the Dutch are contemplating a regular steam service from Batavia. Plenty of cheap freight will do much to link the eastern and southern lands together.

I see that some Fiji coffee has sold for only 8½d per lb. here. Mr. D. Mitchell says it was poor stuff. From what I hear, the Fijian archipelago is much more likely to be a formidable competitor of Mauritius and Queenslaud in the production of sugar, than of Ceylou in the growth of coffee.

MESSRS. JAS. HENTY & CO.'S LETTER ANENT MR. DUNN'S ANALYSES OF CEYLON TEAS.

Melbourne, 8th December 1880.

A. M. Ferguson, Esq., Commissioner for Ceylon, M.I.E.

DEAR SIR,—We now hand you the report of Mr. F. Dunn, of the Government Laboratory, on the average samples of Ceylon teas handed to him for analyses, as advised in our last of 24th ulto.

The orange pekoe, pekoe, pekoe souchong and souchong are highly satisfactory, the percentage of extract being very large, of soluble salts full, which, with a low percentage of ash, stamps these teas as of the greatest purity.

Congou, which is usually considered the commonest tea, turns out very good for its class, the percentage of extract 37·40 being well over the standard of extract for lowest class genuine tea, say 30f.

There being only two samples of green tea to show, it was hardly a fair average, but turns out very

high for extract, soluble salts fair, but theine low. In green tea we look for a high percentage of theine and can only account for present result by the method of manufacturing, these two samples forming the average.

We think you have every reason to feel satisfied with the result of analysing the 78 samples in your Court, and which fully confirms the high opinion formed of your exhibits by Mr. Sibthorp and ourselves, and we leave you to judge of what the result would have been if only the best samples had been selected and sent in for analyses.—We remain, your obedient servants, Jas. Henty & Co., per J. O. Moody.

Mr. Dunn's Analyses of Ceylon Tea.

Industrial and Technological Museum Laboratory,
Deer. 8th, 1880.

Report on six samples of tea received from James Henty & Co. :—

Marks.	Name.	℘ cent of ash.	℘ cent of extracts.	℘ cent of soluble salts.	℘ cent of theine.
81	Orange Pekoe	4·60	44·80	3·06	2·15
82	Pekoe	4·92	43·80	3·32	1·82
83	Pekoe Souchong	5·04	42·80	3·12	1·86
84	Souchong	4·84	40·40	3·20	1·84
85	Congou	4·80	37·40	2·96	1·82
86	Green tea	4·72	44·00	2·66	0·94

The high percentage of extract, soluble salts and theine (with the exception of the congou and green tea) found by analysis, proves these teas to be of first-class quality.

The low percentage of mineral ash (which is generally between 5 and 6 per cent) may be accounted for (1) By the quick growth of the tea plant. (2) By the careful manner in which the leaves have been collected and sheltered from the dust, &c.

A low percentage of mineral ash is detrimental to the quality of a tea when the soluble salts fall in percentage (that is below 3 per cent).

It would prove of scientific interest if a larger number of these teas were carefully analysed with especial reference to percentage of mineral ash.

Frederic Dunn.

Industrial and Technological Museum, Laboratory.
29th October 1880.

Report on 15 Samples of Indian Teas received from James Henty & Co.

N.B.—British Analysts' Standard of lowest class genuine Tea ... 5 to 8	30	3·06	

Melbourne, 23rd Decr. 1880.

Dear Mr. Bruce,—The fortnight has been taken up largely in filling in and amending schedules and finally in sending specimens of teas and coffees to Mr. Newbery's office, to be submitted to the proper jury. I gladly availed myself of the proffered aid of Mr. Moody, of Messrs. Jas. Henty & Co., in choosing the samples, and he took good care that, especially in the case of the teas, such samples (4 oz. in each case called for) should be in the best possible condition. They were taken from the *middle* portions of carboys or packages, as the case might be. I desire to impress most strongly on the Colony I represent at this truly magnificent Exhibition a sense of the services rendered by the firm of Messrs. J. Henty & Co., especially in bringing into favourable notice our young but most promising tea industry. Amongst other measures taken by them has been the distribution of very considerable quantities of Ceylon tea which they had purchased previously to my arrival, and which Mr. Moody had satisfied himself was of a quality certain to secure popular approval, which it has done. Many persons who complain of the good strong teas of India, as harsh, declare that Ceylon tea is the best they ever tasted. I have now commenced adding to the tea for distribution, and the attendants of a room in the Exhibition to which ladies resort, having asked for and obtained some of our tea for the use of the ladies, have put up a notice to the effect that the tea is "Ceylon tea: the best in the world"! Yesterday Mr. Leighton, the Commissioner for Queensland, introduced a gentleman from the Darling Downs, who at once said: "I never tasted better tea than that from Ceylon. I have had some pounds of it from my friends the Weinholts, who are interested in properties in Ceylon, and who receive their tea direct from the island. I only wish I could buy chests of such tea as I required it." This was a purely voluntary statement, and such sentiments frequently uttered by unprejudiced consumers ought to console Ceylon tea growers for the persistently depreciatory remarks of London tea-tasters. Even they may not be infallible, and the Mr. Brown I formerly mentioned said some significant words to the effect that those interested in the tea trade feel and express much annoyance at being troubled with comparatively small samples from such places as Ceylon, the question being satirically asked "Are we to have tea from the Isle of Wight, next." The brokers and tea-tasters have the market almost entirely in their hands, however, and tea growers in Ceylon and elsewhere must try to meet their criteria of leaf and liquor. I have been so struck with the history of the Java tea trade with this market, that I requested Mr. Moody to favour me with a paper on this and other points of interest in the tea market of Melbourne, a market which supplies not only Victoria but other colonies, such as New Zealand. I hope to have Mr. Moody's paper to enclose, but meantime I may say that at the meeting summoned by Mr. Buck to discuss the question of increased communication between Australia and the East, the Dutch Consul General and Commissioner, Ploos van Amstel, mentioned to me as a discouraging circumstance, the entire collapse of the once extensive import trade in teas from Java to Melbourne. Mr. Brown had previously told me regarding that of London. Java tea has fallen in estimation in both, notwithstanding its perfect make

up as mere leaf, in consequence of the poorness of the liquor. Now looking at the fact that the soil of Java is rich in decomposed lava, I asked Mr. Sibthorp how this poverty of extract was to be accounted for. He at once laid it to the account of the small-leaved tea they grow. "How can that be," I enquired, "when, as you know, some of your own Darjeeling teas which fetched the highest prices at the late sales were the product of China tea bushes?" "The climate makes the difference" was the reply. I ventured to suggest that perhaps the volcanic soil of Java might be wanting in iron and possibly some other substance necessary for tea? He could not say, but he stated as his experience after having had the oversight of a score of gardens in Assam, that the goodness of the tea made is generally in proportion to the richness of the soil in which the trees are grown, the topsoil being supported by *a subsoil of rich, rather stiffish clay.* I underline the words, which describe the soil in Dikoya, Yakdessa, Ambagamuwa, Dimbula, and other districts in Ceylon, where tea is being largely grown:—flourishing in clays too stiff for cinchona roots to penetrate. Mr. Sibthorp added that all his efforts, continued for several seasons, to get tea of strong liquor from a group of estates opened at the upper end of Assam *in light sandy soil* had proved fruitless, and he had to advise that the best must be made of the *light* teas yielded by such soil. The bearing of all this information on the enterprise in Ceylon is obvious and important. The vast bulk of the trees we grow are of the very best Assam or Hybrid-Assam kinds, and ferruginous clay is only too plentiful in our mountain regions, as cinchona growers know to their loss. Having the right kinds of soil, the right climate (witness the results of the chemical analyses), and the best species or varieties of tea, what remains is that we do our new product justice in the preparation. I cannot but feel sanguine that the information I have transmitted to Ceylon since my arrival at Melbourne will largely aid in this direction. If Mr. Sibthorp, whose engagement with the Tea Syndicate, so profitable in results, terminates at the end of this month, goes back to India at the end of the Exhibition, I have urged him to give Ceylon a visit. But there is a probability of his settling here.

P.S.—The following are replies to queries put by me to Mr. Moody:— Melbourne, 23rd Dec. 1880.

A. M. Ferguson, Esq., Commissioner to Ceylon, M. I. E.

DEAR SIR,—We will endeavour to give the information you ask for by answering the queries put to us. Java teas were largely imported into Melbourne a few years back, but are now entirely out of consumption. The teas are somewhat like Indian descriptions in leaf, but are thin in liquor and the bulk of them inclined to be herby in flavor. At first extreme rates were obtained for the handsome leaf Pekoe and Pekoe tips, but the trade found them of little use for mixing purposes, and prices steadily declined, till in September 1878, the last sale of any importance took place, say 1,131 packages offered at auction:

Congou realizing	5¾d to 9d per lb.	in bond.
Pekoe Souchong realizing	8¼d to 1s 6d	do
Souchong do	10d	do
Pekoe and Broken Pekoe	1s 0¼d to 1s 1½d	do
Flowery Pekoe	1s 3¼d	do

Java teas will stand no chance against Ceylon and Indian teas in the Melbourne market, and we do not think they will be shipped here again. Consumption of tea in Australia: by last accounts from China, 20 million pounds weight had been shipped to the Colonies: this is in excess of previous season, but so far it has caused no downward tendency in prices.

Victoria will probably require for home consumption ... ... 4,500,000 lb.
Do. export trade and stock purposes ... ... 4,000,000 lb.
or say 8½ million pounds for the year.

Tare is not of so much importance as in London; we do not weigh every package, but strike an average from 6 or 12 hf. chts.—If hf. chts. are filled in 38 lb. nett. the customs here would pass them at that after turning out and proving the nett weight of some 4 packages of each mark.

A 20 lb. tin is a mere question of expense, because for shipment to the Colonies the tin would require a wooden box for protection. In many parts tea is mixed to suit the public taste and packed in 1 lb. and ½ lb. fancy tins, and a 20 lb. tin would stand no chance against these; a 12 lb. tin tea would be far better.

We intend sending to Ceylon a consignment of wooden cases suitable for packing tea in. These will be branded, and full particulars supplied to you when they are ready for shipment.

Will give you some information about the Foochow tea trade when the mail has left.—Your obedient servants, JAS. HENTY & Co., per J. O. MOODY.

(From the *Ceylon Observer*, 1st February 1881.)

There is one point to which we desire to call special attention, namely the question of opening up the American as well as the Australian markets for Ceylon teas. It strikes us that, for several years to come, our tea-planters will have to put forth all their energies in order to maintain the favourable impression already made on behalf of their produce in Melbourne, Adelaide and other adjacent towns. There is no use making the name of Ceylon tea widely and favourably known if there is not produce enough to keep up a supply adequate to the demand created. So far from sending any of our tea to America, we would say, stop all shipments to England and concentrate all our exports on the Australian market, the most favourable as regards prices, for the present, until an appreciable share of the total consumption is supplied by Ceylon tea. Out of the twenty-five millions of pounds weight of tea annually consumed in Australasia, it is surely not too much to hope that one-tenth would, in the present year, be made up of Ceylon kinds provided the tea were available. It is not impossible that our planters may eventually secure the lion's share of the Australian tea trade, but there is the danger of our losing the good impression now made through the small quantity sent forward during the present year and even the next two or three years. What is the use of proclaiming to the Australians that Ceylon tea is the best in the world, if we cannot give them a continuous and fairly adequate supply. It surely behoves tea-planters and shippers, therefore, to devote all their attention to the Australian trade. The miserable prices recently paid for Ceylon teas in London—7d to 1s 1d per lb.—will surely put a stop to any further consignments from this Colony to Mincing Lane for some time to come. One shilling in Melbourne is as good to the Ceylon planters as a shilling in London, and so far as we can judge the maximum price obtainable in the English market is likely to be the minimum in Australia. We hope, therefore, that a general effort will be made to direct all our tea crops, limited as at best they must be, during 1881, to the Australian makets in the hope of confirming the name already secured, and of maintaining the continuity of the demand already created.

What the present demand for tea is in Australia and what the future expansion of the trade in this one article is likely to be, the statistics collected at my request by Mr. Moody of Messrs. Jas. Henty & Co. will shew. Mr. Moody writes:—

Re China Teas.

Melbourne, 15th Jan. 1881.

MY DEAR MR. FERGUSON,—As requested I will endeavour to give you some account of our Tea trade with China.

The season generally opens here in June or July, and sales by auction are frequent from that period till the close of the year, or say for 6 months. After this time, buying as a rule is reduced to supplying immediate wants. Tea dealers keep their stocks low and trying to clear out before the new comes in, in June.

For many years past buyers have found China teas keep badly, and when new season's musters are shown old stock is reduced in value fully 2d to 4d per lb. on teas above 1s per lb. in bond and proportionately on lower priced grades, whilst frequently teas selling at 1s 9d to 1s 10d in April-May may realize only 1s 2d to 1s 4d in July-August. The cause is due entirely to the old teas being flat and stale when compared with even common chops of new congous.

The usual course of Melbourne Trade is to buy sparingly of medium to fine teas early in the season, or say during July to August, and such teas are almost entirely used for mixing and to freshen up old stock, therefore only a limited quantity is sold and generally the best quality of the year. Very little of this new tea is sold straight to consumers, because it is considered by them to have no strength and too much flavor. The fact is Victorians have been educated up* to a bad standard of tea.

First crop China teas are always the best in liquor, though not in leaf. The bulk of these teas come forward in July-August, and most of them are sold privately. The heaviest sales and cheapest prices usually rule during September-October, and very little business is done from January to May.† Buyers often find their purchases made early in the season have gone off in quality, so a brisk demand is experienced late in the season for scented teas and other mixers.

Last season 1879-80 was exceptional owing to a heavy rise in prices in London reacting on our market here and causing shipments of tea from this to England, and unusual profits were obtained on sales made late in the season. This sudden expansion of trade is evidently the cause of the heavy shipments of tea, advised this season from China to Australia, and we learn by telegram of 22 million pounds weight shipped as against 15 million pounds weight shipped same time in season 1879-80. The fact of this large export has had a depressing effect on our market, and prices may go still lower, though for the first 6 months of the season rates have been well maintained.

The quality now coming forward is very low, and it may be that China is clearing out all the rubbish accumulated for some time past, in which case our bonded stores are likely to be the gainers in rent, unless the London market again comes to the rescue, as it did last season, taking from us some very old friends.

For your information I give the following synopsis of sales by *Public Auction of China Teas only*, for six months ending 31st December 1880:—

lb.		per lb.	lb.		per lb.
67,000	sold at	7¾d to 8d	128,000	sold at	1/1¾ to 1/2
106,000	...	8¼ ,, 8½	185,000	...	1/2¼ ,, 1/2½
135,000	...	8¾ ,, 9	135,000	...	1/2⅞ ,, 1/3
370,000	...	9¼ ,, 9½	132,000	...	1/3¼ ,, 1/4
376,000	...	9¾ ,, 10	44,000	...	1/4¼ ,, 1/5
308,000	...	10¼ ,, 10½	50,000	...	1/5¼ ,, 1/6
235,000	...	10¾ ,, 11	46,000	...	1/6¼ ,, 1/7
209,000	...	11¼ ,, 11½	46,000	...	1/7¼ ,, 1/8
199,000	...	11¾ ,, 1/	38,000	...	1/8¼ ,, 1/9
245,000	...	1/0¼ ,, 1/0½	4,000	...	1/9¼ ,, 1/10
170,000	...	1/0¾ ,, 1/1			
163,000	...	1/1¼ ,, 1/1½	3,391,000 lb.‡ total.		

From this statement you will see that 2,005,000 pounds weight sold at and under 1s per lb. in bond and 1,386,000 do do 1/0¼ to 1/10 do This gives no idea of the sales of fine tea, which is usually disposed of privately, for it is found difficult to obtain over 1s 8d per lb. publicly for any class of tea.

The sales of tea outside of the Auction Room for the six months ending 30th Dec. 1880, will probably amount to 2½ million pounds more, bringing up the total sales of China teas to not far short of six million pounds weight.

Hayter's Statistics for Victoria shew increased prosperity for the country, and we have increased returns for our staples:—Gold, wool, wheat, &c., money is now very cheap here, and all this means larger consumption of tea which we cannot produce.

Our market closes to-day with a full supply of common to medium grades of tea and prices lower for same, but with a small stock of good and a scarcity of fine qualities of Congous, and rates ruling higher for these sorts.

A large proportion of tea consumed in Victoria is sold in half-chests 38 lb., boxes 11 lb., with a few quarter-chests 20 lb. weight. These packages are generally taken by the squatters, selectors, farmers, &c., just as received without any mixing and price generally guides the buyer, but he won't have posts and rails (viz. large leaf and stalky samples) or dusty teas. A small quantity of finest quality is taken at any fair price by the wealthy classes, other balance of consumption consists of the trade of towns and retailers generally. Most of this class of tea is mixed, and therefore the weight of packages is not of so much importance, though the small retailers object to lay out too much money on heavy packages. A considerable amount of the mixing is primitive and varies with seasons. First the gentle and long-suffering public is treated to Canton gunpowder, &c., which has its day, then Canton scented caper has a turn, followed by Canton long leaf scented Pekoe. Now, Canton short leaf scented Pekoe and Kooloo teas are the fashion. When the consumer has been educated up to this standard of Canton nastiness, no wonder it is difficult to get a delicate pure tea appreciated, and we see at once why so many doctors generally denounce tea as injurious; but why don't these gentlemen discriminate between good and bad tea?

Our retail grocer looks to tea to recoup the whole expenses of his shop and give him a profit beside. The public know nothing about tea, but competition forces the prices down of all things that can be easily judged; so Brown cuts his sugar, Jones sells jam below cost, Robinson follows suit with butter, Smith pushes his pickles, and so on;—but Brown, Jones, Robinson and Smith all get good profits out of tea.

The Chinese hawkers are found in all our cities. "John" (our pet name for a Chinaman) sells a compound of nastiness by the packet, and he ("John") is a judge of human nature. He calls at a house on his rounds, sees children in the garden and gives each some lollies, and so finds his way to the heart of the mother who cannot refuse to take a packet of tea from "John," and so gradually the taste of the family is spoilt. The grocer complains that the Chinese hawker is cutting him out and he must have tea with more "grip." I know what he wants and expostulate with him—no good—so get him some Canton nastiness; next time he tells me his customers like the new mixture.

As a stranger in the land and only biassed in favour of Ceylon tea, tell me who is to blame for the above state of affairs? Is it the mother: then would you crush out the maternal feeling that delights in the happiness of her children? Work the problem out for me.—Yours sincerely, J. O. Moody.

P.S.—From Hayter's Statistics just published, it

* Query *down*?—A. M. F.

† It would seem as if the present season were to be exceptional, for a large sale is to take place to-morrow, and heavy cargoes are en route.—A. M. F.

‡ Of course this refers to Melbourne only, and takes no account of private sales.—A. M. F.

appears Victoria can take 5½ millions lb. of tea for home consumption for a year, and 4 millions of tea for export for a year or 9½ millions lb. in all; these figures seem large. J. O. M.

Mr. Moody's graphic description of the mode in which the taste of a people who are specially tea-drinkers has been vitiated will be read with interest in Ceylon, and producers of the pure and in every way superior article will see the difficulty of inducing consumers to prefer the pure and good to the cheap and nasty. The latter has the one advantage of cheapness, but on the little packets given away at the Ceylon Court, first by Mr. Moody, and now out of the teas placed at my disposal for this purpose, care is taken to state that one-half the quantity of Ceylon leaf will make a better infusion than can be got from common China. The testimony of the vast majority is "We never tasted better tea." And more than this: Mr. Dunn, who conducts the analyses under Mr. Newbery of the Technological Department, had a long conference with me about the results obtained from some of our Ceylon teas, especially the few specimens of green, in testing for tannin. Although this is the substance which makes over-infused or *boiled* tea so unpleasant, yet its presence in good quantity is regarded as of much importance. With reference to an elaborate paper on Indian teas which Mr. Dunn is preparing for the *Argus*, Mr. Dunn has been addressing himself as a chemist to ascertaining the proportion of tannin present in the various qualities, and he told me he found some of the Ceylon teas, and especially the green, so exceptionally rich, that he is anxious to obtain all possible information as to the character of plants, modes of culture and preparation, and so forth. I have of course given Mr. Dunn the benefit of all the knowledge I possess, and I have promised to send him, on my return to Ceylon, specimens of plant and leaf in every stage of growth and preparation. Perhaps some planter, say Mr. James Taylor, will at once prepare and send a box of specimens with memoranda to Mr. Dunn, addressed to my care? Mr. Dunn's paper is likely to be published in about a week, and, as Ceylon teas as well as Indian will be noticed, I shall, of course, send copies to Ceylon with such remarks as may be suggested.

Melbourne, 1st February 1881.

I have attended to the request of Mr. C. S. Armstrong by distributing his samples of teas amongst brokers and dealers, taking it upon me to include the editors of the *Argus*, *Age*, *Telegraph*, and *Herald*. In the paper first-named, a very favourable notice appears, while Mr. Robinson, the Commercial Editor of the *Age*, to a favourably verdict adds good advice about not burning our teas. When the boxes sent by Mr. Armstrong were opened at the office of Messrs. J. Henty & Co. Messrs. Moody, Sibthorp and Brown spoke very favourably of all except the large-leaved kind. But even of this, Mr. Brown, after smelling it, said: "This would give excellent liquor." It was explained to me that, apart from appearance, tea large in the leaf would be objected to by brokers and consumers on the ground of bulk in proportion to weight. Consumers, measuring by teaspoonfuls, would require to alter their standard for large as compared with small tea. The large leaves must be subjected to the cutting machine, and Mr. Moody said to me yesterday with reference to possible objections to the appearance of cut tea:—"You seem to have plenty of pekoe tips in Ceylon. A good quantity of them mixed with the cut tea would largely disguise the signs of cutting and would greatly improve the tea." It seems clear that if we can send from Ceylon a tea so prepared as to be ready to go at once into consumption on its own merits, without giving the dealers the trouble or affording them the profit of the processes of mixing and blending, it will be much to our advantage. I do trust—and I have good reason to hope—that this result will be gained by means of the information I have elicited and sent to Ceylon. Of course the flushes of Assam hybrid tea are much larger in size than those of the China plant. But, no doubt, a large proportion will, on sifting, be small and well curled. If this tea and the tips are added to the big-leaved tea after the latter is cut, the result will, I should think (preparation being good) be a perfect tea, for the Australian market, at least. Broken and red leaves and dust ought, of course, to be separately packed. The sample packets made up by Mr. Moody and sent to Ceylon, and the statements regarding packages (chests), ought to guide those interested in tea.

FIJI:—COFFEE, COTTON, COCONUTS AND SUGAR.

I have stated why I doubt the capability of the Fijian group of islands to become a great coffee country. They will be more formidable competitors with Queensland as producers of sugar and New South Wales in the growing of maize. And I suspect that groves of coconuts will yet cover most of the scores of smaller islands. Yesterday, a Wesleyan missionary came to the Ceylon Court to consult me about getting coconuts from Ceylon for planting purposes. He stated that he and a brother-missionary owned an island of 2,000 acres area, on which they wished to start their sons as coconut planters. A third missionary, name Carey, who has a brother in Ceylon, had advised them to get nuts thence, as being superior. I told him if he would write me a letter I should send it to Ceylon, but I stated my belief that Ceylon coconuts were not likely to be superior to those of the South Sea islands. I also gave emphasis to the great cost of freight for coconuts, which, to be of use for plants, must come in the husk. While agreeing, too, that coconut planting required but small capital, and that, once grown, the trees required the minimum of culture, I took pains to shew him that we in Ceylon who had gone into the details of the subject and its statistics were not responsible for sanguine statements about trees bearing in seven years and giving one to two hundred nuts per annum. In a pamplet on Fiji, prepared with reference to this Exhibition, I find it stated that the average yield of nuts in Ceylon is 90 per tree annually. One-third the number is really nearer the mark. But on the higher number is founded the calculation that, in Fiji, it is safe to estimate 80 nuts per tree, per annum, or one ton of copra per acre, selling for £14 and yielding £13 profit! I advised the cutting down of this by one-half. Even then, 200 acres, at £6 *profit* per acre, would mean an income of £1,200. If the young men can "watch and wait" for returns, the island of 200 acres ought to be a good inheritance to them. "But come," I said, "let us have a look at the coconuts in the Fijian Court." We went and found the normal coconuts just the fellows of our Ceylon ones. But our attention was also drawn to an elongated coconut with a depression in the middle which neither Mr. Dawson nor I had seen in Ceylon. The man in charge shewed us specimens of peculiarly long fibre, suitable for brush-making purposes, obtained from these coconuts, and he assured us, that, as a rule, nut was obtained from each end of the fruit! If further enquiry shews this to be true, I must see about getting seed nuts from Fiji, instead of sending them thither.

KAPOK OR TREE COTTON.

Mr. Moody, with reference to a market for coir in Melbourne, having repeatedly told me that it had

been largely superseded by an article from Java known as "kapok," and he having asked me if Ceylon could supply that article, I replied that I could not tell until I knew the proper name of the palm from which it was obtained: for that the article which had superseded coir was the product of a palm, I never doubted. At length Mr. Moody accompanied me to the warehouse of a leading cabinet-maker and upholsterer here, a gentleman who has done much to bring the beautiful wood of the Huon pine of Tasmania into notice as a material for furniture. You can imagine my amazement and amusement when I was shewn a specimen of the short-staple but beautifully fine wool of what we know in Ceylon as the *silk* cotton tree, or tree cotton! The common green-stemmed tree, with its regular whorls of perfectly horizontal branches, is common around Colombo and over the western and southern portions of the island, near native cottages or in fences. There is a thorny variety in the Kandian country, and the scarlet-blossomed or Malabar variety is one of the most beautiful objects possible when in flower: witness the fine specimen at the Pavilion, Kandy. The tree resembles *Erythrina Indica* in casting its leaves and in shewing first the blossoms, then the pods, and then the leaves. The cotton, which is easily separated from the seede, is used in India and Ceylon for stuffing pillows, but in our hot climate it is rather soft and warm for mattresses. As I have seen much of the cotton blown to waste, I think it probable that, with cheap freight obtainable, the article might be profitably exported to Australia. Java, however, is nearer to Australia, and freight to the colonies is more abundant. The want of freight from Ceylon is shewn by the fact that quite a quantity of Patna rice, much wanted in this market, was left behind by last P. & O. steamer. My recollection is that tree cotton for pillows cost generally 2d per lb. If that is the price for *clean* stuff, there is a good margin, for Mr. Moody tells me the price of "kapok" in Java is £4 per cwt. It could of course, be screwed into bales of small compass, but supposing quantities can be obtained at a moderate price, the great difficulty will be that of freight. I was told yesterday, however, that a vessel recently arrived from Ceylon belonged to Harper & Co., and that she made regular voyages. The publication of this letter may draw attention to the subject and lead to trial shipments. In any case I should be glad if a few well-ripened but unopened pods were sent to me, which I could hand to Mr. Guillefoile for his museum, after shewing them to those interested. But for personal inspection, I certainly never should have suspected that the successful competitor of Ceylon coir in the Melbourne market had been tree cotton, going under the name of "kapok" (the *a* pronounced as in the first syllable of *fatal*).

CEYLON, INDIAN AND CHINA TEAS.

Melbourne, 15th Feb. 1881.

Pure China teas, can, no doubt, be procured, but in the "Laboratory Notes" for 1878 of the Melbourne Industrial and Technological Museum there are some astounding revelations made regarding the stuff which has been palmed off on Victorian tea drinkers. Genuine tea yields about 5 to 7 per cent of mineral ash, 3 per cent of which consists of soluble salts. The extract runs from 32 to (in choice samples) 50 per cent. Some Ceylon tea which Mr. Dunn is now analysing has given the latter result, Mr. Dunn stating that it took him a whole day to exhaust these extraordinary tea leaves. The more extract the better, provided the soluble salts equal 3 per cent of the mineral ash. But any quantity of mineral matter beyond 7 per cent indicates adulteration. Now the first specimen analysed at the Museum in 1878, a green tea selling 3s. at per lb., yielded 27·19 grains of mineral matter against 25·70 of extract and 2·60 of soluble salts. In the case of a two-and-sixpenny green tea, the soluble salts were only 1·15 grain and the extract 20·09. Regarding the first the remarks are:—"Bad. Highly faced with Prussian blue and turmeric. Leaves genuine; adulterated with clay, sand, magnetic oxide of iron, and sulphate of lime. These are entirely covered by the curling up of the leaf." Of the second specimen quoted by me, I find it stated:—"Very bad. Faced with Prussian blue and turmeric, genuine leaves very much broken, and adulterated with foreign leaves, withered leaves, excess of stalks, sand, clay, magnetic oxide of iron." The above are two out of 15 specimens of green tea, and to shew how difficult it is to get persons reconciled to an article, however good, with the appearance of which they are not familiar, I need merely repeat what was stated to me by Mr. Moody of Messrs. Jas. Henty & Co., that when, in consequence of such revelations, a consignment of genuine green tea was introduced, unfaced and unadulterated, the small dealers and consumers indignantly rejected the tea as "trash," and the consignment had to be sold at a large loss. We need not, therefore, wonder at the difficulties experienced in reconciling to pure Indian and Ceylon teas persons whose palates have been sophisticated by the "lie" teas of China. Of black teas (China) fourteen specimens were analysed, and the results were as might be expected, nothing like so bad as in the case of the green teas. One specimen, indeed, imported direct from China and obtained at Beechworth, was fit to rank with the best Indian or Ceylon. This three-and-sixpenny tea (well worth the price) yielded 5·12 grains of mineral matter; no less than 45·779 of extract, and 3·57 of soluble salts. But such teas are rare exceptions. A two-shilling black tea gave 5·60 grains mineral matter, only 19·57 extract, and only 2·49 soluble salts. In another case soluble salts were so low as 4·21. Of both teas the record is:—"Bad. Large quantity of stalks and exhausted leaves, small particles of Prussian blue and turmeric." Of course the superior tea, unadulterated by exhausted leaves, was far cheaper at 3s. 6d. than the rubbish sold at 2s. This is what we want the tea drinkers of Australia to understand in regard to our perfectly pure Indian and Ceylon teas. But as some people cannot endure genuine coffee unadulterated with chicory, so persons accustomed to *tonic* mixtures of tea and magnetic iron (the latter producing an inky black liquor) require a gradual education into a liking for genuine tea. That education the Indian Court to a large extent and the Ceylon Court in a more modest degree are giving.

Mr. Sibthorp urged the necessity of bulking and blending teas for the Australian market. I find that what he recommended was a good base of the stronger Assam and Cachar teas, with fine flavoured pekoe, &c., from the Kangra Valley and Darjeeling added. So long as the teas used are good of their kind, the impression I have received is that the more different teas of pronounced but different flavours are mixed together the better. As Mr. Moody put it, the more the flavours are mixed, the less is the consumer able to fix on any one flavour to which he can object. In fact a tea drinker who would reject six different teas in their separate state enjoys and approves of the whole when judiciously mixed. Whether a Ceylon Syndicate be possible or not, here is an opening for individual merchants or firms in Ceylon, who are experts or who have such in their employ: different teas, low-grown and high-grown, of different qualities and prices, can be bought at market value and bulked and blended, so as to be exported in large breaks. Of course a producer like Mr. Elphinstone, who grows tea from the heights of Oliphant down to the low ranges of Yakdessa and the flats of

Awisawella, can bulk and blend for himself. But it would probably pay a Colombo merchant to mix the high-grown teas of say Calsay and Abbotsford with those of Agrawatte and Strathellie, and of the more forward estates at elevations, like those of Assam, ranging from 100 to 1,000 feet above sea level. It is quite clear that if the different teas are sent separately to this or any other market, where blending is a necessity, the purchaser can only purchase at a price which will allow him a good margin to pay for the expense and trouble of unpacking, blending and repacking. To a certain extent this will be true in regard to a purchaser in Ceylon. But the matter is worthy of consideration. The danger to be guarded against in unpacking, blending and repacking in a hot, damp climate, like that of Colombo, is that of the tea absorbing moisture But with properly heated and protected rooms this danger can surely be averted. Provided tea can be made suited for a market on its own merits, no doubt the perfection of tea making is to pour into the chests and hermetically seal when the leaf is dry and hot, without even the intermediate deposit in the bin. But what is best is not always possible, for a considerable proportion of our teas will need sifting and cutting. You will see that the operations of the Calcutta Syndicate are to be continued for at least another season, and extended to America and Canada. The experience obtained in these extended operations will be of equal value to Ceylon planters as to their Indian brethren, and if information is sought on points which have not been publicly discussed I feel sure a reference to Calcutta will be cordially responded to. A special blending of Indian teas is now selling in this market under the name of "Sibthorp's mixture." In writing all this I do not forget the established fact, that, as a general rule, Ceylon teas, as they reach this market, are much better suited to go into immediate consumption, unmixed and unblended, than are the bulk of the Indian teas. But all seem to be improved in quality and value by *judicious* mixing and blending.

Kapok or Tree Cotton.

By last steamer Mr. Moody (Henty & Co.) received a specimen of "kapok" or tree cotton from Calcutta. The specimen was not well freed from seed, but the price mentioned leads to the conclusion that henceforward the article can be supplied from India at a cheaper rate than from Java. I suppose trial shipments will be made from Ceylon also. It is possible that a regular plantation of tree cotton would pay? The pods when ripe could most of them be brought down by means of a sickle or catty attached to a long pole. In the case of the taller trees a ladder might aid the operation. If the trade developes largely regular cotton gins might be employed to separate the seed from the wool. The former may be valuable as feed for cattle? Attention being drawn to the subject, all such points will be investigated and settled. At the base of the Eastern Himalayas the forests literally blaze with the blossoms of the scarlet-hued variety, which also vies with the *Erythrina Indica* in Ceylon.

Trade between Ceylon and Australia.

Melbourne, 3rd June.

Dear Mr. Bruce,—I beg to draw your attention and that of all interested in the tea enterprise to the letter which Mr. Moody has addressed to me in view of the close of our intercourse, during which he has shewn me great kindness personally and enabled me to obtain and forward a great deal of information valuable to Ceylon planters and merchants. The testimony which Mr. Moody is good enough to bear to my own efforts to promote the interests of Ceylon though too flattering is naturally gratifying to me. But the more important portion of the letter is that which makes statements and gives advice regarding the trade of Ceylon with Australia and which I commend to the careful consideration of all concerned. While Indian teas, in the face of vested interests and strong prejudices, are making their way in the market here, there can be no doubt that many prefer the Ceylon teas not only to the impure China stuff but to the pure Indian leaf. The general testimony is that Ceylon tea can be used to go direct into the pot and not merely as an addition to weaker stuff. The difficulty is that of price, the rubbish from China having been sold at such low figures that dealers and consumers are unwilling to give prices calculated to remunerate Indian and Ceylon growers. But I trust a better state of things will soon be brought about. In the past season 22½ millions lb. of tea came from China against 15 millions in the previous year. And yet place has been found for about 1 million pounds of Indian and Ceylon teas, which are gradually getting into demand, not only in Melbourne but at outstations and in the other Colonies. No doubt the London market will largely rule that of Melbourne, but there can be no doubt as to the effect on the London market itself of the diversion of considerable quantities to other markets. But I cannot too often impress on planters and merchants the importance of not injuring the prospects of Ceylon tea by sending leaf of a low standard of quality. The Exhibition has shown what the Ceylon planters can do, and now it remains that they should be true to themselves and the product on which so much depends.

The following are the results of the sales on 10th May:—

Under instructions from the Importers, Messrs. James Henty & Co.,

Ex "Rosetta," and others from Ceylon, Season, 1880-81.

	s.	d.
31 half-chests Loolecondera Pekoe 40 lb, small black very even leaf few ends, strong maltry rich very brisk, Pekoe flavour ...	1	4½
24 half-chests Loolecondera Pekoe Souchong 40 lb, well twisted greyish black leaf, rich and full ripe malty Pekoe flavour ...	1	5
48 half-chests Loolecondera Pekoe, Souchong 40 lb., blackish brown well curled leaf, strong full ripe Pekoe flavour	1	2
11 half-chests Calsay broken Pekoe 38 lb., small black very even leaf full of tips, pungent thick heavy and very flavoury	1	0½
10 half-chests Calsay pekoe 38 lb., brownish black, rather loosely twisted leaf, extra fine very flavoury brisk pekoe kind ...	1	1½
11 half-chests Calsay Souchong 36 lb., bold black fairly curled and even leaf, strong and pungent ripe full flavoury	0	10½
18 half-chests Calsay pekoe Souchong 38 lb., blackish brown well curled leaf, pungent and strong full ripe flavour	1	1½
38 half-chests Boos pekoe Sonchong 38 lb., very handsome small wiry leaf full orange pekoe tips, rich full ripe, malty pekoe flavour ...	passed.	
20 half-chests Rookwood broken pekoe 43 lb., small black very even leaf, orange tips, brisk burnt very flavoury malty pekoe	1	2
45 half-chests Kandal Oya pekoe Souchong 38 lb., boldish black fairly curled evenish leaf, strong and rather pungent rich flavoury ...	0	11½
18 half-chests Kandal Oya Souchong 38 lb., bold greyish brown curled and twisted leaf, full ripe brisk flavory	0	10½

You will see that Pekoe Souchong from Loolecondera sold at 1s 2d per lb. more than the Pekoe. If the prices are disappointing, the facts mentioned by Mr. Moody must be taken into account, viz.

that at the close of the season dealers are more anxious to clear off old stocks than to make further purchases. But this question of season may be modified by the appearance of Indian and Ceylon teas in the market, and there is much reason to believe that the great losses of middlemen in China during the past season will lead to greatly diminished shipments in the season about to commence. This will be the opportunity of the Indian and Ceylon tea growers, and I trust the tide taken at the flood will lead on to fortune. The teas which did not sell are those described in the catalogue :—

Ex "Ships" from Ceylon,
Season, 1880-81.

44 half-chests Kandal Oya Pekoe Souchong 38 lb., well made brownish black twisted leaf, strong and ripe full brisk very flavory... ...
23 half-chests, Kandal Oya Fannings 44 lb., broken open brownish leaf, strong full brisk flavory ... ...
17 chests Windsor Forest pekoe Souchong 80 lb., blackish grey well twisted even leaf, strone rich ripe full Souchong flavor... ...
29 chests Windsor Forest broken pekoe 90 lb. very handsome small wiry blackish leaf full orange tips, choicest ripe rich malty pekoe flavor
14 chests Windsor Forest Souchong 90 lb., Fairly twisted even blackish leaf, strong full ripe flavor ... ...

All passed no offer.

Ex "Khedive" from Ceylon,
Season, 1880-81.

26 half-chests Ceylon pekoe ... ...

From the catalogue of the sale of 26th May, I observe that the highest prices, after Darjeeling Pekoe at 1s 5½d, were realized by Chittagong tea packed in tins, thus :—

7 cases (each 4 22-lb. tins) Chittagong pekoe souchong reddish black even twisted leaf. Very rich full ripe pungent, dark red liquor 1s 4½d.

3 cases (each 4 20-lb. tins) Chittagong souchong. Reddish black even curled leaf. Full rich ripe pungent, dark red liquor 1s 4d.

Darjeeling Pekoe in half chests of 50 lb. went for 1s 3d, while 100 quarter chests of Cachar Pekoe Souchong realized 1s 3½d. It is evident that nature and size of packages tell as well as quality and appearance of leaf.

Now follows the catalogue of Ceylon Exhibition teas and the prices realized, with the reservation that in this case the duty of 3d per lb. on tea and coffee had been paid and that in a good many instances the tea was in nice small boxes.

Products Exhibited in Ceylon Court.

Under instructions from A. M. Ferguson, Esq., Commissioner for Ceylon, Ceylon exhibits of tea from the Melbourne International Exhibition. Duty (3d.) paid.

Exhibitor, T. C. Owen, Oonoonagalla Estate.—38 1lb. packets Ceylon tea. 112 2 lb. packets Ceylon Tea. 1 5 lb. packet Ceylon Tea.———267 lbs. 1s 6½d.

Exhibitor, C. A. Hay, Windsor Forest Estate.—box Pekoe Dust, 14 lbs. 1 box Broken Pekoe, 9½ lbs. 1 box Orange Pekoe, 11½ lbs. 1 box Pekoe, 10½ lbs. 1 box Pekoe Souchong, 10¼ lbs. 1 box Souchong, 12 lbs. ——67¾ lbs. 1s 10½d.

Exhibitor C. S. Armstrong, Rookwood Estate.—1 box Broken Tea, ¾ lb. 1 box Broken Pekoe, ½ lb. 1 box Pekoe, 6 oz. 1 box Pekoe Souchong, ¾ lb. 1 box Souchong, 1¼ lb. 1 box Congou, 1 lb. ——4 lb. 91 1 lb. packets Ceylon Tea. 47 ½ lb. packets Ceylon Tea 76 2 lb. packets Ceylon Tea———284½ lbs. 1s 8¼d.

Exhibitors, Keir Dundas & Co., Loolecondera Estate. —A. 2 tins Flowery Pekoe, 2 lbs. B. 1 tin Flowery Pekoe, tips, 1 lb. C. 1 tin Orange Pekoe, 1 lb. D. 1 tin Orange Pekoe, tips, ½ lb. E. 1 tin Orange Pekoe, 1½ lb. F. 2 tins Pekoe, with Orange tips, 3½ lbs. G. 1 tin Broken Pekoe, with tips, 1½ lbs. H. 2 tins ordinary Pekoe, 3½ lbs. I. 2 tins Souchong, 2⅜ lbs. K. 2 tins Pekoe Souchong, 2⅜ lbs. L. 1 tin Congou, 1½ lb. M. 2 tins Under-fermented Tea, 2½ lbs.—23 lbs —6s. M. 7 boxes Underfermented tea———147 lb.; 1s 10d.

Exhibitors, Haldane & Anton, Calsay Estate.—1 box Pekoe, 4½ lb. 1 do Pekoe Souchong, 3½ lb. 1 do. Souchong, 5½ lb. 1 do Unassorted, 4½ lb. 61 packets, each 2 lb., Ceylon Tea. 47 do each 1 lb. do. 1 packet, 12lb. do———203½ lb., 1s. 7d.

Exhibitor, A. J. Stork, Blackstone Estate.—5 packets, 2 lb. each, Ceylon Tea, 10lb,. 1s. 11d.

Exhibtors, Ceylon Company, Limited, Sogama Estate. —1 box Broken Tea, 3 ¾lb. 1 do Broken Tips, 2½ lb 1 do Pekoe, 2½ lb. 1 do Orange Pekoe, 5 lb. 1 do. Flowery Pekoe, 3 lb. 1 do Pekoe Souchong, 4 lb. 1 do Congou, 2 lb.———22 lb., 0s. 10d.

Exhibitors, Ceylon Company, Limited, Hope Estate — 1 box Orange Pekoe, 5½ lb. 1 do Pekoe Souchong, 4½ lb. 1 do Souchong, 5½ lb.———15½ lb., 1s. 10½d.

Exhibitors, Ceylon Company, Limited, Koladenia Estate.—1 box Silvery Pekoe, 4 lb. 1 do Broken Pekkoe, 6½ lb. 1 do Orange Pekoe, 5½ lb. 1 do. Flowery Pekoe, 4½ lb. 1 do Pekoe Souchong, 4½ lb. 1 do. Souching, 3½ lb. 1 do. Congou, 4½ lb. 1 do. Unassorted, 3¾ lb. 1 do Hyson, 6¼ lb. 1 do Young Hyson, 7¼ lb.———50¾ lb., 2s.

Exhibitors, Ceylon Company Limited.—309 2 lb. packets Ceylon Tea. 169 1 lb. do do. 300½ lb. do do. 1 5 lb. do do———942 lb., 1s. 3½d.

Exhibitor, P. R. Shand, Sembawattie Estate.—1 box Pekoe, 9¼ lb. 1 do Pekoe Souchong, 9¼ lb.——— 18½ lb., 2s.

Exhibitor, P. R. Shand, Strathellie Estate.—1 box Pekoe, 9¾ lb. 1 do Pekoe Souchong, 10¾ lb——20 lb., 2s.

Exhibitor, P. R. Shand, Dunedin Estate.—1 box Pekoe, 12 lb. 1 do 9¾ lb.———21¾ lb., 2s 2d.

Exhibitor, G. & W. Leechman, Agrawatte Estate. 1 box Pekoe. 1 do Pekoe Souchong, 26 lb. 1s 11d.

Exhibitors, Mackwood & Co., Galboddie Estate. 1 box broken Pekoe, 18½ lb. 1 do Pekoe dust 19¾ lb. 1 do Orange Pekoe, 16¼ lb. 1 do Pekoe Tea, 13¾ lb. 1 do Pekoe Souchong, 15¼ lb. 1 do Souchong 12¾ lb. 96¼ lb 2s.

Exhibitors, Mackwoods & Co., Galboddie Estate. Packets, each Ceylon Tea 110 lb 2s 1d.

Exhibitor, J. A. Smith, Lonmay Estate. 15 tins, each 2 lb Ceylon Tea. 10 packets, each 1 lb do. 1 packet, 5 lb do 45 lb 1s 11d.

Ceylon Exhibits of Coffee, from the Melbourne International Exhibition,

Exhibitors, Whittall & Co. Thoteulagala Estate. Duty 2d paid 1 barrel Peaberry, large size, 14½ lb. 1 do large size Plantation 13⅞ lb. 1 do bulk size do 15¼ lb. 1 do small size do 13 lb. 1 do Peaberry, large size, 13½ lb. 1 do do smallsize, 14 lb—84 lb 1s 3½d

Courthope Bosanquet & Co. 4 lots plantation coffee 47½ lb 1s 6¾d.

Exhibitors, Whittall & Co. Loolecondera Estate. 1 1barrel bulk size Plantation, 14½ lb. 1 do large siy do 13½ lb. 1 do bulk size do 14½ lb. 1 do Peaberre large size, 14¼ lb. 1 do do small size, 13¾ lb—70½ lb 1s 3½d.

Exhibitors, Whittall & Co. 1 barrel large size Plantation, 13¾ lb. 1 do bulk size do 15¼ lb. 1 do small size do 13 lb. 1 do Peaberry, small size 13½ lb —52½ lb 1s 2¾d.

Exhibitors, Whittall & Co. 1 bag large size Native, 11 lb. 1 1 do bulk size do 13 lb. 2 1 do small size do 13¼ lb. PB 1 do Peaberry do 12½ lb—49 lb. 10½d.

Exhibitors, Delmege, Reid & Co. Tillicoultry Estate. 1-1 barrels Plantation Coffee, 12¾ lb. 2-1 do do 12 lb. 1 do Peaberry 12lb—36½ lb 1s 6d.

Delmege Reid & Co. Kintyre Estate 25 lb 1s 4d. do do 12½. 1s 6¾d do Langdale Estate 37½ 1s 6¾d.

Exhibitors, Armitage Brothers. 0 1 barrel Plantation Coffee. 224 lb, 1 do do 224 lb. 1 do do 224 lb. 1 do Peaberry 224 lb—896 lb 1s 4½d.

OTHER EXHIBITS.

Exhibitor, Sampson Rajapakse, Mudaliyar.—1 bale, 100 lb., Superfine Cinnamon; 1 do No. 1 do; 1 do 2 do; 1 do 3 do; 1 do 4 do, 1s 5d.

Exhibitor, Hendrick de Silva.—1 bale, 100 lb., No. 1 Cinnamon; 1 do 2 do; 1 do 3 do, 1s 6d.

Exhibitor, J. F. Drieberg, Ekelle Estate.—1 bale, 10 lb., superfine Cinnamon; 2 bales, each 20 lb., 40 lb superior do; 1 bale, 20 lb, No. 1 Cinnamon; 1 do 2 do; 1 do 3 do; 1 do 4 do, 1s 8d.

Exhibitor, S. Jayetilleke, Mudaliyar.—5 bottles Vanilla, 33s per lb.

Ehibitors, Delmege, Reid & Co.—6 coils ½ inch to 5 inch Coir Rope, 34s per cwt. 4 Ballots Coir Yarn 4 do do Fibre, not sold.

Exhibitors, Delmege, Reid & Co.—I glass-barrel Coconut Oil Carboys. 38s the lot.

The coffee exhibited by Messrs. Armitage Brothers, was sent to the sale by Messrs. Jas. Henty & Co., and the auctioneers will render accounts to them and not to me. From the prices realized of course charges as well as duty will have to be deducted. I am disappointed with the prices paid for the cinnamon, especially the five exhibits of Mudaliyar Sampson Rajepakse, but the market for this spice is limited. You will see that Mudaliyar Jayetilleke's vanilla realized 33s per lb. and that Mr. Moody asks what price pays. Mr. Jayetilleke will be able to say. Considering the state of the market and all the circumstances I am assured that the exhibits sold well.

For the first time I have seen the circulars of two of the principal dealers in coffees here. Messrs. Harper & Co. and Parsons Brothers & Co. The latter is surmounted by a design framed in by two well-executed branches of coffee in flower and fruit. The trade-mark, a lion, a sheaf of corn and a pair of balances, has for motto "*Justus esto et non metue*," and Messrs. Parsons Brothers & Co. describe themselves as "coffee, spice and rice merchants," and also as "chicory and oatmeal manufacturers," the latter a curious conjunction. What seems, inexplicable is, that, while in both circulars chicory is quoted at exactly half the price of coffees, a mixture of pure coffee and pure chicory is sold at only 1d lower than coffee alone! The proportion of *coffee to chicory* is not stated, but the general impression is that it varies one-fourth to a half. If so, surely a greater reduction of price for the mixture should be made. Messrs. Parsons Brothers say about their

"Globe" & "Crown" Brand Coffees is that there are mixtures of the fine high-grown Plantation with Pure Victorian Chicory, in such proportions as have been found from long experience to be most generally approved.

That is all. There is a pure "Pasha mixture" which is described as

A superior blending of high-class Indian, Turkey, and Ceylon Coffees, specially imported. For strength and fine Aromatic Flavour this mixture cannot be excelled.

Then there is the

"Elephant" & "Crescent" Brand Coffee are First-class medium Coffees with Chicory.

Raw coffee in bond is quoted as follows

	s.	d.
Plantation, Ceylon No. 1	0	10½
do do No. 2	0	10½
Java, fine plantation	0	9½
Native Ceylon	0	8
Mocha, superior quality	1	2½
Jamaica, finest	1	1½

and here are the closely equal prices of pure ground coffee and pure coffee with pure chicory

Pure ground coffee.		
Plantation, Ceylon, No. 1	1	2½
do do No. 2	1	2½
Pasha Mixture	1	2½
Java, very fine	1	1½
Native, Ceylon	0	11½
Mocha, superior quality	1	5
Jamaica, finest	1	7½
Pure Coffee with pure Chicory.		
Globe, brand, sq. tins	1	1½
do do rd. tins	1	1
Crown do sq tins	1	0½
do do rd. tins	1	0
Elephant Brand	0	11½
Crescent Brand	0	10½
Australian arms	0	9½
Ship Brand	0	8½

Chicory alone is quoted 5d at 5½ per lb. The quotations of cinnamon are

Spices.	per lb. s.	d.
Cinnamon, whole, finest new stick	2	3
do do second	none	
do ground, loose, or in tins	2	9
do second do	2	0
Cassia, whole, finest	1	0
do ground loose or in tins	1	3

Messrs. Parsons Brothers state:—

We respectfully intimate that all goods of our manufacture are guaranteed Pure, and in strict accordance with the word used upon the wrappers; that the words "Coffee," "Chicory," and the like refer to those substances in their pure state; and that when the words "Coffee with Chicory" are used, they refer to a mixture of pure coffee with pure chicory; and we undertake and agree that this guarantee shall render us responsible for the purity of all goods sold under it.

The "Market Reports" are to the following effect:—

COFFEE.—*We have been awarded the only First Prize given for Roasted Plantation Coffee; also, a First-class Prize for Pure Ground Plantation Coffee.* Our latest advice from Colombo are to the 27th April and 11th May. Coffee was scarce, and likely to remain so for a few weeks, when fresh supplies were expected down from the interior. Business almost nil. The shipments of Coffee from Ceylon during the ten years between 1870 and 1880 give a grand total of 7,057,759 cwt., or an average per year of 705,775 cwt.; and the exports to the Australian colonies during the six months ending March 31st last were 10,044 cwt., against 6,270 cwt. for the same period last year. Here we have experienced throughout the past month a steady active retail demand for the various descriptions required by the trade; but in sales on an extensive scale there has been nothing doing worthy of note. Prices same as last month.

CHICORY.—*We have been awarded a First-class Prize for Chicory.* The article we send out is the product of Victoria, carefully selected and carried through the various stages of manipulation under our own personal supervision. It has always given the highest satisfaction, and it will be gratifying to our customers who have used no other brand for many years to learn that our manufacture has obtained a First-class Prize at the International Exhibition. Prices same as last month.

Messrs. Parsons Brothers got the only first award for pure plantation roasted coffee and also a first award for chicory.

Messrs. Parsons Brothers do not seem to deal in cocoa, but Messrs. Harper & Co., give the substance the foremost place in their Price Current thus:—

We have much pleasure in submitting to the Trade our manufactures of these articles. While leaving the final decision on their merits to the public, we can assure our Customers that the careful selection and direct importation of the raw material, the perfect machinery used in the various processes, and the fact of skilled labor from the principal European Mills having been employed in the manufacture, should be some guarantee that our different brands will be in every respect equal to the imported article, and indeed superior to the extent of the injury done to the latter by the sea voyage to these colonies. The get-up of all Packets, Tins, and Boxes will compare; favourably with any other make, while, in our "Theobroma,"

pure cocoa essence or "Cocoatina," and in our "Perfection" Cocoa we have aimed at eclipsing the efforts of all other manufacturers; and we issue these quatities in ¼ lb. tins net weight, handsomely labelled, packed in 16-lb. and 20 lb. fancy tin boxes, panelled, and with glass lids covering Chromo-Lithographs of various Australian Scenes, specially lithographed for the purpose. We call your attention to Price List, and solicit your valued orders. The lithographed tins in which this firm sells its goods are certainly very handsome. But why should they style mixtures of coffee and chicory "Oriental Coffee" thus:—

"Oriental" Coffees.

We desire to call the attention of our customers to a new brand of Coffee and Chicory called the "Oriental" Brand Nos. 1 and 2, which we are now issuing packed in (netweight) 1lb. and 2lb. tins, of a novel and elegant shape, and is specially got up to meet the demand for a first-class Coffee, the quality of which can be depended upon to be uniform. The Standard of these Coffees being so high, and always maintained, connoisseurs will find their requirements met by them, and we think the trade will see it to their interest to always have some on hand to supply the wants of those requiring a very superior article. Messrs. Harper Brothers & Co. sell the mixtures of coffee and chicory under the names of "Lion, Anchor, Castle, Harp, Chariot and Shah" brands, at prices varying from 11d to 1s 4d per lb. Ceylon growers of cocoa may be interested in the following list of preparations and prices:—

Cocoa.	s.	d.
"Theobroma" Cocoa Essence in ½-lb. tins, in 16-lb. Fancy Boxes, 6 Boxes in case ...	3	0
"Theobrama" Cocoa Essence in ½-lb. tins, 10 doz. tins in case.	2	8
"Theobrama" Cocoa Essence in 1-lb. tins, 6 dozen tins in case.	2	6
Perfection Cocoa in ¼-lb. tins, in 20-lb. Fancy Boxes.	1	4
Homœpathic Cocoa in ¼-lb. tins, in 20 lb. Wood Boxes.	1	2
Crown Cocoa in ½-lb. tins., in 20 lb. Wood Boxes.	1	0
Granulated Cocoa in ½-lb. packets, in 25lb. Wood Boxes.	0	10
Preparation of Cocoa in ½-lb. packets. 14-lb. parcels—no boxes.	0	9
The above loose in Bags. 7-lb. and 14-lb. Tins, ½d. per lb. less. Charge for tins, 9d. and 1s. each.		
Cocoa Nibs in 7-lb. and 14-lb. tins. ...	1	6

It is added

Cocoa.—We quote for our various preparations of this article, which we commend to our customers as the best of their class. We would direct special attention to our Cocoa Essence or Cocoatina, which is finer than the imported brands, and cheaper.

I do not think I need make any apology for the above copious quotations referring to the mode in which products which Ceylon colonists are interested are sold in the Melbourne markets. I have already written that Messrs. Harper & Co., Messrs. Parsons Brothers, and Messrs. Mackenzie & Co., have for years enjoyed a practical monopoly of the coffee trade; but that "outsiders," Messrs. Bright Brothers & Co. for instance, have recently ventured on importations. The result remains to be seen.

The Review of Trade in this morning's *Age* fully and strongly confirms what I have already written about the condition of the tea market and its prospects in view of the disastrous nature of the business done in China in the past season: all the accumulated rubbish in the tea districts seems to have been recklessly purchased and shipped. The result is widespread ruin amongst the buyers and bankers. It is, therefore, pretty certain that shipments from China will be very much circumscribed in the season about to open, and that consumers will have to learn to pay higher prices even for China tea. This will be the opportunity of those who have pure Indian and Ceylon teas to dispose of. The paragraph in the *Age* is as follows:—

Teas.—Active market. On the 30th ult. 400 boxes of fine common congou sold at 1s. At auction 239 packages quitted at 6¾d to 8¾d for dusty and broken leaf, 13¼d for Kaisow buds, and 11d for broken Indian pekoe. On the 31st broken leaf sold at auctionat 1d; medium congous, at 13½d. There appears to be a well-grounded expectation that the season will open late at Foo Chow this year, and probably owing to the peculiar financial difficulties which have arisen of late amongst the tea buyers, owing to the disastrous results of last season's operations, quite a new system may have to be adopted. About one half the amount of dollars has been sent up the country to purchase tea this year, and no less than nine of the old purchasing Hongs have ceased to operate, whilst even those still in good reputed credit have had to curtail their buying. Under these circumstances, it is probable that the tea growers will have to consign direct to Foo Chow for sale, and this change of business must entail delay, and it is impossible to forecast what prices may open at. Prospective engagements are the S. S. "Killarney" for Melbourne, the S. S. "Brisbane" for New Zealand, and the S. S. "Menmuir" for Sydney as first ships, to be followed by the "Galley of Lorne" for Melbourne and Sydney.

Messrs. J. Henty & Co., Mr. Burstal, Mr. Hector Mackenzie, &c., are now on the *qui vive* with reference to the first shipments of teas to this market, via Queensland, by the British India steamers. The competition between this line and the P. and O. Company will, no doubt, lead to considerable reductions in freight. Mr. Hector Mackenzie, in conversation to-day, confirmed what I have previously written about the desirability of forming a Syndicate in Ceylon to purchase, blend and ship teas. I hear of quite a number of gentlemen formerly connected with Ceylon intending to take up the sale of our teas. So far good, but the danger will be that some, like the redoubtable Rowbotham, will do injury to the trade by offering rubbish as "Ceylon tea." The operations of a Syndicate such as exists in Calcutta would be a check on mischief of this kind. In regard to coffee the *Age* reports a steady market and gives the prices I have quoted from Messrs. Harper & Co.'s report. But the difference between exhibition specimens of Fiji coffee and that sent to market is shown by the statement that "a small lot of Fiji sold on 31st ultimo for 7½d per lb."

June 6th.—I see that the *Argus* of to-day notices the inferior character of Indian teas recently sold as accounting for the lower prices. Another paper reports the arrival of the "Glammis Castle" with the first of the new season's teas. Mr. Moody explains to me that this can scarcely be regarded as the opening of the season. At the same time he mentioned to me that he had been writing to Ceylon about a consignment of Ceylon tea which sold badly, being over-burnt. This is a fault to be specially avoided, because whenever over-fired tea from China reaches this market the inference drawn is that it has been burnt to hide faults, and it is only natural that the same inference should be drawn in other cases. I can but repeat what I have already stated, that our teas are far more likely to suffer in market value from over-fermenting and over-firing than from the reverse processes.

I have seen such favourable accounts of Hunter's Disinfectant, as perfectly deodorizing night-soil, that I wrote asking the manufacturers if they would send a small quantity to the Chairman of the Colombo Municipality. Portions could be sent to leading planters. A gentleman from the firm has been here and promises to send a specimen shipment and to give me all information in time for the mail of the 21st.—Yours faithfully,

A. M. Ferguson.

THE AUSTRALIAN TEA MARKET:

CEYLON TEA IN MELBOURNE. THE COMMISSIONER'S WORK.

The following is Mr. Moody's letter referred to in the Commissioner's communication to Mr. Bruce published yesterday. This letter should, in fact, have preceeded the extracts from price currents, &c., given by the Commissioner :—

Melbourne, 3rd June 1881.

DEAR FERGUSON,—I am serving on the Jury of our Supreme Court for a few days, so must write you regarding some matters, which might otherwise be communicated verbally.

Enclosed you will find the following marked Auctioneers' Catalogues, say of

Ceylon Teas	offered on	10th	May 1881.
Ceylon Exhibits	do	10th	,,
Calcutta Syndicate's Teas	do	26th	,,

Other sales of both Ceylon and Indian teas have been made at auction and privately, but only of trifling extent in comparison with above.

In imitation of style adopted for the Calcutta Tea Syndicate, I endeavoured to make an attractive Catalogue of Ceylon Teas for sale by public auction on the 10th of May, and you will observe the result in the 11 lots offered by Jas. Henty & Co., which the auctioneers supplemented by seven other lots, so making the catalogue more imposing in its character.

The lots were certainly a long way off from Exhibition Standards, but 10 of the lines offered by us sold at fair prices, leaf considered: the rest of the teas did not sell.

If your planters would now send regular supplies of good leaf teas to Melbourne, our market is ripe to take a fair quantity, at similar prices to what the same quality of Indian teas sells at. In fact, two of our leading grocers are most enthusiastic in favor of Ceylon teas.

Owing to the small quantity of individual exhibits to be offered by auction on the 10th inst., I directed the auctioneers, on your behalf, to show no samples and so prevent the waste consequent on the usual method of selling, viz., by giving the trade samples of each lot offered. This I must admit was a great disadvantage to the exhibits offered, but there was no other course open, and, after all, nearly every one in in Melbourne had carefully examined the exhibits in the Court, and knew all about the respective merits of each grower. To give samples would have absorbed the entire lot of some of the smaller lines offered.

Considering this novel mode of selling tea and coffee, the prices realized may be considered satisfactory. For Loolecondera tea, there were many bidders, it being finally knocked down at 6s per lb, duty 3d paid. The bidding for coffee was free and brisk, some lots selling up to 1s 6½d per lb, duty 3d paid. Cinnamon realized from 1s 5d to 1s 8d. Vanilla was eagerly competed for and sold at 33s per lb. We have enquiry for more: what is it worth?*

The show cases, carboys, etc. sold at wretched prices, but Melbourne is glutted with these goods since the close of the Exhibition.

Catalogue of 26th May will show you we have again placed a large lot of Indian teas on the Melbourne market. The quality was inferior to previous shipments. There was no fine tea and a good deal of broken and dusty samples, so prices may seem low, but are really as good as could be expected, especially as we are just at the end of our season.

* The finest Bourbon vanilla realizes no more than 37s. (as a maximum), so that Mudaliyar Jayetilleke's parcel has got a tiptop price. The average price in London is 15s. to 25s. per lb.—ED.

In 1879, the season opened on the 6th July by the arrival of the "Brisbane" steamer direct from Foochow. In 1880 the "Killarney" arrived on the 26th July. This year the arrival may be delayed to early in August. Our Tea Buyers usually try to clear off old stocks before arrival of new teas; so this makes May to July bad months to sell in.

If during the coming season teas of a desirable quality are steadily shipped from India and Ceylon, I expect to see them take a very firm hold throughout Australasia.

The auctioneers hope to have account sales ready for you by Saturday, and this will close up our connection together in Exhibition work—an event I deeply regret, for your uniform courtesy and genial nature has endeared you to me and a very large circle of Melbourne residents.

Your zeal on behalf of Ceylon is undoubted. The newspapers throughout the Colonies testify to your untiring energy in bringing Ceylon and its products prominently before the public of Australia, and Sinhalese names and terms now slip as glibly from the tongue, as our Australian native names do.—I remain yours most siucerely, J. V. MOODY.

AUSTRALIAN FRUIT FOR CEYLON AND INDIA.

The letter which we published on Wednesday from Mr. A. M. Ferguson, Commissioner for Ceylon at the International Exhibition, gives an encouraging account of an experimental shipment of Australian grapes made to that island. A box containing 40 lb. of fruit, packed in "nice, clean sawdust," was placed in the ice-room of one of the P. and O. boats, and arrived in perfect condition. The voyage from Adelaide to Colombo occupied 25 days, but "not a single berry showed "the slightest sign of injury or decay." "Superlatives," says Mr. Ferguson, "are resorted to in order to de-"scribe the perfect condition in which the fruit had "arrived and its deliciousness." No doubt conveyance in a cool chamber had a good deal to do with the success achieved, but the absence of such accommodation, as a rule, need not discourage those who think of engaging in the trade. Before very long, we shall probably see all large steamers fitted with a refrigerating room to accommodate the fresh provision trade. It will be a part of the provision for carrying ordinary cargo. People in Australia are vitally concerned in promoting the business alluded to, as the productive powers of the country in every way are far beyond the requirements of any population we are likely to have for a century or more. It appears to us that they might do a great deal towards obtaining the sort of accommodation spoken of at an early date by a little organisation. Steamship Companies would be more likely to fit up their vessels with the necessary cold-producing appliances if they knew that there were several associated bodies ready to commence shipments of various articles of food, than if they were left to incur expense on an uncertainty. Our reason for thinking that they would prefer dealing with associated bodies is that certain losses are generally incurred in obtaining experience in a new trade, and when these fall on individuals they are apt to become discouraged, or unable, from want of means, to continue operations. Those engaged in producing articles suitable for export, we submit, lose a great deal through want of co-operation. We should like to see the wine producers, the dealers in dairy produce, the fruit growers, and those prosecuting other food-producing industries, associated for the purpose of sharing the expenses inseparable from the establishment of a "name" in the English and foreign markets. If they were to go to work intelligently and liberally, always bearing in mind that a little

present loss is wisely incurred if only it will lead to future profit, we believe that great things might be accomplished within one-tenth of the time, and with only a tithe of the loss which desultory effort will require.—*Melbourne Argus.*

SAIGON.

A Report by Consul Tremlett on the Trade, Commerce, and Navigation of Saigon and Cochin-China for the year 1880 appears in a Blue-book which has just been published.

Crop of 1881:—Reports from the interior to the end of November, from all districts, were published, and were not so favourable as was expected, about half only announcing the crop as satisfactory; later accounts do not alter the impression, and there seems to be an indisposition to giving a decided opinion of any sort.

Gamboge.—Rather more than usual came to market, but still only a small quantity—400 piculs.

Cardamoms.—This valuable article is receiving more attention, and the production has been quintupled—1,350 piculs.

Pepper.—The trade has fallen off sadly during the last twelve months—only 3,000 piculs having appeared, against double the quantity for some years past.

Cotton also shows a remarkable decrease, no doubt owing to the unfavourable weather in the early days of the year; only 6,882 piculs were exported against an average of 25,000.

Sugar.—The efforts by Europeans seems to result in a drain of all available resources and a final collapse.

Silk.—The export, if not the production (in French Cochin-China), is fast increasing; the more frequent opportunities of communicating with Tong King favours the trade, and 660 piculs passed through our hands—no great amount, but more than double that of late years.

As to Agriculture, the following remarks and facts are interesting:—

The usual donations were granted several enterprisers from the fund set apart for that purpose, principally to the sugar plantation at Lacan, which received 15,000 fr.; pepper plantation at Thudaumot, 2,500 fr.; pepper plantation at Phu-quoc, 15,000 fr.

The sugar plantation of the Nouvelle Esperance has been wound up, and the whole property realised $19,100 at auction on November 18. The purchaser, probably with a view to ascertain the actual result of three years' cane growing, is cutting and crushing the whole; the outturn will be the most valuable critique possible upon the advisability of continuing or extending this branch of agriculture.

The Société Agricole, which started large plantations in this colony and Cambodia, is, I hear, being wound up.

An exhibition of products and manufactures was held during March, and medals distributed as under—8 gold, 89 silver, 111 bronze; the variety of the manufactures was surprising, embodying such widely different articles, as orange wine, bear, aerated waters, crystalised sugars, chocolate, coconut oil, preserved fruits, arrowroot, flour, silk fabrics, cotton stuffs, embroideries, cordage, mats, bricks, and tiles, agricultural implements, and jewellery in profusion.

Coffee.—I do not hear any very satisfactory accounts about this plant, though a little of Phu-quoc growth has been on sale.

Perak.—Mr. H. S. Deane writes:—"I am at present preparing for the Straits Government a general map of Perak, Penang, Province Wellesley No. 1, and I hope soon to send you a copy. Evidently the Government of the Straits mean to avoid the how-not-to-do-it policy in opening up their lands available for plantations.

A NEW CEYLON INDUSTRY: JUTE.

Mr. Elliott is good enough to inform us:—

"About *jute*—I was some months ago at Chilaw and my attention was attracted by seeing a cart load of what appeared to be a curious sort of straw. On enquiring, I was told it was used for making the twine used by fishermen. Not knowing what it was I brought down a couple of bundles and showed Mr. Wm. Ferguson a specimen, who at once recognized it as the jute plant. I send you these bundles. I was told the plants grow plentifully in the Pitigal Korale of the Chilaw district—just north of the Maha Oya. One of the Mudaliyars could, I should say, give better information."

The bundles in question appear to contain a very promising sample of jute, the stalks being well grown and nearly four feet long. We shall endeavour to get a mercantile opinion of their value, failing which, it must be arranged to send samples of the Chilaw jute to Dundee for report.

THE GOLD-BEARING DISTRICTS OF SOUTHERN INDIA.

To the Editor of the Melbourne Argus.

Sir,—Having visited the Devalah gold-mines some three and a half years ago, I am not surprised at the accounts now published of the success of the first large experiment in quartz crushing. As I was the first Indian editor who had gone to see the operations of the Alpha Mining Company, Mr. Minchin, Mr. Ryan, and the other directors were present to receive me, show me over the works, and afford full information regarding their operations and their success so far. At parting they presented me with a piece of gold-bearing quartz, computed to contain about two guineas' worth of the precious metal. The fractured surface of this specimen was covered with specks of gold, quite obvious to the naked eye, while a magnifying-glass brought out the real richness of the stone. As I have handed the specimen to Mr. Cosmo Newbery, who has kindly promised to report on its character and value, those having interest in the subject can see the quartz, and when the pressure of his engagements in connexion with the Exhibition awards is lightened, I have no doubt Mr. Newbery will confirm my opinion as to the promising character of the stone. As the means of the original Alpha Company were limited, they had not been able to run a shaft much below the surface, so that the quartz which they were crushing had still a large portion of pyrites in its composition, and had patches of a rusty brown colour, such as I have seen on some of the specimens of auriferous quartz shown at the Melbourne International Exhibition. Having read the reports by Mr. King, of the Indian Geological Survey, on the Wynaad quartz reef, and seen for myself, I formed and published the conclusion, which I have never seen reason to qualify, that deep shafts would lead to the finding of stone exceptionally rich in ore and much less mixed with pyrites than the quartz on or near the surface. The results already obtained seem to justify the opinions I had formed, and there can be little doubt that there is a great future for Southern and South-western India as a gold-yielding region. It has been that to a certain extent from far-back antiquity. It was interesting to see the surface of the out-cropping quartz dotted with pot-holes, some of them probably thousands of years old, in which the natives of Malabar had, since the time of Solomon, and probably long before the era of the monarch in whose time silver was not accounted of, because gold was so abundant, conducted their simple crushing operations. Granted that the Ophir of the Hebrew scriptures was not a particular country but a region, there seems little reason to doubt that the Malabar

coast of India, as well as the Island of Ceylon (Taprobane), were included in the region whence gold of Ophir, with apes and peacocks, was brought. The fact remains that the names for apes and peacocks are not Hebrew words, butthe Tamil names by which monkeys and peacocks are still called in Southern India.

More interesting to a large class of your readers than the discussion regarding Ophir is the now ascertained existence of a wide extent of rich auriferous quartz in Wynaad and Mysore. The danger is that the accounts received may lead to a "rush" of miners from Australia to the Indian gold-fields. I feel it a duty, therefore, to a country where I have experienced so much kindness, to utter a word of warning. Devalah, the scene of the successful experiments now reported, is exceedingly insalubrious for a considerable portion of each year. The district lies at the base of the great Nilgiri (Blue Mountain) range, at an elevation of 2,500 ft. above sea level, while the plateau in which the neighbouring sanatorium of Ootacamund is situated is 7,000 ft. altitude, with peaks rising, as in the case of Dodabetta, to considerably over 8,000 ft. As is the case with all places so situated in India, and even in Ceylon, Devalah is haunted by malarious fever—the "jungle fever" of the tropics, from which the northern regions of even this favoured land of Australia are not exempt. What the deadly "terai" of the Eastern Himalayas is to the delightful hill region of Darjeeling, which looks down on the rich but pestiferous plain below, that Devalah, with most of the Wynaad, is to the Nilgiri (Neilgherry) mountain ranges, in which the fine sanataria of Coonoor (6,000ft. elevation) and Ootacamund (7,000ft.) are situated. Bracing climate and pestiferous are separated by only a few miles of distance. Superior elevation is an important factor in the difference, but there are other conditions. The soil at the bases of the Indian ranges consisting of the *débris* of the mountains, washed down during thousands of years, and of humus resulting from decayed vegetation, is rich, but gives out pestiferous gases when stirred. The rainfall, too, is very heavy, but badly distributed, the great bulk of 200 in. or more falling in four months out of the twelve, the remaining eight being generally distinguished for but seldom broken drought. That condition alone (of rainfall) involves insalubrity, and the greater salubrity of the mountain region of Ceylon is due to the more equal distribution of the monsoon rains. Of course there is the qualifying circumstance that in the Wynaad, a healthy and health-restoring region is close to the fever region, and could be rendered easily accessible by a winding railway (I have strong objections to the ladder-railway, Rhigi pattern, by which it is proposed to connect Ootacamund with the "low country"). It is possible that rich quartz, brought to the surface during the healthy period of the year, might pay the expense of transport up to a healthy altitude, there to be crushed. In that case the digging, mainly by natives (who, though they suffer, do not suffer so much as Europeans from fever), might go on all the year round, the crushing and other operations being conducted above the fever region by Europeans. This is a crude idea of mine, and may probably be pronounced impracticable. If European miners seek employment in the Wynaad, they must take the risks of the position, looking at the qualifying fact that a sanatorium is close at hand. It is right to add, however, that some constitutions, once affected by a full dose of the fever poison, are never able to throw it off, even by the generally potent aid of quinine, and "sending the patient into purer air." Some of the Mysore districts are healthier than those of Malabar, but it must be understood that besides the ordinary influences of a hot climate in enervating Europeans and rendering them unfit for manual labour, the dangers of malarious fever and the consequences which follow are present and formidable. It is possible, to doubt, that the auriferous reefs may be followed up to the healthy altitudes, but the vast proportion of the reefs are in the sub-ranges—low, hot, and generally feverish.

Gold prospecting is now going actively forward in Ceylon, and with good hopes of success. Gold in minute particles is abundant in some of our rivers, and the natural conclusion is that deep digging towards the sources of those rivers may reveal quartz rich in gold. A little more than a quarter of a century ago we had our "rush" in the Indian Island. A couple of diggers from Australia reported gold in the Maha Oya, a stream turbid and unhealthy from the sea almost up to its source. Persons flocked to the scene and found gold dust, but no nuggets, and in a few weeks all were dispersed by fever. The Australians, subsequently, tried digging up in our sanatarium (Nuwara Eliya, 6,200ft. altitude), and Sir Samuel Baker, who was resident there at the time, has in his books on Ceylon strongly expressed the opinion that if means had been provided to sink shafts to a proper depth, success would have been the result. The question will soon be set at rest, and I trust Ceylon will soon take rank amongst the gold-yielding countries of the world. Any amount of "black" labour is available in Southern India and Ceylon, and what I wish to impress on the mining class here is that neither India nor Ceylon is "a good working man's country." The true function of the white man in the tropics (and I do not except the tropical region of Australia) is to act as a director of Asiatic labour; he to find and exercise brain power, they to supply the bone and sinew. For a certain number of intelligent, educated European miners suitable employment will, no doubt, offer in connexion with the Ind an gold mines. But a "rush" to India of labouring miners is greatly to be deprecated, because sure to be disastrous, from the insanitary conditions I have felt it my duty to describe.—Yours, &c.,

A. M. FERGUSON,
June 10. Editor *Ceylon Observer*.

CEYLON TEAS.—Messrs. Greig and Murray sold this day (says the Melbourne *Age* of 11th May), at their rooms, under instructions from Messrs. James Henty & Co., 274 half-chests. Ceylon tea, up 1s 4½d per lb. in bond; on other accounts 263 half-chests Foo Chow tea at 9d to 1s 6½d per lb. in bond; 250 boxes candles, 8¾d to 9½d; 168 bags rice, £9 5s to £13 per ton in bond, all faults; Mauritius sugar up to £34 15s for grey crystals. Under instructions from Mr. A. M. Ferguson, Commissioner for Ceylon, Ceylon teas, at from 1s 3½d to 6s per lb.; 25 barrels plantation coffee, at 1s 2½d to 1s 6d per lb.; cinnamon, 1s 5d to 1s 8d; rope 34s; oil, 38s. On other accounts, coffee 1s 4½d.

THE JAVA COFFEE CROP.—BATAVIA, 21st May.—Messrs. J. Peet & Co. write:—Coffee, Java: A Samarang crop of 2500 piculs, held back by the planter in expectation of an improving market, was sold by tender and realised for—Demerara kind, fair, f. 40.40; good, f. 27.30 to f. 38.05; inferior, f. 33.60; ordinary prepared, f. 34.05 to f. 35.50. The Demerara kind way very much discolored. Advices since received by telegram state a further decline in the European markets, and above prices may now be considered very full ones. The Government Java crop of coffee for the current year is estimated at 815,300 piculs, equal to 49,500 tons, and it is expected that it will fully reach this figure. The private crop for 1881 will probably come to about 17,000 to 18,000 tons. One hundred thousand piculs of Government Java coffee will be offered by public auction in Batavia. Coffee, Padang: Some estimate the June sale at 30,000 piculs, or in an case at fully 26,000. On the 7th inst. there were in store 11,495 piculs, with 9 per cent. fancy qualities.—*Melbourne Age*. [Total 1,340,000 cwt, or nearly twice the coming Ceylon crop.—ED.]

Correspondence.

To the Editor of the Ceylon Observer.

JUTE.

Colombo, 15th July.

DEAR SIR,—Referring to the bundles of jute you sent round the Fort to-day for inspection, I notice you hint in your issue of last night that, failing your getting a mercantile opinion here, of its value, samples may have to be sent to Dundee for report

As jute, I believe, is not sent to Europe in its natural state, but only after its conversion into the fibre or jute of trade, would it not be better, in every respect, if you were to send a sample to Calcutta, whence the article is exported so largely? It occurs to me that you would obtain all the information you require from this quarter more completely and in less time than from Europe.—Yours faithfully, Z.

NEW COFFEE SEED AND LEAF DISEASE.

SIR,—The further progress of the small plantation of Blue Mountain coffee at Henaratgoda should be of paramount interest to planters at the present time when our once faithful friend from Araby the Blest has failed us so signally.

To have used the same seed as we have been doing for about half a century seems, as far as the purpose for which we cultivate this plant—its fruit-bearing capability—is concerned, little short of slow murder. I verily believe the appearance of the fungus in one of the last planted of the coffee districts was due to a blindly suicidal custom of putting in the same old seed. Parts of the Madulsima estates were planted with stumps from abandoned land belonging to Gowarakelle, which land was abandoned, not because it would not bear, but for the reason that it was too distant from the pulping-house. Local influences, such as an excess of humidity, might have caused the development of a fungus in the already weakened and degenerate plant.* For instance, I remember there was a long continuance of wet weather towards the end of 1868. It lasted nine weeks with only two or three days' cessation. So persistent were the rain and mist that despite constant turning, the coffee was sprouting in store, and in about the following May leaf disease showed in its most virulent form—I have never subsequently seen a worse-stricken patch—on a portion of Galoolla, but on the adjacent estates very partially, as an affected leaf only here and there could be found.

Old planters who can look back some five lustres will readily admit that the general bearing of estates was much greater then than at any time afterwards, and that a gradual decadence has occurred. Sixteen cwts. an acre was not rare, ten cwts. on very many estates was as a matter of course yearly looked for, and if there was a sufficiency of coolies on the place was yearly obtained. Indeed it would be difficult to say what the bearing powers of the trees were then, as in the majority of cases a large proportion of crop was lost from a want of coolies to pick it. It is said the Bambarabotuwa estates were abandoned twenty-five years ago, because they would not bear more than five cwts. an acre.

An old Ceylon planter, now a proprietor in Coorg, mentioned to a friend that the old fields of coffee there, possibly enough planted with Ceylon seed, were now quincunxed with the indigenous Nakanand variety, which he asserted gave him at the rate of eight cwts. an acre. If that can be done in Coorg, it is surely worth a trial in Ceylon. All varieties of coffee, as Dr. Trimen recently pointed out, are liable to the fungoid contagion, but it does not follow all are equally unhealthy; and I assume it is quite analogous to say that a constitutionally healthy person would easily recover from a contagious disease that might cause the death of a constitutionally unhealthy one. —Yours &c.,

A TWENTY-FOUR YEARS PLANTER.

*We see in the mineral kingdom subjects that are in the last stages of weakness or sickness become the victims of insect parasites.

"THE CHILAW JUTE" *NOT* JUTE BUT CEYLON HEMP!

AN OLD PRODUCT: SUNN.

DEAR SIR,—In reference to a paragraph in your issue of yesterday headed, "A New Industry—Jute," I can scarcely think that I misled Mr. Elliott by calling his bundles of fibre-producing stems from Chilaw jute, which is the Bengali term for the fibre of the Corchorus capsularis, and C. olitorius, about which you extracted an account from Maunder's *Treasury of Botany* a short time ago. I at once recognised Mr. Elliott's bundles as the produce of Crotalaria juncea, Linn., the Hana of the Sinhalese, called Ceylon Hemp. Sunn is the Hindi name for this plant or its fibre, and under this name it is known in most parts of India. The Sunn, Crotalaria juncea, is no new product in Ceylon, as it has been cultivated and manufactured by the Sinhalese into twine, time out of mind, and fields of this plant grown in the Chilaw district, with its broom-like flowers, are very conspicuous.

The two species of jute plants, Corchorus, are common enough about Colombo, and several years ago the late Sandy Brown tried an experiment in growing them from Indian seed, but with no useful result that I can recollect. As already stated, the Sinhalese have grown the Sunu plant for their own use, time out of mind, but I question much if we have the soil and the labour in Ceylon to compete with India in the cultivation of jute or sunn for export.

I send you with this branches of corchorus capsularis, with ripe and unripe fruits on it, which I found growing near the Bridge of Boats this morning. —Yours truly,

W. FERGUSON.

[Nothing like giving the jute plant a trial, and Mr. Dobree must have both good soil and abundance of labour near Galle for the purpose.—ED.]

MR. GRAHAM ANDERSON'S VIEWS ON COFFEE LEAF DISEASE.

Barguni, Muuzerabad, Mysore, 26th June 1881.

DEAR SIR,—As you have not yet honored me by passing your promised detailed remarks on my essay on "Fungoid Disease," I feel sure you will pardon me if I venture to draw attention to the gratifying manner in which I consider Mr. Schrottky's lucidly expressed opinions support many of the views I have long entertained in regard to the chain of events which precede an attack of leaf disease. I am naturally proud to find that portions of my theory—founded on a careful study of the subject during the last six years—have at last obtained the support of such an eminent authority, who, having brought so much talent and energy to bear on the investigation of the scourge, is peculiarly well fitted to express a matured and reliable opinion. I now feel that many of my remarks in regard to the analogy which exists between the causes of certain zymotic diseases which afflict the human being, and those conditions which induce, or at least precede or accompany, some forms of parasitic disease in plants have received most satisfactory confirmation. My constant endeavour has been

to draw special attention to the fact that a fungoid disease is the natural result of a vitiated condition of the sap and of a gradual alteration in the condition of the contents of all cellular structures. Mr. Schrottky supports my conclusion that the presence of food congenial to the life and requirements of the fungus occurs during a peculiar state of the starchy and sugary constituents, and I have clearly stated my opinion that the deficiency of alkalies and phosphates in an available form in the soil is the cause of an abnormal continuance of this otherwise transitory condition.

Owing to the fact that there is no longer any chance of remuneration from the Government of Java, I feel the element of rivalry has been entirely eliminated, and the more healthy spirit of emulation has been encouraged among all those who have interested themselves in the investigation of the disease.

Having read of the careful researches of Drs. Emmerling and Wagner in regard to the effects of the exhaustion of the mineral constituents of the soil, I venture still to maintain my long cherished opinion that constitutional treatment can alone be trusted to effect a permanent cure.

I am a firm believer in the benefits to be derived from surface stirring and the proper utilization of organic matter; but, while endeavouring in every way to improve the mechanical condition of the soil both by superficial and deep culture, I am still convinced that, to be enabled to continue the persistent cultivation of a special crop, due attention must be paid to the maintenance of the necessary quantity of mineral plant-food.

In conclusion, I may be permitted to say a few words in regard to the effects which I am led to believe may result from the application of antiseptics to the soil. Professors Schœsing, Müntz, and Warrington, after elaborate experiments relative to the ferment theory of nitrification, have conclusively proved that the presence of an antiseptic in the soil entirely prevents any oxidation, and, as leaf disease appears generally at a time when nitrogen in an available form is supposed to be deficient, I shall await with great interest the experiment of applying carbolic acid to the land.

Doubtless, the addition of lime may alter the conditions, but I still suppose it will be granted that as long as the carbolic acid retains its virtue as a remedial agent for the cure of the disease, so long must its antiseptic powers be in full force and be calculated to hinder the conversion of nitrogen into an available state as plant food.

I may remark, for the benefit of my brother planters, that potash, magnesia, ammonia, and phosphates, have been found by Professor Jamieson to give the best results in the recent Aberdeen Agricultural experiments, that Professor Jamieson has come to the conclusion that "finger-and-toe" is mainly caused by the application of large quantities of forcing manures highly saturated with sulphuric acid. (*Field*, 28th May 1881.)

I have recently been making inquiries in regard to the price at which my neutral sulphate dressing can be supplied, and have been informed that, if it is to be composed of the very best articles, it will cost about £10 10s. per ton in Scotland.

A commercial friend has favored me also with information in regard to kainit, and recommends it as being a cheap source of sulphate of potash and magnesia.

Doubtless a mixture composed of kainit, sulphate of lime (gypsum), mineral (undissolved) phosphate, and some local form of ammonia, would prove a most valuable manure, but I have one very great objection to kainit—the large percentage of chloride of sodium it contains (30·5)—a substance which, I have found in my experiments, most materially interfered with the action of the sulphate dressing recommended by me.

I am aware that on some soils and at certain seasons of the year salt may be used with good results, in conjunction with various forms of ammonia, but, as far as I have tried it, I am of opinion that in unskilled hands it may often do more harm than good. Will any of your contributors kindly oblige me by giving information in regard to the recorded effects of kainit in conjunction with ammonia on coffee.—I am, dear sir, yours faithfully,

GRA. ANDERSON.

[Simultaneously with the above letter, we receive an official paper from the Government of Madras with opinions on Mr. Anderson's experiments, from which we quote as follows :—

Government of Madras, Revenue department, 11th June 1881. Read the following papers: From Colonel R. H Beddome, Conservator of Forests, to Surgeon-Major G. Bidie, M.B., Superintendent, Government Central Museum, Madras, dated Ootacamund, 6th May 1881, No. 125.

I think that the applications recommended by Mr. Anderson are worthy of trial on small given areas, but it will probably be found that the expense would be prohibitive in relation to large estates, so the application will be really of no practical value even if as efficacious as anticipated.

Government have no coffee cultivation on which to experiment, so it can only be done by private planters; but, considering the ravages of the leaf-disease, the question would be zealously taken up if planters anticipated any practical results.

It would be an advancement in our present knowledge to prove that the attacks of the Hemileia fungus are the consequence of the juices of the coffee plant being in a vitiated condition, and if such be proved no trouble or expense should be spared in testing what applications will most cheaply and quickly prevent this; but, as far as my experience goes, young and exceedingly healthy-looking plants are constantly attacked as well as plants out of condition or old plants, and the assertion that a cessation of growth precedes an attack of the leaf-disease is not, I think, correct, as I have seen fine young plants one to two years of age in full growth on virgin soil suddenly and seriously attacked, and the disease generally kills these young plants right out, when the old trees, though often in poor condition and unhealthy-looking previous to the attack of the Hemileia, are seldom, if ever, actually killed.

From Surgeon-Major G. Bidie, M.B., Superintendent, Government Central Museum, Madras, to the Secretary to Government, Revenue Department, Madras, dated 1st June 1881.

In returning the publication which accompanied G. O., No. 604, of 6th April 1881, I have the honor to forward a letter from Colonel Beddome regarding Mr. Anderson's Essay on Fungoid Disease, and to state that I agree with Colonel Beddome generally in his recommendations and conclusions.

It also accords with my observations that when leaf-disease appears on an estate it attacks young and vigorous plants as well as those in poor condition, but there can be no doubt that chemical manures like some of the kinds indicated by Mr. Anderson would be of great service in helping the coffee to recover condition after an attack of leaf-disease.

In a paper by Mr. William Bidie of Coorg, which was recently read before the Linnean Society, he stated that he had observed that coffee plants raised from Ceylon seed were much more liable to an attack of leaf-fungus than Coorg plants, and implied that possibly the germ of the disease lurked in the seed. Since that paper was read some Cryptogamic botanists have, it is stated, been investigating the subject and are said to have found that the embryo of a seed may contain the germs of fungoid disease. This would explain why, as pointed out by Colonel Beddome, young plants are often attacked, and also in some measure why the disease should prove so virulent in them. It further points to the necessity for exercising great care in the selection of seed.

It would be premature, I think, to say more at present as regards leaf-disease, seeing that an expert has been specially sent out from England by the Colonial Office

to investigate the subject in Ceylon. These inquiries are still progressing, and, pending the final report, it would be unwise, I think, to give any dogmatic opinion or advice.

It may be mentioned that Mr. Anderson was good enough to forward me a copy of his essay some time ago, and that having brought it to the notice of the Agri-Horticultural Society, they published his practical "conclusions" in their Proceedings.

Order thereon, 11th June 1881. Colonel Beddome is of opinion that the remedies proposed by Mr. Anderson might be tried on small given areas, but considers the expense attending the trial prohibitive as regards large estates.

While concurring generally with the Conservator's conclusions, the Superintendent, Government Central Museum, thinks that chemical manures would assist the coffee shrub in recovering its condition after an attack of leaf-disease; but recent investigations would rather point to a selection of healthy seed as being the main preventive of the disease, as it is not improbable that germs of the leaf-disease lurk in the seed.

The above is addressed to the Commissioner of the Nilgiris; the Conservator of Forests; he Superintendent, Government Central Museum; the Honorary Secretary, Nilgiri Planters' Association; the Honorary Secretary, Wynaad Planters' Association.—ED.]

CINCHONA C. LEDGERIANA PLANTS ON YARROW AND ST. ANDREW'S ESTATES, CEYLON.

St. Andrew's, Maskeliya, 16th July 1881.

DEAR SIR,—The origin of the Yarrow Ledgeriana trees is probably of interest, and as the paragraph in the local *Times* is hardly correct I may as well give the following particulars.

When the late Mr. McIvor was in Ceylon in 1875, I had the benefit of a visit from him, and he gave me, amongst other seeds, a small quantity of the C. Calisaya, saying that it would yield a very rich bark, but would never be more than a stunted shrub in size. While his opinion as to the richness of the bark has proved true, his idea as to the growth of the plant, founded on his experience at 7,000 feet elevation, has proved wrong, when the proper elevation is selected.

The oldest of the plants resulting from this seed were put out on this estate in June 1876, and, as an exporiment, I plauted the remaining plants and some cuttings on Yarrow in December 1877.—Yours faithfully, THOS. NORTH CHRISTIE.

HIGH PRICES FOR RED BARK.

Kirkoswald, Bogawantalawa, 18th July 1881.

DEAR SIR,—In reply to "Peruviau" and "Cateador" in your issue of 12th inst, the Kirkoswald succirubra trees, which produced the 5s 5d bark referred to, were eight years old. The following extract from Messrs Brookes & Faith's Fortnightly Report describes the bark :—

Mincing Lane, 9th June 1881.

* * * "Succirubra—Importers were free sellers, and nearly all offered sold at very irregular prices, but ordinary up to middling quality quill showed a decline from 2d to 4d per lb., excepting sightly Druggists quality, which sold with capital competition at full values. We would call particular attentiou to 12 cases mark "Kirkoswald" recently arrived per "Navarino." The quality of these was the finest and most handseme we have seen in this market for a considerable time past, being very bold, fine stout, even unbroken selected sightly quill, about 2 feet long, and realised 5s 5d per lb. We understand the analysis turned out well, but the high price obtained was due to the fine appearance. Other lots of druggist's quill sold from 2s 10d to 3s 8d per lb.

I quite agree with "S. T." in your issue of 16th intant in considering this district eminently suited for cinchona cultivation, for in no other have I seen more luxuriant growth, nor have I heard of better analyses being obtained from trees of the same age.

From the 8 year old trees *cut* down in February last, the average weight per tree was 9 lb. (stem and branch only) dry bark.

I strongly recommend the packing of good druggists' quill in cases, on the estate, to prevent its being damaged in transport; and feel certain that had I packed the contents of the 12 cases (mentioned in B & F.'s report) in ordinary bags, they would not have reached England in as good order, or fetched as good a price.—Yours truly, R. B. ARTHUR.

ENGLISH FRUIT TREES IN CENTRAL AFRICA.—A correspondent of the *Times* states that a small selection of English fruit trees—apples, pears, apricots, cherries, figs, plums, etc.—despatched to Central Africa last December to one of the upland stations of the Universities' mission, bore the three months' journey so well as to show signs of life and growth within a very few days of their being planted in their new home.—*Colonies & India.*

THE YARROW LEDGERIANA TREES.—It appears the "Ledger" trees on Yarrow, from which the famous sample was takeu which obtained a valuation of 17s. a lb., were grown from a quantity of the true seed obtained by Mr. MacIvor from Mr. Ledger, and by the former given to the extent of a quarter of an ounce, to the present proprietors of Yarrow estate. From this small quantity a number of plants were raised which were partly distributed to two friends, and the balance are now to be seen on Yarrow; now about three years old, of which one hundred and forty are of the undoubted "Ledger" variety, the remainder of a less certaiu character, though evidently very good. The sample analysed, for it was only sample, was taken from a few trees: they are about twelve feet high and six or eight inches in circumference and are now coming into flower. The whole of this valuable seed will be kept for forming nurseries with which to plant up the remainder of the Yarrow estate, making it a most valuable property.—*C. Times.* [Seeing that Mr. McIvor died early in 1876, he could scarcely be the person who gave the proprietor of Yarrow seed some four years ago?—ED.]

AMERICAN TEA.—Some tea from Georgia found its way into the New York market, and has been discussed by the trade there. The tea was grown by Mr. H. Jackson, formerly of Assam, from wheuce also the plant came. We learn that the experts—"After testing the different samples, were united in the opinion that the teas were very good when compared with Indiau tea—which, however, is a kind very little in use in the United States. It was also remarked that the American tea lacked the strength of that grown in India. The experts further said that in order to test the quality of American tea it is necessary to prepare it as Japan teas are made, and it was promised that the next samples would be so prepared. The estimated cost of the tea on exhibition was from 16c. to 20c. per lb." We quote this from a trade journal. It is difficult to understand why the American teas "were good when compared with Indian tea," when it is admitted that they "lacked strength" by the same comparison. With all due deference to the experts, we are of opinion that the American consumer will be less anxious about the preparation of this tea according to the Japau fashion when he learns to appreciate Indiau tea.—*Home and Colonial Mail.*

NEW AND OLD PRODUCTS.

THE RAINY SEASON—CRICKETS—BLOSSOM ON LIBERIAN COFFEE—CACAO AND WHITE ANTS.

Western Province, 16th July.

I see many complaints from various districts, of nsufficient rain for planting purposes. I am glad to say that since the middle of March the longest spell we have had without rain was eight days in the middle of May. We have had nothing like the thunder showers of the first four months of the year lately, but we have had ample rainfall for the growth of our cultivated plants in June. I suppose the amount would not have made a great figure on the register of a rain-gauge, but there was no day on which more or less did not fall. In 1879 we had no rain from 23rd June to 26th July, and in 1880 there was hardly any rain in June. July so far has given more sunshine than usual, but we have had rain enough to maintain the growth of the weeds, which have been, and continue to be, very troublesome,—so much so, that I had all hands weeding during the whole of last month, and I have had to make some addition to my labour force, to enable me to deal with them.

I have ascertained the number of plants destroyed by crickets to be 19 per cent. The whole proportion cut was 34 per cent, but 15 per cent are growing again, but they are, and will continue to be, six months behind those that remained untouched, which now range from nine to eighteen inches in height, and the most forward have begun to branch. I was absent for four days last week, and on my return I saw a decided advance, that I would perhaps not have noticed had I seen them daily as usual.

The nursery plants are so far advanced, that I might plant at once, if I could be certain of the weather, but we dare not assume that the next three months will be as favourable as the past three.

There was a small blossom ten days ago, but the heaviest blossom is still to come, and, if the weather is tolerably favourable, may be expected towards the end of this month. The numerous varieties of the Liberian coffee have each their special habit as to flowering. One variety branches at fifteen inches and bears heavily on its primaries without producing a secondary; while another, that commonly begins to branch at two feet, produces little or nothing on its primaries, but throws out its secondaries by the time the primaries are a foot long. Those that run up from three to five feet, before branching, bear well on the primaries, but show much more inclination to grow to suckers than secondaries. This variety is, I fancy, the tree coffee, that is said to grow thirty feet high and yields 30 lb. of produce. (?) There is still another variety, with a long smooth leaf with a much lighter shade of green than the others, that is extremely liable to leaf disease, and once attacked is never able to shake it off. My idea of the proper method of dealing with this kind is to root them out and burn them, but I will give them a respite till I see they get on, between now and the opening of the north-east rains. I have on my place near the Mahaoya a single plant that came up among the Liberians, and that was planted out in the field with the others, in November 1879. It produced its first flowers in January last, and has now about a dozen half-grown berries, and has a very full blossom forming. It has dark green rather curly leaves, nearly as broad as long; it is two feet high, and has fifteen pairs of branches, the lowest about a foot long; it has the appearance of perfect health, and a stiff sturdy aspect, that seems to challenge any wind that blows to do its worst. Of course I propose to use all the fruit of this plant for seed, but whether the produce will keep true to the parent type, or whether its cultivation will turn out profitable, are questions for the future.

The white ants still continue to cut the cacao plant. Their boldest exploit was a plant thirty inches high with a stem an inch and a half in girth, but at this size they are generally safe from this foe. The older cacao plants are growing very freely, but the smaller ones still suffer from the wind, and on the more exposed spots look very forlorn: many of the large ones are flowering, one especially for the last six months, but there is no fruit forming. It appears to me now that they will take up all the space allotted to them. The branches extend rapidly, and as the stem becomes a branch as soon as others come out to balance it, the growth comes out in width, rather than height. White ants got into my nursery baskets, and destroyed nearly 100 plants in one night, I promptly removed them to other ground, and saved them from further ravage. I am told that a blend of a bushel of hydrate of lime with two ounces of arsenic, dusted over the trees, is a perfect protection.

Since writing the above, I have filled up 500 vacancies in the coffee. I did not like to let the fine showery weather we had for four days pass without availing myself of it. Everything will depend on the weather we may have between to-day and the end of August. Another season like 1879 would kill them off; but we never have two seasons alike, and in this climate it is somewhat of a venture to plant in any season.

TOBACCO IN THE NORTH OF CEYLON.

The trade in this article seems to suffer from great depression, produced by causes which are not far to seek. Tobacco exported to India last year remains in stock, there being no demand. The Indians turn out as good tobacco as any sent from Jaffna. The crop produced in India this year is reported to be sufficient to meet the demand there. Another cause is that a larger number of men than in any preceding year having taken to tobacco cultivation the outturn is far in excess of the demand. This year's crop has been gathered in and the market is now flooded with tobacco. Prices have considerably fallen. We are assured by men whose veracity is unimpeachable that it is found difficult to sell tobacco even at a rate that would barely cover the expenses of cultivation, the cultivator making up his mind not to charge for his labor and trouble. This is indeed a sad state of things. None but those who are acquainted with Jaffna affairs are able to understand what depression in tobacco means. As we have often remarked the chief industry of the place is the cultivation of tobacco: when tobacco produced at great trouble and expense lies in hands uncalled for and unsold, you may safely conclude that distress and want have made their appearance. Money is very scarce: tobacco cultivators struggle hard to keep body and soul together and we fear that should this depression continue even for a short time it will affect the well-to-do classes.

The only class of men that seem to derive benefit from the existing depression are the cigar traders. They combine and keep down prices. The mysteries of trade are so strange that what is ruin to one is a benefit to another. Now that there is no demand in India for tobacco, the cigar traders buy it cheap, and rejoice in the prospect before them.

Times of depression are also times of sickness. When tobacco is dull or when paddy is short, you may expect with certainty the appearance of some sickness. Want generally drives people to live upon unwholesome articles. It was so in 1877. A speedy change in the trade is very desirable and any measure calculated to effect it will be heartily welcomed.—*Jaffna Patriot*, July 9th.

PLANTING ENTERPRISE IN MANILA.

The *Oceania* of the 25th May, in an article on the progress of the now flourishing province of Isla de Negros, which remained almost uncultivated until Government liberality induced many Spanish planters to settle there with labourers from the provinces in 1851, thus notices how a British merchant powerfully contributed to develop planting enterprise in that quarter:—

"With failing resources and a year of low prices, the planters in Negros had a bad time of it until 1855 and 1856, when effective aid reached them. This was from a British merchant, also consul for his nation at Hoilo—Mr. Nicholas Loney. This remarkable man, whose memory is so cherished in the Visayan provinces, had a thorough and scholarlike knowledge of our language, our classic literature being familiar to him. He had not only this qualification, but also appeared to be partial to our customs. During the years he had spent in Manila before going to Hoilo, he had studied the country and the law. That port being then recently opened to foreign trade, he determined to encourage direct consignments. His sympathetic character, his sound judgment, and practical knowledge of the country and its resources, did the rest. Without Loney, Negros might not perhaps have attained its present prosperity and great progress. He succeeded in facilitating the importation of machinery for many of the Spanish planters who were full of energy for work, and even in imparting useful ideas to some, he also setting a good example by buying land which was cultivated on his account. Planting enterprise in Negros under the leadership of Spaniards for so many years, is now the most progressive throughout the Philippines, notwithstanding that amongst other difficulties, it had to struggle against want of ports for shipping produce."

The *Oceania* of the 2nd June draws attention to that fact that former rises in the price of Manila hemp similar to the rates then ruling (9 to 10½ dollars per picul) had always been followed by so great a fall in value that many cultivators, becoming discouraged, abandoned hemp growing, the preparation of the fibre being too toilsome a process for low prices to prove remunerative. During the last 40 years the Government made vigorous efforts to extend hemp cultivation in Luzon, the result being that the plant was found to flourish only on volcanic soil in the Eastern provinces exposed to breezes from the Pacific. The *Comercio* urges extension of hemp cultivation.

The Minister for the Colonies has decided that there shall be continued at Manila, the levy of 1 per cent on the imports into that city for defraying the expenses of the harbour works there, but that no dues shall be levied for that pupose on imports and exports in other parts of the Philippines.

Several inhabitants of Manila, who intend to build substantial houses here, have ordered models of houses from the United States to try here something like the elegant buildings so much in fashion in Cuba and Porto Rico.—*Straits Times.*

THE PLANTING INDUSTRY OF CEYLON.

[Being one of a series of reviews in the *Madras Mail* based on Ferguson's Ceylon Handbook and Directory for 1881.]

An enquiry into the causes that have produced the present depression in the coffee enterprise in Ceylon, would not be of much value, if it omitted to take account of leaf disease. At the same time there is room for difference of opinion as to the degree in which the blight has contributed to the downward tendency. Leaf disease, we may be quite sure, is charged with much that should with more justice be attributed to bad management. There cannot, however, be a doubt that, had this pest not made its appearance, fewer estates would have fallen into liquidation. The disease first showed itself in 1869 in Madulsima, in the extreme eastern division of the coffee districts. Next year it had spread to the western or Kandy side, but did not become very general till the following year. It is worthy of remark as bearing upon the connexion between short crops and leaf disease, that 1870 was the year in which there was the largest export of plantation coffee and the greatest average out turn per acre; the export being nearly 900,000 cwt., and the average per acre 5·53 cwt. Owing to the larger area brought under cultivation, the export in several succeeding years, to wit, in 1871, 1873, 1875, 1877, rose above 800,000 cwts., but the average per acre has never again reached 5 cwt. while in four years it has fallen below three. During the seven years previous to 1870 the out-turn ranged from 4·10 cwts. per acre, in 1864, to 5·22 in 1869. These figures point to the injurious effect of leaf disease on productiveness: a conclusion which will appear all the more certain when it is remembered that this diminution in out-turn since the appearance of leaf disease has taken place in spite of liberal manuring and a higher style of cultivation than was carried on previously. The planter has therefore good reason to conclude that his diminished returns are to a considerable extent due to the ravages of disease. Meanwhile, as Dr. Thwaites, late of the Botanical gardens, Peradeniya, says in his report for 1874, it seems to be conclusively established "that judicious cultivation enables the coffee tree to produce a succession of profitable crops, notwithstanding it may suffer from periodical attacks of leaf disease." This is well exemplified by the obvious fact that no. where has the disease committed such havoc as in native plantations, where cultivation is almost entirely neglected. Previously to 1870 planters were divided into two opposite camps—the party that advocated manuring, and the party that opposed it. How long it might have been in the then state of things before a satisfactory solution should have been arrived at, it is not easy to say. The inroads of leaf disease have led to the matter being speedily and practically settled in favour of high cultivation.

The effects of short crops and low prices might have been mitigated had planters been less exclusively dependent on the one product coffee. Having their eggs all in one basket, a mishap to it could not fail to be followed by serious consequences. Coffee must for many years to come prove the staple product. but had they been as fully alive ten years ago as they are now to the importance of cultivating other products, their losses on coffee would have been more made up But here again they had to pass through the school of adversity before they could be taught the potential wealth of recourses that surrounded them. First to be mentioned among these new products, though not the most important, is Liberian coffee, which grows at elevations unsuitable to the Arabian species. A the end of 1877, there were, according to Ferguson's *Handbook* (from which the following figures are mainly derived), about 500 acres planted with Liberian coffee. There seems to be some difficulty in determining the area under cultivation at the end of 1880, the estimates varying from 4,000 to 7,000 or even 10,000 acres. Though not enjoying complete immunity from the attacks of leaf disease, the growth and productiveness of the trees have not, so far, been affected by it. It remains to be seen whether this coffee will command a ready sale in the home market London dealers are said not to appreciate it very highly, but it has been favourably received in America.

The cultivation of tea, though still in its infancy is likely to become one of the most important industries in the island. Began about the year 1867, at which time about 10 acres were planted it made small progress till 1875 when the acreage was estimated at 1,080.

Since then the increase has been more rapid, the area under tea at the close of last year being estimated at close upon 9,300 acres. As in the case with Liberian coffee, the increase of tea cultivation does not imply a reduction of the area under coffee, the soil and climate best suited for the one being more or less unsuited for the other. The rapid rise of this industry is seen from the exports for the past five years, as given in the Customs accounts :—

Year	lb.	value.
1876	757	R 1,907
1877	2,105	3,457
1878	19,607½	20,900
1879	95,969	85,229
1880	139,752	——

This does not represent the whole annual out-turn, there being a large local consumption. The crop for the current season is estimated at about 500,000 lb. The Ceylon planters are sanguine that they will be able to produce a finer tea than that of Northern India, and at a cheaper rate. In support of the latter consideration they adduce their superiority in the matter of cheap transport and labour, as well as in being nearer the commercial centre. As to quality, they appeal to their long list of awards at the Melbourne Exhibition, and to the comparative results of the analyses of Ceylon and Indian teas made by the Victorian Government analyst. Indian tea-planters need not grudge their southern brethren this consolation, considering the cold reception accorded to Ceylon teas in Mincing-lane. The colonists are more indignant than discouraged at their failure to conciliate the vested interests of the London brokers, upon whom they are at present inclined to turn their backs altogether, looking to Australia as the market for their teas.

A still younger industry than tea is cocoa, which gives promise of being a valuable addition to the vegetable products of Ceylon. Demanding a lower elevation and more sunshine it can be grown in situations where the Arabian coffee cannot., It is grown successfully in districts as widely apart as the Central Province, Galle on the South-West and Trincomallee to the North-East; a fact which indicates the suitability of Ceylon for the plant. On many estates where climate and soil are suitable, cacaos are planted between the rows of coffee trees. This makes it difficult to judge precisely what progress has been made in extending their cultivation. At the end of 1877 only 500 acres were planted. At the end of last year this had increased to about 5,400 acres. Little has yet been exported, the demand for seed having nearly exhausted the indigenous supply. Ten cwt. were exported in 1878, 42 in 1879, and 121 in 1880 In the matter of spices, with which Bishop Heber's hymn has associated the name of Ceylon in the minds of the Sunday school-going youth at home, the island scarcely keeps up its reputation. It is estimated that about 30,000 acres are cultivated with cinnamon, but the area is hardly at all extending. It shews the fluctuations that occur within a short period in certain articles of produce, that though there are at the present moment prosperous coffee planters in the island who made their first step on the road to fortune through remunerative investments in cinnamon, its cultivation does not at present yield a profit sufficient to attract capital. Cardamoms have of late been profitably cultivated, but the area covered by them is not great, though increasing.

But of all the newer products now being cultivated in Ceylon it is to cinchona that the planter most looks for the re-adjustment of the financial equilibrium so grievously disturbed of late years. It is hardly possible to obtain anything like accurate information as to the extent of this cultivation. There are considerable patches in different parts of the country devoted to cinchona alone; but almost all estates, especially the older ones, have trees planted along road-sides or in the midst of the coffee. In some instances, cinchonas are planted only in places where the coffee trees have died out, but in other estates, almost the whole acreage has been planted with them in regular rows between the lines of coffee. Some of the species are grown at lower elevations than have usually been considered suitable. Thus they are said to grow in the Yatiyantota district on the western slope, at 500 feet; and at Kalutara, about 30 miles south of Colombo, nearly at the sea level. The number of cinchona plants growing in Ceylon at the beginning of this year is estimated in Ferguson's *Handbook* at from 50,000 000 to 100,000,000. *C. succirubra* is the most numerous, being reckoned at more than one half. The remainder consists of *c. officinalis*, and *c. calisaya*, with such varieties as *c. ledgeriana* and *c. pubescens*. Of course, the majority of these are very young, say, not more than three years of age; the cultivation not having increased at a very rapid rate till about 1877, when the depression in coffee forced planters to look about them for something to take its place. It will consequently take some five or six years before there will be any marked increase in the export of bark. By that time a serious fall in price may happen; and in any case, it can hardly be expected that prices will continue to maintain their present level after Ceylon, in common with other parts of the world, has begun to pour a largely increased supply into the home markets. But the Ceylon planters do not despair of a profit on the cultivation, even should prices fall to one-half or one-fourth of their present rates. The following is the official Customs' returns of the export of cinchona bark for the past eleven years :—

		Value R.
1869...	28 oz.	50
1871...	80 packages	313
1872...	11,547 lb. & 694 pkgs.	64,102
1873...	44,836 ,,	32,667
1874...	40,354 ,,	25,277
1875...	19,152 ,,	17,963
1876...	14,932 ,, & 1 pkg.	14,720
1877...	72,127 ,, & 1 ,,	88,738
1878...	186,797 ,,	1,71,292
1879...	507,368 ,,	5,19,086
1880..	1,161,989 ,, (say)	12,00,000

It is not expected that the rate of progress indicated by the figures of the past two years will be kept up during the next three or four years, as the hard times recently experienced led many planters to cut or bark their trees prematurely.

THE CULTIVATION OF CINCHONA CALISAYA.

The following paper from one of the June numbers of the *Journal of the Society of Arts* is of value as shewing the idea entertained of the best mode of cultivating the richest of the cinchonas in their native habitat. We must be prepared to find the cultivation succeed in some parts of the Southern "United States".

CINCHONA IN THE UNITED STATES.

Consul General Adams of La Paz, Bolivia, states that he has no doubt but that the cinchona may be cultivated in some parts of the United States, where the soil and climate are favourable to its culture. After a full investigation into the cultivation of the *Cinchona calisaya* in Bolivia, he gives the following information to those wishing to make the experiment of growing the tree in the United States, which is taken from the *Oil and Drug News* :—"The seed is sown broadcast upon a hot-bed, such as gardeners prepare in the spring

for their early vegetables. The manure of the llama, for which, in the United States, sheep manure might be substituted, is freely mixed with the surface soil of the hot bed, and, as the seed is very high, it should be slightly raked under, and the surface kept moist. As soon as the sprouts appear a shade should be constructed over the bed covered simply with leaves, straw or branches of trees, which, while it protects the tender plants from the hot sun, may allow the rain to penetrate and fall gently upon them, and it is advisable to locate such hot-beds on a hill-side, so that the water may quickly run off, continuous and limited moisture being required, rather than quantities of water and heavy falls of rain. As soon the plant has grown to a height of from six to eight inches, it is ready for transplanting. The ground chosen for a quina plantation should also be sloping, if possible on the south side of hill or mountain, as experience has shown here that those located on level land do not prosper, and steep mountain sides are here preferred. The plants are set at regular intervals eight feet apart, and it is only necessary, if not better, to prepare the soil within a foot of where each plant is placed, as I am assured that by ploughing the whole field too much moisture would be retained in the soil. The plants are then slightly covered with fallen leaves or other rubbish to protect them from the hot sun a while longer until they show a strong and healthy growth, after which all further care seems to be unnecessary, in Bolivia at least, where even the weeds are but superficially removed. A damp, warm climate, with heavy dews at night, and cloudy sky during the days, rather than a hot, burning sun—such as may be found in the mountainous regions of some of the Southern States, like Alabama and Georgia, where mists and threatening clouds hang over the mountains in summer and still no severe frosts occur in winter—this seems to be what is required for the cultivation of this plant: and I should not be surprised if the experiment should, under such conditions, prove successful, a result which would, undoubtedly, add greatly to the wealth and prosperity of the South. Bolivia being in the southern hemisphere, the seasons for sowing and transplanting in the United States will have to be changed; the former, instead of October here, should be done in April, and the latter in July, instead of January here. From these intervals it will be seen that the seeds require a long period to germinate and attain their first growth, but from all accounts, if the above directions are followed, and a little patience shown in the beginning, very little, if any, cultivation and trouble is necessary after the plant is transplanted and becomes firmly rooted and shows a healthy growth. In from five to six years the tree grows to a height of about 10 feet, and 5 to 6 inches in diameter, and at that age the bark contains the greatest per-centage of quinine, and is worth in Bolivia from 180 dollars to 200 dollars per quintal of 100 pounds. When the tree has attained this size and age, it is cut down close to the roots, the bark stripped entirely from the trunk and branches, and one of the new shoots from the root is allowed to grow into a new tree. In India, I am told, the custom prevails to strip only half of the tree, and allow this to grow again before the other half is taken off; but by this process, I am assured, the per-centage of the sulphate contained in the second growth is much smaller than that gained by the method practised here. The seed which I have transmitted I have procured from one of the best plantations, and is warranted to be of the calisaya species—the best of the cinchonas. Lately, since the cultivation of this tree has assumed such large proportions in Bolivia, this seed has become an article of local commerce; so that, should the experiments in the United States prove successful, there would seem to be no difficulty in obtaining the necessary seed in larger quantities."

NORTH BORNEO.

At a meeting of the Royal Geographical Society on 14th Feb. Mr. W. M. Crocker of Sarawak read a paper on that country and northern Borneo. Regarding the portion ceded by the Sultans of Bunei and Sulu to Messrs. Overbeck and Dent, he said it comprised a computed area of 18,000 sq. miles. It seems, however, that the Dutch have shifted their boundary to the north, so as to include a good deal of the eastern portion of this ceded territory, but what ground they have for doing so we do not know. However, even without this disputed portion, Sabah, as the ceded territory is called, is larger than Belgium, and has bays and rivers in which a fleet could anchor. It also includes the famous mountain of Kini Balu, though the lake of that name turns out to be a myth. Mr. Crocker pointed out a feasible route of exploration by the Rejong and Belongan rivers, the first on the west, and the second on the east of Borneo. He believed that the natives of the Sabah were being ruled according to Rajah Brooke's policy, *i.e.* through the chiefs, and that the results would be good. As the Russians had strongly fortified stations on the northern shores of China, and were casting covetous eyes on the Corean harbours, it was necessary that the British should maintain their supremacy in the Malayan Archipelago. Mr. Dent, one of the representatives of the Company to whom the land had been ceded, gave an outline of the operations undertaken, and spoke highly of Chinese labour, and in this opinion he was supported by Dr. Lockhart.

THE NEEM TREE BARK AS A SUBSTITUTE FOR CINCHONA.

We read in the proceedings of the Agricultural and Horticultural Society of India, that

"The Lady Superior of St. Vincent's Home informs the Secretary that since she has planted *Neem* trees 'Azadirachta' in her grounds, the inmates have been specially exempt from fever; there is no doubt this plant possesses fever-dispelling properties, and as the seed can be procured for the gathering in Calcutta, the experiment of planting the same in the fever districts is worth trying. The plant is easily raised and needs no special care.—In connection with the virtues ascribed to the *Neem* tree in the above report, the Secretary drew attention to the fact stated in O'Shaughnessy's *Bengal Dispensatory* that Dr. White of Bombay used the *bark* of this tree as a substitute for Cinchona and found its success nearly equal as a febrifuge remedy. He further submitted a note from Dr. D. O'Brien of the Beheating estate, Debrogurh, applying for seeds of *Eucalyptus rostrata*. Dr. O'Brien states that he raised some plants of that variety five years ago, and they are now 25 to 30 feet high, but very slim. "They were planted about the compound of my bungalow, and to these trees I must attribute freedom from fevers, although the people (coolies) about me very subject to fevers."

We think the statements in the above paragraph are of rather a mixed and apocryphal character and should be taken *cum grano salis*. But, the neem tree is what we know in Ceylon as the margosa, a very common cultivated tree, doubtlessly wild. The oil from its fruits—margosa oil is well-known, its bark is bitter and has been used as a febrifuge or anti-periodic by the natives before cinchona was introduced into India. The tree is sometimes planted in avenues, but, being quite deciduous in the hot dry weather, it is about the worst that could be used for this purpose. It is the Melia azadirachta, Lin. The idea of its being a preventative of fever in a growing tree because its bark is bitter and is used as a febrifuge

is rather far-fetched and indeed absurd. It is a rather common belief now that some of the gum trees of Australia, notably the blue gum, have similar properties, but the more reasonable explanation is that these eucalypti are capable of absorbing the moisture and drying up swamps in which they are planted and consequently of absorbing and dissipating malaria. Very probably the Eucalyptus rostrata may be useful in this respect. On the other hand, dense shade and superabundant vegetation in the tropics conduce to fever and other disease; moderate shade is desirable, and under the circumstances we have referred to as well as other peculiar conditions, the planting of deciduous neem trees and species of eucalyptus may be very beneficial.

COFFEE PLANT DISEASES.

(From our London Correspondent.)

At last I am able to send you by this mail the copy of the Linnean Society's journal for the present month, which contains Dr Cooke's and Mr. Bidie's communications to that Society on the subject of coffee leaf disease. Dr. Cooke's paper was, as you will see principally relative to that form of it which has made its appearance in South America; but I have been unable by my perusal of it to decide whether the fungi described by him have any connection with that which you referred to me a short time back as having made its appearance on the Guatemala plantations. Dr. Cooke has described one species which is said to have a strong phosphorescent smell, and it may be that the taint of sulphur which the Guatemala disease was said to give out is identical with it. If that be so, we might be justified in coming to the conclusion that some degree of identity was established by the fact, but I have not as yet been able to ascertain Dr. Cooke's views on this point. I fear his paper is too scientific for me to be able to discuss it here, but it is a new feature, as far as my experience or reading goes, to learn from it that the coffee leaf disease is, *sui generis*, identical to a great extent in all its forms, and that it is only by the different form of fungus which it developes that its various classifications can be determined. I am glad to see that the learned author considers—as he states—that "we are now in a fair way of knowing all that can be known of its life history: and this is the only safe basis on which to hope for a radical cure." The determination of the last appears, however, to be at present as far off as ever; though the disease in Mysore appears to have engaged Dr. Cooke's active investigation as far back as 1876. He describes that as the "black rot" and states it to be unknown in Ceylon, giving that special form the scientific nomenclature of *Pellicularia Koleroga*. It was in the year above named, 1876, he states, that the existence of destructive parasites on coffee became apparent in South America, and primarily in Venezuela. The varieties of the disease named by Dr. Cooke seem to be legion in number, and all of them, though having the same basis, and due probably to the same cause, possess distinctive features, as I have said, in the character of the resulting fungus: it being ascertained during 1877 that in South America alone there were three distinctive classifications of the disease, one at all events being identical with the so-called "black rot" of Mysore. The Commissioner of Agriculture at Bogota described this particular form of fungus as having a phosphoric smell and as emitting phosphorescent light at night. It was said by him to occur more frequently in damp places than in dry ones, and to show its ravages most severely in localities where the trees were closely planted together. It also attacked the trees grown to afford shade to the coffee bushes. Further on in the paper, Dr. Cooke affirmed that the disease may exist without any visible fungus upon the leaves and exhibit no trace of *mycelium* in the tissues. Altogether, he considers the disease to be a complicated one, and he is not prepared to state its cause. Leaves forwarded to him by Mr. Morris from Jamaica showed an entirely distinct form of the disease from those he had previously known, and he classifies it under the title of *Cercospora coffeicola*. The localization of this form in one particular locality renders it still more difficult, Dr. Cooke writes, to answer the question: "What is the cause of this form of coffee disease?" A plate accompanies the paper, which gives illustrative magnified details of the disease of South America. Mr. Bidie's remarks on this subject are embodied in a letter addressed by him to Mr. John Cameron, the Superintendent of the Botanic Gardens at Bangalore, who communicated it to the Linnean Society, and they have reference to the form of the disease prevalent in Coorg. It was only developed there some four or five years ago, and Mr. Cameron thinks it was imported from Ceylon, or from a coffee district in Mysore, bearing the euphonious name of "Chickmoogloor," the latter place being only sixty miles distant from the plantations of Coorg. It will be useless for me to enter upon Mr. Bidie's remarks. They appear to me to be pretty identical with what I have previously read in your columns; but I cannot pretend to say that they may not embody some new points of interest to those better acquainted with the subject than I can possibly be a from my rather cursory reading respecting it.

A NEW MAURITIAN INDUSTRY:—FISH MANURE.

The *Mauritius Mercantile Review* publishes a report on a new industry lately started by Mr. Bernard with the assistance of several Mauritian planters, viz., that of making manure from the fish caught at the shoal of Saya de Malha, the most extensive in the Indian seas.

On April 7th last, Mr. Bernard freighted a vessel, the "Rodolphe" and sailed from Mauritius, reaching the shoal on the 14th. The shoal is about 200 miles long and 15 miles in average breadth, situated between 56° and 60° E. long., and 9° and 11° S. lat. Over the whole extent of this submarine bank of sand, coral, and seaweed, the depth varies from 12 to 15 fathoms. On account of the shallowness of the water, the fish were caught with the greatest facility. The shoal covers an area of more than 2,000 square miles, about five times the size of the Mauritius, over the whole of which fish exist in such quantities that they may be said to be inexhaustible.

Mr. Bernard fished with lines, and scarcely were the lines cast into the water, when fish were caught varying in weight from 2 to 3 lb. Sharks and other large fish were taken occasionally. In fourteen days' fishing ten men filled 120 casks, each containing 320 lb. of fish or an average of 300 lb. of fish for each man per day. No nets were used, and the work was carried on during the whole time under every disadvantage. The fishing hooks were all too small. On this account four-fifths of the sharks, which might have been caught with proper hooks, were lost. Notwithstanding that circumstance, 25 or 30 sharks were taken every day. 300 lb. of fresh fish represent 100 lb. of dry fish manure, containing 11 or per cent. of azote, under the form of organic matter in close combinatoin with phosphates entirely assimilable. Mr. Bernard calculates that the cost of the manure ready for sale will be less than $50 per ton. He asserts that boats for fishing purposes are far better than small vessels, on account of the greater facility in drawing the fish out of the water. Fishing operations can be carried on during eight months of the year, from September to May. In June, July,

and August the south-east monsoon makes fishing almost impossible.

Mr. Bernard concludes his report by saying that on account of the great extent of the shoal of Saya de Malha, of the extraordinary abundance of fish, and the numerous facilities which the operation offers, it might become the place of an important and lucrative trade, capable of supplying large quantities of manure rich in azote, which it would not be possible to procure in the ordinary course of commerce.—*Colonies and India.*

CEYLON TEA AGENCIES IN THE MOTHER COUNTRY.

We give special prominence to the following relation of the practical difficulties in the way of pushing a trade in Ceylon Tea in the old country, which comes from the correspondent who contributes our "News from the North." The writer's suggestions are deserving of careful consideration :—

I am glad to see by last received *Observer* that Sir Wm. Gregory's suggestion of a London Agency for Ceylon Tea is likely to be carried out by a Ceylon Syndicate. I now feel called on to break the ominous silence I have maintained respecting the success of the "Ceylon Tea and Coffee Agency" established by me in this town some eight months ago, as the experience of the first and only retail agency in this country solely devoted to Ceylon produce may afford hints for the guidance of the Syndicate, when arranging how they shall place Ceylon teas before the British public. To the Syndicate, and also to those who, having a high opinion of the excellence of Ceylon tea (as I had before entering on this business), and who may think of taking up a special agency for Ceylon produce, I address my remarks. To the latter, I would say : Don't let your individual tastes delude you into the belief that you have only to open a shop and announce the sale of Ceylon tea to meet with a brisk demand. If you have not already a good connection, you will find the public slow to make trial of a new thing, unless it be constantly forced on their attention by advertisement. To do this *efficiently* involves an expenditure that few private individuals are able to meet, or would care to risk, as the prospect of return would be too far off, the taste for Ceylon tea having to be acquired. The great majority of people do not appreciate good tea and don't know it when they get it. This is no mere opinion. I have proof of it. British notions of tea, to a great extent, are ruled by the darkness of the cup, with almost universal ignorance as to the shade of colour a really good tea should have. To simply announce that you have Ceylon tea for sale and expect to draw customers is certain to lead to disappointment. You must advertise persistently—chant its praises, issue circulars and distribute handbills. Have I done these things? Yes, more perhaps than my means warranted. On to the glass of my shop-window I have pasted a large poster which says :—" Important Announcement. Ceylon Tea surpassed all other Teas at the Melbourne Exhibition of the present year 1881."

The Committee of Ladies having charge of the Ladies' Refreshment rooms at the Melbourne Exhibition selected Ceylon Tea for use, and placarded the walls of the rooms thus :—"CEYLON TEA, THE BEST IN THE WORLD." In my handbills which have been distributed in the streets and sent round to families (a style of advertising now much practised) I say :—

"PURE CEYLON TEAS IMPORTED DIRECT FROM THE GROWING ESTATES.

Finest quality, 3/4 per lb. } Liberal Discount given
Second " 3/— " } on Quantities.

57

"W. W. begs to intimate that, since commencing business, he has sent Large Parcels of PURE CEYLON TEA all over Scotland, to many places in England, to Wales, and as far south as Bournemouth, on the English Channel; that he is constantly receiving Repeat Orders and the most flattering eulogiums on the superior excellence of his Tea. The following are specimens :—

"It is really the most refreshing cup I ever tasted." ——"I never knew what good Tea was till I got yours."——"Your new Ceylon Tea is perfectly delicious."——Scores of times has he been informed :—"I have tried all the principal shops in town without getting Tea to please me like yours;" and "I would never wish to drink better Tea." —A lady, whose husband is a family grocer in Union Street, being entertained to a cup of Ceylon Tea at a friend's house, said, "Oh! what delicious Tea this is. Where did you get it? What a beautiful colour it has when the cream is added! My husband never sent me Tea like this."

"Having abundant proof that CEYLON TEA only wants to be tried to become popular—in fact, to supersede the taste for China, Assam, and blended Teas, he most respectfully solicits a Trial.

"The CEYLON TEA Growers wish their Teas supplied to Consumers in a thoroughly pure condition, without any admixture, having every confidence in its growing popularity."

On the window I have a copy of this handbill. After each fresh distribution of bills there comes a crop of customers who make trial of a quarter of a pound. Of them a very small percentage become regular customers. In general, those who do come a second time speak highly of the tea. "They never tasted better," but slowly indeed is progress made in public favour. A *few* like Ceylon tea at first tasting, and pronounce it delicious. One fact that indicates the future popularity of the tea is that—almost without exception,—those who at once ordered 7 lb. have repeated their order. Some of them tell me they did not like it very well at first and did not intend having more, but by the time they got done with it they found they liked it very well. For eight months I have been "casting my bread upon the waters," paying for an experience I offer free to whom it may concern. In no single week of these eight months has the sale of Ceylon tea yielded me a profit equal to half the salary I gave up for it. Having thus probed the market with so little success—of ultimate success I have no doubt, as I am now having a slow but steady increase of sales—my experience points to another method of bringing Ceylon tea before the public. I fear it is hopeless to expect wholesale tea merchants to sell Ceylon tea as long as they have such a conceit of their skill in blending. Every wholesale tea merchant has two sets of customers: those who buy blended teas and those who buy India and China teas and blend for themselves. To the former, it is most likely he would recommend his own blends in preference to Ceylon tea that does not need his skill, and the latter confess their preference for the harsh teas of India to regulate quality with the weaker growths of China. One thing to be kept in view is, as Ceylon tea gains favour, there is a danger of blends being offered as pure Ceylon tea, and so check the reputation of the genuine article. Were I asked for my opinion as to how the Syndicate might proceed, I would tender the following hints : uniform quality must be maintained by blending the best teas, as quality of an estate's tea varies. The object one to blending teas in Colombo have already been discussed in the *Observer*'s columns. Consignments could be made to an "Agency" in London, where an expert could value, credit the estate according to his judgment, and make blends of Ceylon tea of different qualities, to

be known by, and sell at fixed prices. The general consumer will never come to know a Ceylon tea by the name of an estate. He can find no indication of quality in an estate's name, and *not one consumer in* 500 will put himself to the trouble of *asking* samples of different estates' tea. It 's by price he speaks of his tea :—" It 's the 3s 4d Ceylon tea, or the 3s Ceylon tea." I would suggest—to meet all grades of tea drinkers—that blends to sell at 3s 4d, 3s, 2s 6d, and 2s be made, and put up in 1 lb., ½ lb., and ¼ lb. tin foil packets bearing name of "Company" and price. This is how some large firms put out their teas to agents all over the country. In large towns, it is principally bakers, confectioners and druggists who sell packet teas, but in country villages the general merchant goes in for them, grocers preferring to sell from bulk. Doubtless they too would keep them if it were not that their own blends are as a rule of better value. There are two ways of opening up the trade. One by advertising and inviting applications for Agencies. This plan is adopted by the Assam Tea Company. Here is their advertisement :—" Agents, &c., wanted to sell our celebrated teas at eighteenpence per lb., and prices upwards ; in packets or loose ; good profits. Write for price list, etc.—Assam Tea Company, 132 Upper Thames Street, London." I don't think they dispose of much by agents, as I have seen no one, either by card in window or newspaper advertisement, announce his being agent for this Company's teas. The other way is to send out travellers to induce shopkeepers to order a stock and push it among their customers. There is a big difference between acquiring a set of new customers and pushing a new thing among one's regular customers. If the price at which the tea is sold to grocers, leaves them the same profit as they get on their bulk teas, they would have some inducement to push it, in its being made up and an article they could honestly recommend. These "hints" lead directly in the teeth of my own interest, as they recommend *opposition* to the business I am trying to establish. "Sufficient until the day be the evil thereof"—one agent will do for Aberdeen. The mighty "Date-coffee-abomination" Company has but one agent in this town, and he supplies grocers with all they manage to sell.

I see a London starch manufacturer, Orlando Jones, has gone in for advertising on an expensive scale. He has sent men over all Aberdeen calling at shops and private houses with a sample of his starch. The presented packets are neatly put up and contain about 2 oz. If he has made a like distribution in all the large towns of the kingdom, as likely he has, before he would have sent so far, it must have cost him a tidy sum.

We feel sure Ceylon tea planters will appreciate the energy and perseverance of their agent for "Aberdeen and the North." We have had to-day a visit from Mr. Paterson, junr., of Cranley, who is about to proceed to England in order to devote his whole time and attention to the establishment of a Tea Agency or rather Tea Agencies for the sale of the Ceylon product. Mr. Paterson will not confine his attention to the sale of the produce of any one plantation or group of plantations. He will be impartial in this respect, and in another direction, he will take care not to clash or interfere with the provincial agencies already started, for instance, in Glasgow and Aberdeen. There is undoubtedly abundance of room, in the metropolis for instance, and all over England, in the North of Ireland (where the strongest and best teas are drunk), and in those large Scottish towns which are so far unoccupied. We trust Mr. Paterson, in conjunction with other friends of Ceylon in London, will be able to give effect to Sir Wm. Gregory's suggestion, by the establishment of a West End store and, perhaps, restaurant, where Ceylon tea and coffee (and by-and-bye cocoa) would be specialties. To such an undertaking all old colonists ought to lend their support and patronage, and if, in the same way, the many old Ceylon residents scattered througout England at different provincial centres took some interest in the establishment of local agencies, a great deal could be done to create a steady demand for Ceylon tea. A correspondent has already shewn in our columns, that a very considerable quantity of tea would be called for if only every family in the old country connected with, or interested in Ceylon, made a point of using no other than this Colony's produce. Let this become a point of patriotism with retired planters, mechants, and civiliaus, as well as with gentlemen going home on business or on furlough, and very soon throughout the length and breadth of the United Kingdom, Ceylon tea will become as familiar in the mouths of the great English tea-drinking public as "household words."

GOLD IN CEYLON.

We learn that Mr. Evans, the gold-miner, is hard at work on the Dolosbage reef in the property of Messrs. Alstons, Scott & Co. He has made a *pro tem.* report of a satisfactory nature, but more work must be done before a conclusive opinion can be formed of the value of the reef.

On the other hand good news comes from Maskeliya. The best sample of Ceylon quartz that Mr. A. C. Dixon has yet seen, he has received from Mr. Grigg of Theberton estate. In it gold is clearly visible, and there is every reason to believe that a paying auriferous reef must be available in this neighbourhood.

It is stated that Mr. Jas. Theobald, who has had experience in quartz mining in Australia, is prospecting in Rangala. Mr. E. P. Eastwood, who also in "the days of old" had a practical business acquaintance with a great many Bendigo and Sandhurst mines, is good enough to remind us of the simple passing tests which the ordinary prospecting miner used to apply to quartz to distinguish betweeu mica, pyrites and gold. These tests are based on the fact we have already mentioned that gold does not lose its colour or become tarnished as the inferior metals do—and hence in wetting glittering mica or pyrites with the tongue, or in looking at them in different lights, a change of colour will be perceptible which is not observed in gold under similar circumstances.

NEW ZEALAND FLAX.

A correspondent writes :—" I sent you a book on New Zealand—'The Official Handbook of New Zealand'—edited by Sir Julius Vogel, from which you could probably give 'R. R.' the information touching New Zealand Flax." There is little or nothing of a practical character in the book in question ; the following being almost the only references. In writing of Otago one contributor says :—

"Another enterprise in which the Province must embark is the growth of flax and hemp. Every element of success exists, and there is only wanted skilful adaptation of labour to bring about a profitable result. It will not do for the farmers to confine their attention to the production of the ordinary grain crops alone, as these change so much in value. The growth

of flax and hemp commends itself for their immediate adoption. The fibre which each produces is in constant demand both for home and foreign trade, and the prices usually ruling are highly remunerative. Besides the fibre, the seed of the flax yields a high price and if not exported as seed it can be pressed so as to produce oil, much used by painters, and the residue be sent Home as cake for cattle-feeding."

And in the description of Auckland we read of :—

"*Phormium Fibre* (*New Zealand Flax*).

"There are scattered over the Province numerous mills for the preparation of this fibre, but in consequence of the fall in price the quantity produced has lately diminished considerably ; mill-owners finding that the present rate for good prepared *Phormium* (£13 to £20 per ton) will not remunerate. The chief cost in connection with flax-mills is the motive power The machines are all locally made simple of construction and cheap. The plant itself grows wild in nearly all parts of the Province, and the right to cut flax upon waste lands may be purchased from the Government at a very low price. The building required for a flax mill need not be a large or expensive erection ; but it is necessary to have a good dry store-room and a press for packing the bales. The profits from flax preparation depend in a great measure upon the situation of the mill, and the cost of getting the green leaf to the mill and the prepared fibre to market. Boys and women are largely employed in these mills. The prepared *Phormium*, suitable for rope-making, exported from the Province in the year 1873, was 1,497 tons, valued at £27,783."

"*Rope Making.*

The manufacture of rope from prepared *Phormium* is now an industry of some importance in Auckland but might be more extensive. In consequence of the opposition of English rope makers to the use of *Phormium* or at least to paying for it a price proportionate to that given for Manila hemp, it has been found more profitable to manufacture the ropes here than to export the fibre in bales,—Auckland-made rope generally meets with a ready market. The cordage from Auckland manufactories has been tested on Her Majesty's war vessel visiting the port, and has been highly commended ; and similar commendations from the officers of an American and an Italian war vessel, which visited the port have been published. It has also been put to the most trying tests in ordinary wear, and has come out satisfactorily. During a late severe gale at Auckland, it was found that the rope, when subjected to the same strain as manila, remained unbroken, while the other gave way. This industry is worthy of the attention of practical rope makers contemplating emigration, the cheapness and plentifulness of the material being of the utmost importance, while the market in this and the neighbouring colonies is almost unlimited. During 1872, cordage to the amount of 1,057 cwt., and in value £2,406, was exported from Auckland. There was also of course a large quantity used within the Province or sent to other parts of the Colony. Samples of Auckland rope in common wear may be seen on most English vessels trading to Auckland. A cable of 12 in. in circumference and 120 fathoms long, was lately placed on board the ship "Hindostan," to order, and should be inspected by all interested while that vessel is in London." Since giving the foregoing to the printer, we have received the following from the correspondent who originally called attention to the subject.

NEW PRODUCTS FOR THE HILLS: NEW ZEALAND FLAX.

To the Editor, Ceylon Observer.

Dear Sir,—Your correspondent in your issue of the 5th inst. asks some questions anent the cultivation of Phormium tenax in Ceylon. It is with a view to reply thereto and to other enquiries which I have received through the post that I again venture to trespass on your space. Flax seed can be got in any quantities, and almost at any time in the year, from New Zealand, and can be relied upon as fresh. Three months is about the time that will take a letter to reach New Zealand and get a reply. "Mode of cultivation," is rather a difficult question for me to answer. But I would advise that the seed should be sown in a small nursery sufficiently far apart to allow of a reasonable growth without the trouble of transplanting or picking out. After the flax is a decent size, it can then be propagated from roots the same as mana or quisna grasses. I have noticed in New Zealand, that flax in warm hollows was more luxuriant in its growth than at higher elevations. This leads me to think it could be grown with greater success in Ceylon, where the climate is tropical and forcing, than in New Zealand, where there are the seasons, spring, summer, autumn, and winter. There are very violent winds in New Zealand, stronger than any I have felt in Ceylon, not even excepting Maturata, and I cannot say that I ever saw any bad effect to the flax therefrom. The very formation of the leaf is suggestive that nature intended it to withstand the strongest of winds. I see your correspondent "J. Hawke" asks for information about aloe fibre. The cultivation of this cannot in any way be compared to flax. The former is nearly all pulp and little fibre. The latter has little pulp and is nearly all fibre. In this particular I challenge contradiction.

The Maori used to make neat fancy basketwork from flax before their land was settled by Europeans. The Maori name of the clean fibre is "jnto."

In New Zealand very little flax was ever raised from seed ; the popular and best way was to cultivate from roots. I cannot go into particulars of cost of cultivation and opening an acreage. Any planter can form an approximate estimate. 4 × 4 I would suggest as about the correct thing to plant out. After planting, weeding is all that is required till such time as the flax is old enough to take care of itself. There is not any pruning, handling, or suckering required.

In harvesting, the outer or oldest leaves only ought to be cut ; the centre one or shoot should be left untouched. The flax leaves are not unlike a man's hand when open, and the fingers extended, the middle finger representing the shoot, and the outer ones the older leaves. In regard to soil, I don't think that it requires a rich one, but fancy it would take more kindly to an open and free than to a clayey soil. It does not take much from the ground, and unlike coffee it has not any crop to bear. Flax blossoms once in three years—I think that is the time, but am not quite sure. At this time a stick grows from the centre of the bush with great rapidity to a height of about ten feet. After blossoming and shedding its seed, the stick becomes dried up and withered, at which time, if split in half, the inside makes a capital razor strap. The Maori name for the flax stick is "kaladdi."

The Lokomariro and Sairiri plains in the middle island are not much above sea level : so low in fact that the sea flows a long way up the rivers of the same name and overflows a great deal of low-lying land. Accordingly, if a very heavy and continuous fall of rain takes place at a spring tide, a great deal of damage is done by flooding the plains. The Maori have a tradition that, if the kaladdi begin to grow too early in their blossoming season, it is a sure indication of a heavy flood. Whether it is true or not I cannot tell, but strange to say the last two floods I remember were both predicted by the Maori.

I cannot answer "R. R."'s fourth question as to

the yield per acre and profit over cost, but later on I may be able to contribute further and useful information.

It takes much longer to grow a nice matured bunch from seed than from roots. In the former case the seed must sprout and become a seedling, the seedling a plant, and the plant a bush. But after it has once formed good roots it will grow from that stage much quicker.

By the way, by to-day's post I received a letter, the following of which is an extract:—"Dear Mr. Phormium tenax, would you kindly send me *two ounces* of your flax seed? Could you give me any information as to whether it will stand wind? Does it want rich soil? How long will it take to reach maturity? Shall I put the seed in a nursery? What is it like, etc.?"

I recognise in the writer of this a kindred spirit to my *own*. He must be my affinity, whatever that means. My soul yearns to embrace him. He is one like myself who has offered himself a victim on the altar of experimental planting I like him, but would like him better if he had sent me a quire of note-paper and a rupee worth of stamps.

I have no doubt, my dear Mr. Editor, you 'll be pleased to learn that the spirit of enterprise which animated the Anglo-Saxon in bygone years is not dead, but occasionally bursts the bounds of prudence and finds an outlet in extensive orders for flax seed.

—Yours truly, P. T.

The following paragraphs from "Spon's Encyclopædia" refer to other New Zealand productions of which seed might be got:—

"CORDYLINE AUSTRALIS—NEW ZEALAND CABBAGE-TREE.—Endogen; 10-20 ft. A native of Australia and New Zealand; found chiefly in swampy situations, but grows also on hill-sides. It may be readily propagated from seed, and grows rapidly. The stem is thickly fibrous, and the leaves, which are long and ribbon-like, about 2½ in. wide, contain much fibre. It is said that the whole plant might be made into paper-pulp.

"C. [DRACÆNA] INDIVISA—TOI, MOUNTAIN FLAX.—Endogen; stem 6 ft. A native of New Zealand, growing on the higher slopes of Mount Egmont, at altitudes of some 3,000 ft., where the forest proper gives place to scrub. The leaves attain a length of 4 ft., and a breadth of 4-5 in., and contain an abundance of fibre, which diverges from the centre to the edge and top of the leaf. It is therefore shorter than the leaf, and not of the same strength throughout; but it is prepared with greater care than the New Zealand flax (*Phormium tenax*), and is better for cordage purposes, as it does not contract in water. The natives use it in the manufacture of rough mats, employed as a cape to keep off the rain, it being more durable than phormium fibre. Though the fibre is coarse, it seems well adapted for ropes and paper-making."

WYNAAD, 3rd July.—Plants from my last Liberian coffee-crop have just been put out in a new clearing, and I hope will come on satisfactorily. I got nearly half a bushel as first pick off my two trees last month; there are lots of half ripe berries left. It was amusing to see the cooly, *climbing* the tree to get at the top-most branches. How do they manage in Ceylon about the pulping? It seems to me that nothing short of pounding will be of any use; the rind of the bean at its ripest, being so very hard and tough, that I should imagine the ordinary machinery would have little or no effect upon it. Another neighbour died last week to our great regret—six since January. It is very saddening to think of the many kindly faces that have passed so lately away from our midst.—*Madras Standard.*

DUNEDIN TEA.—A sample of this tea has reached us, of which we cannot speak too high praise. The tea looks very fine and well rolled, and the flavour is strong but not bitter and most agreeable and refreshing. It promises well for the prospects of low-country tea.

COFFEE PLANTING IN JAVA.—Extract from a Java letter to a correspondent in Ceylon, kindly placed at our service:—"Leaf disease does not do any harm at —— estate this year. I have not seen one leaf diseased, but at other estates I hear they are not totally exempt from it, but it has no great influence on the crop. I have 4,000 piculs this year from 970,000 trees bearing fruit. The whole plantation when in full bearing will be 2,070,000 trees." Our correspondent writes:—"The cost laid down in Samarang of the 4,000 piculs will be about R11 per picul." The picul is 133⅓ lb., so that, nominally, this means coffee delivered at the shipping port for about 18s per cwt.! This certainly beats anything ever done in Ceylon, but we must remember the system of serfage which prevails in Java. It is a most convenient system from the point of view of the planter, and the native is also well off materially; but of course, one would rather be the free planter than the bondsman labourer, and, indeed, would rather be the free, if lazy and sometimes hungry Sinhalese, than the apprenticed well-fed even if well-worked Javanese. The yield of crop reported above is nothing wonderful, say that the 970,000 trees are equal to 1,000 acres in Ceylon, it would amount to about 4½ cwts. per acre.

THE FIRST SUGAR known to have been produced in Queensland was made by M. Buhot, of Barbados, from cane grown in the Botanic Gardens, Brisbane—this was in May 1862. Later on, the Caboolture Cotton Company started sugar growing; but in October of the same year the Hon. Capt. L. Hope, to whom the palm is conceded of having first placed the sugar industry on a commercial footing, began to prepare his first 20 acres at Cleveland, and by the end of November had already planted 15 acres. In 1863 Captain Hope had 20 acres under cane, with more to follow, and in his wake followed all the small settlers who needs must also have their patch of cane. During the whole of this year cane-growing spread, and the London Society of Arts offered as an inducement a medal for the first ton of sugar made in the colony. The movement continued to spread with fluctuating success, until by the end of 1867 there were nearly 200 acres under cultivation, and the six mills in existence manufactured 168 tons of sugar. Throughout 1868 the mills were not able to keep pace with the farmers: but in 1869 they put on a spurt, for at the close of that season there were 28 mills at work crushing the cane from 1,230 acres out of over 5,000 acres under cultivation. The industry continued to prosper, every year seeing more land brought under cultivation and more mills erected—steam mills quickly superseding the antiquated cattle and horse-power erections. Matters thus went on until 1875, when the season turned out very bad: the canes being nearly drowned in wet, became unhealthy and died, giving next to no returns. This so-called disease (they call it rust) felt like a thunderclap amongst the planters, for to most of them it meant utter ruin. But the evil effects of 1875 passing away, the sugar industry has since, and up to the present moment, between more or less a success. The output for 1879 will probably have been over 15,000 tons for the whole colony; this is about the amount that Demarara exported in 1803. British Guiana has been about 150 years a cultivated colony; it is only 20 years since Queensland has been brought under cultivation. Twenty years ago Maryborough (Central District) was just making a start; and Mackay, which this last year produced over 9,000 tons of sugar, was unknown to civilized man.—*Trinidad Chronicle.*

Philippines Coffee Seed.—We have received from the importer (Mr. W. P. Ferdinands) a sample of Manila coffee. It is dried in the cherry and the seeds are in a good state of preservation. We trust this fresh seed will receive a fair trial at different altitudes and succeed well in Ceylon. An advertisement appears elsewhere.

The Tobacco Crop, having been favoured with an excellent planting season this year, has matured in good time, and has now been completed in Virginia. But less tobacco has been shipped from the State to England during the past year than in any previous year since the war, because the British market was found to be overstocked.—*Overland Mail.*

Kirkoswald Red Bark.—With reference to the enquiries elsewhere, we were just going to ask Mr. Arthur, manager of Kirkoswald, to favour us with particulars of the age and yield of his trees, when his letter came to hand this afternoon. The price realized is certainly very good. We are not sure that it has been beaten in the case of Ceylon red bark (?), although we have seen in Mincing Lane old red bark which fetched up to 8s and 10s per lb. for a certain quantity required by druggists for show purposes. In regard to both India and Ceylon, 5s has been generally considered the maximum per lb. for red bark.

Ledgeriana Cinchona in Ceylon.—It appears from Mr. Christie's explanation in another column that there are Ledgerianas from the same seed as those producing the rich Yarrow trees, on St. Andrew's estate, Maskeliya, fully five years old from the date of planting out. We made a mistake (or rather our printer did) in putting down 1875 as the year of Mr. McIvor's death. Mr. McIvor visited Ceylon in the latter part of that year, and his lamented death occurred in June 1876, just as Mr. Christie was planting out his first Ledgeriana plants. Although only a little over three years from the date of planting out, the Yarrow trees must surely be debited with a greater age if the plants were over 18 months in a nursery?

Liberian Coffee.—"The old disc pulper," after being abandoned practically for a great many years, is now, we learn, found to be suitable for the pulping of Liberian coffee, and is found in some cases to do its work well. Such is the report from a planter who saw an old disc used for Liberian coffee in the Kurunegala district. But on enquiry we find that the result of a series of experiments made by Messrs. J. Walker & Co. has proved that the disc pulper will not meet the requirements of the case, and that two machines, specially adapted, will be needed to pulp Liberian coffee thoroughly. This firm is, we believe, supplying two mercantile firms owning Liberian coffee plantations with the machinery which they have demonstrated by full trials to do the work efficiently.

Cacao in Ecuador.—The *American Mail* tells us that the Christmas crop of Cacao in Ecuador (usually a fair indication as to the probable yield of the entire crop of the year) proved to be very small, and cacao on the spot was quite scarce. There had been continual and heavy rains, to a considerable extent destroying the blossoms. Consequently only a small crop is expected in 1881. The total production of 1879 was 315,342 quintals, and that of 1880 has been ascertained to be 338,785 quintals. The quintal is 100lb. but whether the lbs. are the same as the English lb. we do not learn. The French metrical system is the only legal one, but commerce still clings to the old weights —as it does with us for cacao to the arroba, of 110 lb. English, instead of the cwt., or the very convenient cental of 100 lb. Engl. introduced into Liverpool for certain articles, from New York. Ecuador had 35 m. of railway in 1877. Its public revenue in the year 1876-77 was £740,966.—*Trinidad Chronicle.*

Australian Apples in India.—In January 1878, a member of the Calcutta Agricultural Society (Mr. S. H. Robinson) brought out on the "Khedive" a hamper full of apples from Devonshire of the ribstone pippin and flatnosed pippin kinds, both keeping or storeapples. In this hamper 60 were brought, lightly packed in the hamper, each in separate pieces of paper. After a voyage of six weeks two only had decayed, and four were somewhat bruised: the rest were all good and retained their flavour fairly. The hamper was kept in the cabin the first two weeks of the voyage, and for the rest of the voyage was kept cool in the ship's ice room, but not in the ice.—*Agrihorticultural Society of India.*

Bombay Agricultural and Manufacturing Co.—The prospectus of this Company, lately issued, states that it has been formed for the purchase of an estate of 7,000 acres in the Kunnah valley in the Bombay presidency, on which it is proposed to grow cotton, Liberian coffee, tobacco, oil-seeds &c. Regarding the Liberian coffee, the prospectus says:—"The climate, altitude, and soil of the estate appears to be of a most desirable nature for the culture of this tree. It is proposed to cultivate about 1,500 acres with the Liberian coffee tree; this, taking only four hundred trees to the acre, is estimated to produce about 5,000 cwt. of coffee." The capital of the Company is 250,000 shares of £1 each, of which the vendor takes 45,000.

The Tea-planters are crying out about agencies for the sale of their teas at home, without offering the slightest assistance to the struggling agency as advertised in your columns. I guess few have been to the trouble of cutting out the advertisement and forwarding it to their friends at home. If every one interested in the cultivation and the prosperity of the tea in Ceylon had done so, your late correspondent's friends need not have gone to so much trouble to procure the rubbish described at 5s per lb. The agent for the sale of Ceylon teas in Aberdeen and the North will be pleased to communicate with those who think their teas are not known or have not been sufficiently brought to public notice. I enclose *my card*, and shall be glad to hear from any one who is willing to encourage an agency for the sale of Ceylon tea.—*Cor.*

Australian Apples and Meat Biscuits.—We have received a number of appreciatory remarks on the apples which were sent by the Ceylon Commissioner as an experiment, and which we distributed as widely as possible. The Lieut.-Governor's Private Secretary writes:—"His Excellency the Lieut-Governor desires me to convey to you his thanks for the kind present of a box of apples forwarded to him by you from the Commissioner for Ceylon at the Melbourne Exhibition. They are of most excellent quality." The manager of a Colombo firm wrote:—"Many thanks for the two beautiful Victorian apples which you sent me. Will try them at dessert to-night, and if these prove as good as they're bonnie they'll be relished." A Kandy gentleman writes:—"I forgot to write and thank you yesterday for the Australian apple which was simply delicious. It will indeed be a great blessing, if we can manage to import these fruits at prices which will bring them within the reach of ordinary mortals. The Commissioner certainly deserves the thanks of the Colony for what he has done at Melbourne." As we said, the experiment was not an entire success, about 25 per cent of the apples being bad on arrival, but we hope this will be remedied in future consignments. The shipment to Calcutta was even more unfortunate, for we read in the *Friend of India*:—"We have had the pleasure of trying the quality of an experimental consignment of Australian apples which have been received by a mercantile firm in town, and

though the experiment has not been an unqualified success, the causes of the partial failure are, we understand, remediable, and it is not improbable that next hot season we may be able to regale ourselves to our heart's content with the finest of Australian fruits, fresh and full-flavoured. The present trial has been made by some fruit-growers in the neighbourhood of Melbourne in consequence of a memorandum on the export of fruit from Australia to India, issued by the Executive Commissioner for India at the Melbourne Exhibition. The apples were packed at Victoria between the 16th and 21st April and shipped by P. & O. steamer on 23rd April. After transhipment at Galle they arrived here on the 20th of May, but, unfortunately for the success of the experiment, the cases were, by some misunderstanding, left lying for a fortnight at the Custom-house. There is little doubt that this delay in delivery is largely accountable for the deterioration of the fruit, and the consequence is that only about one-third of the apples were found to be in sound condition. The packing also was not quite suitable for this climate, but this is a matter that can easily be rectified on the next occasion. The apples regarded as sound are very good indeed, but with better packing and prompt delivery there is good reason to expect that the flavour will, in future, be better preserved. It is also hoped that the P. and O. Company will run a steamer direct to Calcutta, and thus save the time lost, and the transhipment, at Galle. If, as we understand is the case, the fruits of Australia can be brought at a really reasonable price into the market here, we should say there is every likelihood that a brisk trade in them may soon spring up, in spite of the fact that the fruit season of Australia occurs at the time that will send them into our market just when it is full of our best indigenous fruits." As to Messrs. Swallow & Ariell's meat biscuits, these seem to have been greatly appreciated. We can testify to their being very palatable additions to soups, stews etc., and a gentleman writes :—"I have to thank you for the box of biscuits. I find them excellent carried, and they will certainly be very useful for travelling." A Scotchman says :—"Man, that was a delicious biscuit you gave me. It had the taste of solidity about it, but I found but little of the beef." A gentleman who has good teeth wrote :—"I did not wait to cook them in any way, but ate them 'straight off.' They smelt very wholesome and tasted more so." One of the railway officials said :—"I think about getting some up from Australia at once, for myself."

Jackson's Tea Drier.—We have received a circular relating to the apparatus patented by Messrs. W. and J. Jackson for drying tea, to the efficacy of which testimony is borne by a number of tea planters. The price complete with four spare trays and pyrometer is £104 4s. Messrs. John Walker & Co. are the local agents.

Ceylon and China Tea in Australia.—"W. B.," writing from Melbourne on 9th May to the Calcutta *Tea Gazette*, says :—There are plenty of people here interested in China tea whose great delight is to catch the Indian tea man "tripping," and samples of some very much damaged Ceylon tea that was sold a short time ago at 4*d.* per lb., were sent to the Editors of all the principal newspapers and made the subject of a letter on the PURITY (?) of Ceylon tea. This tea turned out to be no Ceylon tea at all, but something recovered from a wreck and packed in Ceylon,—at least, so say the consignees; but a little fire like this can be made to produce a great smoke, especially in an article that has excited as much jealousy as "Indian tea in Australia." Indian tea should be, like Cæsar's wife, *above suspicion*. Trusting this will meet with attention in the right quarter, &c.

INDUSTRIES IN FIBRES:

Jute, and Tree Mallow.

We call attention to Mr. Dobree's interesting letter on another page. He has forestalled our suggestion and has sent us an elaborate "Report on the cultivation of, and trade in, Jute, in Bengal, and on Indian Fibres available for the manufacture of paper, by Hem Chunder Kerr, Deputy Magistrate on special duty," which shews that he has had the best possible means of guiding his course as a planter. It has been stated that a Jute industry could not be profitably conducted in Ceylon, because of the poor soil and the comparative dearness of labour; but there are exceptions to the former rule, along the banks of the Gintara, for instance, and in other parts of the Southern as well as in the Eastern Province, while in regard to labour it will often happen that planters of new as of old products, have work to find for a labour force which they think it wise to keep up. Kerr's elaborate Report, accompanied by lithographs, gives a list of the principal fibre plants in Bengal, deals at some length with Hemp and Flax, and then takes up the Jute plants. The physical and chemical character of Jute land, and favourable climatic conditions, are described. Chapters are given on seeds, reaping, "retting" (steeping &c.), separation of the fibre, and on the cultivation and uses of the Jute plant. We shall make extracts and refer to some of the more practical portions on a future occasion.

Meantime we owe an apology to Mr. C. A. Hay, of Dolosbage, who lately sent us a sample of tree-mallow bark fibre, the produce of four months' growth and the result of an experiment Mr. Hay has made with seed introduced from Britain. An essay by Mr. Wm. Gorrie (which took a prize from the Highland and Agricultural Society of Scotland) on the tree mallow (*Lavatera arborea*) as an agricultural plant for cattle feeding, paper making and other purposes, affords very great encouragement for the cultivation of this plant. Mr. Hay, we are glad to see, has got out seed enough to cover an acre. He writes :—

The tree from which the bark was taken was only four months old, 5 ft. high and 3 inches in diameter. Unfortunately some animal ate all I had, but two. However they are getting on well, though they get the full force of the south-west wind and rain.

From Spon's "Encyclopædia" we quote as follows in reference to another of the same family :—

"Abutilon Indicum [Sida indica, S. populifolia]—Country Mallow.—Common in most parts of India and in Burmah. Stem yields a strongish fibre, fit for rope-making, and occasionally applied to that purpose in the Baucoorah district.

"*A. cxycarpum* is a shrub of various parts of New South Wales, Queensland, W. and N. Australia; yields a textile fibre. *A polyandrum* on the Nilgiri Hills, and about Nundidroog; yields a long, silky, hemp-like fibre, suited for ropes. The fibres of *A venosum*, *A. amplum*, *A. auritum*, *A. molle*, *A. striatum*, are utilized in S. Africa, Brazil, Australia, and the E. Indies. In Algeria, *A. indicum* is extensively cultivated."

But Mr. Gorrie's report leaves little to be desired by way of information apart from that which only practical experience can afford. He was thus led to enquire about the plant :—

"In July 1870 I spent some days near Kildonan, in the south of Arran, when I was much struck with the

gigantic size and showy appearance of the many fine tree mallows which were there grown for cottage-garden ornamentation, and had become naturalized in some waste places. Two of the former were found to measure fully 12 feet in height, while few were under 9 feet. In a long, hedge-like belt of the latter I came upon a continuous mass of fibre, stretched among a thick growth of grassy herbage, which turned out to be the only remains of a large mallow plant that had fallen or been broken down the previous season, and all else of which had rotted away. This fibre I took with me, along with a sample of fresh bark; and having subsequently secured specimens of the matured plants, as well as a supply of the ripe seeds, I handed a portion of each to David Curror, Esquire, Secretary to the Chamber of Agriculture, who had the bark tested for its fibre properties by Messrs. A. Cowan & Sons, of the valley-field Paper Mills, Penicuik; and the seeds analysed by Dr. Stevenson Macadam. In a note which Mr. Curror sent me, dated 21st November 1871, he stated, 'the results are that the stalks are worth £5 per ton for paper-making; and the seeds as valuable for feeding as linseed cakes.'

An analysis of the seed is given as follows with a favourable report of growth:—

"Analysis of sample of 'Tree Mallow Seed,' received from D. Curror, Esquire, Secretary of the Chamber of Agriculture, Edinburgh. Grown at Kilmonan, Island of Arran.

Moisture	15·56
Oil	11·78
Albuminous compounds	18·45
Starch, gum, and sugar...	43·83
Woody fibre ...	4·96
Ash	5·42
	100·00
Nitrogen	2·96
Phosphoric acid in ash equal to ordinary bone phosphates ...	1·68

"The tree mallow seeds possess the nutritive constituents of a good feeding stuff, and well deserve a trial by the feeders of stock. It is not so rich in albuminous or flesh-producing ingredients as linseed, or other well-known cakes, but considering the loss of nutrient value in the manure when the richer cakes are given to cattle, it is possible that the tree mallow seed would not be much behind ordinary cake in feeding qualities. Stevenson Macadam, Ph. D., F.R.S.E., Lecturer on Chemistry.

Mr. Archibald Gorrie, then wood manager for the Earl of Leicester, Holkham Hall, Norfolk, wrote on the 17th August and 3rd September 1874:—"A plant of the tree mallow No. 1, grown by itself, yielded 10 lb. of green bark, which was reduced to 4 lb. by drying and its dried seed weighed 2 lb. 13 oz. Plants 2, 3, and 4, grown in a row about 2 feet apart, yielded 16 lb. of green bark, which when dried was reduced to 8 lb., and their dried seeds weighed 7 lb."

We then have the following statement of the uses and best mode of cultivating the tree and preparing the bark:—

In addition to the *cattle-feeding* and *paper-making* properties of the tree mallow, it may be beneficially and economically employed for other purposes such as *Sheltering sea exposed gardens*, and other grounds. At a meeting of the Scottish Arboricultural Society, held on the 1st of Nov. last, I recommended the tree, or as it is sometimes called the sea mallow, as a nurse for sea exposed young plantations, it being peculiarly adapted for affording protection to the young trees before these attain sufficient sizes to shelter one another. When thus employed it is advisable to sow the mallow seeds in nursery drills or beds towards the end of June, so that they may not flower next year, and transplant them as soon as they are 4 to 6 inches high, where the forest trees are to be planted next spring. For succession, another planting of like sized mallows should be made in July or August following, to remain green and so maintain the shelter after those first planted have seeded and been harvested. Afterwards the seeds that will get scattered annually, even with careful harvesting, will suffice to keep up a sufficient succession as long as the sheltering aid of the mallows may be needed.

That "*nutritive mucilage*," which is peculiar to the *Malvaceae*, or mallow family, and for the esculent, emollient, and other properties of which the okra (*Hibiscus esculentus*), the marsh mallow (*Althea officinalis*), and others are much reputed, is also abundantly present in the tree mallow, from which it may be obtained in sufficient quantities to allow of its being used as a condiment in the less nutritious animal foods, such as cut straw, chaff, &c., in addition to its more extended employment in culinary dishes, comfits, and the manufacture of toilet soaps. The okra above mentioned is extensively cultivated in tropical and sub-tropical countries for its pods and seeds, the former in their young state being pickled like those of kidney beans; the latter impart a mucilaginous thickening to soups, and are used in the manner of green peas; when ripe they are boiled like barley, and roasted as a substitute for coffee. The okra has also been long recognized as a textile plant, and a patent has recently been taken out in France for making paper from its fibre, for which it is being extensively cultivated in Algeria. Its fibre is prepared solely by mechanical means, in a current of water, without any bleaching agent, a mode that is also likely to be applicable to that of the tree mallow.

For *green manure*, to be dug or ploughed into the ground, the rapid and luxuriant growth of the tree mallow renders it particularly suitable. Some have assumed that, in consequence of its immense growth, it must be a very scourging or soil-exhausting crop. In reality, however, this does not appear to be the case, for the plants have comparatively few, and by no means farspreading roots, and throughout the whole period of their growth, but more especially in that of the first year, they shed an abundant, continuous succession of their large succulent leaves, which overspread the ground surface with a thick leaf-manure covering. Thus the plants are not only large producers of their own nutriment, but seemingly derive much of their sustenance from the atmosphere, as is evinced by the forementioned tenacity of life in the unmatured plants.

For *distillation*, the seeds of the tree mallow are likely to be useful. A friend to whom I showed them, and who in America had much experience in distilling from buckwheat, as well as from Indian corn, and the ordinary cereals, stated he had no doubt but they would yield over a gallon of proof spirit per 50 lbs.

As *an ornamental plant* for garden and shrubbery decoration the tree mallow has few equals; whether for the tropical like luxuriance of its first season's foliage, or the exuberant abundance in the second year of its gracefully displayed mauve coloured flowers, which resemble those of the common mallow—*La mauve* of the French; and may yet be brought by horticultural skill to yield an endless variety both in colour and form.

Cultivation.—The tree mallow accommodates itself to a wide range of soils and situations, not excluding from the former bogpeat, if sufficiently drained to free it form stagnant moisture; and although it thrives inland provided the temperature does not fall too low, it is most at home on the cliffs, and among the earthmixed debris of sea-side rocks, or among sea sand-hills on their partly consolidated slopes and hollows. Under cultivation it will grow on most soils that are suitable for ordinary farm

crops, and in many places where the exposure is too much for these.

Ordinary farm-yard manure may seldom be available for tree mallow culture, but a convenient substitute will often be found in those immense quantities of sea-weed or wrack that are often thrown ashore near places that are highly suitable for its growth. The droppings of sea birds on its native cliffs suggests the application of guano; and in inland localities common salt could not fail in being highly efficacious. The period at which plants naturally sow or disperse their seeds is generally deemed the best, or at least a good time for sowing them in their native countries. To this rule, however, the tree mallow may be deemed an exception; as a good many of its earliest fallen seeds vegetate in mild periods of the succeeding autumn and winter months; and although in very sheltered places these may escape, yet in many cases most of them will succumb to the succeeding winter and spring frosts. Hence it will generally be found preferable to sow the seeds between the middle of March and the end of April, as if much longer delayed many of the plants will not flower the next year, but assume a triennial in place of a biennial duration. The seeds being sown either in drills or broad-cast, the young plants, when about 6 to 10 inches high, should be transplanted to where they are to remain, or in case of the ground being then filled with an early crop, such as early potatoes or pease, they may be temporarily transplanted at 4 to 6 inches apart till such crop is removed and the ground prepared for them; when they should be planted out either by the dibber or plough at from 18 inches to 4 feet apart; till more experience shows the distances that are most suitable for them in different soils and situations. When to be grown on the most exposed sea-coasts, either as an exclusive crop or for sheltering young plantations, they should be planted out when about 4 inches high, or the seeds sown in the places where they are to grow. No plants—those of kale and cabbage not even excepted—stand transplanting better than those of the tree mallow; but when its seeds become sufficiently abundant, it may in some cases be found bet to sow them by machines, and afterwards thin ou the young plants as is done with turnips. Intending cultivators should guard against getting their seeds off inferior varieties, such as that of the Bass Rock, which is dwarfer, as well as more horizontally spreading and more branching than the one here recommended. They should also avoid getting seeds from Southern Europe or other warmer climates than those of its British habitats. This last precaution may be deemed as of only temporary application, seeing that from the number of experimental growers, and the quantity of plants they have already planted out, or that will be so sufficient early next summer; and abundance of home seed for sowing as well as for practically testing its cattle-feeding qualities, will be produced in the autumn of 1878. And as with other cultivated plants the tree mallow can doubtlessly be improved by selection, careful cultivators will do well to select their "stock seeds" always from the best plants.

The thrashing or separating of the seeds from the stalks or haum, may either be done by rippling combs, as with the flax; by flails, or by machinery. It is probable that it may be found advisable to cut off or separate the seed-bearing twigs from the thicker branches and stems, as doing so would likely facilitate the after operations of stacking or storing, thrashing, and peeling.

Peeling or stripping off the bark is easily done at all times during the growth of the plants, and only a little less so when the seeds are sufficiently matured for pulling or cutting the crop; while even after the stalks are dried by stacking, or standing them out on end through the winter, the bark comes off quite freely if they are saturated for a short time in water, or even thoroughly wetted by rain.

The principal advantages to be derived from the cultivation of the tree mallow are its production of two crops or returns—*seeds* and *fibre*—either of which would alone remunerate its growers; its suitability for extensive districts which are now almost worthless, or only capable of bringing low pasture rents; the the prevention or abatement of river pollutions, as little if any caustic soda or other deleterious chemicals will be required in the preparation of its fibre; ier resistance of injury from wet weather at, andaft st harvesting.

We think we have quoted enough to enable our agricultural and planting readers to feel that the "tree-mallow" is a plant deserving of attention even in Ceylon, and we shall follow with great interest Mr. Hay's Dolosbage experiment. The sample of fibre sent to us is most promising, but it will be impossible to say what its value may be without reference to home commercial and manufacturing authorities.

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.—*Manure experiments.*—The following have been sown.—Maize. bujra, sun, dharus, in the economic portion of garden, under the same conditions, as at the experimental farm at Bangalore; the seed has germinated well, and in due course will be reported on. Over half an acre of ground is now planted out with American maize seed, acclimatized at Nepal, and presented by Mr. Girdlestone lastly as to the Society. This seed germinated well, and the plants are looking vigorous and healthy, and will be fully reported on hereafter. *Panicum spectabile.*—Raised from seed, occupy a small plot in our economic garden, and are making vigorous growth.

THE PACKING OF INDIAN TEA FOR THE AUSTRALIAN MARKET.—The following extract, from a private letter received from a gentleman in Victoria, has been kindly placed at our disposal:—If tea planters want to foster the Australian trade, let them send down quantities in *half* and *quarter* chests to some agent who will sell for *cash* only, and at as cheap a rate as will pay the exporters. The Australians are the greatest tea drinkers under the sun, but what we want is a medium tea at a fair price, and the tea put in good boxes that will not require to be tied up. I often wonder why your tea planters cannot get a machine like the one which makes the kerosine tins, and have them after the same size and shape: they would be air-tight, and the tin would save the lead lining, and as they would be made all the same weight, this would save finding out the tare, &c. The subject is a most important one, and deserves the best attention of those who are shipping teas to Australia. The P. and O. Co. will not receive larger packages of tea than half chests of 40 lb. for shipment to Australia, but quarter chests containing 20 lb. might, we think, be shipped to advantage. We have several times of late heard it stated that the best method of packing teas for Australia is in the patent lacquered tin tea boxes manufactured by Messrs. Harvey Bros., and Tyler. The above extract and the London Letter from "One concerned"—published in our last issue—certainly bear the statement out. The only question that arises is, will tea keep in tin packages without deteriorating? Some there are who assert that it will not, and that tea must be packed in lead if it is to retain and keep uninjured its properties; from others we have heard that the tin imparts an unpleasant flavour to the tea. We shall be glad to receive the opinions of any of our friends on this subject who may be able to speak from experience.—*Indian Tea Gazette.*

Correspondence.

To the Editor of the Ceylon Observer.

CEARA RUBBER.

Dear Sir,—Can you or any of your correspondents inform me how many Ceara rubber seeds are contained in an oz. ?—I am, dear sir, yours faithfully,

W. S.

COFFEE ESTATE ECONOMY.

15th July 1881.

Dear Sir,—I am glad to see that "Hard-up Proprietor" has called attention to the question of coast advances. Many estates last year refused to make any reduction in kanganies' and coolies' pay, and on many others the pay was not greatly reduced.

I think your correspondent is wrong in saying that "the coolies remained well satisfied." Numbers of them have left us and will not return till times improve.

Advances are now being given out by many estates which last year carried out the Colombo instructions, and many others are so short-handed that it is time the Cheap Circular Council began to procure the labour supply that we are so much in want of.

It would be of great use to many of us if the number of railway coolies were published monthly, because there is no doubt that many of those who are not well-satisfied with their agents' little alterations seek easier employment on the new line.

As regards the subject of coast advances, experience shows that the agents were wrong in trying to suppress the system *in toto*. Admitting that many kanganies obtained their advances without any intention of using the money to procure labour, why should the honest be made to suffer with them? And what grand inducements can the agents offer to the coolies, in times like the present, when necessity does not suggest their visiting Ceylon?

Is it not possible for the Planters' Association (if properly supported) to appoint agents in the various labour centres?—Yours faithfully, REFORM.

JUTE IN CEYLON.

Udugama, July 18.

Dear Sir,—On the 3rd of April last I sowed some jute seed in showery weather at Ginnidomine, It was up within three days, but the weather being unusually dry much of it withered up. Out of about twenty thriving plants the stalks on the greater number of them are now 3 ft. 6 inches long, and the seed pods on the lower end of the stalks are ripe. This growth of only 3 feet 6 inches is very poor, but I believe is caused partly by the seed having been sown too early and before the rains had properly set in, and partly by the ground not having been sufficiently dry and prepared for the reception of the seed.

The jute seed sown was the "Corchorus olitorius" which has an elongated seed pod.

I send you, by to-day's post, a report on the cultivation of jute made for the Indian Government which gives all particulars as to cultivation and cost. The crops seem to vary from 1,000 lb. to 4,000 lb. per acre, and the value in Calcutta from 3 cents to 6 cents per lb., i. e. in 1871-72. What it is now I do not know. This price i. e. 6 cents per lb. would yield very little profit, if any, at 1,000 lb. per acre. At 4,000 lb. per acre, the profit should be at least R120 per acre. It has, however, still to be shown what crop the Ceylon soil can yield. In the appendix to the report I send, there is a statement of the American crops and prices the average crop being put down at 2,000 to 3,000 lb. per acre and the prices from 12 to 26 cents (Ceylon coinage) per lb. These crops and prices would, if they can be realised, yield an enormous profit. I think jute should be tried on the Trincomalee side, sowing the seed at the commencement of the N. E. rains, but not in land liable to inundation.

I intend sowing some seed here at the commencement of the N. E., and will be able to give it a fair trial then, which it certainly had not before.—I remain, yours faithfully, T. S. DOBREE

CINCHONA CALISAYA FROM MR. McIVOR'S SEED IN DIMBULA.

Langdale, 21st July 1881.

Dear Sir,—If the Yarrow trees were grown from cuttings and other plants from Mr. McIvor's seed, then I have the same on Easdale, and I think they are to be found on Abbotsford also and other places. Speaking for myself, Mr. McIvor, when here, gave me seed of *all* the kinds he had, and amongst this was certainly calisaya, which, as Mr. Christie says, he stated would be good, but would not make a big tree. My experience so far is that it did *not* make a big tree, and so far analysis does not shew it any thing out of the way in quality. However, it is a good bark, and I fancy the elevation may have something to do with the quality, and that the analysis may improve with age. I am sorry to say I have not raised very many trees, nor have I at present any seed or cuttings available, but I shall certainly now set to work to collect these, and, if they won't do well up here, they may do as well as the Yarrow trees, if planted at a lower elevation.—Yours faithfully,

E. HEELIS.

COFFEE LEAF DISEASE AND CULTIVATION.

Wattegama, 21st July 1881.

Dear Sir,—I was glad to read from your London Correspondent's letter of June 24th, that my statement that other trees, besides coffee, are affected with leaf disease, made some time ago, and to which I steadfastly hold, has been confirmed by such men as the Commissioner of Agriculture at Bogota, and Dr. Cooke viz. :—"It also attacked the trees grown to afford shade to the coffee bushes." I can now, from particular observation, go further, and state that where my coffee was badly affected with leaf disease, and I used my remedy, it left the coffee (you may say, like a swarm of bees, although not visible to the eye), and settled on shade trees close to: on del, jak, custard-apple, cashu-nut, or cinnamon, whichever of these was nearest the spot, and each one of these trees so affected died, unless, as soon as discovered by me, I cut off all affected branches, or even cut the trees down to 4 feet above ground: there have been other trees, the orange and croton, which were ablo to shake off the disease and recover. We also have the disease in three forms: the pin-spot, the rib disease, and the black rot. The pin-spot is the worst (such is my humble opinion). At the same time, I am not afraid of either. We can keep leaf disease from doing as much damage by proper manures and disinfectives applied in proper time and get good crops. More power must be given to the superintendents who are on the spot: and visiting agents should not be appointed to go all over the country, but each firm should have one manager in each district to look after their superintendents and estates in that district only, and one of the firm should do the general visiting, say once every three or six months.—Yours faithfully,

J. HOLLOWAY.

P.S.—As regards the idle reference in "Everybody's Column," 'go it Maria, &c.,' you know I have always made public my style of work &c. As regards crop, I have only 110 acres in bearing—yes, 6 cwt. per acre, and have already picked 400 bushels parchment. Seeing is believing: let any sceptic come and see.

CARDAMOMS FROM SEED.

July 22nd, 1881.

DEAR SIR,—As I have heard doubts expressed as to whether cardamom bulbs raised from seed grown in Ceylon will fruit or not, I shall be much obliged if you, or any of your readers, will inform me on the subject.—Yours faithfully, PLANTER.

CORRECTIONS: PHORMIUM TENAX.

Maturata, 22nd July 1881.

DEAR SIR,—In my last letter on the above subject there are one or two small errors which I write to correct. One sentence reads: "The Maori name of the clean fibre is juto." Kindly read "feeto" instead. Again: for "The Lokomariro and Sairiri plains in the Middle Island" read "Tokomairiro and Tieari." I have no doubt the fault is mine, as my reputation as a distinct writer is not a good one.—Yours truly, PHORMIUM TENAX.

CEARA RUBBER SEEDS.

Rangala, 23rd July 1881.

DEAR SIR,—For the information of "W. S." writing in your paper of Thursday last, I have just weighed an ounce of Ceara rubber seeds, which number 48.

I am much pleased with the *Tropical Agriculturist* and enclose an order for it. L. B.

RECEIPT FOR GUM FOR TEA PACKETS.

(*Indian Tea Gazette.*)

DEAR SIR,—The following is a recipe for what we use to gum our Tea packets and labels with. A tea cup full of rice, the coarser the better, two tea cups of water. Bring the water to a *boil*, add the rice, keep stirring till the rice is thoroughly dissolved and forms a pouring but thick substance: strain this through coarse cloth to make it smooth, apply it to your labels, &c., and put them in the sun to dry, or by the fire. It holds in damp weather, and has no odour, agreeable or otherwise. I hope "Griff" may find it useful.—Yours, "PLANTER."

COCONUT CULTIVATION.

TO THE EDITOR OF THE "MADRAS STANDARD."

DEAR SIR,—In one of your late issues you strongly advocate "coconut cultivation" in Madras, as it would be a source of great revenue not only to the proprietors of the trees but also to Government. Admitting that the juice of the coconut tree is useful, yet, the fruit of the trees grown in the town cannot be used for curries or sweets, or in making oil as the coconuts grown on the Western Coast or in Ceylon. The fruit of the coconut tree cultivated in Madras is never used, and a reference to our cooks will verify my statement. The tender coconuts are extensively eaten by Hindus and others during the hot weather, and these are sold on the roadways and purchased by weary travellers, to whom they are welcome. I am glad that you have mooted the subject of coconut cultivation, and hope it will not end here, but that some persons who have funds at their command would carry out the suggestions contained in your article. Had I the means, I would readily take the hint, rather than invest in gold mining and bite my fingers in the end. T.

CONSUMPTION AND MANUFACTURE OF QUININE.

We publish on next page extracts relating to the consumption of quinine in the United States, and the manufacture of the drug in Italy. It will be seen that in 1879 there were imported into the United States 46,700 bales of cinchona bark and 228,348 oz. of quinine. Congress having in June of that year abolished the duty on the manufactured article, in 1880 the figures were :—416,998 oz. of quinine and only 32,800 bales of bark. That the action of Congress did not benefit the population much, however, is seen from the fact that the price of quinine remained at the same average, $2·66 per oz.: this was due to the fact of the duty being retained on the bark, and to the manufacture of the drug remaining in the hands of speculators. We hope Congress will remove the duty from the raw article as well, for, as we recently pointed out, the population of the States dwell for the most part at a low level above the sea, where febrifuges are more needed. As to nthomanufacture of quinine in Italy, it will be e ticed that not less than two-thirds of the English supply is derived from the Milan factory, Holland also getting half her supply from the same source. This is remarkable, considering what large growers of cinchona these two countries are. There is nothing new to our readers in the report of Mr. van Eetvelde on the culture and manufacture in India. Germany it seems has five quinine manufactories, the most important being the Zimmer one at Frankfort, which has large estates in Java.

ADULTERATED TEA.

TO THE EDITOR OF THE "AGE."

SIR,—The name of this firm having during the last few days been prominently brought before the public by Mr. Bowman, M.L.A., in connection with certain teas recently imported by the "S. S. Glamis" Castle, and as his statement, together with others which have appeared in public prints, are calculated to place us in a false position, we are desirous of making a statement of the actual facts of the case, so far at least as they concern us individually. A consignment of teas per s.s. Brisbane was made to us by a Hong Kong firm of the highest repute, for sale on their account, and was brought on here from Sydney by the steamer "Glamis Castle." On its arrival, and acting in accordance with our instructions, we offered this parcel to the trade at auction, through Messrs. Fraser and Co., and cleared out the whole without reserve. The teas no doubt were of inferior quality, and realised correspondingly low prices, but which, we are not prepared to admit, represented the full intrinsic value of the consignment. After this, and observing the action taken by Mr. Bowman, and before endeavoring to deliver a single package, we took three general samples, numbered 1, 2, and 3 and submitted them to Mr. Kruse for analysis. His report, which is given herewith, shows the teas so far as represented by the samples to be free from adulteration and certainly not unwholesome, no deleterious substance or mineral ingredients having been found to be present. At the same time, we also handed Mr. Kruse a sample (marked No. 4 in the report) of a parrel of 130 quarter-chests of gunpowder tea imported by another firm, and purchased by Mr. Bowman, M. L. A., on the 26th ult. From the analysis of this compound it will be seen that it contained no less than 16·5 per cent of mineral substances, consisting of clay, turmeric and Prussian blue, and therefore highly detrimental to health. The purchase of this parcel, Mr. Bowman stated in the House, he passed on to another party: but whether this be the case or not, it does not materially alter the fact that

he was, by doing so, without exposing its quality, practically assisting in the distribution and consumption of a spurious compound of quite a different nature from the teas which have been proved by analysis, however inferior their quality, at any rate not prejudicial to the public health. Apologising for occupying so much of your valuable space, and trusting that both the trade and the public generally will now be able clearly to recognize our true position in this matter.—Yours, &c., Dalgety, Blackwood & Co.

Melbourne, 18th June.

QUININE MANUFACTURE IN ITALY AND GERMANY.

(From the *Journal of the Society of Arts.*)

The following account of the manufacture of sulphate of quinine in Italy, with suggestions as to the cultivation of the cinchona tree in the United States by Consul Crain, of Milan, is taken from the *Journal of Applied Science*. The manufacture of salts of quinine is an important Italian industry. It has been carried on at Milau and Genoa since 1870. Twenty-two thousand five hundred pounds are consumed yearly in Italy, of which one half is made at Milan, 6,750 lb. at Genoa, and the balance imported from Germany. Forty-five thousand pounds of quinine and salts of quinine are produced in Italy. The production of the world is estimated at from 230,000 lb. to 260,000 lb. per year, as follows :—Germany, 56,250 lb.; Italy, 45,000 lb.; France, 40,000 lb.; England, 27,000 lb.; America, 63,000 lb.; India, 12,250 lb. The two Italian factories produce 45,000 lb. of the sulphate of quinine viz. 40,500 lb. at Milan, and 4,500 lb. at Genoa. The first of these employs 45 hands, the second 15. The Milan factory ships largely to all parts, furnishing large supplies to Russia, France, and Austria. England receives two-thirds of her supply, and Holland one-half of hers from the same source. Efforts will be made to acclimatise the cinchona in Italy, to increase the supply and lessen the cost of the product. Its successful culture in India and Ceylon encourages the belief that it will grow wherever the soil is dry, the rainfall large, and climate temperate. Many parts of the United States fulfil these conditions, and notably where its product is needed. The culture of the cinchona in America would cheapen an indispensable medicine, and open a new industry to capital and labour. In this connection some facts reported by Mr. E. Van Eetvelde, the Consul-General of Belgium in India, are instructive. He reports that the best varieties of cinchona have been successfully acclimatised in British India. The Government there cultivate chiefly the "Cinchona succirubra," which contains a large quantity of febrifuge alkaloids, and the "Cinchona calisaya," which is better suited to the manufacture of quinine. The culture of the first has been successful. Uncertainty still exists as to the "Cinchona calisaya," and the Bengal Government are examining the plantations of Java, where it has been cultivated with entire success. The cinchona plantations are in two distinct regions of India—in the north of the Neilgherry Hills, in the Madras Presidency, and on the slopes of the Himalayas. Those of the Government are as yet the most important, covering 1,300 acres on the Neilgherry Hills, and nearly 3,000 acres in Sikkim. There are several private plantations of later date already producing marketable bark. The red bark (*Cinchona succirubra*) has many febrifugal alkaloids, but little quinine. It was important, therefore, to determine the therapeutic value of the alkaloids and the cheapest means of extraction, in order to furnish a good febrifuge at a moderate price. The Medical Commission recommended the extraction of cinchonine, cinchonidine, and of quinine by simple means, and the Government now sells a mixture of these three alkaloids under the name of "Cinchona febrifuge." As the price does not exceed 2s 7d per oz., this febrifuge is used in nearly all the hospitals of India, and sold in large quantities to the public. The chief surgeon of the north-east province reports that the doctors are unanimous in declaring that the "Cinchona febrifuge" is a medicine of recognised efficiency in the treatment of ordinary intermittent fevers, and that it is an excellent prophylactic for those who live or travel in marshy countries. Most doctors are, however, of the opinion that it is inferior to quinine as a therapeutic agent, that its effect is slower, and that it is insufficient to cure severe intermittent fevers. That it is a medicine of value is shown by the increase in its use in the Indian hospitals, which, as the following figures show, is remarkable :—1874-75, 48 lb. ; 1875-76, 1,940 lb. ; 1876-77, 3,750 lb. ; 1877-78, 5,162 lb. ; 1878-79, 7,007 lb. The hospitals took more than 5,500 lb.; in 1878-79, and, as the use of quinine diminished in the same time about as much, it is a proof, considering the cost of the last-named alkaloid, that the Indian Government saved about £25,000. At the present time the Government chemist of India is trying to produce a better febrifuge, by mixing three sulphates, viz., cinchonine, cinchonidine, and quinine, of which the cost would be a little higher. Financially, the plantations of Sikkim gave last year a net profit of nearly £4,000, although not fully developed, or 4½ per cent. on the sum invested

From an official report recently published, it appears that within the German Empire there are five quinine manufactories, of which Prussia, Wurtemburg, Baden, Brunswick, and Hesse have one each. The most important German establishments are those of Zimmer, in Frankfort-on-the-Maine ; of Böhringen, in Mannheim ; and of Jobst, in Stuttgart. The Zimmer establishment was founded by Dr. Conrad Zimmer, in the year 1837, and soon acquired considerable renown. It is now a very complete and extensive manufactory ; it consumes about 50 bales of cinchona bark, and produces about 50 kilos of quinine daily. The principal preparations of the German establishments are the sulphate and muriate of quinine. Of unbleached, or so-called hospital quinine, made from various alkaloids, they produce very little ; while the cinchonidia sulphate is manufactured in large quantities, especially for export to the States. The efficacy of this drug is said to be similar to that of quinine, while its price is only one-third or one-fourth that of the sulphate of quinine. Amongst the numerous other salts and preparations of quinine made in Germany are chiefly to be mentioned the preparations of the amorphous quinines, especially the muriate. These preparations, being perfectly soluble, are much employed for injections in cases of fever resulting from wounds, and are therefore of particular importance to army hospitals. The German manufacturers get their cinchona bark mostly from London or Paris, which are the principal markets for that commodity. The bark is also brought extensively to Amsterdam from Java by the Dutch Government, and of late years occasional lots have been imported at Bremen.

The Zimmer factory at Frankfort, two or three years ago, bought large territories in Java, and now employs about two hundred natives in clearing ground and planting cinchona.

The Assam Company.—At the meeting of the shareholders of the Assam Company a dividend of 7 per cent. was declared. The chairman (Mr. W. Prideaux) referred to the depressed prices which Indian teas have recently been realising. He stated that the latest shipments have been of a better quality, and he looked to an improvement in the position of the company in future.—*Overland Mail.*

THE CULTIVATION OF RED BARK AT HIGH ELEVATIONS.

Nothing could be more satisfactory for the cultivators of cinchona succirubra than the prices obtained for the Kirkoswald bark referred to the other day. If prices approaching to 5s 6d per lb. could always be obtained, the cultivators of the quick growing and heavy cropping species of cinchona might consider themselves as well off even as proprietors of the far-famed Ledgerianas. But it must be remembered that the Kirkoswald trees were fully eight years when the bark was harvested, and that period will be considered by many too long a time to wait. The bark in question too was bought chiefly on account of its fine appearance due to careful harvesting and preparation as well as to its age. It is of interest, therefore, to know what prices may be expected for renewed red bark of younger growth, sold according to its intrinsic analytical value, and we think that from this point of view the following statement respecting the Abbotsford bark disposed of at recent sales will be deemed satisfactory. It will be noted that renewed strips which had been under moss for only two years realized from 3s 3d to 3s 9d per lb. :—

CINCHONA SUCCIRUBRA NATURAL AND RENEWED UNDER MOSS.

Abbotsford Estate, Lindula. Elevation 4,600 to 5,300 feet.

Natural Bark.—From trees 5 to 8 years old, some of which had been stripped before, others for the first time : majority of strips 6 to 8 feet long—broken into lengths of 2 feet for packing. (Fetched 2s per lb.)

Renewed.—Strips 3 to 5 feet in length, broken up as above for packing : had been under moss 2 years. (Fetched 3s 3d to 3s 9d.)

CEYLON AT THE MELBOURNE EXHIBITION.

ADULTERATION OF TEAS.

The Melbourne *Age* of June 25th, which, with a mass of other papers, I send to the Editor of the *Observer* by the outgoing mail, contains Mr. Robinson's trenchant article on the adulteration of China teas. In the same issue appears a mass of correspondence on the subject of adulterated and pure teas, including a letter addressed by Mr. Moody to the Board of Health with reference specially to "faced" green. The information embodied in this letter is interesting and valuable, but it is unfortunate that my good friend should *seem* to plead for the use of Prussian blue and turmeric in the case of one class of teas. You will see that the *Age* does not allow of any exception. The difficulty is to alter public taste once formed. I think I wrote you on a former occasion that Messrs. Henty & Co. once got a consignment of unfaced green tea from China and that it was returned on their hands by the dealers. Following Mr. Moody's communication is one from Mr. Everard, who, professing to be a great friend of pure Indian and Ceylon teas, asserts, in the face of all the analyses published by Mr. Dunn, that only a *few* of the China teas are bad The very converse of the proposition is true, and never in the whole history of the trade was such abominable rubbish poured into the Melbourne market as during the season just closed, while this season's teas are reported as not better but worse. "A Retail Grocer" follows Mr, Everard, giving credit to the leading Melbourne firms for setting their faces against the import of bad teas. Then comes my letter in which I point out that in view of all the disclosures made an adulteration act is certainly needed, but that, meautime, the public can protect themselves by using the perfectly pure teas supplied by their own countrymen in India and Ceylon. In the *Argus* of 28th June, Mr. Inglis, the Commissioner for India, followed, repeating my argument, with force and emphasis. "An Ex-Ceylon Planter" follows in the same paper and shews that in some respects Ceylon teas are superior even to those of India. In the *Argus* of the 30th Mr. Everard came out at great length and most characteristically. Mr. Inglis, in the *Argus* of July 2nd, made excellent use of an article quoted into the *Weekly Ceylon Observer* from the *North China Herald*, shewing the pure Indian teas were rapidly superseding the inferior China produce. A very important contribution to the literature of pure versus adulterated tea is the elaborate review of the tea season 1880-81, by Mr. Robinson, in which he had the competent assistance of Mr. Moody. It appeared first in the *Leader*, a weekly paper published at the *Age* office, and in this paper I have marked it for insertion in the *Observer* as soon as room can be fonnd for it. The figures shew that the import of tea into Australia last season was beyond all precedent, the amount being nearly 23 millions of pounds against an average of about 16 millions for the previous three seasons. Out of the 23 millions 10⅝ millions came to Melbourne, of which over 6 millions were delivered for home consumption. An overdone trade and low qualities led, of course, to a lowering of prices, from which the markets are still suffering. An extract from the *North China Herald* is taken to shew that in 1880-81 the *increase* in exports of tea from China and Japan was 40 millions of pounds, a quantity equal to the whole increase in eleven years previously! No wonder if the markets were glutted and the prices of tea lowered to the injury of Indian and Ceylon teas as well as those from China. Of 4,395,000, sold by auction at Melbourne, of China teas, I notice that 11,349,000 sold at 9½d to 10½d per lb. The range was between 3½d and 1s 10d. Such prices cannot possibly be remunerative to Indian and Ceylon tea planters, and it is doubtful if they left any profit to producers in China, or at least to purchasers in the China markets. It indicates the approach of an important revolution in the Australian tea trade, to find that nearly half the review of 1880-81 is devoted to the first appearance in appreciable quantity of the produce of India and Ceylon. Both countries owe much to Mr. Robinson of the *Age* and the firm of Henty & Co. The latter, I know, are determined to do full justice to the pure teas, even if at first their operations should involve considerable loss. The quantity of Ceylon tea sold in Melbourne in season 1880-81 was 54,000 lb., over which quantity, I doubt not, each successive following season will shew a large increase. Our planters must do their best to produce superior quality tea as economically as possible. The traditions of low prices are difficult to eradicate. Besides the article and letters to which I have specially referred, there are numbers of paragraphs, which I have marked in papers sent to the *Observer*.—A. M. F.

COCOA-FIELDS in the Kurunegala district are reported on very favourably : trees little more than three years old are bearing a heavy crop, in some individual cases at a rate up to 7 or even 10 cwt. per acre.

OSTRICHES are being successfully reared on a farm of 30 acres, four miles out of Sydney, by Mr. J. W. James, who two years ago brought some birds from the Cape. He has nine young healthy birds already from two pairs of imported ostriches.—*Colonies & India.*

CEYLON AT THE MELBOURNE EXHIBITION.

(Editorial from the Melbourne "Age," 25th June 1881.)

As *The Age* was the journal which first directed, on the 8th inst., public attention to the fact that certain very inferior or adulterated teas were likely to find their way into consumption unless the Government interfered, it is satisfactory to find that our warning has not only had the desired effect of stimulating the efforts of the health authorities to prevent this, but that the analysis we asked for has conclusively proved that our suspicions as to the character of the tea in question were merited. Mr. Frederic Dunn's analysis may be taken as conclusive on the point. From two samples drawn from the bulk of the teas sold at 3¾d. to 4¼d. per lb., the following result was obtained:—

Price paid.....	3¾d.	.....	4¼d.
	Per cent.		Per cent.
Ash...	6.25	... ...	...6 60
Soluble salts... ...	2.45	... ...	...2 48
Extract...	27.0	... ...	...24.0
Theine	0.56	... ...	...0.75

According to a very recent analysis made by Mr. Cosmo Newbery of the teas packed by the various Melbourne firms, we find that the genuine article shows: Ash, 5.06 to 5.74 per cwt.; extract, 29,90 to 39.35; soluble salts, 2.90 to 3 54. (The highest percentage was obtained by the Oriental Tea Company.) The prices of these teas range from 2s. to 3s 6d per lb., duty paid. But in addition to the want of quality shown by the samples objected to, Mr. Dunn further sets at rest the question of whether they are adulterated or not by stating that the difficulty was to find "a perfect and genuine tea leaf in the samples." "The stuff," he adds, "consisted for "the most part of decayed, exhausted or foreign "(other than tea) leaves, foreign stems, tea sweepings, "held together in little nodules by starch, paste and "pieces of bark, husk and nutshells." In fact Mr. Dunn endorses on examination of our statement of the 9th inst. that "the common process by which the rubbish "is obtained appears to be to collect the refuse or ex- "hausted leaves, and the coarse, half-decayed *débris* of "the tea garden, which, after being dried, are colored "with gypsum, lampblack and plumbago, remilled, and "packed as fresh teas for market." And he concludes his report with this highly pregnant statement: "All "this rubbish (the samples under analysis) was faced "with plumbago to give it a black appearance, and "was totally unfit for dietary purposes."

Upon the face of Mr. Dunn's analysis, which is certified to by Mr. R. W. E. MacIvor, a member of the Central Board of Health, it might be assumed that the authorities would have power to prevent this tea from going into consumption. Mr. Everard, however, in a letter which appears in another column, states that even this conclusive evidence is not sufficient to ensure so desirable a result. The Government analyst* has got some fiction in his head about "the coloring of commerce," and hence public health is to be made subservient to this. Now, let us see how this matter is dealt with in England; and as very considerable difference of opinion appears to exist as to the provisions of the Imperial statutes in regard to the admission of exhausted as well as adulterated teas into the United Kingdom, we make the following extracts with a view of showing how stringent is the law respecting imports of this character. The 30th section of the Sale of Food and Drugs Act provides that "from and after the 1st of January, 1876, all tea imported as merchandise and landed at any port in Great Britain or Ireland shall be subject to examination by persons appointed by the Commissioner of Customs for the inspection and analysis thereof, for which purpose samples may, when deemed necessary by such inspectors, be taken, and with all convenient speed examined by the analyst, and if upon such analysis the same shall be *found to be mixed with other substances or exhausted tea* the same shall not be delivered; but if on inspection and analysis it shall appear that such tea is, in the opinion of the analyst, unfit for human food, the same shall be *forfeited and destroyed.*" The 31st section of the same act explains that the term "exhausted" shall mean "and include any tea which has been deprived of its proper quality, strength or nature by steeping, infusion, decoction, or other means." There is nothing said here of the coloring or admixture of foreign substances as a commercial matter being permitted; quite the contrary for no tea found to be mixed with other substances is to be delivered for consumption, not even if the same consist only of innocuous but exhausted teas. Under the provisions of the act already quoted, the inspectors in England are required to examine each chop of tea by inspecting a portion of the contents of the packages selected for taring, and if necessary by infusing a portion thereof, and they are at once to pass the tea if genuine and sound. If, on the contrary, they have doubts, samples are at once to be forwarded to the analyst for tea at the Customs, who finally determines whether or not the shipment shall be allowed to go into general consumption; so the greatest precautions are taken in England to prevent both adulterated and exhausted teas finding their way into consumption. As regards coloring, a board order of the Imperial Custom House, dated 18th February, 1876, grants power, to seven surveyors or assistant-surveyors of customs personally to pass tea which, on careful examination, they are satisfied contains only a small percentage of facing or coloring matter, if in other respects genuine. This concession is made in favor only of green teas, which are sold in England with this special condition attached.

The present permission to ship any amount of rubbish to this market is not only detrimental to the public health, but it places firms of undoubted standing and reputation for strict compliance with mercantile usages often in an unpleasant position. Clients abroad or strangers may ship their consignments, the value of which they may be wholly unware of until they are submitted to the verdict of the trade at auction. Preventive legislation would be as welcome to the merchant as it is to the consumer, if not more so; for the legitimate ventures which the former makes on his own account will not be prejudiced by by competition at sale, or by mixing afterwards with spurious compounds merely sent haphazard to the market to be sold for what they will fetch. On the other hand, if the legislature declines to step in, the frauds which are committed under the guise of adulterations will not only continue, but will extend, until at last the difficulty will be to obtain anything genuine. In a trading community like our own, where competition is so fierce amongst retailers, it cannot be denied that there is an inducement to utilize the permission now accorded to the admission of exhausted and adulterated teas, to offer a cheap article to the public without regard to quality. It is no infringement on the rights of dealers for the Government to take steps to ensure that this cheapness goes hand in hand with freedom from deleterious ingredients, and this result may be obtained in Victoria of the provisions of the Imperial statute entitled the Sale of Food and Drugs Act.

* The "Government Analyst," Mr. Johnson, does not seem to be regarded with all the confidence which is reposed in Mr. Newbery of the Technological Museum, and his assistant, Mr. Frederic Dunn. Both the latter have devoted much attention to the chemistry of tea, and Mr. Dunn is making a special study of the numerous typical specimens collected at the late Exhibition. The result of this gentleman's researches is likely to be a considerable raising of the chemical standard for pure teas.—A. M. F.

FIBRES.

(From *Spon's "Encyclopædia"*)

Fibrous Substances [derived from Plants] (Fr., *Fibres Vegetales*; Ger., *Pflanzenfasern*).

The "fibrons" portion of plants consists essentially of cellulose $C_6 H_{10} O_5$, a carbohydrate which shows great resistance to re-agents that produce a marked effect on the other portions of plants. This resisting property constitutes the value of such fibres for the production of textile and other fabrics. The industrial application and commercial value of a fibre depend principally upon its physical qualities of length, strength, elasticity, firmness, and colour, and upon its capacity for taking dyes. The majority of these qualities are affected more or less by the mode of cultivation, the period of harvesting, and the method of preparation.

The varying position of the fibres of different plants has given rise to a threefold classification:—

(1) Monocotyledons, or endogens, are plants which do not form a true bark, and which grow by virtue of a building up of tissue from within. These plants yield "foliaceous" fibres, imbedded in the cellular tissues and pulp of their roots, stems, and leaves, which fibres rarely attain sufficient development to be of commercial utility, except in tropical and subtropical regions, and may, in almost all cases, be separated by simple mechanical processes.

(2) Dicotyledons, or exogens, are plants which do possess a bark, and whose growth is purely of an external character. Their fibres reside in the sheath of bark or bast, and hence are called "cortical." They are abundant in temperate climates. The fibres are in an agglutinated condition, held together by means of a tenacious gum, the removal of which necessitates special, and in some cases laborious, treatment.

(3) In a few plants the seeds are enveloped in a hairy covering within the pods; these are termed "seed hairs," or "capsular" fibres.

Examination.—Having regard to the fact that many fibre-yielding plants still remain to be examined, and for convenience of reference to the characters of, and means of distinguishing, fibres treated of in a subsequent part of this article, instructions for conducting chemical and microscopical investigations, as suggested by Vétillart and others, may here be briefly given.

The first step is the separation of the fibres from the remaining portions of the plant, which may be effected by boiling the sample in a solution containing 6 per cent of carbonate of potash or soda. When the separation is accomplished, the sample is well washed, pressed, and dried. If the washing does not suffice to complete the disunion of the fibres, they may be bruised under water in a porcelain mortar, with a pestle of hard polished wood. The separated fibres are then divided into three portions:—(1) For examination longitudinally in neutral liquids; these are at once placed to macerate in water and glycerine; (2) for longitudinal examination under re-agents, are put aside to dry; (3) for examination in transverse section; this sample is straightened as well as possible, and then put to dry.

A.—Of sample (1) some threads are taken and placed on a glass slab under a microscope; they are then bathed in pure concentrated glycerine, two or three entire isolated fibres are picked out, laid parallel, and moistened with sufficient glycerine to keep them in place. Care must be taken that the ends are intact and the fibres entire. Their length is then estimated, and the operation is repeated upon a number of samples. The mean length is, perhaps, most correctly stated as that which occurs the greatest number of times.

(B).—These fibres are next examined in neutral liquids having a refractive power as nearly as possible like that of the object itself, such as a solution of chloride of calcium of the consistence of clear syrup or glycerine, either alone or with the addition of a little camphor-water and a few drops of acetic acid. One or two fibres are laid in the liquid on a glass plate being curled spirally to diminish their length, and are covered with another thin sheet of glass. Repeated observations are then made as to whether the fibres are solid, or in flattened bands; whether rounded or prismatic; whether smooth, or fluted, or striated; whether an internal cavity is visible, and whether it is large, continuous, or interrupted. A number of measurements of the diameter of the fibres are then made, carefully noting the maximum, minimum, and mean, and the degree of tapering or irregularity.

C.—Sample (2) is next examined under re-agents—iodine solution and sulphuric acid diluted with glycerine. The former is prepared as follows:—1 grm. pure iodide of potassium is dissolved in 100 grm. distilled water, and an excess of iodide is added to ensure constant saturation. It is kept in glass-stoppered bottles, always containing a few pieces of the iodide. The solution is liable to change at the end of a few months, and must then be renewed. The dilute sulphuric acid is thus prepared:—2 volumes of pure concentrated glycerine (Price's) are mixed with 1 volume of distilled water in a flask; the latter is plunged into cold water to the level of its contents, and 3 volumes sulphuric acid, sp. gr. 1·845, are added with constant agitation. This solution also undergoes gradual change by absorption of moisture, when a slight addition of acid becomes necessary.

Some thoroughly dry fibres in a complete state of division are selected from the sample and briskly rubbed between the fingers; they are then placed on a glass plate on the object-holder, and covered by a few drops of the iodine solution. The latter is allowed to thoroughly penetrate the fibres, and the excess is removed by blotting-paper. The test is then covered with a small piece of glass, along one edge of which are poured a few drops of the sulphuric acid preparation. The liquid penetrates between the two glasses, and advances towards the other side, where slips of blotting-paper are placed to absorb it. The current is maintained for a little while by occasionally adding a few drops of the acid and renewing the blotting-paper. The result of this operation soon becomes evident in the distinct coloration of the fibres. Wherever cellulose is present, it assumes a blue or violet tint; where the cellulose is lignified or penetrated by foreign matters, it becomes yellow. This tint, which varies from bright yellow to brownish-yellow, appears also in the fragments of tissue adhering to the fibres, and in the matters occasionally found in their interior cavity. The coloration must be clear and pronounced, and the fibres must be in perfectly sound condition; when the results are imperfect, the sulphuric acid preparation may need strengthening. The blue colour will disappear in a few hours, and the yellow will not last beyond a day or two. The re-agents occasionally disclose striations or transverse lines of deeper tint, generally arising from folds in the fibre which afford additional characteristics.

D.—Sample (3) is divided into transverse sections, perpendicular to the axis of the fibre; these furnish the most precise indications of the form, structure, and thickness of the walls of the fibres. Sufficient fibres are taken to form a bundle about as thick as a goose-quill. About 1 in. of this is cut off and tied in the middle by a thread. One end of the bundle is placed in thick glue, and then the other end, and both are pressed between the fingers to ensure the close adhesion of the fibres and to express the superfluous glue. The bundle is then hung up to dry, an operation requiring at least 12 hours in summer and

24° or more in winter. When the mass is firm enough to bear cutting, it is divided by a razor into very thin sections, which give the best results when they exhibit the consistence of wax. Several examples should be taken from different parts of the sample, and especially from both ends of the fibres.

E.—The sections are next examined in one of the neutral liquids before prescribed. If the glue does not dissolve in it, recourse may be had to boiling in distilled water. After drying between blotting-paper, the sample is submitted to the microscope while lying in the neutral liquid. The fibres are occasionally flattened and present an oblong section, which should be measured both ways.

F.—The application of re-agents follows. Into 2 or 3 drops of the iodine solution is put some powder or fragments of the glued sample. In cold weather the glass plate should be warmed to facilitate the solution of the glue. The iodine solution should be absorbed gradually, and the powder should be spread as equally as possible. The excess of iodine is removed by blotting-paper, the sample is covered by a second glass, and the sulphuric acid is introduced as in previous tests. Notes are made of the exterior form of the sections, the thickness of their walls, and the form of the central cavity. Some fibres appear to be composed of a compact and homogeneous substance, others have concentric coats, which assume various shades of blue; some present fissures or perpendicular striations on both the interior and exterior surfaces, and which seem to radiate from the centre; some contain a yellow granular matter, while others are empty, and some are bordered with a yellow line.

G.—It is often useful to examine the fibres as they exist in the plant to determine their position, relative abundance and nature. Sections are taken of the fibre-yielding portion of the plant, which must be either freshly cut or soaked in water. These are placed to macerate for several hours in a mixture of glycerine and water, and are then treated with a few drops of concentrated glycerine, which penetrates them and renders them transparent.

H.—These sections may also be examined under re-agents, in which case they are not macerated in dilute glycerine but in alcohol, in order to eliminate any resinous matters they may contain. They are then dried before the treatment with iodine.

The foregoing tests are intended for distinguishing the fibres of one plant from those of another. To discriminate between vegetable fibres and animal fibres (see Hair, Silk, Wool), the following observations will suffice:—

Vegetable fibres, heated in solutions of alkalies or acids swell up, dissolve, and decompose into glucose or grape sugar. They burn readily and with a flash.

Animal fibres, boiled in solutions of caustic alkalies swell up, dissolve and decompose with evolution of ammonia. They carbonize with difficulty, and only on continued application of heat, and emit an odour like burning horn or feathers.

A ready method of estimating the proportion of fibre (cellulose) yielded by a plant is to macerate it for some hours in water; crush it by passing it between wooden rollers, subject it to the action of a weak (6 per cent) solution of carbonate of soda, and then to steam at a pressure of 4-5 atmos., until the cellulose is extracted as a yellowish-brown mass. This is a preliminary test of the value of a plant for paper-making.

Agave Americana—Century-Plant, Mexican or Spanish Aloe (Fr., *Pite, Aloes*; Mex. *Pita Maguey*).—Endogen, 24-36 ft. Indigenous to all parts of Tropical America, from the plains to 10,000 ft., now naturalized in S. Europe, Mauritius, Algeria, throughout India, and the Pacific Islands. The plant requires about 3 years to come to perfection, but it is exceedingly hardy, easy of propagation, very prolific, and grows in arid wastes where scarcely any other plant can live. It perishes after inflorescence, which does not occur till the 8th-20th year, but it then sends up numerous shoots. In Mexico, 5,000-6,000 plants may be found on an acre. The average number of leaves is 40, each measuring 8-10 feet long and 1 ft. wide, and yielding 6-10 per cent by weight of fibre. The culture of the plant is being extended in America, but not in the proportion which its value deserves. In India, it is all but neglected; it grows wild in many parts, and is sometimes cultivated as a hedge-plant, but its fibre, seldom and badly prepared, is harsh and brittle, though of good colour. Care would effect great improvements.

The native methods of preparing the fibre are very primitive:—(1) The leaves are cut and steeped in water, then beaten with sticks and rubbed with stones or scraped with shells or wooden blades to remove the non-fibrous portion, and finally washed and bleached in the sun. This plan causes stains and a tendency to rot, and thus reduces the value of the fibre. (2) The leaves are cut and deprived of about 6 in. of the pointed end, then well beaten or bruised with wooden mallets on a smooth surface of stone or wood, tied in bundles of 4 leaves, and laid in heaps to ferment. The beating removes much of the sap, and the fermentation helps to loosen the fibre without damaging it. When the heat has subsided, the bundles are thrown into water, and steeped for about a fortnight; after washing, the fibre appears clean and white. It is then dried, shaken and packed.

The process of retting has been proved injurious to the fibres of all endogens, and mechanical contrivances have been invented for separating the fibres from the leaves of the agave and similar plants. In employing the machines described below, an abundant supply of water is a matter of great importance, as its copious use expedites the process and ensures a fibre of good colour and strength. The leaves should be cut before they are over-ripe: it is preferable to cut them too soon rather than too late, as over-ripe leaves produce coarse fibre of inferior colour. They should be put through the first process immediately after they have been cut, as the longer they are allowed to lie before crushing, the more difficult is the separation of their fibres.

The machines described above are made by Thos. Barraclough, of Manchester, who was good enough to furnish the drawings which illustrate them. They can be driven by steam, water, or cattle power; a gear suitable for 2 horses or 2-4 bullocks suffices to drive a small set of machines, viz., one crushing-machine, one squeezing-machine, and two scraping-machines, being that portion of the set which is used during the time the leaves are being cut. The same gear is afterwards used for driving the two scraping-machines, transformed into brushing-machines, and the softening-machine (where required). The squeezing-machine is also made to be worked by hand. The hydraulic pumps for the press can be easily worked by hand in the absence of steam or water power.

The length of the fibre varies from 3 to 7 ft.; the colour of the commercial article is white to straw-colour. Its main faults are the stiffness, shortness and thinness of wall of the individual fibres, and a liability to rot; but these are greatly reduced by the crushing of the fibres in the above-described machines, so as to liberate the interior viscid juice. The breaking strain of a rope of this fibre has been stated at 270-362 lb., as against Russian hemp at 160 lb. Its uses are various. In its native countries, it is applied to the manufacture of ropes, twine, fishing-nets, hammocks, &c. It is exported for admixture with Manilla hemp (*Musa textilis*), for all kinds of cordage. Bleached and dyed, it is made

into matting and imitation horsehair cloth, with good effect. The short fibre separated by the processes described above, may also be carded and spun; while the waste is an excellent material for strong wrapping and envelope paper. The fibre, exposed for 2 hours to steam at 2 atmos., boiled in water for 3 hours, and again steamed for 4 hours, lost 5·55 per cent of its weight as compared with Manilla hemp, 6·07; phormium, 6·14; hemp, 6·18-8·44. Some slips of sized paper weighing 39 gr. made from this fibre, bore an average weight of 89 lb., as against Bank of England note pulp 47 lb. It is the most highly approved of all paper fibres, making a strong, tough, smooth paper, which feels like oiled paper, and even while unsized, may be written on without the ink running. Its price is governed by that of Manila hemp, being generally £7-£10 a ton less than the latter. With proper care in the preparation, this difference should be much reduced. The fibre prepared in India is harsh and brittle, though of good colour; it is not met with in commerce.

Crotalaria Juncea—Sunn Hemp.—Exogen, 4-8 ft. It is indigenous to S. Asia, and is widely dispersed throughout Tropical Australasia; it is common in every part of India, and is extensively cultivated, especially in the N.-W. provinces, where it takes the place held by jute (*Corchorus*) in Bengal. Some 50,000 acres are occupied by it in the Punjab.

Cultivation.—The plant is grown in various kinds of soil. In Bengal, high, rich land is preferred, well ploughed, and freed from weeds; in the N. Circars, a strong clay suits it best; in the Deccan, any soil seems to suit it, and it kills out weeds. The season for sowing depends upon the rains. One crop, sown in June, is generally harvested about August-September; another, sown in October, is gathered in April. The quantity of seed used varies between 80 lb. and 125 lb. an acre. It is sown very thickly during showery weather, and is covered by harrowing or other rough means. It grows very rapidly, and if sown thick enough, keeps down weeds. Scarcely any attention is necessary. The yield of fibre averages about 700 an acre. When required for fine purposes, the plants are gathered in flower; when greater strength is sought, they are left till in seed, or even until the seed is ripe. The harvesting is effected by uprooting the plants, and reaping is very rarely resorted to. After the plants are gathered, they are laid in ridges for 5-12 days, which causes the leaves to decay and fall off.

Extraction and Preparation of the Fibre.— When the stems have been cleansed of leaves, &c., they are submitted to a retting process of varying duration according to the season. It is usual for the first day to submerge only the lower portion of the stems, which, being thicker, require longer maceration than the more tender parts. It has been suggested that the fibre would be improved by first sun-drying the stems for 2 days, and by reducing the term of retting. The latter is continued till the fibre separates easily from the stem, when it is cleansed almost exactly in the same manner as already described with jute (p. 943). After thorough washing, it is dried and combed.

Characters and Uses of the Fibre.—The dimensions of the filaments are:—length: max. 0·472 in., min. 0·157 in., mean 0·30 in.; diameter: max. 0·0020 in., min. 0·001 in., mean 0·0015 in. The dressed fibre varies in length from 3 ft. 6 in. to 7 ft. Experiments made upon its strength gave a breaking strain of 407 lb. Samples of the fibre exposed for 2 hours to steam at 2 atmos., boiled in water for 3 hours, and again steamed for 4 hours, lost only 2·93 per cent by weight, as against flax 3·50, Manilla hemp 6·07, hemp 6·18-8·44. The average weight sustained by slips of sized paper weighing 39 gr., made from the "raw" fibre, was 64 lb., as compared with Bank of England note pulp, 47 lb. One batch was reported to make a nice, clean, smooth paper of good colour, but not taking ink well; another worked "wet" during pulping, but bore ink well. The fibre is remarkably well adapted for cordage and netting. Large quantities are shipped for the English market, and it forms the bulk of the so-called "hemp" exported from India.

Patent Manures.—In accordance with a suggestion of Colonel Beddome the Government have sanctioned the expenditure of a sum not exceeding R. 1,000 for the experimental trial of various patent manures. It is understood that valuable artificial manure can be obtained from the firms on the West Coast, Mr. W. Rowson, Assistant Superintendent, Government Chinchona Plantations, Neddivattum, having proposed "that our soils be sent home for analysis, and that suitable patent manure be procured from England." The Government have replied that no analysis of the soils need be made at present.—*Madras Mail.*

Why so much Quinine is required in the United States:—Malaria seems to be developing with alarming rapidity around New York. One large jewellery manufactory in New Jersey is to be abandoned in consequence of the unhealthy character of the neighbourhood, new buildings being erected on a safer site at considerable expense to the owner, and this, as the *American Architect* points out, is only one piece of evidence of the growing gravity of the malaria question. A generation ago malaria was as little dreaded about New York as it would be in London, but now some of the most beautiful suburbs of the city are becoming depopulated from this cause, and town after town is attacked by the ague, which never again releases its hold.—*Graphic.*

Cure for Coffee Leaf Disease.—Mr. Jacob P. Storck, of the Rewa, informs us that the coffee trees which he has cured of Hemileia Vastatrix, and the treatment of which was discontinued in July last, continue perfectly free from disease and are rapidly growing in size. The unimpaired state of health of his nursery, as well as the circumstance of self-sown seedlings springing up clean are indisputable proofs of the thorough and lasting disinfection of the once badly infected area. Mr. Storck claims to be the first who has succeeded in effecting the cure without employing any chemicals dangerous to vegetable life. The treatment is adaptable to the largest estates, is economical, and possesses other points of merit which he hopes to see appreciated at no distant day. The trees are treated in full foliage, and the process would cost about four pounds per acre to be effected [at the end of say three months of sharp work.—*Fiji Times*, April 13th.

Artificially Raised Japan Teas.—We take the following paragraph from the *Japan Herald Mail Summary* of the 14th May 1881:—Within the last two or three days, a few small parcels of artificially raised Teas of this season have come to hand, amounting from a few catties to perhaps half a picul in one muster. The first small lots commanded a rate of from $150 to $200 per picul, but recently prices paid have been about $80 to $90 per picul. The total amount of these which will go forward by the steamer will be some 5 to 6 piculs. It is to be regretted that this anxiety has been exhibited to obtain Teas which can merely be looked on in the light of a curio, as they, being artificially raised, will not convey the slightest information regarding either the quality or style of leaf of coming first crop. The accounts of prices paid will find their way into the native papers, and be reproduced therein with sundry embellishments, which, being read by the producers up country, will greatly tend to make them hold out for exorbitant prices when the market for the New Crop really opens.—*Tea Gazette.*

OSTRICH-FARMING.

(From *Spon's "Encyclopædiae."*)

The rearing of ostriches has assumed considerable importance, notably in our S. African colonies. The natural home of the bird is there found in the "karroo" plains and sweet-grass flats of the interior, and though it sometimes resorts to the long sour-grass of the coast, it will not thrive on the "strand veldt" or sour-grass of the sandstone ridges. This is explained by the fact that alkalies are essential to the health of the bird and the proper development of its feathers; and where care is taken to supply this deficiency, in the shape of food, less difficulty will be found in selecting a site for the farm. The country must be open, and the soil should be sandy in places. Opinions vary as to whether the birds should be confined in a narrow area, and fed by hand; or be allowed to run free over a large space, and pick up their own living. The latter plan seems to produce feathers of the best appearance. The paddocks must be well fenced with loose stone walls, or post and wire fencing, about 4 ft. high. The number of birds allowed on an acre may vary from 30 birds on 8 acres, to 2½ birds on 50 acres, according to the nature of the land, and the amount of food artificially supplied. Shed accommodation must be provided for the birds to seek shelter in by night or during storms, and over-crowding must be carefully avoided. The birds require water, and are fond of bathing during the hottest season. In the matter of food, considerable latitude is observed. For young birds, lucerne, thistles, herbs, and indigenous grasses suffice; as the season advances, these may be supplemented by fruit and grain (barley, maize, &c.). A mature bird will require 20 lb. of lucerne, or 3 lb. of grain, daily. If necessary, lime must be supplied in the form of bones, besides which, a little sulphur and salt should be provided.

The birds are paired at the age of five years, one male being coupled with one or two females. Separate pens are provided for this purpose. Nidification begins in July. Laying commences in August, and lasts for about six weeks, the eggs numbering 15-20 from each hen. If not removed for artificial incubation, the birds take turns in sitting on them, till they are hatched, in October. On taking away the young brood, the hen will lay again about December, but is then not nearly so prolific. It is seldom that the birds are allowed to hatch out their brood, much better results being obtained by the use of artificial incubators. The form of incubator most commonly employed is that devised by A. Douglass, of Hilton. It consists of a deal box, about 3 ft. square, open above, and resting upon a copper or zinc pan 3 in. deep, and of the same area as the box. This pan contains hot water, the vapour of which ascends through suitable openings into the box above. The temperature of the water is maintained by an oil lamp burning beneath a portion of the pan, separated by a wall from the incubating room, to avoid the ill-effects of the fumes upon the young chicks. The heat is constantly regulated by means of thermometers: the temperature of the box should be 39° (102° F.) when it receives the eggs; after 2 weeks it is reduced to 37½° (100° F.); and, in 2 weeks more, to 36½° (98° F.) Incubation lasts for 42 days. The eggs are turned and aired by opening the box and removing the blanket covering once or twice daily. A fortnight before the incubation is finished, the eggs are examined against the light, to ascertain how soon the hatching may take place; and a week later, those containing weak chicks are carefully punctured near the small end, to assist the occupants in effecting their escape. The proportion of failures should not exceed 1 in 12; in natural hatching it amounts to 4 in 20. Another good reason for adopting artificial incubators is that the birds' feathers are in primest condition at the time of incubation, and that many of them get spoilt during the time when the birds are sitting. As soon as hatched, the chicks should be kept in a warm but well-ventilated coop, which may be constructed of a box, containing a lot of chenille or other warm material hanging from the roof. They are fed at first on bread crumbs, bran, and water; on the fourth day they may be let out during the day into a little enclosure made around the incubator, and may then have grain, bread, and green vegetables. They are taken in at night. Until 3 months old mortality is great among them, and even after that age many break their legs and have to be killed.

The bird yields its first plumes at the age of 8 months, and continues to do so at intervals of 8 months throughout its life, which varies, according to different authorities, from 8 to 100 years, but may probably average 25-35 years. The first feathers are small and of little value. The gathering of the plumes is a delicate operation, performed either by plucking them out bodily, or by severing them near the base by means of a sharp knife. The former plan was long the only one, and gives the greater weight of feather; but it is now generally superseded by the latter, as it often produces a kind of irritation fever in the birds. When cutting is adopted, the stumps require pulling out about a month or 6 weeks later, unless they have already been shed naturally. Neither method appears to cause the bird any appreciable pain. The operation is performed while the birds are placed singly in a padded crib, or are so densely packed as to leave no room for kicking.

Ostrich-farming is being experimentally undertaken by the Acclimatization Society of Victoria, on the Wimmera and on the Murray Downs, and has quite recently been instituted in South Australia. Many circumstances have had an unfavourable influence upon the results attained, so that these have not hitherto been encouraging; nevertheless, the industry is being persevered in, and a parcel of the feathers sent to the London market were pronounced better than any from the Cape. Still more recently it is stated that African ostriches have been introduced into the Banda Oriental and the Argentine Republic; it is intended to keep the breed quite distinct from the native Rhea, as cross-ing them produces a sterile race with inferior plumes.

Classification, Value, and Uses of Ostrich Plumes.— As the feathers are gathered, they are sorted according to their quality, the operation being generally entrusted to negroes. The best white plumes known as "bloods," are only the tail and primary wing feathers; the black plumes are secondary wing feathers. The classification of Cape ostrich feathers for London markets are as follows:—(1) WHITE; *wild*:—bloods, fine; Prima, best; Prima, long usual; I. and II. mixed; seconds: seconds and thirds mixed; thirds; *tame*: finest quality, cut quill; Prima, usual; Prima, ordinary defective tops; seconds; seconds and tairds mixed. (2) FEMINA:—light color, good quality; usual; hafida k; dark. (3) BYOKS:—white, with black spots. (4) BOOS:—tail feathers, white usual, light fem.; dark fem. (5) BLACK:—long and medium g oil; medium and short; short. (6) DRAB:—gr y, long and medium; medium and short; short. (7) SPADONES:—white and light fem: fem; drab. The relative qualities of the feathers from different countries are in the following order, beginning with the best:—(1) "Alppo," from Syria; the finest in plumage, breadth, grace, and colour; very rare; (2) "Barbary" from Tripoli; (3) "St. Louis" from Senegal; (4) "Egypt" do not bleach thoroughly white; (5) "Mogador" from Morocco; (6) "Cape" as good in colour as "Aleppo," but of inferior quality; (7) "Yemen," or (erroneously) "Senegal," from Arabia; plumage thin

and poor. Prices fluctuate somewhat, and range from over £60 a lb. down to a merely nominal figure. In spite of enormously increased production, the demand seems to keep pace with the supply, though the price has fallen somewhat. Wild weathers always sell more readily than tame ones, the reason being that the latter are much stiffer and less graceful, have "galleries" in the quill, and resume their stiffness even after dressing and curling. The principal application of the plumes is for the decoration of court and military dresses, ladies' bonnets, hearses, &c.

Before use, the plumes are either bleached or dyed. They are first washed in soap lather, rubbed well with the hands, and passed through clean scalding water. The bleaching of white feathers is performed in the following way:—The feathers are first exposed to the action of sun and dew for about a fortnight, are washed in a hot bath containing Spanish white—the softest and purest white chalk—and are then passed through three clean waters: next, they are blued by a rapid passage through a cold bath containing indigo; after this, they are sulphured, by being suspended in a sulphuring stove; and are finally hung upon cords to dry, being occasionally shaken to open the fibres. A more recent process, invented by Viol and Duplot, is to immerse the feathers in resinous essences, such as turpentine or in essential oils at about 30° (86° F.), and to subject them to the action of light for a longer or shorter period, according to the degree of decoloration desired. After this, they are finished in the usual way by scraping the barbs with a blunt edge, so as to produce the much-admired curl. Dark-hued feathers, after being bleached by the last-named process, may be dyed almost any shade. Another method of bleaching is by a bath containing 4·5 parts permanganate of potash in 1,000 parts water; a similar solution of sulphate of magnesia is added, and heated to 60° (140° F.) max. The previously washed feathers are put into the bath, taken out, rinsed, and passed through sulphuric acid at 1½°-3° Tw.

Artificial Ostrich Feathers.—The Americans are said to be manufacturing large quantities of artificial ostrich plumes, the quill being composed of celluloid, or rattan cane, and the barbs of silk waste.

Other Plumes.—Besides the ostrich there are many giant birds belonging to the families *Struthionidae* and *Apteryyidae*, possessing plumes of more or less value. One of the most important of these is the Rhea or South American ostrich (*Rhea americana*), whose range extends from Bolivia, Paraguay, and S. Brazil, as far as the Straits of Magellan; while two other species, Darwin's Rhea (*R. Darwini*), and the long-billed Rhea (*R. macrorhynca*), share with it portions of the same territory. The birds are at present ruthlessly hunted, and, a few years since, were being killed at the rate of 300,000-500,000 per annum. Though, from their hardy nature and omnivorous habits, the birds are easily kept in confinement, little has yet been done in this direction. The feathers are collected chiefly in the Banda Oriental, Bahia, Blanca, Entre Rios, as well as Patagonia, and are shipped from Monte Video and Buenos Ayres. The exports from Argentine Ports in 1874 were:—To the United States, 19 tons; France, 18 tons; England, 2 tons; other countries, 21 tons. Their value is put at about 4s a lb., the male feathers bringing the higher prices. They enter European commerce as "vulture feathers," and the majority of them, the dark-greys, are made into feather-brooms.

Imports of Ornamental Feathers.—Our imports of ornamental feathers, including ostrich plumes, in 1878 were as follows:—From France, 120,928 lb.; British Possessions in S. Africa, 78,947; British E. Indies, 25,313; Egypt, 12,394; Aden, 4,946; Malta, 4,485; Holland, 4,346; Morocco, 3,083; Belgium, 1,551; other countries, 8,806; total, 264,799 lb.; value £1,002,902.

ENEMIES OF OSTRICHES.

A serious plague among young ostriches has been spreading over South Africa during recent years. A post-mortem examination made by Mr. Arthur Douglass discovered the trouble to arise from the presence of myriads of small thin worms adhering to the coats of the ostrich's stomach. Specimens were sent to Dr. Spencer Cobold, of London, who pronounced them unknown to science, and named them *Strongylus douglassii*. The importance of the discovery may be estimated from the fact that ostriches are worth from 750 dol. to 900 dol. a pair, while the ostrich industry is a source of great revenue to South Africa. The cause of the plague being known, some means of destroying the parasite may be looked for.—*Australasian.*

THE USE OF THE FEET IN SOWING AND PLANTING.

(From the *Fiji Times*, 28th May 1881.)

[Read before the American Association of Nurserymen at Cleveland, O., by Peter Henderson, of Jersey City, N. J.]

It may seem useless to throw out suggestions relative to horticultural operations to such a body of practical men as is now before me. Yet I candidly admit that although I have been extensively engaged in gardening operations for over a quarter of a century, I did not fully realize, until a few years ago, the full importance of how indispensable it was to use the feet in the operations of sowing and planting. Particularly in the sowing of seeds I consider the matter of such vast importance, that it cannot be too often or too strongly told, for the loss to the agricultural and horticultural community by the neglect of the simple operations of forming the soil around seed must amount to many millions annually. From the middle of April to nearly the end of May of this year, in many sections of the country, there was little or no rain; such was particularly the case in the vicinity of New York City; where we have hundreds of market gardeners who cultivate thousands of acres of cabbage, cauliflower, and celery; but the dry spring has played sad havoc with their seed beds. Celery is not one-fourth of a crop, and cabbage and cauliflower hardly half; and this failure is due to no other cause than that they persist in sowing their seeds without ever taking the precaution to firm the soil by rolling.

We sow annually about four acres of celery, cabbage, and cauliflower plants, which produce probably five millions in number, and which we never fail to sell, mostly in our immediate neighbourhood to the market gardeners, who have, many of them, even better facilities than we have for raising these plants if they would only do as we do—firm the seed after sowing, which is done thus:—After ploughing, harrowing, and levelling the land smoothly, lines are drawn by the "marker," which makes a furrow about two inches deep and a foot apart. After the man who sows the seed follows another, who, with with the ball of the right foot presses down his full weight on every inch of soil in the drill where the seed has been sown; the rows are then lightly levelled longitudinally with the rake, a light roller is then passed over it, and the operation is done.

By this method our crop has never once failed, and what is true of cabbage and celery seed, is nearly true of all other seeds requiring to be sown during the late spring or summer months.

On July 2nd, 1874, as an experiment I sowed twelve rows of sweet corn and twelve rows of beets, treading in after sowing every alternate row of each. In both cases those trod in came up in four days, while those unfirmed remained twelve days before starting, and would not then have germinated had rain not

fallen, for the soil was dry as dust when planted.

The result was that the seeds that had been trodden in grew freely from the start, and matured their crops to a marketable condition by fall, while the rows unfirmed did not mature, as they were not only eight days later in germinating, but the plants were also to some extent enfeebled by being partially dried in the loose dry soil.

This experiment was a most useful one, for it proved that a corn-crop sown in the vicinity of New York, as late as July 2nd, could be made to produce "roasting ears" in October, when they never fail to sell freely at high rates; but the crop would not mature unless the seed germinated at once, and which would never be certain at that dry and hot season, unless by this method.

The same season in August I treated seeds of turnips and spinach in the same way; those trod in germinated at once and made an excellent crop, while those unfirmed germinated but feebly, and were eventually nearly all burned out by a continuance of dry hot air penetrating through the loose soil to the tender rootlets.

Of course this rule of treading in or firming seeds after sowing must not be blindly followed. Very early in spring or late in fall, when the soil is damp, and no danger from heated dry air, there is no necessity to do so; or even at other seasons the soil may be in a suitable condition to sow, and yet be too damp to be trodden upon or rolled. In such cases these operations may not be necessary at all, for if rainy weather ensues, the seeds will germinate of course; but if there is any likelihood of continued drought, the treading or rolling may be done a week or so after sowing, if it is at such a season, as there is reason to believe that it may suffer from the dry hot air.

Now, if firming the soil around seed to protect it from the influence of a dry and hot atmosphere is a necessity, it is obvious that it is even more so in the case of plants, whose rootlets are even more sensitive to such influence than the dormant seed.

Experienced professional horticulturists, however, are less likely to neglect this than to neglect in the case of seeds, for the damage from such neglect is easier to be seen, and hence better understood by the practical nurseryman. But with the inexperienced amateur, the case is different. When he receives his package of trees or plants from the nurseryman, he handles them as if they were glass. Every broken twig or root calls forth a complaint, and he proceeds to plant them gingerly, straightening out each root and sifting the soil around them. But he would no more stamp down that soil than he would stamp the soil of his mother's grave. So the plant, in nine cases out of ten, is left loose and waggling, the dry air penetrates through the soil to its roots, the winds shake it, it shrivels up and fails to grow. Then comes the anathemas on the head of the unfortunate nurseryman, who is charged with selling him dead leaves or plants.

About a month ago I sent a package of a dozen roses by mail to a lady in Savannah. She wrote me a woful story last week, saying that though the roses had arrived seemingly all right, they had all died but one, and what was very singular, she said, the one that lived was the one that Mr. Jones stepped on, and which she had thought sure was crushed to death, for Mr. Jones weighs 200 lb. Now, though we do not advise any gentleman of 200 lb. putting his brogan on the top of a tender rose plant as a practice conducive to its health, yet if Mrs. Jones could have allowed her weighty lord to press the soil against the root of each of her dozen roses, I much doubt if she would now have to mourn their loss.

It has often been a wonder to many of us who have been workers in the soil for a generation how some of the simplest methods of culture have not been practised until we were nearly done with life's work.

There are few of us but have had such experience; personally, I must say that I never pass through a year but I am confounded to find that some operation can not only be more quickly done, but better done, than we have been in the habit of doing it.

The improvements loom up from various causes, but mainly from suggestions thrown out by our employees in charge of special departments, a system which we do all in our power to encourage.

As a proof of the value of such improvements which have led to simplifying our operations, I will state the fact that though my area of green-house surface is now more than double that which was in 1870, and the land used in our florist's business one-third more, yet the number of hands employed is less than in 1870, and yet at the same time the quality of our stock is infinitely better now than then.

Whether it is the higher price of labour in this country that forces us into labour-saving expedients, or the interchange of opinions from the greater of nationalities centreing here that gives us broader views of culture, I am not prepared to state; but that America is now selling nearly all the products of the green-house, garden, nursery and farm lower than is done in Europe admits of no question, and if my homely suggestions in this matter of firming the soil around newly-planted seeds or plants will in any degree assist us in still holding to the front, I will be gratified.

USEFUL GARDEN RECIPES.

TO MAKE BLACK VARNISH.—One gallon of coal tar, half a pint of spirits of turpentine, 2 oz. of oil of vitriol, stirred, and laid on like paint. Mix with a piece of wood or stick the tar and vitriol, and then add the turpentine, and apply it with a brush. Mix no more than you can use at once, and then apply it as it becomes thick.

BONE-MEAL.—The value of bones (says the *Journal of Horticulture*) in various forms as a manure is admitted, and bone-meal has been frequently recommended in our columns as a good and safe manure for plants and crops. We extract the following from our small manual *Manures for the Many*:—All bones contain more than half their weight of phosphate of lime, and are beneficial as a manure, because that chief constituent phosphate of lime is also a constituent of all plants; and the gelatine which is also in bones is of itself a source of food to them. The bones must be applied to the crops in very small pieces, or in powder; and 10 lb., at the time of inserting the seed, are enough for 30 square yards, if sown broadcast; and a much smaller quantity is sufficient if sprinkled along the drills in which the seed is sown. There is no doubt that bone-dust may be employed with advantage in all gardens and to all garden crops; but it has been experimented on most extensively with the turnip and potato, and with unfailing benefit. Mixed with sulphur, and drilled-in with the turnip seed, it has been found to preserve the young plants from the fly. Mr. Knight found it beneficial when applied largely to stone fruit at the time of planting; and it is quite as good for the vine. To lawns the dust has been applied with great advantage when the grass was becoming thin. As a manure for the shrubbery, parterre, and green-house it is also most valuable; and crushed as well as ground, is employed generally to mix with the soil of potted plants." The value of bone-meal has been rendered in the following expressive and suggestive verse, which students in schools of agriculture might well commit to memory:—

"No bone-dust, no turnips; no turnips, no wheat;
No wheat and no turnips, no cattle, no meat;
No turnips, no cattle, nor manure in the yard,
Make bills for the doctors, and farming go hard."

THE JAPAN PEA.

There is nothing in the list of forage plants that excels the Japan pea for our soil and climate. T. E. Martin and R. T. Rutledge, both progressive farmers of our country, tell me that the Japan pea is the most productive as well as good food that they have ever grown, for all kind of stock; horses, cattle, sheep, and hogs will eat the peas, stems, and leaves, if harvested before fully matured and cured like other hay, with as much relish as they do corn. Then there is no pea for the table, if soaked in water the night before cooking, that has a more exquisite flavor. They grow on a stout bushy stalk from two to three feet high, somewhat resembling the cotton plant. The main stalk, as well as the branches of limbs, are literally loaded with small pea pods filled with little yellow peas, similar in color, size and flavor to the English garden pea. They can be grown with the corn crop very successfully, by planting a hill or peas between each hill of corn at the second ploughing, same as the ordinary stock or field peas. But the way to get the greatest yield is to plant in hills two and-a-half feet each way, allowing but one stalk to the hill to remain after the first working. That will give you 6,960 stalks to the acre, and on ordinary land, cultivated the same as corn, will average at the lowest estimate, a pint of shelled peas to the stalk, or a fraction over 108$\frac{3}{4}$ bushels per acre. I doubt not that with high cultivation and good soil it would be an easy matter to double that yield, besides, there is no other crop that will yield more hay to the acre. In fact, I know of no crop so remunerative as the Japan pea. It is a sure cropper, as clearly demonstrated by my experience with this season's crop. Neither wet nor dry weather materially interferes with the quantity or quality of the yield. —*Mississippi Patron.*

ARTIFICIAL SEASONING OF TIMBER.

Mr. C. René, painoforte manufacturer, of Stettin, Germany, as reported in *Engineering*, has devised a plan by which he utilises the property of oxygen, particularly of that ozonised by the electric current, to artificially season the timber used for the sounding-boards of musical instruments. The first impulse to experiments being carried out in this direction was given by the well-known fact that wood, which has been seasoned for years, is much more suitable for the manufacture of musical instruments than if used soon after it is thoroughly dried only. Mr. René claims that instruments made of wood which has been treated by his oxygen process possess a remarkably fine tone, which not only does not decrease with age, but as far as experience teaches, improves with age as does the tone of some famous old violins by Italian masters. We are further told that the sounding-boards made of wood prepared in this manner have the quality of retaining the sound longer and more powerfully. A number of painos manufactured at Mr. René's works, and exported to the tropics several years ago, have stood exceedingly well, and seem in no way affected by the climatic dangers they are exposed to. While other methods of impregnating woods with chemicals generally have a deteriorating influence on the wood fibres, timber prepared by this method, which is really an artificial ageing, becomes harder and stronger. The process is said to be regularly carried on at Mr. René's works, and the apparatus consists of a hermetically closed boiler or tank, in which the wood to be treated by the process is placed on iron gratings; in a retort, placed by the side of the boiler and connected to it by a pipe with stop-valve, oxygen is developed and admitted into the boiler through the valve. Provision is made in the boiler to ozonise the oxygen by means of an electric current, and the boiler is then gently fired and kept hot for forty-eight or fifty hours, after which time the process of preservation of wood is complete.

THE WOOD APPLE.

Wood apple (*Feronia elephantum*). Hindi, *Kyath* or *Cavitte*; Telugu, *Yalag-kai*; and Tamil, *Vellam*. This tree is considered by not a few to be useless perhaps, because it grows wild, and is to be found in almost every place, especially in the jungles. Hence, I surmise, it has met with only a cursory notice in our Garden Manuals, and is said to be—"not entitled to a place in the garden." To disabuse the minds of some folks I shall here note some of the many purposes to which this tree (that is prettily clustered with fruit) is applied to. I shall commence with its—

(*a*). *Fruit*, when ripe, and after the globular shell is broken, it has a very strong odour. The tartish pulp is *farinaceous* and granular which is eaten with sugar; some make a hot weather beverage of it like the "*mangy fool.*" A most delicious and palatable jelly is made from the juice of the pulp, and which, if properly made, will gratify all *connoisseurs*. The colour of the jelly is of a lovely ruby, and a better kind could hardly be made from any other Indian fruit. Certainly it cannot be excelled. (Wood Apple and Guava mixed also make a good jelly). Although "Firminger" pronounces the jelly "to be such as it is not likely would be approved of by many," but I beg to differ from this opinion. The *unripe fruit* is made into pickle and "*chutney.*" The next is the—

(*b*). *Shell* from which humming tops are made. Rockets are also manufactured from it for making Mr. Stripes uncomfortable in his den. Now I come to the—

(*c*). *Foliage.*—The tender leaves which have a sweet *aroma* are much prized by natives; they use it extensively for curing flatulency.

(*d*). *Timber* containing saccharine matter is much relished by "borers," and renders it useless; but it finds a ready place in the kitchen.

(*e*). The *viscous* juice produced from this useful tree is equal to the gum obtained from the *Babool* (*Acacia arabica*) commonly known as "Gum Arabic." Last, though not least, I conclude with its—

(*f*). *Medicinal properties.*—The *unripe* fruit when made into *decoction* acts like an *astringent*. The *ripe* fruit is an *anticscorbutic*, its effect being much similar to the *Bael* (*Ægle marmelos.*)

After enumerating the above uses of this generally despised *Wood Apple* tree, I fail to see why it should not be entitled to a place in the Indian Garden Manuals.

* * * * * *

The *Feronia* belongs to the *Aurantiacae* or orange tribe, as also does the *Ægle Marmelos* or *Bael* of the Punjab. The young fruit of the wood apple is almost a perfect substitute for the *Bael*, and universally procurable throughout India while the *Bael* is not.—*Asian.*

AGRICULTURAL COMPANY OF MAURITIUS.—The eighth annual general meeting of the Agricultural Company of Mauritus (Limited) was held on June 29th, at the offices, Change Alley. Mr. J. A. Longridge presided, and in moving the adoption of the report, expressed the satisfaction of the directors at being enabled to lay before them such a gratifying report. They recommended a dividend of 1s. 6d. per share, making, with the *interim* dividend 15 per cent. for the year; and they further proposed a bonus distribution of 1s. per share, being at the rate of 5 per cent. The report was adopted.—*Overland Mail.*

BAMBOO IN CEYLON.

(From the *Journal of the Society of Arts.*)

In the discussion that took place after the reading of Sir Arthur Phayre's paper on British Burma, on the 13th May, I see that a quotation I read, bearing on the growth of bamboo, from the *Gardener's Chronicle*, of the 30th of April, is (inadvertently) omitted referring to the Royal Botanical Gardens at Peradeniya, Ceylon. H. J. E, a keen observer, writes :—

"Perhaps the most striking objects in these gardens are the extraordinary clumps of giant bamboo, which exceed anything I have ever seen or heard of. In some of them not less, and probably many more, than 200 culms of over 100 feet high are growing, as tightly packed together as possible. Some of the stems must be very nearly, if not quite, a foot in diameter, and the average, eight or nine inches. This splendid bamboo is, I believe, a native of the Malay Peninsula, and is the most remarkable instance of rapid growth I know of, each of these immense stems being formed in a few months."

To lovers of botany, a fine specimen of this bamboo may be seen at the Duke of Northumberland's garden, at Sion-house, Chiswick. I have a stem here from that clump, nearly 70 feet high, the top of which pushed its head through the roof of the conservatory.

THOMAS ROUTLEDGE.

Claxheugh, Sunderland, 30th May, 1881.

TEAK IN CEYLON.

Teak is the name of two kinds of timber, valuable for shipbuilding and other purposes, one of which is known as Indian Teak, and the other as African. The trees which produce them belong to very different orders. Indian Teak (Tectona grandis) is a tree of the natural order Verbenaceæ. It is found in the mountainous parts of Malabar, and elsewhere in Hindustan, and in the Eastern Peninsula, Java, &c. It has been introduced in some parts of India, in which it is not indigenous. Dr. Roxburgh introduced it in the low grounds of the Circars in 1790. It is a beautiful tree, attaining a height sometimes even of 200 feet, and rising above all the other trees of the East Indian forests. It has deciduous oval leaves of 12 to 24 inches long, covered with rough points, large panicles of white flowers, with 5 to 6-cleft corolla, and 4-celled drupes about the size of a Hazel-nut. Its flowers are used medicinally in cases of retention of urine, and its leaves by the Malays in cholera. Silk and cotton stuffs are dyed purple by the leaves. The timber is the most valuable produced in the East Indies; it is light and easily worked, strong, durable, and not liable to the attacks of insects. It abounds in silex, and resembles coarse Mahogany. It is extensively used for shipbuilding, for which purpose it is imported into Britain. All the finest ships built in India, and many built in England, are of Teak. The most extensive Teak forests of the present day are in Pegu. It has been planted in Ceylon in a few places, but not yet with much result, as it takes sixty to eighty years to grow a large size. Some of the largest trees in the island are growing at Kalutura, on the sea coast, about thirty miles from Colombo. In India, owing to the able and systematic "Forest Department," the planting of Teak and other valuable timber trees is receiving great attention. In Ceylon we are far behind, do not possess such an institution, but have a few foresters that know as much about timber trees as a city clerk. A great want would be easily remedied by extending the Indian Forest Department to Ceylon, and placing it under our able botanical head. I trust the day is not far distant when such will be fulfilled. African Teak, sometimes called African Oak, is a timber similar to the East Indian Teak. It is now believed to be the produce of Oldfieldia africana, a tree of the natural order Euphorbiaceæ. *F.* (? J.) *Alexander*, May 25.—*Gardener's Chronicle.*

HAPUTALE LIMESTONE.

We have been favoured with the following for publication :—

Colombo, 11th July 1881.

Messrs. Carson & Co., Colombo.

DEAR SIRS,—Herewith I send you analyses of the Broughton lime received from you on the 5th inst., and additional samples on the 8th.

The first samples sent appeared much of the same character, and it was my intention to analyse one only. The samples sent on the 8th seemed to differ much, and I have therefore done both.

They contain much silica and silicious matter, and the unslaked has become partly air-slaked. The value of the lime, if fully burnt, is about three fifths that of Colombo coral, but on a district so remote from rail, it would be higher than this, as lime sent from here would lose much of its causticity before it reached Haputale.—I am, dear sirs, yours sincerely.

ALEXANDER C. DIXON.

Analyses of sample of unslaked lime (Broughton estate) received from Messrs. Carson & Co., on 5th and 8th July.

Moisture	4·74

LIBERIAN COFFEE.

The species of coffee which is indigenous to Liberia, in West Africa, seems destined to have an important influence on the industry of those countries in which the coffee-blight has almost extinguished the Arabian coffee plant. A little pamphlet by Dr. H. A. A. Nicholl, just published by Messrs. Silver and Co., gives some interesting information on the cultivation of Liberian coffee in the West Indies, and especially in Dominica. The plant was first grown in England in the Royal Gardens at Kew during the year 1872, and from thence seedlings were forwarded in 1874 to Dominica and to several of the colonies in the West Indies. Fifty years ago

Dominica was essentially a coffee country; at one time, indeed, over three million pounds of this staple were exported annually, and the coffee was of so fine a quality that the Dominica produce usually obtained the highest price in the English market. Unfortunately, however early in the present century a blight attacked the tree and within a few years it committed such ravage that the cultivation of coffee became almost extinct. Naturally, on the introduction into Dominica of a new species of coffee, more vigorous than that of Arabia, hopes were entertained that the leaves would be impervious to the ravages of the blight, and these hopes, happily, were fully realized, for the young plants soon shot up into vigorous large shrubs free from blight, and loaded with flowers and ripe and unripe berries. This immunity from blight enjoyed by Liberian coffee is, as Dr. Nicholls says, of the utmost importance to the welfare of Dominica and the neighbouring colonies, both English and French, for there is now nothing to prevent the islands of the Lesser Antilles from being once more large coffee-supplying countries. In Dominica the cultivation of coffee may be said to be re-established, although it is only yet in its infancy, and the productiveness of the Liberian trees is a matter of astonishment to those of the older residents, who remember the coffee estates of 40 years ago. The Liberian coffee plant is much larger than that of Arabia, being, indeed, in its native state, a small tree. It has several other characteristics which render its cultivation different from that of its Arabian congener, and gives it several advantages all in favour of the planter. Its leaves are much larger; it flowers for several months, so that flowers and berries may be found on the same plant, and the berries are twice the size of the ordinary coffee bean. The ripe berries do not fall from the tree, like the ordinary coffee plant, but remain on the tree, without detriment to their quality, for weeks; an important feature where it may be difficult to procure the labour necessary for speedy gathering. Dr. Nicholls gives many useful details as to the mode of cultivation and preparation. The flavour of the coffee, he maintains, is excellent, and he adduces evidence to show that it is quite as good as Java coffee. The success of the Liberian coffee in Dominica has been so great that already large supplies of berries are exported to several neighbouring islands. The history of the establishment of the new cultivation, Dr. Nicholls tells us, is full of promise to the future of the island. The plant is thoroughly acclimatized, the young trees are unaffected by blight, and their fruitfulness surpasses all expectations. In the island there are many abandoned estates, and large tracts of virgin soil, well watered with fine streams eminently adapted for the cultivation of coffee and limes and other tropical plants. The plant has also been introduced into Ceylon, and Liberian coffee from that island has lately obtained 93s. per cwt. in New York market—that is, 12s. above the quotation at the time for middling plantation Ceylon (Arabian) coffee to the London markets.—*London Times.*

THE PROFIT OF CASUARIANA CULTIVATION.

I shall suppose that five or six acres of ground are available in the neighbourhood of the reader—it matters not where he may be—perhaps in Tripasore, perhaps in Madras, or it may be in Salem. The land need not be very good, common waste land will do very well. I shall also presume that the reader does not care of risk much. Then let ten neighbours club together. If you read this article through you will see how, for a very trifling outlay, a large return may be obtained in three or four years. To begin from the very beginning. Purchase 12 lb. of Casuarina seed from Madras. The cost will be R6. Sow it in 24 small beds 10 feet long and 5 wide. Sow on the surface and cover slightly with the fine soil and well-rotted manure, some cut straw being spread over the beds to protect the seedlings from the sun. Each bed will produce about 1,000 plants. It is calculated that the 24,000 plants will cost at the outside R48. To save the trouble and uncertainity of raising them from seed they can be purchased for R5 a thousand, *i. e.*, R120 for 24,000. Having got the plants transplant them on cloudy days. The land should be prepared to receive them in the following manner. Plough twice, harrow and ridge. Let the ridges be 2 feet apart. Plant the seedlings on *alternate* ridges and let each be 3 feet in front of the other. Thus each plant will have 12 square feet. Water immediately after transplanting. The cost of transplanting will not be more than 12 annas per thousand plants. The ridges between the lines of casuarinas should be sown with castor oil beans. These will soon germinate, and as they grow up will afford shade for the young casuarinas, and the sale of beans ought to cover the expense of watering for the first year. Casuarinas should be planted from each other at the distances specified and then only will they grow upright, if too far apart the main stem is liable to fork and produce many side branches, thus considerably reducing the value of the tree. The trees will need to be watered only for the first year. It is estimated that under very unfavourable circumstances as much as 100 Rupees per acre will be required for the first year. In preparing the following estimate, two rules have been observed, first to calculate all outlay at the highest possible rate, and all income at the lowest. Land for casuarina cultivation may be had at 10 Rupees an acre. I shall put it down at 20 Rupees to be on the safe side.

A casuarina tree four years old will fetch as it stands, not less than one rupee, I shall value it at 8 Annas. The profits from the castor oil-beans are left out altogether. Here then is the cost of raising a plantation 6 acres in extent for four years.

	R.	A.	P.
24,000 plants at R5 per 1,000	120	0	0
Ploughing 6 acres at R3 per acre ...	18	0	0
Planting and first watering at As. 12 per 1,000	18	0	0
400 cart loads of manure at 8 As. per cart	200	0	0
Watering for first year	600	0	0
Cost of watching and all sundries say	444	0	0
Total R1,400	0	0	

Each acre will contain 3,630 plants—allowing 12 square feet for each. Supposing one sixth dies away we have left 3,000 per acre.

	R.	A.	P.
Sale of 3,000 x 6=18,000 plants at 8 As. each	9,000	0	0
Deduct gross expenditure ...	1,400	0	0
Net profit ...	7,600	0	0

or a return of 550 per cent.!

Now if ten persons shared expenses the risk of each would be R140 at the utmost, and the profit 760. If R140 be put by in a Bank the most one will get in 4 years will be 20 or 25R.—*The Eurasian and Anglo-Indian Advocate.*

TEA CULTIVATION AND PREPARATION: QUANTITY WITH QUALITY.

(From the *Indian Tea Gazette*, 2nd July 1881.)

I understand that a certain plantation made 81,930 lb. of tea on a gross outlay of R36,706, equal, as your correspondent says, to an average of 7 annas 2 pie per lb.; and that 63,046 lb. of this was sold in Calcutta for R27,247, or, say, 7 annas a pound, being a little under the cost of production and delivery. What the balance of 18,884 lb. sold for is not stated,

but we are told that 32,440 lb., that is the biggest half of the 63,046, only fetched 5½ annas gross, and the question is put forward as to whether it was advisable that this 5½ annas tea should or should not have been made and sent to market. Your correspondent maintains that in a financial point of view it was decidedly to the interest of the garden to make it, since it could only have "cost R4,211 to place in the market," whilst it "sold for R10,732." If these figures are reliable, of course it is all right enough,—the profit on the transaction is obvious, and there is no necessity to waste a word or a moment in arguing about it. But I beg the liberty to doubt the possibility of making and placing in the market now-a-days anything like saleable tea at 9 pice a lb. We may try to figure it out and say,

Cost of gathering leaf sufficient to make 1 lb. of tea, say	3 pice
Cost of manufacturing, including charcoal, and something for wear and tear of machinery	2 ,,
Cleaning, sortiug, and packing ...	2 ,,
Box and lining	2 ,,
Total ..	9 pice

But there is no provision for carriage or Agency charges, and cultivation and pruning are left out altogether. These last are neither of them light charges, unless the out turn per acre is very large. And there is a proportion of such matters as management, buildings, tools and baskets, Factory-fittings, tea-house, stores, carriage, medicines, discount, rent and taxes, stamps and stationery, and others, which, ignore them as you may, will not be put altogether out of the count, but will make themselves felt in the long run, or say "in due course," to those who look properly into the state of their affairs. I don't think any concern in India can turn out tea and send it to market at 9 pice a pound. Even nine *annas* a pound might not be further from the mark I think, but if the "Chiel," from amongst the notes he has taken, thinks he is able to prove that his figure is the right one, I shall be glad to be convinced upon sufficient proof.—HEGZN BAYKN.

1stly.—Would "The Chiel" kindly inform us whether it costs more to place a pound of fine tea in the market or a pound of coarse? By my own calculations I make out there would be little or no difference in the cost.—*Vide* table.

1 lb. of fine tea requires—	1 lb. of coarse tea requires—
Plucking. Charcoal.	Plucking. Charcoal.
Rolling. Sorting, sieving.	Sorting, sieving.
Firing. Packing	Rolling. Packing.
	Firing. Packing.

Freightage of Calcutta charges being the same on both.

Your correspondent gives us, from the report on which he goes, total tea sold in Calcutta, viz., 63,046 lb.: deducting from this what he terms very low tea or trash 32,440 lb., leaves 30,606 lb. of what he terms good teas. It costs, he says, R4,211 to place this 32,440 lb. of tea or trash in the market, and it sold for R10,732, which gives a profit of R6,510. As I maintain it costs as much to place a pound of coarse tea in the market as one of fine (open to correction), it follows that the 30,606 lb. of good tea that remained would cost a little less. Going by the above figures, say R4,000, the total cost of placing 63,046 lb. in the Calcutta market is then only R8,211, which is impossible. I therefore challenge the statement, 32,440 lb. of tea, or trash that only cost R4,211 to place in the market, and therefore the conclusions drawn from this statement favourable to his argument of a quantity are not trustworthy. The question at issue is Quality *vs.* Quantity. Is it fair to put down quality at 8 as. 7 pie. If one only got the same for coarse and fine teas per lb., then the question is solved at once, and quantity would rule the day. By going in for *quality*, I understand fine plucking and fine teas, and in arguing the question it would not be fair to put fine teas as only realizing the same as coarse ones.

If a planter, going in for fine plucking, reduced his outturn by half, but doubled his former prices, it would pay him. He would obtain the same amount as before for his teas, but his expenses would be decreased to half the former cost of plucking, rolling, manufacturing, packing, boxes, freight, etc. But it is very unlikely that fine plucking should mean such a decrease: even ¼ is putting it rather above the amount it would be. I myself am no advocate for extremes one way or the other, and I think, besides the two leaves and bud, a portion of the third might be taken whenever it is soft. Is there any reason why one who plucks so, should not turn out as fine a Pekoe or B. Pekoe as one who only takes two leaves and the bud, labour being ample?—DALANG.

While agreeing with your correspondent at to the inadvisability of plucking too fine, yet I think he has argued the case unfairly for the other side, as, in the case he mentions, it can hardly be doubted that if the outturn were reduced by 32,000 lb. coarse tea, out of a total of 63,000, the fine tea made would not only fetch a higher price (in this case I should say 10 annas at least), but there would have been more of it made. The same may be said the other way. According to your correspondent it cost R4,211 to make the rubbish and trash (rather a fine distinction) which sold for R10,732; but at what figure does he estimate the deterioration of the fine tea? In my opinion the only way to obtain both quantity and quality is to pluck separately, *i e.*, to pluck two leaves and a tip, and then take separately the fresh Soucbong leaves; but to do this a good labor force is required. I would like to see the question discussed in your columns.—J. A. H. J. *Upper Assam*, 14th June 1881.

RUBBER AND CACAO IN BRAZIL.

In *Scribner's Monthly* for June 1879 appeared an interesting paper on "The Mediterranean of America," in which the writer described a trip up the mouth of the Amazons. At the beginning of the paper the town of Breves, situated in the midst of deadly swamps, but prosperous from its rubber industry, is referred to, and the following account is given of the method of collecting and treating the milk of the rubber trees:—

In the early morning, men and women come with baskets of clay cups on their backs, and little hatchets to gash the trees. Where the white milk drips down from the gash they stick their cups on the trunk with daubs of clay, molded so as to catch the whole flow. If the tree is a large one, four or five gashes may be cut in a circle around the trunk. On the next day other gashes are made a little below these, and so on until the rows reach the ground. By eleven o'clock the flow of milk has ceased, and the *seringueiros* come to collect the contents of the cups in calabash jugs. A gill or so is the utmost yield from each tree, and a single gatherer may attend to a hundred and twenty trees or more, wading always through these dark marshes, and paying dearly for his profit in fever and weakness. Our *mameluca* hostess has brought in her day's gathering—a calabash full of the white liquid, in appearance precisely like milk. If left in this condition it coagulates after a while and forms an inferior whitish gum. To make the black rubber of commerce the milk must go through a peculiar process of manufacture, for which our guide has been preparing. Over a smothering fire, fed with the hard nuts of the *tucumá* palm, he places a kind of clay chimney, like a wide-mouthed, bottomless jug; through this *boaio* the thick smoke pours in a constant stream. Now he takes his mold,—in this case a

wooden one, like a round-bladed paddle,—washes it with the milk, and holds it over the smoke until the liquid coagulates. Then another coat is added, only now, as the wood is heated, the milk coagulates faster. It may take the gatherings of two or three days to cover the mold thickly enough. Then the rubber is still dull white, but in a short time it turns brown and finally almost black, as it is sent to the market. The mass is cut from the paddle and sold to traders in the village. Bottles are sometimes made by molding the rubber over a clay ball, which is then broken up and removed. Our old-fashioned rubber shoes used to be made in this way. Twenty million pounds of rubber, valued at $6,000,000, are annually exported from Pará; in the dry season many thousand people are engaged in gathering it. But the business is altogether a ruinous one for the province, as Brazilians themselves are fully aware. The *seringueiro*, who gains two or three dollars from a single day's gathering, has enough, as life goes here, to keep him in idleness for a week; and when his money is spent, he can draw again on his ever-ready bank.

The present wasteful system is spoken of as follows:—

The half-wild *seringueiros* will go on submitting to impositions and dying here in the swamps, until Brazilians learn that by purchasing this land from the government and planting it in rubber-trees, they can insure vastly larger profits, and do away with the evils of the present system. It is what must eventually be done. The rubber gatherers, in their eagerness to secure large harvests, have already killed an immense number of trees about the Pará estuary; they have been obliged to penetrate farther and farther into the forest, to the Tocantins, Madeira, Purús, Rio Negro, and eventually even these regions must be exhausted, unless they are protected in some way. The trees, properly planted and cared for, will yield well in fifteen years, and, of course, the cost of gathering would be vastly reduced in a compact plantation; half the present labor of the rubber collector consists in his long tramps through the swampy forest.

Further on the writer refers to the Cacao industry. He says:—

Between the Rio Negro and the Xingu, the most important lowland crop is cacáo. It is true, the trees will grow quite as well or better on the *terra firma* * but Brazilians prefer the *varzeas* for their plantations because the ground is easily prepared and takes care of itself; besides, the orchard arrives at maturity much sooner. We hardly notice these cacáo plantations from the river; the dark green of the foliage is so like the forest, and generally there are other trees near the shore. But for miles the banks are lined with them, mostly the orchards of small proprietors, who own a few hundred *pés* of cacáo, though some of the estates have twenty or thirty thousand trees. In our wanderings about the lowland we often pass through these *cacoaes*. They have a rich beauty of their own,—the dense foliage, the twilight shade beneath, and the dark stems, four or five together with the fruit growing, not among the leaves, but directly from the trunk and main branches, attached only by a short stem. The ground is quite clear and free from underbrush, and in the summer when the fruit is gathered is for the most part dry. The harvest months are July and August when the gatherers go every day to pick the ripe fruit from each tree and bring it in baskets to the house. There the oval, ribbed outer shell is cut open and the seeds are washed from the white pulp; then they are spread over mats and placed on raised stagings to dry in the sun, care being taken to turn them at intervals. Most of the seed is exported in this form; a little is roasted, pounded, and made into cakes with melted sugar for the delicious chocolate of the country. Unfortunately on the Amazons the sun is a very uncertain drying agent; frequently there are heavy showers, and the sky is clouded for days together; so it often happens that the imperfectly prepared seed gets musty and half rotten before it reaches the market. Much of the Pará cacáo therefore, does not rate very high with the manufacturers. All this might be avoided by the introduction of a simple drying-machine, such as is used at Rio for coffee. Stopping at the *fazendas*, we frequently get a refreshing drink, made from the white pulp which surrounds the cacáo-seeds. Enterprising planters prepare from this pulp a delicious amber jelly, which if it were placed in the market would be much more popular than guava-jelly. Even the shells are valuable; they are dried and burned, and from the ash is prepared a very strong brown soap—a necessity to every Amazonian washerwoman.

* On the Amazons this term is applied to all land that is not alluvial or swampy. *Varzeas* or *vargens*, are the flood-plains.

We could call the attention of cacao planters in Ceylon to these last sentences, from which it will be seen that the cacao pod is of value in more than one way.

BAMBOOS AND MANGOES.—A correspondent writes to the *Times of India*:—"Bamboos will flower and mango trees bear plentifully only under favourable circumstances, viz., a moist atmosphere for mangoes and hot sun for bamboos to put forth their inelegant blossoms. A mango famine fortells a grain famine, light rains, but healthy weather; flowering bamboos are a sign of light monsoon, famine and pestilence. Mangoes in excess foretell heavy rains and plagues; therefore if with this excess, bamboos flower, natives are in dread suspense of a coming ominous calamity. If mangoes ripen before rain falls, it is considered dangerous to partake of them. There is a saying among natives, 'Eat a mango before it rains and dig your grave.' Bamboos blossom every fifteen years, but natives imagine they flower but to prophesy."

Mr. TOM HUGHES says in reference to the recent unfavourable reports of the colony of Rugby:—"There is not one of our English lads who came here with the intention to work who is not at work. We have probably two or three who have no love for work they can avoid, but I believe you will find such in any community. We have tried to have no young men sent out here whose parents are not able or willing to offer a premium for their instruction in work during the first year, but we have some whose work under instruction is already worth their board. I think it very unjust to criticise our colony as one fully established might be criticised. We are here but eight months as yet, hardly out of our packing-boxes—you might say—everything is new to us; but I feel assured we shall succeed very well, and that before long too."—*Times of India*

THE USEFUL SUNFLOWER.—In South-western Russia, between the Baltic and the Black Seas, the sunflower is universally cultivated in fields, gardens, and borders, and every part of the plant is turned to practical account. A hundred pounds of the seeds yield forty pounds of oil, and the pressed residue forms a wholesome food for cattle, as also do the leaves and the green stalks cut up small, all being eagerly eaten. The fresh flowers, when a little short of full bloom, furnish a dish for the table which bears favorable comparison with the artichoke. They contain a large quantity of honey and so prove an attraction to bees. The seeds are valuable food for poultry; ground into flour, pastry and cakes can be made from them; and boiled in alum-water, they yield a blue coloring matter. The seed receptacles are made into blotting-paper; the woody portions are consumed as fuel, and from the resulting ash valuable potash is obtained. Large plantations of them in swampy places are a protection against intermittent fever.

THE AUSTRALIAN TEA-SEASON 1880-81.

The review of the Australian tea-season for the year ending 30th June last, which appears below, is deserving of the attention of our tea-planting community. Three facts arrest attention at once: the Colonies which make up Australasia received in the past twelve months nearly 50 per cent more China tea than the average imports for the previous three seasons; India made her first good appearance and sent one million pounds of tea; while Ceylon tea was, for the first time, introduced to the notice of Australian dealers and received a special measure of appreciation. How largely Melbourne is the seat of trade for the Colonies is shewn from the fact that she received nearly one-half (10¾ million lb. out of 24 million lb.) of all the tea imported, although the population of Victoria is only 860,000 out of 2¾ millions belonging to Australasia. The remaining 12½ millions of pounds were imported direct by Sydney, Brisbane and New Zealand ports. The rate of consumption in Victoria for 1879-80 was more than 7 lb. per head per annum against only 4·80 lb., in the United Kingdom. The consumption per head for all Australasia cannot be much under—indeed, the imports for 1880-81 would show it is rather over—the Victorian rate. It is evident, therefore, that the Australasian people take the lead as the greatest tea-drinkers in the world next to the Chinese themselves, who are said to drink tea morning, noon and night.

The remarks of the *Age* reviewer on Indian and Ceylon teas will be read with general interest. "Pekoe-Souchong" is recommended to the Australians as the best Indian tea for general drinking, while the average quality of the Ceylon teas is widely appreciated, and the produce of Loolecondera, Windsor Forest, Rookwood, and Calsay, specially commended.

REVIEW OF THE AUSTRALIAN TEA SEASON 1880-81:

1ST JULY, 1880, TO 30TH JUNE, 1881.

(From the Melbourne *Age*, July 2nd.)

The tea season (1880-81) just closed is probably one of the most remarkable in the annals of the colonies, showing, as it does, the largest quantity of tea ever received in one year by Australasia, say in the aggregate—

	lb.
From all China	22 982,085
Against season 1879-80	15,081,776
Against season 1878-79	17,250,151
Against season 1877-78	16,399,029

In addition to this quantity we have India making her first good appearance on the list, with an export to all the colonies of nearly 1,000,000 lb. weight.

Ceylon also appears, for the first time, as a tea producing country, and though the quantity forwarded to this market was small in amount, yet the quality has been highly appreciated on this side of the water.

The total import of teas into Melbourne from all quarters is as follows:—

	lb.
From 1st July, 1880, to 30th June, 1881 ...	10,754,724
From 1st July, 1879, to 30th June, 1880 ...	8,093,720
From 1st July, 1878, to 30th June, 1879 ...	8,666,065

Amount of tea delivered for exportation from Victoria—

	lb.
From 1st July, 1880, to 30th June, 1881 ...	2,751,500
From 1st July, 1879, to 30th June, 1880 ...	3,604,921
From 1st July, 1878, to 30th June, 1879 ...	3,237,188

Amount of tea delivered for home consumption in Victoria—

	lb.
From 1st July, 1880, to 30th June, 1881 ...	6,168,486
From 1st July, 1879, to 30th June, 1880 ...	5,422,721
From 1st July, 1878, to 30th June, 1879 ...	5,611,370

The above returns are furnished by the Custom House authorities.

Season 1879-80 was a red letter one in the history of the tea trade, for owing to speculation and a heavy rise in prices in the London market a briskness was communicated to the Melbourne trade, which resulted in a large business and unusually good profits being obtained at the latter part of the season. A few parcels of tea were shipped from Melbourne to London, and our new season, opening on the 1st July, 1880, commenced with a very small stock, both in bond and duty paid, in the hands of distributors.

Without this low stock, such a large import as we received during season 1880-1 would have completely glutted the market; as a fact, however, partly owing no doubt to the trade being bare of stock, and partly to the heavy operations of two or three houses, prices were well maintained for the first six months, and though the latter part of the season showed fair demand for good to fine sorts, which were scarce, yet the prices obtained for common to good leafy sorts ruled in favor of buyers, and latterly have shown considerable loss to the importers, and heavy stocks of these descriptions will be carried over to season 1881-2.

The present stock in bond of all kinds at the commencement of the season as compared with the two previous years:—

	lb.
1st July, 1881	2,178,328
1st July, 1880...	1,336,076
1st July, 1879...	2,177,775

In estimating the stocks in bond, chests have been taken at 80 lb., half-chests at 40 lb., and boxes at 12 lb. Actual on 28th June, 18,945 chests, 39,220 half-chests, and 44,494 boxes,

Not only are the stocks heavy in bond, but the trade as a rule are all well supplied with tea. This fact, taken in conjunction with the eagerness of Australian buyers (*vide* telegrams to hand) in purchasing heavily in Foo Chow, resulting in an export within nine days of 3,000,000 lb. to all the colonies, should induce great caution in buying on this side.

The following extract from the *North China Herald*, just to hand, illustrates the peculiarity of the late season from an exporter's stand-point:—"The most remarkable feature of the season (1880-81) now closing is the enormous increase in the export from all China and Japan to foreign countries. In 1868-69 the total export from all China and Japan to all foreign countries was about 205,000,000 lb. Eleven years afterwards, in 1879-80, it was nearly 245,000,000 lb.; the increase in eleven years being 40,000,000, half of this increase being in Japan teas. This shows a wonderful expansion, considering that in these same eleven years Indian tea assumed enormous proportions. But this last year (1880-81) has seen an increase as large as in the whole previous eleven years. The total export last year was 285,000,000 lb., or 40,000,000 above that of the previous season. Japan is only responsible for 5,000,000 lb. of this increase, the export of China tea alone being 35,000,000 lb. above that of the season ending in 1880. Half of this increase went to London. America, Australia and the continent divided among them the other half. It is easy to understand the present depression of the London market, and to ap-

preciate with what caution buyers should approach the campaign now opening."

For Melbourne direct the "Killarney" and "Lorne," steamers, are advised as sailing on the 9th June, and the former has already arrived, and a considerable portion of her cargo is announced for public sale.

The following review applies to the Melbourne market only:—

CHINA TEAS.—Season 1880-1881 was fairly opened by the arrival of the "Killarney" on the 26th July, 1880, and the first public sale by auction took place on the 27th July, when 8214 packages were offered, and the bulk sold. Since that date sales by auction have been frequent and heavy, amounting in the aggregate to 4,395,520 lb. weight, disposed of through this medium, details of which we give below:—

19,240 lb.	sold at	3¾d to	4¼d.
32,520 lb.	sold at	7d to	7½d.
183,480 lb.	sold at	7¾d to	8d.
224,760 lb.	sold at	8¼d to	8½d.
253,560 lb.	sold at	8¾d to	9d.
483,640 lb.	sold at	9¼d to	9½d.
423,000 lb.	sold at	9¾d to	10d.
376,640 lb.	sold at	10¼d to	10½d.
284,720 lb.	sold at	10¾d to	11d.
233,560 lb.	sold at	11¼d to	11½d.
247,560 lb.	sold at	11¾d to	1s.
293,440 lb.	sold at	1s 0¼d to	1s 0½d.
189,600 lb.	sold at	1s 0¾d to	1s 1d.
189,960 lb.	sold at	1s 1¼d to	1s 1½d.
156,600 lb.	sold at	1s 1¾d to	1s 2d.
198,320 lb.	sold at	1s 2¼d to	1s 2½d.
152,000 lb.	sold at	1s 2¾d to	1s 3d.
132,000 lb.	sold at	1s 3¼d to	1s 4d.
46,000 lb.	sold at	1s 4¼d to	1s 5d.
59,440 lb.	sold at	1s 5¼d to	1s 6d.
52,640 lb.	sold at	1s 6¼d to	1s 7d.
52,840 lb.	sold at	1s 7¼d to	1s 8d.
38,000 lb.	sold at	1s 8¼d to	1s 9d.
6,000 lb.	sold at	1s 9¼d to	1s 10d.

4,395,520 lb. Total at auction.

Or say,

2,829,680 lb. sold at 3¼d to 1s per lb. in bond.
1,565,840 lb. sold at 1s to 1s 10d per lb. in bond.

It is not so easy to arrive at the sales made privately, but there is no doubt as to their being very heavy, from the fact that at the close of the season the importers hold very little stock, the bulk being in the hands of the trade, therefore we are under the mark when we fix 5,000,000 lb. weight as about the quantity of China tea sold privately.

The qualities of the teas imported were on the whole much lower than any previous season within the last ten years, and this is borne out by the large quantity sold at auction under 1s. per lb., say nearly 3,000,000 lb. A reduced quantity of fine tea reached this market, with a heavy supply of common to low teas, of which a large proportion were boxes, and this latter quality constitutes the bulk of the stock we carry to season 1881-1882.

Musters of the fine teas offering were really s few as to call for little remark. Packlums were decidedly the best, and showed better make and more tip than previous seasons. Panyongs, Seumoos, Seuykuts, Saryunes and Kaisows come next; other descriptions turned out irregular, and are not worthy of remark.

The quality of the second and third crop teas was decidedly low in the cup, with little appearance to help the importer in saving a loss. Foochow scented pekoes were decidedly inferior to last season's being deficient in leaf and scent. Some S. capers came to hand. of fair quality, but the trade did not appreciate them.

Canton congous, green and S. O. pekoes much inferior to previous season's, some imports by the Chinese being unfit for use; but the lowest point was reached when a public sale took place, on the 8th June, of 250 half-chests and 750 boxes at 3¼d and 4¼d. per lb., in bond. The importation of such trash cannot be too strongly condemned, and shows the immediate necessity that exists of an Adulteration Act in Victoria.

INDIAN TEAS.

The introduction of these teas to the Victorian, people has been one of the features of season 1880-81, and we warmly welcomed the arrival of this import, not only because the country in which it is grown forms a part of the British Empire, and is the outcome of the enterprise of British subjects but because India in return is likely to become a large consumer in the immediate future of Australian products.

The formation of the Calcutta Tea Syndicate was a happy thought, and the mode in which they brought Indian tea prominently before the public by means of our great International Exhibition no doubt considerably helped the Syndicate to the success that has crowned their efforts during the past season.

We take credit to ourselves for first bringing and continually urging the necessity of reciprocity between India and Australia on the public; and it is satisfactory to be able to state that the foundations of a good trade have been laid, with prospects of highly remunerative returns to all parties concerned.

The first sale under the auspices of the Syndicate, and of any importance, took place on the 13th October 1880, when 783 packages were sold at high prices owing to the rush of buyers to purchase. Several public sales have been steadily held throughout the season, that on the 18th March 1881, calling for particular attention, as being the largest quantity of Indian teas ever sold in Melbourne in one day, amounting to 3,046 packages.

The total sales by public auction of India and Ceylon teas amount to 561,000 lb weight, and privately about 110,000 lb have been sold, giving a total quantity of 671,000 lb. Darjeeling teas, with their fine sweet, flavory and fruity liquor, speedily established themselves as first favorites. Some choice Kangra Valleys realised high prices, but the bulk of consumption has run on Assam, Cachar and Sylhet teas, which are liked for their pungency and full body and flavor. They meet with ready sale, and are used largely for mixing with China teas. Other sorts are used but too small a quantity has reached this market to criticise fairly.

Latterly some broken leaf and dust have come to hand, which, though rich and heavy liquoring, are not suitable from their appearance for Australian trade.

The terms given by our Indian and Ceylon cousins to their teas, viz.,

Pekoe
Pekoe souchong
Souchong
Congou

are rather misleading to China tea drinkers. The pekoe is a fermented tea, suitable for drinking by itself, and not as the China pekoe, which is underfermented and used only for mixing purposes.

All the Indian teas, as above, are fermented, and very few greens or underfermeuted teas are made. Such estates as do turn out these generally style them Namuna or sample pekoe, and so on.

Pekoe Souchong is usually the best India tea for general drinking. Souchong and congou are very good, but the leaf is often very large and unsightly. The liquor, however, is good.

High prices were obtained at the commencement of the season, as much as 2s 7½d per lb in bond, being realised for a Darjeeling, but latterly prices have fallen considerably, placing Indian teas within the reach of all at very moderate rates.

CEYLON TEAS.

Ceylon teas have come into the market for the first time this season, and about 54,000 lb have been sold. This quantity is included in our sales of Indian teas already given.

The parcels to hand have been readily taken by the trade, and the public seem to appreciate the quality thoroughly—some teas from Loolecondera, Windsor Forest, Rookwood and Calsay estates deserving special mention.

Small lots of Japan tea were sold during the season; the leaf in some cases perfect and liquor very good, but the bulk of them seem too highly fired to suit Australian tastes.

In conclusion we would draw attention to the show of teas lately held in the Melbourne International Exhibition, which was certainly the grandest display of such products ever witnessed in the world before, some 507 different samples being constantly on view.

The jury, all skilled and tried men, deserve credit for the care and attention they devoted to the work of examining and classifying the various samples, a matter of long time and patience, and the fairness of their awards must be endorsed by every tea expert who examined the samples in the Exhibition.

Some fine musters were shown by China, and it is a matter of regret that through some rule of the commissioners, whereby exhibitors not being producers were debarred from taking any awards, the whole of the Chinese exhibits could not be placed by the jury.

The following is a list of the awards:—

India takes 35 first order of merit.				
Ceylon	11	,,	,,	
Japan	1	,,	,,	
Melbourne	1	,,	,,	(blending and packing).
India takes 77 second order of merit.				
Ceylon	3	,,	,,	
Japan	2	,,	,,	
Melbourne	1	,,	,,	(blending and packing).
India takes 104 third order of merit.				
Ceylon	22	,,	,,	
Japan	14	,,	,,	
India exhibits		339	samples.	
Ceylon		78	,,	
Straits Settlements		1	,,	
Japan		35	,,	
Melbourne and China		54	,,	

JOHORE TEA.—An old Singapore merchant writes from London regarding tea raised in the Maharajah's experimental garden as follows:—"Everybody is astonished at the Tea which arrived in samples here having been gathered from plants raised from seed only a year old."—*Straits Times.*

CINCHONA IN MAURITIUS.—An interesting annual report from our energetic Superintendent of Botanical Gardens has just been submitted to Government for last year, from which it seems that 287,000 useful trees, shrubs and plants had been propagated in the Gardens during last year, the greater portion of which were either planted on public lands or on the road sides, or else sold. In other respects, the gardens appear to have been satisfactorily conducted. The Lieut.-Governor, in placing the report before his Council, stated that the Eucalyptus and Cinchona plantations had been successful, but that, in regard to the latter, it was under consideration to try an additional plantation at 2,000 feet above sea level, this being the lowest attitude at which it is believed the cinchona plant thrives most in these latitudes.—*Straits Times Cor.*

Correspondence.

To the Editor of the Ceylon Observer.

AUSTRALIAN WATTLE OR ACACIA.

Dikoya, July 21st.

DEAR MR. EDITOR,—As I have heard divers opinions as to the merits and demerits of the wattle or black acacia (by the bye are they same thing?), I shall feel much obliged, if you, or your numerous correspondents, will enlighten me on the subject, and I should like all the information I can get. Does it propagate from the root? Does it make a better break-wind than the gum? Does it grow faster or as fast, and does it require constant topping to make it a strong tree? Is it possible to keep its root within bounds by cutting a trench on either side of it, as I hear its roots kill everything that it comes in contact with? I send by to-day's tapal my subscription for the *Tropical Agriculturist.* It will be a great boon to all of us.—I am, yours faithfully,

DIKOYA PLANTER.

[All the wattles are acacias: the black wattle is *A. affius* or *mollissima.* It propagates only too readily from the roots, spreading all around, and being difficult to keep within bounds: a very deep trench must be cut for the purpose. It does not need topping; but grows very fast and shrubby, much more so than the gum. It is an excellent breakwind.—ED.]

MAKING TEA: PRUNING.

Lemastota, July 25th, 1881.

DEAR SIR,—Would some one of your readers kindly tell me what to do with my tea bushes? They are two years old, have been pruned from seven feet to three feet, and a flush has been picked. I want to know what to do to get my bushes into shape for the next year. Should I pick the flushes or should I prune? Tea making is a loss at so early a stage (though I am gaining experience), and I want to act to the benefit of next year.—Yours obediently, YOUNG TEA.

[The writer of "Tea Cultivation in Southern India and Ceylon" (a copy of which our correspondent should have) says:—"No harm will be done the second year by picking the tops of all shoots exceeding three feet or three feet and a half in height, and manufacturing the leaf so obtained. But, at the end of the second year, I recommend that the bushes should be cut across with the pruning knife, at about three feet or three and a half feet and be left alone for at least three months from that date. Picking may then be recommenced, but care must be taken that only the central shoots that grow upwards are picked: the sides should be left to expand, and from a strong lateral growth. I shall leave all further discussions of this subject alone, until I come to consider the question of pruning. My parting and earnest advice to the planter is, do not overpick your bushes when they are too young to bear it. Some of our best Bengal planters prefer to leave the bushes alone, as regards picking, until they are four years old, merely moderating the upward growth with the knife. They then guarantee a yield of 400 lb. per acre. This system is, I think, carrying the matter a little too far; and throwing away what is of some importance to small capitalists, viz., a little return in the third year after planting. At the same time, it would be far better to leave the trees alone for five years, than to overpick them when young."—ED. C. O.]

CALISAYA LEDGERIANA ON ANNFIELD.

Annfield, Dikoya, 26th July 1881.

DEAR SIR,—The enclosed is Dr. Trimen's reply to my letter sending him specimens of one variety of the Annfield Calisayas—*Calisaya Ledgeriana*.—Yours truly, T. C. ANDERSON.

Peradeniya, 25th July 1881.

DEAR SIR,—I think you are correct in calling this chinchona C. Ledgeriana. You will see that the form of the buds is quite that of the true plant.—In haste, yours faithfully, (Signed) HENRY TRIMEN.

T. C. Anderson, Esq.

A WINGED SEED.—A correspondent writes from Lemastota:—"I send you a seed with 'wing' attached. The wing measures five inches across, and the length of each thread is rather more than 2½ inches. The threads, are what the silk trade would know as six-deniers and in color and quality and fineness it surpasses white novi silk, which is worth 35s per lb. If you hold it in the sunlight the brilliancy of the wing is surprising. Throw it up, and you will see it may have come from far. The coolies say it does not exist near here. What is it? Any use as a new product?" "W. F." reports on this as follows:—"The single fruit with its pappus-like appendage is no doubt one out of a follicle of one of the *Dogbanes* (Apocynaceæ) and is likely from the *Gaerandi-dool* Sin. —*Anodendron paniculatum* A.D.C. or a member of that order, or of the Asclepiads, from the latter of which the floss of the *Calatropis gigantea* has been collected but it has no staple to enable it to be mixed with cotton, &c. I do not think your correspondent could collect a lb. of this stuff in a district, and if he did it would be of no value that I know of."

THE ABSORPTION AND SCATTERING OF HEAT BY LEAVES.—In order to rightly understand the *rôle* of heat in the growth of plants, it is important to know what part of the heat rays which strike the leaves is absorbed by them, what part is thrown back and scattered, and what part passes through them to lower organs. An inquiry of this nature has been recently made by M. Maquenne. Of his method we will merely say that he used, as constant heat-source, a Bourbouze lamp (in which a platinum wire is kept glowing by a regulated mixture of coal gas and air); and for some experiments with low temperatures he employed Leslie's cubes. The results of the research are briefly as follows:—1. All leaves scatter a part of the heat they receive vertically to their surface; with the Bourbouze lamp this diffusion is about 0.55 of the whole heat, with a Leslie cube a small percentage. 2. Generally the under side scatters more than the upper, but the reverse sometimes occurs. 3. Leaves absorb a good deal of the heat from the Bourbouze lamp, the absorption being due to the presence of absorbing substances, especially chlorophyll and water, in the tissue, and to the diffusion taking place internally at the surface of each cell; it is generally greater at the upper side than at the lower. 4. Thick leaves absorb more than thin leaves. 6. The absorptive power of leaves for the heat of boiling water is very nearly equal to that of lamp-black. 6. Leaves let heat pass through better the thinner or younger they are. 7. The radiating power of leaves with a great excess of temperature is pretty near that of lamp-black; it decreases a little when the inclination increases. 8. The absorptive power of chlorophyll is, on an average, equal to that of water for rays of the Bourbouze lamp, and increases proportionately to withdrawal in one direction or the other, from the heat *maximum*.—London *Times*.

CEYLON EXPORTS OF TEA AND CINCHONA.

We have been asked by a merchant to afford some idea of the probable exports of cinchona bark and tea from Ceylon during the next four or five years. It is not an easy matter making such an estimate, and we have need rather to sit at the feet of visiting agents and merchants than to place before them our opinions on the subject without previous consultation. However, if our figures only provoke criticism and correction, their publication will do good rather than harm, and for this reason we venture to give the following:—

In respect of tea, the Customs returns shew that last year (1880) Ceylon exported 162,000 lb., and we find that already this year the export has exceeded this quantity: for the seven months probably 170.000 lb. have been shipped. The total exports for 1881, therefore, ought to be between 250,000 and 300,000 lb., but, even if the latter figures be reached, the quantity is comparatively a mere trifle. It is only when Ceylon can send several millions of pounds per annum that Indian planters and home tea-dealers will care to take much notice of her as a tea-producing country. Our estimate is that in 1885 Ceylon should ship about 3,500,000 lb. of tea, and for the five calendar years ending with 1886 our total exports may approximate to 11 millions of lb.

As regards cinchona bark, it is far more difficult to estimate the future exports. Last year we sent away 1,162,000 lb., and during the seven months of 1881 about 900,000 lb. have been shipped. It is impossible to keep up this rate of increase steadily, we believe; but so much depends on the state of the home market, the financial difficulties of planters, and the extent to which the new system of shaving may be adopted, that nothing but the merest guess can be given of our exports during the next three or four years. We have in our Handbook ventured to anticipate that after 1884 Ceylon should be able to send away every year between 3½ and 4½ million lb. of bark, and, under due encouragement, to keep up this rate of export steadily for an indefinite period. Let us suppose that 1881 will close with a total export of 1,350,000 lb., and we can scarcely hope to see the million lb. much exceeded either in 1882 or 1883, but 1884 should probably see it nearly doubled, while during the following year a still large quantity of bark should be fit for stripping or cutting if the proprietors so required or desired, and the estimate of 3½ million lb. might then be attained.

NEW COMMERCIAL PLANTS AND DRUGS, No. 4.—By Thomas Christy. London: Christy & Co. 1881. Among the commercial plants described by Mr. Christy are the Ceara, the Mangabeira, and the Apocynaceous rubbers, Landolphias, from Western Africa, and Chinese and Japanese peppermint plants. Chaulmugra oil, as a substitute for cod liver oil, varieties of bark, caroba leaves, Chian turpentine, and some plants already noticed in this *Journal*, are included under the head of new drugs. The descriptions of eleven new drugs from Japan, used for rheumatism, congestion, and many other diseases, conclude this part. One of them —mahng dah-rah-gay (*Datura alba*) is used by the natives of India for poisoning, and professional poisoners are often called dhaturees, on account of the use made of this drug.—*Jornal of the Society of Arts*.

COFFEE PROSPECTS.

Notwithstanding the unexpectedly large exports which the season ending 30th June last showed from Brazil, there is good reason for anticipating a gradual rise in the price of our staple. In their circular of 8th January 1881, so eminent a firm as Messrs. Fred. Huth & Co. estimated the exports of coffee from Brazil for the following six months at 103,553 tons, or 50,000 tons below the actual result which is 154,724 tons! Talk of estimates wide of the mark: we in Ceylon have never done so badly as that. It is no wonder, however, after this though firms should fight shy of forecasting the future of Brazil exports, but Messrs. Robert von Glehn & Sons (to whose monthly report we are indebted for the foregoing information) remark:—

That advices received from reliable Rio firms respecting the smallness of the bean and the poorness of the new crop, warrant the belief that the estimate of 3½ million bags will not be reached. As regards business in general, both in Europe and America, the improved weather and improved crop prospects have created a more cheerful and hopeful feeling, and business men look forward to a brisk and prosperous Autumn season. For coffee in particular the undercurrent of feeling is full of confidence and hope, even though there is an absence of the exhilarating but delusive boom of the Yankees.

The latest statistics of Messrs. Rouse & Co. for the three great coffee-growing countries are as follows:—

BRAZIL.

Exported during the crop year endiug 30th June.

	1880-81.	1879-80.
Rio to Europe...	...113,300 tons	54,200 tons
,, the States, &c...	140,700 ,,	118,800 ,,
Total from Rio...	254,000 tons	173,000 tons
Santos to Europe	... 56,300 ,,	48,800 ,,
,, the States	... 14,000 ,,	11,500 ,,
Total from Santos	70,300 tons	60,300 tons

The new Rio crop is estimated at 3½ million bags (=208,000 tons), and the old coffee in the interior at ½ to ¾ million bags (=30,000 to 45,000 tons) The new Santos crop is expected to yield 1½ to 1¾ million bags (=90,000 to 105,000 tons).

CEYLON.

Exported 1st October to 30th June.

	1880-81.	1879-80.
Plantation ...	... 16,000 tons	26,200 tons
Native ...	... 1,300 ,,	1,900 ,,
Total ...	... 17,300 tons	28,100 tons

About 3,000 tons are expected to be shipped in the next three months, against a similar quantity in the corresponding period of 1880. The general impression is that the next crop will be about 35,000 tons; but a large out-turn is by some considered probable.

JAVA.

The Government Crop.

1881.	1880.	1879.
815,300 bags*	558,800 bags	1,260,000 bags
or	or	or
48,400 tons	33,200 tons	74,800 tons

* Latest estimate.

DIVI-DIVI; LIBI-DIVI; LIBI-DIBI.

A correspondent asks: "What is the Sinhalese name for divi-divi?" We do not know that there is any Sinhalese name, the natives not being acquainted with the divi-divi, which are the astringent pods of *Cæsalpinia coriaria*, a tree which is described as follows in the *Treasury of Botany*:—"*C. coriaria* is a small tree twenty or thirty feet high, native of several of the West Indian Islands, Mexico, Venezuela, and North Brazil. The primary divisions of its leaves vary from nine to fifteen, each bearing from sixteen to twenty-four narrow oblong blunt leaflets, marked with black dots on the under surface. It has branched racemes of white flowers, which produce curiously flattened pods, about two inches long by three-fourths broad, and curved so as to bear some resemblance to the letter S. The large per-centage of tannin in these pods renders them exceedingly valuable for tanning purposes: they are known in commerce under the names of Divi-divi, Libi-divi, or Libi-dibi, and are chiefly imported from Maracaibo, Paraiba, and St. Domingo."

A "kinder sarcastic" correspondent has sent us a long review of "*Another New Product*" referred to in the issue of our morning contemporary of yesterday, but instead of publishing it *in extenso* we make the following extracts which we believe give the essential facts respecting this supposed new product:—In Day's *Gardener's Dictionary*, v. 2, p. 452, the 4th section of Cæsalpinia is given as *Libidibia*, from Libidibi, the name of the pod of this plant in Curaçoa, the Cæsalpinia coriaria of Willdenow, which is a native of Curaçoa, Carthagena, and St. Domingo, in salt marshes by the sea-side. The legumes of this plant are called Libidibi and are used in tanning leather when ripe by the Spaniards and natives. The tree grows 15 to 20 feet.

From the *Bombay Flora* of Dalzell and Gibson published in 1861 this plant is noticed as follows:—

"Cæsalpinia coriaria. Libi-Dibi. Native of South America. A spreading, umbragcous tree. not high; leaflets minute; legumes very numerous, variously contorted; has been raised extensively at Hewra and Dapooric from seed received through the late Dr. Wallich. This tree is likely to be of great importance, on account of the excellent tanning material which it affords."

We may mention the fact that the Messrs. Leechman introduced the seed of the plant to Ceylon some years ago, and the result was that several of them germinated but died down immediately afterwards.

On other hand, this is what Dr. Trimen writes:—

R. Bot. Garden, Peradeniya, 3rd Aug. 1881.

SIR,—It may, perhaps, be instanced as a good example of the habit of passing by what is close to us without notice, that neither you nor your morning contemporary, in your remarks on "Divi-Divi" have seemingly been aware that the seeds of *cæsalpina coriaria* are regularly advertized in your columns, along with other useful plants on sale at these Gardens. The fine old tree of this species near the entrance to Peradeniya affords an abundant crop of pods every year, and there can be no doubt that the plant would flourish generally at the lower elevations in Ceylon.—I am, yours faithfully,

HENRY TRIMEN.

FORESTRY AND TIMBER IN THE STRAITS.

Mr. H. J. Murton of the Singapore Botanical Garden, in concluding a series of papers on the "Timber Trees of the Straits" published by the *Straits Times*, makes the following observations, which the Ceylon Government and their advisers may well take into consideration:—

As regards future supplies of timber, the Straits have little need of the introduction of exotic species of timber trees, if the indigenous kinds are properly attended to; as in addition to those described in my former contributions, there are numerous indigenous timber producing *Dipterocarpæ*, *Laurineæ*, and *Leguminosæ*, etc., etc., which as yet are but slightly known to the systematist, although native woodmen are perfectly familiar with them, and their distin-

guishing characteristics. The Government might well consider the advisability of attempting to impart some rudimentary knowledge of forestry and the distinguishing characteristics of our indigenous trees to the Government Forest Rangers.

For this purpose no scientific botanical training is necessary, as the very few technicalities that are requisite should be easily mastered, and if they had free access to such works as Brown's *The Forester*, Brandis's *Forest Flora of India*, and Kurz's *Forest Flora of British Burmah*, etc., etc., they would soon been to feel an interest in the subject, and the study would be taken up more for the sake of the pleasure and gratification it would afford than for the increased pay such knowledge—when acquired—might secure.

Visitors to Singapore would not then be shocked by the sight of the grotesque objects on the roadsides, now designated trees, which are periodically cut and hacked to suit the taste and fancy of some Kling coolie, until they have lost all trace of Nature's handiwork beyond a few shrivelled leaves at the ends of skeletonised, moss and lichen-covered branchlets, which forcibly remind the most casual observer that if it be true that "a thing of beauty is a joy for ever," there is also a reverse of the quotation.

Nothing would advance the knowledge of our timber trees or create an interest in forestry so much as the establishment of a Wood Museum at the Botanical Gardens, after the style of the Wood Museum at Kew.

The nucleus of such a collection has long since been formed—and if a typical collection of our indigenous timbers could be got together there, where their vertical and transverse sections, their adaptability to polishing, the characteristics of their barks, etc., could be studied and compared with the growing trees in the grounds, a useful school of forestry would be established, and an interesting addition be made to the Gardens.

By such a typical collection, intending exhibitors at International and Intercolonial Exhibitions would be able to systematically name their collections, and the most casual observer would always find something in it to interest him.

A CEYLON PLANTER'S COLONY IN THE FAR WEST.

We call special attention to the interesting communication from an ex-coffee planter in Minnesota addressed to a friend in Ceylon. It describes, graphically and instructively, an entirely novel phase of life, in the experience of our wandering colonists at least, and it also shews how widely Ceylon men have got scattered since the depression in coffee commenced in 1878. We hear of them, from time to time, in the Straits, Java, Borneo, Fiji, New Zealand, the different Australian Colonies, South Africa, Brazil, West Indies, and now in the Western States of North America. Certainly, the Minnesota picture of an industrious but cheerful and healthful life* is not the least attractive to men not afraid of work, and we should not be surprised to find several in our midst, now on the lookout for "new fields of enterprise," taking their departure for the Far West. What a lesson there is here for the many in Ceylon who are afraid or ashamed to dirty their hands with good honest hard work! Such have, in this Minnesota letter, evidence of how contentedly Englishmen, who, one day, may be called to lord it over and direct hundreds of servants, coolies and others, doing their bidding,—are found the next, handling the plough for themselves and working as hard with their hands as if they never had a servant in their lives. Ceylonese young men who are directing their thoughts towards agriculture as the one likely means of livelihood in the future ought to ponder this lesson and lay it well to heart:

Honour and shame from no condition rise;
Act well your part—there all the honour lies.

* News has since come of a terrible tornado sweeping over Minnesota, destroying life and property.

WHAT CEYLON PLANTERS CAN DO IN THE FAR WEST.

A LITTLE CEYLON COLONY IN MINNESOTA.

[Matale, July 29th.—I enclose you a letter I have just received from my late superintendent, portions of which may be of interest to your numerous readers and especially to those who would fain seek pastures new.]

May 29th, 1881, Minnesota, U. S. A.

I hope things are not such a dazzling blue as they were when I left Ceylon. I was only at home for four months and got very tired of doing nothing, so cut my stick and set out for this "great and enlightened country," which, on the whole, I like very well, though of course in a new country you don't find everything ready cut and dried for you, like you do in Ceylon, but must make up your mind to make the best of and laugh at everything that happens. We are right on the prairie, and Heron Lake, a small village and our post town, is about 4 miles distant; there is also a railway station there, which makes transport easy. We are getting quite an English colony around, and Ceylon is well represented. There are A. B. Kier, of Haloya, Nilambe; Blenkiron, Morawak Korale; Peto, Rakwana; Thomson, Haputale; (expected 20th June), and myself besides about 8 other Englishmen. The balance is composed of Yankees, Germans, Dutch, and Norwegians. I consider it a particularly good opening for any young fellow with a small capital, who is not afraid or ashamed to work with his own hands. Of course, later on we shall manage to employ more men and so do less ourselves, but labour is exceedingly expensive, and so we just "buckle to" and share all work equally with the farm labourers. Up at 5; water horses, milk cows, and harness teams. Then breakfast; when finished "hitch up," and each goes off with his plough and works away until 12, at which time dinner. Then plough on till 6.30, water horses, &c., and home to supper about 7-30. We only put in £1,000 each, but if one has capital you need only do the "boss." Living here comparatively nothing, as you raise everything you consume, with the exception of tea, tobacco, and oil, which you trade for your butter and eggs. We are going in chiefly for stock raising (as this line of farming pays better and is less risky than grain), only raising enough grain to feed our stock and ourselves. You can procure railroad land at $5 per acre in the state it was made, but the better way is to purchase improved farms from the present settlers at about $8 to $10 per acre. These men are poor. They have previously had land (160 acres) granted them, but having *no* capital to commence with, and having gone in for expensive machinery for which they never can pay, are hopelessly in debt. They are such fools—every petty farmer going in for his own machinery instead of joining together and getting it. The heat here in summer is intense, the thermometer often showing 90 degrees in the shade; while in winter the cold is equally unbearable, the thermometer sometimes being 25 to 30 degrees below zero. However, the Ceylon men have not suffered and say that they would "never have known it except for the thermometer." There are still heaps of snow under the manure heaps and

a sheet of ice about 3 inches thickness in the cistern. I have never felt so fit in my life. There is no liquoring "Ceylon madiri" here. You can get beer *sub rosâ* in the lake, but we never keep it. Kier came up from St. Paul's the other day, and brought up a bottle and unexpectedly brought me out a glass while I was ploughing, and I can tell you it was nectar. What would not I give for a gang of coolies advanced *ad libitum*! I came with the Hon. George Hamilton who came out to see what sort of an investment it would be. He's the son of Lord Some-one, and on arriving in New York he sent his valet back. On arriving at the hotel up here, he saw a lot of common-looking men hanging about (and did not understand you had to live with livery stablemen, &c.), and went up to one and said: "Who is the man who has to clean boots," and was answered: "Well, stranger, if you want your boots cleaned, I guess you'd better do it yourself;" which the hon. gentleman did and made me laugh by remarking: "Well, this is the first time I've ever cleaned my own boots, and hanged if they're not much better done than yours." That's the style here. Every man is your equal, and though it's rough work, you must not mind Bill Smith, the ploughboy, addressing you thus: "I say, Captain, give us a smoke," at which you're expected to hand over your pipe for B. S.'s use! At this, however, I draw a line, and politely but firmly decline to accommodate the said Bill. At the hotels, the enlightened American uses his *one* knife to help himself to butter and also to eat with, whereas the unenlightened Britisher still maintains the use of the fork for eating purposes, and does not consider it necessary to whet his knife in his mouth before making a "swoop" on the butter. This is trying, but there's money to be made. The first year you can with *ordinary* luck make 10 per cent on your capital, and of course the first year is mostly paying out.

I liked the life in Ceylon, but consider it not worth the candle. Take for example such men as ————. He gets his screw and spends it. What will he do in his old age, or what would his wife do in the event of his death? Were he down here, with £1,000 he could secure himself a permanent home, and probably in a few years have enough to retire on. Land is cheap at present, but is going up every day, and ere long my land will realize 50 per cent more than I gave for it. I have only £1,000 in at present, but directly things are "fixed up," I am going to put in another £1,500. Only any fellows thinking of coming down here should be warned to avoid all land-agents and advertizers, Shearman, Close Bros., and all others. I have been offered 5 per cent on all lands I can sell for the railway, but have declined, as I have an agent in London who sends me out fellows to "learn the ropes" who pay me a premium, but if I was in any way connected with the railroad land it would look fishy and I can make more the other way. I have two coming out to me shortly, and the railroad company still think they will get over my prejudices and have presented me with a through ticket and I am quite a "big boss" when down at St. Paul's. So I calculate I have scored one off the blooming Yankee already. The society here is very fearful. We have an ancient dame who keeps house for us, who is a very nice person—*for a Yankee*. We also have a farm help, a Norwegian, a very decent fellow, but the *general* run are really ghastly. It is common to give "socials" where the neighbours all congregate and honour you by spitting tobacco over your carpets and making themselves generally agreeable. I politely but firmly declined to have my house turned into a pig-sty, and received a lecture from my neighbour, who told me we ought to do our utmost to civilize the people around us. I told her I was not a missionary and did not intend to make a martyr of myself for all the Yankees in creation, but would be glad to subscribe to the school, would attend church or do anything reasonable, but I drew a line at making my dining-room a public spittoon. This will all change as we take deeper root. I have an agent in London canvassing for me, and I board gentlemen (for a premium) "on very advantageous terms." I don't regret leaving Ceylon *now*. I did at first, as I liked the old place, but there, unless you go into coffee, which is generally a pretty permanent investment, you have no settled home.

THE PRESENT TEA SEASON.

Although the Tea season has only just fairly commenced, still the views we expressed on the subject of speciality are borne out by the prices which have already been obtained on the market. At the public sales New Season's Teas were sold at rates which cannot be deemed satisfactory to importers, considering that it was the first steamer, and a clear week is given to sell the teas in. In many instances a rather gloomy view is taken of the future. We do not share in the extreme pessimists' opinions, because according to advices from India the present crop in that country is also much below last year, and as a consequence the imports to this country will for some time fall short of expectations, and there will therefore be an opening for the China produce. But, on the other hand, the experiences even thus early in the season are once more such as to force on the importers the necessity for greater caution in their purchases. India is undoubtedly making great inroads on the market, and the care bestowed on the manufacture in the European supervised estates is producing an article which is maintaining the position it has taken up. We trust as the season advances a better tone will prevail for China Teas, and the losses now incurred may be made up by subsequent gains; but that anything like adequate profits will be realised is much open to question. The subject is really a serious one for importers, and it is time they took some steps to do away with the abnormal competition which exists amongst them. We shall wait and watch events before alluding to the subject again, and if the worst is realised, perhaps this last disappointment may bring about the desired result. —*London and China Express.*

ROBERT VON GLEHN & SON'S MONTHLY COFFEE CIRCULAR.

LONDON, July 5th, 1881.

During the first two weeks of last month there was a sudden rush to buy Coffee. In Havre the purchases for the first week exceeded 50,000 bags; the telegram from Rio of the 6th June advised purchases for Europe amounting to 107,000 bags; and at the Dutch Sale on the 15th June the competition for the 92,000 bags offered was so great, that good ordinary Java sold at 38 cents—2½ cents above valuation, and 15 per cent. above the price at the May sale. This was one of those feverish and excited movements to which we are always exposed when the price of an article is on a really low level, as is the case with Coffee at present. It may be taken as a sample of how rapid and how important will be the advance when something really turns up favourable to the position of the article. We believe that the rush was greatly stimulated by the fact that the bulk of the European stocks are held by persons outside the Coffee trade, and not by the usual middlemen of the Coffee trade, who hold little stock but are extremely desirous of getting into stock whenever they think the lowest point reached.

The rush to buy was premature, because absolutely without reason, and consequently the advance in price has since been lost.

The position however, remains the same, a large part of the stocks are held by outsiders, and the merchant the trade sees or think they see a reason for an advance, they will make another rush to get into stock at low

prices, and they will find the stock very strongly held.

In the "pink circular" of 1st July, Messrs. J. C. & Co. remark that on the strength of the holders of the Havre stock the future course of prices will greatly depend. As regards the strength of these holders we are in a position to speak with some certainty, and we believe it to be undoubted, and that they comprise in their number one branch of the biggest banking firm of the world.

A perusal of the following comparative Table of Prices will, we think, show to how safe a level prices have now fallen :—

At the commencement of a new Brazil Season when the air is rife with rumours about the coming crop, it may not be out of place to go back and see what was the opinion entertained six months ago of the crop just finished.

In their circular of 8th January, Messrs. Fred. Huth & Co. estimated the exports of Brazil from 1st January to 30th June, 1881—

From Rio	...	...	77,800 tons
„ Santos	...	...	25,783 „
Total exports from Brazil for six months ending 30th June, 1881 ...			103,583 tons

Taking the exports for the 5 months from 1st January to 30th May according to Messrs. Kern Hayn's circular of 1st June, 1881, and the exports for June as per Reuter's telegrams, we find that the exports for the above period have been

From Rio	...	...	119,430 tons
„ Santos	...	..	35,294 „
Total			154,724 tons

Messrs. Huth's estimates have therefore been exceeded by 50,000 tons.

Now this is no trifling mistake especially when we remember that the English Rio firms report that the quantity of 1880/81 crop now remaining up country, amounts to between 500,000 and 1,000,000 bags. It was therefore possible that high prices in Europe might have drawn out a further 50,000 tons, and it comes to this, that half way through the crop—that is in January—Messrs. Fred. Huth & Co. did not know within 100,000 tons what the Brazil crop was. Keeping this fact in mind, we recommend our friends to accept with extreme caution all estimates of the Brazil crop 1881/82.

So far the most favourite estimate of this Rio crop is 3½ million bags, but within the last week smaller estimates have been received and though great reluctance is shown to adopt them by those who under estimated the last crop, we cannot help remarking that advices received from reliable Rio firms respecting the smallness of the bean and the poorness of the new crop, warrant the belief that the estimate of 3½ million bags will not be reached.

As regards business in general, both in Europe and America, the improved crop prospects have created a more cheerful and hopeful feeling, and business men look forward to a brisk and prosperous Autumn season. For coffee in particular the undercurrent of feeling is full of confidence and hope, even though there is an absence of the exhilarating but delusive boom of the Yankees.

PLANTING IN DELI, SUMATRA.

May 27th.—Some remarks on Deli, which I see you have given some attention to lately, will probably be of interest to your readers. The soil of Deli being of an exceedingly rich kind, every tropical produce could with success be grown; why, therefore, is the cultivation limited to tobacco only. The following will give some explanations:—The Dutch in annexing quietly the East coasts of Sumatra have taken over only the revenues of the country, leaving the land to the Sultan and his chiefs; but the Sultan is not allowed to give out contracts as he might like, the conditions are prescribed to him by the Dutch Government. The contract granting the use of the land for a certain number of years requires the confirmation of the Resident, as also does the transfer to another name, therefore the planter cannot freely

dispose of his plantation. By this measure Government can prevent giving out contract or sale of contracts to obnoxious people; but at the same time the Sultan and his chiefs being left owners of the land, he and his chiefs are responsible for the contract: for any revolts or disturbances that might occur by the natives of the district, &c., &c. The dodge is clear, the Dutch Government have their hand over the country without having either the responsibility or expense for police. A second reason, is the unsatisfactory relations between employer and labourer.

As Mr. Cramer writes in his *brochure*, the planter does not require any especial protection, but let planter and workman have equal law. Entering a contract, the planter on one side advances the workman a certain amount of money, and gives certain promises. The coolie, on the other side, promises to do a certain amount of work. Now the planter is sure to be made to adhere to the contract; but the coolie, if he likes to desert from the estate, and by so doing break his contract, gets for desertion one to three months' imprisonment; that does not do him a great harm, as he remains in prison only as long as it suits him. But suppose the coolie is good enough to wait in prison until his time of punishment expires, he cannot be forced to adhere to his part of the contract. The planter can lodge a civil complaint against the coolie for debt, but what one can get out of a coolie is soon told; the planter not only loses his money, but also the work.

Speaking of the prison, I may just mention what a Deli friend gave me as a fact. In the course of the last twelve months twenty of his coolies were imprisoned. Out of the twenty only two men returned to the plantation on the expiration of their terms, the others having either escaped from, or died in prison, causing to the estate a dead loss of $900.

Recently a new law has come out, trying to improve the relations between planter and coolie. The intention of the legislator is good, but the law being only partly applied, in default of a sufficient staff to work it, it has turned out only another vexation to the planter, and a new tax of fl. 1 per coolie a year. Moreover, the native population not living under Dutch rule, an efficacious execution of the law will depend greatly on the goodwill of the Sultan and his chiefs.

Another want badly felt is that of good roads to open a country; to secure a high lasting cultivation good roads are of first necessity. But up to-day there is in the whole of Deli not one single road made by Government. To bring a little heavy machinery up country would be perfectly impossible during nine months of the year, a good shower rendering the roads impracticable. A sugar, tapioca, or other estate producing articles that cannot stand much transport expenses would certainly come to grief, only on account of the roads; the roads being bad the carts cannot be properly loaded, and wear and tear on cattle carts would rise up to the end of a season to a ruinous amount.

Another great drawback is the costly labour, the Government not having succeeded or tried to get the permission of free emigration to Deli, either from Madras or China, the planter has to pay high advances and commissions for procuring labourers. With a little goodwill and perseverance the Government might yet succeed in getting permission of free emigration from the above-named countries, and would by that confer a boon upon all concerned in the country.

At present the country yields to Government a net profit of about fl.500,000 against which nothing has been done yet for the benefit of the country, and very likely nothing will be done until it is too late. The tobacco plantations have land left to plant only for a few years more. Planting for a second time on the same land does not pay, trials made with tobacco south and north of Deli have turned out failures. So the next question is, what will be the future of Deli? It is pretty soon said; if the Government does not try to remedy the existing evils, in a few years more the planters will have to leave a ruined country, being very likely ruined themselves.—*L. and C. Express.*

CINCHONA CULTIVATION IN CEYLON.

(From the *Pharmaceutical Journal.*)

By the courtesy of Dr. Trimen, who about eighteen months since succeeded Dr. Thwaites in the charge of the Royal Botanic Gardens in Ceylon, we have been furnished with a copy of his report for the year 1880. This memorandum shows many indications of the energy of the new Director, and contains much information respecting experiments made in the cultivation of various economic plants. But the portion most interesting to readers of this Journal is that which relates to the cultivation of cinchona, and from which therefore a few details may be selected.

During the year 1880, the cultivation of cinchona in Ceylon underwent a development unparallelled in any previous year, and it has now become general on all estates in suitable situations. The species principally grown are *C. officinalis* and *C. succirubra*, and of these many planters have now extensive nurseries, so that the demand at the Royal gardens for seed has almost ceased, and it is not thought necessary for the Government to continue longer the propagation of those species to any great extent. At elevations above 4,500 feet, the climate is found to be very suitable to *C. officinalis*, but lower down the other species do better. The *C. officinalis* exhibits considerable variation in the form of the leaf, which ranges from narrow lanceolate to broad oval. A quick-growing broad-leaved form, much in favour in Ceylon and incorrectly called *C. Condaminea*, is thought to be possibly the result of crossing with *C. succirubra*. A sample of the bark of the narrowest-leaved variety (*C. crispa*) has been submitted for examination to Mr. J. E. Howard, F. R. S., who has reported that it corresponded to the bark formerly known as "crespilla bark" (the Quina fina de Loja), and that it contained 5·2 per cent. of total alkaloids, of which 4·1 per cent. was quinine, or equal to 5·45 per cent. of quinine sulphate. Some of this bark, obtained by coppicing, was in February last sold in Mincing Lane at 7s. 6d. per lb.

Of the still more valuable *C. Ledgeriana* there were only about 3,000 plants in the Government garden at Hakgala, most of them raised from seed obtained from Java in 1878. Only about 1,250 plants have therefore been distributed, but there is reason to believe that many planters are in possession of plants raised from seed obtained by themselves from Java. The important observation has also been made that although *C. Ledgeriana* is difficult to propagate by cuttings it may readily be grafted on *C. succirubra*.

A note of warning is raised as to the danger of allowing opportunities for hybridization, such as have no doubt injuriously affected many cinchona cultivation experiments. It is urged that if any of the inferior kinds of cinchona are growing in the neighbourhood of the *C. Ledgeriana* trees they should be at once destroyed. Further, it is recommended that the bark from selected trees should be analysed by a competent chemist, and the results compared with the characters of the trees, and that only those varieties yielding a good bark analysis should be preserved as seed trees and all others ruthlessly exterminated.

A few plants of *C. officinalis*, var. *pubescens*, a fast-growing variety, which some time since was spoken of very favourably by Dr. de Vrij and Mr. J. E. Howard (see *Pharm. Journ.*, vol. viii (1871), p.p. 805 and 825), have survived the journey from the Nilgiris and are doing well. They are, however, reported as having at present much the appearance of *C. succirubra*.

CEYLON TEA IN AUSTRALIA.—An ex-Ceylon planter who has established a Tea-retail Store in Melbourne, making up packets in a neat fashion at 2s., 2s. 6d., and 3s. per lb., has sent out a number of travelling Agents to sell in the country at a profitable commission. In this way, Ceylon tea must rapidly make its way and Melbourne merchants say that our tea in time, will be largely used in the Colonies.

WEST INDIAN PINE-APPLES.—The *Grocer* says that the first cargo of new season's pineapples from Antigua arrived in London yesterday week. The first portion of the cargo was immediately placed on the market, and was readily sold at full prices, a few fetching as much as 21s. to 26s. per dozen. Some of the pines were bought for export to France the same day. The pines generally were in fairly good condition, though rather green.

CINCHONA PLANTERS' MANUAL.—We have to acknowledge with thanks a copy of Mr. Owen's Cinchona Manual published at the *Observer* Office for the use of planters. It is not in our power to do more than own receipt of it in our present issue, but we shall take an early opportunity of giving the work a notice such as its contents appear to deserve. As a Manual it deals entirely in the propagation, cultivation and harvesting of Cinchona, and this in a very full and exhaustive manner.—*C. Times.*

CROPS IN KELEBOKKA, 29th July.—You have evidently misunderstood what I said the other day. I did not say that the *district* in 1879-80 and 1880-81 gave an average of 2½ cwt. per acre, but that *many of the estates in it have done so.* This year many places have 4 cwt. an acre on them. I enclose you a memo of the crops on this estate for the past 10 years, which gives an average of 4 cwt. per acre for that period :—

	Crops on ———		
1871-72	560 cwt.	1876-77	2,120*
1872-73	1,690 ,,	1877-78	450
1873-74	690 ,,	1878-79	1,550
1874-75	1,560 ,,	1879-80	355
1875-76	850 ,,	1880-81	640
	5,350 cwt.		5,115

Average of 5 years 1,070 cwt.; next 5 years 1,023 cwt. 250 acres coffee. Weather continues very dry and leaf disease, I am sorry to say, is rather bad.

THE CINCHONA PLANTER'S MANUAL.—The local *Messenger* of August 2 has an appreciative notice of this work, from which we quote the following :—"Mr. T. C. Owen is already favourably known to the public in connection with coffee planting literature, and he has now prepared a book of 218 pages on cinchona cultivation which, it is no flattery to say, is a work of high scientific merit. The book seems to be exhaustive of all that is at present known on the subject of cinchona, as Laborie's work was of all that was known of coffee cultivation in his time, and we do not think there is any exaggeration in saying that Mr. Owen's book will have the same relation to all future treatises on cinchona cultivation that Laborie's has had to all subsequent manuals of coffee planting. Cinchona is, however, a much more scientific subject than coffee, and requires a man of more scientific knowledge to write a book on it than coffee does. . . . The book is neatly bound and printed, the paper of good quality, and the whole is very creditable to the *Observer* press. The only typograpical error we have noticed is in the following passage on page 54:—'Java, which is situated as many degrees south of the line as Ceylon is north, has at 500 feet a temperature of 63° Fahr., &c.' Here 500 must be a misprint for 5000, but we know from experience how liable mistakes are to occur in the printing of numerals, so that is a very excusable fault."

* Besides about 60 cwt. sold of inferior coffee.

SOCOTRA.—Dr. Schweinfurth writes from Aden :—"Just back, after an absence of three months, of which two were spent on the sea. The island (Sokotra) is wondrously beautiful, relatively cool, healthy, and the inhabitants are patterns of harmlessness. I had to gather up all I could find day or night, so as not to be behind Balfour, who had sent me his catalogue. Very much satisfied with my booty. Did no cartographic work. A regular survey of the island is, however, much wanted, for the existing maps leave much to be desired."—London *Athenæum.*

JALAP TUBERS.—In a letter dated the 8th ultimo, the Acting Commissioner of the Nilgiris, requested the sanction of Government to sell the jalap tubers grown at Ootacamund at a moderate price, to be determined in communication with the Superintendent of the Gardens. "There is a large demand for the, plant and up to the end of March last 4,201 tubers were supplied to applicants from various parts. In one case Mr. Jamieson inadvertently charged for 1,000 tubers at R. 5 per 100, and received the amount R. 50. It is impossible to meet the large demand out of the very limited cultivation of jalap now carried on in the Gardens, while to extend it for gratuitous supply would partly absorb the small revenue derived from other sources." The Government have approved of the sale of the tubers at a very moderate price.—*Madras Mail.*

BONE-DUST MANURE.—The Officiating Secretary to the Government of India in a letter to the Secretary to the Government N. W. Provinces says in respect to bone manure :—"Mr. Fuller is of opinion that bone-manure could only come into any general use in Indian cultivation in the form of bone-dust, untreated with sulphuric acid, as the cost of converting it into superphosphate of lime would be prohibitive to the ordinary cultivator. He adds that the solubility of the bone-dust is much less than that of the superphosphate, and hence that the full effect of its use would not be known till the second year after its application. No doubt he will note the character of the next crop which is taken off the plot experimented upon.—*Madras Standard.*

MUSHROOMS.—While agriculture, as at present exercised in England, is threatened with ruin from American rivalry, and hard-headed farmers are being assured they must take to growing strawberries in summer and cabbages in winter, it is consolatory to find that something may be made of mushrooms. Strawberries would scarcely find consumers if extensively grown, even though produced at a penny a pound. At all events, they should be left to gentlemen farmers, since they would scarcely answer for rough cattle-feeding. With cabbages it might be otherwise : nor could even that culture be looked down upon. Diocletian declared plaintively that if his friends could only see the charming cabbages he had planted at Salona, they would never advise him to quit his retreat for the imperial dignity. But of the respectability of mushrooms there can be no question. Unfortunately, however, if English agriculturists took largely to their production, American rivalry is here again likely to be an obstacle to profit. We learn that the immense Mammoth caves of Kentucky are being now utilized for this Cryptogamic and savoury plant. A Frenchman originated the happy idea, and has been granted the privilege of trying the experiment in one of the passages of the Cave, a mile and a half in length, which heretofore was remarkable for little save the vast flights of bats provoked by the steps of human visitors. Deposits of guano have existed in the avenue for ages, and it is believed that the finest mushrooms in the world will be produced there.—*Pioneer.*

CINCHONA.—A planter writes:—"At first glance, Owen's book seems just the thing I have long wanted and could not get. It gives descriptions of the many varieties which will be some guide, though not so good as an actual inspection of specimens would be. Can these be found at Peradeniya or elsewhere? I mean, of course, *all* varieties named." [We trust one of the first improvements at the Hakgala Gardens will be to provide specimens of every known variety of cinchona for the purpose of aiding planters in identifying, apart from other uses.—Ed.]

SPONGE CULTURE.—There is every reason to believe that the newly developed art of sponge-culture will settle down into a profitable industry. The process employed is an extremely simple one. A living sponge is cut into small-sized pieces, and each portion is fastened by a small stake to the sea bottom. These detached sponges at once begin to grow, and in a period varying, according to different authorities from three to seven years, are large enough for the market. Professor Oscar Schmidt has succeeded so well with experimental culture conducted in this way that he has been commissioned by the Austrian Government to continue the work on a larger scale on the Coast of Dalmatia. Full information relating to this interesting subject will be found in the report of Professor Baird, the Fish Commissioner to the United States, and also in a report recently prepared by Professor Ray Lankester at the request of the Secretary of State for the Colonies.—*Graphic.*

DEER, CINCHONA AND FENCES.—Complaints are frequent of the ravages of Sambur among young cinchonas. In a week one planter informed us that he had a thirty-acre field of flourishing plants eaten down to a disheartening extent. Indeed, as he could not afford the necessary appliances for an efficient fence, and did not possess on his own ground the material to cheapen the erection of a wire fence, he thought of abandoning the cultivation. If anybody wishes to inspect a work of magnitude in this way, he has but to go over to Deva Shola and see what has been done in enclosing a thousand acres of cinchona. The proprietor is wisely planting blue-gum just outside the fence, the plants being put down about a foot apart. The rapidity of the growth of the blue-gum which in this locality attains a height of five or six feet in a year, makes it quite reasonable to expect that before the decay of the posts that now hold the wires, a fine and impenetrable natural hedge of blue-gum will have grown up, which with the wire transferred to live supports will completely frustrate all the efforts of the enemy to get unto the cinchona. In connection with the subject, we have heard it suggested that all the expense of wire fencing might be saved, if cinchona growers would take to keeping a few dogs of a proper breed, namely, a cross between a fox hound and a grey hound. A gentleman at Kodaikanal has a few dogs of this breed, and neighbours complain that the dogs so thoroughly hunt the sambur, that a shot within miles of their estates cannot be had of these animals. We have ourselves known an ordinary pariah dog trained by a Native Shikaree seize the leg of a sambur, but the dog was too slight to make any impression on the movements of the sambur, and was shaken off.—*South of India Observer.*

THE TALLOW TREE.—A planter writes:—"Can you give me any information about the Chinese tallow-tree: i. e. its value or the price the seeds fetch in the home market?" From the *Treasury of Botany* we take:—"Stillingia.—The Tallow-tree of China is the best-known representative of this genus of *Euphorbiaceæ*; but there are two or three other Chinese and Japanese species, and as many more natives of the Southern States of America. With the exception of the tallow-tree and one herbaceous species, they are shrubs; and all have alternate entire leaves, and terminal catkin-like spikes of flowers. The fruit is a capsule composed of three one-seeded opening pieces, and is girded at the base by an enlarged bract. *S. sebifera* the Tallow-tree, is a native of China and the adjacent islands, but it has been introduced into and partly naturalised in India and the warm parts of America. It has rhomboid-shaped sharply taper-pointed leaves about two inches broad, on slender stalks with two prominent glands at the point of attachment between the stalk and leaf; and its flower-catkins are from two to four inches long. Its fruits are about half an inch in diameter and contain three seeds thickly coated with a fatty substance which yields the tallow. This is obtained by steaming the seeds in large cauldrons then brushing them sufficiently to loosen the fact without breaking the seeds, which are removed by sifting: and the fat is afterwards made into flat circular cakes and pressed in a wedgepress, when the pure tallow exudes in a liquid state, and soon hardens into a white brittle mass. This tallow is very extensively used for candle-making in China; but as they get soft in hot weather the candles generally receive a coating of insect-wax. A liquid oil is obtained from the seeds by pressing. The tree yields a hard wood, used by the Chinese for printing blocks, and its leaves are employed for dyeing black."

PLANTING NOTES.—The contrast between coffee properties cared for and cultivated and others neglected:—You will not be surprised that nothing has yet, *virtually*, been done for ———. It is now a waste of weeds, and is a standing proof of what can be done by good cultivation, and what an estate suffers from the want of it. This place and it lie alongside, and the contrast, to a spectator, from the opposite side of the ravine, is most striking. One side of the boundary line, the colour is a beautiful dark healthy green; on the other a most sickly mixture of pale green and yellow. Then go into the coffee, and the ——— trees are covered with leaf disease, and are succumbing to it, but those on this place, not excepted from the pest, seem very little put about by it, and if they should begin to give, I can manure them at once I note your leading article and your Great Western correspondent's remarks. He and I differ on one point, viz., pruning. He thinks I ruin my trees by "slashing" them, as your correspondent on pruning the other day would call it (very sensible letter that). But I would go further in pruning than even he. Last year when pruning a piece of this place which had always lots of wood but no crop, ——— passed through and told me what a mistake I was making. That very piece has this year a heavy crop! In some places, I would have bigger crops if I pruned less. But put *two* crops of a well pruned estate against two of another badly pruned, and the former is sure to have the advantage in quantity and the *better quality* of coffee, which causes a great difference in the proceeds of the sales in London. Thus, an estate which nets 90/ per cwt. and has only 780 cwt., is as good as—aye better than—one that has 1,000 cwt. and only nets 70/ per cwt.; for the expenses are less. If ever I see the ——— question settled, I shall try to give you an outline of it, for it touches the interests of all interested in coffee, and our members in Council should be pressed to take notice of it, for there is much wrong in the law relating to increase when the increase may have to wait till the estate has *literally ceased to bear*, before it can take possession of the property which he accepts as security for the money he lent upon it! That is good news for some people that Government will reserve all forest above 5,000 elevation—you should see cinchona at 6,000 and over.

1878 ,, —16·78

While I write it is better than ever. Woe to the coffee trees that have too much crop!

SPRING VALLEY COFFEE COMPANY, LTD.

The Directors have pleasure in presenting their annual statement of accounts, with the completed returns of crop 1879-80.

It will be seen that the total sum realized from sales of coffee, with the proceeds of a small shipment of cinchona bark, was £31,823 8s 8d, and that after charging the entire expenditure in Ceylon and London for the 12 months, a profit has been obtained of £10,199 7s 3d or 12¾ per cent on the capital of the Company. This, in these days of leaf disease and small crops, must be looked upon as a highly satisfactory result.

With the balance carried forward last year of £1,243 17s 4d, there appears a total revenue of £11,443 4s 7d, out of which an interim dividend has been paid of 4 per cent, or £3,200. It is now recommended that a further dividend be paid of 4 per cent, making 8 per cent for the year, or £6 400 free of income tax; and from the balance remaining, the Directors propose that £3,498 8s 6d, be employed in writing down the cost of the estates to the level of Share Capital £80,000. leaving a balance of revenue unappropriated of £1544 16s 1d.

It may, perhaps, be as well to remind you at this point that the total sum applied from the revenues of the Company in payment for extensions and improvements other than the ordinary costs of cultivation has been no less than £27,119 5s 5d; and that the area under coffee will now stand in the books at a cost of less than £52 per acre, leaving out of account forest, grass land, and fields planted with cinchona.

It is hoped that during the next few years, surplus profits may be availed of to make considerable additions to the Reserve Fund, and so your Company will hold a position second certainly to none connected with the island of Ceylon.

At the time of paying the interim dividend in January, it was hoped that the crop, now being gathered on Spring Valley, would be not less than that of 1879-80; but the autumn blossom upon the lower and older fields failed in a large measure in consequence of the dry season, and the outturn of the two properties will probably not exceed 6,700 cwt.

Spring Valley is reported to be in most respects in a satisfactory condition, though leaf disease has again ravaged parts of the estate and affected the production of crop materially. Energetic measures are taken, and appliances are being brought to bear to increase the manured area year by year, but, unfortunately the cost of those portable artificial manures, which by careful application would immensely benefit the property, is almost prohibitory so long as cart transport only is available; and it is with much regret that the Directors have to announce that the authorities at the Colonial Office are, with all the information at their disposal, not alive to the fact that the revenues of the Colony, which are said to be falling off, would, no less than the interests of all connected with the Island, be better served by an extension to Uva or Haputale of the line now in course of construction, than by any proposition which has been before them for many years.

Not only do they decline to entertain this extension, which would cost but £600,000, and be immediately a handsome source of revenue, but they refuse to allow it to be constructed by private enterprise, which would be at once forthcoming.

The extension of Cinchona planting on Spring Valley, and of Cocoa and other products on Oolanakande, has been actively prosecuted during the year, and thus returns for the future, independently of coffee, are being secured without outlay of capital.

If prices be maintained, there seems no reason to look for other than good and substantial returns from your property in years to come.

UVA COFFEE COMPANY, LIMITED.

Presented herewith is a statement of the Company's Accounts, including the closed return of crop 1879-80.

The sales in London comprised 9,837 cwt. of coffee, and the net profit realised, after payment of all charges for the year in Ceylon and London has been £15,334 1s., a result which cannot be considered other than highly satisfactory.

The balance unappropriated last year was £1,750 15s., so that the total revenue now to be dealt with is £17,084 16s.

In January last a dividend was paid of 8s. per share, and it is now proposed to divide an equal amount for the second half year, making 8 per cent. for the year, payable as usual free of income tax.

From the balance remaining the Directors recommend that £1,000 be added to the Working Expense Fund, and that £8,084 16s. be held in reserve.

The crop of 1880-81, which is now in course of shipment, is to be smaller even than was thought probable when the Circular of January last was issued: hence the necessity for carrying forward so large a balance from the previous year's revenue. It is not likely that shipments will aggregate more than 4.000 cwt. of coffee, but the returns will be supplemented by the proceeds of a considerable quantity of bark peeled from the cinchona trees first planted on some of the properties, and now brought to market.

The prime cause of so great a reduction in the quantity of crop secured has been no doubt the failure of blossoms, through prolonged drought; but it is none the less disheartening to confess that the hope expressed in last year's report on the subject of the leaf disease has been ruthlessly upset by one of the smartest attacks of the pest yet experienced in Uva. And so long as the estates are subject to these periodical visitations, it is no easy matter to calculate on results from even the most carefully liberal cultivation.

It is, however, satisfactory to be assured, as the Directors are, by those in charge of the properties, that the trees are in a promising condition for yielding remunerative crops, in 1881-82. And they consider that their proposal to equalise dividends by reserving the excess obtained in a prosperous year is one which should commend itself to shareholders.

Expenditure during the current year has been as much as possible kept within the value of the crop expected to be picked; but the importance of extending the application of fertilising agents has not been lost sight of, and at the present time appliances are in course of being perfected, by means of which large deposits of manure removed from the town of Badulla to a central depot are to be distributed over three of your estates. A considerable area of grass land adjoining Ballagalla is also by this means to be cultivated in coffee.

Twenty-five acres of forest lately cleared adjoining Glen Alpin estate are this season to be planted with cinchona, for which an abundant supply of fine plants is available.

On Rockhill and Ballagalla, it is thought that cocoa can be cultivated successfully, and nurseries have accordingly been prepared.

The Directors cannot close their report without expressing the disappointment which they in common with others have felt on reading the despatch lately sent by Lord Kimberley to the Ceylon Government on the subject of the railway. The Secretary of State does not see his way to meet the demand for railway extension from Nanuoya to Haputale, and it appears doubtful whether the line already sanctioned and now in course of construction to the former point, will prove remunerative.

Proofs are not wanting that only by tapping the rich and fertile districts of Uva, Haputale, and Madulsima, can traffic be expected in quantity on the line now

being made, and looking to the readiness with which private enterprise would, if permitted, undertake the construction of the extension so urgently needed, and which would so certainly conduce to the welfare of the entire Colony, it is much to be regretted that those who are in power are not endowed with a clearer perception of the financial resources at their disposal.

TEA.

Australian Tea Season, 1881-1882.—11 Little Collins Street West, Melbourne, 1st July, 1881. Messrs. Jas. Henty & Co., report as follows:—By the Steamer "Killarney," from Foo-Chow, we have full supplies of New Season's Teas, of finest quality, consisting of Paklums, Soomoos, and Sneykuts, in half-chests and boxes, also some Kaisow Buds in quarter-chests and boxes. These are all fine Teas and carefully selected. The Steamer "Hungarian," advised as having left Foo-Chow on the 28th ultimo, brings us further supplies and a full assortment of Tea. We also have advices of full supplies of India Teas, being shipped to us, consisting of Assam, Cachar, Darjeeling, Kangra Valley, Sylhet, Dooars, &c., and our letters inform us that the quality of the New Indian Crop is unusually fine. Musters of the "Killarney's" shipment are now on view at our Office.

"The Tropical Agriculturist."—A planting correspondent writes:—"It would surely not be much additional trouble to you to group all letters referring to each separate cultivation in *each* number of the *Tropical Agriculturist*. As at present published, one has to search each number for what one wants." [We have already announced that grouping is to be adopted, so soon as we get out new type. The arrangement entails more trouble and expense than outsiders can understand, as it prevents the use of the same type over again so often as is usual.—Ed.] Is the *Tropical Agriculturist* a separate paper, or must each communication first pass the ordeal of the *Ceylon Observer* or other papers? I ask, for some men might only be able to afford the former paper, and it might be some time before you reprinted the reply to a letter to the *Observer*, while, if written direct to the *Tropical Agriculturist*, the answer should be available in the following issue. [Whatever appears in the *Observer* bearing on tropical agriculture will be republished in the monthly, but the latter will also contain a good deal that may be considered too long, dry and technical for a daily paper. At the same time, we do not mean to make the *T. A.* a rival to the daily, or to encourage correspondence to the former only. We shall always try to give both enquiry and reply published in successive number of the *Observer* in one and the same monthly issue of the *Tropical Agriculturist*. What may be excluded from the *Observer* will be long Government reports, or essays from Agricultural Journals published in India, Europe or America, from such publications as *The Field*, *Gardeners' Chronicle*, *Grocer*, *Pharmaceutical Journal*, *American Agriculturist*, and French and German periodicals. This will, we suppose, [illegible] up [illegible] [illegible] sure that [illegible] left out of the [illegible] really [illegible] will, as usual, [illegible] *Observer*, [illegible] monthly up to [illegible] will [illegible] a day.—Ed.]

66

BENGAL CINCHONA PLANTATIONS:

LARGE NUMBER OF VERITABLE LEDGERIANAS IN THE SIKHIM GARDENS.

The most important statement in Dr. King's Report for the year ending 31st March last, which has duly reached us with all connected documents, is undoubtedly that in which he confirms the belief that a large number of calisaya trees in Sikhim are veritable *Ledgerianas*. "During the year," he adds, "99,415 plants of that variety of calisaya were added to the permanent plantation," and we read elsewhere that as much as R3,269 was realized through the sale of Ledgeriana seed and plants chiefly to Ceylon planters. But when we remember how freely calisaya seed from Sikhim was obtained from Dr. King some years ago for Ceylon, our belief is strengthened that as Dr. Trimen has found one and another of the Emelina and Annfield trees turning out to be pure Ledgeriana, so it may be found that a considerable number of the trees there, and on other estates raised from their seed, or from seed got some time ago from Calcutta, may prove to be of the variety which is surpassingly rich in quinine. It is quite evident at least that Dr. King and Mr. Gammie are determined not to be behind Mr. Moens in their propagation and cultivation of this species, and if success attend their efforts in Northern India, how much more may we expect to see the Ledgeriana enterprise flourish in the genial climate of our Central Province. The total number of calisaya trees now in the Sikhim plantations is 412,000, but there is a nursery stock of an equal number ready to plant out. Mr. Gammie and his assistants have been busy uprooting all the bad kinds in the permanent plantation, Mr. Wood's analysis having enabled them to distinguish the Ledgerianas by their leaves. Of inferior and doubtful sorts of calisaya which were uprooted, the crop has made up no less than 81,225 of yellow against 296,000 of red bark harvested during the year, and this policy of uprooting inferior calisayas is to be continued until the yellow bark plantation is one of pure Ledgeriana. At the same time that the inferior yellow bark was sent to the English market—being the first consignment of this kind from India—Dr. King included a small quantity of really good Ledgeriana bark so as to get some idea of its commercial value. The result was most satisfactory: 625 lb. fetching at auction 10s 10d per lb. Of the inferior Calisaya, one lot of 2,655 lb. sold for 7s 6d, and others brought from 5s 1d to 2s 9d per lb. There is, however, no intention of continuing to sell bark from Northern India: all the crop is to be retained and used for the production of febrifuge or of quinine for the use of the people of India. The febrifuge is made from red bark, of which there are now over [illegible] millions of trees on the two plantations—[illegible]—and these are capable of producing a [illegible] larger quantity of the [illegible] than [illegible] demand [illegible] [illegible] [illegible] [illegible] deal [illegible] [illegible] and [illegible]. The [illegible] [illegible] [illegible] [illegible] febrifuge is

estimated at 16½ lakhs of rupees: the saving last year alone being equal to half the total expenditure on the plantations including compound interest at four per cent! Regarding Mr. Gammie's experiments so often referred to in our columns, we read:—

"Not only has Mr. Gammie conducted the routine of febrifuge manufacture with precision and skill, but he has spent much time on attempts to increase the percentage of it extracted from the bark. These attempts, I am glad to say, promise to end in success. Mr. Gammie has also succeeded in turning out a crystalline preparation of the febrifuge which, being free from the amorphous alkaloid, may prove pleasanter medicine than the febrifuge in its present form. Mr. Gammie's crystalline febrifuge is a very pretty preparation, being nearly as white as quinine itself. It is now under trial in various Government hospitals, and if it is reported well of, arrangements can be made for its production on a large scale. Mr. Gammie has continued to direct his attention to the economical manufacture of sulphate of quinine. Decided progress has been made in this matter since last year, but further experiments will be necessary before I can advantageously submit a full report on the results."

Dr. King does not afford much information this time as to the average yield of bark, but he mentions that the crop of red bark harvested was got by uprooting the trees (11 years old) over 75 acres, the result being an outturn of 1,510 lb. of dry bark per acre. This result is a very poor one, since 2 or 3 lb. of dry bark per tree has been a common experience in Southern India and Ceylon from trees of less age; but Dr. King confesses that his patch was not a good one, and we suppose there were many blanks. A new unnamed variety—a hybrid yellow bark tree—of which there are 200,000 trees on the plantations is referred to. The bark has been found to be rich in quinine, but Dr. King does not give analyses nor inform us whether its growth or suitableness for climate and soil is more marked than that of Ledgeriana. Respecting the Carthagena bark trees recently imported, Dr. King reports a hard struggle in propagating, the original 6 plants having only increased to 60 rooted and 90 partially rooted cutting at the end of the year. Every effort will be made to increase the stock of this interesting species which yields the Columbian bark of commerce.

In regard to Mr. Moens' method of shaving the bark and grafting the Ledgeriana on succirubra stocks, the following has been the Sikhim experience:—

"The method consists in shaving off the greater part of the bark of a living tree to the height of from eight to ten feet from the ground, care being taken to leave everywhere a sufficiently thick layer of bark to cover the wood. This method has now had more than a year's trial on the Sikhim Plantation, a certain number of trees per month having been shaved since the beginning of the year 1880. The results have been favourable. Every month's trees have renewed their bark well, those shaved during April having done so (Mr. Gammie tells me) rather better than any of the rest. The bark of the trees earliest shaved is now about as thick as was the original bark, and it is clean, healthy and uniform. There is no doubt, therefore, that under this plan bark renews perfectly. What now remains to be seen is whether the renewed bark is equally rich in medicinal alkaloids with the original. In order to test this, I intend to have some analyses made of samples of renewed bark and the results of these analyses I hope to give in my next annual report.

"The Dutch plan of grafting *Ledgeriana* on *succirubra* stocks has also been tried during the year, but I regret to say with little success. The experiment will, however, be persevered in. In the matter of propagation of *Ledgeriana* we are now very well off; for the bad varities of *Calisaya* having been nearly all uprooted from the plantation, the seed yielded is now much more reliable than it has been heretofore. Our stock plants are, moreover, now in fairly good condition, and yield a considerable number of cuttings."

Again, regarding the cultivation of Ledgeriana, we read:—

"Contrary to all expectation, *Ledgeriana* and our quinine-producing hybrid are found to thrive better on land with a southern exposure than on land that slopes to the north. Mr. Gammie has therefore prepared for planting a considerable area of land which had hitherto been regarded as unsuitable for any kind of cinchona. In planting *Ledgeriana* last year, Mr. Gammie took the precaution of putting two plants to each stake, with the view of cutting the second of them out, should it turn out to be of a bad sort, or of transplanting one, should both plants turn out true *Ledgeriana*. The majority of these recently put out plants are, however, turning out pure *Ledgeriana*; there will, therefore, be a considerable number of transplants available from this source during the approaching planting season."

It will be seen, from the foregoing summary, that Dr. King's Report on the present occasion is both interesting and instructive. We shall publish it in full, with the appended papers, in the *Tropical Agriculturist* where it will be available for ready reference to all engaged in cinchona cultivation.

PROSPECTING FOR GOLD.

(Summary of HINTS from a Colombo Agent to an Estate Manager instructed to prospect.)

Samples to be not less than 14 lb. of quartz from each reef, or supposed reef, to be packed separately in small gunny bags made for the purpose and numbered. Unlikely looking quartz to the eye has sometimes proved richer than others apparently of A-1 quality; for instance, stone with five to six ounces of gold to the ton does not always shew any signs to the eye! White sugary crystallized quartz is no good: it must have some colour in it—look metally in fact—quartz with a red or yellow tinge is preferable to a perfectly white quartz, although the latter may be valuable if interspersed with colour. Reefs which are likely to prove valuable are those which in a seeming upheaval stand up abruptly, leaving solid walls distant from each other from one to three feet, having between these walls a formation of loose crumbly quartz of a good metally colour. When such reef is found to dig away the earth at the sides, say 6 or 7 feet down, so as to get some distance below the quartz as it lies in its probably undisturbed state, and then to take samples. Such reefs as these generally descend for hundreds of feet, the quartz being loose and crumbly—if tapped at some distance down the hillside, the quartz is easily secured, as it drops with very little effort from the reefs, and the rocky walls on either side hold it well together until removed.

(From our pamphlet "All about Gold, Gems, and Pearls in Ceylon.")

A bottle of nitric acid is a sure test. If the minera

found be gold, it will not touch it; if a baser metal, with the exception of one or two not commonly found in Australia, violent action takes place and gaseous fumes arise. By this means spurious gold dust may be detected: if it be pure, no action whatever will take place, and the liquor will not be discoloured; if impure, violent action will take place, red vapour will arise, and the acid will be discoloured.

The weight of a lump of quartz as estimated by poising it in the hand is generally sufficient to determine whether it contain gold or not, quartz having a specific gravity of about 2½, whilst the specific gravity of gold is from 18 to 19. This accounts for gold being found in grains and nuggets—the water having had sufficient power to break up and wash away the lighter rock, but not the gold itself. Hence it may be inferred that when large lumps of gold are found, the matrix itself cannot be far off—from the impossibility of the current washing these to any great distance. On the other hand if the gold be in dust or scales, it may be, and is frequently distributed over a large space of ground.

The unpractised miner is apt to take several substances for gold which have no alliance with that metal. The first of these is yellow mica: this may, however, be readily distinguished by its lightness. The next is iron pyrites. This is as easily distinguished. Stick the point of a penknife into a scale of gold, and it will penetrate it, but the pyrites would be found too hard for this. Place a little of the substance on a shovel, and put it on the fire. If it be pyrites, a strong smell of sulphur will be perceived, and the residuum after the sulphur is driven off will become red iron rust. Dissolve the mineral in muriatic acid, and add a few drops of nitric acid. Add to the solution a little hartshorn, and, if iron pyrites, rust is precipitated. With a solution of nut galls common ink is produced. With prussiate of potash Prussian blue is formed. Any of these tests will decide between iron and gold.

Should a lump of quartz be suspected to contain gold, the fact may easily be established as follows:—Pound the quartz finely—the finer the better. Boil this for a considerable time in an equal mixture of nitric and muriatic acid, filter the solution through linen or cotton. It will destroy these, but that is no matter; the experimenter must also be careful not to get any of the acid on his clothes, or it will destroy them. If he burn his fingers with the acid, he will not do so a second time. Now add carbonate of soda to the solution when cool, and this will precipitate all baser metals. Filter again, and add a solution of oxalic acid till it ceases to effervesce. The gold will now be thrown down in the form of a black powder, which may be converted into the usual form by melting.

TEA IN AUSTRALIA.

(*From the Ceylon Commissioner.*)

Melbourne, 15th July 1881.

Mr. Moody's letter on the tea question, in reply to Mr. Everard's effusion, appeared in the *Argus* of the 5th, which I will post to the *Observer*, with the number of the same newspaper for the 6th. The issue of the 5th contains the letter from Mr. Moody which I mentioned in my last communication to you. Mr. Moody, who, besides his qualifications as a teataster, is very competent chemist, easily disposes of the "scientist" invented by Mr. Everard who could not distinguish between tea and wattle leaves. Mr. Dunn is making satisfactory progress with his analyses of teas from India, Ceylon, Java, China, Japan, &c. He believes that the report he will ultimately give to the world will revolutionize the standard for teas in favour of those of India and Ceylon. He unhesitatingly said to me that the vast bulk of the China teas, which by tradition and in consequence of their cheapness hold, or have until lately held, possession of the Australian markets, are either adulterated, exhausted, or inferior in all the qualities which constitute good tea. Mr. Moody, in pursuance of his determined efforts to give Indian and Ceylon teas their proper position here, is preparing a pamphlet, of which 5,000 copies at least are to be circulated. In this brochure, of which I have seen the first portion, the history of the Syndicate movement, the results of the Exhibition, of ordinary tasting and scientific analyses, will be summed up. Slowly, it may be, at first but in the end surely and completely, the pure, genuine teas of India and Ceylon will supersede the adulterated, exhausted and worthless stuff so largely entering into the shipments which are now, by their arrival as "First of the Season's Teas," creating such excitement amongst "the trade" here. Sales of considerably over 20,000 packages take place to-day.

DO BATS EAT BEETLES?—Mr. Haldane in his Essay on "Grub" (shortly to see the light) raises this question. An authority answers it in the affirmative, as follows:—"Bats do eat beetles. I have often found in the early morning large quantities of the elytra of beetles under the verandah of our house, punctured by bats' teeth. The bats suspend themselves on a bell-wire after capturing the beetles, and devour them at their leisure." Planters must therefore look upon bats as their friends and allies in the destruction of coleoptera.

CAWNPORE EXPERIMENTAL FARM.—The Government of India have reviewed the report on the operations of last autumn at the experimental Farm, Cawnpore, last August, it was noticed by them that the superiority of the European over the Native system of ploughing had not been demonstrated, and it was requested that the results of the two methods might be further compared. The present report of Mr. Fuller contains a good deal of interesting evidence which bears upon this point. The conclusions suggested by his carefully recorded experiments, and by the accounts received from the Court of Wards' Estates and elsewhere, seem to the Government to be that in the case of shallow-feeding plants, such as maize and other cereal grasses, inversion of the soil may be unserviceable or even injurious, unless the freshly turned clod is given time to mature; but that for crops, like cotton and the pulses, which strike far into the ground by a tap root, deep cultivation is likely to be beneficial, particularly in seasons of scanty rainfall. Mr. Fuller is of opinion that bone-manure could only come into any general use in Indian cultivation in the form of bone-dust, untreated with sulphuric acid, as the cost of converting it into superphosphate of lime would be prohibitive to the ordinary cultivator. He adds that the solubility of the bone-dust is much less than that of the superphosphate, and hence that the full effect of its use would not be known till the second year after its application. No doubt he will note the character of the next crop which is taken off the plot experimented upon. To judge from the results of the comparative cultivation of exotic and indigenous fodder crops, the common country *jaur* is practically equal in value to the black-seeded sorgho, and greatly superior to *Reana luxuriana*. Guinea grass seems to be a more promising crop than the other exotics tested, and its further cultivation will be watched with interest. The experiments in foreign cottons may possibly, as is pointed out in the report lead to the introduction of suitable cotton plants in districts where the native variety is not grown. The "Kaisar" plough appears to be now well established in the market, and some improvements have been effected in the experimental water-lift. —*Madras Mail.*

Correspondence.

To the Editor of the Ceylon Observer.

CASUARINA CULTIVATION

Maturata, August 1st, 1881.

DEAR SIR,—In your issue of the 30th of July, I notice a paragraph on the cultivation of casuarina and the profits to be gained thereby. Could you kindly inform me : firstly, where the seed could be procured ; secondly, what makes the casuarina give such a good return ? In fact, in what does its value consist ?

The above-mentioned paragraph states that common waste land is good enough for the purpose. Would a paddy field suit ? I should be glad to hear your opinion, as I am intersted in the cultivation of all new products.—Yours, INQUIRER.

TEA CULTIVATION.

1st August.

DEAR SIR,—"Young Tea" (if his plants are Assam hybrids) would do well to take off everything growing close to the ground, to at least six inches above the surface ; remove all suckers ; top the plants down to 2′ 6″ or 2′ 9″ ; and clear out the centre round the stem something in the same way as in coffee. This will insure a strong growth laterally, but no picking of flushes should be attempted until there are from six to seven buds on each shoot, *i.e.* that each shoot would be about 7 or 8 inches in length. I am not certain what month the cold season is due at Lemastota, but pruning should only take place in the cold weather when little or no wood is being formed. —Yours faithfully, SWADDY.

PLANTING AND COFFEE PROSPECTS IN JAMAICA.

Botanical Department, Gordon Town, Jamaica,

21st June 1881.

DEAR SIR,—I beg to send you by this mail a copy of our recently issued Handbook of Jamaica, which I send your worthy coadjutor and yourself as a memento from the Far West.

Since my arrival here I have been nearly overwhelmed with work, in a great measure arrears of former times when the department had no chief.

I nevertheless follow events in Ceylon with great interest, and read the *Observer* as a record of efforts of industry and energy which, perhaps. no other part of the world can shew. I sincerely wish you every success.

In reply to a question received a short time ago, I am happy to say we have no prevalent and widespread disease affecting our coffee estates, which in spite of the late hurricane, are promising most abundant crops. Dr. Cooke's remarks could not possibly apply to Jamaica, and he was evidently misinformed as to the existence of disease on our estates.—I am, very faithfully yours, D. MORRIS.

[We copy Mr. Morris's suggestions for the improvement of the coffee industry in Jamaica into the *Tropical Agriculturist*.—ED.]

"C. URITUSINGA" IN UPPER HEWAHETA.

Mooloya, Deltota, August 1st, 1881.

Dear Sir.—I have just received from my brother, Mr. J. F. Deane-Drake, who is at present at home, the enclosed, which is a copy of a letter he received from Messrs. Howard & Sons. The bark here referred to was a small sample taken from four trees (8½ years old) which are growing on this estate. There are, I should say, from 20 to 30 trees of the same species and age at present growing here, and I have been lucky enough to secure over two pounds of ripe seed from them in the last three months. Should you care for the analysis, I shall be glad to forward it to you on its arrival from England. I may add that these trees are growing in a rather poor dry sub-soil, and were last year manured with cattle manure.

One tree which I measured was 1′ 10″in circumference at the surface of the ground : four feet from the surface it was 1-1½ in circumference, and its height would be about 22 feet.—Yours faithfully,

C. F. DEANE-DRAKE.

(*Copy.*) Stratford, London E., 28th June, 1881.

Dear Sir,—With reference to our interview yesterday, our Mr. J. E. Howard, F.R.S., called here this morning, and the sample you left us has been identified by him as C. Urituginga, probably grown in rather a dry soil for this variety. We propose submitting a portion of your sample to a chemical analysis and on completion of the same we shall have the pleasure of communicating with you again. Thinking they will probably be of interest, we have sent you by this post samples of the Dutch Government barks just arrived from Java viz., C. officinalis, variety Urituginga, &c. Calisaya, Ledgeriana. You will at once notice in the former the singularly close resemblance to your sample. —We are, dear sir, yours truly,

To Deane Drake, Esq. (Sd.) HOWARD & SONS.

[The C. Urituginga of Howard, original Loxa bark, is now more generally spoken of as the Condaminea variety of crown barks : renewed bark of this kind has sold as high as 10s per lb., so that the Mooloya seed from trees eight years old ought to be valuable.—ED.]

SHORT CROPS DUE TO POOR CULTIVATION.

July 31st, 1881.

SIR,—I agree with your correspondents who hold that crops which are short this year are due, not so much to season or elevation, since there are so many instances where a line of coffee separates, on the one, 10 cwt. per acre from nothing per acre, on the other.

It would, surely, be a very extraordinary thing if a line which was not a mountain ridge could so influence as to separate the season on its either side ! The fact is, that wherever coffee was cheaply worked last year, there the crop is bad : let this cheap course be repeated, and next year the crop will be worse.

In most instances, wherever coffee was highly cultivated, especially in manuring, there the crop is very good. Where manure failed, the wood was too late and unmatured. This wood is *now* ready, but unfortunately this is not the blossoming season.

No improvement, but the reverse, unless they change hands, can be hoped for from estates too involved to afford manure.

Very much prominence is given to the Kelebokka valley this year, where some places which have always been highly kept up are doing just tolerably well.

But the crops there cannot hold a candle to some in Dimbula, and, after two such very short seasons, would have, three years ago, caused more grumblings than congratulations.

Is there not an error in the statement "that the crops from average estates there amounted to as much during the last five as during the five previous years"?

There was, it is true, a very heavy crop from every estate in the dry season of 1876-77, the surplus of which, by spreading it over succeeding seasons, helped to uphold the average, but its influence for such a purpose was expended some time ago, and if the average for five years, ending with the coming crop, were placed beside that of the five previous years, it would compare most unfavorably. With a generous expenditure upon manure, Kelebokka will, however, hold its own beside most other districts in the country.

TRAMP.

CINCHONA CULTIVATION.

Nineteenth Annual Report of the Government Cinchona Plantations in British Sikkim by SURGEON-MAJOR GEORGE KING, M.B., F.L.S., *Superintendent of the Royal Botanical Garden, Calcutta, and of Cinchona Cultivation in Bengal.*

The avowed object of Government in maintaining its Cinchona Plantation in Sikkim is not to grow bark for sale in England or elsewhere, but to produce raw material for the manufacture of cinchona febrifuge for the use of the people of this country, and in strict accordance with this principle it has been conducted from the first. We have now had about four years' experience of the manufacture of febrifuge on a large scale, and for about the same period the medicine has been in general use in this country. We have therefore some information to guide us, both as to the amount of febrifuge which the plantation can produce, and as to the amount which is likely to be consumed annually. The issues of febrifuge for the year 1879-80 amounted to 8,164 pounds, while the plantation is capable of producing a considerably larger quantity than that. Febrifuge being prepared from red bark, I do not consider it necessary or advisable to increase the stock of red bark trees for the present, and accordingly during the year which has just ended none were planted out. The number of red barks on the two plantations of Mungpoo and Sittong stands at more than four millions, and many of the trees are quite young. These are sufficient to provide raw material for a considerably extended consumption of febrifuge. Notwithstanding the good estimation in which febrifuge is now held by the medical profession in India, there still exists, and probably always will exist, the necessity of supplying Government hospitals and dispensaries with a certain amount of sulphate of quinine. It is therefore of importance to stock the plantation with a sufficient number of quinine-producing bark trees to meet the Government demand for quinine. Of such trees we have two sorts on the plantation—namely Calisaya, and a supposed hybrid variety which appeared on the plantation some years ago. Mr. Wood's analysis showed that this new variety yields a bark rich in quinine, and steady efforts have therefore for years been made to increase it. During the year 85,000 plants of this hybrid were put out at Mungpoo and 5,000 at Sittong, bringing up the full number now on the plantation to close on two hundred thousand. As has been frequently explained in previous reports, Calisaya is a specific name which covers a large number of varieties, many of which produce barks which are essentially druggists' barks, being well suited for preparations such as decoctions and tinctures, but being unsuited for the manufacture of febrifuge, and containing too little quinine to be worked profitably as sources of the pure sulphate of that alkaloid. One of the varieties of Calisaya is surpassingly rich in quinine, and this, in compliment to the Collector who brought the seed of it from South America, has been named Ledgeriana. Mr. Wood's analysis of the various forms of Calisaya enabled us to distinguish the bad ones by their barks, and my recent visit to the Dutch Plantations in Java confirmed the belief that our best trees of Calisaya are veritable Ledgerianas. Every effort has therefore been made to increase our stock of Ledgeriana, and during the year 99,415 plants of that variety of Calisaya were added to the permanent plantation. The difficulties of propagating this sort make progress rather slow, and the total number of Calisaya trees on the plantation still reaches only 412,000. There was, however, at the end of the year, a considerable nursery stock of young plants (namely 380,000), and during the year we have now entered upon, the Ledgeriana plantation (saving blight and bad weather) should be considerably increased. The total number of trees planted out on the two plantations is given in the following table :—

Total Trees in permanent Plantation.

	Red. (C. Succirubra)	Yellow. (C. Calisaya.)	New unnamed variety.	Other kinds.
Mungpoo Division	2,902,335	393,915	146,020	30,592
Sittong ditto	1,132,200	18,780	53,878	...
Total...	4,034,535	412,695	199,898	30,592
Grand total of all kinds on both plantations... Mungpoo			...	3,472,862
Sittong			...	1,204,858
				4,677,720

2. *Details of the year's crop.*—The crop for the year consisted of 377,525 pounds of dry bark, of which 348,560 pounds were taken from the old and 28,965 pounds were got by thinning the new plantation. Of the yield of the old plantation 267,335 pounds were red bark, and 81,225 were Calisaya; the new plantation bark (28,965 pounds) was all red. This crop exceeds that of the previous year by about 16,000 pounds, and is the largest which has yet been gathered. The increase is due to the large quantity of Calisaya—a bark which has formed but a small proportion of any former crop, while this year it forms nearly a fifth of the whole. And the largeness of the amount of Calisaya bark is due to the fact that during the year a great number of trees of inferior and doubtful sorts were uprooted. This was done as part of the policy of reducing the yellow bark plantation as quickly as possible to one of pure Ledgeriana. When this object has been completely effected, good trustworthy seed of a pure quinine-yielding bark tree may be hoped for, and propagation of the best species should thenceforward be made easier. The Calisaya bark got from these uprooted trees being, as already stated, unsuited for the manufacture either of febrifuge or of quinine, there was no way of disposing of it but by sending it to London for sale, and, with the sanction of Government, a small consignment of it was shipped to England in the early part of the year. Yellow bark of any kind from India has never before been offered in the London market, and indeed, except at Mungpoo, it is not grown anywhere in British India. Opportunity was therefore taken to add to the consignment of inferior barks a small quantity of our really good Ledgeriana bark, so as to get some idea of its commercial value. The result was most satisfactory. The 625 pounds of Ledgeriana bark which were brought to auction in London sold for 10s 10d per pound. The inferior barks also brought

excellent prices, one batch of 2,655 pounds having been sold for 7s 6d per lb. Other barks brought 5s 1d, 3s 10d, 3s 9d, 3s 8d, 3s 7d, 2s 10d, and 2s 9d per pound, and the average price obtained for the 12,519 pounds that were sold was 4s 6½d per pound. Steps have been taken, with the sanction of Government, for the clearing out, in a similar manner, of a further quantity of the inferior yellow bark now stored at the factory, and the results of the sale of this second lot will appear in the accounts of the present year. There is, however, no intention of sending to market any bark which can be used in the factory either for the production of febrifuge or of quinine. The red bark crop was taken by uprooting seventy five acres of eleven years old trees, the result being an outturn of 1,510 pounds of dry bark per acre. This is a poor yield, but the patch was not a good one. The remainder of the red bark crop was obtained by thinning out trees where they stood too closely together. The exact figures will be found as an appendix to this report.

3. *Expenditure for the year.*—The expenditure for the year amounted to R71,705·10·4, and thus fell short of the budget estimate and allotment by R1,783 5·8. Of this expenditure there was incurred on the young plantation at Sittong the sum of R11,424·3·1, and that sum is chargeable to the Sittong capital account. The whole of the remaining expenditure, namely R60,281·7·3, was incurred on the old plantation and is chargeable as working expenses, and against it there is to be set the crop for the year. The figures stand thus—

	R.	A.	P.	R.	A.	P.
Total expenditure for the year				71,705	10	4
Capital expenditure.						
Expenditure on Sittong Plantation	9,132	5	0			
Proportion of European, Native, and office establishment	2,291	14	1			
				11,424	3	1
Working expenses.						
Upkeep and working of Rungbee, Rishap and Mungpoo...	48,187	15	3			
Proportion of European and office establishment ...	12,093	8	0			
				60,281	7	3
				71,705	10	4

Against the working expenditure on the old plantation there has to be set a bark crop of 348,560 pounds of dry bark, the cost price per pound of which is therefore annas 2 pies 9·2053, or equal to something less than four pence sterling. The whole of this bark, as well as the bark from Sittong (which for convenience of account I have valued at the same rate), has been made over to the factory, and the value of it (at cost price) has been debited to the factory. The value of the Sittong bark will be credited to the Sittong Plantation, and this practice will continue annually to be followed until the Sittong Plantation comes into full bearing. The accounts of this Sittong Plantation ought, when it is completed, to be of much interest to cinchona planters, as they will show at how cheap a rate a plantation can be put out when the price of experience does not form, as it so often does in new enterprises, a very heavy item in the capital expenditure.

4. *Carthagena bark.*—In last year's report I gave an account of the introduction, through Mr. Cross and the Royal Garden of Kew, of a new species of cinchona, namely the species (as yet not botanically identified) which yields the Carthagena or Columbian bark so largely imported to London from the northern part of South America. Four plants of this were brought out to India by the late Mr. Biermann in January 1880. They arrived in good condition, and during the year, they were increased largely by cuttings. Propagation went on most favourably for some time; but later on in the year the young plants were severely attacked by the pest only too well known to gardeners as "thrip." The usual treatment was applied with vigour, but in spite of this, when the year ended the six original plants had been increased only to 60 rooted plants and 90 partially rooted cuttings. Every effort will continue to be made to increase the stock of this interesting species.

5. *Distribution of Plants and Seed.*—The high prices got by the Dutch Government for their Ledgeriana bark has created a brisk enquiry for the seed of this variety, chiefly amongst Ceylon planters Succirubra seed has also been in some demand. During the year the sum of R3,269·10 realised chiefly for the sale of Ledgeriana seed and plants was paid into the Treasury as Government revenue. This sum will be found entered in the general cash account given as an appendix to the Quinologist's report.

6. *Land rent.*—The sum of R1,430·10 raised from settlers within the cinchona reserve was paid into the Darjeeling Treasury as land revenue. This does not appear amongst the plantation receipts.

7. *Survey of Sittong.*—The survey of the outlying parts of the reserve which are suitable for cinchona planting has now been completed, and by the courtesy of General Walker, C.B., Surveyor-General of India, I have been supplied with copies of the map. The map appears to be an excellent one, and it will be of great use in working the plantation accurately.

8. *Estimated Crop of* 1881-82.—In accordance with the principle of working the plantation solely as a source of supply of raw material for the factory, the bark crop of 1882 must have reference to the demand for febrifuge; and to meet that demand I estimate that it will likely be necessary to take a crop of from 300,000 to 350,000 pounds, an amount which is considerably within the producing power of the plantation.

9. In my report on my visit made during 1879 to the Cinchona Plantations of the Dutch Government in Java, I described a mode of taking the bark crop which had recently been proposed by Mr. Moens, the Director of those plantations. This method consists in shaving off the greater part of the bark of a living tree to the height of from eight to ten feet from the ground, care being taken to leave everywhere a sufficiently thick layer of bark to cover the wood. This method has now had more than a year's trial on the Sikkim plantation, a certain number of trees per month having been shaved since the beginning of the year 1880. The results have been favourable. Every month's trees have renewed their bark well, those shaved during April having done so (Mr. Gammie tells me) rather better than any of the rest. The bark of the trees earliest shaved is now about as thick as was the original bark, and it is clean, healthy, and uniform. There is no doubt, therefore, that under this plan bark renews perfectly. What now remains to be seen is whether the renewed bark is equally rich in medicinal alkaloids with the original. In order to test this, I intend to have some analyses made of samples of renewed bark, and the results of these analyses I hope to give in my next annual report.

10. The Dutch plan of grafting Ledgeriana on Succirubra stocks has also been tried during the year, but I regret to say with little success. The experiment will, however, be persevered in. In the matter of propagation of Ledgeriana we are now very well off; for the bad varieties of Calisaya having been nearly all uprooted from the plantation, the seed yielded is

now much more reliable than it has been heretofore. Our stock plants are, moreover, now in fairly good condition and yield a considerable number of cuttings.

11. The general condition of the plantation is satisfactory. The older trees look quite as well as ever I recollect to have seen them, and some of the younger planting is very fine indeed. The growth of succirubra on the new plantation at Sittong is not, however, so satisfactory as could be wished. Contrary to all expectation, Ledgeriana and our quinine-producing hybrid are found to thrive better on land with a southern exposure than on land that slopes to the north. Mr. Gammie has therefore prepared for planting a considerable area of land which had hitherto been regarded as unsuitable for any kind of cinchona. This satisfactory result will postpone for a few years the necessity for planting in the recently acquired cinchona reserves in Bhutan. In planting Ledgeriana last year, Mr. Gammie took the precaution of putting two plants to each stake, with the view of cutting the second of them out should it turn out to be of a bad sort, or of transplanting one, should both plants turn out true Ledgeriana. The majority of these recently put out plants are, however, turning out pure Ledgerianas; there will therefore be a considerable number of transplants available from this source during the approaching planting season.

12. The financial aspect of the whole cinchona enterprise will be found treated of in detail in paragraph 8 of the Quinologist's report. It is only necessary for me to state here that the result of the working of the old plantation for the year has been an actual profit of R80,000, which is equal to eight per cent on the capital, and that (valued at cost price) the stock in hand in the godowns at the end of the year was worth R94,924. These are the actual cash results, but they by no means represent the whole of the advantage which Government has derived from its cinchona property. During the year 5,500 pounds of febrifuge were used in Government hospitals and dispensaries in substitution of quinine. Quinine during the whole year ruled at a high rate, and in a trustworthy London Trade Circular, the average wholesale price for the year is given at 12 shillings per ounce. Calculated at a rate of exchange equal to 1s 8½d per rupee (and including nothing for the cost of transit to India), this is equal to R112 per pound. But even taking R100 as the price which Government would have had to pay for quinine, the cost of 5,500 pounds of it would have been R5,50,000, whereas an equal quantity of febrifuge was used at a nominal cost of R90,880. There was thus effected a clear saving of more than four and a half lakhs of rupees, a sum pretty nearly equal to half the total expenditure on the plantations (including compound interest at 4 per cent) since their commencement. The savings effected by similar substitutions of febrifuge for quinine in former years amounted to eleven and three quarter lakhs, the total saving now therefore stands at sixteen and a quarter lakhs of rupees. As the object of Government is not to make money by its plantation, but to provide the masses of the people with a good remedy for fever, cheap enough to be within reach even of the poorest, it may soon become a question whether the selling price of the febrifuge might not be reduced.

13. During the year two additions were made to the plantation staff by the arrival from the Royal Gardens, Kew, of Messrs. Kennedy and Parkes. Mr. Pantling, who was formerly second assistant, was transferred early in the year to the curatorship of the Botanical Garden, Calcutta, and Mr. H. Crofton was appointed to officiate for him. Mr. Lister, the first assistant, has worked well during the year, and in him Mr. Gammie has had a most efficient and trustworthy helper. Mr. Gammie's own merits are already well known to Government, and during the past, as during former years, he has done admirable service.

14. The usual annual returns (five in number) are appended.

GEORGE KING, M.B., Surgeon-Major, Superintendent, Royal Botanic Garden, Calcutta.

QUINOLOGIST'S REPORT FOR 1880-81.

The operations at the factory during the year may be summarised as follows :—For a factory expenditure of R85,921-6-3 (including the cost of the bark used), 9,296 lb. of cinchona febrifuge were produced, of which 8,653 lb. 13 oz. were disposed of to the Government Medical Depôts and to the public.

2. The budget allotment of the factory for the year was R35 700, but of this sum only R27,784-10-9 were spent, so that there was a saving of R7,915-5-3. The details of the factory expenditure are given in the following table :—

		R.	A.	P.
Paid for acid, 29,007 lb....	... ...	5,424	8	6
,, packages for ditto	... ...	222	8	0
,, carriage of ditto	... ...	3,026	12	9
,, ,, of empty jars...	...	1,552	11	3
,, soda, carriage & storage of ditto		5,950	5	3
,, charcoal	...	202	13	6
,, casks and other plant...	...	472	14	9
,, carriage of ditto	... ...	201	13	3
,, sundry expenditure	... ...	1,075	0	7
,, labour in factory	... ...	2,596	6	9
,, Quinologist ...	... ...	3,912	14	5
,, travelling expenses	... ...	206	4	0
,, carriage of febrifuge	... ...	731	10	6
,, tins for ditto	... ...	1,192	5	3
,, advertisement charges ..	...	557	4	0
,, labour in packing, &c.	...	458	6	0
	Total...	27,784	10	9

	R.	A.	P.			
Cost of bark, 218,005 lb. (crop of 1879-80), at annas 2-6·4147 per lb. ...	34,534	2	3			
Cost of bark, 136,475 lb. (crop of 1880-81), at annas 2-9·2053 per lb. ...	23,602	9	3			
				58,136	11	6
				85,921	6	3
By febrifuge produced, 9,296 lb., at R9-3-10·625 per lb.				85,921	6	3

3. These figures shew that the net cost per lb. of the febrifuge was R9-3-10·625, which is about (14½)

fourteen and a quarter annas less than the cost of the produce of 1879-80. They also show that the proportions debitable to raw material and to cost of manufacture are as follows:—

	R.	A.	P.
Price of bark used in making 1 lb. of febrifuge	6	4	0·760
Cost of manufacture, thinning, advertising, and sale	2	15	9·865
Total ..	9	3	10·625

This decrease in net cost per lb. is due to the low price of the bark which was principally that of 1879-80, which stood at only annas 2 pies 6·4147 per lb.

4. During the year, 8,653 lb. 13 oz. of febrifuge were disposed of as follows:—

		lb.	oz.
To Medical Depôt, Calcutta	...	3,000	0
Ditto, Bombay	...	2,000	0
Ditto, Madras	...	500	0
Sold to the public	...	3,150	11
Given as samples, &c. ...	..	3	2
Total...		8,653	13

This result is better by 489 lb. than that of the previous year, during which only 8,164 lb. were disposed of. The most gratifying feature about it is, however, that the improvement is mainly due to the increase of 393 lb. in the sales to the general public, with whom the febrifuge is daily increasing in reputation as a thoroughly good cure for fever.

5. When the outturn of the past year is added to that of former years, the total production of febrifuge at the factory since its commencement is brought up to nearly 37,000 lb. The subjoined table shows the exact result.

Febrifuge produced from commencement to 31st March 1881.

	lb.	oz.		lb.	oz.
Manufactured in			Supplied to Medical		
1874-75 ...	48	10	Depôt, Calcutta...	15,454	3
1875-76 ...	1,940	6	Supplied to Medical Depôt, Bombay ...	5,200	0
1876-77 ...	3,750	12	Supplied to Medical Depôt, Madras ...	1,100	0
1877-78 ...	5,162	0	Supplied to Straits Settlements ...	30	0
1878-79 ...	7,007	0	Sold for cash ...	10,393	8
1879-80 ...	9,434	13	Samples, &c. ...	93	1
1880-81 ...	9,296	0	Stock in hand on 31st March 1881 ...	4,368	13
Total..	36,639	9	Total ..	36,639	9

The stock on hand at the end of the year (4,368 lb.) may appear large. It is however, equal to only about six months' consumption, and in my opinion this is not at all too large a reserve to have in hand to meet any possible sudden demand which may arise.

6. As has been explained in former reports, the plantation and factory are worked financially as one concern. It is necessary for me therefore here to refer to the results of the working of the plantation. As will be seen by the plantation report, the total expenditure on the part of it which is in bearing was R60,281-7-3, and in return for this there was harvested a crop of 3,48,560 lb. of bark. This bark was taken over by the Quinologist at cost price, namely annas 2 pies 9·2053 per lb. Besides this bark from the old plantation, there was got by thinning the trees on part of the young or Sittong plantation 28,965 lb. of bark. The Sittong plantation is not yet in bearing, and its produce and accounts are kept separate from those of the old plantation. As a matter of convenience, however, these 28,965 lb. have been brought into the accounts at the same rate as the produce of the older plantation. The total produce of both plantations, namely 3,77,525 lb., was thus made over to the factory at a uniform rate of annas 2 pies 9·2053 per lb. Part of this bark was used in the factory during the year, a small part (unsuitable for manufacture or febrifuge) was sold in London in June, and of the balance part remained in store at the end of the year, while part was on its way to London for sale there. The small consignment sent to England in June was brought to auction in London, and £2,825 19s 11d were realized for it. The Accountant-General has not as yet given the plantation credit for this sum. Account sales have, however, been duly supplied to me, and from these I am able to compile the following account:—

	R.	A.	P.
Proceeds of sale of 12,519 lb. of yellow cinchona bark, *net* £2,825 19s 11d., at 1s 5¾d per rupee	33,084	13	3
Less freight and other shipping charges	744	5	10
Total...	32,340	7	5

7. The stock account shows little change since last year. The exact state of it is as follows:—

Stock at 31st March 1880.			
Chemicals and stores	5,848	0	0
Febrifuge 3,726¾ lb. at R10-2-0·845 per lb.	37,732	0	0
Bark	55,125	13	5
Total...	98,715	13	5
Stock at 31st March 1881.			
Chemicals and stores	6,500	0	0
Febrifuge 4,368 lb. 13 oz. at R9-3-10·625 per lb.	40,380	0	0
Bark 277,802 lb. overhead at A2-9·2053 per lb.	48,044	0	0
	94,924	0	0
Decrease in value	3,781	13	5
Total...	98 715	13	5

8. Collecting these figures, the financial result of the working of the plantation and factory may be tabulated as follows:—

Dr.	R.	A.	P.
To value of stock at 31st March 1880	98,705	13	5
To value of bark yielded by the new (Sittong) plantation during 1879-80, viz. 15,850 lb. at As. 2·6·6147 per lb. (omitted in last year's accounts) ...	2,510	13	0
To value of bark yielded by the new (Sittong) plantation during 1880-81, viz. 28,965 lb. at As. 2-9·2053 per lb.	5,008	5	0
To cash received from Treasury during 1880-81 for expenditure on old plantation	60,281	7	3
To cash received from Treasury during 1880-81 for factory	27,784	10	9
Profit on the year's working	80,290	1	6
Total...	2,74,581	2	11

Cr.			
By value of stock at 31st March 1881	94,924	0	0
By cash receipts for sale of febrifuge, seed and plants	56,136	11	6
By credits from Medical Depots for febrifuge, viz.:— R. A. P.			
Calcutta 49,545 0 0			
Bombay 33,030 0 0			
Madras 8,305 0 0			
	90,880	0	0
By sale of bark in London	32,340	7	5
Total ...	2,74,581	2	11

The profit of R80,290 shown in this statement is equal to a dividend of eight per cent on the capital of the plantation, and of this dividend 5 per cent are derived from the sale of febrifuge and three per cent from the sale of a small quantity of yellow bark.

This, however, does not represent all the advantage which Government derived from its cinchona property during 1880-81. For, as is shown in my report on the plantation, the saving effected by substituting febrifuge for quinine in Government hospitals and dispensaries during the year slightly exceeds four and-a-half lakhs of rupees, or in other words is nearly equal to half the entire capital expenditure on the plantation.

In addition to his duties as manager of the plantation, Mr. Gammie has been in executive charge of the factory during the year, and I have again to bring to the notice of Government the admirable efficiency with which he has discharged his onerous duties. Not only has been Gammie conducted the routine of febrifuge manufacture with precision and skill, but he has spent much time on attempts to increase the percentage of it extracted from the bark. These attempts, I am glad to say, promise to end in success. Mr. Gammie has also succeeded in turning out a crystalline preparation of the febrifuge which, being free from the amorphous alkaloid, may prove a pleasanter medicine than the febrifuge in its present form. Mr. Gammie's crystalline febrifuge is a very pretty preparation, being nearly as white as quinine itself. It is now under trial in various Government hospitals, and if it is reported well of, arrangements can be made for its production on a large scale. Mr. Gammie has continued to direct his attention to the economical manufacture of sulphate of quinine. Decided progress has been made in this matter since last year, but further experiments will be necessary before I can advantageously submit a full report on the results. The head writer in the cinchona office, Baboo Gopal Chandra Datta, has worked exceedingly well during the year, and to him my acknowledgments are due.

10. As an appendix to this report, I give a tabular statement of the details of the cash receipts for febrifuge, &c., for the year.

Cash Income for 1880-81.

	R.	A.	P.
Cash received for sale of febrifuge and paid into the Bank of Bengal and other Government Treasuries ...	52,673	0	0
Credit for cash paid for febrifuge into Dinagepore Treasury by Civil Surgeon of Dinagepore during 1880-81	74	9	6
Credit for cash for febrifuge paid into Hooghly, Burdwan, Jessore, Rungpore and Dinagepore Treasuries by Civil Surgeons of these districts during 1879-80, but credit not previously given to this office	295	8	0
Credit for cash paid into Bank of Bengal during 1880-81 by Superintendent of Lock and Police Hospitals, Calcutta, for febrifuge indented for during 1880-81, but supplied after the year had closed	124	0	0
Cash paid into Bank of Bengal, Calcutta, and into Darjeeling Treasury on account of sales of seeds, plants, and bark	3,269	10	0
Credit for febrifuge supplied to Medical Depôts, viz.:—			
Calcutta 49,545 0 0			
Bombay 33,030 0 0			
Madras 8,305 0 0			
	90,880	0	0
Total credited by Accountant-General...	1,47,316	11	6
Net proceeds of sale of bark in London (not credited by Accountant-General)	32,340	7	5
Total...	1,79,657	2	11

NOTES ON GUMS, RESINS, AND WAXES.

By C. G. WARNFORD LOCK.

(From the *Journal of the Society of Arts.*)

The following economic notes, from the journals of recent travellers, seem worthy of reproduction in a collective form:—

Senegal Gum.—The product of acacias which grow in the neighbourhood of the Sahara During the harmattan winds, the gum exudes from the bark of the trees in tears, and solidifies in the open air, the amount of exudation depending upon the force and duration of the wind. The production in 1871 was 3,161,906 kilo (of 2·2 lb.).

Mpafu.—A large tree yielding a sweet-scented gum-resin, much valued by the natives on the Victoria Nyanza.

Gum Arabic is produced by *Acacia gummifera* (*Mimosa gummifera, Acacia coronillæfolia, Mimosa coronillæfolia, Sassa gummifera*), a scarcely known plant of Morocco, occurring abundantly as a thorny bush in the lower region of south and west Morocco, according to the testimony of the natives, who call the plant *alk tlah*. The gum does not seem to be collected in the western portion of its range in South Morocco, but in Demnet, whence it is carried to Mogador. Possibly it is only in the hotter and drier regions of the interior that the gum is produced in quantities to be worth gathering. At any rate, its gum is yielded only during the hot, parching months of July and August, and increases according to the hotness of the weather and the sickly appearance of the tree, being least after a wet winter and in a mild summer.

Some accounts suppose the Moroccan gum Arabic to be derived from *Acacia arabica*, which is found in Senegal; but all the inquiries made by Consul R. Drummond Hay, for Hooker and Ball, agree that this plant, the *alk awarwhat* of the Arabs, is not found in Sus, no such tree existing either north or south of the Atlas Mountains, its gum being brought from Soudan, and of inferior quality to that of *A. gummifera*. It is further stated that this latter species grows chiefly in the provinces of Blad Hamar, Rahamma, and Sus.

Elemi.—This used to be brought in large cakes to Bembe (West Africa), and is said to be very abundant at not many days' journey.

Jutahy-seca.—A resin or gum which exudes from the bark of the jutahy tree of Brazil (*Hymenæa mirabilis*); universally employed for varnishing native pottery.

Copal.—Red gum copal is almost entirely the product of the Mossulo country (Angola), though it exists farther north, as at Mangue Grande. Until 1858, it was a principal export from Ambriz to America, but the war stopped it. According to native accounts, it is found below the surface of a highly ferruginous hard clay, at a depth of a few inches to two feet. It probably exteuds much deeper, but the natives are too lazy to look for it. It occurs in irregular flat masses up to several lbs. The natives only dig for it during and after the last and heaviest rains in March-May, and restrict the export to maintain the price. No trees and but little grass grows over the spots. The tree is said to be abundant in the woods adjoining the inner side of the wilderness in Usambara (East Africa), but does not extend farther inland.

A great staple of the district traversed by the newly-made road from Dar-es Salaam, through the Wazamaro country, is gum copal, which is found in many parts. This fossil resin seems to exist, even in the richest diggings, only in patches, as though it were produced by isolated trees. The natives appear to work the country nowhere systematically; they sink test-holes, and, on finding traces of the resin, work that part thoroughly. In many places, test-holes have been made and the place abandoned as useless,

although not far off a patch has been well worked. The fossil resin, now found underground usually in red sandy soil, is undoubtedly the produce of the same species of tree as still exists in these jungles, and which now yields an inferior sort of resin. The difference between the two products seems to arise from chemical or molecular change effected by time. The copal tree grows throughout the Uzamaro country, and is by no means confined to the sea coast, but is even more abundant inland beyond the first coast-ridge. It is not seen, however, where the old lime-stone formation of the interior makes its appearance.

Chian Mastic.—The mastic country of Chios is usually flat and stony, with little hills intervening, and with rare streams. Rain is destructive of the harvest; frost is rare, but much to be feared. The resin is a product of *Pistachia lentiscus*. The principal villages engaged in the industry are Calimassia, Saint Georges (south of Anabato), Nénita, Mesta, and Kalamoti, besides which there are about a dozen of minor importance. The mastic occurs in white grains, varying in size from a pin's head to a pea. The shrubs yielding it are about the height of a man. It occurs also in Africa and Arabia, but always of inferior quality, though no satisfactory reason has yet been adduced for the fact. In July-August, a great number of incisions are made in the stems of the shrubs, and renewed three or four times. Repeated visits are then made to collect the resin which exudes. A shower of rain during this period produces disastrous results, by washing away the resin. There are four qualities of mastic:—(1.) Cake mastic is composed of large pieces, and is considered the best by connoisseurs; it is sold chiefly for use in the seraglios, all Turkish women chewing mastic; its price is 120 to 130 piastres, and even more, per oke of 1,300 grm. (2.) Mastic in large tears is worth 90 to 100 piastres ordinarily. (3.) Mastic in small tears or pearls is worth 70 to 85 piastres, and is used industrially. (4.) Mastic mixed with fragments of leaves and sand is used to make so-called "mastic brandy," the well-known Turkish liqueur, called *raki*. It is made by digesting mastic in the brandy obtained from dry grapes, re-distilling the product, and flavouring with aniseed and sugar. The best qualities of mastic are used in the Levant; Europe imports the inferior grades for making varnish.

Chian Turpentine.—Afforded by *Pistachia terebinthus*. That which exudes from the shrub is very white and aromatic, but the quantity is very limited.

India-rubber (from *Ficus elastica*).—The collection of the rubber in Assam is conducted under rigid restrictions in the case of all trees growing in the timber reserves, but cannot be enforced on scattered trees. The Chardwar rubber plantation has an area of 80 square miles. The exports from Lakhimpur in 1871 were 260¾ tons, value £8,340. Immense forests of these trees existed on both banks of the Subansiri river, and on other streams, but the reckless treatment they received from native lessees of the forests caused their ruin. In 1876, the leasing of these forests ceased, but there is now little or no rubber left in the plains of the Lakhimpur district. The tree grows to heights of 15 to 35 feet, and its girth, when fit to be tapped, is 18 inches to 6 feet. A high yield for the first tapping of a tree is 35 to 40 lb. of rubber. It is then allowed to remain untouched for three or four years, when another collection is made, but the yield is then much less. It is estimated that the forests of Cachar could yield upwards of 2,000 cwt. of rubber annually. It is stated that the trees yield most during the rains.

Of India-rubber, 20,000,000 lb. are annually exported from Pará (Brazil), chiefly derived from *Siphonia elastica*, but a few other species are admitted. The utmost yield from each tree is one gill. In the wet season, from February to July, the gum is weak, and the tapping is stopped. The trees will grow on the *terra firme* when planted, but their seeds naturally lodge in lowland swamps. Trees properly planted and cared-for yield well in fifteen years. Brazil is being gradually cleared of its rubber; gatherers now go to the Tocantins, Madeira, Purus, and Rio Negro, and will soon clear there also. Straus's method of preparing rubber, instead of smoking, is to drop the milk into alum solution; it is stated to be superior, but is not adopted.

India-rubber plants grow on the slopes of the Cameroons mountains (West Africa), but the people do not yet know their value. India-rubber trees abound on the River Djour, in the province of Bahr el Ghazal. The natives of the Marutse-Mabunda empire, on the Upper Zambesi, trade in India-rubber with the tribes to the west.

The *Landolphia* vine is known from Pangani inland all the way to Handei (in Usambara, East Africa), and at Magila the rubber is made into balls for export.

The giant creeper, *Landolphia*, grows chiefly on trees near rivers and streams in Angola and the Congo. Every part exudes a milky juice when cut or wounded, but this will not run into a vessel placed to catch it, as it dries so quickly as to form a ridge on the wound, which stops its further flow. The blacks collect it by making long cuts in the bark with a knife, and as the milky juice gushes out, it is wiped off continually with the fingers, and smeared on their arms, shoulders, and breast, till a thick covering is formed. This is peeled off their bodies and cut into small squares, which are then said to be boiled in water. From Ambriz the trade in this rubber quickly spread south to the River Quanza, where considerable quantities are exported.

Within 20 miles of the coast from Liawa and the Lindi estuary (Masasi and Rovuma, East Africa) the forest becomes almost entirely formed of India-rubber vines, affording an abundant supply of fine India-rubber, at present gathered only in a very desultory manner by the natives, who gash the plants, and collect the rubber as it issues in a liquid form, and dries hard after short exposure to the air. Rolled into orange-like balls, it is taken to Lindi, where what is worth 7 to 8 dol. fetches 2 dol. The width of the belt is 15 to 20 miles. On the Victoria Lake (Central Africa) are one or two kinds of tree which produce caoutchouc of good quality.

Dr. Kirk has just determined, with accuracy, the plant which yields the best East African India-rubber, and has obtained seeds of the species for introduction into India. It occurs in great abundance along the newly-made road from Dar-es-Salaam, in a west-south-westerly direction, for about 100 miles towards the interior of East Africa, through the Wazamaro country; it is apparently but little affected, except in the immediate neighbourhood of the villages, by the reckless mode of tapping employed. In many parts, a native can still collect 3 lb. of rubber daily. There are five species, but only one is considered worth tapping.

Rubbers and Guttas of Borneo and Sulu.—The Kadyans and their Murut neighbours collected a quantity of gutta percha and India-rubber in the surrounding forests. The gums are afterwards manufactured into lumps or balls, and conveyed to Labuan for sale. The gutta is obtained from four or five species of the genus *Isonandra*, all large forest trees. The trees are felled and their bark is girdled or ringed at intervals of two feet, the milky juice or sap being caught in vessels formed of leaves or cocoa-nut shells. The crude juice is hardened into slabs or bricks by boiling, and is generally adulterated with 20 per cent of scraped bark. Indeed, it is said that the Chinese traders, who buy up the gutta from the gatherers, would refuse the pure article in preference for that containing bark, to which the red colour is mainly due.

India-rubber in the north-west districts of Borneo is the produce of three species of climbers, known to

the natives as *manoongan, manoongan putih,* and *manoongan manga.* Their stems have a length of from 52 to 100 feet, and a diameter rarely exceeding 6 in.; the bark is corrugated, and coloured grey or reddish-brown. The leaves are oblong, green, and glossy; the flowers are borne in axillary clusters, and are succeeded by yellow fruits, of the size of oranges, and containing seeds as large as beans, each enclosed in a section of apricot-coloured fruit. These fruits have a delicious flavour, and are much prized by the natives. The stems of the India-rubber creepers are also cut down to facilitate the collection of the creamy sap, which is afterwards coagulated into rough balls by the addition of nipa salt.

The fallen gutta trees lie about in all directions in the forest, and the rubber-yielding *Willughbeias* are also gradually, but none the less surely, being exterminated by the collectors in Borneo, as throughout the other islands, and on the Peninsula, where they likewise abound.

It was formerly thought that gutta-percha was the produce of only one species of tree (*Isonandra Gutta*), but that obtained from the Lawas district is formed of the mingled saps of at least five species, the juices of a *Ficus,* and of one or two species of *Artocarpeæ,* being not unfrequently added as adulterants. The Bornean *gutta soosoo,* or India rubber, again, is the mixed saps of three species of *Willughbeia,* with the milks of two or three other plants surreptitiously introduced to increase the quantity.

The gutta trees are slow to attain maturity, and are difficult to propagate, except from seed. The *Willughbeias,* on the other hand, grow rapidly, and readily lend themselves to both vegetative and seminal methods of propagation; hence these are especially deserving of the attention of the Government of India, where they may reasonably be expected to thrive.

There are, doubtless, yet many thousand tons of rubber and gutta in the Bornean woods, but as the trees are killed by the collectors without any thought of replacing them, the source of supply must recede constantly farther from the markets, and prices will rise in consequence. The demand for India-rubber from Borneo is of quite recent growth, yet in many districts the supply is already practically exhausted.

In Assam, Java, and Australia, rubber is afforded by *Ficus elastica,* which is cultivated for the purpose. There are many milk-yielding species of *Ficus* in the Bornean forests which, with careful experiment, may possibly be made to contribute remunerative quantities. The Malayan representatives of the bread-fruit family also deserve examination, as an excellent India-rubber is derived from *Castilloa elastica,* a South American plant of this order.

Lac.—Secreted by an insect (*Coccus lacca*), on the branches and twigs of certain jungle trees, principally *khusum* (*Schleichera trijuga*), *plas* (*Butea frondosa*), and *ber* (*Zizyphus jujuba*). The lac from the first is more esteemed than that from the others. To some extent, the lac is found occurring, so to speak, spontaneously, and is collected by forest tribes, and brought by them to the fairs and bazaars for sale. Where, however, there is a regular trade in stick-lac, propagation of the insect is steadily carried on by those who wish for a certain and abundant crop. This propagation is effected by tying small twigs, on which are crowded the eggs or larvæ of the insect, to the branches of the above-named species of trees. These larvæ are technically called seed. The larvæ, shortly after sowing, spread themselves over the branches, and, taking up position, secrete around themselves a hard crust of lac, which gradually spreads till it nearly completes the circle round the twig. At the proper season, the twigs are broken off, and on arrival at the factory, are passed between rollers, which admit of any degree of approximation. The lac is thus crushed off, and is separated from the woody portion by screening. It is next placed in large tubs half full of water, and is washed by coolies, who, standing in the tubs, and holding on to a bar above by their hands, stamp and pivot about on the heels and toes, until, after a succession of changes, the resulting liquor comes off clear. The lac having been dried, is placed in long cylindrical bags of cotton cloth of medium texture, and about 10 ft. long and 2 in. in diameter. These bags, when filled, are taken to an apartment where there are a number of open charcoal furnaces. An operator grasps one end of the bag in his left hand, and slowly revolves it in front of the fire; at the same time, an assistant, seated at the other end of the bag, twists it in the opposite direction. The roasting soon melts the lac in the bag, and the twisting causes it to exude, and drop into troughs placed below, which are often only the leaves of *Agave americana.* When a sufficient quantity in a molten condition is ready in the trough, the operator takes it up in a wooden spoon, and places it on a wooden cylinder, some 8 to 10 inches in diameter, the upper-half of which is covered with brass—in some places the freshly-cut, smooth, cylindrical stem of the plantain is used for this purpose. The stand which supports the cylinder gives it a sloping direction away from the operator. Another assistant, generally a woman, now steps forward with a strip of *agave* in her hands, and with a rapid and dexterous draw of this, the lac is spread at once into a sheet of uniform thickness, which covers the upper portion of the cylinder. The operator now cuts off the upper edge with a pair of scissors, and the sheet is lifted up by the assistant, who waves it about for a moment or two in the air, till it becomes quite crisp. It is then held up to the light, and any impurities, technically "grit," are simply punched out of the brittle sheet by the finger. The sheets are laid one upon another, and, at the end of the day, the tale is taken, and the chief operator is paid accordingly, the assistants receiving fixed wages. The sheets are placed in packing-cases, and when subjected to pressure, break into numerous fragments. In the fresh state, the finest quality has a rich golden lustre.

The dark-red liquor before referred to, as resulting from the washing, is strained, in order to remove all portions of woody fibre and other foreign materials. It is then passed into large vats, where it is allowed to settle; the sediment is subjected to various washings, and at last allowed to settle finally, the supernatant liquor being drawn off. The sediment, when of the proper consistency, is placed in presses, from which it is taken out in the form of hard, dark-purple cakes, with the manufacturer's trade-mark impressed upon them. This constitutes what is known as lac-dye. The dye which is thus separated from the lac by washing is said to be the body of the insect—not a separate secretion.

It might appear that some mechanical arrangement would be more efficacious and economical for washing and separating the lac from the dye, but human labour is so cheap, that this is not the case. The daily pay of the women is 1d. to 1½d.; of the men, 1½d to 2d. No evil effect on the feet of the stampers is to be observed. The great and sudden oscillations of price in the London market render this trade very risky, and the aniline dyes have well-nigh ruug the knell of lac-dye in European industry.

In Assam, a small quantity is produced in the district of Darrang. In some districts, the insect is artificially reared on the *jhuri* tree (*Ficus cordifolia*).

Indian White Wax.—This is produced by the female of the *Ceroplastes ceriferus,* an insect allied to the *Pela* of the Chinese, whose product is so largely used for making candles for the Buddhist temples. The Indian insect deposits its wax in small masses upon the twigs and branches of several trees, but more particularly on the *arjun* (*Terminalia Arjuna*); it does no appear to have ever been propagated, nor has the wild product

been collected in quantity. Though an article of undoubted value, it would perhaps scarcely repay expenditure of European time and capital; but the natives might surely render its cultivation a very profitable undertaking. The wax is soluble, or nearly so, in boiling alcohol, also in benzine and ether, but only very slightly in turpentine and carbonic disulphide ($C S_2$). Its composition is $C_{12} H_{24} O$. It is found at many widely-distant points throughout Sirguja, and is abundant, and suitably situated for experimental cultivation, on the *arjun* trees growing upon the embankment of the Purulia lake.

The Gum Trade of Somali Land (East Africa).—The gum, or *habak*, always sold in grades, bears the name of *ankobib*. On sifting, it is always found mixed with a small quantity of other sorts which make weight in the balance; these are the *habak euddé* and the *habak foltata*. The incense, or *luban*, sold in grades, takes the name of *beiho*. The *saphi*, or "triage," is divided into three qualities. The 1st, *fasous*; the 2nd, *nagoua*; the 3rd, *medjigel*. The *saphi*, or "triage," is made into *doukans*, when the arrivals are not too great, by women and children, who are paid about 6d. a day.

The myrrh has but one quality, but it is necessary to be on the guard against the admixture of false myrrh, of the same colour, but more powerful odour, which the Arabs call *addi*. It is easy to recognise this latter, which always appears oily.

The *maidi*, called in Europe "gum elemi," is a kind of incense in large bleached tears. It presents the same grades as incense, and buyers aim especially at preserving the tears unbroken to heighten the value.

The *adet*, or *mourcoud*, is a grey gum, with an exquisite odour recalling that of ambergris.

The *addi*, or false myrrh, whose odoriferous wood is mixed with the wood of *djirmeh*, has an odour when burnt closely resembling that of "seraglio pastilles."

The *fabah-fallah* is a resinous bark, which is burnt to give off a peculiar odour, under the name of *habak droun*.

Statistics of the annual receipts of gums and incenses at the ports of the Medjourtine coast:—

	Bohars.
Bender Ziyâda	250
Bender Gâsem	1,200
Abou Régabé / Bender Baâd	900
Borah	300
Gandala	500
Bender Khor	1,000
Râs Orbé	250
Merâya	1,500
Gnersa	200
Guesli	400
Bender Felix	700
Atloûla	1,000
Total	8,200

The bohar is equal to 136 kilo., or, say 8,200 bohars are about 1,200 tons; this increases to 2,000 tons in a good year.

Myrrh reaches two places only—

Bender Gâsem ..... 30 Bohars.
Borah ..... 3 ,,

Halfoûn, in 1877, received 25 bohars.

Magnificent incense-trees, two to three feet in diameter, are found on the lofty mountains towards the north coast of Somali Land. Marcych, an important village, lying over 30 miles west of Capo Gardafui, has a large export of myrrh and incense.

Obeuh, the capital of Kordofan, is the centre of a large trade in gum, which is collected in the woods by the women and children, and taken to their villages, where it is disposed of to petty itinerant traders, for ultimate dispatch to Europe.

Moroccan Gum Ammoniacum (which must not be confounded with the Persian product of *Dorema Ammoniacum* or *ushak*), is an object of commerce with Egypt and Arabia, where it is employed, as of old, in fumigating. The plant affording it is called *fashook* in Arabic, and has been hitherto referred to *Ferula orientalis*, or *F. tingitana*; but Ball and Hooker consider it decidedly an *Elaloselinum*, probably *E. humile*. Learned was told that this plant grows at a place two days from Mogador, on the Morocco road; but Hooker and Ball were assured that it is found nowhere along that route, nor nearer to it than El Araiche, a place lying north of Morocco city, which is confirmed by information gathered by R. Drummond Hay, to the effect that it occurs near Morocco, and chiefly around Tedla.

Gum Sandarach is a product of *Callitris quadrivalvis* (*Thuja articulata*, *Frenela Fontanesii*), a tree indigenous to the mountains of North Africa from the Atlantic to East Algeria, its eastern limit being undetermined. The resin, once a reputed medicine, is collected by the Moors, and exported from Mogador to Europe, where it is used in varnish-making.

Euphorbium gum is produced by *Euphorbia resinifera*, a tree confined to the interior of Morocco. The juice flows from incisions made with a knife, and hardens and drops off in September, the produce being abundant only once in four years. The people who collect the gum tie cloths over their mouths and nostrils, to exclude the small dusty particles, which provoke intense sneezing. The gum once had a wide medicinal use, but the trade in it is now rapidly declining, and its consumption is restricted to veterinary practice, and as an ingredient in a marine paint.

SUGGESTIONS FOR THE IMPROVEMENT OF THE COFFEE INDUSTRY IN JAMAICA.

(*Extracts from Mr. D. Morris's Lecture on "Some objects of Productive Industry" delivered at the Town Hall, Kingston, May* 17, 1881.)

When speaking of the high prices obtained for Blue Mountain Coffee exported from Jamaica, it is well, however, to bear in mind that, relatively, it bears but a small proportion to the whole quantity exported from this Island. I have been unable to procure exact returns, but, I believe, I am not far wrong when I assume that most of the high-grown and best qualities of Jamaica Coffee are shipped to the Liverpool market. If this assumption be correct, then we may set down the proportion of the *best* Coffee at about one-ninth or at the most at one-eighth of the total quantity exported. For instance, during the year 1879, the total exports reached 99,715 cwts.; of this 10,109 cwts. or less than one-ninth are given as having been shipped to the Liverpool market. It is owing to this fact, no doubt, that we find Jamaica Coffee quoted at such low figures in the London and New York markets—its merits there being evidently based on the produce grown by settlers and small proprietors who possess neither the means, nor the requisite skill, for curing the coffee properly.

In the Parish of Manchester, for instance, coffee of very good quality is grown; and, I am glad to find several very energetic and successful planters are devoting increased attention to the subject. As Manchester coffee, grown at elevations from 1,800 to 2,800 feet, obtains from 90s. to 100s., and sometimes 120s. per cwt., it may reasonably be supposed that nearly, if not quite, all the settlers' produce, forming the vast bulk of our exports, would obtain much higher prices if it were carefully cured and sent to the market in a sound condition. The great drawback to improvement under this head arises from the want of central curing establishments, either i

close proximity to the districts where settlers' coffee is mostly grown or in the neighbourhood of the shipping ports.. ....and I conceive that no greater service could be rendered to coffee industry in Jamaica —in view of the great and increasing quantity grown by settlers—than the establishment of such central curing mills where the greater portion of the coffee might be carefully cured and shipped in a sound condition. [I am well aware that at present each large coffee property in the Blue Mountain and Manchester districts acts in a measure as a central curing establishment, and by buying up settlers' produce within its reach and curing it in a satisfactory manner assists in bringing up the proportion of good coffee, but they evidently fail to meet the difficulty, for in spite of their influence, the fact remains that settlers' produce, forming the bulk of our exports, leaves the Island in a most unsatisfactory state.] As far as the coffee itself is concerned, that grown by many settlers is equal to the best Plantation Coffee, but, owing to bad curing and the want of proper selection of the different qualities, the prices realized are often only one-half of what they ought to be. The loss thus entailed must amount to thousands of pounds annually, and this loss is the more regrettable that it is capable of being saved with only a little of the energy and industry which has been expended upon the cultivation itself.

Assuming that only two-thirds of the coffee raised in Jamaica is settlers' coffee, and taking the loss on account of bad curing and careless shipping at even 20s per cwt., we have here an actual annual loss to the Island of nearly £50,000 in this one industry. [At the present time when Jamaica (settlers') coffee in the London market is quoted at only 45s. per cwt., one property that had bought settlers' Coffee in the cherry and cured it thoroughly obtained 110s. for it in the Liverpool market. This is a difference of nearly 65s. per cwt.]

Turning again to the question of curing coffee in the plains and establishing mills near the shipping ports, I am quite aware that many experienced coffee planters believe that coffee cured on the hills, where the heat is less intense and the process of drying the bean is more gradual, tends to develope good tone and colour, and contributes to the production of high class coffee. As long as the moisture in the bean is gradually dissipated, and, as long as there is sufficient care and attention devoted to the curing to develope good tone and colour, without undue or prolonged exposure to sunlight, there can, however, be no doubt that the plains are much more convenient and more suitable for curing coffee than the hills.

* * * * * * * * *

If there were central curing establishments, with good water power, say at Gordon Town or near Kingston for the St. Andrew, Red Hills, and Castleton Districts; at Porus, near the Railway terminus, for the Manchester Districts; at Dry Harbour or St. Ann's Bay for the St. Ann District; and at Buff Bay or Port Antonio for the Portland Districts, these establishments would buy or receive the coffee either in berry or in parchment, according to the distance it has to travel. Coffee in parchment would only need to be dry enough to bear the journey without injury, and when once it had been placed under the influences of a drier and warmer climate, assisted by machinery of the best and newest description, the coffee might be cured and finally prepared for the market at fully one-half the present cost.

* * * * * * *

As another important and decided step towards securing the better preparation and improvement of settlers' coffee, there might be established at each of the principal ports, and especially in Kingston, a careful system of inspection under Government control, whereby no coffee, whatever, could be shipped unless it was pronounced by a competent officer to be thoroughly sound. With curing establishments at work, there would be less reason than exists at present for shipping bad coffee; but, I fear, unless something is done by coffee planters and coffee merchants, to improve and maintain the general character of Jamaica coffee, its name and position in the markets of the world will, before long, be seriously compromised.

It is impossible within the limits of this lecture to give more than a bare outline of the scheme now advocated; but, if we take a lesson from our enterprising neighbours and adopt some elements of their efforts to foster important industries, and maintain by judicious systems of inspections the good name and value of their exports, we would soon place our coffee industry on such substantial and permanent lines that it would become in the future, as it was in the past, the pride and glory of the Island. Summing up the substance of the preceding remarks, what we evidently require are:—

Firstly—a judicious extension of coffee cultivation, with only such necessary buildings and barbecues as are required for pulping the produce and despatching it to the plains as parchment coffee. [Under this arrangement properties of 50, 100 or 150 acres of coffee could be established for sums, varying from £500 to £1,800; whereas if works and barbecues are built sufficiently complete to cure and despatch coffee fit for the market, nearly double these sums would be required, and fully one-half the money would lie idle in unproductive buildings.]

Secondly—the establishment of central curing mills, under trustworthy and efficient superintendence, where coffee received in parchment [or bought in cherry] might be cured, sized, and shipped in a thoroughly sound condition. [The actual cost of curing coffee already received in parchment and despatching it ready for the market would, under these circumstances, be less than 24s. per tierce. The regular charge by well-known firms in Southern India and Ceylon is only 3s. per cwt., but as pursued at present in Jamaica, by having the work done independently on each property, and by maintaining people that are often only partially employed and using indifferent machinery, curing and preparing coffee costs fully twice as much as it would cost if done by skilled labour continuously employed in a large mill.]

Thirdly—the organization of a system of inspection under government control whereby coffee, *and indeed all other agricultural produce*, might be carefully examined at the port of shipment and passed with an official mark, declaring it to be sound and in good order. [On this point a careful perusal of the Consular Reports of the United States will show how greatly the character of their produce is maintained by a strict system of State Inspection at the port of shipment. By means of a well organised Chamber of Commerce or by direct legislation on the subject, due inspection of our agricultural produce, prior to exportation, offers a most satisfactory means of checking evils which at present threaten to thwart and counteract all efforts to improve the agricultural interests of the Island.

SOIL-EXHAUSTION TESTED BY MR. LAWES.

(From the *Field*, 2nd July, 1881.)

Mr. Lawes, in his pamphlet entitled "Fertility," inculcates quite a new theory, which he claims to be fully established by those important experiments he is carrying on at Rothamstead—one, however, so thoroughly antagonistic to many old-established, long-settled conclusions and convictions, that it will have

to be tried over and over again by other experimenters, and in a great many different soils and places, ere it is likely to be generally accepted as "proven." Probably the grand scope of the issue laid open by Mr. Lawes will be best understood by quoting a reply which he makes to M. Ville, the celebrated French agriculturist chemist, which is to be found in the concluding part of the pamphlet. M. Ville, in his work on artificial manures, which has been translated into English by Mr. Crookes, maintains that crops always yield more nitrogen than is supplied in the manure, and that this excess is derived not from the soil, but the atmosphere; that leguminous plants, and particularly such as peas, beans, clover, and lucerne, take practically nearly the whole of their nitrogen from the air; while others, such as beetroot and colza, require a certain amount to be supplied by manure in order to establish active growth, but that after this they draw their supplies from the atmosphere. In reply Mr Lawes states:—

The facts I have adduced and the conclusions I have drawn from them are quite inconsistent with those put forward by M. Ville, and more especially those relating to the sources of the nitrogen of the leguminous and root crops. I maintain that the amount of nitrogen supplied to our crops from the atmosphere —whether as combined nitrogen brought down by rain, or that absorbed by the soil or the plant—constitutes but a very small proportion of the total amount they assimilate; and that the soil itself (or manure) is practically the main source of their supply. Indeed, it is a question whether, on arable land, as much or more may not be lost by drainage or otherwise than is supplied by the atmosphere.

This is rather a startling dictum, not only for those who all their lives have entertained a fervent belief in the possibility of transferring immense quantities of nitrogen from the air to the soil by means of broad-leaved plants, but also to the thorough cultivators, who fondly imagine that, by continuous steam tillage, autumn ploughings, scarifyings and stirrings, together with those rough furrow exposures in winter so well known to be salutary, a great deal of nitrogen may be attracted and retained by the soil itself. Everybody knows that all these influences effect a vast amount of good, and that lands become capable of yielding much better crops after they have been subjected to them than they were before; but Mr. Lawes asserts that this is not because of any fresh-inherited wealth from atmospheric sources, but owing to a liberation of nitrogen which was already in the soil beforehand, the treasures of which only require to be unlocked by a skilful hand to be rendered up very freely. The theory which Mr. Lawes inculcates is simply this: that all soils have been furnished more or less with latent nitrogen, owing to the ages they remained in a state of primeval wildness, bearing vegetation of some kind which, after coming to maturity, decayed on their surfaces, to form mould and be incorporated as legacies for the future. The popular idea, no doubt, is that except in vales, alluvial soils, and those of well-known natural fertility, a large proportion of this original endowment of nitrogen has long since been exhausted; but Mr. Lawes says this is not so, and he offers facts to prove his case. Adjoining the Rothamsted trial fields is a piece of permanent pasture, which he has analysed, and finds that, after removing all vegetable matter, the first nine inches of the finely sifted mould con ain 5,700 lb. of nitrogen per acre, while the second nine inches contain 2,500 lb more.

The adjoining arable field, which has never been remembered in pasture, has been experimented on since 1840, and Mr. Lawes believes that it possessed at that time about 3,000 lb. of nitrogen in the first nine inches, and between 2,100 lb. and 2,200 lb. in the second nine inches. Since that period this field has grown thirty-eight successive crops of wheat, and certain portions of it have been totally unmanured during the whole forty years. Under the latter circumstance Mr. Lawes estimates the loss of nitrogen from the soil at from 1,000 lb. to 1,200 lb. per acre; so that, although he has been drawing contiuually on the stock of nitrogen on the soil for forty years, without adding any to it, there is still a considerable residuum to draw upon remaining.

If there are no loopholes for error in these deductions, or a possibility that much more nitrogen may come from the atmosphere, even to the Rothamsted unmanured wheat plots, than Mr. Lawes supposes, he certainly advances evidence in the above that there is nitrogen remaining latent, even in comparatively poor soils, in rather large quantities. Neither is it very difficult to understand by this theory why steam tillage, autumn cultivation, winter and summer fallows, lining, &c., always occasion such heavy crops. The soil, by being acrified and atomised, yields up its latent nitrogen, which is converted into nitric acid by the fermenting influences which are occasioned. Even the fact of the Rev. S. Smith having grown his splendid crops of wheat thirty-three years in succession without manure, but by spade-dug, well-stirred intervals, becomes explicable without entertaining the idea that a single particle of the manure came from the atmosphere. But what a startling conclusion are we compelled to come to after all this; for, if Mr. Lawes be in the right, greater inroads must have been made into the pre-existent stock of nitrogen in the soil the more these forces and influences have been applied; and it amounts to this, that the best and most assiduous cultivators must be the worst for landlords' interests, because they exhaust in greatest degree the stores of laud fertility, which, as alleged, are of so much consequence; and, reasoning thus, we must also accept the logical outcome that bad farming exhausts land far less than good.

The conclusions of Mr. Lawes seem also to fix us on the horns of a dilemma in another matter. He alludes, in the concluding part of the sentence quoted above, to the losses of nitrogen arable soils sustain by drainage and other influences, and says it is as much or more compared with the quantities they receive from the atmosphere. But if the nitrogen coming from atmospheric sources is washed out again to this extent, so also must be the free nitrogen, which is supplied direct in the shape of manure, or by feeding stock with artificial food; and if such a factor in the account be duly entertained, it must lessen very materially the validity of tenant farmers' claims for compensation when they have employed largely either artificial manures or artificial foods for stock, in all cases in which nitrogen is supposed to be the chief legacy imparted. Mr. Lawes, in the early part of his pamphlet has the following passage:—"As the claims of tenants for unexhausted fertility are becoming more and more recognised, the time seems to have come when some effort should be made to draw the line between the natural fertility inherent in our soils, which is given in exchange for rent, and the additional fertility which the tenant brings upon the land at his option, but cannot altogether remove." This is, perhaps, a somewhat unhappy pretext to make for the inquiry, inasmuch as the whole of the logic and facts adduced by Mr. Lawes tend to the conclusion that the grand source of fertility lies latent in the soil; and, judging solely by what the pamphlet contains, one would scarcely suppose it possible that the most industrious and enterprising occupiers could contribute to it to any very valuable extent. In one place he says:—"Large as the amount of imported cattle food may appear, it will be found that its consumption is confined to a comparatively limited area, and that it has but little influence on the general fertility of the country at large. As a proof of

this fact, I may say that the addition of only 1 lb. of nitrogen per acre to the 31,000,000 acres of cultivated land in Great Britain would require an import of about 500,000 tons of corn and cake, and the consumption of the country does not reach this amount." What of that? Does not Mr. Lawes know, better than any one can tell him, that a far higher manurial legacy for the soil is left after the consumption of cake and corn in phosphates than in nitrogen? The latter may no doubt be washed out again, or evaporate, just as he assumes the nitrogen is which comes from the atmosphere, but the former becomes a fixture until the roots of plants appropriate it. So far as the book bears on the tenants' compensation question, a kind of special pleading for landlords' interests will be found running through almost every page. For instance, the principle is laid down that "in most cases profitable agriculture involves a slow but continuous exhaustion of the soil;" that "practically the source of the whole of the nitrogen in our crops is the store within the soil itself;" that "rent is paid for the right to remove without restoration a certain amount of the stock of fertility in the soil;" and that "the various restrictions introduced into leases, covenants, and customs were designed for the purpose of limiting as much as possible the removal of this stock of fertility." Mr. Lawes, however, admits that, "in the face of the increasing competition with the agriculture of the world, it is *hopeless* to bind the tenant's hands or cripple his energies by the restrictive covenants of a bygone age;" but, he adds, "if at the commencement of occupancy a brief agreement could be drawn up between landlord and tenant, to define the amount of fertility which the latter was entitled to remove in exchange for his rent, the task of any arbitrator or judge called in to decide between conflicting claims would be made lighter."

This can only mean that whenever an outgoing tenant presents a claim for the legacy of imported fertility he had left behind in the soil, the landlord should be empowered to call in an analytical chemist to ascertain whether he has not exhausted the original stock of fertility more than ordinary farming would do it, or beyond the limit agreed upon by the respective parties in the first instance. Apart from the fact that this would render confusion worse confounded by introducing a new matter of disputation, it lands us on the very unsatisfactory ground that, according to Mr. Lawes's views and conclusions, the best farmers, who had grown heaviest crops, and kept the land more thoroughly under aerifying, abrading, and fructifying influences, would be punished most, and, although leaving their farms in much better condition, according to ordinary powers of observation, than they were in when they took them in hand, might be mulcted in heavy fines for having drawn too heavily on the pre-Adamite stock of fertility which is the landlord's property.

But a truce to all vain speculations of this nature. Every intelligent, experienced farmer thoroughly believes that when he puts land into what is termed a good state of cultivation, the landlord's interest is advanced quite as much as his own, however persistently he may apply the high pressure of intensive tillage. In fact, most men have become accustomed, as the result of their own observations and researches, to conclude that the same rule may be applied to soil fertility as to capital—the larger the amount obtained and available for use, the easier it becomes to get more. The interesting but revolutionary theory which Mr. Lawes has built up would do away with this thesis altogether, but there must surely be a woof in the former somewhere or other, if we only take the pains to seek and discover it. Probably it lies in his ignoring too much an active principle, which must exist in most soils, of fixing nitrogen after being obtained either from the atmosphere or in the shape of manure, and of afterwards retaining it to add to the stock of fertility which previously existed. In his pamphlet we find allusions to a principle capable of converting nitrogen into nitric acid, and also frequent reminders that arable land is in danger of losing a great deal of the latter when there are no roots of growing plants to take it up as rapidly as it is formed; but, on the other hand, another process, which Professor Way taught us to believe to be continually going on when fallowing is conducted on right principles, receives no attention whatever. Does not the latter, however, more than compensate, adding to the stock of nitrogen which can be retained, for all that is taken away? This point will have to be settled ere the conclusions of Mr. Lawes can be accepted in good faith, for it seems reasonable to suppose that the original stock of fertility accumulated in primeval times become retained by the same process. The laws of nature are eternal, the same forces operating to-day as had existence long before man became a tiller of the ground. Mr. Lawes believes that the action of man as a cultivator always has been, and will be, exhaustive of the soil fertility previously laid up in store for him; but most scientific men, as well as practical agriculturists, have always deemed it possible by adopting the best systems of management, not merely to retard soil exhaustion, but add greatly to the fertility pre-existent, even when taking continually heavy produce. Of the highest importance is it to have facts and experiments to give information on such a vital point; consequently, everybody ought to feel deeply indebted to Mr. Lawes for his researches; but his dictum ought not to be accepted without many other soils being tested, and the application of a very crucial examination to every point of the inquiry.

AGRICOLA.

COFFEE AND ITS MEDICAL PROPERTIES.—From an extended work published by Dr. Henry Segur on coffee and its medical properties, we take the following paragraphs: It is an error, he says, to believe that the use of coffee affects the nerves and brings about ill humour as the result of its hurtful action on the digestive organs. Other causes of a different nature produce the ill humour and general discontent characterising modern society. The causes are wholly moral. Ambition, and the desire for riches boundless and untrammelled by conditions, are the causes of the evil, and not the delicious and beneficial coffee bean, as is wrongly and held by many of the faculty. On the contrary, coffee taken in moderation comforts the system, enlivens the mental faculties, and stimulates pleasantly without any of the disagreeable after effects inseparable from narcotics or stimulants. It gives strength for mental or bodily labour, clears the imagination, cheers the mind, strengthens the body and predisposes it to bear fatigue and sleeplessness. The mental pleasure, sleeplessness, and activity which it promotes have inspirited more then one poet, wise man, and distinguished author by noble and lofty ideas. Not inappropriately is it called "intellectual drink" or the "nectar of the wise." It cannot be denied that the direct action of coffee is on the nerves, but its effects are not injurious as some believe, but are in fact wholesome. The nervous excitement produced by it is not weakening like that from narcotics. In fine, it acts as a cordial, enlivens the brain, strengthens the imagination, and brightens the understanding. It contains, besides, peculiar nutritive and medicinal properties. In intermittent fever its effects are wonderful, as is also the case with malignant ones. Spasmodic asthma, hysterical affections, inflammation of the kidneys, chronic diarrhœa and even croup and diphtheria, are alleviated by coffee. It is also remedial in cases of opium poisoning.—*Straits Times.*

CHINA MATTING.

(From the *Gardeners' Chronicle*, 16th July 1881.)

In a recent number of the *Journal of the Society of Arts* is a report by the United States Consul at Canton on the manufacture of matting in China. The substance of this report was contained in a paper by Dr. Hance in the *Journal of Botany*, vol. viii., p. 99; but as the subject is one of much interest, and the paper of the American Consul is fuller in many of its details, we make the following abstract :—

It is well known that enormous quantities of matting are now made both for use in China as well as for export. It is used largely for sails on the native sailing craft, as it is much cheaper, if not more durable, than the ordinary sail-cloth. It is also used for coverings for boxes and packages, in which tea, sugar, cassia, &c., are exported; besides which, moneybags are made from it, being a very convenient mode of handling dollars, especially when broken up into small pieces by their constant stamping or "chopping," as is the custom in China.

The plant from which the mats are made is commonly known as "aquatic grass," or "rush." It is cultivated in the Shunhing department on the West River, about 75 miles in the interior from Canton. It is grown in a similar way to rice, in fields flooded with water. It requires very little care in its cultivation, as it propagates itself by shoots from the root, and attains a height of from 6 to 8 feet. It is brought to market in bundles of about 12 inches in diameter, and if of proper length and good quality sells at about 10d per bundle, each bundle being sufficient to make four bed mats, or six such as are used for making sails.

The district of Tung-Kuan produces large quantities of this material, but of a kind used almost entirely in the manufacture of floor-matting. It is said to grow better in the vicinity of salt water, when the water flooding it is sometimes brackish. It is planted usually in the month of June, from slips. These are allowed to grow for about two months, when they are replanted in rows, the soil being plentifully manured with beancake; it requires nearly a year to mature. When it is cut the stems are split in two with a knife, and when partially dried in the sun packed in bundles, and manufactured into matting at the city of Tung-Kuan, or brought to Canton, where there are several extensive manufactories. When brought to the factory, the grass, as it is called, is carefully sorted; it is then made into bundles of 2 or 3 inches in diameter, and placed in large earthenware jars holding about 10 gallons of water. It is then allowed to remain in soak for three days, when it is taken out and dried in the sun for a day. If it is to be dyed the ordinary red colour which has been for years much in vogue, it is placed in jars containing a liquid dye made by soaking sapan-wood chips in water. It remains in these jars for five days, then dried for a day afterwards, again immersed in the dye for three days, when it is usually ready for use.

It is only within the last two or three years that other colours, such as green, yellow, and blue, have been used to any extent. The solution for colouring yellow is produced from the seeds and flowers of a plant common to China, the "Fruifa." A yellow colouring matter is also made by boiling for several hours 25 lb. of flowers of Sophora japonica in 100 gallons of water, and adding when cooled 1 lb. of alum to each 10 gallons of the solution. Green and blue are produced from the twigs and leaves of the "Lanyip," or "blue plant," which grows in abundance near Canton. To the solution thus produced a small quantity of chemical dye is now added. In dyeing these colours, the culms or "straw" as it is technically called, are soaked in water for seven days, and then immersed in the colouring matter for a few hours only, the dye being hot.

In relating a visit to one of the largest of these matting factories, fifty looms are described as being in full work, eight of which were large and forty-two small. The large ones are identical with the ordinary silk looms, and are used in making the very wide, and also the damask or carpet patterns. Three men are required to work each of the large looms, their wages being from 1s 3d to 1s 8d per day. Eight yards of matting from each loom is considered an average result of a day's work. The small looms are rude and simple, each being worked by two small boys, who are paid from 7d to 10d per day each, and who daily weave 5 yards of the most perfect matting of the more ordinary patterns. The loom is composed of two uprights driven into the ground, about 5 feet apart, and about 4 feet in height; two cross-bars fit into sockets in the uprights, one at the top, the other about 8 inches from the ground.

The warps, which are strings of Chinese hemp 22 yards in length, are then passed over the upper and round beneath the lower cross-bar, and being drawn taut are fastened by both ends to a long, thin piece of bamboo, placed parallel with and just below the lower cross-bar. The weaving-bar and the most important part of the loom consists of a piece of wood varying in length according to the width of the matting required, and about 2 inches square; through this small holes are pierced at different intervals, into which the warps are passed; the bar can thus be worked up and down in the warps by means of handles near the extremities. These holes vary in distance from each other, according to the pattern desired, alternately on top and bottom. The holes are enlarged or formed into slots, converging at the centre of the stick. When the warps have been thus arranged, and bundles of different coloured straw, sufficiently damp, deposited near the loom, one of the boys raises the weaving-bar to the top of the warps, tipping it forward, the slits in the bar allowing the alternate warps to remain perpendicular, the holes carrying the others forward, thus separating them sufficiently to admit of a single straw being passed between them. This is done by a long flat piece of bamboo, a notch being cut near the end, into which one end of the straw is placed and then used as a shuttle.

When the bamboo is withdrawn the weaving-bar descends, carrying the straw to the bottom; the bar is then raised again and tipped down, thus carrying the warps backward which had just before been passed forward, the work of the shuttle being repeated. As the weaving bar presses the straw down, the weaver gives the end of the straw a half turn round the outside warps, the operation being repeated until the warps are full, the edges trimmed, the warps untied, the matting, now 2 yards in length, removed, and a new set of warps put on. The matting thus woven is then dried in the sun and over a slow fire. The shrinkage consequent on this drying is nearly 4 yards in forty.

When dried, the matting is stretched on a frame and worked down tight by the hand, then sent to the packing-house, where men are engaged in fastening the 2 yards' lengths together, it requiring twenty lengths to make the ordinary roll. The fastening together is done by taking the projecting ends of the warps of one piece, and by means of a large bamboo needle passing them backwards and forwards through the ends of another piece, in fact binding them together; each roll of 40 yards is then carefully covered with a coarse plain straw mat, marked and numbered ready for shipment.

It would seem from Dr. Hance's paper before alluded to, that two distinct plants are used in the manufacture of the above-mentioned mattings, the

culms of Lepironia mucronata being used for sails, and those of Cyperus tegetiformis for floor matting. The "Lamyip" or "blue plant" used in dyeing the culms, is considered to belong to the natural order Acanthaceæ. Polygonum tinctorium is a well-known Chinese blue dye plant, and it might be supposed that this would be sometimes used. By far the largest quantity of these mats go to the United States of America, where it seems they are universally used in summer instead of carpets. The consumption in this country is also very great, their chief use with us being for bed-rooms.

COFFEE CULTIVATION AT BANGALORE IN 1828.

(From the *Madras Mail.*)

BANGALORE, —— 1828.—The cultivation of coffee at this place has never been carried to any extent. No individual paid attention to it until Major G. Waugh, an officer of the Coast army, planted it in his garden, in the Native cavalry lines here, in 1814 and 1815, while he held the situation of military paymaster in Mysore, an office which he had filled for many years with great credit to himself and benefit to the public. The shrubs planted by him are now of considerable size, and bear luxuriantly; great care was taken of them when young, regularly watering and manuring them. The situation of the plants in this garden is also very good, being near to a good tank, and sheltered by large trees of other descriptions.

A few coffee plants are to be found in other gardens in the Cantonment, but, for want of care and attention they yield little. There are also a few very large trees in the fort, in a garden adjoining the old palace, occupied by the general officers commanding the Mysore division of the army. These have, in some seasons, yielded very abundant crops, and have attained a greater size than any coffee plants to be found here, being about twenty feet high and full of branches. I understand they were planted in 1806 and 1807 by a Dr. Hayene, at that time botanist and naturalist in this establishment. They were originally raised here from the seed brought by Dr. Hayene, he having been the first who introduced coffee into this place. He had also as fine plants in the Laul-Baug garden, but these, having been neglected until lately, have come to no perfection. There are some trifling plantations of coffee in villages adjacent to this, but the natives pay little attention to it, in consequence of the length of time that elapses, ere it begins to repay the cultivator, and the trouble attending it when young.

From different native gardeners and others conversant with the subject, I have collected the following information:—The plant is propagated by seeds which should be sown after they are gathered from the tree, for if kept any considerable time out of the ground after being gathered, they will become too dry to vegetate. A dark rich soil, rather dark with a slight admixture of sand, or the rich red earth common in Mysore is the fittest for the cultivation of coffee: on wet cold ground or on clayey soils the plants pine away or vegetate slowly, and yield fruit of an inferior quality. A sheltered situation is found best for raising the plants from the seed. The ground ought to be well manured and turned up from twelve to fourteen inches deep, the mould broke and pulverised; and, previously to the seed being planted, it ought to be formed into beds of four feet square. The berries intended for seed must be allowed to become as fully ripe on the tree as when they are gathered for use, then to be rubbed out of the husks and mixed up with a small quantity of wood ashes, and after being exposed for a few hours in the sun, they are put into the ground about two inches as deep and six inches as under. It has been found better to plant the bean whole than to separate it, the seed vegetating better and producing much stronger and healthier plants. The beds on which the seed is planted must be regularly watered every twelve hours, if practicable; not deluged, but gently watered, so as always to keep them moist. The plants will appear in forty or forty-five days, if the watering has been regularly attended to; but if this is neglected, from three to four months often elapse ere the plant appears, and then it is not a strong shoot. On the plant appearing, attention must be paid to keep the beds free from weeds of every description; these will sometimes spring up two plants together, one of which should be destroyed. Unremitting care is required during the two first months to rear the plants with attention, sheltering them from heavy falls of rain or scorching heats, both of which are alike injurious.

When about two months or ten weeks old, they will be from six to nine inches high, and are then transplanted to a second nursery, which must have been previously well turned up and richly manured. The nurseries ought to be in sheltered situations if amongst peach trees, or others not of so large a size as to preclude the air. The plants will come on quickly in the second nursery; they ought to be set from nine to twelve inches asunder, and continue here from twelve to eighteen months, attention being paid to water them daily, and every month slightly turning up the ground, adding some good manure, and keeping down all weeds. The plants are removed from this to the ground intended for the coffee plantation, which should be prepared in a similar manner to the nurseries; they are here planted at a distance of from six to nine feet according to the soils, holes being dug about two and-a-half feet deep, and filled up on putting in the plant, with good earth and dung. After this the plant becomes very hardy and requires but little attention, except in dry seasons, when it must be watered. When the plant is removed, great care must be taken not to injure the roots nor should they be kept any time out of the ground for, if the fibres be suffered to dry, they are apt to mauld and perish soon after. At three years of age the plant begins to bear fruit, and at six years is in full bearing, and will continue in vigour from twelve to fifteen years, after which it fails; trees of five or six years' standing will yield yearly from four to six pounds, some of these large trees in the Fort formerly mentioned bear from ten to twelve pounds. The coffee plant is an evergreen, and yields a crop yearly; it has a beautiful appearance at every season of the year, particularly when in blossom, the flower being a pure delicate white from the time of budding, and flowering until the fruit is gathered, includes a period of six months, and in wet seasons rather more. The fruit, when ripening, changes colour from green to a pale pink, and gradually becomes brighter as it ripens; when fully ripe, the husks are of a bright red like a cherry, and perfectly dry on the stalks; the mode of separating the fruit from the husks is performed by beating them slightly in a wooden mortar; they very readily separate, if not gathered before being fully ripe. An acre of ground planted with good coffee trees, at the distance of 9 feet, will contain 1,613 plants; and if these are properly attended to, carefully watered and manured, they will, after the third year, yield an average of four pounds each, or nearly 6,500 pounds from the acre, and continue to yield at this rate from ten to fifteen years. There seems to be but one species of coffee known here, although the appearance of it differs considerably, owing to the soil and mode of cultivation; some of it is a pale yellow, and another kind a dark yellow nearly green.

The price of coffee varies much in Mysore: at times it is as low as four rupees, at others as high as ten rupees a maund of twenty-five pounds.

—*Oriental Herald*, August 28. W. T. L.

CINCHONA PLANTER'S MANUAL.*

(COMMUNICATED).

This book will be found to be very useful to all engaged in the cultivation of this valuable tree. It is a handy volume of over 200 pages demy octavo containing the cream of information known regarding cinchona.

As in most works so in this a few errors have crept in. On p. 1 it is said "all alkaloids consist of carbon, hydrogen, oxygen, nitrogen alone." This is not the case, for there are a large number of alkaloid- which contain no oxygen, *e.g.* nicotine from tobacco, conine from hemlock, &c. On p. 4 "The stem (endogenous) is enlarged." This must refer to the height and not diameter. A little further on we are told "reproduction does not commence till the plant is provided with a store of accumulated food"; this is somewhat at variance with the statement on p. 78, for, when a tree has reached a sufficient size and becomes impoverished, it generally makes an attempt to reproduce its kind. In the second chapter, on p. 11, it says:—"warmth of climate accelerates changes and hence bark grown at low elevations contains less quinine," but the next statement "it follows that the quicker the plant grows," &c. is somewhat awkward, for warmth generally accelerates growth and cinchona thrives very well at sea level. A very fine specimen was growing a very short time ago in the Cinnamon Gardens, of no great age, about five or six years, was over 20 feet high, with a girth of more than three feet. Although this tree was quickly grown, the quinine was slight. It is tolerably rich in alkaloids but they are in an uncrystallizible condition. Nevertheless it would make fine druggist's bark.

On the same page the value of quinidine ought to be placed before cinchonidine.

A little further on "the act of flowering does not appear to have any direct influence on the amount of alkaloid in the bark" requires verification. In several plants *e.g.* tobacco, the flowering has an effect on the alkaloids secreted.

The formula for quinine on p. 15 is a misprint. The error is cleared up in the explanation following on p. 28. "It (Ledgeriana) is greatly given to sporting but always within certain limits" reminds one of the wonderful sporting on a Maskeliya estate, so much so that the plants have been pushed out of the category Ledgeriana They are, however, good percentage quinine yielders, which is the great point to look after.

Chapter III. deals with soil, &c. On p. 45-51. 61. certain statements are made regarding the suitability of soil which generally hold good, but it might be noted that in some parts of Ceylon cinchona trees thrive in stiff clay soil near a swamp and give a good proportion of quinine.

The analyses on p. 47 need not have contained the item "Sulphuric acid, carbonic acid, and chlorine not determined," for they must have been absent, as the other constituents make up the 100 parts.

On p. 50, reference is made to "phosphoric acid not being so high as in soil formed from sedimentary geological formations." It must be remembered that our chief formation is but a metamorphosed sedimentary one, and metamorphic action would not destroy phosphoric acid.

With regard to the chapters on weeding, roads, draining, planting, nurseries, they are based on experience, and will hold good generally. Part IV. deals with *manuring*. On this there is much to be learnt, as very few experiments have been tried and the bark tested by analysis. More information on this is very desirable.

Messrs. Rucker and Bencraft's unit value of 1/9 or 1/9½ is too high except for high percentages. Allowance must be made for manufacturer's charges.

It would be interesting to know why the outer cells of the bark, as stated on p. 28, and 112, are richer in quinine, which is correct, but this does not agree with the order of the formation of the alkaloids given on p. 11. First uncrystallizable quinine; next crystallizable quinino to cinchonidine to cinchonine.

Mr. Karslake's process will no doubt be found to be exceedingly good. It is a capital way of punishing a tree and at the same subjecting it to a minimum of harm. Quinine and its partners are stored up in the bark, and by punishing a tree in this way its energy is then diverted to making good the loss of that which has been or is *about to be* (in Mr. Karslake's process) taken away.

The great changes to which bark is subjected, pointed out on p. 141, should be a sufficient inducement to establish a local manufactory here, and ship home either the *crude* alkaloids or the pure, which could be done for a moderate outlay and would prove remunerative. The latter part of the first paragraph (p. 165) is somewhat complex. Are we to gather from this that, when a tree is dying from ringing or other causes, the alkaloids are actually drawn up to the leaves, and that disorganization of tissue below prevents its return? Although it may be regarded as a *fallacy* that checking a tree increases the richness of the bark, yet there is every reason to believe that, checking, by stripping, shaving, or Mr. Karslake's process does make it richer, and there is also evidence to show that other modes of reasonable injury serve the same purpose.

Dr. Trimen's chapter on the characters of the different species will be a great guide to those who wish to follow up the outward characters of the various kinds. A little information might have been given on the dry bark characters, as far as is known. On p. 188 appendix, regarding the analyses A. and B., the salts of the alkaloids should not be added to the cinchonine alkaloid and then called total. The total alkaloids in A. and B. would be much less than the quantity stated.

Mr. Owen deserves great credit for this work, and we trust that a second edition will soon be required. It is a book which ought to be in the hands of every planter, of cinchona as well as of those interested in quinine.

Mr. Owen writes, with reference to the above criticism of the Manual, as follows:—

"I have to thank your correspondent for his notice of the 'Cinchona Planters' Manual,' but hope I may be allowed to reply to one or two of his remarks. I am sorry the paragraph on the formation of the alkaloids is not clear to your correspondent, but I cannot help thinking the meaning is plain. The effect of the warmth at low elevations is to cause the higher alkaloids to change into the lower; it also causes the tree to grow quicker and secrete the more valuable alkaloids (which are just formed) more rapidly, hence the former effect is modified by the latter. Allusion is distinctly made to 'the accelerated growth at low elevations.' As to the influence of flowering on the alkaloids in the bark, the only authority on the subject is Mr. Broughton whose words I quote, and he adds in his report of December 9th, 1869, that this is 'a point on which I have made a careful enquiry.'

"In the formula for quinine on page 15, two numerals have dropped, but the printer's error is made plain in the next few lines.

"I cannot understand cinchona 'thriving in a stiff clay soil near a swamp.' As far as our knowledge and

* The Cinchona Planter's Manual, by T. C. Owen. Colombo: A. M. & J. Ferguson. 1881.

experience go the trees invariably die off at an early age in such situations.—The analyses and remarks on pages 47-50 are by Mr. Hughes. His item 'sulphuric acid, carboinc acid, and chlorine not determined' must have had some meaning, though on the face of it, it seems superfluous.

"Messrs. Rucker & Bencraft's unit value of 1/9 and 1/9½ was correct at the time it was written and quoted, and is borne out by the sale list immediately preceding.

"The order of formation of the alkaloids as decided by Mr. Broughton is not necessarily at variance with the fact of the outer cells of the bark being the richest in quinine, for in this part such changes as take place are slow and probably consist merely of a storage of alkaloid, the *younger tissues* being the scene of the changes described by Mr. Broughton (*vide* pages 45 and 46 of the previously mentioned report).

"The disappearance of the alkaloids from the bark of a dying tree is a fact difficult of explanation, and apparently antagonistic to the theory that checking the growth of the tree increases the secretion of the alkaloids, in support of which theory there does not appear to be any evidence which is not capable of explanation on other grounds."

AGRICULTURE IN SCOTLAND.

(From a Correspondent.)

The reports by assistant commissioners of the Royal Commission on Agricultural distress are now published in a Parliamentary Blue-book. From one of them I take the following figures that show at a glance how matters stand with farmers here, as it is of importance that the planter having farming predilections, who manages to "get out" with a thousand or two, be posted up in latest facts and figures, that his change may not be to a fire from a frying-pan :—

A. Rent £600, farm occupied by tenant. Caitbness.						B. Rent £350, farm occupied by proprietor. Ross.

Better by far that he build his "Lanka Villa," invest his money in house property that yields a certain income of 5 to 10 %, and live at home at ease. Agriculture will right itself when Government gets time to enact laws to facilitate the sale and transfer of land. Good seasons alone will not suffice in the altered state of the produce market to restore prosperity to the farmer. The axe must strike at the root of the evil; land must be marketable. Till then the ex C. P. will keep his funds "in better heart" by laying them out at interest. A leading article in last week's *N. B. Agriculturist* concludes with:—"After what has happened —after a few very bad years, and a full crop such as last year's in Scotland failing in many cases to square accounts for the year—the confidence of the most sanguine farmers in the stability of their profession is being rather rudely shaken. Very material changes on the conditions under which land is rented in this country cannot be far off One other unfavourable year, such as in some respects the present threatens to be, will unquestionably play sad havoc in farming circles, the results of which are melancholy to contemplate." More figures, this time from the *Aberdeen Free Press*, show that the "sad havoc" has begun in our immediate neighbourhood.

PLANTING IN MADAGASCAR.

(From our Mauritius Correspondent.)

I translate the following from a letter of the French correspondent at Madagascar to one of our leading papers. The writer is a native of this colony, and has travelled in Australia and elsewhere. He has also had a good deal of experience here in planting matters:

"In Queensland and the other Australian Colonies the land is low and sandy and labor is dear. At Fiji the plantations succeed perfectly; but there are terrible hurricanes there. The country is unhealthy: dysentery exists there permanently, and Sir A. Gordon has upset the system formerly followed in regard to the employment of laborers by forcing the planters to feed them on bread and meat. At Zanzibar, the cane grows well; but the country is too dry. At Mayotte and Nossibé (French settlements on the east coast of Africa) canes thrive wonderfully; but the climate is unhealthy and labor is very scarce. Several mills have been abandoned for want of hands. At Johanna (Comora Islands) the sugarcane also succeeds; but Europeans are subject to malignant attacks of fever and the Island is too small to afford space for more than four or five plantations, three already existing.

"Madagascar remains to be spoken of. For every competent and reflecting man it will be found the most suitable for the cultivation of the cane. The land is still virgin, and plantations can be had at an any elevation and at a nominal price, while the vegetation is splendid without either guano or manure. Labor is abundant, costing only R4 to R6 per month, including the cost of rations, and there are no vexatious police regulations."

The question of irrigation applied to our cane fields continues to occupy the public mind here to a great degree; and, at the last meeting of the Council of Government, two extensive schemes for irrigation in the windward and leeward districts of the Island were discussed, the Colonial Secretary reading a report thereon to the members of the board.

There can be little doubt, from the attitude of Government in reference to the proposed enterprises, that the question of irrigation on a large scale, applied to the culture of sugarcane, will soon be practically solved here. It has been remarked, and probably correctly, that however unsuccessful irrigation schemes have been in other countries, where the agricultural produce was of less value than our staple, our colonists should not take such results as conclusive for the non-adoption of similar enterprises here. In proof of this, it may be mentioned that irrigation to a by no means unimportant extent has already been carried out with considerable financial success on some of our most prosperous estates.

MAURITIUS.—The subject of ostrich farming is causing some interest here, this species of industry having been introduced by one of our wealthy landed proprietors, Mr. Chéry Liénard, who imported several pairs of birds from Arabia and the Cape. These ostriches have already hatched broods; and, as there is plenty of barren land on the coast of the island, it is probable that, before many years pass over our heads, ostrich farming will be one of the "things that be" in Mauritius. The Cape papers are eagerly searched by our Creole and French colonists for items in regard to the rearing and sale of ostriches &c., and a translation in French, from a Natal paper, has just been published in the *Cernéen*, our leading French journal, reporting the sale of some pairs of these birds at from 50 to 87½ guineas per pair.—*Cor.*

PLANTING IN FIJI.

A correspondent ("Pioneer") favours us with the following :—

"I heard from a friend in Fiji the other day, who writes :—'The prospects of coffee do not seem very brilliant in Fiji at present. I have heard nothing of the result of the experiment on Great Amalgam, but am afraid it has not been successful, as one would have heard if the disease had been checked.

"Stephens has gone to another coffee plantation on the island of Taviuni. The owner of Great Amalgam lately sent in a claim of £20,000 to the Government for damage done to his estate during the treatment by the Government. The matter has been referred to arbitration, and has not been settled yet.

"There was a man of the name of Lanyon down here, three weeks ago, engaging natives to work on a cocoa plantation, which he is opening on the island of Vanua Levu. He has been in Fiji for nine years and was one of the first to grow coffee here. He was in Ceylon before that. He is very despondent about the prospects of coffee in Fiji.

"Cinchona is being planted by two or three men. Copperah, cotton and sugar are the main products of Fiji, and the export of the first and last will very largely increase when the wide acreage of coconuts planted within the preceding five years comes into bearing, and when the three large new sugar mills now being put on Viti Levu are crushing to their full power."

CEYLON TEA IN MELBOURNE.

Mr. Hector Mackenzie advises having sold the Kandaloya estate "pekoes" in Melbourne at Is 10d per lb., two pekoe souchong at Is 3d, and dust at 10½d per lb. in bond. He was sending on a lot of pekoe souchong to Dunedin, where he expects to get Is 5d to Is 6d per lb. Mr. Mackenzie has been offered from Dunedin, New Zealand, 9¾d per lb. for Ceylon coffee, but is holding out for 10½d, as he thinks prices are sure to go up. He also asks if Ceylon planters have done anything about the "Syndicate" business, adding: —"I am not afraid of taking up most of the working here. I agree with you that it is a mistake to force the market. I think if you can't work a Syndicate, if I were appointed agent for one or two good estates, I am sure I could always get pretty good prices. I am working all my sales privately, and won't go to auction as long as I can sell to the grocers privately."

THE ADULTERATION OF TEA.

TO THE EDITOR OF THE MELBOURNE ARGUS.

SIR,—My letter to the Board of Health, copy of which was published in *The Argus* of 25th June, was called forth by the confusion then existing regarding the character of green tea versus black tea. In that letter I maintained and proved successfully by documentary evidence that all green tea is artificially coloured.

"The four samples of green tea in the office" may be passed over. They are probably pure undermented teas. Other statements and assertions in Mr. Everard's letter are simply unsupported, and cannot rest for a moment against the positive documentary evidence I adduce to the contrary. Further, he must show better authority than his own for doubting scientific investigation, and I see at once that to Mr. Everard's scepticism on this point is due the lamentable ignorance he displays in discussing this tea question. If he had any knowledge of the manufacture of tea—and there are plenty of works on the subject—he would not have asserted that "withered tea leaves were sent home," because all tea is withered in the first process of manufacture, and it is a most unlikely fact that any tea planter would have exported his produce at this stage.

Wanklyn on tea analyses clearly and scientifically proves how easy it is to tell the true tea leaf by its botanical character, from all other leaves. Again, the true tea-leaf is noted by its extraordinary richness in nitrogen over all other leaves.

The ash of tea, remaining after incineration of the leaf, is another good test, and tables given by leading analysts are a pretty certain guide to the detection of adulteration.

Perhaps the extract of tea, or that part drunk in the infusion or cup of tea, is the most important, and no tea should fall below 30 (the standard at home). Some of the Indian and Ceylon teas go to 52. This extract contains the essential oil or flavour which pleases the palate; and the active principle, theine (tasteless), which mostly invigorates the drinker.

I think it will now be perfectly clear to the intelligent reader that the analytical chemist should be the best judge of what is wholesome to the tea-drinker and that "wattle-bark" would be instantly detected by such a judge, however much Mr Everard might disguise the same in his samples of tea.

The tea-taster is probably the best authority on the flavour of tea, and in a ready way can give an opinion on the leaf and strength, but beyond this he cannot go.

Messrs. Cosmo Newbery and Dunn must have analysed some 500 samples of tea, and they may be considered first-class analysts of this product, and their efforts to raise the standard of tea used by the community should have the support of all tea merchants and others connected with the trade. The Chinese are masters of the situation. We can only take what they will give us, and they are perfect adepts in the manipulation of the leaf. They dye and face their teas so well that we have the example of Mr. Everard filling your columns with praises of praise in favour of his blooming green teas of the north, the same tea in the hands of the expert and analyst showing facing and dye material. I am, &c.,

July 1st. J. O. MOSLEY.

SIR,—In the Assembly last Thursday the Attorney-General admitted his inability to deal thoroughly with this question. He stated that 10 years ago he was Commissioner of Customs, and now, as the highest law officer of the Ministry, he was in order to be counsel of the customs of the law in such cases. He also stated that he had the agent-general in his room. I will remind him that he had the Chamber of Commerce in his rear, but all, all are silent.

Will you please allow me to state it is up to the time of the expiry of the East India Company's trading charters in 1834—or rather the suspension of the charters, viz. the statute William IV—it was the custom in England to deal with tea condemned or otherwise unfit for consumption to place

it on board a hulk or a hoy sent down the Thames to sea reach, and there, under the supervision of revenue officers, it was started into the sea. About 10 years after this period two vessels, tea-laden, were wrecked near the mouth of the Thames. One vessel was the "Westminster," the other, I think, the "Lady Flora." The tea was immediately recovered and sent up to the East India Docks in steamers. On petition, the sound was allowed to be separated, and the sea-damaged washed in bags and dried in the open air. One condition was that the sea-damaged was to be offered for sale as "sea-damaged and washed," but the tea never reached the consumer with this character. The process was neither satisfactory to the merchant nor to the Government. I believe that the operation was never repeated. Not very long before this, some spurious tea, not imported but manufactured in England, was seized, sent to the Excise office, Old Broad street, and condemned to be burnt. If we go very much further back, we find on record that in the year 1427 Rainwell, the mayor of Loudon, seized 150 casks of wine for being adulterated. The casks were staved, and the contents started into the gutters—6 Henry VI.

Surely the law officers, with the Imperial statutes at large at their hands, might find some remedy for such-like iniquities.—Yours, &c. JOHN ELLA.

Collius-street west, July 2.

SIR,—In your issue of to-day is a letter in answer to mine of 28th June, on tea, from Mr. Moody, in which I am accused of a "tirade of abuse." If that gentleman will show me where the abuse comes in I shall be delighted to withdraw it, but I suppose in my ignorance I may have abused when I thought I was closely following up an argument, showing Mr. Moody's attempt to gloss over an importation of the vilest rubbish imagiuable, by comparing it with some of the finest green teas in the world (not "Ping Sueys" as quoted by Mr. Moody), because there may be some slight colouring on the finest kinds. What I wished to show was that teas like those per "Ocean" were a simple swindle on the gullibility of the public, and that the colouring was not so bad, as compared with the article itself. This correspondence has, however, done some good, as it has moved off this abominable rubbish, I am sorry to say, to another colony, when its last resting place ought to have been either in the middle of Hobson's Bay or "incinerated" by the Customs authorities.

Mr. Moody accuses me of a want of knowledge of the manufacture of tea, I think "lamentable ignorance" is the term; and I shall let that question pass for what it is worth. But perhaps he will allow me to tell him that there is a distinction between "withered tea-leaves" and "tea-leaves withered" for commercial purposes. But as on this subject I merely wished to dispose of the assertion of another correspondent in regard to tea shipped from India, I shall decline following a gentleman who condescends to answer a person who actually knows a tea leaf when he sees it as well as the scientific Wanklyn, but who certainly cannot tell what kind of "vegetable" extract comes from a gunpowder made of the dust of other leaves, not tea, with a combination of other rubbish.

I have nothing further to say in regard to Mr. Moody's letter. If Messrs. Dunn & Co. like to enter the field it is open to them, but I think, sir, you will agree with me that I did not sing the praises of colouring tea. Still, I am certain there is no more harm in bloomiug the finest green teas (which are never used here) than in the use of sulphur for hops or burnt sugar for brandy. Far better without, if the gentle public would prefer a dark olive colour, almost black, to the slight facing, which really much improves the appearance of fine green teas, a kiud of tea I almost question if Mr. Moody has ever seen.

In the whole of this discussion on tea, from my first letter of January 16th, 1880, I have avoided as much as possible saying anything that might be construed as either offensive against individuals, or against the growth of tea of any particular nationality.* I have used my pen only against wholesale denunciations of the Chinese article, as unjust and unworthy. During the season just ended we have imported about 10,000,000 lb. of tea from China, nearly every shipment of which I have seen tasted, and under the most stringent act (similar to the English) not above 50,000lb. weight could have been either destroyed or confiscated, including the "Ocean's" shipment and the "Glamis Castle"; and for this 50,000 lb. weight letters are written wholesale about the poisonous Chinese article, as if the whole produce was one mass of adulteration.

I may add, in conclusion, that during the last few days fully one million of pounds weight of tea (season 1881-2) have been sold out of the s. s. "Killarney," in every instance from very fine to nice sweet-flavoured teas, not one parcel of which would show a low extract, or be rejected by dealers on account of inferiority of quality.

As I have frequently seen Mr. Dunn's name quoted as an analyst, I shall be pleased to give him small samples of the teas I have named if it will be any advantage to him to obtain them for analytical purposes; indeed, I think it would be advisable for him to know both sides of the question, and not rest satisfied with thinking that the teas (green especially) he has analysed are the best products of China. I will also add that the finest and most valuable teas do not necessarily contain (I mean pure tea) the highest percentage of extract, any more than silent spirit 60 per cent. over proof is better than the finest old cognac 8 to 10 under proof.—I am, &c.,

J. EVERARD.

32 Collins-street west, July 5.

Sir,—I am much surprised to see the following statement in Mr. Moody's letter in this morning's *Argus*.—"In that letter I maintained and proved successfully, by documentary evidence, that all green tea is artificially coloured."

Such a statement coming from a man of Mr. Moody's high standing in the trade, must have weight, and should not have been so rashly made. The documentary evidence only referred to China tea. I am prepared to show actual fact. The Indian green teas consigned to me have been analysed and found to be perfectly pure. Fact surely is before theory, especially if the theory is a little stale.—Yours, &c., CHAS. W. HUGHES.

87 Chancery-lane, July 5.

CINCHONA PLANTING ON THE PULNEYS.

The nature of the planting advice tendered to the home public is illustrated by an extract from a letter in the *Field* of July 2nd, on "The Kannan Devan Mouutains in South India." We quote as follows:—

For a planter, and for a man with a small income who wished to set up house on the Pulneys, these hills present undeniable attractions. It is easy to get across from Kodekânal. Some three months ago, a gentleman left the latter station with his wife and her maid, and travelled across to Devikolum, stayed there some weeks, and returned the same way. The path connecting the two places is in process of construction, and one or two residents of Kodekânal have already taken up lands on the Kannan Devans, and are opening cinchona estates. The labour market is close at hand, and the supply of coolies presents no difficulties. The adaptability of the climate and soil for growing tea and the best sorts of cin-

* Oh!—ED.
